The latter part of May and the early part of June is always a busy time in flower gardens. Bedding-out, as it is termed, then requires full attention, and, previous to beginning to plant, every thing should be in readiness, in order that the work may be done quickly when it is started and under favourable weather. It is always a safe plan to have the soil for bedding plants moderately rich and firm in the beds. For this purpose we never use cow manure, but the Grass which we are now cutting in the pleasure grounds is all thrown into a heap, and in autumn is mixed with its own bulk of leaves, and in February or March it is dug into the flower beds. This is found to be an excellent manure for all kinds of bedding plants. When it is dug in the beds should be left in a rough state, unless they have been filled with spring flowers, when the manure must be dug in immediately before the beds are filled with their summer occupants. In that case the surface may be made fine and ready for planting at once. Most people will, of course, please themselves as regards the way in which they make their beds, but in my opinion raised hillocks of soil are much more unsightly than flat surfaces. All the hardiest plants should be planted out first. *Calceolarias* may safely be put out the first week in May, and so may *Pyrethrums*, *Carnations*, and all kinds of plants not required to be grown in a strong heat in spring. Before any of the plants are put in the beds, however, each bed in the design should be roughly traced out on paper, and the position which each plant is to occupy should be marked on it. This obviates confusion at planting time, and in the case of some plants being put out before the others, such as a row of *Pyrethrum* round one bed and a centre of *Calceolarias* in another, they can always be planted in their proper places, and the right distances left to fill in with other plants. A plan thus prepared to work by is a great help at bedding-out time, but it is of still greater assistance in autumn, when the numbers of each plant required can be recorded. Where there are only a few beds to fill and plenty to put in them, people can indulge in putting the plants in close enough for immediate effect, but in large gardens this can seldom be done. When plants are put in widely apart the soil in which they are planted should always be rich, because when they begin to grow they soon fill the beds; on the other hand, when they are put in closely together, the soil should be rather poor, or the plants soon become a disorderly mass. *Calceolarias*, *Pelargoniums*, *Verbenas*, and plants of that kind may be planted from 8 in. to 1 ft. apart in ordinary soils. For present effect, some plant as close again as this, but the result in the end is not more satisfactory than in the case of wide planting. *Alternantheras*, *Iresines*, and all dwarf carpet bedding plants should be put in from 3 in. to 4 in. apart. A moderately rich soil suits these plants much better than an excessively rich one; both growth and colour are more refined in the former than in the latter. All kinds of succulents of the half tender type should nearly touch each other when first planted together in beds. The hardy or Alpine sorts may be allowed space according to their habit of growth, but none of them should be planted too wide, as few of them, except creepers, will extend very far in one summer; and to see more space bare than is covered with plants is not desirable.

The most important matter connected with bedding out, however, has yet to be named, and that is, hardening off the plants. I know from experience that this is often more difficult than raising or planting them out. In many places there is no scarcity of accommodation for bedding plants in early Vineries,

Peach houses, &c., in February and March, but it is bringing them from these warm houses to the open beds in May without injury that requires study. Light deal frames with glass sashes are the proper places in which to harden them off, but few indeed have enough of these to meet their requirements. Many temporary erections can be put together, such as screens, but when these cannot be depended on to ward off 5° or 6° of frost and cold winds, the plants should not be placed in them until, say, the 1st of May. Previous to this they must be kept in the coolest house available. Our plan is to grow every plant as rapidly as possible up to the first week in April, and then to begin to harden off as gradually and as quickly as circumstances will permit. It is, however, wrong to do this too quickly, especially if the plants have been grown in a strong heat previously. Some plants may not seem to suffer much from a sharp change such as this, but it does check them, and they often show it even after midsummer. In our own case we always harden off as soon as the plants are large enough. Our earliest spring-rooted *Coleuses*, *Iresines*, *Verbenas*, &c., have been out in the open air since May 1, and they look now in the best of health. After working the lights off and on them in frames for three weeks, they were turned out between the Raspberry rows, which are 6 ft. apart and about the same in height. They are completely sheltered from the wind here, and at the same time they are fully exposed to the sun during the best part of the day—conditions exactly what they require, as sunshine is the best of all hardening agents. Plants set under the shade and shelter of trees and walls never get properly hardened off, and when they are kept there, until they are taken straight to the beds and planted they suffer about as severely as planting them direct from under glass. Showery weather is a fortunate occurrence during bedding-out time; the labour which it saves is very great, and the advantage which it confers in starting the plants freely into growth at first is no small advantage at the beginning of a hot summer. When the ground is so wet as to stick to the feet boards should be used in planting. As each bed is planted the Dutch hoe should be run carefully between the plants, leaving the surface neat, level, and free from large stones. This should be done whether the soil be wet or dry. When the plants have to be turned out during dry weather, they should be thoroughly watered two or three days after planting; one good watering at that time will do more good than damping the surface every day for two months. Tender plants of a sub-tropical character should be planted last, and careful and gradual hardening off is especially necessary in their case, as a check to them at first often makes them unsightly during the whole season. Surplus plants of all kinds should never be thrown away when a spare corner can be found in which to plant them, for they produce cuttings in autumn and save the bedding plants, which is no small consideration, as many flower gardens are much disfigured by half of the plants being out away for cuttings just when they are at their best.

CAMBRIAN.

### NOTE ON A NEW RHUBARB.

From a note by Professor Baillon in the Monthly Bulletin of the Linnean Society of Paris, we learn that M. Colin, pharmaceutical chemist at Verdun, the author of a creditable "Thèse" on Rhubarbs, received some time since (as stated by Professor Baillon in the "Dict. Encyclop." (3, iv., 428), from Mgr. Chanvean, the plant which the latter considered to be the source of true Chinese Rhubarb. This plant has now flowered, and from an examination of a specimen forwarded by M. Colin, Baillon is of opinion that the species is *R. hybridum*, of which, however, it must be considered a variety characterized by more elongated leaves that are also more acute at the apex and more irregularly out at the margin. The flowers are small and white, often male, and constructed nearly as those of *R. hybridum*. A piece of the root presents the characters of a very good Rhubarb, analogous to that of *R. officinale*. The author proposes to call the plant *R. hybridum Colinianum*. This further tends to corroborate the opinion already expressed by the author that the origin of the good kinds of Chinese Rhubarb is multiple. Thus we have *R. hybridum Colinianum* and *R. officinale*, from the latter of which he has seen Rhubarb of very good quality in Parisian commerce, whilst Prejevalsky states that *R. palmatum* undoubtedly affords the excellent Rhubarb of Thibet. The author insists on the influence exercised

on the quality of the drug by the method of collection, the season when this is made, probably also the process of drying, &c. He adds that it is also necessary to take into consideration the part of the plant which constitutes the drug, as this determines its histological characters. A Rhubarb furnished by the stem or a part very close to the stem will differ from one obtained from the root. In R. officinale, for instance, where the aerial stem and its subterranean portion takes on a great development relatively to the root, he has found that the latter part may also acquire a considerable development, and that portions taken from it, and which would be naturally employed in commerce, present very considerable differences from those shown in the stem, and, indeed, have scarcely any of the characters there found and considered essential in a Rhubarb of the best quality.—“Pharmaceutical Journal.”

### NEW DWARF CANDYTUFTS.

THESE are in reality very dwarf tufted-growing and highly floriferous forms of *Iberis umbellata*. The following are the descriptions of them printed in the Report on Annuals grown at Chiswick in 1877, and published in the “Journal of the Royal Horticultural Society” (v. 42):—

“*I. umbellata nana rosea*.—Height, 9 in.; umbels very large and flat; petals broad, white, tinged with rosy-pink. A novel and very effective variety.”

“*I. umbellata nana alba*.—Height, 9 in.; umbels large; the petals broad, pure white. A very showy, distinct, and splendid variety.”

These were the only two certificated out of fifteen kinds of Candy-tuft grown for trial, their superiority being so distinctly apparent.

Dwarf Hybrid Candytuft.

Being hardy, free-blooming annuals, as suitable for the smallest as for the largest gardens, we have no doubt they will become highly popular, as they deserve to be. The plants branch from the very base, forming a corymbose tuft of branches only a few inches high, each branch being tipped by one of the showy broad-petalled umbellate flower-heads. The white is valuable for its density of growth and purity of colour; the rose-tinted one for its novel and beautiful colour in addition to its dwarf tufted growth. Our descriptive notes run thus:—

*I. umbellata nana rosea*.—Height 9 in. to 10 in., densely branched, forming a flat head of numerous corymbs of flowers; branches stout, erect, crowded, each bearing a succession of flower-heads; leaves alternate, linear, lanceolate, with a depressed central rib; flowers in dense, flat, corymbose heads, the individual blossoms large, unequal-petaled as in the type, of a beautiful soft rosy-pink. Quite a new colour amongst the annual Candytufts, and very chaste and pleasing.

*I. umbellata nana alba*.—Habit, stature, and general character as in the former; flowers and flower-heads large, pure white, very showy. A really useful acquisition.—“Florist.”

*Iberis gibraltaria*.—Allow me to direct attention to the tender and delicate beauty of this *Iberis*. Cuttings of it taken last summer are now each crowned with a beautiful head of bloom, in colour soft rosy-lilac, fading off to white at the edge. Unfortunately, the frosts in March killed my original plant, which covered a considerable area of rockery. Perhaps this *Iberis* is not perfectly hardy.—H. M., Bromsgrove.

## THE INDOOR GARDEN.

### ACHIMENES AND THEIR CULTURE.

AMONGST the many forms of Gesneraceous plants there are none more generally useful for decorative purposes than the Achimenes, as with ordinary management, and the aid of a little artificial heat at starting, they may be grown and flowered in any warm greenhouse with the greatest success. To amateurs, therefore, who have only a limited amount of room, and who wish to make the best display of which their means at command will admit, Achimenes are just the plants, as not only are they very showy, but, as they die down at the end of the season, they may be stowed away during the winter, and thus afford room for other plants to occupy their places. This is a great consideration, for in a general way plants when they have done blooming, get so maltreated that they are of little use afterwards, but with such as go to rest naturally and require no further attention till the time of starting them again arrives there is no danger of this, as they may be left to themselves. The only care requisite with Achimenes is to see that they are properly ripened during the autumn after their tubers are fully formed, and the way to get them in this desirable condition is, when their flowers fade, to stand them in any cold pit or frame where they can be kept close and syringed or watered overhead occasionally, so as to maintain their foliage fresh and healthy as long as possible. The mistake many make with these plants is in drying them off too rapidly, and when this occurs the tubers shrink away or rot; if they do not do this, they never possess that amount of strength or produce such fine plants as they otherwise would. The best place to store them is in a warm house or shed, where they can be stowed free from drip or moisture, as the soil must be perfectly dry to insure their safety; and not only this, but it is necessary that they should be left in that in which they grew, as in no other way do they winter so well. I have tried them repeatedly in sand, but never found it satisfactory, and now always leave them intact in the pots, where I find them in first-rate order when spring comes round.

Those who have not the good fortune to have a stock of these most useful plants will find the present a good time to procure them, as they may now be packed in a small compass and easily sent by post or rail. The following dozen are among the best and most distinct and are sure to please:—*Adelaide*, *Delahorte*, *Aurora*, *Eclipse*, *Excelsior*, *Gibsoni*, *longiflora*, *longiflora alba*, *Harry Williams*, *Mauve Queen*, *Meteor*, *rosea magnifica*, *Stella*, and *Williamsi*. To make a good mass in a 6-in. or 8-in. pot requires from seven to twelve tubers, according to the strength of the variety grown, and whether it be naturally of a branching habit or otherwise; but as most of them admit of being trained well out, the latter number will not be too many. The best way to grow them is to start them in pots about three parts filled, and as they get a few inches high, gradually add more soil, in which they soon form surface roots, and start away with great freedom. Being exceedingly fond of water, after they get well established, free drainage should be provided by using plenty of crocks, and over these some half-decomposed leaves or coarse peat, that the interstices may be kept open and clear, for although they are moisture-loving subjects, anything approaching a wet, sour condition is inimical to their welfare. For growing them in, nothing suits them better than about three parts leaf-mould or refuse peat to one of loam, a mixture in which, with a little sand added, they will revel and increase at a rapid rate by forming a great number of tubers. A common hotbed or any forcing house where a genial, moist atmosphere is kept up answers well to start them, but wherever placed they must be shaded, and if stowed where they can get this naturally without the light being obstructed, they will come much shorter jointed and be all the stronger for the fuller exposure. In summer, when the light is more intense and the sun bears greater power, an ordinary frame or pit, where they can have a thin mat thrown over them, will be found to answer admirably, as then they may be closed early and the floor kept damp by heavy syringing, which is just what they like and require to keep them in good health and full vigour.

Besides being so serviceable for pot culture, Achimenes are even more ornamental grown in light wire baskets and sus-

pended from the roof, in which way they show off their beauty to the greatest advantage. When required for this kind of work they should be started first, and the baskets prepared to receive them, by being coated with Moss inside, and then filled with rough peaty soil, in which the plants may be distributed and either pegged or tied, so as to regulate them and give them the requisite support. In pots, sticks are necessary for this; the neatest and best for which purpose are the small twigs from the Privet. These, being of the same colour as the stems of the Achimenes, are not observed, which is a great thing in their favour, as nothing detracts so much from the beauty of any plant as to see it studded all over with skewers, like a porcupine's back. In cases where it is desired to add to the stock of any kind that might be scarce and dear, it may readily be done by means of cuttings about 3 in. long made from the tips of the shoots. These should be put in in close, moist heat, where they will root in less than a fortnight, and make strong-flowering plants in a month or two. Those from which they are taken will soon break again, and be little the worse for the loss. S. D.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Selaginella denticulata for Bordering Shelves.**—I was greatly struck by the appearance of this Club Moss, a few weeks ago, in a conservatory where it was planted on the extreme edges of the benches or shelves. In my estimation a more graceful and pretty plant could not be found for the purpose. It was about 3 in. wide, and hung quite 6 in. below the bench on which it was planted, while at every 3 ft. apart were placed plants of *Panicum variegatum* and *Tradescantia zebrina* alternately. All three are common old plants, but are far too useful, I think, to be allowed to die out. Anyone having a few *Selaginellas* will be amply repaid in a few weeks' time if they will stick a few pieces of it around the edges of their house shelves. It is a rapid-growing plant, and when, so to speak, it gets shabby, it only wants cutting close in, when it will break out again thicker and greener than ever. I put in a thin layer around the centre bed of a Fernery a fortnight ago, and I am pleased to say that it is forming already quite an attractive border.—J. PERKS, Worcester.

**Shading for Houses.**—Properly-constructed and serviceable blinds are expensive, and exterior contrivances of this kind are of little value unless they can be secured from damage from wind, &c. The old practice of whitewashing a roof is useful, but it has a glaring and ghastly appearance under bright sunlight; and it is in violent contrast with the foliage about it. For something like 150 superficial feet of glass a good mixture can be made of  $\frac{3}{4}$  lb. of Brunswick Green and 3 lb. of size; the latter should be boiled, in order to melt it, then the two should be mixed together, and diluted when wanted. If this be laid on carefully in spring, it will last all through the summer. It is particularly recommended for a cool-house, or for a Fernery.—D.

**Renovating an Old Marechal Niel Rose.**—About six or seven years ago I planted a Marechal Niel Rose at the back of a new Viney; it was a young plant, budded the previous year on a Brier stem about 2 ft. high. It grew famously, and for several years produced an abundance of its fine golden blossoms in March and April. About eighteen months ago I noticed all round the point where the bud had been inserted the bark cracked and contorted, and evidently in a most unsound condition; the health of the plant, too, was falling off, as evinced by the weakly growth and smaller flowers. Well, I had a wooden case made 12 in. square to enclose the stem on three sides, and secured to the wall by a halfpenny on each side. The box or case was long enough to reach from the ground to a point 6 in. above the junction of the bud and stock, enclosing that part completely. When finished the box was filled with rich, turfy soil, and kept moist; this was done about a year ago, and I find the box is now nearly full of healthy roots, that have pushed out from the part which appeared so unsound at the point of union. The plant also is pushing strong young shoots, and appears to have taken a new lease of life. The remedy is simple and easily applied; and this Rose, on both the Brier and Manetti, after two or three years is very apt to become unhealthy and ultimately die, from a cause to which may be attributed an imperfect union or some incompatibility of the stock to supply so strong-growing a Rose. I have previously seen with dwarfs on both Brier and Manetti, by top-dressing annually, I could draw out a new stock of roots from a higher point up the stem, and the plants seem to benefit from this annual renewal, as it were.—E. HOBDAY.

#### TANGLED THICKETS.

The æsthetic mind is influenced by very various types of beauty. Now we are pleased with grace, elegance, finish in form, refinement in colour; now by sombre hues and rugged boldness of outline. Whilst we admire the "meadows trim with Daisies pied," the stately Oak or specimen Conifer, and the wondrous sheets of blue and green in our coppices, now filled with Dog's Mercury and wild Hyacinths, we may yet retain a thorough admiration for the less striking colours and less regular features of the tangled thicket. Some of the most graceful and altogether most charming combinations of native plants ever seen are those in these same tangled thickets. The Honey-suckle clambering over the wild Rose, waterside Willows half smothered in white Convolvulus and purple Bittersweet, or such a mass of Brambles and Bracken, as that in our engraving from the woods of Meudon. The lovely forest queen, the silver-rinded Birch, under whose shade the thicket grows, is perhaps the best tree for such a purpose, owing to its irregular outline and the scant shade of its green waterfall of leaves, which allows most herbaceous plants to grow beneath it. Foxgloves, double Gorse, or Broom look well in such a situation, while Heather and Harebells enjoy a sandy soil as much as the Birch itself. The beauty of the double pink Bramble, and of several foreign species, is not half recognised at present, nor is the autumnal value of the berries, ranging from green through reds to black, or, in the Dewberry, "Shining, dim powdered with a downy blue." Three plants could hardly be found with a finer contrast in outline and colour of foliage than the Birch, the Bramble, and the Brake. If the bright green of the graceful Fern is not sufficient relief to the sombre leaf of the Bramble, there is the added light of the silver stems, and nothing can excel the tints of Bracken in autumn. The beauty of the combination is seen in all its natural glow in Miss Alice Havers' "September," in the Royal Academy exhibition. When every large establishment has its wild garden, we shall hope to enjoy near home the charms of many a tangled thicket. G. S. BOULGER.

**Out-door Propagation of Chrysanthemums.**—I am probably not the first to try cuttings of the *Chrysanthemum* in the open air without protection from the winter's cold. Nevertheless, there may be among your readers some who will be interested in the experiment, and would like to know the result. Those sorts only were tried which happened to offer the greatest number of cuttings. They are *Astrea*, *Eve*, *Guernsey*, *Nugget*, *Lord Derby*, *Mrs. Sharpe*, *Princess of Teck*, *Queen of England*, and *Golden Queen of England*. No hand-glass or covering of any kind has been used to protect them, and their locality is that of a well-sheltered border, which, owing to the presence of some buildings on its eastern side, the sun's rays do not reach till about the beginning of March, and which is always in shadow after mid-day. Nearly all are growing vigorously, and one or two look as if they intended to outstrip all that I have raised in the usual way. Most of them were put in during the months of January and February. I find late spring cuttings of *Pelargoniums* to strike readily in this border.—B. S., Uppingham.

**Buffalo Horn Manure.**—This is simply the very fine shavings and scrapings from the manufacture of horns. It is of extremely light composition, one bushel weighing about 30 lb., and has somewhat the appearance of chopped Lichen. It was in due course tried and tested in various ways, in comparison with ordinary stable manure, guano, some patent chemical manures, &c. 1. By admixture with the soil for the potting of plants, and for planting; also as a top-dressing. 2. As a top-dressing by itself. The subjects operated upon were Vines planted out—Vines in pots; Peaches and other fruit trees in pots; Fuchsias, *Pelargoniums*, &c.; each of these subjects being treated in a corresponding manner with the other manures. The soil used in each case was the same—a pure, sandy loam, totally devoid of organic matters, and so wretchedly poor that those plants treated without any of the manures scarcely grew at all. The results as to growth in each example treated with this manure were eminently satisfactory, the plants soon assuming a very deep green hue of foliage, and growing most luxuriantly; more marked than in either of the others. Where used as top-dressing, also, the roots very soon permeated through, and grew most luxuriantly. In my opinion—after two seasons' trial of this manure—I consider it to be one of the most efficient, easy of application, and certain in its results.—A. F. BARRON, in "Journal of the Royal Horticultural Society."

A TANGLED THicket: BIRCH, BRAMBLES, AND BRACKEN.

## GARDEN BOTANY.

(Continued from p. 441.)

CLASSIFICATION OF DIVIDED SIMPLE LEAVES.—The remarks on the venation of leaves will help us here, as the lobing of the leaves follows the same type as the venation, and there are palmately and pinnately-lobed leaves. When the lobes radiate from the apex of the petiole, as in fig. 147, the leaf is palmately lobed; and when they diverge from the midrib the leaf is pinnately divided (fig. 148). Each of these two types of lobing present different degrees, but we need only recognise

Fig. 147.—Palmately lobed, simple leaf of *Abutilon venosum*.

two of each type. When the lobing is not below the middle the affix *fid* is used, when below the middle the affix *partite*. Thus the leaves when divided, as in figs. 149 and 150, are termed palmatifid, and palmatifid when more deeply cut, as in figs. 147 and 151. The pinnately-divided series exhibit the same modifications (figs. 152 and 153). The divisions of cut leaves are called lobes or segments, and these may be entire or toothed, or again lobed. In *Echinops sphaerocephalus* (fig. 148) the leaf is pinnatifid and the lobes pinnatifid; but, in order to avoid circumlocution, the leaf might with propriety

Fig. 148.—Pinnately lobed simple leaf of *Echinops sphaerocephalus*.Fig. 149.—Palmatifid leaf of *Sterculia platyfolia*.

be termed bipinnatifid or twice pinnatifid. Division is sometimes carried to the third or more ramifications, as in the Parsley and Camomile families, and then the prefixes *tri* or *multi* are used, and the outline of the entire leaf and the ultimate segments described. It may be well to remind the reader again that many botanists call these deeply-divided leaves compound, whether the segments are jointed to the petiole or midrib, or continuous; but, in so doing, it seems to us the only valid distinction is sacrificed without any counterbalancing advantage.

CLASSIFICATION OF COMPOUND LEAVES.—These are of two types, the digitate (figs. 154 and 155), and the pinnate (figs. 156 and 157). The separate parts are called leaflets, and they are either sessile or stalked (petiolulate), but usually very shortly. In strictly compound leaves the leaflets are distinctly jointed

Fig. 150.—Palmatifid leaf of *Lavatera arborea*.

or articulated to the petiole or its ramifications. The ramifications of the petiole are termed primary rachis, secondary rachis, &c. Leaves of the digitate type vary principally in the number of leaflets. A very common number is three, as in Clover (fig. 154) and many other members of the same family; such leaves are called trifoliate. The genus *Oxalis* offers a familiar example of this type of leaf. Occasionally there are only two leaflets (binate), and in many of the Orange tribe the leaf is reduced to one leaflet, which is distinctly articulated to the top of the petiole. The Horse Chestnut (fig. 155) usually has seven leaflets, and some of the Araliaceae even more. In *Epimedium alpinum*, &c., the leaves are twice or thrice divided in a ternate manner, that is, in triple ramifications, the ultimate branches (rachises) bearing each three leaflets on long petiolules. The Meadow Rue (*Thalictrum flavum*) has a compound leaf of the digitate type. The pinnate pattern presents more numerous modifications; and is pinnate, as in the Roses, bipinnate in *Casalpinia*, *Acacia*, *Mimosa* (figs. 156 and 157), and *Gleditschia*, and tripinnate in *Aralia spinosa*, according to the number of branchings. At first sight, the leaflets of some of the compound leaves, especially of the very large ones, might be mistaken for leaves;

Fig. 151.—Palmatifid leaf of *Potentilla reaca*.Fig. 152.—Pinnatifid leaf of *Scolymus hispanicus*.

but the absence of buds at their bases indicates their true nature. The ultimate branches which bear the leaflets are called, leaflets inclusive, pinnae, and the usual number of pinnae is mentioned in descriptions. In *Mimosa pudica* (fig. 157)

there are only two pinnae to each leaf, whilst in *Acacia* (fig. 156) they are quite numerous. The approximate number of leaflets on each pinna should also be noted, and this is expressed by *uni*, *bi*, *tri*, or *multi*-jugate, according as there are one, two, three, or many pairs of leaflets, or by the number of leaflets in figures. Another thing to observe is the odd or even number of leaflets on each pinna; when there is an odd terminal one, as in *Rose* leaves, the leaves are termed *unequally pinnate*; when there is no odd leaflet, equally pinnate.

**DIFFERENT KINDS OF LEAF ON THE SAME PLANT.**—The prevailing rule is that the leaves of a plant are very much alike, or present no remarkable differences from each other; but

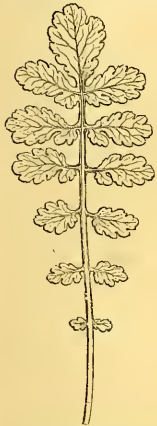

Fig. 153.—Pinnatifid leaf of *Chelidonium majus*.

Fig. 154.—*Trifolium pratense*; an example of a plant having trifoliate leaves.

there are several noteworthy exceptions to this general condition of things. For example, the first leaves of seedling plants above the cotyledons are frequently very unlike those which follow, or are characteristic of the adult plant; in other plants the leaves on flowering and barren branches are very dissimilar;

Fig. 155.—Digitate leaf of Horse Chestnut.

the root-leaves and stem-leaves of herbaceous plants are commonly different; and, finally, there are plants which almost invariably bear two distinct types of leaf.

**DISSIMILAR CAULINE AND RADICAL LEAVES.**—The leaves borne around the crown of the root at the base of the stem are termed radical leaves or root-leaves, in contradistinction to cauline leaves, or those scattered on the stem. It is useful to make this distinction, because the radical leaves often differ materially from the cauline, usually in being more highly developed. Frequently the cauline are sessile and the radical petioled, one set entire and the other lobed. The Hare-bell (*Campanula rotundifolia*) is a good illustration of this peculiarity. When this plant is in flower, we usually find only the

long, narrow, sessile, cauline leaves, and we may be pardoned for believing that the specific name is an inappropriate one; but the radical leaves, which soon decay and often disappear, have long petioles and a roundish blade. Another instance—the Fiddle-leaved Dock (*Rumex pulcher*), which has the first

Fig. 156.—*Acacia grandiflora*; leaves bipinnate.

radical leaves constricted in the middle and somewhat fiddle-shaped, and the upper ones oblong without any constriction.

**VARIATION IN THE LEAVES OF THE SAME SPECIES.**—Although the leaves of trees and shrubs rarely deviate from their normal form, it sometimes happens that a branch here and there will put forth leaves of a totally different shape or colour, and the same thing often occurs in a batch of seedlings from the same parent. As a rule, these varieties or sports can only be propagated by asexual means—that is, grafting or budding, or

Fig. 157.—*Mimosa pudica*; leaves bipinnate.

from cuttings—though varieties of this kind become fixed in time. One of the most remarkable instances of variation in the foliage of different individuals of the same species is afforded by *Karivia umbellata*, an Indian Cucurbitaceous plant.

W. B. HEMSLEY.

**Violas.**—Let me recommend Dickson's *Viola multiflora* as an excellent *Viola*, of a colour as rare as it is beautiful. I would also recommend for an effective bed *Viola* Sir Walter Scott (Perfection or Blue Bell will do almost as well) and the improved dwarf *Dactylis elegantissima*, placed alternately. Nothing can be more delicately refined; both plants are hardy and easily propagated.—HERBERT MILLINGTON, *Bromsgrove*.

## GOLD-LACED POLYANTHUSES.

It is pleasing to observe that these hardy spring flowers are being so much sought after, but it is to be regretted that spurious kinds are being sent out for good, old, coveted sorts. A far better way to stop this imposition than that suggested by Mr. Dean (see p. 406) would be to prosecute the culprits; or, if this would be considered too troublesome, the next best plan would be to publish their names and addresses. When in the north of England, a few weeks ago, I made inquiries about the old varieties of Polyanthus, and I find that some of them, so far as is known, are lost to cultivation. Two of the sorts named by Mr. Dean are not to be had, viz., Beauty of England and Kingfisher. Of the last-named, the Rev. F. D. Horner has one plant, which probably represents the stock of it. Probably the best Polyanthus in cultivation, Cheshire Favourite, can be purchased for 1s. 6d. to 2s. 6d. per plant. Exile and President are about the same in value. Earl of Lincoln, Lancer, George IV., Formosa, Rev. F. D. Horner, Bonny Bess, Black Prince, and Telegraph are all more or less plentiful in the hands of private growers about Manchester and Newcastle; and that very old sort, Pearson's Alexander, is in existence, but as only a few of it are in the hands of private growers, it may be difficult to obtain it. Indeed, I know several growers who will not part with their plants, except by way of exchange. Still, when a person who knows how to manage his plants is able to get the right sorts, it does not take very long to make them plentiful. It is interesting to raise seedlings, and seed saved from the very best sorts will certainly produce something good. Cheshire Favourite would be the best variety as a pollen parent; it seems to have all the best qualities of a Polyanthus in the highest degree, and, as it is now very freely distributed in all directions, it only remains for growers to do their best to produce something better. Exile is also a good flower; indeed, it stood "premium and first" at Manchester in competition with Earl of Lincoln, Cheshire Favourite, Lancer, President, George IV., &c. It has the fault of not fattening in the pip, but on the above occasion this was not apparent. Buck's George IV. is a grand flower, and should be in every collection. It was shown in fine condition early in April at Newcastle-upon-Tyne.

In order to grow the Polyanthus well it requires a rich, unctuous loam, and when the flowering period is over the plants should be put out in the open ground; they must be kept quite clear of red spider and green fly, both of which play sad havoc with the leaves. Green fly is easily destroyed by fumigating; red spider will not thrive if the leaves are frequently syringed, and the plants kept in a healthy growing condition. For border cultivation seedlings are in a healthy state. The seeds should be sown at once in boxes, using fine loam, leaf-mould, and a little silver sand. If the box be placed in a hotbed, the seeds will germinate quicker and better than they otherwise would do. When the seedlings are old enough to handle I prick them out either in boxes or on a piece of prepared ground out-of-doors. The plants should be about 2 in. or a little more apart, and when the leaves quite cover the ground the seedlings may be transferred to their blooming quarters, either as isolated specimens in the herbaceous border or in beds; I prefer the latter. A bed of lacéd Polyanthuses, planted at Loxford nearly ten years ago, has flowered finely every year since. The only attention required is to keep the ground free from weeds and to dig out portions of the plants where they are too thick; the bed has also occasionally been surface-dressed with fine soil, well enriched with rotten manure.

J. DOUGLAS.

**Naturalising Primroses in Woods.**—"A. P." is right in drawing attention (see p. 407) to the naturalising in woods and waste places of the many and varied forms of garden Primroses which we possess. Lovely as is the common Yellow, it would in no respect suffer by being associated with its more brightly coloured relations. Of the many plants that are fit subjects for naturalising, the Primrose is that which is best calculated to repay any labour that may be expended on it. It has, too, the additional merit of being one of the easiest to obtain a stock of. On many estates the Primrose grows in wild luxuriance. In these natural situations some thousands might be turned out annually at a trifling expense and with the best prospects of success. Why is it that many of our choicest kinds are so scarce, and that few can boast of a really fine and early display of bloom? Simply because they have to exist in conditions which are foreign to their nature and inimical to their well-being. The Primrose thrives in shady woods and hedgerows, where it is protected from the strong summer heat either by the foliage of trees, or by herbage. In gardens, on the contrary, it is often exposed to the full blaze of the summer sun either in beds or borders. An extra hot summer comes, and the plants are so enfeebled, that they never recover, and eventually disappear. I cannot imagine anything more interesting than the introduction of our garden varieties into the woods and dells of this country.—J. CORNHILL, *Blyth*.

## PLATE CXXVIII.

## ABELIA FLORIBUNDA.

Drawn by H. HYDE.

Few Natural Orders include more valuable subjects for the garden, taking into consideration the number of species contained in them, than the Caprifoliaceæ or Woodbine tribe. Consisting chiefly of flowering shrubs and climbers that are either hardy or require but slight protection in winter, and being, moreover, of remarkably easy culture, there is scarcely a garden in which representatives of the Order are not to be found. Although the individual flowers are generally small, and in but a few species particularly brilliant in colour, they are freely produced and often in large corymbs that afford a beautiful display; many of them are also delightfully fragrant. The flowers of the Weigelas, Viburnums, Loniceras, and Snowberries are always interesting, on account of their simple and modest colours. Among the most beautiful members of the tribe is the subject of our plate, a plant long known to British horticulturists, but one which of late years has unaccountably gone out of favour. The *Abelia floribunda* is a low shrub of sub-erect habit and somewhat straggling branches; the leaves are opposite, small, and smooth; the flowers axillary, and produced at the extremities of the branches, either singly or in corymbs of twos and threes; they are 2 in. or more in length, and, as will be seen, of a purplish-crimson colour; the tube, which is narrow at the base, gradually enlarges upwards and expands into five equal lobes. It is a native of Mexico, and was discovered about thirty years ago by Galcott, on the Cordilleras of Oaxaca, and by Linden on the peak of Orizaba, at elevations between 9000 ft. and 10,000 ft. All the other *Abelias* are natives of China and Japan, with the exception of *A. triflora*, figured previously in THE GARDEN (see Vol. X., p. 55), which is found in Northern India. *A. floribunda* is tolerably hardy in Devonshire, Cornwall, the Isle of Wight, the south of Ireland, and in a few other favoured localities, but in England generally it must be treated as a greenhouse plant. It was successfully cultivated as a rock plant by Messrs. Veitch at Exeter, where its branches were almost pendulous, and its large showy flowers extremely effective. When grown in pots a mixture of loam and peat in equal parts makes a suitable compost for it. In order to induce the plants to flower freely, medium-sized pots should be used, good drainage secured, and the wood well ripened, which is best effected by the plants not being re-potted till after the roots have completely filled the pot. Under ordinary greenhouse treatment, they will flower during the spring months, and continue a long time in bloom. Our plate was prepared from specimens supplied by Dr. Moore, from the Botanic Gardens, Glasnevin.

**Tropæolum speciosum.**—It is quite true, as Mr. Hemsley observes (see p. 443), that though this fine species is being continually recommended in the gardening papers, it is a plant one rarely sees. I know where it grows without any care, but here no amount of coaxing will induce it to grow successfully, nor do I know of a single good plant of it anywhere in this district. It seems to prefer the north. At Drumlanrig Castle, in the wet climate of Dumfriesshire, I believe it does well, and I have seen it growing in the most gorgeous profusion in front of a cottage just under the shadow of the Etrick Forest, near Gala Water. I have heard of it doing well in some parts of Nottinghamshire, but good examples of it are the exception rather than the rule. *T. polyphyllum*, I am afraid, is something after the same nature, so far as I have yet seen; and, besides, it is from the same country, which strengthens the suspicion. The south of Chili, I suppose, more remarkable for its rains and moisture than anything else, and it would seem that these *Tropæolums* cannot thrive under any other conditions.—J. S. W.

**Persian Lilace for Forcing.**—Any one having large bushes of these in the open ground, if not otherwise required, may turn them to good account by cutting off their roots to within 15 in. of the stems, lifting the stems, and placing them in large pots or tubs. If kept well supplied with water, placed in heat, and kept well syringed overhead, they will receive little or no check, and will yield abundance of blossom. After flowering they may be again planted out to be re-lifted in autumn. In this way Mr. Ollerhead, of Wimbledon House, gets more bloom from a few plants than could be obtained from a large quantity of such plants as are usually employed for forcing.—S.

## THE KITCHEN GARDEN.

## CULTIVATED LETTUICES.

By D. GUIHENEUF.

The cultivated Lettuce (*Lactuca sativa*\*) is not a species, not having, as yet, been found growing wild anywhere, but an improvement on a wild sort, probably due to skilful cultivation. Lamarck believes the Oak-leaved Lettuce (*Lactuca quercina*) to be the starting point, but this is doubtful; and, being now a cultivated sort, it has lost its natural characteristics. Besides, the Oak-leaved Lettuce is a native of the Isle of Caroline, in the Baltic Sea, whilst Lettuces were first cultivated in southern and eastern countries. *Lactuca perennis*, now grown in France, cannot be the type, being perennial and having blue flowers. De Candolle says *Lactuca sativa* is from *Lactuca Scariola*, but he adds afterwards *Lactuca Scariola* is probably the *Lactuca sativa* returned to its wild state. Others, with more reason, say that it is the *Lactuca virosa*, which, being brought under cultivation, has lost its poisonous properties and hairy appearance. This is, however, a matter which will never be satisfactorily settled until some persevering horticulturist sets about the improvement of our wild species. Another difficulty is the fact that some varieties have white seed and others black or yellow seed. But if we know little or nothing of the origin of our cultivated Lettuces, the history of their introduction into English gardens is still more obscure. Turner mentions that in 1530 a gardener received a reward for bringing Lettuces to Hampton Court, and in 1597 Gerard describes several sorts, but throws no light upon their introduction into England. He only says that at that time Lettuces were eaten before supper. In 1640 Parkinson describes many varieties, and in 1652 Lettuce was a common vegetable. In French bibliography we find that about the year 1540 Rabelais sent from Rome to the Cardinal d'Estrées, at Paris, the first seeds of Lettuce which were sown in France; but, prior to 1530, I know of no record of Lettuce being grown in England, and must suppose that it was imported by the monks, who at that time had the widest connections abroad; but, should the Dutch have grown it before the above-mentioned dates, it is probable that it was imported from Holland. Lettuces have been cultivated from the remotest times by the Greeks, the Romans, and the Egyptians, who perhaps received them from China or other places in Asia. Herodotus (484 years before the Christian era) called Lettuce *Thridax*, and says that it was a pot herb and salad of the first rank, and that it was eaten before and after meat. The Romans ate Lettuces after supper with the view of procuring sleep, but in Doinicien's time the custom was changed, and they were served as *entrées* at their festivals; and this prevailed for a long period, even until Gerard's time, in England. The Lettuce was called *Lactuca botica* by Columella (forty-four years after the Christian era), and Pliny says that great pains were taken to earth them up with sand to blanch and make them heart. What sorts of Lettuce were cultivated at that time it is impossible to say, from the diffuse and uncertain descriptions given of them. Sueton says that a statue was erected to the memory of Antonius Musa for having cured the Emperor Augustus with Lettuce. After this Lettuces were in great repute at Rome, and were grown all the year round.

## Uses.

The cultivated Lettuce when young contains plenty of water and mucilage, and a milky juice when old, which makes it bitter and narcotic; these two last properties, however, are removed by blanching. Lettuce is cooling and of easy digestion, but contains little nourishment. It promotes sleep; therefore, it should not be much used after dinner, especially during hot weather. Lettuce is cultivated nearly all over the world, and its daily consumption is enormous. It is used in the form of salad, seasoned with oil, vinegar, salt, and Pepper; even mustard, according to taste, is added in some localities

in France. Country people substitute melted butter or cream for oil, and sugar is also sometimes added. To Endive, Corn Salad, Celery, Celeriac, and all other salads, Lettuce is a good addition. Some kinds, such as Neapolitan and Bossier, are good when boiled, on account of their coarseness; hearts of young tender Lettuce are delicious, if boiled with Green Peas. In lobster salad Lettuce is indispensable. The Curled varieties are not only useful as food, but valuable for garnishing cold meat. Indeed, the French, who excel us in making Lettuce salad, would not consider a dinner complete without it. In order to have the true flavour of Lettuce, the outer leaves should be cautiously taken off, the blanchéd heart only being used without being washed, and the leaves should not be cut to pieces, as is generally seen on English tables. Of the immense quantities of Cos Lettuces that are consumed in England, chiefly in London, during summer by the working classes, some idea may be formed by the hundreds of cartloads that are brought weekly to Covent Garden Market. Of these the largest portion is eaten raw at tea-time with salt and bread and butter.

## Seed.

The seed is white, black, or yellow; small, flat, oblong, sharp and pointed at the upper extremity. It retains its vitality for about four years. One ounce contains about 23,000 seeds. Lettuce seed is sometimes sold very cheap, but in most cases such seed is grown without the least care, the seed-bearing plants not being selected or even transplanted. Good seed is invaluable, and therefore a fair price must be paid for it.

## Varieties.

There are three classes of Lettuces, viz.:—1, Cabbage Lettuces (*Lactuca sativa capitata*); 2, Cos Lettuces (*Lactuca sativa romana*); 3, Cut-leaved Lettuces (*Lactuca sativa foliosa*); each class consisting of an indefinite number of varieties. Other classes could easily be made were the colour of the seed taken into account and the curled varieties; but this would only complicate the descriptions already too much confused. Each variety being popular in certain localities, I have described a great many; but still I have been careful to select the best. Old varieties, of doubtful value or name, for want of accurate descriptions, have been omitted. Two centuries ago only some dozen varieties were described, some of which are still under cultivation, with new names. At the end of the eighteenth century a collection of 100 varieties could easily have been procured from France, Germany, and Holland; and at the present day over 200 varieties are in cultivation, exclusive of some 600 synonyms. Most of these have originated in France, Germany, and Holland; a few come from America, and a very few have been raised in England. The task of eliminating the varieties is a very hard one, and requires a good deal of practice; therefore, errors may have crept into the following list, which I will be obliged by anyone pointing out:—

## Class I.—Cabbage Lettuces.

Including those with spreading, round, or flat heads; such Lettuces are by far the best flavoured and most crisp, and are those chiefly grown on the Continent. The different sorts may be divided as follows: Spring or forcing Lettuces, summer Lettuces, and winter or hardy Lettuces.

## Spring or Forcing Lettuces.

Cabbage Lettuces are seldom forced by English growers; in fact, all the Lettuces which are sold during the spring in Covent Garden Market are imported from Paris; they are very tender, crisp, and sweet, and the price moderate, being about 2d. each. It has been said that Lettuces could be forced with the same success in London as in Paris, but that is a mistake. A clear atmosphere and sunny weather, as in Paris, are indispensable for such culture, and the damp, rainy, cloudy winter months in London will always baffle the most skilled gardener in his attempts at Lettuce forcing.

1. Earliest Forcing Black Lettuce (French—*Laitue orpèe à graine noire*, L. *petite noire*; German—*Grüner früher schwarz korn steinkopfsalat*).—Hearts readily, not very firm, quite white. The name black Lettuce has been given on account of the seed being quite black. This variety is the only one which can be forced closely

\* Nearly all the popular names of the Lettuce are derived from *Lactuca*, as may be seen by the following:—English, Lettuce (Lettuce of some old writers); French, *Laitue*; German, *Lektich*; Italian, *Latuoga*; Spanish, *Lechuga*; Portuguese, *Letuça*; Brazilian, *Alface*; Dutch, *Letuw*; Danish, *Lektuk*; Swedish, *Laktuk*; Polish, *Laktuka*; Russian, *Lektuk*; Lettick; Indian, *Kahan*; Celtic, *Letuz*, &c.

shut up. It is the sort chiefly used by the Paris market gardeners for forcing as follows: The seed is sown in the beginning of September in a well-prepared spot, under a frame or cloche (bell-glass), and the young seedlings are transplanted as soon as they are fit to handle. When ready for planting, about October 10, a cold, slanting bed, about 3 ft. wide, is prepared and covered with about 3 in. of leaf-mould. If the cloches are to be used they are placed alternately in three rows; their places are marked on the soil, and five Lettuces are planted under each. If in frames six rows in each will be sufficient, but care is taken to keep the plants as near the glass as possible. They are shaded if necessary, and in time of frost covered with mats. Old beds can be used for that purpose after stirring and cleaning the soil, as the Lettuces need little or no heat, but they should be kept clean and close. Such Lettuces will be fit for use in the beginning of December. This variety succeeds well under cloches when it often fails under frames on account of the unavoidable admission of air. A second sowing should be made about Oct. 10, on a mild bed under cloches, sufficient seed being put in to produce from twenty-five to thirty plants under a cloche. These should be transplanted as soon as they have made a few leaves. In the beginning of December prepare a slanting hotbed, about 16 in. high; cover it with 3 in. of leaf-mould; dispose the cloches or frames as before, and plant four or five Lettuces under each cloche, or fifty or sixty under each frame. These will be ready for use about the end of January and February. Do not under any circumstances admit air, and keep out frost by means of mats, but in the case of sharp weather put hot fermenting material around the frames and between the cloches; but light must be given as freely as possible. Should the Lettuces get frozen, do not expose them to the sun until they have become thawed. Examine the beds often in order to destroy insects, and clear off decayed leaves, so as to keep everything clean and sweet. Take up the young Lettuces with great care, and replant them with the finger instead of a dibber. Sowings and plantings are made in succession to meet the demand; but the last period for planting this variety is February, to be ready in March. Some plant a Cos Lettuce in the centre of four others under a cloche; others plant their Lettuces on a Carrot bed under frames, the Lettuces being removed when the Carrots want room. Lettuces for exportation, packed with their roots in small boxes in Paris, reach London in about thirty-six hours. The above is the small white Lettuce seen in Covent Garden in winter.

**2. Earliest Forcing White-seeded Lettuce (French—Laitue crêpe à graine blanche).**—This is similar to the preceding, but differs in the colour of the seed. It is not, however, so much esteemed by market gardeners as the black-seeded, and therefore it is not so frequently used for forcing. The two varieties just named often withstand the winter in the open ground when slightly protected, but their size is insignificant, and when sown in the open ground in March they run to seed before hearing. They are only good for forcing.

**3. White-seeded Gotte (White Tennisball).**—This is a very early small kind; leaves spreading, yellow-green, slightly wrinkled; heart of medium size and loose; the earliest after 1 and 2. It is well suited for forcing under frames, but not under cloches unless

White-seeded Gotte Lettuce.

plenty of air be admitted. It is preferable to No. 1 for private gardens. Sow in October and transplant as in the case of No. 1, planting definitely from December to February. The produce will be ready for use in March and April. Paris market gardeners plant on the same beds after No. 1 has been used, thus producing a constant succession of new Lettuces. It requires air as often as the weather will permit; if planted under a cloche three plants are sufficient.

**4. Black-seeded Gotte (Black Tennisball).**—Almost similar to the preceding in appearance, and can be used for the same purposes. These two varieties are used for early sowings in January and February under cold frames, and then planted in the open ground on a well sheltered border. It is a common practice to sow them in February and March in the open ground amongst Leeks, Carrots, Onions, and other slow-growing vegetables, their quick growth allowing them to be removed before they damage the crops with which they are associated; but in the open ground they seldom attain perfection before running to seed. Seedlings left on the beds are useful for planting in the open ground in March, and the produce will be fit for use in May.

**5. Tennisball (Green Tennisball, Black-seeded).**—This is one of the oldest of Lettuces, and one which was extensively cultivated on the Continent 100 years ago. It is now chiefly grown in England and America. Leaves small, few, concave, wrinkled, blistered, and dark green; head small, tolerably solid, crisp, tender, and somewhat flat; it is a good keeper, and a hardy and early variety for forcing in spring or for the open ground during winter. If sown late even strong established plants will not bear the frosts. In summer the head is loose, and runs quickly to seed. Inferior to many other sorts.

**6. Laitue Dauphine (Black-seeded).**—One of the many varieties used in France for forcing or for early sowing. Leaves small, undulated, wrinkled, and of a dark green colour; head small, flat,

Laitue Dauphine Lettuce.

green, stained with brown on the top; of second-rate quality. It should be sown in February under glass for forcing, in March for spring use, and in September for winter. It is grown only on account of its hardness. If protected it runs quickly to seed.

**7. Victoria Red-bordered (White-seeded).**—Leaves small, undulated, a little wrinkled, and light green in colour; head of moderate size, green, tinted with brown on the top, crisp, tender, and well flavoured. It can be sown in January and February under glass for forcing, in March on a bed or in the open ground between Onions, Cabbage, &c., and in September for winter use, but for the last season other varieties are better adapted. In summer, or during dry weather, it runs to seed before Cabbaging. It should be planted about 15 in. apart, if possible, on a sheltered border.

**8. Tom Thumb, or Stone Tennisball (Black-seeded).**—Leaves numerous, small, thin, and wrinkled; plant, dwarf, compact, and early, producing a delicate head, firm, tender, and whitish-green. One of the best of Lettuces, forming a beautiful heart, with scarcely any outer leaves, and standing long before running to seed. On account of its earliness it can be used for forcing, for early sowing

Tom Thumb, or Stone Tennisball Lettuce.

in the open ground, for summer, and for late sowing for autumn use being small, it should not be planted far apart. It will grow in any soil, but will not stand the winter. It is a kind which cannot be too highly recommended.

#### Summer Cabbage Lettuces.

Some make the curled varieties a section, but that is somewhat difficult to do, for some are only half curled. The Cabbage Lettuces are much the best flavoured, the most productive, and of easy cultivation and quick growth. They are everywhere grown in great quantities. The curled varieties are the largest, but they are coarse and of inferior quality. They, however, withstand rough weather and bad soil better than the common Cabbage kinds.

**9. Brown Genoa (Black-seeded).**—A first-class, medium-sized Lettuce, cultivated all over the Continent, where it is known under a great many synonyms. It is, however, but little appreciated in England. Its leaves are small, crimped, and dark green in colour, with a few brown spots; head small, firm, round, and pale green, becoming brown-red on the top; very tender, delicate, and well-flavoured; half early, and a good cropper. It should be sown in February under glass, in March in the open ground, in April for

summer use, in June for autumn, and in August for winter, but it must be protected against sharp frosts. It is a kind which cannot be too highly recommended.

**10. Greystone (White-seeded).**—A first-class summer Lettuce, and one which is grown in almost every country under a multitude of synonyms. Leaves large, round, slightly wrinkled, of a green-

Brown Genoa Lettuce.

grey colour; heart tender, crisp, very large, round, brown-red at the top, not very firm. The chief merit belonging to this variety is its outer leaves being few and comparatively small. The seed should be sown in March and April under glass or in the open air, and successively, in order to have a constant supply during the summer, even until October. Transplant about 1 ft. apart; it is in every way a capital

Greystone Lettuce.

Lettuce, and one well deserving of extensive cultivation. It is largely used by the Paris market gardeners, a fact in itself sufficient to recommend it.

**11. Royal Summer Cabbage (White-seeded).**—The number of synonyms which this variety bears shows it to be one of the best of summer Lettuces. It is about 10 in. across, firm and regular, outer leaves large, slightly wrinkled, often torn or lacerated on account of

Royal Summer Cabbage Lettuce.

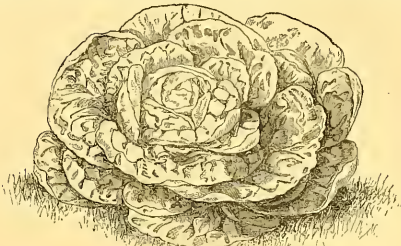

their crispness and tenderness. The whole plant has a peculiar yellowish-white colour. Dry, hot weather suits it perfectly, but it often gets spoiled through wet; therefore, it is strictly a summer Lettuce. It should be sown from March to May.

**12. Berlin Summer Lettuce (Black-seeded).**—This has a somewhat golden colour, quite distinct from all others; head large and firm; leaves large, blistered, very tender, and of first quality, except in wet seasons. It should be cultivated exactly like the Royal Summer Lettuce, to which it has some similarity in appearance. It will not stand the winter.

**13. Versailles Summer Cabbage (White-seeded).**—One of the best of summer Lettuces. It resembles the Royal Summer, but is earlier, larger, and much hardier; head large, oval, and firm; leaves large, wrinkled, and of a whitish-green. It can be had in spring, summer, and autumn, but not in winter.

**14. Grand Admiral (Grand Admirable, Admirable Imperial).**—This is a white-seeded sort of the first quality, provided it does not suffer from drought or wet; leaves large, wrinkled, undulated; heart of medium size, firm, and tender. A dwarf flat Lettuce, of a fine yellow colour, stained with brown on the top and at the extremity of the leaves. It should be sown in spring for summer use only; for other seasons it is too late and of doubtful quality. One of the best of summer Lettuces.

**14a. Negro-head or Normandy (Yellow-seeded).**—Leaves round, undulated, and occasionally wrinkled; head globular when fully developed, not firm, green, washed with brown-red at the top; where the soil does not suit it or the weather not genial it shoots from the base. It is a second early Lettuce of doubtful quality; it

Grand Admiral Lettuce.

does not turn out well even in dry summers, and it will not withstand a severe winter; it cannot, therefore, be recommended, though it is a favourite in some parts of America. Its name, Negro-head, is derived from its colour, and the colour of the seed is peculiar. Another yellow-seeded variety, quite green in colour, is used in summer, and is also cultivated in France, but this, I think, has never been introduced into England. These are the only two yellow-seeded Lettuces with which I am acquainted.

**15. Perpignan Lettuce (White-seeded).**—This was sold as a novelty in Germany a few years ago, though it was known in France for some sixty years or more. Leaves large, round, fleshy, lying flat on the ground, and of a dark green glazed colour; ribs large and strong; heart very crisp and tender. It is a kind entirely different from all other varieties. It grows well in dry soil, and bears heat better than any other Lettuce with which I am acquainted without

Perpignan Lettuce.

running to seed. It should be sown in spring for summer use only. Some seedmen are trying to obtain two or three varieties of this Lettuce, but in doing so they will only destroy the good qualities of the original type.

**16. Imperial (Asiatic Imperial Head).**—This is a white-seeded kind, with large almost round leaves of a tarnished green colour; head large and firm, regular, and of uniform colour. One of the best summer Lettuces, half-early, tender, and crisp, but it soon runs to seed. It will withstand a mild winter. The Turkish or Butter Lettuce is similar to this, but it is black-seeded.

**17. Brown Dutch (Black-seeded).**—Leaves large, round, waved, green stained with brownish-red and much wrinkled; head of medium size, globular, and loose. One of the leading varieties, both in America and in England. It is of good quality, especially if grown in rich soil, but it will only succeed out-of-doors in mild winters.

**18. Spotted Cabbage (French—Laité panachée or sanguine).**—This is a white-seeded kind; it has leaves of medium size, round, undulated, and wrinkled; in colour it is copper-green spotted with brownish-red; head globular, but loose. Very fine and curious looking in salad, tender, and second early. It succeeds equally well in winter, spring, and summer, but it is chiefly used as a winter Lettuce. An improved strain of this is now offered by seedsmen; it heads better, and the plant is wholly brownish-red in colour instead of being only spotted.

**19. Spotted Cabbage (Black-seeded).**—Head firm, regular, green, washed and spotted with bright red on the top. A curious-

looking variety, but superior to the white-seeded. It will not, however, stand the winter. The two above varieties, though very attractive, are seldom if ever cultivated in England.

*Curled Summer Cabbage Lettuces.*

**20. Early Simpson Lettuce (White-seeded).**—Head large, oval, but not firm; leaves large, undulated, somewhat curled at the margin, and wrinkled in the centre. The whole plant is of a distinct whitish-yellow colour; very crisp and tender; an improvement on

Early Simpson Lettuce.

the Curled Silesian; a favourite in the United States, where it is largely cultivated at the present time by market gardeners. It should be sown in spring from March to May, for summer use only.

**21. Californian Curled.**—This American Lettuce has been sold this season in England for the first time. It is described as being curled, lacinated, and very ornamental, keeping long before running to seed, and growing to a large size. Last summer I saw about 100 plants of it (probably the first grown in Europe); they were about 8 in. in diameter, elegantly curled, slightly wrinkled, of a fine yellow-green colour, and quite distinct. It is a pretty pyramidal kind, and one which is very useful for table decoration if grown in pots.

**22. Neapolitan Cabbage (White-seeded).**—One of the largest and latest. Leaves undulated, of good substance, much wrinkled, and curled at the margins; ribs thick; head large, round, and regularly Cabbage-shaped. The whole plant is of a pale green colour, but during hot weather the top sometimes gets brownish. Its heart is so

Neapolitan Cabbage Lettuce.

firm, that seedmen are obliged to divide it to allow the stem to run to seed. It is sweet, tender, and very mild flavoured, though not so delicate as some other sorts. It should be sown in spring for summer use only, and should be planted 2 ft. apart. It grows freely in any soil.

**23. Malta or Drumhead (French—Laitue de Malte; German—Trommelkopfsalat).**—This fine white-seeded variety has now become

Malta, or Drumhead Lettuce.

a standard Lettuce, which is much more cultivated in England and in America than on the Continent. It is said to be a variety of the white Silesian. Leaves undulated, large, a little cut but not curled at the margin; ribs large; head high, flat, drumhead-like (whence the name), large, crisp, and tender. The whole plant is of a uniform

pale green colour. One of the best of summer Lettuces, and one which has a great number of synonyms, a sure indication of its excellence. Successional sowings of this variety should be made from March to June for summer use. It withstands the winter well if slightly protected, though it cannot be recommended as a winter Lettuce, many other varieties being superior to it.

**24. White Batavian (White Silesian, Laitue Batavis blonde).**—Leaves large, wrinkled, pale green, bordered with brown; head very large, loose, Cabbage-shaped, yellowish-green tinted with brown, crisp, commonly coarse, but liked by some. This, the type of a great many varieties, is well adapted for summer, autumn, and winter use if protected from sharp frost; but for forcing or for early spring

White Batavian Lettuce.

sowing it is too late, and takes up too much space, each plant of it requiring 24 in. It grows in any situation, withstands summer-heat well, and is a favourite with most people.

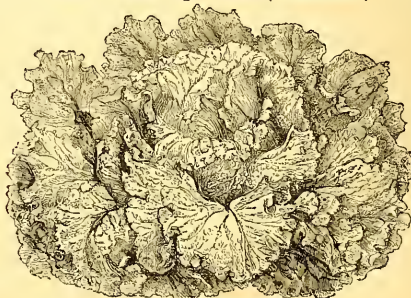

**25. Brown Batavian (Brown Silesian, Laitue Batavia brune).**—A large, late, white-seeded variety, the outer leaves of which are large, fleshy, coarsely wrinkled, undulated, and frilled on the margin; it

Brown Batavian Lettuce.

head brownish-green, large, and moderately firm. It is a hardy, free-growing Lettuce, of second-rate quality on account of its large, coarse midribs. It is well adapted for summer, and also for winter use if the frost be not too severe; being so late, it requires to be sown early in March and April. The annexed cut hardly does justice to the plant.

**26. American Gathering Lettuce (White-seeded).**—This was

American Gathering Lettuce.

introduced from America into Germany in 1872, and into England in 1873. Its habit is that of a Cabbage Lettuce, but it does not heart

at all; the leaves are beautifully curled and wrinkled, the outer ones spreading, the inner ones closely folded together, forming a large, white, tender, crisp centre. The plant grows to a very large size, is very hardy, dark green, elegantly stained with brownish-red over the top and at the extremity of each leaf. It has a fine appearance. It should be sown early in spring for summer use.

**27. The Hanson Lettuce (White-seeded).**—This was obtained a year or two ago from America. It is said to attain a very large size, and to be very hardy, but up to the present time, its qualities

The Hanson Lettuce.

have not yet been ascertained. It resembles the Neapolitan Cabbage Lettuce in habit, hearts well, and grows freely, the whole plant being of a beautiful butter-yellow colour.

**28. Bossin Lettuce (French—Laitue Bossin).**—This is the largest of all Lettuces. It is a black-seeded late variety, which was brought into general cultivation on the Continent about ten years ago. Its leaves are large and curled at the margins; midribs very thick and prominent; heart very large, but loose. It is a Lettuce of the Slesian type, and one which in appearance and colour is intermediate between the white and brown sorts. It is used for culinary

Bossin Lettuce.

purposes only, its coarseness making it unfit for salad. It should be sown from February to the end of May in the open ground or under cover, and it should be planted at from 1 ft. to 2 ft. apart. It bears the heat of the summer well, but is not good for winter.

#### Winter Cabbage Lettuces.

The following are the only sorts in general cultivation which can be trusted to stand the winter well, but many summer varieties are also occasionally cultivated during winter on the Continent, where the temperature is milder than that of England. As a rule, they are planted on a southern aspect on an elevated border along wall sides, and consist chiefly of the following sorts, viz., Tennisball, Dauphine, Victoria, Brown Genoa, Imperial, Brown Dutch, Spotted Cabbage (white-seeded), Drumhead, and White and Brown Batavian; but a severe winter will destroy a quantity, if not the whole of them.

**29. Hardy Hammersmith (Green Winter Cabbage Lettuce).**—This is a white-seeded kind, and the best winter variety in cultivation, being very hardy and keeping long before running to seed. It is,

therefore, largely grown by London market gardeners, standing, as it does, the frosts better than any other sort; leaves of good substance, wrinkled, of a glossy dark green or whitish-grey colour; heart medium-sized, moderately firm, crisp, and well flavoured. It should be sown two or three times in succession from the 15th of August until the 15th of September, and it should be transplanted in October, giving it a well-protected border, consisting, if possible, of a light, dry soil. It will be ready for use in April and May. When planted in a wet, cold soil it throws out in spring several shoots from the bases of the bottom leaves.

**30. Large Winter Cabbage or Madeira (White-seeded).**—A good winter sort; head of medium size, not very firm, green, brownish on the top; leaves broad, large, undulated, stained with brown; remains long before running to seed, and is ready for use at the same time as the Hardy Hammersmith. Its quality varies in accordance with where it is grown; it requires a warm, dry, south border, and should be treated in every way the same as the Hardy Hammersmith.

**31. All the Year Round (White-seeded).**—A fine variety much esteemed in England; leaves wrinkled, and much folded alongside the midribs, of a pale green colour; head small, crisp, and tender. As is indicated by its name, this variety can be grown all the year round, and sowings of it must be made accordingly. It is a good spring and summer Lettuce, though other varieties are superior to it. Its quality is better than that of ordinary winter sorts, but a long and severe winter will destroy quantities of it if not protected, and the remainder will soon run to seed; nevertheless, it is well worth extensive cultivation in this country.

**32. Brown Winter Lettuce (White-seeded).**—Leaves numerous, small, folded, and wrinkled; head of good size, globular, and moderately firm; in colour green and brownish-red on the top. One of the best of winter Lettuces, very hardy, tender, keeping well, and of good flavour. It is extensively cultivated in the western districts of France.

#### Class II.—Cos Lettuces.

French—Laitue Romaine, or Chicou; Italian—Lattuga Romana; Portuguese—Alface Romano; German—Bind Salat (*Lactuca sativa romana*; *Lactuca sativa longa*).—The word Cos is said to be derived from the Isle of Cos, or Stanchio Island, Asiatic Turkey, where it was at one time largely grown; others say the Isle of Cos is its native country, whence it was imported to England. It derives its French name, Laitue Romaine, from this Lettuce having been extensively cultivated by the Romans; in fact, the first seeds of Lettuce sown in Paris came from Rome, but I presume that a century or so ago all kinds of Lettuces were called Laitue Romaine, and we can see from the more or less diffuse description of Lettuces given about that time that numbers of Cabbage Lettuces were called Laitue Romaine. It is only a form of the Cabbage Lettuce; in fact, plants intermediate between the two types are occasionally met with. It differs from the Cabbage Lettuce in the leaves (instead of being folded and inverted over each other, and forming a heart like a Cabbage) standing nearly upright, more or less spreading, and in some varieties a little folded over each other at the top, thus forming a cylindrical conical shaped plant about 1 ft. high. It is coarser and not so finely flavoured as the Cabbage Lettuce, but is more hardy, and succeeds better under bad conditions than the latter. It never blanches, but the inside leaves become more tender and of a lighter green by tying up. Notwithstanding, it is the leading, and the most extensively cultivated salad Lettuce in England. Cos Lettuces may be divided into summer and winter Cos kinds. Like Cabbage Lettuces, the number of varieties and synonyms is indefinite, each province having its favourite kind, of which a bad and good stock make two or more varieties. The following are the best:—

#### Summer Cos Lettuces.

**33. White Cos (Paris White Cos, Alexander Cos, Hooper's Incomparable White Cos. French—Romaine blonde Maraichère).**—This is a white-seeded kind, and the best summer variety. Its leaves are large, erect, crisp, slightly wrinkled, serrated, pale green, and hooded at top, thus forming a heart, and blanching without tying. It is a large, fine Lettuce, and the one most generally cultivated during summer. To have it in perfection it requires a somewhat heavy soil. It does not withstand the winter well, and runs quickly to seed if sown in the open air too early. It should be sown from March to April, which is the best time for transplanting it into the open ground; it will then be the latest of all Cos Lettuces in running to seed, as it bears heat better than any other popular variety. Like

all good varieties, it has numerous synonyms; Giant White Cos, Sutton's Superb White Cos, and Webb's Monstrous White Cos are only selected stocks of the above. The London White Cos differs

White Cos Lettuce.

from the Paris White Cos in its leaves being more erect, not serrated or wrinkled, and in their being of a lighter green; but, owing to the two sorts being so much mixed together, it is useless to make two different varieties of them.

**34. Green Cos** (French—Romaine verte Maraichère).—A leading white-seeded variety, much harder than the White Cos, which it resembles. Its outer leaves are large, erect, dark green, and hooded at the margin, forming a fine plant, which hearts and blanches without tying. This variety grows a little larger than the White Cos, and the heart is very crisp and tender. It withstands the winter well with a little protection, but runs quickly to seed during summer; therefore it is chiefly used by market gardeners for winter cultivation under glass. It should be sown in September and October, like the Gote Lettuce, No. 4, with which it associates well. Some growers even plant four Lettuces around one Green Cos under a cloche. It should be sown in January, and afterwards yields an abundant crop during spring; this variety is, in short, used for forcing in winter and spring, whilst the White Cos is used for summer and autumn. Though it hearts well alone, a little tying will be an advantage. It is often planted in January and February under glass between Cauliflowers, Carrots, and similar crops.

**35. Kingsholm Cos** (White-seeded).—Leaves large, of good substance, and of a greyish colour, very distinct, the centre ones much hooded at the top, forming a large heart, very tender and of the finest quality. This is by far the best summer Cos, and the best hearting kind without tying. It is admirably adapted for hot climates and dry soils. In many hot places abroad it has resisted the drought better than any other Cos. Furnishing, as it does, a fine salad a month after all other varieties have run to seed, it cannot be too

Kingsholm Cos Lettuce.

much recommended. Market gardeners seldom use it for winter cultivation on account of its being so late and not being very hardy; but, sown during the spring, it will be found invaluable. This variety has never been grown extensively in England or on the Continent, and though it has been known for many years, it has only lately been brought to England under a new name. It has, however, acquired the reputation which it deserves. Synonym—St. Alban's All Heart Cos Lettuce.

**36. Magnum Bonum, or Florence Cos** (Black-seeded).—Probably the largest of all the Cos Lettuces; leaves very large, roundish, thin, spreading, wrinkled; midribs large, of a very light green colour; a very large-hearted Lettuce with the assistance of tying. A capital summer variety, very tender, and running to seed with difficulty, but very late. It should be sown from February to

Magnum Bonum, or Florence Cos Lettuce.

June, and planted about 16 in. apart. It seldom stands the winter. The white-seeded variety is similar to the above, but perhaps larger.

**37. Sugar-loaf Cos**.—A first-class variety of medium size; leaves erect, slightly wrinkled, oval, and regular; brown coloured, and on the top brownish-red, forming beautiful hearts without tying, even when half grown. It should be sown in spring like other Cos

Sugar-loaf Cos Lettuce.

Lettuces. It stands drought well, and should be planted about 12 in. apart. It is well adapted for sowing under glass during winter.

**38. Ground Cos** (French—Romaine pomme en terre).—This new black-seeded variety, which has been known for three or four years on the Continent, is probably derived from the Egyptian Cos, which it resembles, but it is much smaller. Its leaves are erect, hardly wrinkled, of a dark glossy green, the centre ones being yellowish from being much pressed and folded together, but the plant never hearts. It grows nearly in the ground, and hence its name. It has been recommended for winter and summer cultivation, but, when other good

Ground Cos Lettuce.

kinds are taken into consideration, it hardly deserves a place in our gardens at all.

**39. Monstrous Cos** (Black-seeded).—This Lettuce may be said to be about intermediate in habit of growth between the Sugar-loaf and the Bath Brown Cos. Its leaves are spreading, large, and brown-coloured, the centre ones being beautifully bronzed even in a young

state. Good for summer and winter use. It should be planted 14 in. apart.

**40. Spotted, or Leopard Cos (White-seeded).**—Leaves broad, short, narrow at the base, and wrinkled; at the centre irregularly bordered, and all inclined outwards; spotted and streaked with brownish-red, becoming darker in the centre; midribs prominent; does not heart at all, but the centre can be rendered very tender and crisp by tying. This variety withstands summer heat well, and also cold. It is very sweet, beautiful in appearance, and deserves a place in every garden, though moderate only as regards size. It is much later than the White Cos. It should be sown at the same time in spring as other varieties, and it is sometimes used as a winter sort. Watering over the leaves when the sun shines greatly increases the intensity of the spots.

**Spotted Cos (Black-seeded).**—Similar to the preceding, from which it only differs in the colour of the seed.

**41. Artichoke-leaved Cos (French—Romaine à feuille d'Artichaut; German—Artischocken blättrige Bindsalat).**—This is a black-seeded, monstrous variety, brought into reputation by the celebrated French agronomes, Mathieu de Dombasle, but now almost out of cultivation. Its leaves are narrow and jagged, like those of the Globe Artichoke, all radical, upright, very numerous, and forming a thick tuft; midribs brown, sometimes purplish, the whole plant being of a dark or brownish-green colour. It does not heart, but, nevertheless, it is very tender, succulent, and fine in flavour, especially the inside leaves, which are of a pale green colour; tying a few days before it is used greatly improves it. It is a winter and summer variety, but when sown in June or July it is invaluable late in the autumn when other varieties have disappeared or have been killed by frosts; at that time, indeed, its flavour is at its best. It grows in any soil or situation, and is the largest cropper of all Lettuces; therefore it would be useful in little gardens so difficult to crop about London. It grows about 12 in. high. If cut an inch or so above the ground the stem soon produces half-a-dozen small heads. It should be sown from spring until autumn, according to the time at which the produce is required, and the plants should be set from 12 in. to 18 in. apart, according to the character of the soil. If sown in August for winter it will grow to a very large size during the spring.

The preceding summer varieties may also be employed for winter use if planted late and protected from sharp weather, but it would be unwise to trust to them, for a long period of wet, cold weather would partially or entirely destroy them, whilst the following varieties will withstand any kind of weather:—

#### Winter Cos Lettuces.

**42. Brown Cos (Bath Cos, Berkshire Cos, Improved Bath Cos).**—This is a white-seeded variety, the leaves of which are large, spreading, smooth, and brown coloured. It is very hardy, and one of the best for winter cultivation. It grows to a large size, and with a little tying hearts well. Though the brown colour is objected to in salads, this variety is appreciated for its heart, which is large, and contains a quantity of tender, crisp, white leaves, slightly tinged with brown on the midrib.

**43. Bath Cos (Black-seeded).**—This resembles the preceding. Its leaves, which are spreading, serrated, and wrinkled, are of a

Egyptian Cos Lettuce.

greenish-brown colour. Midribs brownish-pink. As to quality, it is the same as that of the above. Donnett's Giant Bath Cos is an improvement on the preceding. Its leaves are thicker, shorter, and more spreading; it also grows to a larger size, and keeps better.

The above are chiefly winter Lettuces, which should be sown in the end of August and planted out in October on a warm border, about 1 ft. apart. If young plants be stored in a warm corner and protected from frost they will be ready for planting in the open ground in February, and will produce a good crop during the spring. The

two above varieties are erroneously called English Lettuces by London groengrocers.

**44. Egyptian Cos (Egyptian Green Cos, Brighton Cos, Early Green Cos).**—A very old white-seeded variety, the leaves of which are closely erect, with a regular margin, oval, and of a dark green colour; midribs very strong. This sort grows to a medium size, and requires tying in order to blanch the centre leaves and render them tender. It should be sown in August and September for winter, and in November and December for spring use. It requires some slight covering in the case of severe frost. In summer it runs to seed before heading.

**45. Green Winter Cos (Black-seeded).**—This, one of the best of winter Lettuces, is somewhat similar to the Paris Green Cos; it is very hardy, but of coarse quality. Its leaves, which are short, strong, wrinkled, and serrated, are of a green colour, and do not heart without being tied. It should be sown in August and September,

Green Winter Cos Lettuce.

and planted out in October in a sheltered place protected from severe frost.

**46. Improved Spotted Cos (Black-seeded).**—An improvement on the white and black-seeded Spotted Cos. Leaves bright green, erect, spotted with brownish-red, forming a heart, which is, however, improved by tying. This variety is hardy, stands the winter well, and is about a week later than the two other spotted varieties.

**47. Red, or Blood Winter Cos (Black-seeded).**—Leaves strong, large, erect, and not wrinkled, the whole plant being of a

Red, or Blood Winter Cos Lettuce.

dark red colour; the centre leaves form a little heart, but do not cover each other. It bears the winter better than any other sort. It should be sown in August and September, and planted out in October and November for use in March and May. It is worthless for summer planting. There is a white-seeded variety similar to it, but of inferior quality.

#### Class III.—Cut-leaved Lettuces.

These are seldom, if ever, cultivated in England. They are, however, appreciated on the Continent, especially in Belgium and Holland. They consist of small early Lettuces, which are sown amongst other vegetables under glass from December to March, and in the open ground from March until spring-sown Lettuces are ready for use. As soon as they have from two to three small leaves they are cut, and are ready for the salad bowl. They are very tender, and really delicious mixed with Corn

Salad, Batavian Endive, Celery, &c., but used alone they are not good, on account of their watery consistence. The varieties from 1 to 6 described above are well adapted for the same purpose, but the best is—

48. Dutch (Kropdunsel), which is very early; its leaves are round, of a fine yellowish-white colour; and it is, in fact, the only sort of Lettuce that is grown in the Netherlands.

49. Endive-leaved or Boston Curled Lettuce.—Leaves spreading, wrinkled, and curled like those of Endive; whitish-green in colour; seeds black and very small; stands the winter well. Neither so early nor so good as 48. It should be used and cultivated like the Oak-leaved Lettuce, about to be mentioned.

50. Oak-leaved (Spinach Lettuce—a species; *Lactuca quercina* (De Candolle), and probably the same as *Lactuca palmata* (Wildenow) and *lacinata* (Roth); Black-seeded).—The annexed illustration is that of a young plant started to seed, and, therefore, does not show accurately the habit of this variety. Its leaves are all radical, from 6 in. to 10 in. long, lyrate, cut, and divided, like those of an Oak. The plant forms no heart, and is cultivated for the sake of its young leaves, which are used in a cut form for salad. It should be sown in February and March under glass amongst other vegetables, or in April in the open ground. The leaves should be cut as soon as

Oak-leaved Lettuce.

they are sufficiently developed, and sowings must be often repeated, as during the summer it runs quickly to seed. If properly treated, after the leaves are cut it soon will shoot again. It is generally grown as an annual, but I presume it would last for many seasons. It is of a yellowish-green colour, and is often confounded with the Endive and Artichoke-leaved Lettuce.

Before concluding my list I must add the two following species, which cannot be classed amongst the preceding:—

51. Perennial Lettuce (French—*Laitue vivace*).—This plant, which is a native of Central Europe, grows from 2 ft. to 3 ft. high, and has smooth, pinnatifid leaves, toothed on the upper part. Its flowers are large and blue, shaded with purple. Though seldom cultivated, it has for a long period been used in France as a vegetable. Roots if buried in the fields by the plough produce during the spring fine white tender leaves, which if cut below the ground just above the roots furnish a most wholesome salad. The young, tender green leaves are also used cut up in salad, and the fully-developed leaves are used like Chicory or for boiling. From seeds sown in April and June, roots will be produced during the next spring which will yield an abundant supply of small and large leaves, or if treated during the winter like Chicory (*Barbe de Capucin*) or Witloof, &c., forced a little, a constant supply of white salading will be obtained during the most barren time of the year.

52. *Lactuca angustana* (Allioni)—(synonyms—Asparagus Lettuce, Aosta Lettuce; French—*Laitue Asperge*, *Laitue d'Aoste*; German—*Spargel Salat*).—An old annual species, said to be a native of the valley of Aosta, between St. Pierre and Villanova, in Piedmont, also of Mont St. Bernard, on the banks of the torrent. Some years ago it was sold as a novelty by German seedsmen. It somewhat resembles in appearance a Cos Lettuce, but it never hearts. Its leaves are entire, toothed, hastate, from 8 in. to 10 in. long, and from 1 in. to 2 in. wide, of a dark green colour; midribs strong and smooth, and sometimes used as Asparagus; hence its name. The flowers are yellow, and the seed white. It should be sown in March under glass, and in April and May in the open ground. The young seedlings should be planted out about 13 in. apart in well prepared soil, and should be seen before they run to seed.

### Cultivation.

Lettuces thrive best in a warm, light, rich soil, the only one in which good-flavoured Lettuces can be obtained. It should not, however, consist of half manure, as it does in the Paris market gardens. Nevertheless, such soils may be cropped to any extent; on one day may be seen a large piece covered with Cabbages, Cauliflowers, or other vegetables; a few days afterwards it will be planted with Lettuces; and eight or ten weeks after that with some other crop. Under such a system three

*Lactuca angustana*.

or four crops may be taken from the same spot during a season. Lettuces grown so luxuriantly by means of manure and water are tender, but watery, and not finely flavoured. Transplanting is necessary to obtain large heads, except in the case of Lettuces sown under glass or in the open ground amongst other vegetables. For planting, select a cloudy day; draw furrows 1 in. deep, plant in them, and water; in about a fortnight afterwards stir up the soil, filling up the furrows. Avoid watering during sunshine, and never water over full-grown plants; it darkens their colour and rots the hearts, especially those of Cos Lettuces. Lettuces germinate very quickly; if dipped in spirits—say pure alcohol—for twelve hours they will show young leaves in from twenty-four to forty hours after sowing. Generally, seed sown in the open ground during summer produces young plants in three or four days' time, if well treated. A covering 1-5th in. deep will be sufficient.

SPRING LETTUCES.—The eight first-named varieties are the best in cultivation at the present time. 1, 2, 3, 4 are the best for early forcing, and for sowing under glass from October to January. 5 and 6 are well adapted for second sowings in January and February, and 7 and 8 for the third sowing in February and March, or for sowing in the open ground as soon as the weather will permit. In France, where the climate is genial enough for sowing Celery, Leeks, and other vegetables in the open ground, the four last-named varieties should be sown at the same time on the beds, and removed as soon as they are ready for use, thus making room just when the other seedling crops require it. 1 to 6 are often sown among Cauliflowers, Melons, and other plants under glass during the winter without injuring them in the least.

SOWING LETTUCES.—No approximate date can be given for sowing; it depends on the weather, the country, and on the purpose for which the produce is required. As a rule, small successional sowings are better than transplanting from the same bed a second time. Sow in beds well prepared and always, if possible, cover with leaf-mould or thoroughly decomposed manure. Protect against sharp weather if early in the spring, and shade during hot days in summer. Keep the beds clean and water when needed; thin out to  $\frac{1}{2}$  in. apart, and plant out as soon as the seedlings have four or five leaves; then destroy the bed. The ground being well prepared, plant at a good distance apart, according to the soil and the variety; 12 in. asunder for common varieties and 18 in. for others will be sufficient. Hoe frequently and mulch in hot countries, and water when necessary. Such attentions will ensure a good crop, for, when Lettuces suffer from drought, they acquire a bitter taste, and soon run to seed, even when young before

hearing. The common Cabbage varieties prefer a light, rich, calcareous, warm soil, whilst the curled sorts are better suited for heavy and wet ground. The order in which they are described corresponds as nearly as possible with their quality. The Tom Thumb, on account of its earliness, may be sown late in summer, when it will be ready for use before winter sets in.

**WINTER LETTUCES.**—Three consecutive sowings, made between the 15th of August and the 1st of October, are necessary in order to get seedlings for planting in October and November. They should be set in a well prepared border, exposed to the south, and when possible protected by a wall. They should be shaded and watered well as often as may be required. If the winter be severe, numbers of the first planting will be destroyed, whilst those of the third planting will withstand it, and afford a good crop a little later, but in mild winters those first planted will be ready for use early in the spring, and the others will come in in succession. Winter Lettuces planted at the same time will come into use all at once, but when protection is at hand in case of sharp weather (leaves, straw, &c.), nothing need be feared. Beware of snails and slugs during mild wet days in February, just when Lettuces commence to grow. At that time a good deeping will be most beneficial, and if a few seedlings have been planted in a corner they will be found useful to replace those which have perished during the winter. The Hammersmith and the Madeira are the leading varieties for that purpose; plant them 1 ft. apart in private gardens, but market gardeners do not allow them so much space.

**CUT-LEAVED LETTUCES.**—About the culture of these there is nothing particular. They may be sown at any time during the winter under glass amongst other vegetables, and in the open ground in spring. Immediately they are cut give the place where they grew a good hoeing to destroy their roots. In the Netherlands, market gardeners sow these Lettuces on every piece of ground which they have at command, until their gardens look as if they were covered with a yellow carpet.

**COS LETTUCES FOR SUMMER AND WINTER.**—These are treated the same as Cabbage Lettuces, but the former are about a week later than the Cabbage kinds, and like a heavier soil. A week before they are wanted tying them round with straw or some similar material makes them tender, and blanches them. Some, however, as the Kingsholm Cos, can do without tying, but others, such as the Florence, Blood-red, and brown Artichoke-leaved are improved by it. For forcing, the Green Cos is the best. I have nothing to add to what has been previously said as regards kinds from 1 to 4. The Green Cos is that chiefly used in France and by Paris market gardeners, whilst the White Cos is the leading sort in England. In short, Lettuces are held to be so valuable on account of their quick growth, that they are planted in every spot, and in all gardens, between rows of Cabbages, Cauliflowers, Vegetable Marrows, and Cucumbers, and on Celery trenches, and they are removed just in time to make room for other crops.

**INSECTS.**—The cockchafer is very disastrous to Lettuces in France; it cuts the roots during summer, but in England this pest need not be dreaded. Snails and slugs are more troublesome, inasmuch as they destroy the seedlings on the beds when planted. Quicklime, which does not injure the plants, spread over the ground during wet, mild mornings and evenings, will destroy all that it touches.

## NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Cauliflowers Buttoning.**—"Cambrin" attributes this to over-maturing, and no doubt this frequently causes "buttoning," but over-frosting is quite as injurious as over-maturing; and the hard frost which we had here on the 1st of April seems to be sending all the exposed plants into buttons, whilst those protected only with glass lights seem safe and sound, and are spreading their leaves wide and looking extremely promising.—D. T. F.

**Potatoes for Forcing.**—I have this season had thirty lights employed in forwarding this the prince of spring vegetables. The varieties which I have grown are Veitch's Ashtop, Myatt's, and Alpha; but for crop and flavour Myatt's are a long way ahead of the others. Alpha, compared with Myatt's, is a lump of clay. Ashtop is good in flavour, but not half a crop. I shall in future grow all Myatt's, and, except a south border for very early lifting, Myatt's Prolific will form the staple of my early kinds both outside and in.—R. GILBERT, *Burghley*.

## GARDENING FOR THE WEEK.

### Indoor Plant Department.

**Pot Roses** that have been forced through the winter, to supply flowers to succeed those that furnished the earliest bloom without pruning from the buds formed through the autumn, will, by this time have produced all the flowers they are capable of, and will require immediate attention to prepare them for another year's work. The principal difference in the treatment of these from such as furnish the first flowers without being autumn-pruned is that they do not require any cutting back in the spring, but treating in a way to mature and solidify all the wood they have made through the winter whilst being forced, and to still further encourage them during the summer to make as much more growth as they are capable of in the open air; for it must ever be borne in mind that the ability in these pot-grown Roses to produce flowers will be proportionate to the size and strength they attain before being pruned and introduced to heat in the winter much more than upon any subsequent treatment they are subjected to whilst undergoing the forcing process.

**Preparation for Turning Out-of-Doors.**—In taking Roses from the house or pit where they have been located through the winter, where constantly under the influence of some artificial heat, they should by no means be placed at once in the open air, as, although the season for cold weather is now passed, exposure directly without any preparation would immediately check both root and top growth, which would stagnate them for some weeks; instead of which it is desirable that as much growth as possible should be encouraged early in the season, so as to afford full opportunity for its getting well ripened before the autumn approaches. With this view the plants should be accommodated in a cold pit for two or three weeks, where, by sufficient air at night without suffering by it, all such plants as require more root-room should at once be potted, using soil of a similar character, and treating them in other respects as advised recently for the earliest-bloomed portion that had produced their flowers about Christmas from last summer's shoots without pruning; the main difference being that in the Roses now under consideration no pruning at the present time must take place, this operation being deferred until shortly before they are put in to force the ensuing winter.

**Position when Turned Out.**—After they have been gradually inured to the open air in the way suggested, let them have a thoroughly open situation where they will get plenty of air and all the sun possible, which will not only further the development of stout summer growth, but render them less liable to the attacks of mildew, to which these forced Roses are always more pre-disposed than such as are never subjected to indoor treatment. At the time of turning out examine every plant carefully to see that it is free from that parasite, otherwise it will quickly spread over the whole of the foliage, which it is most desirable to retain in a healthy condition as long as possible, as upon its existence in a great measure depends the plants' ability to grow on at once freely. Roses that have been forced in such a manner as the above, and on coming into flower were removed to conservatories or ordinary greenhouses for decorative purposes, will to some extent have undergone a hardening preparation for turning out; yet if a few square glazed lights could be placed over them temporarily for a week or two it would be all the better, as the leaves of any plant, however hardy, formed under glass are always extremely sensitive to full exposure to the sun out-of-doors. Plunge the pots of the whole in coal-ashes, as recommended for the plants first removed outside. Such as do not need re-potting, or surfacing with new soil, will be much benefited by the use of manure water. Whether this be made from guano, stable or sheep manure, or the like, it will be a great advantage, and a moderate addition of soot is stirred in with it, sufficiently long before use to admit of its becoming clear. Not only does the soot act as a powerful fertiliser, but, more than anything else, it is distasteful to worms; if already existing in the pots, it will cause them to decamp, and prevent their ingress to such as are free from them.

**Roses on Walls, Buildings, &c.**—The ability to produce a full succession of flowers through the summer and autumn by Chinese, Noisette, and Hybrid Perpetual Roses in such positions as the above is, in a great measure, dependent on the treatment they at present receive. If aphides, red spider, and other insect pests—to which Roses, more than most plants, are subject—are allowed to prey upon the foliage, it quickly loses its vitality, which not only gives the plants, shortly after midsummer, an unsightly appearance, such as they should not assume before autumn, but it proportionately reduces their ability to make a second growth, from which successional flowers are to be expected. On high walls, where the syringe cannot be so effectually used, where there are any considerable quantities of Roses so grown, the garden engine should be regularly employed, never allowing the insects to get ahead. In addition to this, the roots should be well supplied with stimulants. Roses on the walls of dwellings have often a very limited extent of border space that admits of being dug and manured; consequently, it becomes necessary to do all that is practicable to invigorate them. They are extremely fond of manure water, and will bear it applied stronger than many plants, and in no situation can it be used with better effect than to such plants as here described. By liberal applications of it, and keeping the heads of the plants clean in the way recommended, Roses on walls can be kept so as to maintain a healthy appearance, with a succession of flowers, until the autumn, very different from the rusty-brown garb the foliage too often assumes after the first flowering is over, rendering them much more objects painful to look upon than pleasing in appearance. There are two things essential to success in

Rose culture on walls, even much more so than in the open ground—the timely destruction of insects and a continuous supply of fertilising elements to the soil; otherwise, despite their unsparing beauty for the short season in which they produce their principal crop of flowers, it is better to dispense with them and substitute other plants requiring less attention.—T. BAINES.

**Pelargoniums**—show and fancy varieties—will now be fast pushing up their flowers, and will be assisted by clear manure water. For home decoration, it is neither necessary or advisable to tie them out so regularly as when they are intended for exhibition; use only sufficient sticks and ties to support the plants and prevent them having an untidy appearance. For summer and autumn decoration nothing is more useful for greenhouses than the Zonal varieties of Pelargoniums. Keep these near the glass, so as to induce short, stout growth, and do not allow them to become exhausted with flowering at the present time, as they will be much more useful after the show and fancy sorts are over. Pot on young plants of Balsams, giving them soil well enriched with a good sprinkling of sand and one-fifth of leaf-mould, in which all quick-growing plants of this description root freely. Late herbaceous Calceolarias will now be coming into bloom. See that these are free from aphides, or every flower will be crippled. These are gross-feeding plants, and delight in manure water, bringing it strongly to the surface of the soil. The old but beautiful blue-flowered *Plumbago capensis* should be grown in all. It is a plant easily managed, and, when in bloom, well bears removal to a dwelling house, where it continues in flower for some time. It is most useful grown in small pots of a 6-in. or 8-in. size. It will thrive in any soil—loam or peat—sufficiently porous. Kalceanthes, which are easily grown and are excellent decorative plants, will now require sticks and ties to support their heavy heads of flower that are fast coming to maturity. They are subject to aphides, which get into the points of the shoots and completely spoil the flowers, but are not easily detected. In these plants, except by the yellow hue they give to the leaves. Dip in Tobacco water, or smoke any that may be affected.

**Specimen Herbaceous Plants.**—If for exhibition purposes, these are generally grown in pots, and to have them well established, they should be potted last year. The pots should all be of one size, say 8, 9, 11, or 12-in. pots, as may suit special requirements. In order to have the pots well filled it may be necessary to insert therein several plants together, especially such small kinds as Aubrietias. Keep them at present in cold pits, and have the pots plunged in Cocoa-nut fibre or coal ash. If the flowers are backward keep on the sashes, but tilt them to a little, so as to admit plenty of air. The following are commonly used for exhibition purposes, *viz.*, *Yucca filifera*, *Veronica* of different sorts, *Delphiniums*, *Tradescantias*, *Irises*, *Cornifolia*, *Centranthus*, *Dicentra spectabilis* and *eximia*, *Centranthus ruber*, *Iberis coreana*, *Astilbe japonica*, *Spiraea palmata* and *venusta*, *Erodium Manescavi*, *Betonica grandiflora*, *Aquilegia corulea*, *californica* and *glandulosa*, *Campanula persicifolia coronata*, *Pyrethrum roseum fl.-pl.*, *Lychnis viscaria fl.-pl.*, *Phlox decussata*, and *Alpine* varieties, *Primulas* of sorts, *Statis latifolia*, and others.

#### Indoor Fruit Department.

**Vines.**—As each Vine in the early houses is cleared of its crop the foliage should be thoroughly syringed with clean water, so that any insects that might hinder the ripening of the wood may be washed off. Those parts badly infested with red spider or thrips must be syringed two or three nights in succession, and a thorough drenching with the garden engine or some equally strong power once a week will greatly help to preserve the foliage, which should be kept as long as possible in a healthy state. Where it is not necessary to close the ventilators for the benefit of tender plants full air may be left on all night in Vineries after the fruit is cut. Any straggling lateral growth which may have been allowed to grow while the fruit was ripening should be cut in to the part whence it started, so that the buds upon which dependence is placed for next year's crop may have every chance of becoming matured. It is a great advantage at all times, more especially in the case of early forcing, to have the wood completely ripened; and now that the nights are getting milder, air in small quantities may be admitted continuously in all Vineries in which grapes are swelling; this supplies the interior of the house with fresh air, which is more conducive to the free and perfect development of the fruit than a close atmosphere. As soon as syringing is discontinued, admit of the fruit colouring, the flow pipes may be painted over with sulphur. It is a waste of fuel to light Vinery fires on fine mornings; a little artificial heat in the evening is generally sufficient to keep up the temperature, and a liberal supply of air should always be admitted in the morning to prevent the temperature from rising too high and scorching the foliage, which is liable to occur. Planting out young Vines in the growing state is a system which may be practised with the best results. Those propagated from eyes this spring are the most suitable for the purpose; with these I never knew a failure to occur; but that cannot be said respecting those grown in pots the preceding season, out back in autumn, and planted while making their second year's growth. The latter are generally stronger than the former, but a healthy shoot, 4 ft., 5 ft., or 6 ft. in length, with abundance of fresh, fibrous, uncoloured rootlets, makes a substantial and sure formation for immediate and future success. The exact time to plant is not of much importance. It may be done now or at any time between this and the middle of July; but, of course, where the space is empty and the Vines ready, there will be no objection to sowing Vines raised in boxes and root-pruned by cutting the soil and roots into squares, as previously advised, are best for this sort of planting, as they can be lifted and planted without ever being placed in pots, which

sometimes interferes with the right direction of the roots. Those propagated in pieces of turf have the same advantage. If the plants have been confined to pots, which is a common way of growing them, the ball and roots need not be much disturbed in planting. Any which have begun to take a circular course should, however, be spliced and placed in such a direction as to enable them to extend readily into the border. Planting may be done in the same way as that recommended some time ago for one-year-old canes. Watering must be punctually attended to in order to prevent the foliage from flagging; and should extremely sunny weather set in, a shading of thin canvas should be used during the hottest part of the day. With a little attention, the whole matter may be performed without the Vines sustaining the slightest check, and by autumn they will be a two-month in advance of what they would have been had they been retained in pots this season and planted out next spring. Among black Grapes for a small house, Black Hamburg and Black Alicante are most suitable, and among white kinds Duke of Buccleuch and Trebbiano. The first named, both black and white, will ripen well with little attention by the end of June, and the other two will keep in good condition, if protected from frost and damp, until February. For a mixed early house, on a larger scale than that just alluded to, Black Hamburgs, including Muscat Hamburg grafted on the common kind, are most suitable, and among white sorts Foster's Seedling, Royal Muscadine, and Beckland's Sweetwater. For a late mixed house, Lady Downes, Alicante, Gros Colman, Barbossa, and Mrs. Pince are the best black varieties, and Pearson's Golden Queen, Muscat of Alexandria, Syrian, Trebbiano, and Raisin de Calabria, the best white sorts. The first house may be made to furnish ripe fruit from the middle of May to the end of September, when the late Grapes will maintain the supply in a moderate way until well into spring. Some daily growing varieties in one house, but some of the latest Grapes up to the country, come from the same house, *viz.*, Alicante kinds. Where many varieties exist each house may be planted with a different variety, but that is the exception rather than the rule.

**Pines.**—The principal work in Pineries at present consists in airing and damping. On very hot days the pathways should never be allowed to become dry, for an arid atmosphere is not beneficial to many Pines, at whatever stage of growth they may be. Where the damping matter is dry, it should be thoroughly saturated with water. Still shut up early in the afternoons, and a little air should be admitted throughout the night, putting it on at about six o'clock in the evening and gradually increasing it from six o'clock next morning, as it becomes necessary. Keep plants showing fruit successively to the Queens well supplied with water at the root. In addition to the insects previously mentioned as being injurious to the Pine ants, which are plentiful in many places, are often troublesome in the case of the fruit. They do not meddle with it when green, but when ripe they either make holes for themselves, or enter by the reuts which frequently occur in over-ripe fruit, especially in the White Providence and Prickly Cayenne varieties, and it is difficult to get them cleared out when once they get established in such quarters. Their numbers may be greatly thinned, however, by placing a few saucers containing treacle or honey near their runs. Where such enticing traps are employed they seldom pay much attention to the fruit. A sponge soaked in either of these sweets serves the same purpose, and when filled with ants the latter may be destroyed by immersing them in hot water.

#### Flower Garden.

Now plant out Pelargoniums, Verbenas, Lobelias, Ageratums, and Petanias. In putting out these summer bedding plants, account should be taken of the time when the greatest display will be required. When it is desirable to have the whole a complete sheet of bloom as early in the season as possible, it is necessary to put the plants in the beds much closer than when the greatest effect is wanted later in the season. In the neighbourhood of London, in most large gardens, if the flower garden is not at its best before the close of the London season its value is, comparatively speaking, lost. In places where the principal display is not wanted before August, the plants should be put in further apart, or they become exhausted before they are required to be at their best. A medium course will, perhaps, be the best in most cases. The distance between the plants will, in some measure, be determined by their size and strength when planted and the nature of the soil. In this style of gardening it is a desideratum to have as good a sheet of bloom on the beds for as long a period as possible, but the plants are crowded together so that they cannot hold the place of many becoming bad. Individual tastes vary in the arrangement of a flower garden, as in other matters, yet there is no reason why anyone should confine his practice to the conventional ribbons, lines, circles, or segments of circles, which it would appear almost impossible to eliminate from modern flower gardening. There are irregular combinations of different colours and plants many years ago that has never been surpassed in pleasing effect. Take, for instance, the beds of Mangle's Variegated Geranium and Purple King Verbenas, planted together so as to run into each other as irregularly as possible. This and many similar mixtures did much to remove the objectionable formality, with reason complained of by many at the present day. It is not alone by a judicious blending of colours in an informal way that summer flower gardening might be stripped of its greatest defects as seen from an artistic point of view, but much might be done in the form and height of the plants associated together. To do this, it is not necessary to plant large coarse-leaved subjects in the midst of low-growing flowers. From the same point of view, it is not necessary to assess there are numbers of light plants of elegant habit that would relieve the too even surface of colours in mass without hiding or nudly shutting out from view all that it is desirable to be seen from any point. The old

*Humea elegans*, now in the shade by plants not possessing half its merit, is one that well illustrates the habit and style of the subjects required for relieving the even surface of form and colour. *Acacia* *limbata* is well adapted for the purpose, as also *Cordylus australis*, *Acer negundo* variegatum, in specimens varying in height from 2 ft. to 4 ft., according to the situation for which they were required. Where carpet bedding is carried out all the plants used, except those tender ones named above, should be put in the places they are to occupy, filling the others in afterwards. On all dressed ground, such as herbaceous borders and amongst shrubs, the use of the hoe and the rake must be kept up, so that the whole may have a tidy appearance. During the present growing weather the mowing machine must be in frequent use, for, if the lawns be allowed to get too long, not only is it objectionable in appearance, but more labour is entailed. Thin or curly-sown annuals; the remnants of many beautiful specimens are rarely seen during being often sown in out-of-the-way places, under the drip, shade, and impoverishing influence of the roots of deciduous trees. If, perchance, they happen to get an open situation, where they might have a chance of showing their true character, they are too often allowed only a fourth of the room they require. Let every species and variety have enough room to grow to its full natural size, by which means the flowers will individually be much larger, and the duration of the plants flowering will be considerably extended. What are known as sub-tropical plants are generally somewhat tender, and their planting may with advantage be deferred for a short time; if possible, the site selected for them should be somewhat sheltered, as they consist principally of species with large and ornamental leaves, which are very apt to be disfigured if exposed too early to cold and boisterous winds. Such plants should be of considerable size when planted, and should have been gradually inured to exposure in the open air. They should be planted in beds of rich or highly-manured soil, and should be abundantly supplied with water during dry weather, in order to induce a rapid and luxuriant development of the magnificent foliage which constitutes their chief beauty, and which, in suitable situations, amid appropriate scenery, seldom fails to produce an effect which is remarkably pleasing.

#### Kitchen Garden.

The rapid growth that most vegetable crops are making necessitates continual watchfulness. Early Turnips will now require thinning, as also Carrots, as soon as they are strong enough in the top, to do this. It may be taken as a rule that any crop which requires thinning is benefited by this being done as soon as the plants are large enough to handle. We frequently see this deferred until they are so large that their necessary removal always seriously disturbs the roots of such as are to remain. In thinning early crops, especially of such succulents as Turnips and Carrots, too many should not be removed, for, as soon as they are large enough for use, a portion all over the beds may be gathered, which will give more room to those left to increase in size. Early Carrots, 4 in. apart at the sowing, will do well, and need no thinning. Do not get too large before they are staked, as, if broken down by the wind, they never take kindly to the supports. As soon as the surface gets sufficiently dry, ply the hoe on all vacant spaces; not only is this disturbance of the soil desirable for the destruction of weeds, but it is also a means of helping the ground to retain its moisture—a matter of great importance in dry situations. Thin out the early crops of Spinach sown between rows of Peas and in other situations. A not uncommon practice is to leave three times the number of plants of this vegetable that there ought to be struggling for existence, the result of which is that there is not a single leaf more than half-developed, the whole being correspondingly tough and stringy, running to seed much sooner than it would if allowed sufficient room. In thinning, leave the plants 6 in. apart.

**Sowing Late Peas.**—Peas for late use should now be sown. Except in favourable situations these late sowings are very liable to be affected by mildew, but much may be done to prevent or mitigate the evil. There are several causes that tend to develop this parasite—a want of water, sowing too thickly, and an insufficiency of air; and, if the land be poor, the evil is thus aggravated. For these late crops the most open position in the garden should be chosen, and if the rows are at long distances—say 36 ft. apart—with the intervals occupied by some low-growing crop, a better chance will be afforded them of being benefited by the wind, which is unfavourable to mildew. The ground should be well and deeply manured, so that the roots may have plenty to sustain them during intervals of dry weather; they should also be sown thinly. By attending to these matters, and never allowing them to want water, which should be so applied as to moisten the soil as far as the roots extend, Peas may be had late, when, with some, they are held as much in estimation as the earliest crops. For the latest crops many advise the small early sorts to be sown, but these are often not satisfactory, as they produce little, and often come in prematurely. Any approved tall kind, such as Emperor of the Marrows or No Plus Ultra, will be found to succeed the best.

**Tripoli Onions Sown in Autumn.**—Where large mild Onions are required for cooking, these can only be got by giving them sufficient room. They should at once be thinned out 8 in. or 9 in. apart, and, if the soil was not sufficiently rich at the time of sowing, the produce will be much larger if it now receives a sprinkling of guano and soot, mixed in equal proportions. Delicate flavoured Onions are much esteemed for culinary purposes; but, unless they are grown freely in soil well enriched, they cannot be had.

**Planting Cauliflowers, Cabbages, &c.**—The earliest sown Cauliflowers and Cabbages will shortly be large enough for planting out.

If the soil in which they are planted is at all dry, give a good soaking before taking them up, by which means they will lift with plenty of roots, and receive proportionately little check.

**Vegetable Marrows.**—If the weather be warm, these may now be put out in the open ground. See that the plants are thoroughly prepared by gradual hardening in a cold frame, with plenty of air previously, or they will be some time before they make any progress. If hand-lights can be placed over them for a fortnight it will much accelerate the growth, tilting them at the opposite side from which the wind blows in the daytime, and closing down at night. The ground should be made very rich for quick, rank-growing plants of this description. Sow more seeds in a hotbed, Vinery or greenhouse, planting out next month.

**Tomatoes** should now be placed in a cold frame with plenty of air during the day, so as to have them well hardened before planting; where they are turned out whilst in a tender state, even if the ensuing weather be fine, they frequently remain dormant for two or three weeks, which seriously interferes with the quantity of produce, as if the growth be at all checked, most of the warm weather is over before the first fruits are ripe.

**Water Supply.**—The greatest want in many gardens is an adequate supply of water, especially in the kitchen garden, the nature of the crops requiring very much moisture. This is more seriously felt on dry soils, yet it frequently happens that, at comparatively little cost, a copious supply might be drawn from higher ground; in which case it can frequently be made available, in the least costly manner, as regards labour, by the use of a hose pipe and tap turned on amongst the growing crops. Where there is a considerable extent of vegetable ground, and where the walls are covered with Peaches and Nectarines—that must be plentifully watered, both overhead and at the roots—pumping is slow work, to say nothing of the frequent unsuitableness of water so obtained for application to any growing plant. Again, the means of conveying water from wells and tanks to the different crops is often not the best. The ordinary water-barrows sold by the general makers are the very worst used—mounted on miserably low wheels, they require three times the force to drag them that would suffice were they properly constructed and of a reasonable height. There is also very often deception as to the size, whether they be made of wood or galvanised iron. Such as are advertised to hold 30 gallons or so will generally, when measured, be found full when they contain 18 or 20. Where, as is the case in most gardens, large or small, the water has to be applied by hand, there is nothing that effects a greater saving in labour than a good water-barrow; the wheels should be 4 ft. high, with a crank axle under the body of the barrow, which should be made of strong galvanised iron, rivetted, made with a good large spout, and hung so as to enable the load being easily tipped over. It should hold from 60 gallons to 70 gallons, with a handle in front fixed in the usual way to the irons that stand upright from the axle and on which the body is hung. Such a barrow, if properly constructed, and the wheels made to run easily, can be moved about on anything like level ground by one man, and with much greater ease than the low-wheeled inventions that will not hold one-third of the quantity. Those who have the good fortune to garden on deep alluvial soil with a cool bottom, or on moisture-holding, peaty land, may think themselves well off in a dry season, but in far the greater number of gardens, even where everything possible in the shape of deep cultivation, liberal manuring, as well as mulching, is carried out, if water is not used freely the crops will be small in quantity and equally wanting in quality; but, where water is used without stint, the produce resulting from it amply repays the cost. One of the first considerations I should urge upon all who prefer an abundant supply of good, tender, wholesome vegetables to the tough, fibrous produce of dry, hardened soil, is to provide the best means for applying water.

#### Extracts from my Diary.

**May 20.**—Sowing two rows each of the following sorts of Peas: Giant Emerald Marrow, British Queen, No Plus Ultra, and Omega. Potting on large Tomatoes for fruiting in pots. Planting out another three: light frame with Telegraph Cucumbers, and one with Green-flesh Melons. Mulching late Strawberries with chaff cut from stable-litter. Clearing off Broccoli stumps, manuring the ground, and getting it dug up for another crop.

**May 21.**—Sowing Canadian Wonder French Beans, and Early Snowball and Strap-leaf Turnips. Planting out two rows of Williams' Delicieux Celery. Putting in cuttings of Telegraph and Tender and True Cucumbers. Potting on double Potanias and Tricolor Pelargoniums. Pricking off Celery and Broccoli plants. Planting out Leeks in deep drills. Looking over Sea Kale beds and thinning out the crowns. Tying up Brown Cos Lettuces to blanch. Weeding walks and hoeing amongst all growing crops.

**May 22.**—Potting on Pelargoniums of sorts for autumn and winter blooming. Pricking off Stocks, Asters, and double German Wallflowers. Looking over the Asparagus beds regularly, and keeping them closely cut down. Nailing and tying in the young shoots on Rose walls, and washing them where required with Quassa-chip water to kill green fly. Earthing up all Potatoes that require it, and renovating the hings round manure frames.

**May 23.**—Sowing Early Horn Carrots for drawing young. Planting out a large space with Early Dwarf Elm Savoy; also Tomatoes against a south wall. Watering Potatoes, Carrots, and French Beans in frames; also the fresh-planted Cauliflowers, Lettuces, and other plants. Looking over the Peach walls, disabbling the trees where required, picking off

## ANSWERS TO CORRESPONDENTS.

**Phorium tenax.**—"T. S." is quite correct in his statement that seed of this plant, imported from New Zealand, is useless, and should not be sold. But the failure can hardly be due to the mere interval of two months required for the voyage thence. It may possibly be attributable to the changes of temperature experienced by the seed during its transit. Nothing is better proved than the fact that seeds of *Phorium tenax* ripened in Europe will retain their vitality for at least six or eight months. I recently sowed a few seeds of the *P. Colensoi*, of last year's crop, and every seed is growing. I have also on two occasions sown seeds of the *P. tenax* with equally satisfactory results.—W. THOMSON, Ipswich.

**Royal Fern** (*Osmunda regalis*).—Would this grow in the open air in London on the south side of Regent's Park? and what sort of ground does it require? Could I get roots of it in Covent Garden?—W. A. B. [The Royal Fern will grow well in any moist somewhat shady situation, and would doubtless succeed in the locality you name provided these conditions are afforded it. Boggy soil suits it best, but it will grow in any good light garden mould. Roots of it may be bought in Covent Garden, and nurserymen also sell it.—S.]

**Chrysanthemums.**—I inserted some cuttings of Pompones last November, and now they are about 12 in. high. Should I stop them? Do they require another shift, and when should I give them the last?—W. S. [The plants, having rooted, should be stopped at once. They should then be shifted into pots one or two sizes larger than those which they occupy in about ten days (say the 25th of May), and will be ready for another stopping about the middle of June; they can be shifted into their blooming pots (9-in. pots are suitable ones for Pompones) about the end of June, and finally stopped the second week in July. Stopping after this would be likely to interfere with their blooming satisfactorily. By adopting the method just recommended, free bushy little specimens (which are exceedingly handsome and useful for conservatory decoration) will be obtained.—R. T. D.]

**Saxifrages for a Rockery.**—The names of a few of the best Saxifrages for this purpose will greatly oblige.—P. J. N. [Saxifrages are nearly all good for the rockery and therefore it is difficult to select. Try the following—

Saxifraga	Saxifraga	Saxifraga	Saxifraga
sizoides	ceratophylla	granulata	pectinata
Aizoon	coriophylla	Hiculin	purpurascens
Andrewsii	cordifolia	hypnoides	rutosa
arietoides	Cotyledon	juniperia	Rochelliana
sepera	crassifolia	longilata	sermentosa
Biddera	Cymbalaria	lingulata	tonella
cesia	dispensarioides	longifolia	valdensis
caespitosa	Gemm	oppositifolia	

**Raspberry Suckers.**—Can any one suggest any way of preventing Raspberries from throwing up suckers between the rows of plants, where they cannot possibly be left.—J. T., *Macedon*. [Digging deeply between the rows causes suckers to be pushed up in larger numbers than they otherwise would be. Instead of digging, just break up the surface slightly with a fork, and mulch with half-rotted manure. Cut off such suckers as are not required as soon as they appear.—S.]

**Snowflakes.**—In answer to "R. F.," I have to state that my experience of all the Snowflakes is unfavourable. I get plenty of leafage, but little or no bloom.—H. M., *Bromsgrove*.

**Daisies on Lawns.**—Can you inform me what is the best method of getting rid of Daisies from turf? The area is too large for what I believe to be the only really effectual remedy—hand-weeding. Is Watson's Lawn Sand useful?—G. J. P. [It is said to be so; and try it and let us know the result.]

**Names of Plants.**—*A. K.*—1. Scilla nutans. 2. *S. N.* rosea. 3. *S. N.* alba. 4. *A. Ranunculoides*, but too diminutive to say with certainty which kind.—*Thunbergia Welts*, *Cephalotaxa Fortunei*.—*J. D.* 1. *Solanum crispum*, a Chilean shrub. 2. *Eupatorium ageratioides*.—*J. R. D.* *Crataegus lobata*.—*O. 1.* Columbine, one of the forms of *Aquilegia vulgaris*. 2. *Euphorbia Cyprisensis*. 3. Variegated Grass (much smaller and more compact than Ribbon Grass). We think there is a small Bambusa in cultivation very like the Grass sent. 4. Raised from seed from the flower; some species of *Polygonum*, not worth garden culture.—*M. & D.* The flower looks very unlike *Aquilegia scerulea*. It may be a variety or a hybrid from that springing up from seed. Seedlings from this plant vary in a remarkable way.—*Major F.* A very handsome specimen of the *Brompton Stock*.

**Cucumber Disease.**—Permit me to solicit the experience of your correspondents in reference to this disease. I have been a successful grower of Cucumbers for years, and I have at the present time a well-constructed span-roofed house full of well-grown plants apparently vigorous and healthy—such plants as one might expect to cut good Cucumbers from wholesale; but, singular to say, scarcely a fruit will they produce. At a certain stage the fruit cankers and with one or two exceptions refuses to grow, a jelly-like exudation oozing out of both the young fruit and in some cases the leaf-stalk. This in time becomes rusty in colour, and when cutting out surplus growth, this substance exudes freely and looks not unlike ice candles. The varieties grown are Tender and True Improved and Telegraph, for all purposes the former perhaps the best in cultivation. My plants are growing in fibrous loam and leaf soil, in which they root very freely. There is a sort of fungus which we have had some trouble to keep in check, and which I believe proceeds from some

Oak slabs that are laid over the hot-water pipes as a bottom for the bed; but, nevertheless, I do not think it has caused the disease to which I have just alluded.—J. E. ROSE, *Muswell Hill*. [This is evidently a case of "gumming," and a bad one—a disease to which the Cucumber is subject when growing too vigorously in some soils. It is questionable if the plants affected can now be cleared of it. The best thing that can be done is to keep the plants thin and let the shoots grow without much stopping; and the house should be freely ventilated, reducing the supply of moisture overhead at the same time. If this be done and the diseased fruits be cut off, washing the gum carefully off the stems as it appears, the plants may outgrow it, as the Posh does sometimes. Perhaps, however, re-planting in fresh and poorer soil would be the wisest course under the circumstances. It is hardly likely that the fungus alluded to caused the gumming, but it may be harmful in some other way. Wooden bottoms should never be laid under hotheds, as they are sure to germinate fungi.—J. S. W.]

**Black Fly on Peaches.**—Can you suggest any efficient remedy for this pest? Tobacco smoke has been used to such a degree as to partially destroy both foliage and fruit, but all the larger insects survive. Several of my friends, who have purchased trees from the same firm which I unfortunately patronised, are suffering in a similar manner, and have done so for the past three or four years. Every care has been taken during the winter to paint the trees with sulphur, &c., and to whitewash the walls, but all to no purpose. There seems nothing for it but to burn the trees and plant something else. Does this black fly infest Vines?—J. R. C. T., *Birmingham*. [Much the roots of the trees with good rotten manure, and give them plenty of water when necessary, in order to induce healthy growth; also ventilate freely, to keep the atmosphere of the house moist. The best remedy we know of is Quassia chips dissolved in water; but if you procure Quin's book of "Garden Receipts" (Macmillan & Co.) you will find that many other good remedies are therein mentioned.—S.]

**Soil for Oranges and Lemons.**—What is the best soil for Oranges and Lemons grown in tubs?—J. C. G. [The best soil for Oranges and Lemons is, no doubt, the soil of the Azores, particularly that of the island of St. Michaels. In England Oranges are very fruitful in the iron-loom of Sussex; argillaceous loam is poison to them when the lime is in excess. Select a rich loam, as little calcareous as possible, and mix the bulk of the loam with charcoal to the amount of about 10 per cent. In the Italian Orange and Lemon plantations the trees are not manured with stable manure; in fact it is carefully avoided; they are manured with greasy rags. Therefore, to the charcoal add oily rags or wool waste (which can be got from the Leeds and Bradford factories) in the proportion of 25 per cent. or thereabouts, and 65 per cent. of loam free from lime, or as free as can be obtained. Keep the trees in an airy house, but not bright. The rays of the sun passing through glass injure the tough leathery leaves of the Orange.—T. F. R.]

**Plants for a Cool Greenhouse.**—I have been erecting a small conservatory on the north side of my house, merely to keep out draughts and cold, and which I have not means of heating. What plants would be most suitable to keep in it winter and summer to make as much effect as possible? or could I heat it by any oil stove or otherwise than by fire and flue, which I cannot erect?—VENATOR. [The selection of plants for an unheated greenhouse is always a difficult matter, inasmuch as even the hardiest subjects dislike having their roots frozen when confined in either pots, boxes, or tubs, a condition that is almost certain to occur in severe winters where no fire-heat can be applied. I should recommend the house being warmed by means of hot-water pipes and a small boiler, heated by an oil lamp, &c., if there be no way of warming it by a small apparatus of the ordinary kind. The least possible satisfaction is derivable from an unheated plant structure, as through the winter and early spring, when flowers are the most acceptable, few can be had. A conservatory placed on the north side of a dwelling, and consequently shaded by it, is in the worst position for growing plants, and such as will bear shade should principally be selected. They may consist of a few *Camellias*, *Myrtles*, the hardy *Yucca recurvata*, *Chamaerops Fortunei*, or *humilis*; *Acacia lophantha*, *Phorium tenax*, *Richardia aethiopica*, *Agapanthus umbellatus*, *Aspidistra lurida variegata*, *Campanula pyramidalis* (white and blue), *Lachenalia tricolor*, *Lilium lancifolium* *spiosum*, *album punctatum*, and *mburum*; *sanatam*, and *eximium*. These might be placed in the open air in spring, when frosts are over, and brought into the house when coming into flower. A good stock of *Chrysanthemums*, grown in the open air in pots in summer, and taken into the house before injured by frost in the autumn, would be useful, as would also *Fuchsias*, stored away in the winter, out of the reach of frost, and brought into the house in spring, where they would grow

nd flower during the summer. There should also be a good supply of Hyacinths, Tulips, Narcissi, Crocuses, and Scilla sibirica in pots; also autumn-sown Stocks, kept in pots through the winter, Primulas in pots, especially the beautiful *P. cortusoides amœna*, wintered in a frame. These should be intermixed with some of the best pot varieties of hardy Ferns. If no heating be possible, the pots of all plants that are kept in the house through the winter, such as Camellias, Myrtles, and the like, should be well covered with dry Fern (Bracken) during the time of frost; this will doubtless be more or less objectionable in appearance, but it will be less so than anything else that could be employed. I am, of course, presuming that in the centre of the house, where such plants are placed, no stage will exist, but that they will be simply set on the floor; but without seeing the house, or having many more particulars about it, it is difficult to give the most suitable advice respecting it.—T. B.

#### Questions.

**Colourless Blooms of Marechal Niel Rose.**—Can any of your readers inform me of a mode of treatment for this Rose which will render the blooms of the much admired rich golden colour? I have it growing both in the open air as standards and on a wall, and also in a greenhouse, and I find that the flowers are always of a very pale yellow tint, although the trees appear to be in perfect health and blooming freely. I at first attributed the want of colour to their growing on high ground in a somewhat exposed position, but I find that there is the same fault under glass.—B. A.

**Weeds in Ponds.**—Can any one suggest a means of killing weeds in a small pond? Ducks keep them down to some extent, but not enough? Is there any poison which would kill the weeds outright? If so, how should it be applied, and in what quantity? The pond is about 60 yds. long, from 10 yds. to 20 yds. wide, and nowhere deeper than 5 ft. (generally much less). The waste water flows through a deep drain into a river about 60 yds. wide and from 10 ft. to 15 ft. deep (which I mention because, in this case, I imagine there would be no risk in the use of such a poison as I wish to find).—E. W. W.

**Top-dressings for Strawberries.**—At p. 436 there is a paragraph relative to the preservation of Strawberries from slugs, snails, &c., written by Mr. D. T. Fish. He there recommends three dressings of the plants with soot and lime. Will he inform me whether I am to do so now, when the most of my Strawberry plants are in full bloom, or whether it will do the flowers harm?—H. B. J.

**Gorse Covert.**—I want to get up a Gorse covert on a piece of dry granite soil. The land, about eight acres, has a southern aspect, and is now producing bunches of short mow Furze, with coarse Grass in the intervals, which together make a tough surface. I shall esteem it a favour if any of your readers can inform me what would be the best preparation for the land to receive the seed, the proper time for sowing, the quantity of seed per acre, and the kind of treatment that would ensure the most rapid growth.—A Novice.

#### GARDEN CATS.

SOME of your correspondents who write on this subject evidently do not see the difference between cats in a garden and garden cats. Where the garden is used by cats simply as a playground or rendezvous, such as small gardens in the immediate vicinity of towns generally are, there is no doubt that cats are very troublesome, as they merely go there to scratch, fight, and disport themselves in a way anything but calculated to improve the condition of smooth seed beds or newly turned out, delicate plants. In a neighbourhood where cats are plentiful the gardens are certain to be visited by them, whether there is one that belongs to the premises or not, and without a good deal of care these strangers will occasionally be shut inside the houses at the time when the lights are closed, and then, if there happens to be a couple that are strange to each other and a fight takes place, woe to the plants, for one or other of the combatants is sure to take up its ground on the top of any specimen strong enough to support it, and there claw and fight with a pertinacity which, whether or not sufficient to repel the assailant, will be destruction more or less to the plant or plants on which it has placed itself, as I know to my cost, half-a-dozen valuable specimens being almost ruined in a single night. This is, however, altogether outside the question, as such an occurrence is just as likely to happen where no cats belong to the place as where they do. I have tried to do both with and without cats in large garden for many years, and I feel certain that, if properly trained to their work, they are most useful. A good many years ago I had a house of ripe Grapes attacked by a mice, and those who have had any experience of such pests in such a place will not need to be told how injurious they are, going, as they do, from bunch to bunch every night, and destroying the berries on the shoulders of each. On this particular occasion I had a number of bunches that I intended to exhibit at several places where I knew the competition would be very keen. I tried poison and half-a-dozen different kinds of traps, but to no purpose; they

preferred the Grapes to the most dainty baits with which I could tempt them. I tried Gorse tied round the stems of the Vines, pieces of tin similarly applied—both of which under like circumstances I had frequently used before—and every device that I had either ever heard or could think of; but without avail. Night after night the destruction went on. Knowing the dislike they have to being where a cat, however young, is, I got from a neighbour a very tame kitten, about some eight or ten weeks old. It was kept confined to the Vinery altogether, and after the first night we saw no more of the mice. Whether they were caught, or decamped, I cannot say; most likely the latter. Henceforward the kitten was encouraged to remain in the houses, and very soon it got used to moving about amongst the plants—Orchids and others of a valuable description—without ever from the first doing the slightest mischief. After this I brought up two or three kittens (all females; I would not have a male cat in a garden), and never was without several that had been from their infancy used to being in the sheds, houses, and about the garden generally, and I do not recollect on a single occasion afterwards being troubled with mice or rats either in the houses or kitchen garden. All that is necessary is to take care that the cats are, from the first, so thoroughly tame that they are not afraid of any one, strangers included, otherwise they are liable to upset pots in their attempts to get out of the way; and they must also be regularly used to the houses, from the kitten state upwards. Those who speak of cats knocking down and breaking plants in springing after mice evidently have never studied their nature at all. Cats do not run and rush after their prey, but watch deliberately until the mouse, rat, or whatever it may happen to be, comes fully out into an open place, where there is no obstruction, and then they make their spring, rarely failing to secure their prey.

As to poisoning mice or rats about houses, it is a practice to which I would on no account resort. One or two mice, small though they are, that have been so destroyed, and that have crept away to die, will be most offensive for quite a week in even a good-sized house, a fact of which I have often had disagreeable evidence, even when the different preparations of phosphorus have been used, which the vendors say dry up the poisoned animals so quickly that no disagreeable smell arises from them, which is simply incorrect. And where rats have been poisoned, I have known floors to be taken up and drains opened at very considerable cost, whereas if the simple precaution of having two or three cats had been taken, well used to being in as well as outside the houses, no rats would have been seen. In places where game is preserved near a garden, cats are difficult to keep after they get twelve months old. In this case the best way is to bring up a young one or two every six months. There is, too, a great difference in the breeds of cats; the smallest and those that have the least disposition to get fat and heavy are by very much better for the destruction of both mice and rats than large ones, which are comparatively less watchful. T. BAINES.

*Southgate.*

**Blue Tits and Caterpillars.**—I placed an old tea-kettle in an Apple tree in my garden, and it was taken possession of by a pair of blue tits, which reared four young ones in it. When they were being fed, before they could fly, I had the curiosity to count now and then how many times the old ones fed them in a given time (a quarter of an hour), in order, if possible, to calculate at what rate they were destroying the caterpillars which infested my fruit trees and the neighbouring Oaks, and I found that it averaged about once every minute, and they generally had two or three caterpillars at a time. Reckoning them at two would give 120 in an hour, or 1920 in a day of sixteen hours, from four in the morning till eight at night, and at this rate, in the three weeks during which the young were in the nest, 40,320 caterpillars would be destroyed. Of course, the young ones would not require so many the first week or so, but if we take into consideration what the old ones destroyed during the time of building, laying, sitting, and feeding their young, it would be equivalent to make up for what the young did not require during the first week or ten days. My only object in giving these particulars is to show the enormous good such birds do as insect destroyers, and that if they are mischievous among the fruit buds at certain times they more than compensate for the damage during the summer months.—J. HAM, *The Wren's Nest, Ashwood Bank, Worcestershire.*

**Lawn Mowers.**—I find from experience that McKenzie's "President" Lawn Mower is a very good one. It is simple in construction, very easily worked, and the readiness with which the bottom plate can be adjusted to the knives is a great improvement.—J. WOODBRIDGE, *Syon House, Brentford.*

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### TROPEOLUM SPECIOSUM AND POLYPHYLLUM.

SOUTH country cultivators can grow many plants successfully which it is mere waste of labour and time to cultivate in the north; on the other hand, we find many beautiful plants that revel in the moisture and usually sharp soil of the north. Among the latter we may reckon these two beautiful species of *Tropæolum*. To establish speciosum here it is merely necessary to dig in a handful of the long succulent rhizomes in a shrubby border, or at the foot of a hedge or wall. It will not make much show the first year, but in every succeeding year it will increase in beauty and multiply like a weed; but, unlike a weed, it is quite harmless. It does not exhaust the soil, and its tender tendrils swing from branch to branch of the most delicate shrubs, or the stouter herbaceous plants, such as *Larkspur*, *Antirrhinum*, *Campanulas*, and the like, without the least injury to them. One peculiarity it has which is rather bewildering to one not acquainted with its habits—it is a great traveller. Plant a colony of the roots in a carefully selected corner, and they will appear in due course, though of weakly growth the first season. You will look anxiously for them in the same place next year, but probably in vain; they will not appear, and you will think—"Ah! that is just what I heard of this *Tropæolum*; it is a delicate plant, and does not agree with our climate." But you will be surprised some fine morning in July to see a coruscation of coral-like blossoms, set in delicate grass-green foliage, suspended on a bush or trellis several feet, perhaps even yards, from the carefully-labelled spot where you planted the roots. I have seen it forsake a border and break out in the middle of a gravel walk. It will never, however, if soil and climate suit it, forsake a wall or hedge, though appearing at different places thereon. *Tropæolum polyphyllum* does not seem to travel at all. It makes a charming contrast to the other, with its yellow flowers and glaucous leaves; but it is not such a beautiful or striking plant. I think it is fortunate that the same plants do not succeed all over the kingdom. By choosing those which suit the different districts we obtain the best results and avoid that sameness in effect which is one of the besetting snares of modern gardening. I always mentally protest against that favourite phrase of commendation, "This charming plant should be in every garden." *Geranium*, *Calceolaria*, and *Lobelia* are in every garden, and who cares for them now? SALMONICEES.

—Perhaps there may be some truth in the remarks of "J. S. W." (see p. 468) about the capricious nature of *Tropæolum speciosum*, and with me, both north and south, it has always grown and flowered satisfactorily with this exception, that in the north of Scotland it almost becomes a "weed." I was much struck with the beauty of this plant last autumn at the various stations along the Highland Railway, more especially about Forres, where one had to restrain oneself from exclaiming "prodigious!" at the masses of fiery scarlet clinging to the fences. I have found the following mode of treatment to answer in the southern counties. Usually I believe this plant is propagated by means of the fleshy roots, but I merely take off cuttings in the ordinary way when they are about 4 in. long; these shoots are produced freely about the end of September after the plant has flowered, and by placing them in a gentle heat they soon root, and when fit for potting off they are put into 3-in. pots, wintered in a cool house, and finally planted out about the middle of May. When the site is chosen I always take about a barrowful of the existing soil away and replace it with good turfy loam; when planted, it is desirable to place a spreading branch for the plant to cling to. When young, it is impatient of handling, and it never looks so well as when allowed to ramble naturally. Being of a very accommodating character, this *Tropæolum*

can be used in a variety of ways. Last season the most effective combination produced here was by training some shoots of *Clematis Jackmani* over a plant of *Jasminum nudiflorum* and allowing a *Tropæolum speciosum* to ramble freely amongst them. Such a combination as this is pleasing, and takes off much of the stiffness usually seen amongst climbers. *Ragley Gardens, Alcester.* A. HOSSACK.

—Like "J. S. W.," I have not been able to get this plant to grow, though in the north I have seen it in great beauty. At Bowhill, Selkirk, there is scarcely a cottage that is not covered with it, and it grows in the greatest luxuriance; such at least was the case a few years ago. It takes some little time to get it well established, and rainfall and a good climate may have a good deal to do with its success. Bowhill is about 540 ft. above the level of the sea, and has an average annual rainfall of about 38 in.—J. M.

### HORTICULTURE AT THE PARIS EXHIBITION.

THE special competitions which are to take place each fortnight during the exhibition in Paris are held in the twenty houses placed here and there in the gardens of the Champ de Mars and Trocadero. The first two shows have not been so well responded to by exhibitors as might have been expected, a circumstance no doubt caused by the delay that has taken place in furnishing the houses; but several fine collections were nevertheless contributed. Among the first of these, the Rose trees, Rose bushes, and dwarf tree Roses of Messrs. Leveigne & Son and M. Margottin, nurserymen of Paris, were remarkable as regards the quantities exhibited of choice varieties and fine blooms. M. Margottin, jun., had some fine specimens of Roses in pots cultivated in the English style. M. David, of Versailles, furnished a group of *Anthurium Scherzerianum* in flower, a magnificent variety, the spathe of which measured nearly 6 in. in length. M. Bertrand, an amateur residing near Paris, also showed *Anthuriums*, which filled one house entirely. On ten specimens there were no fewer than forty to fifty blooms all remarkable for size and colour; these plants occupied the centre of the house, while the tables around were furnished with younger ones, each bearing from three to six flowers. The general effect thus produced was most satisfactory. M. Lemoine exhibited a fine collection of *Azaleas*. Messrs. Chantrier Bros., nurserymen, Montfontaine, had twelve new *Dracenas* raised by them from seed. These plants differed, entirely in appearance from those of Mr. Wills. Some of these were not all that could be desired; but a brilliant future is no doubt in store for the kinds named—*Regis*, *Bergmani*, *Verloti*, *Chantrieri*, and *macrophylla*; this last has very broad and handsome green leaves, and is altogether a magnificent plant. The collections of *Gloxinias* from M. Duval, of Versailles; the *Calceolarias* and *Cinerarias* from Messrs. Vilmorin, Andrieux, & Co.; the charming varieties of *Primula japonica*, of all shades, from pure white to deep red, and the baskets of annuals, from the same exhibitors, were much admired. The *Pansies* of M. Bastillard, of Boulogne; the plants of *Mignonette* in pots of M. Machet, nurseryman, Troyes; the *Bromeliads* and *Orchids* exhibited from the Jardin de Luxembourg, also deserve mention; but the chief point of attraction is the splendid collection of plants from Mr. Wills, of South Kensington. This is placed in Mr. Boyd's conservatory, and is a marvel of good taste and arrangement. The house is supported by three columns, which are entirely covered by pieces of cork bark, on which are growing *Ferns*, *Begonias*, *Bromeliads*, &c. The bases of the columns are surrounded by charming clumps, in which Palms play an important part, and on cork rockwork are *Ferns*, *Dracenas*, *Anthuriums*, *Gloxinias*, &c., while around the sides of the conservatory are other groups bordered by rockwork, and containing all the new plants introduced within these last few years. Among these many be mentioned *Dracena ignea*, *Elisabethæ*, *Ernesti*, *Mrs. Wills*, *voluta*, *Cantrelli*, and, above all, *Willisi*, a kind remarkable for its fine habit and bright colour. The *Crotons lanifolium*, *Queen Victoria*, noble, *Rex*, *Challenger*, &c., are also grand in their way, as are likewise the *Anthuriums Veitchi* and *Waroqueanum*, *Lomarias*, and *Dieffenbachias*. In short, Mr. Wills' exhibits are as remarkable as a whole as in detail, and they attract universal attention and admiration. The open air *Rhododendrons* form an important feature. They are situated at the foot of the terrace in front of the palace of the Champ de Mars, and cover a surface of more than 5000 ft. Seen from the terrace which overlooks them, the effect of these *Rhododendrons*, covered by millions of flowers, is magnificent. They consist of the best varieties from the nurseries of Messrs. John Waterer, of Bagshot, and Anthony Waterer, of Knapp Hill. Messrs. Truffaut, of Versailles, Moser Croux and Paillet are also among the principal exhibitors. A. T.

## MIMULUS CULTURE IN POTS.

I HAVE occasionally seen, in country districts, Mimulus grown by cottagers as window plants, and with astonishing success. I have also met with good plants of them at cottagers' shows thoroughly well grown and flowered. Mimulus have been much improved of late. The introduction of the copper-coloured *M. cupreus*, some years ago, placed in the hands of cultivators an admirable subject with which to cross other kinds, and it has been successfully and well used for that purpose. We are now familiar with strains having large and handsomely-marked flowers, but they are, nevertheless, not so generally grown as one could desire. The fact is, a little special treatment is needed. The plants require a cool, shaded, airy position, and they should not be allowed to suffer from want of water. A cool north house suits them best, and here a fine display can be had all through the summer and autumn by keeping up a succession of plants. The seed is so small that a mere pinch will produce many plants, and if a little be sown in a pan or pot in some gritty soil in September, by January the young seedlings will be quite strong enough to pot off singly into 3-in. pots, and finally shifted into 5-in. pots to flower; or, if larger specimens be wanted, into 8-in. pots. The Mimulus is quite hardy; no heat is required, but by keeping the plants in a greenhouse all the winter they make certain progress. A little more seed can be sown in the end of February, and the produce of these two sowings will yield quite enough plants to keep up a good supply through the season.

Mimulus succeed best in a north house where the floor can be sprinkled with water and the plants occasionally syringed. In a house where the temperature is high green fly is apt to attack them, but where they are kept cool and growing vigorously in a moist atmosphere this pest rarely troubles them, and, if it does, a good fumigation with Tobacco smoke soon kills them. If there be a few exceptionally good varieties, a selection may be made for seeding from and for propagating by division of the roots. If the plants be cut down after they have done flowering and put into a cold frame they will throw up a number of shoots from the roots, and if these be divided and potted into good soil, they in course of time make excellent plants. But the cultivator should always make a point of raising a few seedlings; it is so pleasant to watch the expanding flowers, and even if some prove of an inferior character, some will certainly be satisfactory. A good strain of seed cannot fail to yield a good supply of plants.

There is no reason why Mimulus should not be grown in the open border, but heavy rains and rough winds injure the plants severely, and soon rob them of their beauty. If planted out, the plants should be supported by stakes so as to lessen the chances of danger from wind, and if dwarf growing plants can be put about them, they will not only act as a screen against wind, but will help to keep the soil moist and cool. A pleasing effect could be secured by a bed of Mimulus somewhat widely planted with mixed Verbenas as a base. This combination would be sure to give satisfaction; and the carpet of Verbenas would supply the coolness and moisture at the roots above recommended. Phlox Drummondii or Petunias kept pegged down and dwarf Chrysanthemum-flowered Asters would also serve for a base; and, in fact, many combinations of this character might be worked out. Above all, a few plants should be well-grown in pots, for it is in this way that Mimulus are seen to best advantage. D.

**Rock Roses.**—In the out-door garden at this season there are few more brilliant sights than that afforded by masses of these beautiful evergreen shrubs, and, as they are of the easiest possible culture, they cannot be too highly recommended. They belong to the genus *Helleborus*, and are, with but few exceptions, dwarf and compact in growth, and their flowers, which much resemble single Roses in miniature, are borne in great profusion, and present a remarkable diversity of colour. The common Rock Rose (*H. vulgare*) is extremely variable both in habit and colour, and from it has sprung the host of varieties enumerated in trade lists; indeed, we need but this species to represent, for garden purposes, the variation, illustrated in all the dwarf shrubby species of the family. There is also a double-flowered and a variegated-leaved variety of it. The kinds forming bushes of all or growth are also very desirable; the most strikingly beautiful in

flower at the present time are *H. formosum*, a Portuguese species bearing large yellow flowers with a very dark spot at the base of each petal, and *H. Libanotis*, a kind that bears smaller pure white flowers. Last, but not least, may be mentioned the *Truffe* *Suo Rose* (*H. Tuberosa*, so called from its truffe-like tubers), a very dwarf herb with broad leaves, very different in aspect from the preceding, and one which bears blossoms as large as those of any of the family, of a bright yellow with a dark centre. All the varieties of the common Rock Rose will thrive in an ordinary border, provided it be exposed, but they look more natural and are more luxuriant on sunny banks, or on rough parts of a rockery. The common sorts are indifferent as to quality of soil, but prefer a rich loamy compost. A collection of named varieties may now be seen in the pleasure grounds at Kew.—A.

**National Carnation and Pinks Society.**—We have received the schedule of the southern section of this Society's show, which is to be held in conjunction with the meeting of the Royal Horticultural Society on July 23. The prizes offered are in every way satisfactory, and ample provision has been made for amateurs as well as for large growers. In most of the classes five prizes are offered, so that a good competition may reasonably be expected.

**Hardiness of Larix Kœmpferi.**—I notice in THE GARDEN of the 20th ult. (see p. 363) [an inquiry as to the hardiness of this tree, and in the reply it is stated that there are no large specimens of it in England. I was in London in 1859, at a sale of plants brought home by Mr. Fortune. Among them were some fine specimens of Larix Kœmpferi. I purchased a number of these for our grounds in America, and the best of them has now a height of 35 ft. Since it has been planted the cold has been as low as 14° below zero, Fahr., and this tree has sustained no injury. It may, therefore, be considered perfectly hardy with us. Our largest specimen is very beautiful. Its rich pea-green tufts of leaves grow on the upper sides of the branches, and, like the Cedar of Lebanon, it is most beautiful when seen from above. It bore cones last year, but they were not fertile. We have endeavoured to propagate it, without success. We can find no stock on which it will grow, and fear we shall have to rely on seedlings only.—S. B. PARSONS, Kissena Nurseries, Flushing.]

**Meeting of Fruit Growers.**—On Tuesday, the 14th inst., a dinner took place at the "White Hart," Borough, professedly of gentlemen of Kent engaged in the growth of fruit, and of salesmen of the Borough Market. Mr. W. Mills, of Farningham, presided. It was remarked, however, that but few of the salesmen attended. Mr. Wood, in responding to the health of "The Growers," said at seventeen years of age he had ten acres of fruit land to manage, and he now had about 200 acres, which, however, he wanted to reduce, owing to the independence of the laborer and other matters. He spoke highly of the salesmen. Mr. Arnold, of Spitalfields, defined "the true grower" as a man who sent his fruit to the salesman to dispose of and stayed at home. A discussion on the practice of demanding a deposit on all baskets before the fruit left the sellers' hands resulted in approval of retaining the practice, one gentleman candidly admitting that he had made a summer-house out of empty crates, &c.

**Erythronium americanum.**—Referring to the notice of this plant (see p. 365), where it is stated to have flowered at Henley-on-Thames, I may add that I have flowered it for some years, having about four years ago collected some hundreds of roots of it in America. I planted it in various situations, but it flowered very sparingly; and the number of roots are evidently greatly diminished.—HARRY BUCKLEY, *Wheeler's Road, Edgbaston, Birmingham.*

**Lobelia pumila and Viola Perfection.**—Referring to Mr. Hinde's excellent notes on these plants (see p. 491), allow me to inform him that if he will substitute *Viola Blue Bell* for *Viola Perfection* he may do without *Lobelias*, and consequently save the additional labor of planting *Violas* to succeed them in August. *Viola Blue Bell* planted in February never fails to give a full succession of flowers from March to the end of November.—W. W.

**Rodgersia podophylla.**—This is certainly a very striking and curious plant. I introduced it from Japan in 1874. Here, however, it is not quite hardy; it likes a peaty soil and a shady situation; it is easily propagated by cutting the stoloniferous rootstock from one of which I remember to have made as many as twenty plants in one year. It was, if I remember rightly, named by Professor Asa Gray, in honour of Captain Rodgers, who had a command in the American-Japanese expedition.—MAX LEONHART, *Baden-Baden.*

**White Asparagus.**—I perfectly agree with your remarks on Mr. D. T. Fish's letter on Asparagus (see p. 452). I have eaten the large white Asparagus both in France and Germany, and have found it edible almost down to the end which one holds in one's fingers, and more delicious than any green English Asparagus. The reason of this is that the cooks abroad not only understand boiling it better, but with a sharp penknife they peel off all the outer hard skin. This latter is the great secret of tender Asparagus.—M. C.

## NOTES OF THE WEEK.

**Fine Clematises Out-of-doors.**—The Hon. and Rev. J. T. Boscawen has sent us from Lamorran, Probus, two magnificent blooms of Clematises. One measured 7 in. in diameter and the other nearly 9 in. Mr. Boscawen states that they were cut from plants that have grown out-of-doors for many years, and that reach half way up to the top of his house. He adds that he never cuts down, so the blossoms are from the old wood.

**Verbasum olympicum.**—A beautiful and stately plant of this is now in full flower here; its flower-stem rises to a height of 6 ft. or more, with many branches, the flowers on which open at the same time as those on the main stem; they are deep glossy yellow, the whole a showy pyramid consisting of many hundreds of flowers.—MAX LEICHTEN, *Baden-Baden*.

**Double-blossomed Furze or Gorse.**—The fine effect produced by this plant may just now be seen to advantage in the park at Farnborough Hill, Hants, where there are hundreds of bushes of it dotted about, and also in groups. Associated with the Copper Beech, especially as a background, the effect is charming.—W.

**A Yellow Torenia.**—Our correspondent, M. Lebenf, informs us that he has a yellow Torenia about to flower. This will at once settle the question as to the presence of yellow and blue flowers in the same genus.

**Lilies at Tooting.**—We are now on the threshold of the Lily season. The first to bloom in my collection is *Monadelphum* and *M. Scovitisianum*, two beautiful yellow varieties; the former is distinguished by its primrose anthers, the latter, as a rule, by its larger flower and its maroon anthers. I hope to give you a record from time to time of what is in bloom among my Lilies, and it would be interesting to compare the time at which they flower in various parts of the country under similar circumstances, *i.e.*, Lilies grown in the open ground without protection.—P. BARR.

**Azalea indica as a Hardy Shrub.**—I have the White Indian Azalea now in flower in the open air in the form of three plants that were turned out into our Rhododendron beds three years ago. Although we never give them any protection, they continue to improve yearly, and promise to be interesting objects amongst choice shrubs. The largest of the three is about 4 ft. high and as much through, and at present on solid mass of bloom. We mean to try a few more in a bed by themselves. *Eriostemon intermedium* and *Nerium splendens* are also doing well with us on a west wall. The *Eriostemon* blooms satisfactorily every season.—JOHN MORRISON, *Narrow Water Castle, Warrenpoint, Co. Down, Ireland*.

**Dendrobium chrysoxum.**—In Messrs. Low's nursery at Clapton hundreds of plants of this showy Dendrobium may now be seen in bloom, making a very attractive display. They are growing in small wooden baskets, and the number of flowers produced from such comparatively small specimens is remarkable, and can only be attributed to the healthy condition of the plants and the matured state of the bulbs. *D. snavissimum*, a plate of which was given in THE GARDEN (see p. 166), is also finely in bloom. Thousands of plants of other kinds are opening their flower-buds.

**Exhibitions of Irises.**—The Iris is now what may be termed in mid-season. *Pumila* and most of the dwarf varieties have done flowering, and the larger forms of the germanica type are rapidly opening. Many of your readers may be desirous of making themselves acquainted with the varieties of this, the freest-flowering and most accommodating of the family, and to give facilities for inspection I have arranged to have a collection on exhibition at the Horticultural Gardens, South Kensington, and also at 12, King Street, Covent Garden.—P. BARR.

**Oxalis violacea alba.**—This is one of the showiest plants in my rock garden. It is quite hardy, has been in bloom since April, and will continue so for several months to come; the individual flowers are large and produced in bunches in great abundance, the clear white of the flowers being brightened by the large somewhat glaucous foliage. I consider this a first-rate plant.—M. LEICHTEN, *Baden-Baden*.

**Rock Plants at Edinburgh.**—We have sent you plants of *Iberis spheerata* and of *Saxifraga Wallacei*, lifted from the rockery here out-of-doors, where for more than six weeks they have been the admiration of all visitors, and, in spite of the changeable, showery weather, they have flowered well; they are certainly most effective plants on the rockery in spring. We exhibited some of the *Saxifraga* at the great show of the Royal Caledonian Horticultural Society here on April 10, and were awarded a first-class certificate for it. It is much finer than any other *Saxifraga* with which we are acquainted.

The *Iberis* is a seedling from *I. sempervirens*, having as large heads of flower as *I. corifolia*, but coming into bloom three weeks earlier, and, as the flowers are of good substance, they last a long time.—DICKSONS & Co., 1, *Waterloo Place, Edinburgh*. [Both the plants sent are very showy and excellent of their kind. The *Saxifraga* is a valuable variety, but whether a seedling or one of the very numerous so-called species of the Mossy group, few but experts in *Saxifragas* could say. We fancy we have seen something like the *Iberis* before under the name of *I. Garreuxiana*.]

**Asparagus Culture in France.**—As an illustration of the extent to which Asparagus is planted in France, we may say that one grower alone, M. Godefroy Lebenf, of Argenteuil, disposed of four hundred and thirty-six thousand plants during the planting season now closing.

**New Park at Hastings.**—The extension of St. Andrew's Gardens, Hastings, to be known hereafter as the People's Park, is being carried forward under the superintendence of Mr. Marneck, and will, when completed, prove an additional attraction to visitors.

**Specimen Orchids.**—A special prize for a specimen Orchid is offered by Sir Trevor Lawrence, Bart., M.P., for competition at the great show to be held at South Kensington, on May 28 and three following days. The prize is of the value of £10, and is offered for the best specimen consisting of a single plant—not a specimen made up with several small examples, as is so often done to the injury of small growers.

**Gladiolus Colvilli albus.**—This is a fine variety for conservatory decoration. Now (May 20) we have plants of it in 5-in. and 6-in. pots, each bearing from sixteen to eighteen spikes, on each of which there are, on an average, four or five flowers. The latter are individually large and pure white, with just a slight trace of pale green down the middle of each petal. Its flower-spikes are about 2 ft. high, and they are thrown well up above the foliage, of which there is no scarcity.—J. M.

**Masdevallias at St. John's Wood.**—There will shortly be a fine display of these brightly-coloured, singular-looking Orchids in the Pine-apple Nurseries. Grown in the front of a large, light, airy house, the plants have made large, thick, leathery leaves, and are furnished with an unusual amount of flowers, which, being stout and hardy, are larger and much brighter than those produced on plants grown under less favourable circumstances, and they also last longer. We also noticed plants of *M. amabilis lineata* bearing flowers of a much richer colour than those of the type, whilst those of *M. Lindeni* and *Harryana* were very bright. Considering how easily *Masdevallias* may be grown in any cool, light, conservatory in any aspect, their culture should extend much more rapidly than is even now the case, for few Orchids possess flowers more brilliant in colour or more interesting in form.

**International Horticultural Exhibition.**—A meeting was held at South Kensington on Tuesday last to consider the desirability of holding an international exhibition in London in 1879. Mr. G. T. Clark occupied the chair. There was a good attendance of the leading horticulturists, among whom were Messrs. Veitch, Williams, Bull, W. Paul, George Paul, Baines, Wills, Dean, Kellock, Moore, Rollisson, Dr. Denny, Dr. Hogg, and others. It was decided that, should an exhibition be held in London in 1879, that a committee and secretary should be appointed to carry out the arrangements.

**Rhododendrons in the City.**—The authorities of the Bank of England have entrusted Messrs. John Waterer & Sons, of Bagshot, to furnish a supply of Rhododendrons to be planted in the garden attached to the Bank, and we understand that the plants are already in the positions which they are to occupy.

**A fete given by Baron Alphonse de Rothschild to the Princess and Princess of Wales during their visit to Paris was remarkable for the beauty and novelty of its floral decorations. In the supper-room, in the centre of a table in the form of a horseshoe, was raised a large block of ice; this was decorated with flowers of the most beautiful description. There were also some plants, too, not yet in commerce, and only to be found in the fine houses at Ferrières, under the direction of M. F. Bergman.**

**Clematis montana.**—I have just now on the front of my house a large plant of this well-known Clematis in full flower, and I never saw anything more beautiful. The greater part of the house is covered with a sheet of pure white flowers, so dense that one can scarcely see any leaves, except those of a Jargonelle Pear, through and over which the Clematis has rambed. This is still one of the most useful of early flowering Clematises, and, being a very strong grower, exceedingly useful for covering walls, trellises, &c. I am surprised that it is not more widely known and planted than it is.—W. W. JOHNSTON, *Edinburgh*.

## NOTES FROM KEW.

**Hardy Trees and Shrubs.**—Unquestionably the most beautiful of the many shrubs at present in flower are those belonging to the Heath family. Omitting the many species and varieties of *Rhododendron*, the hardy *Azalea* deserves special mention. Every shade of colour, from white to blood-red, and from yellow to purple, is furnished by the numberless varieties which, both from natural variation and by the skill of the hybridist, have been derived from *Azalea pontica* from Asia Minor, and the American species *A. celsæ*, *A. nudiflora*, *A. viscosa*, and others. A large collection of these forms in the pleasure grounds is just now one of the most striking features at Kew. For elegance and beauty combined few trees surpass *Halesia diptera* and *H. tetrapetra*, the former from Georgia and Florida and the latter from Virginia and southward. In the United States *H. diptera* is called the Snowdrop Tree and *H. tetrapetra* the Silver-bell Tree; both produce their lovely, white, bell-shaped flowers in great profusion, even in a small state. *Cistus Berthelotianus*, from the Canary Islands, is a splendid species, with deep rosy-pink flowers nearly 3 in. in diameter; it, however, requires a very sheltered position in the open, or else a place on the wall. Another member of the Rock-rose family, *Heliathemum Liliacoides*, from the Mediterranean region, is a neat little shrub, about 18 in. in height, with Gorse-like leaves and panicles of pure white flowers, each of which has a brush-like tuft of golden-yellow anthers. *Gonista hispanica*, from Southern Europe, is a dwarf, spiny shrub, so dense in growth and so covered with its corymbose racemes of flowers as to look, from a distance, like a large, golden-yellow cushion. *G. scariosa*, another South European species, is a desirable plant of neat habit and a very free bloomer; it attains a height of 2 ft. or more, and a small branch of it has a considerable resemblance to the Dyer's-greenweed (*G. tinctoria*) of our English meadows. *Oslearia argophylla* is a shrubby Composita from Australia, having large leaves dark green above, silvery-white below, and much-branched, umbellate panicles of creamy-white flowers; the leaves (like those of the Woodruff of Britain) become very odoriferous when dried, and exhale a powerful but agreeable scent of Musk; this shrub does well on a wall. *Spiræa cana*, from Dalmatia, is a very pretty, dwarf bush, with small, hairy leaves and white flowers. The Russian *S. hypericifolia*, a larger grower than the last, has also white flowers, which are most freely produced. *Ecochordia grandiflora*, from North China, is sometimes classed with the Spiræas; it has, however, much larger and more handsome white flowers than any of the true Spiræas. *Rhodotypos karrerioides* is a Japanese shrub with pure white flowers (followed by purple berries) and toothed, plaited leaves.

**Hardy Herbaceous Plants.**—The finest of this weak's herbageous plants, if we take a blaze of colour as the standard, is the Eastern Papaver orientale var. *major*; this handsome perennial has large brilliant scarlet blossoms, each of the petals bearing a blotch of black at its base. The Columbine too are now furnishing their splendidly striking blossoms in abundance. One of the most striking is *Aquilegia atrata*, an Alpine species, with black-purple flowers. *Ionopodium acaule* is a very dwarf Crucifer from Portugal; this charming little plant hardly attains a height of 2 in. or 3 in., and is covered with its delicate lilac flowers. *Podophyllum peltatum*, the May Apple, wild Lemon, or Racoon Berry of the United States, in a shady and damp situation produces its large white flowers very freely; the active resinous principle from the rhizomes is called podophyllin, and is much in demand in some places as a medicinal agent and substitute for mercurials—it is, indeed, sometimes called vegetable mercury. The Oriental *Ethionema grandiflorum* is a shrubby Crucifer with linear leaves and long racemes of deep rose-coloured flowers. *Saxifraga cymbalaria* is a pretty little annual with bright yellow flowers and leaves exactly like those of the Ivy-leaved Toad-flax (*Linaria cymbalaria*); it is well worth introducing to the rockery, as it will sow itself and never become a troublesome weed. *Viola palmata*, from the United States, is a desirable perennial with pretty palmate leaves and purple flowers. The North American *Pentstemon confertus* is an excellent plant for the front of the herbaceous border; its racemes of purplish flowers are borne on short peduncles and are very pretty. *Camassia esculenta*—the Quamash of the North American Indians—ought to be in every garden; its tall scapes, bearing numbers of handsome, large blue flowers, make a fine show. *Tolipa australis* is a South European species with golden-yellow flowers, the segments of the perianth being narrow. *Borago laxiflora* has the rough leaves of all its class and delicate sky-blue flowers borne singly on rather long stalks; it grows to a height of from 1 ft. to 1½ ft. *Echium rubrum* is a very fine plant, with narrow leaves and red flowers. *Polemonium humile*, from North America and Siberia, is a lovely little perennial not more than 3 in. in height; the leaves are pinnate, and the flowers blue, with a yellow centre. *Anthericum Liliago* var. *algeriense*, an Algerian form of the St. Leonard's Lily, grows taller and bears flowers

rather larger than those of the type, *Astragalus fruticosus* is a Siberian plant of dwarf, compact habit, having pinnate leaves and heads of purple flowers. A colour rarely met with is furnished by *Lathyrus intesus*, a desirable yellow-flowered perennial.

**Greenhouse Plants.**—*Acradenia Franklini*, a Tasmanian member of the Rue family, named after Lady Franklin, may now be seen in flower in the Winter Garden; it has opposite, ternate, fragrant leaves and corymbose panicles of white flowers; it is a shrub of dense habit, and is suitable for planting out in a cool conservatory. *Bossia lynchophylla* is perhaps the most charming and elegant of all the greenhouse plants now to be seen in flower at Kew; the long, slender, pendulous branches are so thickly clothed with fine orange-yellow and red-brown flowers as almost to hide the narrow leaves. *Leptospermum myrtifolium* and *Kunzea sericea* are two nearly allied members of the Myrtle family; both have conspicuous white flowers and are well worth cultivation. *Phyllocactus Schlimii* has large, fiery-scarlet flowers, and seems to blossom well even in a small state; it is a very desirable sort. For training along the rafters of a glass-covered corridor, or even for planting outside in sheltered situations, *Bignonia speciosa*, from North America, can be thoroughly recommended; it is a handsome climber, with dull orange-red flowers. One of the most beautiful of the Indian *Rhododendrons* is *R. Veitchianum*, with large flowers, pure white, with the exception of the base of the upper portion of the corolla, which is shaded with yellow.

**Orchids.**—*Dendrobium anoumum*, from Borneo, is a showy species, with large flowers similar to those of *D. macrophyllum*, and, like those, rather unpleasantly scented. *D. Bensoniæ* has white petals and sepals; the shell-shaped lip is broadly bordered with white, the remaining portion being light yellow, which changes to deep orange, with the exception of two crimson-purple blotches. *Oncidium Schlimii*, from the province of Oçana, in New Granada, has a long, straggling panicle of yellow and brown flowers; it is a handsome and distinct species. *O. sphacelatum* has a long panicle of flowers, which are remarkable for the fine yellow and rich brown of their sepals and petals. *Odontoglossum maculatum* has brown sepals, the petals and lip being light yellow, blotched with brown. The Mexican *Lycaste Deppei* has greenish sepals; the petals are white, spotted with purple towards their bases, the bright yellow waved and crisped lip being bordered and spotted with crimson. *Pholidota imbricata* is much more curious than pretty; it is an Indian epiphyte, with long, imbricated, pendulous, two-ranked spikes of whitish flowers, which present a striking resemblance to the tail of the rattlesnake.—†.

**Erysimum pachycarpum.**—In the Kew collection we noticed the above new Crucifer in flower, and, though as yet not fully developed, it bids fair to be very ornamental. It has stout, erect stems about 15 in. in height, clothed with long lance-shaped leaves. Its flowers are borne in terminal racemes, and are of the colour and size of those of the well-known *E. profusianum*. It is a native of Sikkim Himalaya, and in the "Flora of British India" we find it described as attaining a height of from 2 ft. to 3 ft., with the other parts developed in proportion. Its length of duration is not mentioned, but whether it be a biennial or perennial, it will eventually become, most probably under cultivation, a desirable acquisition.—W.

**Clematis Viticella rubra grandiflora.**—Undoubtedly in the large group of Clematitides now in cultivation we get the finest hardy decorative plants for the garden that can well be imagined. They are useful in many ways—as greenhouse and conservatory climbers planted out to run up pillars, as specimen plants for the house and exhibition table, as climbers for walls, poles, verandahs, &c., in the open air, for covering rootwork, and for bedding out; there is scarcely a spot in which the most robust-growing types will not grow and bloom. They do well as a summer covering for low walls, but it is necessary that the wood be cut back close to the ground in early spring, and the main shoots stopped back three or four times to induce them to push lateral growths. The stopping is done just above the first joint. The effect is to make the plants bloom a little later, but this is compensated for in the immense number of flowers produced. Bright touches of colour are indispensable in the Clematis where telling effects have to be produced. The variety which heads these remarks is peculiarly well adapted for this purpose. It is the variety *par excellence* that can lay claim to be a red-flowered Clematis. "The blooms are not large, but they are produced with remarkable freedom, and it is also a continuous bloomer. It possesses a singularly robust habit, and it is, therefore, well adapted for planting in shaded, moist situations, and where it may be too cold or too wet for the more delicate forms to do well. A selection of six varieties of good, free-growing, hardy Clematitides might consist of *Jackmanni*, *rubella*, *languinosa nivea*, *Star of India*, *Lady Bovill*, and *Viticella rubra grandiflora*.—D.

## THE FLOWER GARDEN.

### CHANGING THE SEASON OF FLOWERS.

THIS is well-nigh as changeable as fashion in dress, and is, possibly, even more capricious. Plants and flowers rise and fall in public esteem without much or any good reason. Fortunately, however, plants, like fashions in dress, return. There are also changes in flowers in regard to seasons, partly, perhaps, inevitable, but many of them are also capricious. Take, for example, two well-known and almost universally grown flowers—Gloxinias and Petunias. Both used to be looked upon as autumnal flowers, as a matter of course, and were looked for and expected as much in the autumn as Deutzias, Spiræas, and Lilacs are now in the early spring. But these fashions have changed. Gloxinias are fast becoming winter-blooming or early spring plants, a purpose for which they are as well adapted as Gesneras; and, as you reminded us in THE GARDEN (see p. 407), single Petunias are among the most useful and showy of spring-flowering plants. The double varieties are almost as useful for these purposes. In fact, while great pains and

many stoppings have been needed to compel the Petunia to bloom in the late summer and autumn months, it is only needful to put in cuttings or sow seeds in the autumn or winter, and to leave the plants alone, to have a fine show of blossom in the spring. Wintered on shelves near the glass, rather under-potted or basketed, Petunias are among the finest and earliest of spring-blooming plants. It is astonishing they are not more employed for brackets and as basket plants, or for the clothing of dwarf walls under glass. The variety amongst them is almost endless, all being beautiful, and the perfume of many varieties as sweet almost as that of Violets, though to some the smell of the foliage is unpleasant.

The succession and profusion of bloom is likewise wonderful. Take another plant—the Crested Celosia, or Cockscob. This has now given place to improved forms of what used to be designated only useless sports, viz., the feathered varieties, but these are now much used for winter decoration, while the old Cockscobs were midsummer or autumnal plants, and one of them in the stove in winter would have been considered as much or more out of place as a large hot Plum pudding on a town tea-table. But the Celosias grace, with their feathery sprays, not a few Christmas tables now-a-days.

These are but mere samples of the change of fashion, and there really seems no reason why the feast of beauty should not only be perpetual, but that greater freshness and newer charms should be added to it by changing the seasons of many more flowers. The immense increase of skill and augmentation of resources within reach of horticulturists, while adding largely to the richness and variety of our gardens, have tended in not a few cases to monotony. One always sees the same flowers and eats the same vegetables and fruits at the same season everywhere. In a word, by our forcings and retardations the feast of beauty and of other garden products is in danger of becoming not only continuous, but also terribly monotonous.

The next great move in advance may probably consist largely in the change of fashion and season of garden produce. To take another simple illustration, Mignonette and Stocks are almost universal in the spring. Why should not a second edition of the same, with variations, return to the window garden and conservatory in the autumn, and be carried far through the winter? The same practice might be adopted with Nemophilas, Virginian Stocks, Clarkias, Collinsias, and many other annuals.

The glorious race, again, of tuberous Begonias can be forced into beauty early in the spring. Many, also, of our modern Pelargoniums respond to the cultivator's wishes in regard to time. Coleuses, too, with all their well-nigh infinite variety of colouring, may be had as brilliant, though of course with more trouble in winter than in autumn. Caladiums respond to heat and moisture, after a temporary rest, at any season.

These examples are sufficient to show that it is possible to change the fashion by changing the season of flowers, and the same principle is equally or even more applicable to fruit and vegetables. Indeed, it has already been largely done, and beauty and plenty in the best gardens have become perpetual.

But this is not what is meant here and now, but rather the creating of a new sensation by having garden produce of all kinds out of season. No doubt such changes may make considerable demands on skill and require additional labour; but, if desirable, these considerations should not hinder their adoption. In purchasing a work of art the first question should not be, What will it cost? but is it genuine and of real merit? If it is, the picture or statue is likely to be cheap at any price in this age of tawdry tinsel and made-up shams. The same rules should be applied to gardening matters, not that these changes of fashion in gardens are necessarily expensive; seeds and plants are cheap enough, and

In the "English" part of the Luxembourg Garden.

the cost of flowering them at one season rather than at another need not be very serious. If such and other changes of fashion in gardens be desirable, they should be adopted and carried through in a generous mood and with a light heart. A parsimonious spirit, ever grumbling at past and fearing prospective expenses, is at once unjust to skill and incompatible with the pursuit or enjoyment of art. D. T. FISK.

**Views in Town Gardens.**—In town and suburban gardens there are frequent opportunities of adding to the beauties of the landscape by allowing portions of adjacent buildings to be seen. To do this effectually, however, requires some skill, as if it be desirable to show portions of certain structures, it is no less so to hide many others. Hiding ugly buildings is, indeed, a more important point with the city gardener than leading the eye to beautiful ones. The example shown in our illustration is in the English part of the Luxembourg Garden at Paris, across the lawn of which the dome of the Pantheon may be seen.

**Primroses in Woods.**—If seed of the richly-coloured garden Primroses could be had as abundantly as seed of the Polyanthus, it might be possible to sow it freely in woods and waste places, and thus secure a stock of plants. But seed is not to be had in abundance,

and therefore it is not probable that anyone will care to trust to the chances of growth in a wood that which they have to raise with so much care for their gardens. Even were it possible to introduce coloured Primroses into woods, could they be secured from the deprivations of flower collectors? However, assuming that seed could easily be sown in enclosed places, why does not some one make a start with seed of high-coloured Polyantheses? And, perhaps, if these were to be grown intermixed with the wild Primrose, some effective hues of colour might be produced on the latter as a result of cross breeding. Mr. Cornhill asks, Why is it that many of our choicest kinds are so scarce? and replies, because they are not grown under natural conditions, but in the full blaze of the summer sun, which induces loss of foliage and feebleness. That such a result might follow if these beautiful Primroses were grown on a hot, gravelly soil, in the full glare of the sun, there can be little doubt; but the character of the soil makes all the difference. Here we have many hundreds of all sorts of colours, and even the choicest kinds growing in beds in the full glare of the sun all the summer, but we rarely lose a plant. The soil is a stiff, clayey loam, moist in winter, and burns and bakes in summer, but the plants do well. From our large number of plants, however, but little seed is to be had, as they begin to flower so early that we do not get hot, warm, dry, fertilising weather until nearly all the bloom is past. A showy plant that has produced over 100 flowers may yield a dozen pods of seed, or loss. Nothing could give us more pleasure than to see these Primroses growing in woods, but few would, perhaps, care to meet the expense incidental to the securing a hundred or so of plants for the purpose.—A. D., *Bedfont.*

### MY WILD GARDEN.

In this, my third article on this subject, allow me to mention that florist flowers, such as the different varieties of Pansies, Dahlias, variegated Pelargoniums, and others of a similar character, would be wholly out of place in the wild garden. Beginners contemplating the formation of a wild garden should collect what seed they can get during the coming season from the wild plants growing about the roadsides, hedges, ditches, fields, and woods, and should sow them at once in beds in order to secure an abundant supply the following year, as well as sow them on selected spots in the wild garden, so that if any of these fail they can be supplemented with little seedlings. Collecting seed, too, from foreign perennials is indispensable, as they can be advantageously grouped to harmonise with the indigenous plants. A few hints regarding the beauty of a wild garden at this season (early in May) may be interesting to some of your readers. To begin, let the eye picture to itself a carpet of Forget-me-not (*Myosotis sylvatica*), with a few single plants of the white variety intermingled sparingly with *Primula sinensis* (which is exceedingly pretty associated with the blue *Myosotis*), Tulips, Wallflowers, Blue Bells, *Die-dytra*, and patches of Cowslips, together with scattered plants of the *Heracleum giganteum*, the leaves of which give a striking effect. These are surrounded by flowering shrubs, such as White Broom, Lilac, *Kerria*, *Ribes aureum*, *Berberis stenophylla*, double flowered and Bird's Cherry, double Gorse, *Lonicera tatarica*, and the common Laurel. Last, though not least, we have the charming *Malus floribunda*, groups of *Trollius* in shady parts, *Oxalis Acetosella*, breadths of *Vincas*, *Asperula odorata*, *Primroses*, and, scattered amongst the Grass, Cowslips. *Orchis mascula*, of which there is a white variety, Blue Bells (common and others), *Narcissi*, and *Liliums* I find often fail if the ground be very wet.

As to planting, let us now imagine a spot somewhat densely shaded by deciduous trees. In such a place I would put the Winter Aconite, single Snowdrop, and *Vinca major* and minor. These should be in large irregular patches, and so arranged as to form one natural mass. With these I should mix *Arums*, *Aralia racemosa*, *Astilbe rivularis*, *Ranunculus auricomus*, *Spurge Laurel*, *Euphorbia amygdaloides*, *Chelidonium majus*, *Fool's Parsley*, *Heracleum giganteum*, *Sphondylium*, and *pubescens*, *Angelicas*, *Dipsacum*, *Hartstongue* and other Ferns, *Paris quadrifolia*, *Borage*, *Funkias*, *Saxifraga cordifolia* and *virginiana*, *Spiræas*, *Glechoma hederacea*, and a few patches of *Enchanted's* Nightshade. These, judiciously distributed, will produce a charming effect. A mount or rough bank might be planted with Red and White Thorns and *Laburnums* at 9 ft. apart for the purpose of supporting climbers, such as the varieties of *Clematis*, *Honeysuckles*, *Calystegias*,

*Briers*, *Virginian Creepers*, *Bryonia dioica* (which, when allowed to trail on the Grass, is very pretty), and *Bittersweet*. Sow the ground all over with *Myosotis disitiflora* and some of the *Rose Campion*; also plant some bulbs, such as single *Hya-cinths* and *Van Thol* and red Tulips. At least two sorts of *Clematis* should occupy one support. Another part of the garden might be filled entirely with the *Iris* family, which are both numerous and pretty, and not averse to partial shade. The ground should be well prepared for their reception, and a little manure would be of benefit to them. A shady place should also be selected for the varieties of *Trollius*, which may be intermixed with *Omphalodes verna*, and also for the *Os-munda regalis*. The place in which these are planted should also be rather damp. The ground should be deeply dug and cleared of all roots. If some peat can be had to mix with the soil, so much the better. By the side of these plant some of the *Spiræa* family. *Oxalis Acetosella* associates well with the *Os-munda*; breadths of *Lily of the Valley* look well, and for this the ground should also be deeply dug, and mixed with a few stones or broken bricks. When the leaves begin to wither divide the roots into small portions, and plant them about 6 in. apart. These soon reward the cultivator for any amount of trouble to which he may be put regarding them. Another interesting patch might consist of a mixture of *Wood Anemones*, *Crocuses*, *Star of Bethlehem*, *Lily of the Valley*, and some of the autumn *Crocuses*. TEWENSIS.

### SOME OF THE MORE IMPORTANT HARDY EXOTIC PLANTS FOR THE WILD GARDEN.

Acanthus	Crambe cordifolia	Iberis	Polygonum
Achillea	Crocus	Inula	Pontederia
Aconitum	Cyclamen	Iris	Potentilla
Aconitum	Delphinium	Lathyrus	Pyrethrum
Ajuga	Dentaria	Leucocjum	Ranunculus
Allium	Dianthus	Lilium	Ranunculus
Alyssum	Dodecaheon	Lilium	Salvia
Anchusa	Eranthis	Lilium	Sambucaria
Anemone	Erigeron	Lupinus	Saxifraga
Angelica	Elymus	Lycchia	Scabiosa

### FLOWERS IN CHURCHYARDS.

As this subject is now attracting attention, perhaps a few remarks from one who resides within a stone's throw of a very pleasant country churchyard where grave-gardening is carried to a great pitch may be read with interest. The churchyard in question is pleasantly situated on the northern border of the county of Durham, and overlooks the valleys of the Tyne and Derwent. It has a northern aspect, and is within a mile of the first-named smoky stream. Although the remains of many rich persons are interred here, it is mainly among the poorer classes that one sees good attempts made at grave gardening. The flowers employed consist chiefly of Wallflowers, common English red and white *Daisies*, and the beautiful *Forget-me-not* (*Myosotis disitiflora*), while what may be termed the permanent stock consists of *Hellebores*, *Rose-mary*, *Weeping Willows*, *Irish Yews*, and in some instances, *Roses* of various sorts, but the *China* or *monthly Rose* predominates. I had almost neglected to mention that *Saxifrages* play an important part, some graves being entirely covered with one or more varieties of them, with an evergreen shrub or a plant of *Christmas Rose* at the foot. One of the handsomest combinations at the present time (May 19) is a centre of dark *Wallflowers* (*Harbinger*) with a belt of yellow *Wall-flowers* (*Raby Castle*), the whole being deeply margined with *Myosotis*

disaiflora. In directing attention to this simple country burial ground, I have no wish that it should be set up as a paragon of excellence; on the contrary, I think that there is great room for improvement. No systematic plan is carried out or attempt to beautify the place in general; each one is content to make what he owns look well, irrespective of what may be next to him. I think that something might be done in the direction of keeping our ancient churchyard in a more becoming manner. For instance, after the trees, flowers, shrubs, &c., are planted by friends over their deceased relatives' graves the place might be kept in order by the powers that be, as far as regards the levelling down of grave tops and keeping the Grass from growing waist-high.

TYNEDALE.

## CUTTING DOWN LILIES.

"DUNEDIN" asks (see p. 386) for the passage referring to cutting down Lily stems before the leaves had faded. His own words (see p. 28) read thus: "I have cut down the stems when the plants were in full and fresh bloom without in the slightest degree affecting the growth of the new bulbs, which at this time are themselves sending down roots, by which they can gain subsistence sufficient to make them independent of the parent bulbs;" and, in reply to Mr. Hovey, "Dunedin" reiterates much more emphatically the advantage of early planting, and states that no harm resulted from lifting the bulbs in full bloom on June 30 and exposing them to the atmosphere during six of the hottest weeks of the year. It was to the evil effects which such advice might have on the uninitiated in Lily culture, who might be led to practise this method indiscriminately in the case of all kinds of Lilies, that I took exception; whereas it was only on the white Lily (*Lilium candidum*) that the experiment was made. And Mr. Hovey's communication, to which I would refer (see p. 387), fully illustrates the different effects which the cutting-down process has upon different classes of Lilies. If "Dunedin" had lifted any of the varieties that only form leaves on their flower-stems, he would not have experienced such satisfactory results. And, to my mind, the result of this experiment upsets much of "Dunedin's" theory respecting imported Lilies; as, if I understand him rightly, it is the seed-bud or germ that is so much affected in the removal, that it fails to germinate if haply it should be liberated, necessarily causing the speedy death of the bulb. Yet, in the case referred to, the parent bulb was out of the ground at the date (July) at which the germ would be formed. "Dunedin" quotes Mr. Baines in one instance as having confirmed his views, but this was only as regards *L. candidum*, for Mr. Baines is too well versed in plant culture to recommend the same treatment for all classes of Lilies simply because they are Lilies. I have read "Dunedin's" arguments with interest, and I feel sure that he would be the last person who would like to have his teaching end in a barren or fruitless controversy. But scientific experiments, however valuable in regard to matters horticultural, may be more than counteracted by an apparently trifling incident in cultural details, and this discussion is no exception to the general rule; for although "Dunedin" states positively (see p. 386) that he has observed a singular similarity in the organisation of all Lilies, it is well known in practice, even by those entirely unacquainted with the organisation of Lilies, that entirely distinct methods must be adopted to attain the maximum degree of perfection in each class, for, as is clearly explained by Mr. Hovey, a grower of lengthened experience, the treatment that would benefit *Lilium candidum* would be death to *L. speciosum*. And as to *Lilium giganteum*, no one expects it to flower a second time; but successive bulbs are grown, so as to have some in flower every year. In the case of this Lily the old bulb decays altogether, leaving some young progeny outside the bulb to keep up the stock. That early flowering Lilies are the best for open air culture I am fully convinced; and although the later autumn flowering varieties of the *L. lancifolium speciosum* section may be grown with tolerable success in favourable seasons and localities, I feel sure that those who have not grown and flowered them under glass have a treat in store; they will not only get finer and more perfect blooms under glass, but better bulbs for succeeding years' operations.

J. GROOM.

— Permit me to say to Mr. E. Harvey (see p. 457) that, in my opinion, his plan is the right one, and that with care he need not fear

arriving at a successful result sooner than he at present seems to anticipate. I think, however, that under glass there will be no necessity for attempting "to promote quick growth, so as to make the plant flower a little earlier each year;" for, if he succeeds in preserving the germ at the critical period of its existence, the plant will itself return to its natural time of flowering. I procured some imported bulbs of *L. auratum* at the end of February last year, and they did not bloom until November (indoors, of course). They are now in the open ground, 3½ ft. high, and indicate a very early bloom this season. It is more than likely, however, that Mr. Harvey will meet with some disappointments through bad bulbs. Those bulbs of *L. auratum* which I got were principally for dissection, and I found, on cutting them open, that the seed-buds, or where they ought to have been, were all eaten away, in more than 50 per cent. of them, by small, thread-like worms, about ¼ in. in length. More might be said on this point, but at present time presses. With regard to his inquiry about "cutting down the flower-stems of *Lilium candidum*," I think he will find some useful hints in my reply to Mr. Groom (see p. 451). I have written another article, which I believe will be found practically useful by many of the readers of *THE GARDEN*; but, in order to make it thoroughly complete, I am collecting and dissecting specimens for the photographer of offsets of the first year, bulbules or small bulbs of the second, third, and fourth years, together with fully-developed bulbs, all showing the interior organs of reproduction, and the wonderful harmony and similarity that exists in the structure of these organs, in a dozen or more distinct species of our Old World Lilies. I have made a careful search at the British Museum and other public libraries, and have met with no book which contains anything that at all comes near to what I propose to produce. I feel, therefore, justified in saying that if the photographic representation be carefully reproduced in the columns of *THE GARDEN*, the number which contains it must become valuable to amateurs and Lily growers in general as being a trustworthy and practical work of reference.

DUNEDIN.

## DICENTRA (DIELYTRA) SPECTABILIS.

MAY I be permitted to make a few remarks *apropos* of "D.'s" article on this most beautiful plant. First, as to its name. It was, I believe, first named by De Candolle *Dielyttra*, the common gardeners' name *Dielyttra*, which is etymologically meaningless, originating in a clerical error. Owing to this fact, most botanists are agreed to cut the Gordian knot by substituting the name *Dicentra*, which has the same meaning as *Dielyttra*, viz., "two spurs." It would be well if this name were universally adopted. A vernacular name, "Dutchman's breeches," which is hardly an elegant one, does not seem generally known. It reminds me of Edmund Lear's admirable parody of the plant, under the name of "Many-peoples *apsidownia*," in his "Nonsense Botany." "D.'s" description of the plant is tolerably accurate, though some of his analogies are rather far-fetched. The leaves are, I think, comparable to those of its allied *Fumariads*, to those of the Columbine, and of some of the Meadow Rues, rather than the *Faony*. The calyx consists of two scale-like, caducous sepals, like those of the Poppy; the corolla of four petals in two pairs, the outer pink, saccate, and semi-ovate (half heart-shaped), the inner white, narrow, and spoon-shaped. It is misleading to students to compare the outer petals to the hooded sepals of the Monkshood. A flower has but one corolla, and the term "perianth," being merely technical for floral envelope, includes both calyx and corolla, and is altogether distinct from a column. In an *Iris* we have simply a six-leaved perianth and three stamens overlapped by the three petaloid lobes of the stigma, and in *Orchide* we have pistil, anthers, and some of the perianth leaves thoroughly blended in a central column. *Dicentra* presents a very remote resemblance to either case, as might be expected, seeing that its position is as far apart from theirs as is pole from pole. The bases of the filaments adhere loosely to those of the outer petals, and the somewhat abnormal anthers and the two little crenulated lobes of the stigma are merely shut in by the two inner petals, which are partially adherent at their tips. The stamens, though in two bundles of three each, seem normally four, since only the middle filament in each bundle bears a whole or two-celled anther, the lateral ones having half-anthers or rather one-celled ones. The flower secretes honey at the base of the two saccate petals, and humble bees reach it by inserting their proboscis through a small hole left between the face of the outer and the back of the inner petals. They probably occasionally effect cross-fertilisation by carrying on their hairy under-surface the pollen of a young flower whose inner petals have just gaped for the first time under the influence of bright sunshine to an older blossom whose anthers have lost their pollen exposing the stigmatic surface.

G. S. BOULGER.

11, Burlington Road, Westbourne Park, W.

## VIOLAS GROWN FOR TRIAL AT CHISWICK.

The following kinds of *Viola* have received First-class Certificates:—

**Flowers Yellow.**—**CORISANDE** (Dean).—Plant of very free, vigorous growth; free flowering; flowers of fair size, pale yellow. A very early flowering variety continuing in bloom for several months. Excellent. **CROWN JEWEL** (Dean).—Plant of free-spreading habit; free flowering; flowers of medium size of fine round form, clear bright yellow. A good variety. **GOLDEN PRINCE** (Fromow, 1877).—Plant of fine free habit; free flowering; flowers of medium size, bright yellow, with eye pencilled. Stands the dry weather well.

**Flowers White.**—**VESTAL** (Dean, 1877).—Plant of fine compact habit; very free flowering; flowers of medium size, pure white. Excellent. **LADY SUSAN GRANT SCUTTIE** (Stuart).—Plant of fine compact habit; free flowering; flowers large, well displayed, and of good form, of a bluish-white. A good variety. **PILGRIM PARK** (Dickson & Co.).—Plant of vigorous branching habit; very free and continuous flowering; blooms well displayed, very large, pure white, with yellow eye.

**Flowers Lilac.**—**ORMISTON** (Stuart).—Plant of fine habit; free blooming; flowers large, well thrown up above the foliage, dark lilac striped with purple. A very showy variety. **RUBRA LILACINA** (Dickson & Co.).—Plant of free dwarf habit; a profuse and continuous bloomer; flowers large, of good substance, rich lilac, with distinct blotch on under petals. Stands dry weather well. An excellent sort.

**Flowers Mauve-purple.**—**BLUE BELL** (Dean). **HILLSIDE BEAUTY** (Stuart).—Plant of fine vigorous growth; very free flowering; flowers large, of a dark mauve-purple colour. An excellent variety, and stands the fine weather well. **AMENA MAGNIFICA** (Dickson & Co.).—Dwarf, spreading habit; free flowering; flowers small, mauve, with distinct yellow eye, and upper petals dark. A good variety. **BLUE KING** (Dean).—Plant of fine dwarf, compact habit; free flowering; blooms well displayed, lightish blue, with distinct bronzy spot on under petals.

**Flowers Purple or Blue.**—**GEORGIA** (Stuart).—Plant of very fine dwarf, compact habit; very free and continuous flowering; flowers well displayed, of a purple hue. A good variety and lasting. **HOLYROOD** (Dickson & Co.).—Plant of dwarf, branching habit; very free and continuous bloomer; flowers large, rich deep purple, with small yellow eye, and distinct blotch. Stands the dry weather well. **SUTTON COURT BEAUTY** (Fromow).—Plant of fine dwarf, spreading habit; very free and continuous bloomer; flowers large, of a fine rich purple colour. A splendid variety. **WAVELEY** (Robertson & Galloway).—Plant of free-growing, spreading habit; very free and continuous bloomer; flowers large, bluish-purple, with large yellow eye, and distinct blotch on the under petals. A splendid variety.

**Flowers Dark Violet.**—**LADY DIANA** (Gray).—This is very similar to *Distinction* and *Lady Sophia*, but is of more compact growth, and consequently was awarded a certificate.—“*Journal of the Royal Horticultural Society.*”

**Iberis gibraltaria.**—This *Iberis* has not proved to be hardy with me, even during such a mild winter as that through which we have just passed. I do not think it can be classed as a hardy plant; on the contrary, it ought to be grown in a frame or cool greenhouse through the winter. Whether moisture or a low temperature killed it I cannot say, but I observed during the winter that the foliage began to fall, and then the stems decayed, and the plants died altogether. I was not particularly charmed with the habit of the plant, as it was coarse and straggling, and in no case developed into a neat, compact bush. I regard *I. corifolia* as the best and handsomest of the family; its small, rounded trusses of pure white flowers are perfect in form and excellent for bouquets and button-holes. The plant has a good compact woody habit, and forms a handsome, neat bush.—A. D.

**Narcissus Bulbocodium.**—This with us flowers every year most freely. We have had its beautiful flowers in profusion, two or three on each bulb, for the last two or three weeks, and it is still out. Our hot, light soil especially suits this and *Iris iberica*.—ALEX. WALLACE, *Calchester.*

**Gentiana acaulis on Mounds.**—Nothing can be more satisfactory than *Gentiana acaulis* grown on mounds. The latter are of small size and covered with a layer of stones. The first attempt in the gardens under my charge to grow this *Gentian* on mounds was made about seven years ago, and the mounds then formed are now so well covered that they appear as if quite solid with bloom. Anything more beautiful than the appearance they present cannot be imagined. Good turfy loam is the most suitable for the formation of the mounds, and September is the best month in which to plant. The only attention requisite after the planting is to water thoroughly three or four times in the course of the season.—“*Gardeners' Magazine.*”

## THE FRUIT GARDEN.

## WALLING IN THE ROOTS OF FIGS.

Of all the different kinds of fruit now grown in the open air, there are none with which so many fail as the Fig; and yet, in its native clime and under certain conditions of treatment, it is one of the most fruitful trees in existence. Those who have seen it in pots with its roots cramped and restricted must have been struck with the great yield of such plants over others ten times the size where they have full liberty to ramble; and, therefore, if we only think for a minute, the cause of this barrenness would present itself to our minds. Gross growth is never conducive to fertility; and with a Fig, the wood of which is naturally so sappy and pithy, and requires so much ripening and hardening, there is no chance of getting it into a bearing state unless coercive measures are used. Under a clear, foreign sky there is no necessity for this, as there the wood made becomes thoroughly mature; but in our moist climate, with but comparatively a small amount of sunshine, this is not the case, and artificial means must therefore be resorted to in order to bring about the desired result. This is the most readily accomplished by bricking a certain space in and concreting the bottom in such a manner as to render it impenetrable to roots; and not only should this be done, but the bricks should be laid in cement, or they will soon find an outlet between them. A pit thus formed that will hold a cubic yard or so of soil is large enough to supply the wants of any ordinary-sized Fig tree, and the expense of doing it is but slight, compared with the permanency of the work and the exceedingly satisfactory returns that will be made for the outlay. No half measures are of any avail, and nothing short of confining them like this is of any use, as, do what one may by way of root-pruning, the effect is only temporary, for they are soon running far and wide again and become as rampant as ever. Until I adopted this plan of walling in, I could never depend on getting a crop, but now there is no difficulty in the matter, as the trees, instead of making a foot or two of soft, worthless wood, only make at most 3 in., and this becomes so hard as to be quite unaffected by frost. Another characteristic of this wood is that it is closely jointed, each of which produces a Fig; and although these may not be quite so large as others obtained from trees where they can run riot, they are always of far better quality. It is singular that the Fig of all deciduous trees should bear removal better at the spring of the year than during the autumn; but it is, nevertheless, a fact that it does so, and this being the case, any one that may have trees that are not as fruitful as they may desire, will do well to set about their improvement at once. Although it is full late to transplant, unless they can be lifted with pretty good balls, it is better to undertake the work now than to defer it, as the corrective measures adopted will at once take effect on the growth and ensure a crop of fruit next year. The way to set about it is, first of all to dig the holes, say a yard or so square more or less, according to the size of the plants to be operated on, and then proceed to line round the sides with bricks on edge laid in some good, quick-setting cement. Previous to doing this, however, the bottom should either be concreted or paved with bats, and the interstices grouted in so as to effectually fill them, and when the whole is dry and hard, it will be ready for putting in the Fig. These being rather advanced, extra care will be needed in digging well round them, that they may be lifted with a good portion of earth, and if this be done, and a heavy watering given when filling in around them, scarcely a leaf will flag, but they will at once set about forming fresh roots and quickly become re-established. The kind of soil most conducive to fertility in the Fig is that containing a large amount of calcareous matter; and, therefore, in planting, fine chalk should be made free use of, first incorporating the same with the earth that was dug out in forming the holes, or if this should happen to be gravelly or bad, then with any other more suitable that may be at hand for the purpose. Manure, rich soil, and stimulants of all kinds should be avoided, as anything in that way can be given in a liquid state later on if required, which, with a heavy crop to carry, is sometimes needed. A mulching, however, of some kind of littery matter is always desirable, as it is a great help in keeping the roots more uniform both as regards heat and moisture; and with all fresh

transplanted trees this is a most important point, that should always be borne in mind, for if their wants were more attended to in this respect, failures would not be of the frequent occurrence they are. Figs treated and restricted in the above-named way require little or no pruning or further attention, beyond an occasional thinning to let in the light and air among the branches, and thus afford a more full exposure of the fruit to the sun. In the case of those on walls, the best way to manage them after confining their roots in the manner advised is to simply secure the main branches to stout galvanised iron staples driven into the joints and allow the breast wood to grow as it will. Occasionally this may be shortened back, or the long portion cut entirely out, so as to keep the whole nearer home, that it may have the full benefit of the shelter and warmth afforded by the building on which they are trained. I always make a practice of doing what little thinning is ever needed during the summer and not later than June, as then the trees have the solar rays to ripen the wood, but, except to remove a few suckers now and then, it is very seldom the knife is required. Pruning, as generally carried out with Figs, does more harm than good, as the cutting out of one strong shoot is often the cause of several others starting to take its place. I would therefore urge all who have hitherto failed in getting a good supply of fruit to try the plan of pinching them for root room, and if they do so, I am quite sure they will be more than satisfied with the result.

J. S.

**Beurre Dumont Pear.**—This is a sample of a young Pear tree (pyramid) as trained in M. Jamin's garden at Bourg-la-Reine,

near Paris—a very instructive little fruit garden, which we advise any of our readers to see who may have time when visiting Paris this season. This young tree was photographed while in fruit, a somewhat difficult condition to show in an engraving. As will be noticed, the tree is much stouter and better furnished below than is usually the case. In these trees every branch and branchlet is under the easy control of the trainer.

#### FEEDING VINES AND OTHER FRUIT TREES.

I HAVE often thought, and constant experience has only confirmed the opinion, that for producing fine examples of fruit we should not depend too much on feeding the plants with liquid and other manures after the fruit has set and begun to swell; the real work is done before that period. What we want in a fruit before we can feed advantageously is a capacity to swell; a framework, in short, capable

of filling. It is certain, at all events, that if you get a strong Vine rod or a robust Pine-apple plant, and both well ripened, you are sure of large fruit, whether you feed or not, though, no doubt, feeding will help them on. A poor weak plant, with proportionately weak buds, can, at the best, only produce small fruit, and no amount of feeding will ever make it large. I notice always that when Vines produce small flowers they produce proportionately small berries—much bulk is not in them. This is also distinctly noticeable in Peaches, Melons, and particularly in Strawberries. I have always been able to foretell quite rarely the probable swelling powers of our forced Strawberries from the size and character of the flowers. If the flowers are poor, so also will the fruit be. The plan with them is to lay the foundation of good flowers by securing strong plants with fine foliage and large buds, and the same applies to Vines and other subjects. I dare say there are plenty who realise this as well as myself, but, at the same time, I am well aware that much stress is laid upon feeding the plant after the fruit begins to swell, and not a few have forbidden feeding before that period. I dare say it is possible to overdo a plant at certain times, and we know that certain plants have a tendency to run to leaf when stimulated by certain manures, but this I attribute more to the manner of feeding than to feeding itself, which, if practised in moderation and according to the needs of the plant and the season of the year, cannot have other than a beneficial result.

J. S. W.

#### MELON CULTURE IN BEDDING PLANT FRAMES.

To no better purpose can frames liberated from bedding plants be put than that of growing Melons—a fruit which in the hot summer and autumn is much prized by most people, and is sure to be doubly acceptable this season, when so few Peaches and Nectarines have been saved from the frost. One or two lights of Cucumbers would be enough for most families, as they will afford a fruit a day if kept properly thinned out and well managed; but with Melons it is not so easy to keep up a succession, for the most a plant will do, unless it has an unusual amount of room, is to bear five or six fruits, and it takes three months to get these, even under the best of treatment, from the time of sowing the seed. So valuable, however, are they, and productive of so much pleasure when grown and managed by oneself, that they are fully deserving of all the care and attention they require, which is not great beyond the first labour of preparing the bed and planting them out. The chief thing to insure success is to start them with a little bottom-heat, which may be done by collecting any fermenting material together, and giving it a sweat previous to using it. This will not only make the warmth it affords more regular and enduring, but will let out the noxious gases, which, if allowed to escape into the frame, are sure to injure, if they do not prove fatal to the plants within. Where they can be obtained, stable manure and leaves are the best ingredients to make the bed with; but failing these, or not being able to procure them in sufficient quantity, the mowings from the lawn, Nettles, rough Grass or herbage from the roadside, hedge trimmings, or anything of that kind may be used separately or in addition. When gatherings such as these are pressed into the service, the best way is to use them outside instead of inside the frame, as then they can be added from time to time as they come to hand, and a gentle steady heat kept up as long as it may be thought desirable. To do this, however, it is necessary to support the frame on a few old faggots or bushes, so as to raise it a foot or so clear from the ground, when the heat from the fermenting materials around will have free circulation under, and thus afford the necessary warmth to the roots above.

A frame made up in this manner has many advantages, as it is of a more permanent character when used for forcing purposes, as the interior need not be interfered with when changing a crop, except just stirring up the soil for fresh planting. After the Melons, therefore, it will be ready for striking late cuttings in the autumn, or for growing winter Lettuces, Violets, or such like purposes. The object I now have in view, however, is not to treat of these, but to point out more particularly how to adapt it to the growth of Melons; and, premising what I have mentioned in regard to making up the frame is carried out, the next thing is to prepare for getting out the plants. This should be done by throwing some litter over the faggots or whatever may be used to form the foundation, and on this should be spread 6 in. or so of half-rotten leaves. A bushel or two of soil in the middle of each light, placed so as to form a slight mound, completes the work for the time; and if the frame be kept closed for a day or two, to draw in the sun and warm up the earth, all will be ready for planting. This should be done in the centre of the mounds, and these should be made firm by pressing them down with the foot at the same time; for, although Cucumbers delight in loose open soil, that for Melons should be the reverse, or they go too much to leaf and are not near so fruitful. The best material to grow them

in is fresh-cut loam, rather inclined to be stiff than otherwise; but so accommodating are Melons, if afforded the requisite heat and moisture, that they will do in almost anything, from common garden earth to leaf-mould, or the latter and clay mixed. Indeed, nothing more suitable than this need be wished for, especially at the final earthing up, which should be carried out as soon as their roots begin to protrude through the hillocks, that they may go on without check. The soil thus put in ought likewise to be well beaten down, and I find it a great help to lightly mulch the surface by scattering over it  $\frac{1}{2}$  in. or so of half rotten leaves or old tan, Cocoa-nut fibre, or anything of that kind, which allows the water to pass through readily, and prevents a too rapid evaporation, thus keeping the roots much more uniform as to moisture than they otherwise would be.

In the training and general treatment of Melons in frames, the first thing is to stop the leading shoot, which forces the plant to throw out laterals, one of each of which should be led towards the four corners of the light, and stopped when it reaches within 1 ft. of the limit in that direction. This second stopping induces side shoots, and on these it is that the fruit makes its appearance. In order to throw the whole strength of the plant into these, a further stopping is necessary, and this should be done at the first or second joint beyond, which will then leave plenty of room in the frame for the full development of the whole of the foliage. This is a very important matter in Melon growing, as every one of the main leaves is of consequence, and should be left perfectly clear, and not overshadowed by others, or it is impossible for them to carry out their functions and finish off a crop in the way they otherwise would do. As regards air, the chief thing to be attended to is to ventilate early in the morning, so as to let out the condensed vapour and allow the foliage time to dry before the sun shines hotly on it; and if this be done it will assume a thick leathery texture that will enable it to stand without shade, and render it less liable to the attacks of red spider, an insect to which Melons are particularly subject. To keep this in check, and aid the swelling of the fruit after it is fairly set, a good syringing should be given every afternoon about three o'clock, and the lights shut close down immediately after, by doing which the temperature will be considerably raised, and a thoroughly moist, genial atmosphere secured. There is one thing, however, to be observed in syringing, and that is not to wet the collars of the plants more than can be helped, or it is apt to cause canker or decay in the stem; and when this is observed making its appearance, the best remedy is a handful of lime dust laid on the affected part. This, from being a rapid absorbent will soon dry and stop the progress of the disease, as will also finely powdered charcoal, or the two mixed. To get Melons to set, they must be fertilised with pollen from the male flowers; and it is essential that as many as are required for a crop should be fertilised about the same time, or within a day or two of each other, otherwise the first takes the lead, and the chances are that the later ones do not swell off at all, or, if they do, they are only of small size and inferior. Once they are set, they must not be stinted for water till they are fully grown, when, to improve their flavour and ripen them properly, they should be allowed to become gradually dry, but not to such a degree as to cause them to flag. It is a glut after being kept without that causes them to burst, and this, occurring as it does just before they are fit to cut, is very vexatious. Besides red spider, green fly is sometimes troublesome; but a whiff of Tobacco smoke will soon settle matters with them if applied during a still day and when the foliage is dry, as it should be to be safe.

S. D.

### THE VALUE OF NORTH ASPECTS.

The best form for a walled garden is an oblong parallelogram, with the longest sides facing south and north; by this arrangement a good extent of south wall is secured, and the northern side is almost as valuable as the more sunny aspects. Plums and Cherries of all kinds will yield as good a result on a north wall, except it may be perhaps in the extreme north, as on an eastern or western exposure. Pears, except the early kinds, are not antitab; but Gooseberries and Currants come in well for late use, and should be utilized to fill up all vacant places between other trees on the walls; and, where a succession of vegetables and salads is indispensable, the most inexperienced cultivator is not long in discovering the value of a cool north border for some of the summer crops. From the middle of May to the end of July, Lettices, Endive, Radishes, and small salading will be more crisp and succulent from a north border than elsewhere, unless the land be exceptionally deep and rich, and water be plentifully supplied. Under any circumstances it is well to grow a part of the crop in a cool north position. Then again it gives a sense of security, if a sudden drought should set in early in August, if we have a good break of Camelliflowers coming on in a cool, moist position, where they will be less likely to bolt, or to burst into a

premature inflorescence the moment they have attained their full growth. Spinach, too, is a more reliable crop in a cool, shady situation; and it is always advisable to have a stock of green Mint, Chervil, Fennel, Sage, or any other herb for which there is a demand, in a cool place for summer use. A good bed of the Elton Pine Strawberry on a north border will prolong the fruit season, and be appreciated, more especially where the Alpine varieties are not grown for autumn use. And another and a most valuable use to which a north border may be put, is to form it, or a part of it, into a nursery bed for the spring bedding plants when they are moved from the flower garden to make room for the summer bedding plants. This is just the place for Dahises, Polyanthus, &c., that have done duty elsewhere in a more conspicuous position, to recruit health and strength for another campaign.—“Field.”

### CONCERNING TWO SPECIES OF APPLE.

ALLOW me to bring before your botanical as well as horticultural readers two species of Apple that I think should be better known, for the purpose of eliciting such information as may exist concerning them.

**Oregon Crab Apple** (*Pyrus rivularis*—Doug.)—It seems to be figured with the incorrect name of *Pyrus coronaria* in the report of the Department of Agriculture, 1870, p. 414. Dr. Vasey, in his report on the Forest Trees of the United States, in the report for 1875, describes it as a “small tree, ranging from California northward into Alaska. The fruit is of the size of a Cherry, of an agreeable flavour, and used, particularly in Alaska, by the natives of the country for food.” In Washington Territory, according to a pamphlet by Mrs. Stuart (1875), “the Crab Apple in many localities forms orchards on the prairies. Its presence is an indication of good soil. The wood is hard and tough, and the fruit well-flavoured.” Has this tree been fruited or planted on this side of the Rocky Mountains? Has the closeness of its relationship to other species of the Apple been tested by budding or grafting one upon the other? Has it more hardiness than other species in endurance of cold, &c.? Does it promise, by such a process of amelioration as the Siberian Crab is now going through, to become a valuable fruit? Leaving these questions to be answered, I would next ask for information concerning the

**Ohia**.—Lindley, in his Vegetable Kingdom, mentions an indigenous and solitary species of Apple as found in the Sandwich Islands. James, in his history of the Sandwich Islands, mentions among the indigenous and plentiful fruits “the Ohia, juicy and red, but of poor flavour.” Whitey, in his Hawaiian Guide Book (Honolulu, 1875), describes the largest Apple orchard in the world: “The wilderness of Koolan, Maui, contains a forest of Ohias (native wild Apple trees) countless in number, stretching from the sea far up the mountain-sides. The trees vary from 40 ft. to 50 ft. in height, and in the harvest season, from July to September, are covered with fruit, some white, but mostly red. We passed through the forest when the trees were loaded with ripe and ripening Apples. What a sight! For miles around us, up the mountain and towards the seashore, was one vast grove of Ohias, literally red with ripe fruit, their branches bending to the ground with the bounteous harvest. Birds of gorgeous colours of mingled red, blue, green, yellow, and black were feasting in countless numbers, and making the forest ring with happy choruses. The crop of these orchards which Nature has planted so generously in this wild and solitary waste would fill a fleet of one hundred steamers of the size of the *Misaki*, for the orchard stretches from five to ten miles wide by twenty miles long, and many of the larger trees bear at least fifty barrels (bushels?) apiece. The fruit furnishes the traveller an excellent repast, appeasing both thirst and hunger. So far as is now known, no commercial use can be made of the Ohia, as when ripe it cannot be kept more than four days.” Who can tell us something of this Apple? I have not been able to ascertain its botanical name, nor learned whether it be a true Apple. Have any of our Southern Californian horticulturists experimented with it? It is possible that for the extreme Southern States here is something worth a trial.—“Gardeners’ Monthly.”

**Manure Water in Vineries**.—Some time ago I recommended manure water to be put in the evaporating troughs in Vineries in order to prevent the increase of insects, and from experience I am convinced that nothing will keep down red spider and other insects in Vineries so well as filling the troughs or damping the paths occasionally with manure water made from pig manure. By this means we always manage to keep our Vine leaves perfectly green and healthy until the end of the season, and I am of opinion that where there are many air roots on the Vines they derive much nourishment from the richness of the atmosphere.—CHRISTIAN.

## THE KITCHEN GARDEN.

### IMPROVED SORRELS.

In large Continental towns Sorrel may be had all the year round, and there is not a garden large or small throughout France and the Continent generally in which a small border of it may not be seen, thus showing Sorrel to be in daily consumption as long as the weather allows it to be, and it is considered to be both most wholesome and useful in many ways; yet in England it is hardly even known as an esculent. Some twelve kinds are cultivated in Continental gardens, but I will only describe the leading sorts.

**Common Sorrel** (*Rumex Acetosus*).—Native of England and other northern countries; flowers dioecious; leaves of medium size, dark green; stalks rather long, very acid, not early, running readily to seed.

**Bellefeuille Sorrel**.—A great improvement on the preceding; leaves 10 in. long, and from 5 in. to 6 in. broad, pale green; leaf-stalks small reddish. This kind is earlier, less acid, and slower in running to seed than the common variety. It is the sort generally grown for the Paris markets and in every good garden.

**Lettuce-leaved Sorrel**.—This has lately gained a good reputation, which it deserves. It has broad, nearly round leaves, of great substance, and possesses all the good qualities of the Bellefeuille Sorrel. The improvements wanted in Sorrels are ample leaves with little stalk.

**Maiden Sorrel** (*Oseille vierge* of the French), known as *Rumex montana*, is also noteworthy. Its leaves are oblong, pale green, 8 in. long and 4 in. broad, very mild, but not early. In this variety the male and female flowers are borne on different plants, and the latter are carefully avoided in order to prevent fertilisation, as the seedlings soon fill up a garden, and become troublesome from the quantity of seed produced and scattered all over the ground; besides, it is readily propagated by roots.

**Patience Dock** (*Rumex Patientia*; also known as *Garden Patience*, *Herb Patience*, *Paris Cabbage*, *Immortal Spinach*), is a native of South Europe. It is perfectly hardy; its root is very long and yellow, leaves not very numerous, lanceolate, from 1 ft. 8 in. to 2 ft. long, and from 2 in. to 4 in. broad, dark green, somewhat wrinkled, and not acid. It is the earliest of all the Sorrels, and, if slightly protected, will afford, early in spring, a most useful vegetable for mixing with forced Sorrel or Spinach. Every stem running to flower should be carefully cut down, otherwise they will grow 6 ft. high, and produce an immense quantity of seed, from which seedlings will spring up sufficient to stock a whole garden.

Sorrel is easily cultivated; it will grow in any soil and in any situation, but good deep garden ground and a north aspect are to be preferred. It should be sown in the open ground in April and May,  $\frac{1}{2}$  in. deep, not too thickly, on a border preferred. Water, if necessary, and gather the leaves as soon as they are large enough to be fit for use. The following autumn or spring take up the best large-leaved seedlings, and plant them in a border 1 ft. apart; if well manured every year they will last from three to five years, though many re-plant them every season. Ashes make one of the best of stimulants for Sorrel, and they keep snails and slugs from eating the leaves. The Paris market gardeners sow it in beds in rows 1 ft. apart, and plant Lettuces amongst it, the latter being removed before the Sorrel requires the whole ground. Watering is not neglected when wanted. It is advisable the first season to cut the leaves 1 in. or 2 in. above the ground, but afterwards they are pulled from the roots. The general way of propagating Sorrel is to divide the crowns, selecting the best and strongest, and planting them like seedlings. This, in fact, is the only safe way of perpetuating a good variety. Sorrel is one of those plants which it is difficult to kill; roots of it may be even left on the ground or in a corner without protection for several months without injury, and if planted after that, they will grow as well as fresh roots. Growers who have to supply the markets with Sorrel begin forcing it in December. Having prepared a hotbed, they take up the old plants, pack the crowns close to each other, and put the lights on. In a short time the leaves appear, and gathering is continued until the beds are exhausted. This kind of forcing is continued until the out-door crop is ready. The *Patience Dock*, growing, as it does, to a larger size, requires to be

planted from 15 in. to 18 in. apart. All stems running to flower must be carefully cut back in order to avoid the seed spreading all over the garden; besides, cutting back gives a stronger growth to the plants, and greater size to the leaves.

Preserved Sorrel, when the crop is plentiful, may often be had during the autumn. The leaves are freely cut, boiled, put in bottles or any other receptacle, and covered with a layer of grease or butter to exclude the air. When well cooked and managed in this way it affords a good substitute for fresh leaves when the latter are not to be had. Sorrel is used for soups, for mixing with Spinach, and in many other forms. The celebrated French soups à l'oseille and Fricandeau à l'oseille are good examples of the way in which it is used. Sorrel leaves are very useful for cleaning copper plates, to which they give immediate brilliancy. Oxalic acid, so universally used for removing grease spots, is also made from it. It is a common practice in France during the summer time for workmen to suck slowly leaves of Sorrel, to prevent or moderate thirst.

D. GUIHENEUX.

### LARGE ASPARAGUS.

As regards varieties of Asparagus, we have grown *Comnover's Colossal* for several years, and it certainly produces heads of a size fit for use earlier than we used to get them years ago; but whether this is to be attributed to the variety or to improved culture, it would be difficult to determine without seeing all the separate sorts grown side by side under exactly similar circumstances. We have some beds that were planted last season with one-year-old plants, the growth of which is quite equal to what our three-year-old beds used to be. I find that the stems are already close upon 5 ft. high; and from some beds that are three years from seed we have this season cut the finest Asparagus which I ever saw. The season has thus far been remarkably favourable one for encouraging rapid growth, and I am convinced that nothing but that will ensure the tender, melting stalks for which Asparagus is so highly prized. If starved in a low temperature the shoots will be hard and stringy, whether green or blanched; but if grown without a check under favourable conditions, I have always found that the larger the stalks the more melting and delicious they were, even if entirely blanched. I may remark that amongst the *Comnover's Colossal* there is a large percentage of plants producing heads that are quite white, and which continue so until they have attained considerable height, a proof that if there be not sufficient distinction to enable separate sorts of Asparagus to be permanently classified, there are, at least, considerable variations in their growth and appearance. The offering of such liberal prizes as those announced in *THE GARDEN*, and the calling attention to the evils of thick planting, will give a stimulus to Asparagus culture in this country. We cannot all have good soils in which to grow it; but all of us can adopt the thin-planting method, which will be a point gained, as the greatest enemy of any plant is one of its own kind in too close proximity, both requiring the same kind of food. Therefore, space must be given to the Asparagus if it is to attain the maximum development of which it is capable. We shall probably find when these prizes are competed for that cultivators have not been idle, and that results surpassing all previous efforts will be obtained.

J. GROOM.

### SOWING LATE BROCCOLI.

No doubt something depends upon sowing at the right time; but far more, I think, depends upon growing the right kinds, and, as far as possible, securing the stocks true to name. For some years past I have grown pretty well every kind of Broccoli that had any reputation for lateness combined with quality. Some of the late kinds have a tendency to grow too large for ordinary table use. This, however, may to a great extent be met by cutting them when in a small state. The best three late kinds I have yet had are *Sutton's Perfection*, *Daniels' King*, and *Gattell's Eclipse*. The latter is, perhaps, a few days later than the others; but either of them may be made to meet the spring Cauliflowers. *Daniels' King* is, I think, the best late Broccoli I have yet seen for use through May and early June. It has a dwarf, sturdy habit, and is capable of standing a considerable degree of cold. The heart is pure white, which quality it retains a long time, in consequence of the way in which the leaves are folded over it. *Sutton's Perfection* is not so good a Broccoli, producing very close firm heads. For use in March and April, *Veitch's Spring White* and *Perkins' Leamington* are excellent; the latter is very hardy, producing close white heads completely protected and ensheathed with foliage, which last feature

is very distinct in this kind. I have sown Broccoli for late use at various times from March to June, but I think from the last week in April to the first week in May is the best time. I never could find any advantage in sowing later, and to sow earlier often leads to the plants being starved and stunted in the seed or nursery beds. Plant out finally in the most open and exposed position, to ensure firm, well-ripened stems, to stand the winter. E. HOBDAV.

#### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Schoolmaster Potato.**—As much has been said of late respecting the merits of various sorts of Potato, I wish to say a few words in favour of Schoolmaster. Last season I grew about forty bags of it, and from that quantity I have not had two bushels of diseased tubers. I consider it to be one of the very best Potatoes in cultivation, and, in proof of its keeping qualities, I send you a few tubers taken from clamps, in which they have been ever since the early part of October. They are, as will be seen, not only sound, but as good when cooked as they were at Christmas. To all who have not grown this Potato I would say, Try it; as I feel sure that it cannot fail to give satisfaction. It is very free from disease, a good cropper, and produces very few small tubers.—GEORGE GREEN, *Enville*.

**Winter Onions.**—It is one of the peculiar features of the market trade that it is difficult to fairly estimate from year to year what quantities of different vegetables may be in request by the consuming public. Winter Onions this year afford a capital illustration of the uncertainty attendant upon the profitable disposal of some crops. Last spring these sold well, so well that they proved to be one of the most serviceable crops of the year, and, as a result, large breadths of ground were sown in the autumn, and in all cases the seed growth was good and the crop thick and abundant. Now winter Onions are a drug; they do not pay to buy and market; they are getting too large; and, in fact, are spoiling. It is doubtful whether they can be converted into pickles, as the Spanish is generally esteemed the best for that purpose, and it is now in spring. Winter Onions need to be kept very clean during the growing season, and therefore necessitate a considerable outlay in labour. The small hand hoes are invariably used for this purpose; and although an active labourer can get over a large space of ground in a few days, yet, if the weather be moist, the work must be oft repeated, or else the weeds will get the mastery and spoil the crop. The small demand for winter Onions in the London markets may be, to some extent, owing to the prevalent mild season which has rendered all kinds of winter vegetables unprofitably abundant. Something is doubtless further due to the general depression of trade, and something may be owing to change of taste amongst the poor, who are the largest consumers of these savoury vegetables.—A. D.

**Culture of Couve Tronchuda Cabbage.**—I have grown this Cabbage in Lancashire and also in Cheshire. It likes a deep, rich soil, liberally manured (it can hardly be too much so), and if sown in autumn should be treated like Cauliflower, *i.e.*, be pricked out in a vacated Cucumber frame, preserved from frost, and gradually hardened for planting out (2½ in. by 18 in., or 2½ in. by 24 in.) during March and April. Its quick growth during spring and early summer, with plenty of rain or water (which it likes), makes it tender and delicious. When full grown try the stalks, cut where tender, and trim away all the green part of the leaves, leaving their stalks skeleton-like around the small loose heart which it makes. The sprouts during the hot, dry months are not worth much, so clear the ground if wanted for a more profitable crop. The spring-sown I have always found more prone to run to seed; true, that during the autumn rains they make better sprouts, but there are then Walcheren and other Broccoli of more value. Perhaps that it has not taken with the English public arises from the fact that seed merchants and garden books recommend spring sowing. Frequently those left in the seed bed survive the winter (after thinning), and if pricked out in March come in excellently to follow those reared in a frame. The mistake in England has been the putting it forward as Asparagus or Seakale. It is essentially an Algarve Cabbage, and is the most delicious of all Cabbages if cooked as such, *viz.*, boiled with a piece of ham. The best crop of it which I ever grew was on new land with the seed turned in between the two spades' depths.—E. PORTER, *Thimbleby, near Hornacastle*.

**Seeds and Seed Beds.**—All kinds of seeds have vegetated remarkably well this season, proving that a moderately dry surface is congenial to the proper development of young plants. When there is moisture below the seed, the root strikes downward in search of food, and consequently the growth upwards is satisfactory; but when the soil is saturated and chilled by continuous heavy rains, the roots do not penetrate the cold, saturated mass, and, as a necessary consequence, the growth above ground is checked in proportion.—J. G. H.

#### PLATE CXXXIX.

##### ROMNEYA COULTERI.

This has been rightly described as the queen of all the Popy-worts—"a swan white flower some 6 in. in diameter, and with a veritable mound of beautiful golden stamens in the centre." Though from a comparatively warm part of California, it will probably prove hardy or nearly so in at least the south of England and in Ireland. Dr. Moore, who has bloomed the plant beautifully at Glasnevin, and from whom the flowers from which our plate was prepared were obtained, thus speaks of it:—"This noble Papaveraceous plant seems to be quite hardy in the warmer parts of Ireland. Just three years ago this month a small plant of it was turned out of a pot in which it was growing, and planted in a border in front of one of the conservatories in the Botanic Garden here. It grew rapidly and flowered sparingly the first year. Not expecting it to survive the winter, it was left uncovered, with the exception of a thin bast mat spread over a couple of sticks, which stood higher than the plant during frost. The following season it grew vigorously until it reached a height of 4 ft. or more, and flowered profusely in August and September. Receiving similar winter treatment, it survived unscathed, and grew on, as usual, but making shorter and more hardy growths, and flowering more abundantly; but the season was so

Fruit of *Romneya Coulteri*.

wet that no seed was ripened. This year it has assumed a hard, shrubby appearance, covered from the ground to the apex with short woody branches, which are all likely to produce flowers. Unlike other Papaveraceous plants, this has the appearance of being a perennial shrub. At any rate, in now beginning its fourth year's growth, it gives no indication of want of vigour. In this damp climate I fear, however, that it will not perfect seeds. We have helped it by dusting its own pollen on the stigmas, which became swollen, but no perfect seed was produced. It is very difficult to propagate from cuttings, and the raising of plants from seeds is uncertain. Some will germinate in a few weeks after they are sown, while the majority will remain dormant in the mould a whole year, and only germinate during the second year. Hitherto it has refused to hybridise with any Papaveraceous plant of different genera with which it has been tried, which is what we might expect to be the case, there being so very few instances of hybrids between different genera. If such a thing could be got as a hybrid between the *Romneya* and *Papaver orientale*, what a magnificent plant it would be; but we have tried in vain to effect this." Mr. Thompson, of Ipswich, says:—"My experience of it leads to the conclusion that, except in favoured localities in the south, it is but half hardy in England. It may, however, be easily wintered in a frame, and it pots up from the borders very well. It evidently loves a moist soil, but will grow fairly well in ordinary

A CALIFORNIAN POPPYWORT. (ROMNEYA COULTERI.)

garden mould. It is not so free a bloomer as could be wished, at least in this latitude. I have never had more than a few flowers fully developed on each stem, but whether that is owing to deficient moisture, or heat, or both, is uncertain, but probably the latter. It must be propagated by seeds or cuttings. It does not divide, so far as my experience has gone." In California it is stated to grow by the sides of streams and to be very floriferous, comparatively small plants of it bearing from forty to fifty flowers at a time. They are more persistent, too, than those of many plants of the same Order.

## THE INDOOR GARDEN.

### DENDROBIUM BRYMERIANUM.

Of this singular Orchid, to which we have already alluded (see p. 407), we now give an illustration. From whence it was introduced is not definitely known, but the stock of it has been placed in the hands of Messrs. Veitch, in whose nursery at

Chelsea it is now flowering. Its chief peculiarity is the beard-like fringe which, as will be seen, surrounds the lip. The sepals and petals are of a waxy character and of a glossy lemon colour, the lip being of somewhat darker hue than the rest of the flower. The plant itself is a free grower, and is one which will doubtless soon find its way into all good collections of Orchids. S.

### "DECORATIVE" PELARGONIUMS.

THIS term is applied to a section of free-flowering Pelargoniums that are invaluable for market and general decorative purposes. They are generally of a close, short-jointed habit, which is invariably productive of successional trusses of flowers. They belong to a section that is becoming so popular among plant cultivators that the florists, who have bred mainly for colour and form in the flowers, are found asserting that the latter are gradually becoming less in demand—a result which might have been anticipated, for while many of the highly-bred varieties are somewhat difficult to grow, the decorative section is easily, if only intelligently, managed, and does remarkably well in a cold greenhouse. Of the few varieties I am this season cultivating, the earliest to bloom is the old Crimson King. Though I had to depend entirely on sun-heat, yet this variety came into bloom a long time since. In a warm greenhouse it might be had in bloom all the winter, if only a proper succession of plants be provided. Next in order of merit I put Triomphe de St. Mandé. What a superb variety it is! A robust grower, having a short-jointed habit, and bearing bold trusses of deep rose-red flowers. This should be grown by every one, and if I had to cultivate but one Pelargonium for the decoration of my greenhouse it would be Triomphe de St. Mandé. A few other fine and useful varieties will be found in Digby Grand, a charmingly fringed-petalled variety, colour white, with a dark blotch on the upper petals; Duchess of Bedford, white, with bright carmine spots, very free and pretty; Empress, white, pencilled with violet-rose on the margins, and handsomely fringed; Madame Charles Keteleer, white centre, maroon spot on the top petals, the lower petals edged with rose; a somewhat delicate grower, but exceedingly pretty; Mons. Bouchardat, deep crimson, very fine;

Rubens, bright salmon-red, very showy; and William Ball, bright carmine, dark blotch and spots, very free.

It is not difficult to get a supply of flowering plants from early spring till the autumn. As soon as the earliest plants are out of flower they should be dried off a little to harden the wood, and when this is done cuttings can be made. It is a good plan to put the strongest singly into very small pots, and the others into stores. Well-drained pots and a light sandy soil are indispensable, and when the cuttings are put in, an ordinary frame will suffice to keep them in. I place my cuttings in the coolest part of the greenhouse, and throw a newspaper over them when the sun is hot and drying. The soil should be so moist when used as that it will be cool and pleasant and yet not stick to the fingers, and when of this character water will not be required for a few days. As soon as the cuttings are rooted they require to be potted off singly into small pots, and when they begin to grow the leading shoot should be pinched out to secure a good bottom. They will require one or two shifts till they get into  $\frac{1}{2}$ -in. pots, in which they will flower. The plants do best when they are grown on in a cool frame during the summer, but many with but a greenhouse, and nothing more, have to grow them on in that all the summer, but by giving the plants careful attention they are kept clean, healthy, and do not lose their leaves. They must not be allowed to want for water. A succession of plants is a most desirable arrangement, and so cuttings put in in August and Sept. make good plants to bloom in the summer and autumn following. Then, by keeping some plants pinched back, the blooming time can be extended. I find it a good plan to keep some of the plants over for the second year. These are re-potted in August, and again early in October, finally getting them into 8 $\frac{1}{2}$ -in. pots, and in these they produce rare heads of bloom in April and May. One of these plants is before me as I write (grown, be it remembered, in a house in which there is no artificial heat). It has three main shoots, from which other shoots branch, and they are literally covered with large bold trusses of richly-coloured flowers. D.

### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Colourless Maréchal Niel Roses.**—I have no reason to complain of lack of colour in this grand yellow *Rosea* grown here under glass in a cool house. My plants are on their own roots, and are growing in a soil bed in the centre of a span-roofed house. One plant is trained to the wall at the end of the house, and the other and largest plant is carried up a support and thence along wirework near the roof. Perhaps the colour is richest where the soil is neither too rich nor too moist, as is the case with mine; or it may be that soils have much to do with the production of colour. In any great Rose show where Maréchal Niel is largely exhibited it will be seen that flowers from different parts, although equal in size, differ considerably in colour.—A. DEAN.

**Chorozeza Hinchmanni.**—This is one of the prettiest and most useful of the Chorozezas. In habit it is dwarf and compact; it grows freely, and, under good culture, never fails to produce a profusion of bright scarlet flowers which somewhat resemble in appearance those of the well-known *Euphorbia splendens*. I lately saw a quantity of small plants of it, in Messrs. Cutbush & Son's nursery at Highgate, loaded with blossoms.—S.

**White Vase Flowers.**—To any one wanting good white flowers for vases, &c., I would recommend the common white Dead Nettle of the hedges (*Lamium album*) with the leaves or bracts cut out. The flowers are of a good white, stand up well, and last long in water.—H. N. ELLAOMARE.

**Selaginella Martenii crispata.**—When seen overlapping the edges of pans or pots, the feather-like leaves of this *Selaginella* have a graceful and pleasing appearance. When well grown the plants assume a drooping habit, and when placed in a moist warm corner of a Fern house, they are by no means unattractive.—S.

**Clerodendron Balfourii on Walls.**—On the back wall of a Pine-stove we have a large plant of this, which, being planted out, cannot be rested by removal to cooler quarters, or the roots subjected to the orthodox supply of moisture; nevertheless, it is every year covered, and, in fact, quite hidden, by such masses of beautiful flowers as make the best of plants of it in pots look poor in comparison. Its foliage is most abundant and fine, proving that the so-called season of rest is not conducive in this case to health and vigour, and, in many instances the resting and drying processes end in bringing out a rest from which there is no awakening.—J. GROOM, *Henham*.

**Luculia gratiissima on Walls.**—Perhaps the most successful way of growing this plant that we have seen is that illustrated at Orchardley Park, Somerset, where it is grown against a wall in a conservatory. It covers a large portion of a wall 16 ft. high, and bore last winter 300 trusses at one time. In spring it is pruned in and dressed like a Vine. In the same garden there is an immense specimen of the Maréchal Niel Rose on the gardener's house. This is freely trained, so that its thousand buds and 200 or so of fully-expanded blooms grow freely forth and droop gracefully from the wall. The naked descending stem is protected from the sun in summer, and a deep coping on the house no doubt helps the plant.—V.

## GARDEN BOTANY.

(Continued from p. 467.)

VARIATION IN THE LEAVES OF THE SAME BRANCH.—Some aquatic plants have heteromorphic leaves, the submerged ones being finely dissected, and the floating ones with a continuous blade. Many of the varieties of the Water Buttercup (*Ranunculus aquatilis*) have two kinds of leaves, and the North American *Cabomba aquatica* (fig. 158) likewise. Heteromor-

Fig. 158.—Branch of *Cabomba aquatica*, with heteromorphic leaves; the finely-dissected leaves are naturally submerged in water, and the entire petiolate ones are flat on its surface, or are raised above it.

phic leaves are found on the same branches of some trees and shrubs. *Laurus Sassafras* (fig. 159), a North American tree, has lobed and entire leaves intermixed.

VARIATION IN THE LEAVES OF FLOWERING AND BARREN BRANCHES.—We have a familiar example of this in the Ivy, the barren branches bearing angularly lobed leaves, and the flowering ones roundish, almost entire leaves. *Ficus stipulata* is also remarkable in this way; the barren form is a climber,

Fig. 159.—Branch of *Laurus sassafras*, with heteromorphic leaves.

having leaves closely appressed to trees or rocks, whilst the fertile or flowering form is of erect habit with spreading leaves of a different shape. Several tropical families, as the Marcgraviaceae and Aroideae, have this character developed to an extraordinary extent.

APPENDAGES AND CURIOUS MODIFICATIONS OF LEAVES.—It is amongst the so-called carnivorous or insectiferous plants that we find some of the most singular productions in the vegetable kingdom. These are in the form of appendages to the leaves, or transformations of the leaves themselves. In the genus *Nepenthes* (fig. 160) the midribs of some of the leaves are con-

tinued beyond the blades, and bear erect, ewer-like vessels with lids. *Cephalotus follicularis* (fig. 161), an Australian plant, has some of the leaves converted into pitchers, and the point of attachment of the latter is near the top, not at the bottom, as in *Nepenthes*. The North American *Sarraceniaceae* have some or all of the leaves tubular and terminating in a hood or cap, as in *Darlingtonia californica* (fig. 162). In *Chives* (fig. 163) the leaves are tubular, but closed at the top. *Venus's Fly-trap*

Fig. 160.—Plant of *Nepenthes distillatoria* (Pitcher plant), with pitchers at the tips of the leaves. Much reduced.

(*Dionaea muscipula*) has some of the leaves furnished with a curious mechanism, and there are many other plants similarly provided, but we cannot spare the space to enter into details respecting their structure. Before leaving the subject, however, we may mention that our indigenous plants include the counterparts of these exotic Pitcher plants, in the Bladderworts, *Utricularia vulgaris*, &c. It is also worthy of note that the plants furnished with pitcher-like appendages or leaves belong to widely different families, and are represented by

diverse forms in the most distant parts of the world. The leaves of the Sundews (fig. 164) are provided with superficial, motile, glandular hairs, which exude an adhesive fluid, and are thus able to entrap insects as well as the Pitcher plants.

REMARKABLE MODIFICATIONS OF THE PETIOLE.—In a very large majority of cases the petiole, when present, offers few characters for comparison; but there are some very singular modifications of it. Many of the Umbelliferae have a broad sheathing petiole, as in *Heracleum* (fig. 165). The blade of the leaf is seldom or never developed, as in most of the Australian Acacias, and the petiole is more or less flattened and elongated. Without any clue to their real nature, these flattened petioles would be regarded as sessile leaves, but young seedlings and vigorous shoots of adult plants of some species occasionally

Fig. 161.—*Cephalotus follicularis* (Australian Pitcher plant), in which some of the leaves are transformed into pitchers. Natural size.

bear the true pinnate blade at the tip of the petiole. *Acacia Melanoxylon*, an Australian species, frequently develops the blade, as does also *A. heterophylla* (fig. 166), a native of Mauritius. Petioles destitute of a blade are termed phyllodes, and they perform the function of perfect leaves. Among British plants having phyllodes we may name *Lathyrus Nissolia* (Grass Vetch), in which they are long, narrow, and flexible. Some botanists regard the Spearwort (*Ranunculus Lingua*) as phyllodineous. *Lathyrus platyphyllus* (fig. 167) has a remarkably dilated petiole, two small flat leaflets, the other three being reduced to thread-like tendrils.

STIPULES.—Leaves are stipulate or exstipulate. At the base of the leaves of many plants there are two small scale-like organs or outgrowths, one on each side, though they frequently fall off long before the leaves. These organs are the stipules,

and they are present in the Oak, Beech, Elm, &c.; but they are inconspicuous, and usually fall soon after the leaves are

Fig. 162.—*Darlingtonia californica*; leaves tubular and hooded. Reduced.

Fig. 163.—*Allium Schoenoprasum*, with cylindrical hollow (hastular) leaves. Reduced.

unfolded. Nevertheless, the presence or absence of stipules is a character of importance not to be omitted from a general

Fig. 164.—Leaf of Sundew, enlarged to show the stalked motile glands.

description of a plant. Moreover, either the position, form, or

Fig. 165.—*Heracleum pubescens*, with broad sheathing petiole.

size, &c., is characteristic of certain orders or genera. In the genera *Rosa* and *Trifolium* (Clover—fig. 168) the stipules ad-

here to the petiole, and are what is termed adnate; stipules

Fig. 166.—Branch of *Acacia heterophylla*, bearing bipinnate leaves and phyllodes (flattened petioles)

Fig. 167.—*Lathyrus platyphyllus*, with a broadly-winged petiole, and the terminal leaflets reduced to tendrils.

Fig. 168.—*Trifolium pratense*, with adnate stipules. which sheathe the stem are characteristic of the Knot-weeds

(*Polygonum*—fig. 169). The Hop (*Humulus lupulus*—fig. 170) has opposite leaves with stipules between the petioles (interpetiolar), a character it possesses in common with the whole of

Fig. 169.—*Polygonum orientale*, with sheathing stipules.

the large family to which the genus *Ixora* belongs. The Magnolias are remarkable in having large convolute stipules, which

Fig. 170.—Interpetiolar stipules of Hop.

fall off as the leaves unfold; and the Tulip tree (*Liriodendron tulipiferum* (fig. 171), a member of the same family, has them

Fig. 171.—Large stipules of Tulip tree.

very large and conspicuous on the young shoots. Usually the stipules are entire, but in *Polygonum* (fig. 169) they are fringed.

Fig. 172.—*Houttuynia cordata*, with axillary stipules.

The stipules of the Pansy are nearly as large as the leaves, and pinnatifid or pinnatifid. Commonly the insertion (attachment) of the stipules is extra-axillary, but in *Houttuynia*

cordata (fig. 172) they are axillary, that is, they proceed from the axils of the leaves. *Ornithopus scorpioides* (fig. 173) has large, stem-clasping stipules; and *Lathyrus Aphaca*, a plant

Fig. 173.—Stem-clasping stipules of *Ornithopus scorpioides*.

occasionally met with in Corn-fields (fig. 174), is remarkable, inasmuch as the leaves are reduced to tendrils and replaced by

Fig. 174.—Branch of *Lathyrus Aphaca*, in which the leaves are reduced to tendrils, and the stipules foliaceous and largely developed.

Fig. 175.—*Milium multiflorum*, showing part of leaf and the ligule at the base.

foliaceous stipules. The ligule of Grasses (fig. 175) is an out-growth of the leaf of a somewhat similar nature to stipules.

W. B. HEMSLEY.

## GARDENING FOR THE WEEK.

### Flower Garden.

**Auriculas.**—The season for these has been long this year; my earliest pipe were open about the third week in March, and there has been a succession until the middle of May. By a little management the season might be prolonged, and many of the trusses could be open by the first week in March; nor would it require anything like a forcing temperature to do this. The trusses of many plants are formed early in November. This is what florists sometimes call "truss bare." If these plants are removed into a warm greenhouse and placed on a shelf near the glass, they will be in flower early in March (I am writing now of what can be done in the neighbourhood of London), and at that time the flowers remain in beauty for a long time; others will come on rapidly from the frames out-of-doors, and by altering the positions of the frames, some of them to face the south and others the north, a considerable difference may be made in that way. The latest sorts should be reserved for the latest positions. All the plants are now in frames behind a north wall, and the lights are removed on all occasions, even at night, when rain is not apprehended. It is now the best time to re-pot, but there is considerable difficulty to find time to do it, as we are in the middle of the bedding out, and Grapes require thinning, &c. When the press of work is over we will then set about re-potting Auriculas; those who can find time to re-pot their plants should see to it at once. The pots ought not to exceed 5 in. in diameter, 3-in. and 4-in. pots being sufficient for many of the plants. Put plenty of drainage in the bottom, and over that some very fibrous turf, from which the particles of mould have been removed. The compost which I use is composed of turfy loam four parts, one part of leaf-mould and one part of sand, with a little pounded charcoal added; press the mould firmly round the roots, from which the greater portion of the old soil has been removed, and the tap root should be shortened. When the plants are re-potted, they should again be placed back in the frame, and the lights be kept rather close over them until they have made fresh roots.

**Carnations and Picoetes** are making very rapid growth, and the more attention they receive at this time the greater satisfaction will they give to their owner at blooming time. The soil used for potting has been unusually full of the roots and seeds of weeds; these have given us much trouble, as it is necessary to remove them in a small state. Decayed leaves from the base of the plants have also been removed, as they are a harbour for garden pests if allowed to remain. The stems elongate rapidly, and they are tied to sticks for security against high winds. It is now time to disbud the plants; when the stem has grown about 12 in. high, or before this, either the centre bud should be removed or the side buds. If the side buds are removed one flower only will be produced; if the side buds are saved each plant will develop three or four flowers, and these will be about a week later than if the centre flower only is allowed to remain. Green fly is a troublesome pest to Carnation growers. I destroy it by dusting Tobacco powder on the affected parts through a Pepper-box. Soft soapy water is also a deadly poison to it.

**Gladioli.**—The last of these have now been planted out. The orms do not appear to have been so well ripened last year as usual, the result of a wet season and rather lower average temperature than usual. I found the roots much shrunk and very light. The weather, so far, has been greatly in favour of those planted out early; gential showers and warm weather are causing a vigorous development. Run the canes through the spaces between the rows as soon as all the plants are through the ground. It is very likely that there will be blanks in the rows, and, even if these are not numerous, they spoil the effect of the beds. A good plan is to pot a number of roots at the same time as the beds are planted; these can be used to fill up the blanks. Instructions were given in a recent number as to sowing seeds; the plants will now be above ground, and they must be well supplied with water, admitting plenty of air, and, if the weather be fine, removing the lights altogether.

**Hollyhocks.**—It has now become extremely difficult to keep up a collection of these, the plants being in many cases quite decimated by the disease. In many places, where the Hollyhock formed one of the chief features, its culture has, perhaps, been discontinued. The result of the fungoid growth has been to destroy the fleshy substance of the leaves, and the desiccated venation rustles in the wind, a hideous spectacle. The most radical cure, if, indeed, there be any other cure at all, is to dig up every plant and burn it root and branch. Those who have a healthy stock of plants should be thankful, and should take great care that the nidus of the disease does not reach their plants. The spring propagated plants may now be planted out; they will flower in September and form excellent back rows to Dahlias, and will flower at the same time. The Hollyhock delights in a very rich deep soil, and I like to put mixture of fine loam and rotten manure round the roots of the plants. Tie the main stems to the sticks at once, and remove all side shoots with the fingers, in order to have a handsome single spike with large flowers. In planting, attention must be given to a judicious arrangement of colours. If the weather sets in dry the plants must be watered and mulched, to retain moisture.

**Tulips.**—These are already in full flower, and the weather has been so favourable for their perfect development that we have not found so much benefit from the glass lights as we did last year; in lieu thereof, some canvas screens, used to shelter the bedding plants from frost, came in useful to ward off the effects of the sun; and when the weather suddenly changed, with a prospect of rain, the canvas was speedily removed, and the glass lights that were close at hand were placed over the skeleton frames instead.

We have tied up the flowering growths of Delphiniums, Phloxes, Pyrethrums, and all such hardy tall-growing subjects to suitable sticks; the ground between the rows has been hoed over to destroy weeds. There has been plenty of rain, and it has not been necessary, as yet, to water at the roots, but if dry weather set in we will do so, and mulch to retain the moisture.

**Pinks** in beds have made excellent growth so far, and give every promise of a fine bloom; the flower-stems will be tied to sticks, removing at the same time the side buds.

**Pansies** in beds are in full flower, but, to keep up a succession of fine blooms, it is necessary to pick all the flowers off a certain portion. Surface-dress the beds and peg the shoots close to the ground. In ten days the bed (if it had previously shown signs of exhaustion) will be a mass of vigorous growth and full-sized blooms.—J. DOUGLAS.

It may be taken for granted that *Calceolarias*, *Zonal Pelargoniums*, *Verbenas*, and similar plants have been already planted out; the putting out of more tender varieties may therefore now be proceeded with, such as *Lantanas* and *Heliotropes*, together with the various kinds of fine-foliaged or sub-tropical plants, and the placing out of doers of such plants when of considerable dimensions must be at once followed by careful staking and tying, and dwarf or trailing species should be rendered secure by being pegged down. Copious waterings must also be given, should the dry weather set in, and it is important that this should be done as late in the evening as is practicable, or when evaporation is supposed to be at its minimum. If it be administered in the morning or during the day, a large portion of the moisture supplied must necessarily be lost, as far as the benefit of the plants is concerned. A few plants of each variety of which the various dimensions must be retained in pots, for a time at least, as accidents sometimes occur, and a reserve force of this kind is often found to be useful. Some of the various kinds of variegated *Pelargoniums*, and other plants which are not of rapid growth, should about this time be planted in the reserve garden, with the view of affording an early supply

of cuttings, thus obviating the necessity of taking them from the flower beds before they can well be spared for that purpose. Let the confusion, which is, to some extent, inseparable from the process of planting out, be set straight as soon as possible. Dahlias should now be planted. Those who get a portion of ground apart for them should on this grow the best-prepared plants, which will be those that have been struck from cuttings, these being less liable to get crowded with shoots, and, consequently, produce finer flowers than plants obtained by dividing the old roots. Where fine flowers are required, the plants should stand 6 ft. apart every way. The ground can scarcely be made too rich. They should be well watered at the time of planting out, and at once secured by good stakes; but the stems should not be tied too tightly, so that their subsequent expansion may be allowed for. Round the stems, for 1 ft., cover the surface 1 in. thick with sharp sand, so as to make it less agreeable for the slugs to travel over. A little Wheat-chaff or hard straw chopped up 3 in. long, does much to impede their movements, for they object to travel over anything that sticks to them, and this is the case with these substances even when wet. The best of all for the above purpose, where they can be obtained, are the short clippings of bristles from brush-makers. Wet or dry, these are equally effective, and are too sharp for slugs to attempt to cross. Lime and soot dusted round the plants will stop the movements of slugs whilst dry; but, with moisture, it soon gets crusted, after which they will pass over it, and repeated applications do harm to the plants. The same material can with advantage be used round any other plants collected by slugs. Iris, *Leucis*, *Colocasia*, and similar tender plants, may now be planted out. Those who may be making a first attempt at carpet bedding should bear in mind that the effect produced by this style of flower gardening is, in a great measure, dependent upon the different subjects employed being planted very close, so as at once to all but cover the surface, an even dense clothing to the ground being essential to give character to the arrangement. It will thus be obvious that a greater space should not be devoted to this kind of bedding than can be furnished with. Many of the hardy herbaceous plants which usually occupy the margins of clumps and belts of shrubs and ornamental trees, will now be in bloom, and may require to have their shoots and flowering-stems regulated and tied up. These matters should not be neglected during the busy season of planting out, as such flowering plants tend very considerably to supply any want of bloom which may exist during the interim between the two periods of spring and summer bedding.

#### Hardy Fruit.

**Gooseberries.**—If means were taken in the winter of putting lime on the soil round the stems of the Gooseberry bushes, as a preventive against caterpillars, little injury from these may be looked for; but in the case of any bushes that were not effected last year without this precaution being taken, their re-appearance may now be expected. When any can be found they should be destroyed at once, or they will spread and quickly denude the trees of their leaves, spoiling the present crop, and doing serious mischief by weakening the bushes for another season. A dusting of dry powdered lime sprinkled over the affected trees will, if fresh and caustic, destroy many, and cause the rest to fall off on the ground, where they must be killed, or they will again crawl upon the trees. This should be done when there is no appearance of caterpillars; for, if wet, the lime will be washed off before it has had any effect. The most certain method for destroying these caterpillars is by using a mixture of white Hellebore (finely ground) and whitening, in proportions of 1 lb. of the former to 4 lb. or 5 lb. of the latter, mixing the whole well up and applying it with an ordinary tin flour dredger, first wetting the leaves thoroughly with the syringe; the powder thus sticks to the foliage, and the caterpillars, feeding, as they do, on the edges of the leaves, swallow the compound, and it quickly kills them. In five or six days not a grub will be found alive, when the trees can be well syringed, in order to remove the powder from the fruit and leaves. The only objection to the use of this mixture is that, the Hellebore being poisonous, care must be taken that it is all washed off before the fruit is used.

#### Indoor Plant Department.

**Temperature for Orchids.**—Now, when the days are approaching their maximum of length, in the houses in which the different temperatures required for Orchids are kept up the heat should be raised to its highest point for the season. I do not mean to say that it is advisable to raise the temperature by fire-heat either day or night nearly to the point it will reach when the weather becomes so hot, as we generally get it through June, July, and August, as the application of artificial heat to anything like such an extent would be highly injurious; in fact, in the cultivation of these plants we do not generally take into account sufficiently the fluctuations in the temperature of the air outside and the necessity for regulating the fire-heat with them; not that it would answer to let the temperature of Orchid houses fall to any gloomy, cold days that we frequently get even in the middle of summer, and still cooler nights which we experience through the same season proportionately to the same extent as the depression that takes place outside in such weather, but that, when this is the case, the internal heat should run considerably lower than it would be even possible to keep it when the external temperature is very high. The attempt which is often made, especially by young growers of these plants, to keep up a uniform day and night temperature through the growing season is productive of the worst results by the weakened, elongated growth that takes place under such conditions.

**Hottest Section of Orchids.**—In the warmest house, wherein are grown *Saccolabnum*, and such of the *Vandas*, *Aerides*, *Phalenopsis*, and

others that need the most heat, in bright sunny weather the day temperature will reach 80° or often 90° with little or no fire-heat, and in the night it will frequently be 70°; but this figure is quite high enough for the night. In dull weather 75°, with a close atmosphere in the daytime, is sufficient, and when the thermometer has to be kept up to this by fire-heat, its growing influence upon the plants will be quite as great as if higher through the sun's power. At the same time, if the weather is cold and cloudy, though fire-heat should be used during the day to admit of some air being given without reducing the temperature lower than the point above indicated.

**Intermediate Orchids.**—For such Orchids as need an intermediate temperature 60° in the night, when fire-heat has to be used to keep the thermometer up to this, is sufficient, although during the next ten or twelve weeks it will often run higher without any fire at all. From 65° to 70° in the day—when, through the weather being cool, firing has to be resorted to to keep it to this—will generally be found sufficient; but here again there should be enough heat in the pipes to allow of air being given in the middle of the day. On hot days 10° higher than the above will do no harm.

**Cool Orchid House.**—From 45° to a few degrees over 50° in the night is enough, but it should even when the weather is cold not be let now for some time to go lower than this, as allowing any plants in this house to receive too great a deal of root moisture, under which condition a low temperature will often produce an unhealthy state. When the weather is comes hot the natural result is that the temperature cannot be kept so low as this; 55° is low enough in the day, and when necessary heat should be turned on to keep it to this, or up to 60°. When the weather is hot it will often range 15° or even 20°, more especially in span-roofed houses fully under the influence of the sun, or in lean-to structures facing the south; under such conditions more light, through thinner shading, will counteract any evils resulting from too much warmth.

**Orchid Insects.**—Where these exist they will now increase apace. Where scale infests any, particularly such as are in a high temperature, the infested plants should be repeatedly gone over, isolating them from the stock free from this pest so far as not allowing any plants that have scale on them to touch others that are clean. A little attention in this matter will save a great deal of labour and facilitate the attempt which should be made to rid the plants of these destructive insects, that are both so injurious and difficult to destroy, as the plants will not well bear the application of any dressing that will kill the insects. Spoging with cold water and a brush carefully applied is the best remedy, being particular not to injure the leaves of such plants as *Vandas* and *Aerides*, where the white scale so persistently gets down between the base and the stem, almost out of reach of the hand. For yellow thrip, persistent spoging and syringing overhead from the plants sufficiently hardy and sturdy to admit of water being applied in this way without injury to the foliage, as I have before urged, is the best remedy. If green fly gets amongst Orchids to any extent it often becomes very troublesome, getting on to the tender advancing flower-spikes, and if allowed to remain for even a few days will frequently destroy their vitality. In an Orchid house where any considerable number of plants are grown there is always a number that do not well bear fumigating, consequently it is better, if possible, to avoid it. Where aphides make their appearance on either young leaves or flowering stems, I have found the best remedy is to dip the affected parts in weak Tobacco water, that is, such as is only just sufficiently strong to kill the insects, and which can only be determined by trying it, as the different kinds of Tobacco, or the material used instead, are so variable in strength as to render it impossible to give any exact directions for the preparation of the liquid. I always used to keep a pailful in hand for the purpose ready made, and by at once dipping any that were affected, or spoging them with the liquid, I found little difficulty in destroying the insects, are sure to be present where the full-grown insects exist. In using Tobacco water for this purpose there is one thing imperative, to see that there is no oily matter floating on the liquid, for if such exist, in dipping or spoging the plants it will adhere to the flower-spikes and young leaves, and do considerable mischief; the oily scum I speak of is generally produced when the liquid is made by either boiling or pouring boiling water upon the Tobacco or Tobacco cloth (the former is preferable) and the insects or their eggs, as the latter, although too small to be discernible, are sure to be present where the full-grown insects exist. In using Tobacco water for this purpose there is one thing imperative, to see that there is no oily matter floating on the liquid, for if such exist, in dipping or spoging the plants it will adhere to the flower-spikes and young leaves, and do considerable mischief; the oily scum I speak of is generally produced when the liquid is made by either boiling or pouring boiling water upon the Tobacco or Tobacco cloth (the former is preferable) and the insects or their eggs, as the latter, although too small to be discernible, are sure to be present where the full-grown insects exist. **Moisture.**—Increased humidity will likewise now be required of the atmosphere. Where troughs for holding water exist on the pipes, this is easily supplied when the water within the pipes is warm, but the worst fault connected with this kind of arrangement is that the most moisture is generated in the coolest weather through more fire-heat being used, and at which time a less humid condition of the atmosphere is necessary; this no doubt admits of regulation through filling more or less of the troughs, but, unless efficient attention be paid to it, under any system of distributing moisture in the atmosphere it is faulty. Whether the necessary humidity is supplied in this way, or by throwing water about the paths, on and under the stages, enough must be kept up to prevent the air of the houses

getting too dry, especially during the hours that external air is admitted; at the same time any excess of atmospheric moisture must be avoided; better even to err slightly in the opposite direction, as if under conditions a little too dry growth will be slower, but this is preferable to the exhausting tendency which an over-humid atmosphere has. The description of houses in which the plants are grown should always be taken into account in calculating the amount of water which Orchids respectively, according to the species and varieties, will bear both at the root and in the air of the house; as the lighter the structure and nearer to the roof the plants are kept the greater quantity of both will they do with.

**Conservatories.**—Seed-vessels of *Rhododendrons*, *Azaleas*, and other plants should be pinched off, so as to throw increased vigour into the young growth. *Clematis* and *Passifloras*, *Ambergrapes*, *Mandarin* oranges, and similar plants now making growth freely, must not be allowed to receive any check from cold draughts or from scanty supplies of water; and the young wood should be judiciously thinned at an early stage, rather than severely pruned when further advanced. Tie in the young shoots gracefully and loosely, yet neatly, and never permit them to twine round each other. All free-growing plants must receive liberal waterings, no matter whether they are in pots or in borders; but at the same time let saturation in all cases be avoided. Remove such plants as have done little or nothing, and those with drooping or withering branches to the green houses.

Plants that are stationary, such as climbers and subjects planted out, unless they are in flower, are greatly benefited by daily syringings, and if green fly, red spider, or other insects present themselves, a little Tobacco water, or water in which flowers of sulphur have been mixed, may be efficaciously employed. Washing with a sponge or soft rag and water, in which some soft soap has been dissolved, is the most effectual remedy for scale.

**Greenhouse Plants.**—Pot singly some of the best *Lobelias* into 4-in. pots for the decoration of the conservatory. *Celosias*, *Comprepnas*, *globose*, and the *marantaceæ salicifolius* should be shifted into larger pots than those they now occupy, as they increase in size; keep them in a moderately warm temperature and near the glass. *Tulips*, *Hyacinths*, *Crocuses*, *Lily of the Valley*, *Astilbe japonica*, and other plants that were forced into flower early in the season should now be consigned to some shady border. Apply a mulching of loam and decayed manure in equal proportions to *Lilies* in pots, and, with the exception of such as are required for early flowering, keep them either out-of-doors or in cool frames. Keep early spring-struck cuttings near the glass in warm houses, shifting them when necessary. Keep *Coleuses* near the light in an intermediate temperature, and re-pot and pinch in their shoots as may seem necessary. Seedlings and offsets of *Cyperus alternifolius* make fine table ornaments; good loam and leaf-mould, moderate heat, and plenty of water suit them well, and 4-in. pots are quite large enough for them. Place old plants of *Campanula pyramidalis* out-of-doors, and keep seedlings of the same in a fair growing condition under glass. Keep up a succession of *Mignonette* in pots; a situation at the base of a wall shielded from the wind, and a culture in the open air, will be established in pots perfectly; but in the case of seed pots, and for some time after the young plants have made their appearance, they should be kept under glass. Retain some specimens of *Humea elegans* for conservatory decoration. *Hydrangeas* for early blooming require a little extra heat, and such shoots as have no flower-truss on them should be cut off and used for cuttings. Shift *Statice* as they require it. Introduce some plants of *Valloia purpurea* into heat in order to induce early flowering. Plants of *Sarcocolla* *Gibbesii* and *Lantheum minimum* should be cut back and placed in a warm moist temperature. *Solanums*, *Ferriandras*, *Abutilons*, and other sub-tropical plants, from which the spring stock of cuttings has been procured, may now be placed in sheltered positions out-of-doors.

#### Indoor Fruit Department.

**Vines.**—Inarching one variety of Vine on another may be successfully done now. Green wood unites to green wood much more easily and quickly than that which is hard and brown. Young canes raised from eyes this spring should be used, and the growth should be from 3 ft. to 6 ft. or more in length, whilst the stock should consist of one of the side shoots which has been pinched at five or six joints from the main stem. A leading shoot, which has been allowed to grow from near the bottom, should be equally cut off, and the advantage of having a fruiting Vine established as near the base as possible, 12 in. being a very good distance. As the stock is generally much further from the ground than this, the pot containing the plant should be raised on a temporary wood stand to the required height. The process of inarching is very simple, and may be rapidly accomplished. A thin slice, about 2 in. in length, has to be taken off the two parts to be united with a sharp knife; when this has been done the two cuts must be laid closely and neatly against each other, and the wound must be so fastened together that the two parts may keep them firm. In about a fortnight the union will be so far accomplished as to warrant the ligatures being loosened, and in another fortnight the matting may be removed altogether. If the union be not perfect by this time, the *Raffia* Grass should be left on until it is. The Vine in the pot must throughout be kept well watered, and, when the union is complete, the small cane in the pot should be cut away close to the bottom of the part connected. The part above this, if not very long, may be left on until the Vines are pruned and dressed in autumn or winter. The kind of stock is a matter of importance, as all are not equally suitable—certain varieties improve on other roots, while with others the reverse is the case. The Black Hamburgh is a suitable stock for many kinds, Muscat of Alexandria is another which seldom fails; indeed, those which produce good fruit generally make

good stocks. Muscat Hamburgh does well on the Black Hamburgh, whilst Royal Muscadine is a poor stock for most Vines; Black Prince and Burchard's Prince are no better; *Barbarosa* (*Gros Guillaume*) produces more bunches on the Black Alicante than on its own roots. Inarching is not always necessary to increase the fertility of this Grape; in many places it does well on its own roots. Inarching is not always done with a view to improvement; it is often performed to hasten the fruiting of new varieties, and there can be no question about the utility of the operation for this purpose.

**Pines.**—The greater part of the Queens started into fruit in February will be ripe or ripening now; little or no water should be given at the root after the fruit begins to get yellow. As soon as the fruit is cut the ball must have a thorough watering to prevent the suckers from suffering. If space for successional plants be scarce, the Queen stocks may be packed closely together, after the fruit is cut, in some spare corner to mature the suckers; successional plants which may be becoming crowded may then be thinned out to a distance which will admit of their free development.

#### Kitchen Garden.

**Cabbages**, **Cauliflower**, and **Broccoli** are, in some gardens, to suffer seriously from the ravages of the root grub. In old gardens the plants are generally the most affected, and to such an extent in some places does this occur that the summer crops of these vegetables are almost destroyed. Besides the whole or partial loss of the crop, this is very annoying to those who take a pride in seeing in their kitchen gardens that unbroken uniformity in the different vegetable growth that gives evidence of good management; yet, in soil which most infested with these pests a little extra labour at the time of planting will secure these vegetables, in a great measure, from destruction. At this season it is well to provide a bushel or two of dry powdered lime, to which an equal quantity of soot should be added; stir the two well together, and keep the mixture anywhere where it will be dry; this quantity will suffice for a good-sized garden. When the different crops for summer and winter use are being put out use the planting-trowel instead of the dibber, make the holes large enough, and, as the plants are dropped into them, half fill them with such earth, then, if the weather and state of the soil are such as to require it, give them a good soaking with water, after which put to each plant, all round the stem, a half-handful of the lime and soot, then draw in the remainder of the soil. This simple process will take a little more time than planting without the use of the mixture; but those who use it will be spared the annoyance through the hot months of July and August of seeing their plants turn that peculiar blue tint in the leaves and flag in the sun which is a sure sign that the roots are gone, and that all affected in this way may be consigned to the refuse heap. Where water is given at the time of planting it is necessary to apply it as shown directed before the lime and soot, as, if the latter be put to the plants first it will be washed away from the stems and only have a partial chance of being effectual. The rains we have had lately will now make everything grow apace, and this will be found a busy time; yet the attention devoted to the flower garden should by no means be allowed to interfere with the equally important kitchen garden.

**Planting Celery.**—Early-sown Celery should now be put out; if the trenches have been prepared beforehand, as advised some time back, run the hoe over the surface to destroy any weeds that may be vegetating. Give the plants a good soaking with water before moving them, and if they have been treated as directed, by being put out in a nursery bed 3 in. or 4 in. apart, they will now be in fine condition; remove them with as many roots as possible, and as much soil as will adhere to them. In moving Celery plants, there should never be occasion for the now almost obsolete practice of cutting off or shortening a considerable portion of the leaves at planting time; on the contrary, Celery, more than most crops, should never, throughout the whole course of its cultivation, from the time the plants appear above ground, until they are fit for use, receive a check more than is inseparable from transplanting them, even when that operation is performed with care. If the trenches have been prepared for double or treble rows, put the plants in 1 ft. apart, each way if for single rows, 9 in. between each plant will be sufficient for ordinary purposes, in making the holes, use a planting trowel, and see that they are large enough to admit the roots without crushing them together; give each row a good watering as soon as planted. Celery costs more in manure and attention to grow it well than most vegetables, and it is worth while to treat it in a way calculated to produce it in good condition.

**Leeks.**—When indifferently grown, these are little better, for the purposes for which they are required, than Onions. To obtain the peculiar mild flavour which Leeks possess when large and freely grown, the plants must not be allowed to become stunted by being too close in the seed-bed; to prevent this, thin them out, so as to leave them 6 in. apart.

**Thinning Onions.**—Spring-sown Onions should be thinned before they get too large. Take advantage of the soil being moist after rain to do this. If it be hard and dry, the limited quantity grown by many may be watered, so that the removal of any need not injure those that remain, which often happens when the ground is hard. As to the distance the plants are left apart in thinning, account may be taken of the kinds grown. Large kinds, such as *Roccos* or *uncham* Park, require double the room necessary for small varieties, like *Danvers* or *James's Long Keeping*. If it is desired to grow well-developed bulbs of the large growing kinds, these should be thinned, so as to leave them 8 in. or 9 in. apart in the row; the smaller-growing, later-keeping sorts will not require more than half that room. Where some are required for pickling, a

portion of the smallest-growing kinds may be left not more than 1 in. apart; or, unless they have come up very thickly, without thinning at all.

#### Extracts from my Diary.

**May 27.**—Sowing Carters' Giant White Cos, Ivery's Nonsuch, All the Year Round, and Tom Thumb Lettuces. Planting out first batch of Asters. Planting out two rows of Celery. Earthing up Potatoes and Broad Beans. Mulching Raspberries with half-rotten stable manure. Mowing and digging up ground for Cabbages, Savoys, and other winter Greens. Making up fresh beds for Cucumbers. Giving Plum trees on walls a good washing with Quassia chip water to keep off green fly. Tying up Lettuces to blanch.

**May 28.**—Sowing Bromham Hall and Golden Perfection Melons; also Telegraph Cucumbers. Potting on Balsams and Chrysanthemums. Looking over Rose walls, nailing in all the shoots that require it, and giving them a good washing to kill green fly. Clearing out another Potato frame and getting it ready for Melons. Renovating frame linings. Thinning Apricots, Peaches, and Nectarines, where not already done by frost. Earthing up Cauliflower plants.

**May 29.**—Sowing Veitch's Autumn Self-protecting Broccoli, to come in for lifting and laying in cold frames for winter use. Getting all bedding plants planted out as fast as the weather will permit. Looking over Vinerias, and stopping the laterals, tying up the leaders, and thinning the grapes where required. Digging out more Celery trenches and getting the manure into them. Sticking and earthing Peas.

**May 30.**—Sowing Green-curbed and Broad-leaved Endive; also Mustard and Cress. Potting off Solanums, Celosias, and Lemon-scented Verbenas. Pricking out Celery and Cauliflower plants. Looking over British Queen and President Strawberries in the open ground, and picking off all the late and weak blossoms, so as to make sure of some fine fruit, and getting them netted. Sticking Scarlet Runner Beans. Cleaning out all catch pools, and seeing that all drains are free, so as to be ready for heavy storms, should they occur.

**May 31.**—Sowing Canadian Wonder French Beans, or Radishes. Potting on suckers of Pandanus Veitchi. Tying in all leading shoots in Peach houses. Hoeing amongst Gooseberries and Currants, and amongst all growing crops. Dusting Turnips early in the morning with lime and soot to keep off the fly. Looking over Peaches, Nectarines, and Apricots, nailing in the leading shoots, and washing them well to kill green fly.

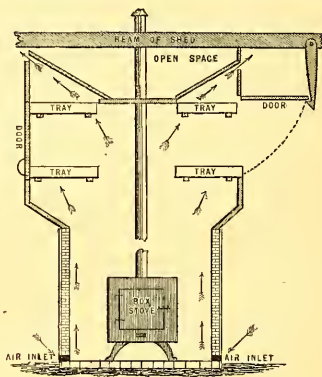

**June 1.**—Putting in cuttings of double Wallflowers and Alyssum. Planting Snow's Winter White and Watercress Broccoli. Looking over Cucumbers and Melons, stopping them, and earthing them up where required. Mowing and cleaning up the pleasure grounds, and rolling down firmly all gravel and Grass that require it. Weeding and cleaning up herbaceous borders. Watering Pines all through; also Carrots, Potatoes, and Celery in frames.—W. G. P., *Dorset*.

**Hedgehogs in Gardens.**—These are invaluable friends to the gardener, as they destroy snails, slugs, woodlice, maybugs, and all sorts of creeping things; in fact, they live exclusively upon them. I have had hedgehogs in my garden for several years without any harm being imputed, even erroneously, to them. From a single pair they increased so much that on one summer evening I found seven full-grown ones together; but now they are very seldom seen, and I suppose that, having exhausted their food, they have migrated to other quarters. The fact is, slugs and snails have now almost disappeared from the place, while formerly I was much plagued with them. They do not touch any plant, not even Strawberries. I have given some to friends to put in kitchens infested with cockroaches, and they soon kept them down beautifully. All they required was a wooden box in a dark corner to sleep in during the day, and a little pail of milk to supplement their feast of cockroaches. They kept running about all night, to the intense disgust of the cats. They soon got sufficiently tame to allow of their being handled without concealing, but they always remained very shy, and not particularly intelligent creatures. To destroy their fleas, you cannot wash them with carbolic soap like the dogs, as they have a perfect horror of water; but smear a large white towel with green soap, put it on the bottom and the sides of a small deep basket, then set the hedgehog upon it and blow some good Persian or insecticide powder well between his spines; the fleas will immediately jump away and stick to the soft soap. Put some Walnut leaves amongst the hay in their nest and you will prevent a return of the nuisance. But after all you might as well spare yourself the trouble, as the immense hedgehogian flea seems quite a different species from the human and canine one. As to egg-sucking in their wild state I have neither presumption nor proof it, but my gamekeeper says they will destroy very young rabbits when still in their breeding holes.—JEAN VAN VOLXEM, in "Gardeners' Chronicle."

**The Rose Season.**—In our Rosery here (May 13) the young growths are about from 2 in. to 3 in. long. The trees were mulched last October with good rotten cow manure, which is already telling its own tale. The foliage is large and dark, and scarcely a green fly is to be seen. I sowed with a mixture of soft soap and sulphur—1 lb. of each to 40 gallons of water—merely as a preventive to insect pests. Making their food distasteful is one of the best ways with which I am acquainted of keeping down insects.—R. GILBERT, *Burghley*.

#### FRUIT AND VEGETABLE DRYERS.

The simplest method of drying both fruit and vegetables by artificial heat is to place them in a stove oven with the door left open; sometimes a rack is arranged over the kitchen stove to hold the articles; both these will answer for small quantities, and are useful auxiliaries in drying by the sun, but require frequent attention, to prevent the fruit from being cooked as well as dried. All the patented dryers are constructed upon the principle of passing a continuous current of heated air over the substances to be dried, and the means of effecting this present a great variety. During the late war we visited an immense establishment for drying vegetables for the army. In this room were arranged with racks for holding a series of shallow trays—merely a wooden frame with coarse cotton cloth tacked on for a bottom. Near the floor was a series of pipes through which steam circulated, to supply the heat, and openings were made to let in cold air below the pipes, and above were others to let out the air after it had passed over the trays. The dryers offered for sale have a stove for wood or coal, to heat the air, trays to hold the fruit or other matters, and ventilators above. These being the requirements, it will not need a great amount of inventive skill for any one who wishes to dry fruit or vegetables to construct something which will answer the purpose. Many years ago, having suddenly to preserve a large amount of sweet Corn by drying, where there was no dryer obtainable, we converted a room into a dryer. An ordinary cylinder stove was set near the door, and the pipe run across the room, about 2 ft. above the floor, to the chimney. Trays were made by tacking some discarded tin roofing to strips, and some tressels were knocked

together to hold them directly over the pipe. The door, being taken off and replaced by a temporary shorter one, allowed cold air to enter near the floor, and a window at the opposite end of the room was let down at the top, to furnish an outlet. The arrangement, even during a long storm, worked in a most satisfactory manner. An illustration more to the point is furnished by Mr. F. Malcolm, of Ontario, who, at a very little expense, extemporised a fruit dryer in his wood shed, which has worked so satisfactorily for two years, and is so simple and cheap, that he wishes others to have the benefit of it. The annexed sketch gives a cross section of it, apparently with the front removed. Mr. Malcolm does not give any dimensions, except for the trays, but that is a matter that will vary with circumstances. All he wishes to show is the principle upon which it is built. The enclosure is made of tongued and grooved boards, and protected from fire by lining exposed parts with brick and tin. A box stove is used for the heater, the pipe from which rises horizontally back to the rear of the dryer, turns upon itself, and then upward to the outside of the dryer and of the shed. This doubling the pipe gives increased heating surface and saves fuel. Eight trays are used; these are 2 ft. 4 in. wide and 3 ft. long; these go in pairs, and are laid, consequently the dryer is 6 ft. long on the inside. These trays slide upon cleats attached to the ends of the dryer, which are not shown in the diagram, nor is a central support which is provided for holding the ends of each pair. Though Mr. Malcolm does not say so, we infer by the arrows showing the direction of the air current that the bottoms of the trays are of elevated slats; at all events, that would be found a great advantage. There is at each side a door running the whole length, to allow the trays to

be put in and taken out; this door turns up, and is held in its place by a hook, as shown at the right hand side of the diagram. An opening at each side near the floor admits the cold air, and outlets are provided above the doors for the exit of the air. The lower openings should be provided with covers or shutters, by which the flow of air may be regulated. In the front of the dryer is a door through which the fire is fed and managed. As to the capacity of such a drier, Mr. Malcolm says: "There are eight trays, and it requires about seven bushels of Apples to fill them; in twenty-four hours the Apples may all be put into two trays, leaving the other six to be filled; by working in this way, a family may peel and core about five bushels every evening. With a moderate fire the Apples will be dry in forty-eight hours. In this and other dryers a high temperature is not of so much importance as a free circulation of air, hence the ventilator, or exit, should be sufficiently large. As soon as air is heated, its capacity for moisture is increased; this passing over the fruit quickly takes up moisture from it, and passes on to the outlet to allow a fresh and, so to speak, thirsty portion of air to come and take up its share of moisture. Besides more certain drying, without chance to spoil, a dryer turns out a much handsomer product than can be made in the open air, as light is excluded, and the fruit remains much lighter coloured. Knowing the principle involved in the construction, and by the aid of such hints as are given by Mr. Malcolm, no one should find any difficulty in constructing a fruit drier. It is not necessary to build it in a shed, as one may be put up by itself with a roof over it, which should project all around sufficiently to allow of operating in wet weather. Indeed, it is much safer to have it quite detached from the dwelling, as woodwork, exposed, as this would be, to a high temperature for many days and weeks, becomes so thoroughly dry, that it will be very inflammable; care is required in this respect, whatever wooden dryer may be used. If small articles, like berries or green corn are to be dried, the bottoms of the trays may be of some loose fabric, or preferably of wire cloth made of wire thoroughly tinned.—"American Agriculturist."

#### THE SEASON AND THE CROPS IN NORTH MIDDLESEX.

It is a good many years since I experienced such a spring as the present. Alike remarkable in different ways, it has in a more than usual manner exemplified the futility of venturing any predictions connected with anything influenced by the weather in our variable climate. Those who were all-depending at what they supposed would result in the certain destruction of the greater portion of the fruit crops by the severe frosts that occurred over a considerable part of the country whilst the trees were in flower, will have learnt one more lesson—that it is not any certain amount of cold, even varied in its effects by the conditions of the atmosphere as to moisture, that will destroy the vitality of the flowers; but that the ability of the bloom to withstand a low temperature is very much greater in some seasons than in others—directly attributable to the wood and bloom-buds being thoroughly matured the autumn previous; and this not alone dependent upon the autumn weather, but quite as much attributable to the summer weather that preceded it. In the south of the kingdom last summer we had considerably more moisture than usual, and consequently escaped the stagnation occasioned by drought in the middle of the season that occurs when the soil gets excessively dry about midsummer, followed by rains a little later on, which cause a strong second growth in the trees that does not admit of time for the incipient flowers getting so thoroughly matured as they were last autumn. From observation, now extending over a good many years in different soils and localities both near the coast and further inland, I have long held that the conditions above alluded to have a great deal to do with the ability possessed by the flowers of fruit trees when they open in spring to resist a low temperature. There is also another matter of which even those who have given it close attention, and favoured by the best opportunities of studying vegetable life, possess only a very limited knowledge, that is, the circulation of the sap, the more or less active condition of which exerts such a powerful influence in plants to withstand adverse conditions of temperature. The almost unprecedented dry state of the soil in this part of the country through the latter part of winter and up to the time of the severe spring frosts could not fail to render the flow of sap usual in the trees at the time considerably less than ordinary; and as the sap in a healthy plant is diffused through every part, even to the organs of the flowers, proportionate in quantity to its existence in the whole, it follows that the sap vessels this spring, at the time the frost occurred, contained much less watery element than usual. To these combined causes, I think, alone can the escape of the bloom be attributed; for whilst Peaches, Nectarines, and the later flowers of Apricots on open walls, with no more covering than usual, and in some

cases no protection whatever, were in full flower, we had on three nights from 13° to 14° of frost, and on another night, after a heavy driving shower of snow and sleet, with the trees all wet, we had 9°, accompanied by a cutting east wind, and yet in one place I have seen a couple of Peach trees on an east wall, fully exposed to the frost and wind, without any covering, and they have set plenty of fruit; but exceptional instances like this, in seasons such as the present, although they may and do lead some growers to ignore the use of covering at all, yet such conclusions are generally based on evidence not extending over a field sufficiently wide to be trustworthy; and my decided conviction is that in nine springs out of ten those who use such coverings as will ward off the greatest degree of cold, taking care that the trees are never covered when they ought not to be, and always covered when they require it, will come off the best with their Peaches on open walls. Probably the most remarkable thing in the fruit prospects is the way in which Apricots generally have withstood the frost, not only in the fruit that was already set and grown as large as big Peas, but also in the later flowers that were expanded when the low temperature occurred, there being several degrees more frost than usually has the effect of destroying all—both the fruit that is formed and the later bloom. Pears that flowered earliest are a thin crop; the later blooming varieties being full enough. Plums are set in large quantities; Cherries equally promising; Currants the same. Gooseberries have suffered severely, and are very thin in most places. Apples smothered with bloom, which has opened and fallen more quickly than I ever recollect seeing it. Strawberries and Raspberries most promising. The hound vegetation collectively has made within the last three weeks is such a few people can remember seeing. Deciduous trees of most kinds are crowded with bloom—Oaks, Elms, and Horse Chestnuts, especially the latter, which fell almost as soon as it opened. Lilacs, Laburnums, Thorns, and other shrubs are full of flower; but in many cases, such as the Thorns, the leaf growth is so great as to half hide the bloom. Even Hollies, such as were not almost smothered with berries last year, are flowering freely. Vegetable crops of all kinds have an equally promising appearance, and grow as if by magic. Gardeners (we cultivators of the soil in any shape are a grumbling set) have to resort to the last pog on which to hang a complaint, that is, that the weather is too favourable to the growth of weeds; and amongst the market fruit growers that fruit will be so abundant as not to be worth gathering. The country collectively could not possibly look better or more promising. Grain of all kinds, both autumn-sown Wheat and Beans, as well as spring Corn, have a uniform vigour and colour about them such as is seldom seen on land of all descriptions, both heavy and light. The hay crop is likely to be the heaviest that has been for some years. T. BAINES.

#### OTIORHYNCHUS SULCATUS AND ROSES.

The Otiorhynchus is a nocturnal feeder, and not very particular in its choice of food. It feeds during this season of the year almost entirely on young buds which are just pushing into growth, and it eats the bark all round such buds, thus destroying not only the buds, but all dormant eyes at the base, and, consequently, all hopes of further growth. In seasons like the present, when the weather is mild and showery, and trees are pushing with vigour and in health, the mischief done by the Otiorhynchus is comparatively small, except in cases of single specimens of Roses, &c., which come more particularly under the observer's eye; but in seasons like last spring, when the weather is dry, the wind in the east, the trees pushing with feebleness and in a somewhat sickly state, the Otiorhynchus is in its glory—it seems to them more fully to enjoy the young bark and buds, and as the growth is delayed by the weather, it has more time for its work of destruction. In such seasons I have seen whole squares in a nursery destroyed or seriously damaged of many shrubs and trees, such as Roses, Thorns, Purple Beech (grafts), Hollies, Cupressus, Lawsoniana, Plums, &c. On making inquiry as to what has done the mischief, I have frequently been told it was the east wind, frost, &c. The sufferer evidently not knowing his foe, probably owing to its nocturnal habits. The larva of the Otiorhynchus is a small white grub, very much resembling a meat maggot, and it will be found chiefly feeding on the roots of the common Yew. It is also fond of Polyanthus roots, and one of its favourite pastimes is to gnaw the bark in a ring round the stem of a Rhododendron just at what sailors call the wind and water line, causing the death of the plant. I am, of course, well aware that many other plants are subject to its attacks besides those I have mentioned. Every year we have a fine crop of beetles emerging from our newly-potted Peaches and Nectarines in the Orchard house, and we are obliged to go at night with a candle and catch them, or they would eat the leaves of the plants in such a way as to seriously damage them. Now, as to the best way of dealing with them. Firstly, having learned to recognise the grub, never

omit an opportunity of destroying them when lifting Rhododendrons, Yews, &c.; look out for them in re-potting Peaches, &c. The perfect insect is a more difficult matter to deal with, as it is nocturnal, and by no means asleep. On approaching the tree on which it is feeding, if one should bring the candle too near or in any way shake the tree, down it drops to all appearance dead, and to find it on the soil is nearly like "looking for a needle in a truss of hay," as its colour so much resembles the soil. Our *modus operandi* is this:—Three persons go armed with a candle and lantern and a large apron. One wears the apron in which is placed a stone to form a convenient hollow, the second carries the candle at such a distance as to show a sufficient light for the work, and the third man bends the tree quietly over the apron, and then gives it one or two sharp taps. The beetles fall into the apron at once, and, being only crawlers, they are, by occasionally shaking the apron, kept at the bottom until the work is complete. In this manner we catch pints, and sometimes quarts, of beetles in the course of one evening, say two or three hours. I have, in my garden, proved the utility of this plan; some of my Roses, which were near some Yew trees, were almost destroyed last season, and with the aid of a friend and an apron we caught forty or fifty from seven Rose trees. Of course the Roses were untied from their stakes during the day to be ready, and we were careful to avoid touching one tree whilst operating on the next.—ALFRED H. PEARSON, *Chilwell Nurseries*, in "Nottinghamshire Guardian." [The genus *Otiorynchus* consists of many species, and the whole of them should be suspected as great enemies to plant growers from the well-known propensities of several of them. They should therefore be carefully collected and destroyed.—W.]

**Slugs in Gardens.**—In searching for slugs in my garden an evening or two ago, I found a species which, I believe, is not a vegetable feeder. It has a yellowish body, shaded off to dirty brown on the back. It is 2 in. or more long when extended, and is not so shiny as the common slug. Finally, on its tail grows a horny substance like a small shell. I was about to destroy a number of this kind of slug, when I saw protruding from the mouth of one a small red earth worm, half swallowed; whereupon, thinking they were friends instead of foes, I put the whole number back on the borders. Can any of your readers tell us anything more about this slug? Since writing to you on this subject (see p. 404) I have had ocular demonstration of the use of a hedgehog in a garden. Mine got shut up one night and lost his usual chance of food, and next day I found him very hungry. On releasing him, and putting him near his customary hiding-place, he began to search for food, although it was still broad daylight, so I picked up some slugs which the wet had enticed out, and dropped them very quietly just in front of him. He devoured them greedily, and a large snail (previously crushed) shared the same fate. Besides what I gave him, he constantly snapped up something on the borders—vermin, no doubt—for he did not touch leaves or any vegetable substance. As this creature commences to feed at dusk, he must in the course of the summer nights destroy a considerable quantity of vermin.—W. J. T., *Brixton*.

**Poison for Red Spider.**—I find from experiments which I have made that sulphuretted hydrogen gas is an easy and effectual means of destroying red spider without injury to the most delicate plants. All other insects are destroyed at the same time, and I think mildew is arrested, but on that point I am not sure. My plan is to take a water-tight vessel, such as a keg, that will hold the plant and leave room on the bottom for a teacup. After placing the infested plant in the keg, I put by the side of it the teacup, about half full of diluted sulphuric acid—about one part of acid to five or six of water. I then wind the end of a fine copper wire 2 ft. or 3 ft. long around a piece of sulphuret of iron as large as a lady's thimble, so as to hold it securely, and, using the wire as a handle, let it down into the cup, and cover all up tightly with a bundle of papers pressed down by a bit of board. After ten or fifteen minutes the cover is raised a little, and the iron sulphuret drawn out by means of the wire. The plant is allowed to remain about half an hour longer. A little strong ammonia will neutralise the odour of the gas, which, however, if the operation be skilfully performed, does not escape in sufficient quantity to make it worth while to do this. The remedy is so obvious to anyone familiar with the properties of the gas, that I think it must have been tried before, but I have never heard that it was.—"Country Gentleman."

**Cucumber Disease.**—I would recommend Mr. Rose (see p. 481) to try *Salus*. It did not quite cure, but checked the Cucumber disease with us last year. I am sorry, however, to add that the disease has re-appeared this year, though fresh seeds, new paint, fresh soil, and every possible preventive seemed tried: Our case, however, was not common gumming, but blotched patches on the leaves and fruits. *Salus* cured the Melons of the same disease completely, and I have seen nothing of it since.—D. T. F.

**Cucumber Peel and Black Beetles.**—I have tried the experiment of placing Cucumber peel in the way of black beetles, and I find that the smell of the Cucumber peel allures them, and that after eating it they die almost directly, some close to the peel, and others as they are moving away from it retire to their holes.—J. S.

## TREES AND SHRUBS.

### THE BARK AND TIMBER TRADE.

THE bark-stripping season was brought to a close generally in this neighbourhood the latter end of last week. We commenced stripping here on the 23rd ult., just four days earlier than last year. The weather has been throughout the season most favourable for bark peeling, being mild and very moist, with southerly winds prevailing, and almost the total absence of frosty nights, which tend to check the flow of sap freely, so unlike the weather last year, when frosty nights and north-east winds were the rule and not the exception; indeed, they continued during nearly the whole time of stripping, and rendered the bark difficult to peel. This season, however, the sap has "run" exceptionally well, and the bark, in consequence, peeled off with the greatest facility. The bark trade throughout the country is very dull; the supply seems to be greater than the demand. From trustworthy quotations received from many parts I conclude that the price is from 15s. to £1 10s. per ton lower than last year. We have recently sold this year's stripping for £4 10s. of 21 cwt. to the ton, put on waggons in the wood at purchasers' risk, in case of stained or damaged bark. As compared with last season's price (which was £6), it is £1 10s. lower. The Government sale of bark in the New Forest took place about a fortnight ago, the average price being 17s. 6d. less than last year. At Stamford, on the 16th inst., Messrs. Richardson & Son offered about 480 tons of new bark for sale, but on account of the low prices bid only six lots out of seventeen were sold, the prices of the lots sold ranging from £3 to £4 per ton of 20 cwt. in the wood; one man allowed for loading on waggons, except the highest price lot (£4), which was for delivery in truck at the railway station. At Newport and other parts of Shropshire I learn that the price is from £5 to £5 10s. of 22 cwt. to the ton, delivered in the tanyard, or at the nearest railway station. In Kent, Sussex, and other southern counties, the price is about £4 15s. of 20 cwt. in the wood, or from £5 to £5 5s. delivered. The price of new hatched bark per load of 50 cwt. in and about London is about £16, delivered in bags at the tanyard. Notwithstanding the low prices, purchasers who buy with all risks are, I fear, likely to be heavy losers in consequence of so much rain; the bark cannot fail to be more or less stained and damaged already, and if this still showery weather continues another week or longer it will cause irreparable and disastrous results to the bark harvest hereabouts. I have not heard of a single load of bark having been delivered in a tanyard about here this season. The showery weather has continued intermittently from the commencement of peeling up till this date, May 21, that it has been utterly impossible to get any bark harvested dry. The timber trade is dull on the whole. Elm is very low in price; the market is almost glutted. This has been caused mainly through the immense number of fine old Elm trees blown down in October last. Oak, excepting first quality and of large dimensions, is not a brisk trade. Ash is still in demand at good prices; clean copse-grown Ash is eagerly bought. Beech is in fairly good demand at last year's prices. Sycamore realises high prices when clean and not less than 2½ ft. in diameter of butt, but small-sized trees are of little value. Lime sells at a high figure when clean grown and of good growth. Larch is always in demand at fair prices. Scotch Spruce, and Silver Fir trade is ruled in a great measure by local demand. In this locality we have a steady sale for them; the timber is converted into sleepers and fencing for railways, and also into staves for soap-boxes in the Bristol soap manufactories. Pitwood prices are low and in little demand, as the pits have been almost blocked up by windfall trees and limbs since the October hurricane. The underwood and fagot trade is not brisk, the prices generally being lower than those of last year. GEORGE BERRY.

*Longleat.*

**Erratic Habit of the Horse Chestnut.**—This tree seems to me to be always halting between two opinions, never exactly sure whether to adopt a creeping or an erect habit of growth. Has any of your readers noticed its habit in this respect? Sometimes a branch will grow straight down like a Weeping Ash, and its neighbour will grow as straight up. Not far from where I write there is a tree about sixty or seventy years of age, the bottom half of which grows down nearly as "weepingly" as a Weeping Ash, while the top, from about midway up, assumes a distinctly erect habit; the one almost looks to be grafted on the other. Some of the branches turn down as soon as they leave the trunk, and grow straight down until they reach the ground, while the top branches spread widely out without the least tendency to droop. Many other trees show the same erratic tendency.—J. S. W.

## PROPAGATING.

**ACHIMENES.**—The tubers of these may be potted and started into growth in the middle of April; the most suitable place for them is a shelf near the light in an intermediate house till they get about 3 in. high, when the tops may be taken off and every little piece will make a plant, if cut as in fig. 1. A good compost for them is a mixture of peat, sand, and a small portion of loam, and the pots must be well drained; the soil should

Fig. 1.

be put in lightly, with a little sand on the top. Give a watering with a fine rosed-pot and insert the cuttings; then sprinkle with water to settle the soil, and put them into the cutting box on a warm bottom, where they will emit roots in about ten days. They may then be gradually inured to the light and got ready for potting off. They make several tubers every year, as shown in fig. 2. Each tuber will make a good plant,

Fig. 2.

Fig. 3.

or it may be divided as seen in fig. 3. If a fine specimen be wanted, several tubers may be placed in one pot or pan. They ought at all times to be near the light, and should have plenty of room between them to keep them from getting too weak.

H. H.

**Shading for Greenhouses.**—We are this season using a shading material which I have not seen mentioned among the receipts given by your correspondents. It is very easily obtained and applied, and is more efficacious than anything we have hitherto tried. The receipt is simply flour mixed with cold water or buttermilk to the consistency of paint, the best way of applying it being by means of a white-wash brush at the end of a stake or lath. This shading has the advantage of obstructing the light less than Brunswick green, which is too dense for anything but Ferns, and also of withstanding the weather extremely well, as has been proved during the last fortnight, when we have had heavy storms of rain at frequent intervals, which to all appearance have not affected it in the least degree.—CHAS. E. PEARSON, *Chilwell, Notts.*

**Lily of the Valley in Market Gardens.**—I have just seen an unusually fine display of this favourite flower in full bloom in Mr. Moore's market garden here. He has six wide rows of it, each more than 600 ft. in length, and it was a rare treat to walk amongst them with a gentle wind scattering their sweet odours. They were planted about four years ago between rows of young Gooseberry bushes running north and south, and are rapidly filling up the spaces between them, the partial shade and protection afforded by the bushes seeming just to suit them. The gardens are in a valley, near the river Tyne; they are growing in common black soil, and require but little attention, and that they well repay. They are cut at this season, made into small bouquets, and sold wholesale in large quantities to dealers.—W. A. T., *Hewham-on-Tyne.*

**Saxifraga nepalensis.**—Of all hardy plants with which I am acquainted this is one of the best, and one, too, which is easily cultivated. A plant of it brought from Corsica in the summer of 1876 is now producing two spikes of flower in our rock garden, where it has been in bloom about three weeks, and in all probability it will keep in that condition for another six weeks. It is a plant which should be in every garden. We have also in flower another pretty *Saxifraga*, viz., *S. Lancastana*, a much dwarfer kind than *S. nepalensis*. That little gem, the *Edelweiss*, is likewise just coming into flower. Can any of your correspondents tell me the time and best means of propagating it? I have tried cuttings in autumn and other ways, but have failed.—H. BROWN, *Pusey House, Faringdon, Berks.* [It grew freely from seeds at Dangstein, sown in spring in pans, in a compost consisting of sandy peat, leaf-mould, and brick dust, and placed in a cool orchard house.]

## LILIUM BROWNI v. LILIUM JAPONICUM COLCHESTERI.

IN part iii. of Mr. Elwes' "Book on Lilies," under *L. Browni*, occur the following remarks:—"I cannot allow that what is figured in the 'Flore des Serres,' t. 2193.4, recently, as *L. japonicum* Colchesteri is distinct from *L. Browni*. Such slight variations as might be discovered in plants grown under very different conditions do not, in my opinion, justify their being treated as different plants, however desirable such a cause may seem to those whose only object is to swell their catalogues or bring out old plants under new names."

Such an insinuation, doubtless levelled at myself as the re-introducer of this fine kind (our *L. japonicum*), or at the late celebrated M. Van Houtte, who figured it, and, in friendly complement, gave it the differential name of *Colchesteri*, is unworthy of the author or of his book on Lilies. We have grown our plant, which is the one depicted in Bury's "Hexand," t. 2, as *L. japonicum*, and by Thunberg in his "Flora of Japan," p. 133, side by side with *L. Browni* for years past, and had we not been convinced of marked differences, we should not have ventured to introduce it as new in our catalogue. We have now growing for the first time twenty-five plants of this fine species side by side with 100 *L. Browni* under the same conditions and aspect, and are therefore in a position to point out their differences, some of which we now beg to enumerate.

*L. japonicum.*

BULB is white or whitish-yellow, never red or brown; broad at base; the scales, which are somewhat narrow and acute at tip, differ in length, the outer ones terminating at about two-thirds of the height of the inner scales.

*L. Browni.*

BULB, on exposure to light, assumes a red or reddish-brown tint; the scales are broad and all pass up, overlapping, and terminate together at the apex of the bulb, thus giving it a peculiar shape, which is well represented in *THE GARDEN*, 1877, p. 134, and there described as "oblate in form, the base being curiously constricted." This form is not found in our *L. japonicum*.

When about 1 in. out of the Ground.

*L. japonicum.*

BUD green; leaves, broad and blunt, are edged with a thin brown line, showing a darker tinted venation; shape of apex, round, flat, blunt.

*L. Browni.*

BUD reddish-brown when first above ground, with no green; when about 1½ in. high a little green shows under the red bracts; shape, acute-pointed.

When about 3 in. to 4 in. high.

*L. japonicum.*

STEM green, thickly irrorated with brown, or green, with brown rings just below the insertions of the leaves; leaves 1½ in. to 2 in. long, of a bluish-green colour, edged with a thin brown line, having a lighter-coloured central midrib on upper surface, erect, bluntly obovate, wide spreading, unfolded to the base of the stem.

*L. Browni.*

STEM and bracts dark brownish-red, the upper 1½ in. of bud showing only a green tint, tipped at the point more or less with brown both on upper and under surface of leaf; bracts pressed close to stem; no leaves unfolded; bud closed up.

When 8 in. to 10 in. high.

*L. japonicum.*

STEM, a blue green, more or less irrorated with brown, getting darker near the base when it leaves the soil; the insertion of the leaf is marked with a brown line or patch; leaves alternate, continued down the stem to a distance from the soil of 2 in.; semi-erect or horizontal, not arched, not curving downwards at tip, broad in the middle, where they are four times wider than at the insertion, diminishing gradually thence to apex and base, about 3½ in. long, of a softer feel to touch; bracts have died off and fallen.

*L. Browni.*

STEM rich dark brown, with brown bracts adherent and fresh, the lower 6 in. unfurnished with leaves; leaves about 4½ in. long, harsher to the touch; lanceolate-pointed, green with broader brown edging, more or less erect, curving in an arc, with the tips invariably pointed downwards. At its broadest part, which is nearer the apex than the bud, it is only twice as broad as at the insertion.

Apex of Bud at Summit of Stem, 8 in. high.

FORMED of four leaves, open, divergent, with their tips directed outwards, as in *L. longiflorum*.

FORMED of four or six leaves tightly closed together like that of *L. auratum*.

Prevailing Tint of Plant.

*L. japonicum.*

Bluish-green.

*L. Browni.*

Dark brown with green leaves.

My gardener, who knows the plants well, says he could tell each kind in the dark by the feel. As the growth progresses, I will, if allowed, specify certain differences in your columns. The reputation of the late M. Van Houtte stands too high to need from me a single line in his defence. The fact that he considered our species distinct from *L. Browni*, figured it and introduced it as such in his catalogue, ought to have sufficed, the more so now he has gone, to have protected him from any unworthy insinuation.

ALEXANDER WALLACE.

## ANSWERS TO CORRESPONDENTS.

**Green Fly on Roses.**—What are the best means of destroying the small green fly which infests Roses? I tried strong Tobacco water last year and constant brushing off with a white feather, and could not get rid of countless numbers of these pests.—H. S. G. [Tobacco water diluted with soap-suds, or soft-soap, made into a strong lather and applied on alternate evenings for a fortnight, is a certain remedy.—W. H.]

**Green Fly on Orange Trees.**—In reply to "S. H." (see p. 414), allow me to say that, where practicable, fumigation with Tobacco paper is always the best way of getting rid of green fly. Fumigate two or three nights successively, and use with the paper a good proportion of dry Moss to prevent any ill effects from an over-dose of Tobacco-smoke. This is a much better plan than attempting to do it in one evening with Tobacco-paper only.—W. W. H.

**Conifers in Shade and Drip.**—What Conifers will thrive best under the shade and drip of trees, and afford good shelter for game?—C. M. [Nothing will succeed so well as answer the purpose better than the Silver Fir, Yew, and Hemlock Spruce.—G. B.]

**Snowflakes.**—Allow me to tell "E. F." that my Snowflakes have blossomed in profusion, though they flagged much in the sun, as they were not planted in a sufficiently wet place. I have always seen them with much leafage, which adds to their beauty.—M. CONYBEAR, *St. Leonard's Grange, Ingelton.*

**Syringing Vines.**—COUGH VINES to be syringed with water from now until the fruit begins to change colour? or had the house better be kept quite dry, and merely the Vine roots outside moistened by watering the border? The bunches are just showing. No heat is used, except a fire at night to prevent damage from frost. My Vines suffered badly from mildew two years ago, which killed every berry, and last year the crop was small.—J. H. W. [No; Vines should not be syringed when once the buds are expanded, but the atmosphere should be kept moist by frequently damping the floors and walls; a dry, arid atmosphere is the last thing that should be thought of in Vine culture. When the Grapes begin to colour, reduce the atmospheric moisture and ventilate more freely. To prevent mildew see that the border has a liberal supply of water.—W.]

**Hair-worms.**—What is the name of the enclosed worm? It was picked up with others of the same species immediately after a heavy thunderstorm on Saturday last. It was alive on Saturday evening, and moved about freely.—H. [The worm sent appears to be a species of *Goviolus*, and probably *G. aquaticus*, not uncommon in the bottom of damp ditches and similar situations. It much resembles a living, rather stout, dark brown-coloured horse hair, and often winds itself up into what appears a complicated loose knot.—W. W. S.]

**Malformed Rhododendron.**—Is the accompanying a common form for a Rhododendron flower (?) to assume? I have a bush a little under shade completely covered with such flowers, no others being on it.—W. H. M. [It is not uncommon for a young shoot to push from the centre of a partially-formed flower. It often occurs in the Rose. In the specimen sent, however, we observe no traces of a flower. What we see are many red bracts or floral leaves attached to the young shoots. A bush well furnished with such appendages must have a handsome appearance.]

**Names of Plants.**—*G. J.*—The leaf resembles somewhat that of the Giant Echium, plants which otherwise resemble the description. It will probably do best in a warm greenhouse. If it flowers we shall be glad to see a bloom. You might be able to identify it from the leaf alone at *Kew. W. C.*—*Asphodelus ramosus* is the name of the plant of which you send the flower. We seldom attempt to name plants from the leaf alone. *J. M.*—No, 3 is *Lonicera tartarica*, from Siberia. The other two had lost their numbers, or rather the writing on the tissue paper was totally illegible. One was certainly *Spiraea levis*, from Siberia, and the other (yellow flowers) most probably a species of *Hibbertia*, from Australia. *Belvis.*—*Cardamine sessilifolia*. It has no claim whatever to a place in the indigenous flora of Great Britain or Ireland. The seeds have probably been introduced with foreign Rye Grass or farm seeds of some sort. *J. F.*—The Orchid is *Brassia Lawrenceana longiseta*, and the Begonia is *B. nitida*.

**Top-dressing Strawberries with Soot.**—"H. B. J." asks if this may be done with safety when the plants are in flower. Yes; with care. But the less soot allowed on the flowers the better, for three reasons. First, a strong dose might injure them; secondly, some of it might remain to spoil the fruit; and, finally, the flowers cannot possibly be benefited by soot. The soil, the plants, the leaves, and crowns may be enriched, stimulated, cleansed by soot dressings; and these might be applied with advantage up to the flowering period. But they are better applied several weeks or a month before it, and the last dressing should be washed off and in by a heavy artificial watering, unless such deluging rains as we have had this season should succeed the dressings. Soot is one of the best of manures for Strawberry plants, but the faintest trace of it on leaf, stem, or soil is ruin indeed to the fruit. Hence dress well, and wash down before mulching. The recent floods and dressings have developed a magnificent show of Strawberries here.—D. T. FISK, *Hardwick House, Bury St. Edmunds.*

**Oiers.**—What are the best sorts of Willows with which to plant an Osier bed, irrigated with sewage? and what is the best time and mode of planting?—F. M. [The best sorts of Willows to plant

under the circumstances are the slow-growing, hard varieties, and of those only certain sorts will withstand the effects of sewage without deterioration. With due attention, however, as regards the selection of cuttings, good crops may certainly be obtained from the following varieties, viz., *Merrin's Yellow Hard Osier*, *Long-skin Osier*, *Black German* and *Pomeranian Willow*; others might be named, but none are better for the purpose than these, unless some speciality be required. The best time to plant is from the middle of November to the end of March. The ground must be well pulverised and cleaned before planting, and the drainage should be good. Cuttings should be used, but the distance apart can only be stated when it is known which sort is to be planted; the larger the Willow, of course the more room it will require. A common distance apart is 18 in. each way.—W. SCALING, *Basford.*]

## Questions.

**Sweet-scented Flowers.**—Would some correspondent of THE GARDEN inform me what is the best succession of sweet-smelling flowers for a conservatory or cool greenhouse for the whole year?—AMATEUR.

**Rose Roots and Lead.**—I have a *Maréchal Niel* Rose in my conservatory which has been planted about two years. It at first grew at a very rapid rate, but during the last twelve months it has been unhealthy, and I cannot find out for what reason. This year it has borne a few flowers, but scarcely any leaves, and when it has turned yellow almost immediately. The shoots also that it makes turn brown and drop off. It is planted against the wall in a half-stone box, and, to prevent the damp penetrating the wall, twelve months ago we had a sheet of lead put between the wall and the earth in which the Rose is planted. Can the lead have affected the Rose?—B. S.

**Blighted Roses.**—Can you suggest a ready method of restoring blighted standard Rose trees to health? I have some half dozen; half of which are doing well, and the other half are very indifferent. I have fumigated them and watered them well, but it is of no avail; in fact, one of the trees seems to be quite dead.—E. J. G.

**Propagating Stove.**—Will some of your correspondents kindly inform me what is the best and cheapest way of putting up a small propagating house? what sort of stove to heat it? and how the pipes should be placed?—J. P.

**Asphalting—How is this Best Done?**—I want it for a walk in a house, and as one end of the house is some 12 ft. higher than the other, the walk in question is very steep. Would it not be advisable to mix with the asphalt a few small gravel stones to make it less slippery? I have had the path gravelled, but do not like it, as it gets carried by the feet into the other houses adjoining, and also gets very green, so that every two or three months it requires a fresh sprinkling. There are, I believe, several kinds of asphalt, but I would like one that could be washed down and made to look clean. Could the asphalt be done by common labourers? and how much would it cost per yard?—H.

**Green-growing Gardenias.**—I have two or three Gardenia plants flowering in 7-in. and 8-in. pots, and have failed to flower them. They are in good health, growing satisfactorily, and have set an abundance of flower-buds; but, instead of opening, as they ought to do, a portion of them drop off, whilst others unfold imperfectly and so slowly that the petals appear like deformed leaves, and are nearly as green. I grow them in a moderate stove temperature during winter and until the buds are fully formed, afterwards I place them in the conservatory; in fact, I have tried them in different houses and temperatures, but all have failed. I may add that they receive manure water as often as we deem proper throughout the growing period. What treatment should I follow with a better hope of getting the buds to open?—S. K.

**Insects Attacking Timber Trees.**—There are two insects, or rather their larvæ, that do much damage to two kinds of forest trees. The caterpillars of the first, said to be a species of *Tortrix*, live upon the pith of the young shoots of different kinds of Conifers, generally choosing the leading shoots, and causing them to die. The other, which attacks the leaves of evergreen Oaks, is the larva of some small insect, which, like the *Celery Fly*, feeds between the upper and under surfaces of the leaf, leaving a dead blotch on the foliage of the size of a fourpenny-piece. Is there any practical method of dealing with these pests? Thousands of the Pine-tree pest have been destroyed by hand-picking, but it is a tedious operation, and can only be done when the trees are in a young state.—J. M.

**Rubus delicosus.**—This was not introduced by Mr. Isaac Anderson-Henry, as stated recently in THE GARDEN (see p. 434), but by me. Mr. Anderson-Henry simply bought seeds or plants of it of me; I forget which.—W. THOMSON, *Ipswich.*

## SOCIETIES AND EXHIBITIONS:

## ROYAL HORTICULTURAL SOCIETY.

MAY 21.

THE chief features of this meeting were groups of plants shown by Mr. John Wills, South Kensington, and by Messrs. Rollisson & Sons, Tooting.

**First-Class Certificates.**—These were awarded to the following new and rare plants:—

**Hemanthus Kalbreyeri** (Veitch & Sons).—A useful ornamental species from the West Coast of Africa and previously described in THE GARDEN.

**Adiantum neo-guineense** (B. S. Williams).—A beautiful Fern of the *A. tenerum* class, with large branching fronds and light pinnae.

**Ptychosperma rupicola** (B. S. Williams).—A graceful Palm, with feather-shaped fronds, which, in a young state, are of a rich bronze colour.

**Cycas media** (B. S. Williams).—A species of medium growth, having dark green leaves of a highly ornamental character.

**Alsophila plumosa** (B. S. Williams).—A small Tree Fern, with light and elegant fronds and finely-cut pinnae.

**Sadleria cyathoides** (B. S. Williams).—One of the most handsome of Tree Ferns, of moderate stature, and having long, graceful fronds resembling those of a Blechnum.

**Gloxinia Mons. Duval** (Society's Garden).—A rich crimson velvety flower of good substance.

**Gloxinia Boule de Feu** (Society's Garden).—A free-growing kind, producing snow-white flowers of good form.

**Pelargonium Mons. V. Lemoine** (Society's Garden).—A free-growing, Ivy-leaved kind, having glossy green foliage and bearing large, double, lilac-coloured flowers.

**Begonia President Burelle** (Laing & Co.).—An attractive variety, bearing brilliant double scarlet blossoms, each as large as those of a Carnation.

**Lilium tenuifolium** (G. F. Wilson).—A small crimson-flowered kind with recurved petals, and, as exhibited, very beautiful.

Mr. H. J. Buchan, Wilton House, Southampton, sent a flowering plant of the rare *Cymbidium tigrinum*, furnished with spikes of singular brown-petaled flowers having a white waxy lip spotted with dark crimson.

**Miscellaneous Subjects.**—In Messrs. Rollissons' group were well-grown examples of the beautiful *Acrophyllum venosum*, bearing large spikes of blossom, the yellow-flowered *Alyssum Weirbeckii*, the beautiful white-flowered *Saxifraga densa*, and the neat purple *Erinus alpinus*. With these also came good examples of Palms, Cycads, and other fine-leaved plants; likewise excellent examples of *Sarcocolla purpurea*, bearing very large, deeply-coloured nodding blossoms. This exhibition was edged with small plants, amongst which was *Nertera depressa* covered with berries. Mr. Wills' group contained seedling *Gloxinias* of an attractive character, *Cattleyas*, the beautiful *Odontoglossum cirrhosum*, and *O. vexillarium*; also *Lady's Slippers* and other *Orchids*. These were plunged in a carpet of Club Mosses, Grasses, and Maiden-hair Ferns, and were backed up with groups of *Spiraeas*, *Fuchsias*, *Arum Lilies*, &c., the whole being overhung with the graceful leaves of *Cocos Weddelliana* and other choice Palms. Several large specimen *Azaleas* were also conspicuous on account of their brightly coloured flowers. Mr. Aldous, South Kensington, showed a group of decorative plants, consisting of *Ericas*, *Pelargoniums*, *Lilium eximium*, and the beautiful *Saxifraga pyramidalis*, intermixed with Palms, Ferns, *Caladiums*, and similar plants. Messrs. Veitch & Sons contrived a collection of *Madeoivalias*, all of which were of an attractive character, and some especially interesting from a botanical point of view. The same firm also sent a plant of *Tillandsia zebrina* major from South America. It is a vigorous growing kind, with broad, zebra-like leaves, and bears brilliant scarlet sword-like spathes of blossom from 2 ft. to 3 ft. long; associated with this were also healthy plants of *Todea plumosa*, *Hemantthus*, and a large variegated-leaved *Crinum*, named *C. Verschoffianum*, from the South Sea Islands. This is a plant of a very ornamental character. From Mr. Douglas, Loxford Hall, came several pretty hybrid *Aquilegias*. Mr. B. S. Williams furnished a group of new plants, in which were noticeable several *Caladiums* of an attractive character, the white-flowered *Anthurium Dechardi* and *A. Patini* well furnished with white waxy spathes; also several new Palms and Cycads. Mr. Knight, Battle, showed a double-flowered striped *Pelargonium*, a sport from *Venusius*. Mr. H. Cannell, The Nurseries, Swanley, sent out flowers

of seedling *Mimulus*, which were much admired on account of their large size and brilliant and varied colours. They served to show that if such attractive flowers can be obtained from seed, propagation in any other way is unnecessary. Mr. Cannell also showed out blooms of *Zonal Pelargoniums* of a choice description, being large, well formed, and brilliant in colour. The best scarlets were *Tom Bowling* and *Nianza*, and the best white, *Jean d'Arc*. Dr. Denny, a purplish-crimson kind, was much admired for its brightness, and a kind named *Czarina*, with large white flowers tinted with salmon was very effective, as was also a rich salmon-coloured flower named *Lady E. Campbell*. Several new kinds were also shown by the same exhibitor, one of which was white, striped with green, and tinted with pink. Messrs. Laing & Co., Stanstead Park Nurseries, Forest Hill, sent some handsome tuberous-rooted *Begonias*, amongst which a kind named *B. Lelia* was much admired on account of its large, waxy, bright crimson blossoms; a kind named *Carnicolor* was also remarkable for its dwarf habit, and its large, light, salmon-coloured flowers. Messrs. Barr & Sugden exhibited an extensive group of cut *Erics*, *Pæonies*, *Ixias*, and *Pyrethrum's*. The *Erics* consisted chiefly of well-known attractive kinds of the German section, many of which bore large and highly-coloured blossoms, but the majority of the buds were unexpanded. *I. eibirica grandiflora precox* was in good condition, as were also *I. neglecta*, *Sultan*, *æqualens*, and *Lady Jane*. Among the *Pæonies*, the rich magenta *P. anemoneflora fl.-pl.* was very attractive. The *Ixias* consisted chiefly of a rosy-crimson kind, evidently excellent for decorative purposes. Mr. J. Wheble, Reading, sent out blooms of a Ghent *Azalea*, of a bright orange colour and of good form and substance. They were stated to have been cut from a plant purchased from the Chelsea Nurseries fifty years ago. Messrs. Little & Ballantyne, Carlisle, showed a plant of *Lychnis dioica* bearing double rose-coloured blossoms. A collection of species of *Pelargoniums* of an interesting character was sent from the Society's gardens at Chiswick. It consisted of *Ivy-leaved*, *scented-leaved*, and other kinds, well worth more extensive culture than they receive. From the same source also came a group of plants of *Harrison's Musk*, which fully illustrated its value as a pot plant; for window decoration it is invaluable. Associated with these were examples of the dwarf variegated *Bamboo* (*Bambusa Fortunei variegata*), a plant not nearly so generally cultivated as it ought to be, for either as a decorative plant or for furnishing material for cutting it is of great value, and it is easily grown. This group was set off to advantage by means of Palms and Indian *Azaleas*. A good collection of *Gloxinias* also came from the Society's gardens. Amongst them the best were *John Gray*, deep purple; *Domenico Scassi*, a bold, bright blue flower with pure white throat; also *Boule de Feu* and *Mont Blanc*. Several speckled kinds of an attractive character were also contained in this collection, adjoining which there were double-flowered *Ivy-leaved Pelargoniums* and examples of the drooping sulphur-coloured *Primula sikkimensis*.

**Fruit.**—Mr. W. Divers, Weirton House, Maidstone, showed several dishes of Apples in good condition for the time of year. They consisted of *Golden Knob*, *Winter Greening*, *Gooseberry Pippin*, *Beauty of Kent*, and others. Mr. C. Howe, Benham Park, Newberry, Berks, sent good examples of green and scarlet-fleshed Melons.

## ROYAL BOTANIC SOCIETY.

MAY 22.

THIS show was in all respects an excellent one. Its most attractive features were the banks of *Roses* (which are always good in May), the stove and greenhouse plants, the choice collections of *Rhododendrons* and Japanese *Acers*, and the new and rare plants. Interesting, too, were the Palms and Ferns arranged in the recesses, but we missed the large *Azaleas* so brilliant at May shows in former years.

**Stove and Greenhouse Plants.**—These were well shown both by nurserymen and amateurs, and occupied the most prominent positions in the show. The best collection in the nurserymen's class came from Messrs. Jackson & Son, Kingston, who showed well-flowered specimens of *Apheloxia macrantha purpurea*, the blossoms of which are a great improvement on those of the original form; *Stachys profusa*, covered with bright purple blossoms, and worth notice on account of the plant being of a less formal character than that of many exhibition plants. Associated with these were the *Flamingo Plant* (*Anthurium Scherzerianum*), furnished with upwards of thirty large, bright scarlet spathes; and a very large specimen of the beautiful *Erica grandiflora rubra*, remarkable on account of its graceful character and profusion of crimson-white-tipped blossoms. In a collection from Mr. Williams, Holloway, was a remarkably fine plant of *Dendrobium nobile*; it was quite 3 ft. high, and as much through, and literally covered with blossoms. A large specimen of *Clerodendron*

Balfour was in equally good condition, and a well-grown plant of *Genetyllis Hookeri* was laden with bright crimson, drooping blossoms. Mr. Williams also showed an elegant *Tetratheca verticillata*, laden with purple, bell-like flowers. The groups of plants shown in the principal amateurs' classes were far in advance of those exhibited by nurserymen, and two collections of equal merit, arranged on a bank near the entrance, formed one of the grandest features of the show. Among them was noticeable a remarkable specimen of a finely-coloured variety of *Bougainvillea glabra*, the bright purple flowers of which could be seen from every part of the tent. Conspicuous, too, was a plant of *Azalea magnifica*, the finest of the kind we have ever seen, literally a mountain of snow-white blossoms; whilst *Erica ventricosa grandiflora* and *E. v. magnifica* were probably never to better advantage. A grand plant of *Anthurium Scherzerianum*, furnished with unusually large spathe, imparted colour to the group and formed a striking contrast to the white *Dracophyllum gracile*; and the beautiful, bell-shaped drooping blossoms of *Erica odora rosea*, one of the most valuable of the Heath, but unfortunately one of the most difficult to grow.

**Roses.**—These were not so numerous as at former May shows, a circumstance probably owing to the unfavourable weather which we have experienced of late being detrimental to the opening of the flowers. The best collection came from Mr. Charles Turner, Slough, whose plants were perfection, both as regards growth and bloom, and the admiration of every one. The foliage was large, abundant, and of a fine healthy green, and the flowers were throughout large, fresh, and bright. A plant of *Madame de St. Joseph* bore quite 150 blossoms, and formed a striking contrast to a large pyramid of the brilliant crimson-flowered *Duke of Edinburgh*, and a remarkably large conical specimen of the deep rose-coloured *Charles Lawson*, with which it was associated. *La France* was probably never seen in better condition than it was on this occasion, either as regards flowers or foliage, and *Madame Valliant* was all that could be desired. Messrs. Paul & Son, the Old Nurseries, Chessent, had a well-grown specimen of *Miss Ingram*, plentifully furnished with well-formed, whitish, pink-flushed blossoms, and associated with it were the brilliant crimson-flowered *Madame Victor Verdier*, the cream-coloured *Celine Forestier*, and a good specimen of *Madame de St. Joseph*. In the class for *Roses* grown in 8-in. pots, Mr. Turner had excellent dwarf plants, well furnished with foliage, each bearing on an average a dozen finely-formed blossoms and buds. Conspicuous among them were the brilliant *Madame Victor Verdier*, the white *Madame Lecharme*, the beautiful pink *Miss Haseard*, one of Mr. Turner's own seedlings, *Star of Waltham*, and *Sir Garnet Woseley*. Messrs. Paul & Son had also a good collection, in which were well-flowered plants of the rich rose-coloured *Magna Charta* and the pink *Abel Grand*; *Francis Michelon* was furnished with large, well-formed blossoms of a rich rose-magenta colour, and *Madame de Montchevean* and the velvety-crimson *Duke of Cornwall* were also in excellent condition.

**Orchids.**—These were fairly well represented. The best group, which came from Mr. Denning, gardener to Lord Londesborough, Norbiton, Surrey, contained a magnificent plant of *Laelia purpurata*, bearing upwards of twenty showy white purple-lipped blossoms; *Odontoglossum cirrhosum*, beautifully in flower; a fine specimen of *Dendrobium thysiflorum*; *Odontoglossum vexillarium* and *O. latopurpureum*, the latter bearing very large flowers having rich chocolate and golden-coloured petals and a white fringed lip. Mr. B. S. Williams, Holloway, had finely-flowered specimens of *Odontoglossum vexillarium*, *O. Alexandræ*, and *Madevalia Harryana*. Mr. James Child, gardener, Grand Hall, Ewell, had a magnificent *Oncidium ampliatum majus*, bearing eight or nine strong spikes of large golden blossoms; also an excellent plant of *Aerides* (Fielding), loaded with drooping racemes of bright pink blossoms. Mr. Heims, gardener to F. A. Philbrick, Esq., Regent's Park, had a remarkably fine example of *Dendrobium Bensonia*, also the beautiful *Vanda oerulescens* Boxall, a good plant of the pretty rosy-flowered *Scaccolabium ampullaceum*, and the curious *Oncidium Kramerii*.

**Azaleas.**—These, though comparatively small in size, were shown in good condition. Mr. Turner's collection contained a fine example of the semi-double pink, white-edged *Souvenir de Prince Albert*, one of the choicest of *Azaleas*, the white *Madame de Cannart*, and *Hanale*, a fine exhibition variety, and the brilliant crimson-purple-flushed *Duchesse A. de Nassau*. Mr. Ratty, gardener to R. Thornton, Esq., Sydenham, had a good collection, in which were noticeable the large orange-scarlet-flowered *Azalea grandis*, the white and salmon-striped *Charles Enke*, and a brilliant crimson-flowered kind named *Grand Crimson*.

**Pelargoniums.**—These formed an attractive feature, though the plants were not quite so full of blossom as we have seen them. The best in the open class came from Mr. James, gardener to W. F. Watson, Esq.; the blooms in this collection were large and well coloured, and

the plants dwarf and well furnished with foliage. The most attractive kinds were *Mary Hoyle*, *Prince Leopold*, *Snowflake*, and *Sultana*. In the nurserymen's class Mr. Turner, Slough, had excellent examples of *Claribel*, a kind with well formed flowers of snowy whiteness, the upper petals being slightly marked with rosy-purple. *Isabella* and *Tronbadour*, a beautiful pink-flowered kind, with white centre, the upper petals being conspicuously marked with dark crimson, *Pompey*, and *Archduchess* were also attractive varieties. Mr. James sent a collection of *Fancy Pelargoniums*.

**Fine-foliaged Plants and Ferns.**—These were well shown by both amateurs and nurserymen. Mr. Williams, Holloway, had fine specimens of *Cycas revoluta*, *Cocos Weddelliana*, *Dasytrich acrostichum*, and *Pandanus Veitchii*; also remarkable examples of the Australian Bird's-nest Fern (*Asplenium Nidus*), *Davallia Mooreana*, *Gleichenia Spluncea*, and the beautiful drooping *Tree Fern*, *Cyathes Barkeri*. Mr. Tudgey, gardener to J. F. Williams, Esq., Hawick Grange, Worcester, showed excellent plants of *Geonoma gracilis* and the massive-leaved *Pritchardia pacifica*; the same exhibitor had also fine specimens of *Cibotium regale*, *Cyathes medallaris*, and well-grown plants of *Adiantum tenerum*. Mr. Rann, gardener to J. Warren, Esq., Hand Cross Park, Crawley, had in his collection gigantic and graceful specimens of *Cycas circinalis*, *C. revoluta*, and *Croton interruptum*.

**Cape Heaths.**—These were not so plentiful as we have seen them at May shows, and the plants were also smaller in size than usual. In the best group, sent by Messrs. Jackson & Sons, were neat plants of *Erica ventricosa coccinea minor* and *E. persipica nana*, completely covered with waxy blossoms. In a collection from Mr. Peed, Norwood, were profusely-flowered examples of *Erica florida* and *E. ventricosa grandiflora*. Mr. Tudgey had remarkably fine specimens of *E. tricolor Wilsoni* and *E. ventricosa coccinea minor*.

**New Plants.**—Of these Messrs. Veitch & Sons contributed a collection, in which were *Gloxinias* of the finest description, *Amaryllis media*, a bright crimson hybrid, well worth attention; several new *Palms*, *Aquilegias*, good examples of *Homanthus Kalmeyerii*, *Colens George Bunyard*, a beautiful *Torenia Fourrieri*, and a beautiful coloured greenhouse *Rhododendron* named *Princess of Germany*. Conspicuous among the *Gloxinias* were *Coupe d'Hebe* and *Boxelans*, both upright-flowered kinds, of a brilliant crimson colour, edged with white. Messrs. B. S. Williams showed an attractive group of plants, in which were various *Dracaenas*, including the new *D. Goldiana*, some new *Caladiums*, *Ferns*, and *Sarracenias*, the whole being backed up by new and rare *Palms*, *Cycads*, *Ferns*, *Aralias*, and *Crotons*.

Botanical certificates were awarded as follows:—To Messrs. Veitch & Sons, Chelsea, for *Adiantum cyclosorum*, *Cinnam Verschaffeltianum*, *Platycentrum Hillii*, *Areca gracilis* and *A. grandiflora*, *Ptychosperma rupicola*. To Mr. Williams, for *Alsephila plumosa*, *A. cyathoides*, *Anthurium Deuchardi*, *Croton Prince of Wales*, and *C. Queen Victoria*.

Floral Certificates were awarded to Messrs. Veitch & Sons for *Amaryllis media*, *Colens George Bunyard*, *Rhododendron Crown Princess of Germany*, *Gloxinia Rebecca*. To Messrs. Laing & Co., Forest Hill, for *Begonia President Burrelle*, *B. Lelia*. To Mr. Fisher, Balham, for *Gloxinia Maggie Wright* and *G. Countess Amelia*.

**Miscellaneous Subjects.**—Messrs. Veitch and Sons showed a fine group of *Rhododendrons*, backed up by and intermixed with bronze and green-leaved Japanese *Aceras*, which were much admired. Messrs. Osborn & Sons, of Fulham, contributed an attractive group of miscellaneous plants, amongst which were well-grown *Palms*, *Pandanus*, *Crotons*, and *Dracaenas*; and Messrs. Cutbush & Sons sent a good display of *Rhododendrons* and *Glox*. *Azalea* backed up by *Dracaenas* and *Palms*. From Messrs. Laing & Co. came a collection of fine foliaged plants, edged with tuberous-rooted *Begonias*, amongst which was noticeable a seedling bearing remarkably large scarlet blossoms, and a cinnamon-coloured kind, named *F. M. dos Santos Viana*, a variety likely to prove the forerunner of kinds with new colours; also the double *Gloire de Nancy* and *President Burrelle*. Messrs. Rollison & Son, Tooting, sent a collection of plants, in which were good samples of *Lady's Slippers*, *Crotons*, *Caladiums*, and hard-wooded plants. Mr. Ware, of Tottenham, sent well-flowered samples of the *Pink called Newmarket* and other valuable kinds.

**Calcocalarias.**—These were shown in fine condition by Mr. James, Teloworth. The plants were admirably grown, and the flowers, which consisted chiefly of self colours, were unusually bright. Mr. James' strain was obtained in the first place by crossing the herbaceous with the shrubby kinds, and the result had been a race the most admired of any in cultivation. Mr. Ripley, gardener to R. Hudson, Esq., Clapham Common, had also finely-grown plants well furnished with variously-coloured flowers.

A list of the prizes awarded on the occasion will be found in our advertising columns.

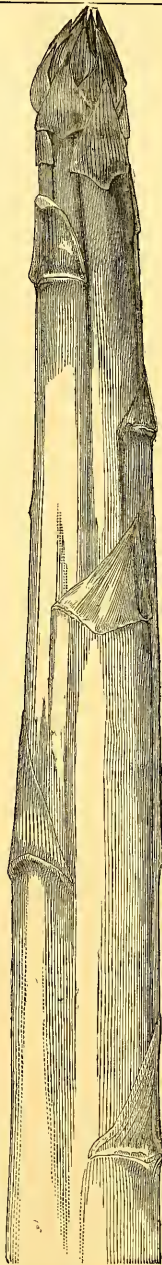

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—Shakespeare.

### FINE ASPARAGUS AT GUNTON PARK.

I HAVE sent you fifty heads of Asparagus grown on the French system, as described in the "Parks and Gardens of Paris." The fifty heads weigh about 7 lb. When I came to Gunton, in 1867, I found the Asparagus beds all on the old system, 4 ft. wide, and the produce of the poorest description. Notwithstanding heavy manuring and salting, it improved but very little. The soil is a sandy loam, resting on wet sand, and the drainage sluggish, owing to the gardens being flat and low. In 1869, having read the chapter on Asparagus culture, I concluded that the plan was the right one, and at once planted seven rows, 102 ft. long. When three years old, the beds had done so well that I began cutting freely, and the following winter I lifted the whole of the old beds, and forced the plants, and since that time we have grown no Asparagus, except in what I may call the new style. Four years ago I made another plantation, 114 ft. by 30 ft., and now we always have an abundance of excellent Asparagus. I, like Mr. Fish, thought when we had the old beds that our soil was not suitable for Asparagus culture; and even now I believe that there are soils much better adapted for the purpose. But what to me proves so conclusively that the French method is the best is the fact that my present beds were raised from seeds saved from the old plants. In saving the seed, I always, however, selected it from the plants that threw up the strongest stems; and before planting I allowed the young plants to grow a few inches, in order that I might select those with the fewest and strongest shoots, as I always find that a plant which, in its young state, throws up a quantity of small young shoots, maintains that habit in succeeding years. A plant of the above description will increase in size rapidly, but will continue to throw up a cloud of small spray, and never by any chance a vigorous shoot. I sowed last year a packet of Conover's Colossal, and have this season planted out two rows, each 102 ft. long and 3 ft. apart in the rows, in order that I may be eligible for your prizes. In my other beds the plants stand  $2\frac{1}{2}$  ft. apart in the rows, which are 4 ft. asunder. I have always thought them rather too close, as at the end of the summer they become a complete thicket. I found amongst Conover's Colossal just the same peculiarity as regards growth which I have described in reference to plants raised from seed saved here. Some of the one year's seedlings of that kind produced some six or seven small shoots, while others had two or three sturdy ones characteristic of the plant. I always maintain that to this matter of selection too much attention cannot be given, if fine Asparagus be the object in view. It may be thought that I allow the Asparagus to get too far through the ground before it is cut, but we like a little more green than the French, as a rule, allow. W. ALLAN.

*Gunton Park, Norwich.*

[With the above interesting communication came fifty heads of the best Asparagus which we have yet seen grown in England. This Asparagus was blanched for a considerable distance up the stem, but not quite so much as the French samples, there being, on an average, about 1 in. more green. There was, however, such a great length of blanched stem, that the Gunton Park samples may serve to throw considerable light on the question of blanched *v.* green Asparagus. The portions cooked were about 7 in. long, and each was edible to its base. For  $1\frac{1}{2}$  in. of the lower part of the 7 in., where the outer skin was tough, the interior was quite tender and perceptibly of a more delicate flavour than that of the upper part. The flavour of the whole was excellent, and the samples well served to show how delicate large and well-grown blanched Asparagus is when cooked fresh. The heads were not so large as the enormous "giant" specimens seen in Covent Garden; but these large heads are often hollow, and not unfrequently

Specimen of Asparagus  
grown at Gunton  
Park (actual size).

"monsters," owing to two stems growing together. Mr. Allan's observation about the different growths of the seedlings is a very interesting one. We would recommend his trying the early and late varieties, so much in favour with the Argenteuil growers, and testing their relative value in England. As regards the blanching, it may be noted that it is only a question of degree between the French and English growers. All good Asparagus that we have seen in either the Paris or London markets is blanched, the best English market-growers' produce being simply blanched 1 in. shorter than that of the French. We believe that there is good reason for this blanching, and that it is not, as many suppose, a mere matter of fashion. It may be remarked that in all well-grown Asparagus, as soon as a shoot gets into the free air, the scales begin to unfold and the head to open out, which, of course, must be avoided, even if flavour be not considered. For our own part, we are convinced that specimens such as those from Gunton Park, with a small portion of the top green, and with 4 in. or 5 in. below that white and perfectly tender, are the most delicate in flavour of all. No distinction can be drawn between these and specimens from the best French growers, in which the head is not allowed to show more than 1 in. above ground before gathering, and which have also from 4 in. to 6 in. of tender blanched shoot below the pinkish or green apex. It may be noted here that Dutch Asparagus is often blanched to a much greater degree than the French.—Ed.]

The following are notes from various correspondents concerning the seven years' prizes recently offered for improved Asparagus culture:—

That many of our notions about Asparagus culture are out of date I have long been convinced, and I am of opinion that all our efforts as respects improvement must lie in the direction so clearly marked out in THE GARDEN, and which should, with thinking men, require no arguments to prove or enforce. If any are dubious about this matter, let them plant half-a-dozen plants 4 ft. apart each way, and watch the result. It is some years now since my eyes were opened to the importance of this by watching the growth of a single Asparagus plant that had sprung up from a chance seed in a shrubbery. Asparagus is a moisture-loving plant, but the site must be well drained; and I am told, although I have not seen it, that it grows wild in the Lincolnshire fens. I should much like to see the Argenteuil system tried on some of the sewage farms where the soil is of a sandy character. Some of the drier parts of the fens would make an excellent trial ground on a large scale in connection with other crops of early vegetables that might be cleared off and marketed before the time the Asparagus growth filled all the space

which would be in July. The plough should then be introduced to stir the surface freely, and be followed by frequent soakings of sewage. To have fine produce the stems must be strong and tall, to nurse and develop the future crowns; and therefore I think it is during the growing period, after the cutting is finished, that liquid manure, or even water itself, would do so much good. But in a thickly-planted bed, no matter how deep or rich the soil may be, there is not room for the growth to expand sufficiently to develop a thicket of sturdy and vigorous crowns.

E. HOBDAV.

*Ramsey Abbey, Hants.*

— In certain soils the Argenteuil system is open to objection, it being inapplicable to districts where clay, heavy marl, or other compact soils prevail; and such soils extend far and wide over England. Asparagus growers in such localities have found by long experience that, in order to obtain a successful result, it is necessary to prepare special composts, and to raise beds above the general level of the ground, so as to keep the roots from penetrating into the cold subsoil, and to secure the increased warmth such elevated beds afford. Asparagus roots will travel 3 ft. beneath the soil, and, reaching clay, they soon decay or fail to act beneficially. The best examples of Asparagus I meet with amongst cottagers and amateurs, where no special care is taken in the preparation of beds, is invariably in districts like Lincolnshire where the soil is light and deep, much of it gravelly sand or light loam resting on gravel. After trying the several plans of surface cultivation, the raised flat-topped beds, and the simple ridge raised from a 3-ft. base, and planted with one row of plants, I have proved that for the soil I have to manage (a modified clay) the last named is far the best plan. It occurs to me also that as your prizes are offered for the largest heads of Asparagus, and not for the amount of produce over a given surface of land, they will reach those who can afford the most space and manure, or will be confined to localities enjoying natural advantages. Could you not restrict the extent of ground, or the number of plants, and make a distinction between Asparagus grown in favourable and unfavourable localities? The economical production of every vegetable should always be made a consideration.

*Belvoir Castle Gardens, Grantham.*

W. INGRAM.

[What is here proposed is desirable, but cannot be carried out. We must do what is best in the interest of all. Suitable soils occur in many localities in every county. Few would expect to produce the best result on unsuitable soils. We have seen good results from the adoption of the thin-planting way on the stiffest and deepest clays in England, though we should not advise anyone to compete for prizes under such circumstances.—Ed.]

— A rich, deep, friable, sandy loam is doubtless the best soil in which to plant Asparagus, and when this is in a high state of culture manure, at the time of planting, is unnecessary. I look upon surface-manuring with far more favour than the more general method of working in so much raw manure at the time of planting, an idea which has done much to deter the public from attempting Asparagus culture so fully as its merits deserve, except in the gardens of the rich. Any ordinary soil, with but little care as regards culture, will produce good Asparagus. Doubtless soils and situation, &c., have much to do with its perfect success; still, our system of cultivation is much at fault.

GEO. WESTLAND.

*Witley Court, Stourport.*

— With the view of improving Asparagus culture in this country, I am of opinion that planting should not be done till May at the earliest. March is decidedly too early in this country, and April, too, in many places. Great blanks would be certain to occur in the beds; and, as by the Argenteuil system very wide planting is recommended, the loss of ground would be great. Certainly, if no preparation of the ground be required at the beginning, it would be a great saving of time and money compared with the old plan, as deep tilth and plenty of manure have always been considered indispensable from the beginning.

J. SIMPSON.

*Wortley Hall, near Sheffield.*

— The cultivation of Asparagus is a subject to which considerable attention has been devoted in various parts of the

kingdom, but, so far as I am aware, always upon the thickly-planted system, whether grown in beds or in lines. The results in the majority of instances are, therefore, the reverse of satisfactory, considering the great expense incurred in the shape of labour and manure in making a plantation. I have already planted some on the principle advocated in THE GARDEN, that is, single plants or stools amongst lines of Gooseberry bushes. I added no manure, but I intend giving heavy top-dressings. My reason for doing so was to let the sun and air in about the plants, to see if I could get them to stand the winter better, as we suffer badly here from their rotting off at the collar during that period. I have tried many plans to prevent this; wide planting in unprepared ground is the last, and I hope it may prove successful.

M. D.

— With regard to the cultivation of Asparagus, I have no the least doubt that the system which you wish to introduce is the best for obtaining large specimens; but I fear it would not answer in the case of market gardeners who have to pay high rents for their land. I consider that my success is partly owing to thin planting compared with that of my neighbours. Last week I paid a visit to a neighbour here who had planted some fresh beds, and who had got three rows in 2 ft. of space, which, of course, is too much crowded. It may answer his purpose for a time, but the beds will soon wear out. I shall plant a few single rows in two different gardens and soils in the manner which you suggest. In America they often grow Asparagus in single rows, but of course land there is much cheaper than here. I have always thought that our plan of growing Asparagus was both troublesome and expensive, and to avoid the facing or earthing up the sides every year I planted two beds about 18 in. below the surface, so that now I have nothing to do but just fork them. I get as many heads in number, but they are not nearly so large, although they have just the same manure as the others. There is also another objection, and that is the cutting, which is a very back-aching job, as both hands must be down on the ground at once. I have not the least doubt that very large Asparagus will be the result of the prizes offered.

A. J. HARWOOD.

*St. Peter's Street, Colchester.*

— I have grown Asparagus on the Argenteuil system for several years, and although I grow it on both systems—that is, in beds and single lines—I consider that that cut from the latter is the strongest and best. I always plant one-year-old seedlings, never older. I leave 4 ft. between the rows and 2 ft. plant from plant, but I think that 3 ft. between them would be better, a distance that I am now trying. As our soil is stony and naturally poor, we trench the ground, incorporating with it at the same time some manure or good loam; we plant in April. As to after treatment, when the plants are established, we apply manure over the roots in autumn and a dressing of salt in spring, when the plants are in active growth, and in dry seasons we give them occasional waterings with liquid manure from a farmyard tank; last, but not least, we have to take great care to support them against wind-waving and breakage, which we do by running a line attached to stakes at proper distances up one side and down the other. This keeps the stems secure.

D. LUMSDEN.

*Blowholm Hall, Sleaford.*

— I like your proposition with regard to the improvement of the culture of Asparagus; there is great room for it, as the majority of gardeners are content to follow in the footsteps of their forefathers, and adhere to the old bed-and-alley system. I have long been of opinion that that system is not calculated to realise the most profitable results, but my aspirations have not gone beyond single rows 3 ft. apart and the plants 18 in. asunder, a plan under which a marked improvement on the old bed system is observable in the size and quality of the heads. It appears to me that the Argenteuil system which you insist upon differs from this only in the greater distance between both plants and rows. As I have not access to any description of the Argenteuil system, I presume the manure is applied annually by way of surface-dressing, and is not pricked in, but allowed to decay, so that eventually it will form a superstratum of decayed manurial matter of a considerable depth, through which the young heads appear in due season. Results which are, however, perfectly easy to attain in some localities cannot

be obtained in others, with double the labour and expense, owing principally to sub-soil and situation.

JOHN COX.

*Bedleaf.*

— Your proposals respecting the culture of Asparagus, of which I much approve, touch one of those cultural points in which I feel myself very deficient, having never got out of the rut of the old thick-set bed system, which gives quantity, but not quality. The only suggestions I have to make to your printed remarks are, that you might mention the depth of the trenches, and also whether or not there is any variety more suitable than another for this mode of culture. I happen to have two rows of one year's seedlings of Connover's Colossal, and those I have planted out in shallow trenches 3 ft. by 4 ft., as you suggest. I have no experience of this variety, and would rather it had been the Giant or Battersea. Your offer of prizes will do much good towards the improvement of Asparagus culture—more so, perhaps, amongst private growers than in market gardens around London and the Vale of Evesham, where it is grown pretty well.

W. MILLER.

*Combe Abbey, near Coventry.*

— Your plan of making the growth of Asparagus more popular is a very good one, and likely to answer the purpose intended; in truth, there is a great deal of ignorance displayed in the cultivation of that vegetable. It is a very common thing, particularly in private gardens, to pile up a great ridge of earth and plant three rows of two-year-old roots on the top of it, thinking that that is the right mode of culture, forgetting that in a few years they will have to pile up more and more, because all those plants which form a number of crowns keep getting to the surface. I believe that growing Asparagus in single roots, about 3 ft. by 4 ft., is the best for many reasons, and one is that it will apparently last for many years if well attended to. I do not agree with some that it is a waste of manure to give it a good supply at the time of starting, and I also think the ground can be too good. The seed should certainly, however, be sown on a piece of the best land, as the stronger the young one-year-old plants are the better. They should not be more than from 4 in. to 6 in. from plant to plant. By this means one gets good strong plants, which will have a good start.

FRANCIS N. DANCER.

*Little Sutton.*

— The prizes offered for Asparagus grown on the Argenteuil system will give a great lift for the better cultivation of that delicious vegetable. At present the greatest bulk of it is grown in beds where the roots are huddled together, and where it is not possible for them to spread so as to produce large heads. I particularly observed a single plant of Connover's Colossal that I planted in the garden here, and which, by keeping it well staked from the time it was a year old till four years, produced very large heads, like the best French-grown Asparagus. The soil was rather stiff, and no extra depth was given it, but well-rotted manure was put on the plant every winter. Since my experience with this plant, I planted in 1876 some in rows 4 ft. apart, and 2 ft. between each plant, and I expect to cut good heads in 1879. I am not an advocate for cutting blanched Asparagus with only the tips green, but it is the fashionable way of eating it at present.

W. TILLERY.

*Welbeck.*

— I have for many years been of opinion that people poison their Asparagus with manure, and many people will not grow it on account of the supposed expense attending its production. I quite agree with the distances apart, plant from plant and row from row, given in THE GARDEN, and think it high time that cultivators and others did away with the fallacy that Asparagus requires any more attention than a plot of Cabbages or Broccoli. Periodical saltings and annual diggings of deep trenches between the beds do no good. The principal thing to be observed in growing Asparagus on the Argenteuil system is the preparation of the ground. Asparagus being a permanent crop, the ground should be dug or trenched at least 2 ft. deep, and never moved with the spade when in a wet or unfriable condition. Of course, in alluvial or sandy light soils the trenching just spoken of may be dispensed with, but depend upon it in about three parts of the soils of Great

Britain a preliminary trenching will ensure success. I have tried Connover's Colossal and find it only the ordinary form of Asparagus when treated under the usual conditions. I have no doubt that larger kinds than any yet grown may be produced, by means of selection, in localities where the plant grows best. I have noticed that Asparagus grown on the oolite in Northamptonshire is very green, and that the tops not over large, but delicious in flavour. Some years ago, when living at Burton-on-Trent, some Asparagus sowed itself adjoining the kitchen garden in a piece of waste ground of a gravelly alluvial character, and this came much larger and finer than the same kind under cultivation buried 6 in. deep in strong pig manure. Ever since then (twenty years ago) I have seen the disadvantage of using so much manure. I do not agree with disturbing the surface of Asparagus beds any more than is sufficient to ensure the destruction of weeds. All clayey soils should be trenched, preparatory to planting, but this may not be always necessary in the case of light ones.

W. ELLIOTT.

*Stapleford Hall, Notts.*

— There are few places inland that can compare with the soil at Argenteuil; besides, the land about Argenteuil is full of Paris night soil before the Asparagus is planted. The same system is practised by Dutch bulb growers. They work into the ground green cow manure to an extent unknown for any crop in England, and first take Potatoes off it. Moreover, there is no soil that I know of in the three kingdoms so light and easy to work as that of Argenteuil. Asparagus is a gross and deep feeder, and can scarcely be too strongly manured. It also likes black, rotten, sea sand. One of the Messrs. Dicksons, of Chester, grows it of very superior quality; but it is grown on one of the reclaimed farms from the estuary of the Dee in salt sand. It also succeeds, under similar circumstances, in the Lothians; and, indeed, any sea-coast place should produce good Asparagus. I cannot help, while upon this subject, expressing great regret that a vegetable so very wholesome and easily obtained should be so completely ignored in cottagers' gardens. A good bed will continue to bear fairly well for fifty years with a little help. If we consider the quantity generally got from even a small amount of ground, say during some six weeks of the year, no other crop of any sort can compare with it. Surely cottagers now-a-days want something else besides Cabbages and Potatoes?

J. FLEMING.

*Cliveden.*

[We may be mistaken, but we believe there are many places in every part of England where soils exist quite as well suited to the culture of Asparagus as those of Argenteuil. We also know, from careful examination of the mode of planting at Argenteuil, that there is nothing whatever in common between it and the Dutch mode of planting bulb; the fact is, that many of the best growers use no manure at planting time. The bulb ground is, on the other hand, lightly enriched. In this connection we may refer the reader to the preceding statements of Mr. Tillery and Mr. Elliot, that chance Asparagus, in waste or unprepared places, did much better than that sown in carefully prepared beds.—Ed.]

— I have read Mr. J. Groom's sensible and practical article on the growth of this, the greatest dainty which our garden furnishes us with. I give also my experience, although only an amateur. For some years I have only cultivated Connover's Colossal, and am convinced that the great increase of size without decrease of flavour is only owing to the better variety, for I believe our fathers took equal pains in making their beds, perhaps more than we do. I plant in this way: Dig a 4-ft. trench 1 ft. in depth; in that place 6 in. depth of broken bottles, shards, brickbats, flints, stones of any kind; then 6 in. of thoroughly good rotted manure, then 2 in. of coarse sea sand, then 4 in. of good earth, next the plants of two year's growth, to be followed by 3 in. of the best mould to be procured; finally, another layer of sea sand, or, if not easily to be procured, a good dressing of salt in any other form, the brine from the pork silt being very good. As to distance, have no more than two lines in a bed 4 ft. wide, so that in no case a plant has less than 18 in. in every direction, nor is the practice to be commended of making the young bed

a nursery for other edibles, impoverishing the soil and destroying the hopes formed of success.

Oregon.

EUGENE E. P. LEGGE, M.A.

[Your system is far from being a good or simple one; it is much too close. It would be worth while to take the broken bottles and bricks, &c., out of the way of the roots. It is not too late yet to try a few yearling plants without any of the attentions described, and you will soon be able to compare results.—Ed.]

**French Asparagus.**—With reference to the common error repeated in a recent issue of "Truth," that "only 1 in. of each piece of the French Asparagus can be eaten," it is necessary to repeat that long experience shows that when French Asparagus is good, fresh, and properly cooked, from 3 in. to 5 in. of the shoot are perfectly edible—and even a greater length than that. Unfortunately, most of the so-called French Asparagus is both stale and tough, from the fact that it is gathered long before it reaches the consumer in London. It does not come solely from Argenteuil, near Paris, where it is so well grown, but also from greater distances. We have lately been trying some samples from Toulouse and Madrid, from both of which great quantities lately came to the London markets. Although good in appearance, their flavour was far from pleasant or natural. Asparagus very quickly spoils when exposed to the air, and one may judge what it must be after being collected in the Madrid market, sent all the way to London, transferred from the wholesale to the retail dealer there, and finally having several days or a week's airing in a greengrocer's window. We do not see why we should eat stale and straggly, if large, Asparagus from Madrid if we can have it both large and fresh in this country. This can be done, we know, and we have offered the prizes for the encouragement of the simplest and best mode of culture. Up to the present time Asparagus has suffered in English gardens through seven to twelve plants being usually placed where one ought to be, and from the needless and costly practice of taking nearly as much trouble in making an Asparagus bed as in the foundations of a house. As to the question of Green v. White Asparagus, that is quite apart from the mode of culture. Those who do not like it blanched have merely to cease blanching it. Our own idea is that Asparagus for eating at table (not that used in cookery) is in its most perfect state when blanched, as at Argenteuil, and also to a slightly less extent in the market gardens round London. The shoots are gathered when about an inch of the top peeps above the little mounds of earth covering each root. In this way the upper portion of each shoot is of a pinkish colour, and the flavour, when fresh, most delicate. This is not our opinion only, but that of good judges who have tried it in all forus in France as well as in England.

**Prizes for Asparagus.**—The Hon. and Rev. J. T. Boscawen has added £5 to Mr. W. Robinson's first year's prizes for Asparagus. The first competition will be held for these prizes at the Bath and West of England Society's Show in 1881. Prizes will be offered for market-garden-grown Asparagus, as distinct from that grown in private gardens.

**Early Flowering of Tritoma Uvaria.**—Whether owing to the open character of the winter or to some other cause I cannot say, but it is certain that this plant near here is displaying remarkable flowering properties. A large bed of it has had some flowers showing all the winter; just now fine spikes are coming up thickly, and in a day or two numbers will be as brilliant as can be desired. There will thus be a glorious sequence of bloom until the winter again sets in. It is a curious fact that, in spite of the many grand properties of this hardy plant, it should hang on the grower's hands like a drug. Yet what a noble decorative plant would it not make for the wild garden, woods, borders, and shrubberies, and for all sorts of situations in which a little colour would be acceptable to light up the surroundings! In such places masses of it would constitute brilliant objects.—A. D.

**Plants in Flower at Heatherbank.**—Among the hardy plants now in flower in Mr. Wilson's collection at Heatherbank, Weybridge, are *Pulmonaria virginica*—the flower-stems 3 ft. high, and the leaves as large as those of a Cabbage, a degree of vigour which we had not before seen attained by this beautiful and long-escarce old plant; *Cypripedium spectabile*—noble tufts in the open border, the handsome flowers well relieved by such masses of "fine foliage" as are not often shown by indoor Orchids; the Pyrenean Rose—charming in flower or bud; *Linnæa trilobis*, in low, spreading tufts, and of a colour that might suit the new "aesthetic" school, and withal not a sad colour; a Solomon's Seal (*Polygonatum latifolium*), with waxy bells in little groups; *Tritoma grandis*—a superb plant nearly always in flower; the Edelweiss in borders; *Dianthus*

*alpinus* in sandy borders; *Myosotis alpestris*—very much larger than it is seen in the north; *Ranonia pyrenaica* in a slightly raised border; *Linnaea borealis* running about quite freely on rockwork; *Omphalodes Lucilia* and *Meconopsis scolastica* in pots. A great number of rare Alpine flowers are growing in perfect health in this garden, showing that the common idea as to their requiring cool, elevated, or northern regions to thrive in is erroneous. With intelligent cultivation, they are as easily grown in Surrey as in Yorkshire. Of course, the soil is "made," and the rock garden not formed on the principle that Alpine plants live on dry air, dust, and brick rubbish—the three elements used in the formation of the ordinary "rockwork."

**Rose-coloured Hardy Water Lily.**—The rose-coloured variety of the common white Water Lily is now in flower (probably for the first time in this country) at Kew, in the pool devoted to hardy aquatic plants in the herbaceous ground. The flowers are as large as those of its lovely white congener, and are of a beautiful deep rose colour. The plants are comparatively small, being in 16-in. pots, and but 1 ft. below the surface. Doubtless, when under more liberal treatment, they will attain the size and luxuriance as exemplified in the type. The variety originated in Sweden some years ago, and now grows wild in some of the lakes and rivers there. We heartily welcome this new addition to hardy aquatics, and hope that ere long it may grace our lakes and rivers in the same profusion as we often see our native Water Lily.—A.

**Plants in Bloom at Norwich.**—The following plants are just now very attractive in my garden, and I comment them to those who do not grow them, feeling sure they will be prized by all who procure them. The first, *Libertia ixoides*, has brownish, yellow-striped foliage and most gracefully-disposed pure white flowers in very large numbers; this is one of the choicest of herbaceous plants. *Hyaacinthus amethystinus flore-albo* is exactly like the species, but has flowers of the purest white. *Habranthus pratensis fulgens*, a most brilliant *Amaryllidaceus* plant, is so unlike most hardy border flowers, as to astonish those who never saw it before. *Gladiolus Histrio flore-albo* is a plant which remains long in bloom. *Campanula Allioni*, one of the dwarfest of the genus, has large flowers half the size of a Canterbury Bell and of the same shape, borne 1 in. above the surface of the border.—J. G. N.

**Lathyrus Drummondii.**—This, though somewhat rare, is a very pretty member of a well-known family. It was put into commerce a few years ago under the above name. I have it growing in an 8-in. pot, trained over a few pieces of spray, and in full bloom. The racemes of blossoms carry from six to nine flowers of a carmine-red colour, and of medium size. The plant is hardy and deciduous, rooting in the winter, and pushing up early in spring from the crown. The form of growth is like that of *Lathyrus latifolius*, but less robust, and the racemes of bloom are produced at every joint. As grown with me, it indicates that, trained over a wire, it might be made into a very handsome greenhouse exhibition plant, and it is certain that a good specimen of it would be regarded as a novel and beautiful object.—A. D.

**Armeria juncea and A. setacea.**—Cultivators have been so long accustomed to the old-fashioned Sea Pink (*Armeria maritima*) and its varieties, that a really good new species is truly welcome. *A. juncea* and *A. setacea* are very similar to each other in general appearance, the former being a little the taller of the two. Both are neat, pretty little Alpines, which were found at a considerable elevation in the south of France in arid, stony places. They form miniature pin-cushion-like tufts  $\frac{1}{2}$  in. to 1 in. high, and 2 in. to 4 in. or more across. The tufts consist of deep green or greyish-green, bristle-like, slightly recurved leaves. The flowers on different plants vary in colour from rose to pink, and in a few instances to almost white, and they have quite a satiny appearance. They are borne in dense clusters on slender wiry stems 2 in. to 4 in. high. They flower so freely, that as many as from twelve to eighteen heads of blossom may be counted on plants not more than 1 in. in diameter. They both grow freely in deep well-drained sandy or stony loam, fully exposed to the sun.—R. P., York.

**Tovaria oleracea.**—This by far the most handsome of all the *Tovarias* or *Smilacinas* yet introduced to cultivation, is now in flower in the herbaceous ground at Kew. It approaches in habit the well-known *T. racemosa*, being about 2 ft. in height, and the stems arch in the same graceful manner. The flowers are borne in broad racemes (about 4 in. across) at the apex of the stems, each individual being  $\frac{1}{2}$  in. across, and produced in large numbers. They are of a pure white colour, which contrasts agreeably with the purplish colour of the stem and flower-stalks. It lasts a long time in good condition. It is quite a recent introduction, having been sent to Kew from high elevations in temperate Sikkim; therefore it is quite hardy in this country.—A.

## THE FLOWER GARDEN.

### MUSA ENSETÉ IN BERKSHIRE.

THIS stately plant is proving as useful and becoming as popular in our gardens as those who knew it long ago supposed it would become. In sheltered nooks in the southern counties it makes a very fair growth in the summer. Last year we were struck with the health and vigour displayed by some plants of it at Park Place, Henley-on-Thames. Mr. Stanton, the gardener there, raised a batch from seed, and it is surprising what noble plants these became in the course of fifteen months from the time of sowing. They were sown in April and planted out early in June, and they became fine plants during the first summer and autumn. Placed indoors early in October, they remained throughout the winter in a warm greenhouse, and were again planted out in June last year, when they formed fine young leaves. The plant is as effective in a conservatory

with no less satisfaction than any other class of plants in cultivation. If we take into consideration their merits as ornamental plants, we find many of them to be simply unequalled, and that there is a charm about them entirely their own; what they lack in height is more than made up in beauty both of flower and foliage. What, for instance, can be more beautiful when well grown than *Gentiana verna*? Nothing that I know of except, perhaps, the *Alpine Forget-me-not* (*Myosotis alpestris*), a plant which grows wild on our Scottish mountains as well as in Switzerland. The individual flowers themselves in some species are not very grand, but, taking the plant as a whole, it becomes all that could be desired.

Alpines may be grown either in pots, in the common border, or on rockwork. Whichever way is chosen, there are three things which ought never to be overlooked, and these are, to see that they have perfect drainage, abundance of water during the growing season, and, most important of all, that the plants are frequently divided. I do not attach much importance to the

Musa Ensete in the open garden at Park Place, Henley-on-Thames.

or any large glass house in winter as it is out-of-doors in warm sheltered places in summer. Our engraving is from a photograph taken at Park Place last year.

### CULTIVATION OF ALPINE PLANTS.\*

THE cultivation of by far the greater majority of Alpine plants is of the simplest possible character; for them no costly erections are required either of glass or stone; on the contrary, every kind of coddling and pampering is death to them. The most that is required in this respect is a cold frame, in which a few of the tenderest kinds, chiefly Indian and North American species, may be sheltered during winter, more from rains than from cold. This frame, too, will serve the purpose admirably of raising seed and striking cuttings during spring and summer. Alpine plants, indeed, may be grown by all with less cost and

kind of soil used; for, except in the case of a few special kinds, as a rule they will thrive in almost any soil. It is a great mistake to suppose that because these plants grow naturally in upland meadows, or it may be on bare rocks, that they will succeed in no other way. The great mass of them will grow freely in any good garden soil, and thrive all the better if there be a little well-rotted manure added to it. All manure should, however, be particularly avoided in the case of a few delicate growing species, such as *Androsaces*, some species of *Primulas* and *Gentians*, &c.; indeed, kinds that are generally termed "miffy" will be found to grow best in pots—at least until sufficient stock is obtained to risk some of them out-of-doors on rockwork or in the front rows of herbaceous borders. Some kinds, particularly *Ericaceous* plants, such as *Andromedas*, *Menziesias*, *Vacciniums*, &c., prefer peaty soil. Growing them in pots is the most convenient way for those who have not much room to spare, and thus treated they are also handy for moving about or for filling up blanks at any time. It is astonishing how well they do crammed into

\* Read by Mr. Robert Lindsay, Royal Botanic Garden, Edinburgh, at a recent meeting of the Scottish Horticultural Association.

small pots; many of them will even keep in healthy condition for years in 3-in. ones. In this way one might grow nearly all the Alpines in cultivation in a very small space. The pots should be plunged to their rims either in sand, sifted ashes, or in ordinary soil; but sand is best, being cleanest. Let them also be well exposed to the sun, and throughout the summer give them a liberal allowance of water. If good specimens be wanted, all that is required is to shift them into larger pots, 6-in. ones being sufficient for most kinds. They should be examined annually, in order to see that the drainage is in good order, and such as require it should be re-potted. Any kinds that it may be desirable to increase should also be torn up into little pieces, each having a crown, and potted singly, an operation to which a great many of them will submit, and spring is the best time for doing it. In the case of kinds which will not divide, cuttings should be put in. With many Alpine plants this constant dividing is the grand secret by which they are kept in a good healthy condition, as when left alone for any length of time they get exhausted, and ultimately die altogether. In low latitudes Alpines seem to live too fast, and become sooner exhausted than they would do on their native hills. There they certainly succeed on the "let-alone" principle, but do they not die out even there? and are there not thousands of seedlings annually springing up to supply their places? In their Alpine home, under clear bright days and cool dewy evenings, they form, while growing, firm, well-ripened foliage, and are induced to flower and produce seed more abundantly than when grown at lower elevations, where their growth is not so well matured. Consequently, we must, especially if they be grown in beds or borders, re-lift occasionally and remove the exhausted parts, which are generally in the centre, keeping the young fresh pieces which are on the outside, and either splitting them up and forming separate plants of them, or squeezing them together again and re-planting them. When grown in small pots we imitate pretty nearly, in some respects, the conditions under which they live naturally; and thus treated they make the same stunted kind of growth that they do in their native habitats. On this account, therefore, the more delicate kinds, such as some of the Androsaces, Primulas, Gentians, and others will be found to succeed best in pots.

The soil best suited for the majority of Alpines when grown in pots should be good fibrous loam, with a little leaf-mould and some roughish sand added; some prefer putting pieces of limestone or sandstone round the collar of the plants, and also in the soil, but I do not think much good comes of such additions beyond that arising from keeping the soil open. A large number, indeed nearly all of them, will succeed in an ordinary border if well drained, but care must be taken to see that they are not encroached upon by stronger-growing herbaceous plants. They are, however, seen to best advantage on rockwork, especially those whose growth is trailing, arranged so that they can hang over the face of the rocks, on which they have a fine effect; but, so far as culture is concerned, it is not at all necessary to have rockwork. As regards the best kinds to grow, it is difficult to say without knowing the positions for which they are wanted, but as they do not take up much room, grow as many as you can get, and if you wish to select the very best, keep an eye on the kinds of which slugs are fondest. So fastidious are the tastes of these pests, that they seldom fail to pick out the choicest on which to feed, passing by with contempt anything coarse or weedy. Hand-picking either at night or early in the morning is the most effectual way of getting rid of them.

The propagation of Alpines, as I have already indicated, is by no means difficult. Most of the Saxifrages and Sedums, some of the Primulas, Aubrietias, and Campanulas, and a great many more should be looked upon as compound plants, which merely require dividing; and, indeed, as I have stated, this is absolutely necessary, in order to keep them in good healthy condition. But there is another section of them which does not form more than single stems, such as Lithospermums, Saponarias, Ethionemas, Onosmas, &c., which may be propagated by means of cuttings. These do best taken off in spring, dibbled into a small frame in a sandy soil, and shaded from very bright sunshine. Thus treated, they will soon take root and form fine healthy plants to take the place of the older ones as they become worn out. No opportunity of collecting and

sowing seed of good kinds should be lost. Many failures in growing Alpines occur through not attending to this. For instance, it is not uncommon to hear people complain that they cannot grow such native plants as *Primula scotica* or *Myosotis alpestris* for any length of time, the reason being that they should be cultivated like biennials. Moreover, though seeds of such kinds be sown, they are very apt to be thrown away before they have time to germinate, *Primula scotica*, if sown in spring, often taking a whole year to come up. If the pots in which they are sown be kept over until the following spring, the young plants will come up so thickly that it is difficult to know what to do with them all. The same thing applies to *Myosotis alpestris*; although it usually does not take so long to come up, yet it should not be thrown away too soon. In both cases the seeds are very small, and in lifting out the seedlings that germinate first you disturb the surface so that the remaining seeds have a better chance of pushing through. After they are pricked out they will make fine flowering plants next spring and summer. The same remarks hold good as regards many more Alpine plants; numbers of the rarest kinds are pretty free seeders, if the plants be at all healthy. *Gentiana verna*, *gelida*, and others, *Dianthus alpinus*, *neglectus*, and other Alpine Pinks, many *Primulas*, *Androsaces*, *Soldanellas*, *Saxifrages*, *Sedums*, and others may be had in abundance from seed, and this is, on the whole, the best way of getting up a good stock of these plants. Besides, you have in this way the chance of getting hybrids, and of selecting forms better than the parent in one respect or another. As yet, but little has been done in the way of hybridising Alpine plants; but there can be little doubt that they are capable of being successfully crossed, all that is wanted being more workers in that direction. The field is a large one and almost new, but now that greater interest is beginning to be taken in their cultivation, we may soon expect to witness important results.

#### THE ROOT HISTORY OF LILIES.

As one of those who have thought, said, and, unfortunately, written not a little that now seems, in the clearer light that "Dunedin" has thrown on the subject, a good deal like nonsense, I wish publicly to express my thanks to this clever writer for his lucid explanations and convincing illustrations concerning the roots of Lilies. I would have done this sooner, but waited to test some of his statements by experiments. As far as these have advanced, they prove conclusively that "Dunedin" is right. The Old World Lilies have a birth and a death a year, and the natural term of the life of most Lily bulbs is two years. Seeing, in such cases, should be equivalent to believing; and "Dunedin's" spectacles have been most useful in enabling most of us to see further into Lily bulbs than we did before. Unlike Butler's semi-classical character, "who consents against his will and is of the same opinion still," I freely admit that "Dunedin" has converted me to his views, in so far as they relate to the root history of the Lily, though I by no means agree with his statements upon leaves contained in his last letter (see p. 451). Catching, as it were, the spirit of modern society, which abolishes childhood and youth and puts mere children into high hats and long dresses, "Dunedin" establishes the independence of germ bulbs at far too early a date. He seems also to unduly narrow the functions of roots, stems, and leaves—all the organs of Lily nutrition—to the flowers. "The functions of the leaves appear to be a combination of the lungs and stomach of animals; they not only modify the food brought to them from the roots, so as to fit it for increasing the size of the parent plant," but of the germ or seed-bulb. No; not the latter, according to "Dunedin." He goes on to say "that the leaves absorb nourishment from the atmosphere, by means of which the vegetative functions are carried on, all tending to the production of the flowers." This sentence is somewhat obscure, though it may be absolutely true, but not the whole truth. The development of the young germ is, however, as much, or more, entitled to be termed a vegetative function as the flowering of the old bulb. But "Dunedin" renders his meaning obvious enough in the next two sentences, and, indeed, throughout the paragraph. That meaning seems to be that the leaves of the Lily have no mission as to the germ bud. Is this really his

meaning? Here is what he says: "When the bloom is complete"—observe not a word about the ripening of the seed even—"When the bloom is complete, the leaves cease to perform their functions, and if not cut down at once they decay gradually, and remain for a long time as unsightly appendages. Nothing can restore them, nor can they in the slightest degree aid the new bulb; for that bulb, even when the parent bulb is in full bloom, is wholly independent of any assistance from outside its own immediate organisation." That is, from the old leaves or parent bulb, I presume. Now, as the seed-germ or succession Lily bulb when first liberated adheres firmly to the core or base of the old bulb, and draws double-refined nutriment from the juice of the tender new core on which it is seated, the question that "Dunedin" has failed to answer is—When does this vital connection between the new germ bud and the old Lily terminate? I submit that the following strong assertions do not answer the question satisfactorily. "To say that either directly or indirectly the succeeding year's flower-stems are affected by cutting down the leaves of the old plant while they are yet green is another mistake; for the roots of the new bulb have been drawing nourishment from the soil for a length of time before the parent bulb has actually begun to bloom." No doubt; but has it not also continued to absorb double-refined food from the core of the old bulb on which it is seated? "Dunedin" adds, "There is no doubt that under such circumstances the new bulb must perfect itself solely by means of its own roots, for all the sustenance that the old bulb could by any possibility afford has been exhausted in bringing to maturity and in perfecting its own bloom." To this it may be replied, that it is as impossible for us to measure the possibilities of Nature as to explain the mysteries of life, and that it is no less a quality of the latter than a function of the former "to incorporate with itself those nutritive particles of matter which it requires, and reproduce structure of its own species or type." Exactly so; and it is as much, or more, the proper legitimate functions of the leaves, stems, and roots to develop the succession bulb or bulbs of the Lily as to cause the older bulbs to bloom. The nutrition of either part of a plant may be mediate or immediate, direct or indirect. For example, food may reach the flowers directly from the roots or through the leaves; it may reach the germ or young bulb in a more roundabout way through the old bulb. Either way, the stem, leaves, and roots, which combine the functions of stomach, lungs, and arteries, are essential to the old bulb, and equally, or more so, to the development of the new one.

The germ bulb, in fact, seems partly parasitic. Cannibal-like, it appears largely to feed upon and finally, and to a great extent, to absorb the old one. Even its own independent roots hasten the doom of the old bulb by cleaving it or draining it dry of juices. It certainly adheres firmly to the core or base of the parent bulb until the latter is well nigh decomposed or absorbed. By this simple process two important purposes are gained. One is the clearing of the old bulb out of the way of the succeeding young one; the other the feeding of the new bulb by the old. A third object may also be gained by this destruction of the central core of the old bulb. The scales become sooner and more widely separated from each other, and, in the case of Lilies, not seldom retain sufficient vitality to form fresh bulletts at their base. Granting that the germ bulbs are thus supported from the old bulbs and their own independent roots, their rapid development is less to be wondered at. They feed at two tables—their own and that of the mother bulb. It is also to be observed that this latter table is sure to be well supplied. It is placed, as it were, in the centre of vitality and growing force on the base or axis of the bulb, where the ascending and descending currents of vitality, those sent up from below by the roots and those sent down from above by the leaves and stem, meet and overflow into the new bulb.

Another point of great importance has also to be noted here. It is more than probable that the major portion of the roots, proceeding from the base of the old bulb, are chiefly occupied after a certain time in feeding the succession or germ bud, rather than the flowering-stem or flowers. Most Lilies have two sets of roots, one proceeding from the base of the stem, the other from the base of the bulb. While the former proba-

bly chiefly feeds the stem and develops the flower, the latter, after a certain stage, doubtless mainly develops the germ or succession bulbs. Still, as the stem and the germ bulb proceed from the same axis, or bottom core of the bulb, it is alike possible and probable that the stem may not only draw strength from the bulb, but also return something to it or its successors. The ability of the stem to do the latter may possibly be measured by the number and size of its leaves, and as these vary much in the different species, it is more difficult than it seems at first sight to lay down or accept any general law respecting the effects of stem leaves on the future bulbs. Were all Lilies as fortunate as the common white or candidum, with its two sets of leaves, one for the development of the bulbs, the other chiefly or solely for the support of the flowers, no doubt "Dunedin's" views and advice in reference to the early cutting down of the stems after flowering might be safely adopted. But the majority of Lilies have no leaves, except on the stems; and as leaves perform the compound functions of stomach and lungs, it follows that to remove them a day too soon may either starve the Lilies, or poison them by impure sap—a fruitful source, probably, of a fatal disease among Lilies. While the leaf of a Lily remains green and has life in it, it ought to be most carefully preserved, for the strong probability is that this Lily leaf is of as much importance to the germ bud near the base of the stem as the Vine leaf to the succession bud in its axil. True, the latter is nearer to the bud, but as until the stem dies the movement of fluids is not arrested, and not even then in and through the roots, the distance between the feeding, converting, consolidating leaf and the germ bud is of little practical moment. At present, therefore, I am unable to accept "Dunedin's" views upon this subject, unless he can make it appear that it is impossible for the germ bulb to be fed through the parent bulb. Experience also teaches that those who grow the finest leaves, and keep them the longest green by liberal culture, also grow the largest Lily bulbs and the most flowers. *Gladiolus* bulbs increase and decay in a similar manner to Lily bulbs. What cultivator has not found to his cost that, by cutting spikes with leaves intact for exhibition or other purposes, the germ or succession bulbs have suffered so much that but few good spikes are produced next season from the plants thus denuded of their foliage? It is impossible to be too careful of the leaves of plants; they are stomach, lungs, and possibly much more; and nothing has yet been proved by "Dunedin" or others to show that Lily leaves are of less moment to Lily bulbs than Potato haulm to Potatoes. Most of us are under great obligations to "Dunedin." I frankly acknowledge one conversion, and am willing to be educated still further by such a clever teacher; but at present my faith is by no means shaken in the power of leaves; and, in regard to Lilies, the more and larger the leaves, and the longer they continue to perform their functions, the finer the flowers of the current year, and the finer also the bulbs for the next.

Since writing the above, I have read Mr. Groom's and "Dunedin's" latest remarks (see p. 489). It will be seen that in the main I agree with Mr. Groom in all that relates to the importance of leaves. Doubtless, too, we will all profit by "Dunedin's" promised further article with fuller illustrations. Perhaps he will excuse me for inviting his special attention to the feeding of the germ Lily bulb through the old bulb, and the time when such feeding terminates. D. T. FISH.

#### AQUILEGIAS FROM SEED.

MANY of your readers would be grateful for particular instructions, derived from successful experience, how to grow these beautiful flowers. *Aquilegia vulgaris* grows and seeds itself readily enough in any garden soil. A packet of mixed Columbine seed, from a good seedsman, if allowed to flower in a piece of spare ground, will afford perhaps one plant in fifty worthy of a place in a mixed herbaceous border, and include pleasing varieties of white, pink, and blue. The plants so selected are well worth the trouble of growing, though the best varieties are most impatient of division and never come true from seed. But your correspondents who tell us (and we are grateful for the information) how we ought to fill our mixed herbaceous

borders recommend us such kinds as *A. Skinneri*, *truncata*, *chrysantha*, *cerulea*, and *glandulosa*, of which we read captivating descriptions and are shown gorgeously coloured pictures at the seed shops, and are told that they will do in ordinary garden soil. I have tried them all, both plants and seeds, and have failed entirely, and have found no one amongst my gardening acquaintances who has done much better. The seeds either do not grow at all or come untrue to name, and the same may be said of the plants. The most beautiful *Columbine* I ever saw in flower was *A. glandulosa*, with which I believe the English market is chiefly supplied from Messrs. Grigor, of Forres, in whose nursery it grows almost wild. I suspect the south of England is too warm for it, as I never could get it to survive a summer. Inferior varieties are often sold for it, especially one with a white centre named at Kew, I think, *A. atrata*, but of no great merit. Others of the choice kinds, as I have read, do very well near Edinburgh, but I have never seen a really good collection of them anywhere in the south. I paid a visit to Kew to-day, where I am sure they would be well grown if the climate admitted of it; but I was particularly struck with the poorness of the collection; there is little else in the bed but varieties of *A. vulgaris*, and these not very good. None of the species I have mentioned above is represented by anything but a name and a blank space except *A. chrysantha*, which does not look very promising. *A. canadensis* also appears as a stunted abortion. The whole bed is a strong contrast to the next, containing the *Thalictrums*, which are models of health and vigour. In conclusion, I may say that I can find no nursery in the south of England where choice *Columbines* are reared; they are generally, I am told, supplied from the north of the island and sold off at once, most of them to perish with the heat of July and August.

Eton. C. W. DON.

### IRIS CRISTATA.

SURELY this charming little plant is not so well known as it ought to be, or it would be met with more frequently than it is? It is one of the best of the dwarf Irises, looking, at first sight, not unlike a lovely Orchid, and there are scores of Orchids not half so handsome. The delicate blue of the flower and its rich markings I shall not attempt to describe. It appears to have some affinity with the *Kämpferi* section of Irises, and is altogether a quaint, delicate plant, which grows from 4 in. to 6 in. high, with very broad leaves for the size of the plant. Its growth is peculiar; it throws out long, slender rhizomes, wholly above ground, which thicken and become fleshy towards the apex, from whence arise the leaves and flowers; here the rooting process again commences, and fresh rhizomes are thrown out, something after the way of the Strawberry; hence, though a very humble plant, it soon covers a considerable space. It is a fine plant for pots and pans. Select the strongest rhizomes with the broadest leaves, and lay them by in the autumn, in some cool shady place, without planting them for about a month; then pot and keep them in a cool pit. This starving, or lifting, process is essential to the free flowering of this beautiful plant, and I have heard that the same process tends to the freer flowering of that noble Iris, *I. susiana*. After all, the way in which to manage *I. cristata* successfully is to plant it among stones, with little or no soil. Thus situated, it seems at home, and the blooms last longer and keep in better condition than when growing on the ground.

Ormskirck.

THOS. WILLIAMS.

*Lobelia pumila* and *Viola Perfection*.—"W. W." (see p. 454) has seemingly missed the drift of my remarks in reference to these plants. The notes referred to (see p. 451) were intended to apply to cases where (as happens here) the *Lobelia pumila* is too much appreciated to substitute anything else. I can endorse all that "W. W." says in favour of *Viola Blue Bell*; it is grown by the thousand in this neighbourhood, and is almost a perpetual bloomer.—W. HURDIS, *Otterspool*.

*Iberis gibraltarica*.—My experience of this differs from that of "A. D.," recorded in your last number (see p. 490). Not only has a large plant lived through the winter, but three or four out of twenty cuttings have survived; indeed, they were all alive at the end of February, and have only dropped off since. *Iberis gibraltarica* is my favourite sort.—BROOKHURST.

## THE INDOOR GARDEN.

### COLOURLESS MARECHAL NIEL ROSES.

I OBSERVE an interesting note by Mr. A. Dean in last week's GARDEN on this subject. The *Marechal* does vary in colour more than any other Rose, and runs through all shades, from the deepest yellow or orange to pale lemon colour, ending at times almost in pure white. This wide range of colour in a single Rose I consider a great merit for decorative purposes. On a back wall in a shady conservatory the *Marechal* is often almost white, while close to the glass on the south side of the same house the flowers are of the deepest orange. The change of colour is almost as great in the open air. The gardens here are large, and we grow the *Marechal* everywhere, on walls of different heights and aspects and as standards in different places. Hardly two of our plants bear flowers of the same colour. On south and west walls it seems partially burnt out; on northern ones it never gets fully developed. Our deepest-coloured flowers have been cut from a plant on the end of a plant stove, the plant thus having an eastern aspect. Next in depth of colour to these are our late flowers on standards, all through July, August, and September. Writing these months suggests to me to add how immensely important it is to plant such a Rose as this all about our gardens. Our most useful *Marechal Niels* are those under glass that come in in April, and those standards in cold borders that continue the supply till the end of the autumn. The late standards generally have their early buds nipped off by the cold spring, and if not they should be removed. The plants have then time to show a fresh crop of buds and produce magnificent blooms late in the season. The *Marechal Niel* is without doubt the most useful of all Roses either for culture under glass or in the open air; and, notwithstanding my passionate love for the sweetest and most beautiful of all English Roses—*Devoniensis*—were I restricted to one Rose, that one would, without hesitation, be *Marechal Niel*. "B. S.'s" experience (see p. 506) is a common one with this Rose. Enormous growths one year, little or none the next, stunted growth succeeded by disease and death at times. The great point is to carry up some fresh shoots every year if possible. A good stock of plants should always be held in reserve. The *Marechal* roots almost as freely as a Willow, and does best on its own roots. I should not think the lead had anything to do with the plants going off.

D. T. FISH.

*Hardwick House, Bury St. Edmunds.*

—Mr. Dean (see p. 495) directs attention to the variations, as regards depth of colour, that occur in this Rose, and for which I am unable to assign any definite reasons. We have had blooms of a lovely deep golden colour grown, as described by "A. D.," in a cool house in full sunlight, while other plants under similar conditions have produced flowers of a pale lemon colour, although equal in size and character to those just adverted to. Perhaps some of our large growers could state positively whether or not variations in colour are wholly attributable to local circumstances, such as soil or culture, as it is by no means uncommon to hear it remarked that a better variety of this Rose is to be procured in one place than another. With plants raised from seed this is feasible enough, but I never heard of anything approaching a fixed character, or what are called "sports" in *Pelargoniums*, occurring in the Rose family.

J. GROOM.

### GREEN-FLOWERED GARDENIAS.

It is not very difficult to see how "S. K." (see p. 506) has failed with his *Gardenias*. The plants love heat, and never more so than when the flowers are expanding. The difference in size and sweetness between flowers opened in the temperature of a conservatory and those expanded in a plant stove, or, better still, a manure or tan pit, with a bottom and surface-heat from 70° to 80°, is something wonderful. *Gardenias* also enjoy a humid atmosphere bordering on saturation. To take them out of a stove temperature and place them in the conservatory when they show flower is to invite failure. When in full flower *Gardenias* will stand in the conservatory, though this injures them. If "S. K." will keep them in heat, without checking them in any way, the flowers will no doubt open and prove whiter than snow. Possibly, too, "S. K." gives manure and more water in excess. *Gardenias* enjoy a humid atmosphere and liberal supplies of water when in full growth in a high temperature; but over-watering in a conservatory would be likely to cause the buds to drop off or not to open. Over strong manure water might also prove as injurious as an excess of water, and manure water is better given after flowering than before. Just as they are making their growth and forming their embryo buds for another season is the time to stimulate the plants with manure water if they require it. After these processes are completed *Gardenias* may be rested for a month or two in a cold

frame, or even on a shady border out of doors. But from the moment they are started until the flowers are fully expanded a warm regimen is best for *Gardenias*; not but what they can be flowered in a lower temperature than that here recommended, but the finest flowers are produced by the treatment just proposed.

D. T. FISH.

Your correspondent should discontinue the manure water, keep them well syringed, and place them in a higher temperature while blooming.

PHILIP LADD.

### DOUBLE-FLOWERED RHODODENDRON.

THE accompanying is a representation (natural size) of the double-flowered *Rhododendron Dalhousie*, of which we gave a short account (see p. 407). It came from Mr. Hossack, Ragley, near Alcester, who gathered it from a truss, in which one flower was single and three

double. Accurate though the illustration is, we regret to say that it fails to show off the full beauty of the flower to advantage.

### TROPÆOLUM AZUREUM AND ITS CULTURE.

MR. HEMSLEY, in his summary of the genus *Tropæolum* (see p. 442), remarks under the head of tricolorum that there appears to be no reason why azureum should not be as easy to cultivate as that kind. There is, indeed, but one reason why it should not be, and that is the delicacy of constitution which it possesses as compared with that of the other kinds. Still, it may be grown well, and when properly treated it is one of the most lovely plants with which I am acquainted. It is one of those floral gems which defy description; the beautiful azure-blue flowers blend so harmoniously with the deeply-lobed, delicately-hued foliage, that once seen in perfection it is not easily forgotten. I would recommend all who have not hitherto grown it to try and master the details of its culture, which are, after all, not very difficult. The fact is, these tuberous-rooted *Tropæolums* have been somewhat overlooked of late. Even the comparatively easily managed tricolorum is far from being extensively grown. This is to be regretted, as they are a beautiful tribe of plants, and well worthy of having a little pains bestowed upon them. Having succeeded in managing them tolerably well, more especially azureum, a few details of my experience may perhaps not be unacceptable. Sound two-year-old tubers are necessary, and they should be potted in the following manner:—Fill an 8-in. pot about one-third full of drainage; on this place a layer of fibrous peat in tolerably large

pieces and some small pieces of charcoal, mixing the two well together; fill up the pot to within 1 in. of the rim with a mixture of fibrous peat, from which the dust has been sifted, and silver sand. Do not make the soil at all hard; on the contrary, merely press it down gently with the hand; then place the tuber therein, just covering it with soil. No ingredient of a close or rich nature must be used in the compost; even leaf-mould I have found too clogging; for this *Tropæolum*, although enjoying plenty of moisture when growing freely, is so impatient of stagnation at the root, that it is absolutely necessary to take every precaution against such an occurrence. It is in this respect that many fail, for if through defective drainage or too close a compost the root be checked or slightly injured, the foliage turns to a sickly hue; the growth of the plant is stopped, and the points of the shoots go in a measure blind. When this once occurs a complete recovery is almost hopeless; the glory of the plant is gone. If the above directions with respect to soil and compost be attended to, there will, with ordinary care in watering, be but little danger of such mishaps. When potted, they should be watered and plunged up to the rim in a north frame, for herein lays one of the chief elements of success, viz., they should never be watered again until they have made shoots some 6 in. in length. If the pots are so placed that they dry out frequently, the bulbs seldom start with any degree of freedom—at least, such is my experience. They must in starting grow away quickly, and this will only be induced by a vigorous root action, to which alternations of drought and moisture appear to be fatal. This *Tropæolum*, like some other bulbs, would seem only to root freely in its early stage of growth, when the soil can be maintained in an unvarying state of moisture—neither wet nor dry. The bulbs should be potted not later than August 1; by the middle of September they will have made quite 1 ft. of growth. A trellis must be affixed to the pot to which they are to be trained, as they will soon branch out from the main stem. During the winter they will have to be kept in a cool, light, dry, airy house, attending to the training, and keeping a sharp look out for fly. By the end of February they will be thoroughly established, and may then have a little weak soot or guano water administered to them occasionally. In March the trellis will be covered and they will commence flowering, when hot sunshine and cutting draughts must be avoided. A well-grown specimen is really very beautiful. I have had them with upwards of 200 expanded blossoms on. It is remarkable how very little known this plant appears to be now-a-days, and very few imagine, on seeing it for the first time, that it belongs to the *Tropæolum* family. I first met with it in flower in Germany, from whence I brought it. These bulbs produced flowers of a beautiful bright blue, but I raised a batch of seedlings from them, and they varied very much, some of them coming quite pale. This pale variety has a much more robust habit, as the bulbs now in cultivation are seedlings raised in Europe, at any rate the greater portion would be so; it is therefore probable that the worst variety now predominates. The true dark kind has in most places probably died out, and seed has been saved from the pale one only.

There is a variety of tricolorum called grandiflorum, which differs only from the type by being altogether larger both in leaf and flower. The flowers differ but little from Jarratti, but with respect to the bulb there is a striking contrast. The bulb of Jarratti, or what I have grown as such, is long-finger shape, so to say, and the stem running underground produces a number of bulbs. I was much surprised, on taking some up that had been planted two or three years, to find quite a handful of tubers in place of the one planted, some of them being quite 3 in. in length, and assuming quite fantastic shapes. Now, grandiflorum has a roundish bulb which has no tendency to increase in this manner. This I have proved by planting the same bulbs year after year; they will increase to the size of a hen's egg, but although I have layered the stem and planted deeply, they have never produced a single bulb. This has often puzzled me, as Jarratti and tricolorum are generally described as one species, and yet the entire dissimilarity of bulb would indicate that they must be quite distinct. Perhaps some of your correspondents may be able to throw some light upon the subject. *Brachyceras* is a very pretty free-growing species, but is, I think, rather difficult to get true. All these kinds

may be planted out, and will thrive admirably in a compost of turfy peat and a little fibrous loam, and they afford a charming contrast when in flower. It would be interesting to know how many kinds are in cultivation, and to have some particulars respecting them. Those of your readers who may have had any experience therein would confer a favour by furnishing a few details. It is time that this elegant genus was looked up a little. I hope to see the day when they will regain their old place in public esteem.

J. CORNHILL.

*Byglect.*

#### FORCED PERSIAN LILACS.

The Persian Lilac, although, as its name implies, a native of Persia, is, nevertheless, a hardy shrub in this country; but it is, at the same time, admirably suited for forcing. Being easily started into active growth, it can consequently be had in flower at any desired season, as it requires but a short period of forcing to bring it into full bloom; and as the flower-buds are formed during the previous season, such plants as are well furnished with them can be readily selected from the shrubberies or the nursery grounds about the end of October. These may be potted and successfully forced into bloom at any time during the winter. It is, however, better to subject plants intended for forcing to a system of preparation, and this is very easily accomplished by selecting a number of suckers with clean stems, which are generally easily obtained from the shrubberies. These should each be furnished with a few young fibres, and the stems should be cut to the length of 9 in. or 12 in., and should be planted in lines in any convenient situation and encouraged to form heads. This they seldom fail to do by the end of the second summer, and the desired portion of them may be taken up with good balls and potted during the month of October, when they will be ready to place in the forcing-house at any time during the following winter. When such plants have ceased flowering they should be placed in any sheltered situation until the middle of April, when the shoots should be all cut close back and the plants again turned out of their pots and planted in the open air. Plants which have not been forced should at this period have the same treatment, as it is necessary that they should be cut back and transplanted every season, in order to prevent their becoming too large. When the planting out has been completed it may, should the weather be dry, be necessary to give the plants a good watering. They will generally produce a multitude of young shoots, which should be slightly thinned out, and most of the shoots left will be found in the autumn to be furnished with a terminal undeveloped flower-bud, and the most promising plants may be selected and again potted for forcing. By this treatment the plants may be kept in good health and forced year after year, but it is better to have plenty of them and to avoid forcing the same plant two seasons in succession. Such plants, in pots some 9 in. or 10 in. in diameter, will generally furnish from fifty to 100 spikes of bloom, which are useful in a cut state, while the plants themselves are exceedingly graceful objects for decorative purposes. Many other species of hardy deciduous flowering shrubs may be prepared in a similar manner, and may with facility be forced into bloom during winter or early spring, such as the Scotch Laburnum, Ribes aureum and sanguineum, the Guelder Rose, various species of Spiræa, Weigela, and Deutzia, and the very pretty double Japan Cherry (*Cerasus japonica* multiplex), with its numerous, snow-white, rosette-like blooms. These are easily forced into flower, and to these may be added plants of suitable dimensions, and well furnished with bloom-buds of such species as the Azalea, Kalmia, and Rhododendron.

P. G.

#### SWEET-SCENTED FLOWERS FOR A COOL CONSERVATORY.

ALLOW me to submit the following list to your correspondent (see p. 506). They all emit an agreeable fragrance, either from flowers or foliage, and in some instances both are powerfully scented; as, for instance, Dicentra, Myrtle, and Geraniums. If a good border of turfy soil could be made many of the plants would do better planted out than in pots. This would include all climbers and such plants as *Luculia gratissima*; Roses, such as *Maréchal Niel* and *Lamarkæ*.

*Heliotropes*, when planted out under glass, attain a large size, and are nearly always in flower if in a light position. *Mignonette* planted in a similar position with the seeds picked off is virtually a shrub. *Magnolia fuscata* should be planted against a wall or pillar, as should also the *Jasmines*. Hardy shrubs, such as *Lilacs*, double *Thorns*, *Syringas*, Belgian and Japanese *Azaleas*, should be potted in autumn and planted out again when the blooming is over. If they could be forced gently, an early bloom will be obtained that would be appreciated. Bulbs, of course, such as *Hyacinths* and *Narcissus*, will be had early in the season, with *Lily of the Valley*, *Tuberose*, and *Lilies* of various kinds following on in succession; but one might write a treatise on this subject and yet not exhaust it. I am assuming that the frost will be kept out, as although a house altogether unheated might be made interesting with hardy plants, or those requiring a slight protection only, yet the enjoyment is much enhanced if the structure be heated so as to keep out frost. *Adenandra fragrans*, *Aloyasia citriodora*, *Azaleas* (Japanese and Ghent), *Boronia megastigma*, *Carnations* (Tree and Glove), *Citrus* (all the Orange family are suitable), *Cytisus Everetti*, *Cheiranthus odoratissimus* (night-scented Stock), *Diosma ericoides* and others, *Doryphora Saesafra*, *Daphnes* (all the family), *Eupatorium odoratum*, and *Eucalyptus globulus* will all be found suitable. The foliage of the *Eucalyptus* yields an agreeable perfume, and when the plants become too large they can easily be pulled up and young ones planted, as it is one of the easiest of plants to raise from seed. *French Lavender*, *Geraniums* (all the old scented-leaved kinds, such as *Lady Plymouth*, *Prince of Orange*, *Radula major* and minor, *citriodora*, &c.), *Humea elegans*, *Heliotropes*, *Hyacinths* (including the *Musk Hyacinth*), *Jasminum grandiflorum* and others\*, *Lonicera fragrans*\*, *Violets* (in pots, specially prepared and potted early), *Lilium auratum*, *giganteum*, and others, *Lily of the Valley*, *Pinks* (including the old white and *Anne Boleyn*), *Lilacs*, *Thorns* (including *Paul's new double scarlet*), *Magnolia fuscata*, *Luculia gratissima*, *Mandevilla suaveolens*\*, *Myrtles*, *Pergularia odoratissima*\*, *Pittosporum Tobira*\*, *Prostanthera violacea*, *Rhynchospermum jasminoides*\*, *Mignonette*, *Rhododendrons* (Himalayan species and hybrids, notably *Edgworthii*), *Roses* (especially *Teas*; lists for culture under glass have often been given in THE GARDEN, and need not be added here), *Musk (Harrison's)*, and *Petunias* (single and double). Those marked thus \* are climbers.

E. HOBBAY.

The leaves of some plants are even more sweetly scented than their flowers, and during the early months of the year the greenhouse should contain plants of such sweet-scented species as the *Myrtle*, *Sweet Briar*, *Aloyasia citriodora*, *Lavendula dentata*; together with several species of the *Pelargonium* from the Cape—such as *crispum*, *odoratissimum*, *tomentosum*, *quercifolium*, *Prince of Orange*, &c.; with the *Neapolitan* and *Lee's Victoria Regina Violet*, winter-flowering or tree *Carnations*, *Mignonette*, *Chimonanthes fragrans*, *Hyacinths*, and *Narcissus*; forced *Lilacs* and *Lily of the Valley*; to be followed by the *Musk-scented Mimulus*, forced *Roses* of the *Hybrid Perpetual* and *Tea-scented* varieties; forced *Pinks*, *Cyclamens*, *Daphnes*, *Magnolias*, *Citrus obtusifolia*, *Jasminum odoratum*, *gracile*, &c. *Diosma ericoides*, *Humea elegans*, single and double-flowering *Petunias*, autumn sown *East Lothian* and *Ten-week Stocks*, *Tuberose*, and a few *Gardenias*, and a plant of *Stephanotis floribunda* might occupy the warmest part of the structure.

*Culturd.*

P. GREVE.

*Lantana* s. *Verbenas*.—*Lantana* and *Verbenas* belong to the same family and come from the same regions; both chiefly from Brazil. Those who are tired of attempting to keep plants of *Verbenas* in satisfactory health through winter should make trial of the *Lantana*. They are not attacked by the insects or mildew that assail their cousins, and they endure the heat and dryness of a sitting-room better, or will keep well in a cellar that does not cool below 40°. The flowers are as bright as and as varied; fine shades of yellow and orange making up well for lack of blue or purple. The bloom is more copious, too, especially on two-year-old plants; and continues longer and steadier. The plants are always neat; no dry, dead, unsightly remains appear, but drop out of sight. The natural habit of growth is ascending and straggling, but they can be kept in any desired form by timely occasional pinching. They may be pegged down, stemmed, round-topped against a wall, or as a green floral pillar, or a lance-stemmed, round-topped miniature tree of bloom. They like full sun and rich soil. Some that were trained here against a white wall facing south-east have been gloriously beautiful, and constantly so until late in Sept., when necessity obliges their close shortening in and potting for indoor preservation from frost. Cuttings are easily rooted in August or Sept., easily kept in a window, and they will begin to flower early in spring.—“*New York Tribune*.”

*Dracæna Incida*.—This is an extremely handsome variety, with foliage of a bright green colour, the older leaves attractively margined with carmine, and the younger leaves rich rose-carmine; the brightness of the colouring enders the plant exceedingly effective.—S.

PROPAGATING.

**CALADIUMS.**—These should be re-potted and started into growth in March, in a stove heat of 75°. After having been at rest during the winter months, all small bulbs that are on the outside of the large one may be cut off and put into pans filled with sandy peat. When large enough, cut off the stem from the bulb (see fig. 1), put it into a single pot, and support it with a stick; drop a little fine charcoal-dust on the bulb where it has been cut (see fig. 2), and cover it over. It will soon push numerous young plants from the eyes; these may be cut

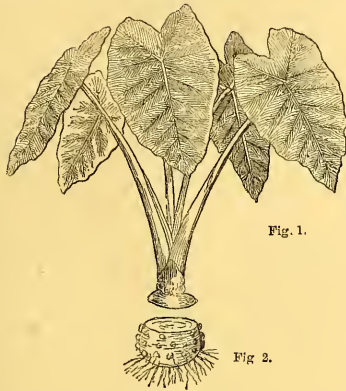

Fig. 1.

Fig. 2.

out and put either into small pots singly or into pans collectively. The tops must be put in the cutting-box for a few days till they are rooted. H. H.

HOW TO GRAFT LARIX KÄMPFERI.

At p. 484 Mr. S. B. Parsons, of Flushing, U.S., informs us of his unsuccessful attempts to propagate this Conifer. As possessor of such fine plants as he describes, he has at command all that is essential to the successful grafting of this plant. It is too late now, but next year, about the beginning of February, or—let me see, spring is later in New York State than here—say end of February, let him dig up a few roots of his large plants, select and cut them in thickness to correspond with either one-year-old or two-year-old scions, and from 4 in. to 6 in. long; cleft-graft them, taking care that the cambium layers of both stock and scion are in contact, and wax over in the way that ordinary root-grafted Apples are done in the United States; pot singly in such soil as he finds to suit the plants, keeping the waxed part above the soil; then place them in a moderately moist case with a temperature of about 65° Fahr. Union of scion and stock will soon take place. From the buds will come forth leaves, leaves so tenderly delicate that the least degree too much moisture or too little will make them rotten or irremediably wilted, the labour being expended for nothing. I can recommend no better plan, pen and ink never yet successfully detailed the “why and wherefore” of the successful graft-propagator, but Mr. Parsons may rest assured that I do not give advice at random, having within easy reach living evidences of personal success in the propagation of *Larix Kämpferi* in this way. It is also, but with difficulty, propagated by means of layering; but, considering the severity of the winters in the Northern States, and the consequent freezing of the soil to a great depth, propagation by this means, of such plants as require to be what is technically known as “down” for two or more years, would be all but impossible, and therefore not profitable. GEO. SYME.

*Lilium pyrenaicum*—This has been the first Lily to flower in my garden this year.—J. E. D., *Epson*.

THE FRUIT GARDEN.

FRUIT GROWING IN SUSSEX.

OUR readers will admit that freely as the columns of THE GARDEN have ever been open to ventilate the nationally important subject of fruit production, yet throughout the discussion we have uniformly endeavoured to impress the fact that very large additions to the fruit-growing power of the country are under preparation in various parts of the kingdom. Not only have we alluded to this extended area for market purposes, but also pointed out that the importation of foreign fruit will continue augmenting until the wholesale price is brought so low as visibly to bring the industry down to be barely remunerative. Worcestershire, Herefordshire, Shropshire, Kent, Somerset, and Hants are all in the field with greatly enlarging fruit acreages. In all the midland counties fruit growing is on the increase, and even far north, up to Scotland, fruit trees have been planted to an extent, limited only by the power of nurserymen to satisfy the wants of those desirous of competing in this new industry. For some years past the sale of fruit trees has been enormous, one firm estimating that 250,000 Apple and Pear trees have been each year absorbed by private gardens of the entire kingdom. The “Sussex Weekly News” calls attention to the plantations of Pear trees, over 60 acres in extent, at Slinfold, in that county. We have been cognizant of these orchards from their first projection, but the owner and planter (Major Walter) has from time to time stayed reference to them, preferring first to remove any seeming doubts as to their prosperity ere speaking of them. With Major Walter pomology has been a twenty years’ pursuit, and he is not a likely man to have settled down in Sussex and to have borne his trees cut and kitten fashion from Cheshire without a beforehand conviction that all was right as to soil and climate; neither has he embarked in fruit tree culture relying on any wild figures as results of existing orchards, however speciously inviting.

The “Southern Weekly News” thus refers to the Slinfold Gardens:—Great interest has been awakened among our Sussex horticulturists by an attempt on a huge scale at Pear-tree growing at Slinfold, near Horsham, and although the enterprise has so far been quietly and unostentatiously prosecuted, yet the work is being watched with interest by pomologists. Notoriety has recently been given these extensive plantations through an article in the “Dumfries Standard,” which runs thus:—“A dear old friend has purchased a charming property in the Weald of Sussex, and turned 60 acres of it into a Pear orchard, in which he has already planted many thousands of Pear trees of the very finest sorts, collected from the best parts of England and the most famous orchards in France, Belgium, and Italy. Some of the trees are as much as twenty years old, raised by the proprietor at his former beautiful place in Cheshire, some from Normandy, and some from the far south of France, and yet but few have been lost. Anything more lovely than the orchard is now, it would be difficult even to imagine. The property is on a somewhat highly-elevated undulating plain, of a clayey-loam soil, deep and rich; when wet as adhesive as mortar, when dry it pulverises and assumes the appearance of delicate yellow ochre dust. Fancy yourself standing on the highest point of ground, where by-and-by a residence will be built, and looking over 60 acres of trees in full blossom, white as sheeted snow, spreading a perfume sweet as the odours that may have floated over the garden of Eden, and then you will be able to estimate the loveliness of the future home of my friend Major Walter. The view is very extensive. Looking to the south, you have the whole of the Southdowns in view, stretching from Chichester almost to Beachy Head; and to the north the lovely Surrey and Kentish range of hills, from Guildford to Sevenoaks, commanding a prospect of nearly thirty miles all round, whilst the central landscape is watered by the Arun, which, winding past the old castle of Amberley and the grand feudal pile of Arundel, enters the sea at Littlehampton. Nithsdale even is not more beautiful.”—It may seem odd that a Scotch writer should first publicly draw attention to this Sussex fruit forest of which the county will doubtless be proud, even though until now its existence has been kept in the dark. The owner, however, is well known in the horticultural world as a Napoleon of Pear-tree culture, and as having been engaged some twenty years at his former home in Cheshire in bringing forward a vast number of these trees now flourishing at Slinfold. Thousands of them varied from twenty to five years old when their removal into Sussex was commenced, now four years ago. That the undertaking is a success no practical fruit grower now doubts. These stand

the trees, and during the last fortnight they have certainly presented a very lovely appearance. When first embarked in, their removal was looked upon by many as Quixotic. As a rule, Sussex men do not entirely believe in matters in which they have had no hand, and, apart from riskiness, much doubt was cast on the suitability of the soil. Many parts of Sussex produce beautiful fruit; we are the nearest to the Channel Islands; in fact, we believe that it vies with the hitherto most favoured districts of England, and may yet prove the garden for the finest fruit products. It is satisfactory to know that this project, fraught with such interest to the county, rests with a skilled and determined hand. A large amount of capital and labour have been expended on these orchards at Slinfold; all the land has been thoroughly trenched, and every means taken that skill can devise to command success. If, therefore, the climate and soil be suited, we may rest satisfied this will be attained; indeed, the undertaking is no longer doubtful."

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Late Keeping Apples.**—Mr. Groom's note (see p. 438) respecting the useful keeping properties of the Norfolk Beesing Apple, which I can confirm from long experience, reminds me that all who must provide Apples all the year round should grow a tree or two of the French Crab, an Apple that keeps sound and good, not for one year only, but two. We generally keep a few over as a curiosity, and though this Apple is not first rate at any age, it is acceptable when no other can be had, and it may also be added that the longer it is kept the sweeter it becomes, which is not very high praise after all. Beesings keep well till Beesings and early Codlins come in, so that Apples all the year is more a matter of consumption and mass to start with than of impossibilities of keeping.—D. T. PISH.

**Market Strawberries.**—One of the finest plots of Strawberries which I have ever seen belongs to an ex-policeman. It is about a quarter of an acre in extent, and consists entirely of that fine market kind Sir Joseph Paxton, which evidently does remarkably well in the rather stiff loam in which it is growing. The plants are respectively three years and two years planted, and are now in full vigour; the bloom has been magnificent and fruit is setting in abundance. Last year this man had from the same bed fruit so fine and so early, that he was able to command 3s. per lb. for the first gatherings. Of course this price was not long continued, but he got all through a good figure, and made a large profit out of the sale. The secret lies in having a good sort, good deep soil, and in good cultivation. There is no rough digging between the rows, which is a barbarous practice, but a top-dressing of short manure is given in the autumn and lightly forked in, keeping the hoe well employed, and then, just as the fruit is beginning to set, littering down well with clean long stable straw—the shakings out of London manure; this keeps the weeds down and the soil cool for the summer. The fine rains and absence of late frosts have rendered the present season, so far, one of the finest on record for Strawberries, and should hot, dry weather ensue, it can hardly now affect the crop, which should be a heavy one.—A. D.

**The Golden Drop Gooseberry.**—In looking over our bush fruits I find that Gooseberries are a thin crop, the severe frosts having caught them just at the most critical time, viz., when the buds were just expanding, and consequently fully exposed to the severity of the weather. After the fruit is set the berries drop down under the foliage, and considerable shelter is thus afforded them. But the above well-known early dessert kind has quite three times as many berries on it as any other variety which we grow. The habit of growth in this kind is more erect than that of the general run of Gooseberry bushes, and therefore not so well adapted for sheltering the fruit in its early stages of growth, but the fruit buds are formed so abundantly on the old wood that, as soon as the leaves commence to expand, they form a compact mass, and afford considerable shelter to the lower fruit buds. As the Gooseberry is a most important crop, some correspondents in different localities may perhaps oblige us with a note on any kind that has proved the most successful this season as a guide for future plantings. This sort may probably find more favour with amateurs and private growers than with market gardeners, as it does not fill the measure so quickly as many kinds; but for hotting green or for culinary purposes we find it most valuable, and, as a rule, it bears so abundantly, that after several thinnings for these purposes a good crop is left to ripen on the bushes. When fully ripe it is much appreciated for dessert, being of good flavour and of a most beautiful golden colour, reminding one at once of its appropriate name the Golden Drop.—JAMES GROOM, *Henham*.

#### PLATE CXXX.

#### ZONAL PELARGONIUMS.

Drawn by MRS. DUFFIELD.

DURING these last few years very considerable improvement has taken place amongst the various races of decorative plants, and in no instance has this been more rapid or apparent than in the case of the family of plants now under notice. The modern Zonal Pelargoniums are, with good reason, supposed to be the result of blending together two or more closely allied species, most probably *P. zonale* and *P. inquinans*, both of which were introduced into this country from the Cape of Good Hope during the early part of the last century or about the year 1710; but for many years afterwards it does not appear that any successful attempts were made to improve them. Within the last twenty-five years, however, they have occupied much attention, and, in order to show how successful the efforts made to secure improvement have been, it is only necessary to glance at the accompanying coloured plate, and to contrast the blooms there represented with the narrow-petalled and windmill-like appearance of the flowers of *P. zonale*, and the coarse habit of growth and paucity of bloom which distinguishes *P. inquinans*. The modern varieties are, on the other hand, characterised by a dwarf and compact habit, foliage of medium size, and great profusion of bloom. The trusses are generally large, set on stout stalks, and lifted well up above the foliage; the individual blooms, too, are large and of the most perfect form, and, as regards colour, that ranges from the purest white to the brightest scarlet and rich purple. There is even on one hand to be found something like an approximation to blue, and on the other an unmistakable approach to yellow. There are oculated varieties, *i.e.*, whites having dark petals with white eyes, and others with white or light-coloured petals and dark eyes; kinds with striped flowers and sorts with double flowers in great variety, from well-formed rosette-like blooms, to semi-double flowered kinds of very large size. The foliage, too, in many cases is highly ornamental. There are golden as well as silver-margined kinds, sorts with tricoloured leaves; and bronze zonals of great beauty. It may, indeed, be said that there are few families of flowering plants so valuable in a decorative point of view as these Pelargoniums are. They materially assist in the decoration of the flower garden during summer and of the greenhouse and conservatory throughout the year; as, under proper management, they are found to be exceedingly valuable as winter-flowering plants. They are of easy culture, and will succeed in almost any description of soil; and the various kinds generally blend or cross readily with each other, hence the numerous sorts or varieties to be found amongst them. The vast improvement, however, which has of late years been effected amongst these plants is by no means to be ascribed to chance or hap-hazard fertilisation, but is, on the contrary, the natural result of the most judicious selection and careful manipulation. All attempts, however, to obtain hybrids between these Pelargoniums and such allied genera as the Geranium and the Erodium, have, I believe, hitherto failed, as have the efforts to induce them to cross with the large-flowered or show Pelargoniums, as they are termed. They blend readily, however, with some of the varieties of Pelargonium lateripes or the Ivy-leaved kinds, and the results of these unions are known as the hybrid Ivy-leaved varieties, many of which are found to be exceedingly ornamental and useful decorative plants. P. GRIEVE.

[The blooms from which our plate was prepared were supplied from the Royal Horticultural Society's Gardens, at Chiswick.]

**The Chameleon Wallflower.**—This plant is the *Cheiranthus*, *Cheiri* var. *Chameleon*, figured long ago in the "Botanical Register." It is very aptly named, as its flowers are continually changing their colour; on first expanding they are of a bright yellow, then gradually become bright purple, and this peculiarity, together with its habit, suggests to me the probability of its being a hybrid between the yellow Scandinavian Alpine Wallflower (*C. alpinus*) or *C. scoparinus* of Tenerife and one of the purple Madeira species—either *C. mutabilis* or *C. arbusculus*. I think it would be interesting if it could be proved; and perhaps Mr. Allen, who has paid much attention to the genus *Cheiranthus*, or some other skilled hybridist, will assist in ventilating this inquiry.—A. W.

A BUNCH OF ZONAL PELARCONIUMS.

## GARDENING FOR THE WEEK.

## Indoor Plant Department.

**Propagating Roses.**—These are not only now propagated much quicker than they at one time were, but also grown on with less delay than they used to be. A favourite method with new and scarce kinds is by root-grafting in the winter, which consists in grafting small scions of the kind to be increased with one or two eyes each upon root-stocks no larger than can be conveniently placed in a quite small pot, and pushed down sufficiently so that after the grafts have taken they will ultimately root from above the juncture where grafted, and in this way get established on their own roots, as they get older if destined for pot culture, or when turned out in the open air if to be so grown. By growing them on under glass with some heat during the spring they attain a considerable size in a very short time, and can, by judicious treatment, be established out-of-doors the summer following; but, if removed from under glass, and planted out without having undergone a little preparatory process by hardening, I have not found them make much progress the same summer; whereas plants that have been grafted at the time and in the way here spoken of have now for a few weeks been kept in cold frames and gradually inured to the air, they may be at once planted out where they are to remain. They should have the soil thoroughly well prepared by moderately deep digging and well enriched with manure, and where of a light sandy nature the addition of sufficient heavy loam, where procurable, and if not a good dressing of marl or clay, which if laid on the surface and exposed to the weather for a few weeks at this season will get so pulverised as to contribute very much to the requirements of the plants. The Tea roses will grow in a lighter nature of soil than most of the other kinds, but the Hybrid Perpetuals, strong-growing Noisettes, and Bourbons will even on their own roots do much better in soil that is either naturally of a strong holding description, or made so by additions of such material as the above. Young Roses that have been so increased I have found with me do better by deferring the planting out till the present time than by turning out sooner, as the check from being grown indoors to full exposure before the weather gets warm has a tendency to stop the progress of shoot development; although there is no doubt that the roots will make considerable advance even if little top-growth takes place, and by this means the plants will be in a position to attain much greater size and strength next year than if kept in pots until the autumn.

**Winter-grafted Roses that are Intended for Pot Culture.**—Such stock as the foregoing, that are to be grown on into pot specimens, should at once be planted as soon as the soil is sufficiently open to occupy are full of roots, as nothing is so much calculated to check healthy development and bring on a stunted condition as insufficient root-room whilst the plants are young. For these, even more than for such as are planted out, it is essential that the soil be made sufficiently heavy, when not naturally so, by the addition of pulverised clay, through exposure to the air, and rotten manure. Ram the material into the pots quite firm, in the way usual in potting operations earlier in the season. One of the chief elements of the success which many of the London market growers achieve, especially with the more tender Tea kinds, is the extremely hard potting they adopt; in fact, the soil is rammed into the pots to an extent that would scarcely be credited by those who have not seen the work done or examined the plants afterwards. The ball of earth is made so close that, even with the sand that is incorporated with it, it might be supposed that the water necessary for the plants would hardly percolate through it; yet such is not the case, and the amount of roots that favourite kinds like Niphetos and Devonians make in soil so closely compressed over that which takes place under light potting is a sufficient proof as to the soundness of the practice, and it may be observed, other cultural details being sufficiently attended to, that the amount of shoot growth and ability to produce flowers will always be proportionate to the quantity of roots which the plants possess.

**Pot Roses Out-of-doors.**—Continue to see regularly to the requirements of the winter-forced pot Roses now out-of-doors by keeping them clear from insects and attention as to water. The latter has been hitherto easily accomplished this season through the more than usual amount of rain we have had, yet not so the destruction of insects, especially aphides, which abound in most places to an extent almost unprecedented.

**Inside Climbing Roses.**—I may again urge the necessity for a free and daily use of either the syringe or garden engine to Roses grown as climbers on pillars, rafters, or the roofs of greenhouses or conservatories, without which it is utterly impossible to preserve them through the summer in a fit condition fair to look upon, or prevent their communicating the pests of red spider and aphides, which they are certain to become a prey to every plant in the house grown under or near them. Not only is this thorough and regular drenching with water essential for the reasons mentioned, but also to enable them to make growth that will produce successful flowers through the summer and autumn.

**Propagating Roses from Cuttings.**—There is no time of the year when Roses cannot be propagated by cuttings, provided shoots in suitable condition can be obtained; and where, as may be said to be almost general, these flowers are held in estimation, it is well to err on the safe side by having enough for pot culture, for should not all the stock be wanted for such purposes, they can be equally well employed for planting out-of-doors. Plants that have been forced through the spring will have produced a quantity of shoots that may either be subject to more air in cold pits, or under temporary lights, or for a few days in the open

air, not having been too long in the latter position, so as to have rendered the wood too hard—will be in a state to afford an abundance of cuttings. For this purpose choose such as are of medium strength, neither too gross nor too weak. Let each cutting consist of two, three, or four joints, inserting them six or eight together in 6-in. pots filled with moderately sandy soil and a little sand on the surface. Give them a good watering immediately, and plunge in coal-ashes in a close frame without artificial heat, but kept shut up altogether for three weeks, shading with mats, so as to keep down the temperature when the sun is on the glass. In this way the cuttings made of say half or three-fourths ripened wood will form a callus at the bottom. As soon as this exists they may be at once plunged in a gentle hothead, where they will root directly, after which time they may gradually be inured to more air and transferred singly to small pots. They will make good little established plants before winter, very much preferable for either out or indoor culture to those struck later in the season.

**Outdoor Roses.**—Those possessing even small collections of outdoor Roses, if they have this year followed the advice repeatedly given through the spring, of taking means to destroy aphides and the Rose maggot, will reap the benefit of the comparatively little labour required by a good display of early flowers, whereas in the absence of such attention, despite the unusual growth which they will have, the evergreen class has made up the whole of the growth, both leaves, shoots, and flowers, is so smothered with these insects as to prevent the possibility of well-developed bloom. This more especially has occurred on walls where insects abound to an extent such as seldom happens, which is, no doubt, attributable to the very mild winter, which left unscathed a greater than usual number of the breeding stock of these pests. Where Roses have been thus neglected, unless immediate means are taken to destroy the aphides now existing, and also the broods of those that will come successively into life, it is futile to expect a satisfactory autumn bloom. In the cultivation of Roses more than most plants, those who give the requisite attention to even a moderate number realise very much more pleasure from the results of their labour than where a greater quantity are grown, yet do not receive sufficient attention at the critical time when the young growth is beset by these pests which are inseparable from the cultivation of Roses.—T. BAINES.

**Plant Houses.**—In the warmer houses air must be admitted early and the houses shut up soon in the afternoon, shading being employed in all cases on bright days. A moist atmosphere and plenty of water at the root, a moderately high temperature and shade are at present necessary for the production of well-developed young leaves and wood; pinching shoots in order to induce a stubby growth, and tying in climbing plants should also be practised. Seedlings and cuttings require potting now and again, an operation to which attention must be paid. Shading must now be given to greenhouses or conservatories, otherwise the plants will quickly shed their petals, and their colours will lose their brightness. All cool houses must be well ventilated, and even at night the ashes may be left a little open.

**Camellias** that flowered early during the winter, and were immediately afterwards put in a little warmth to make growth, will have set, and the buds developed to a considerable size; they must not be kept in heat too long, or they will open their flowers before the time required. If the earliest plants be urged on too forward at this time, it is impossible to retard them afterwards; through inattention in this matter I have frequently seen Camellia flowers opening by the end of August and through September that were not wanted before Christmas. Plants that are sufficiently forward should be at once moved into a cool house, where they will receive plenty of air and be shaded from the sun; see that they do not want for water, as if ever the soil gets quite dry after the buds attain a good size, they will most likely drop, although this may not occur till a long time afterwards, and may not be attributed to the real cause by those not intimately acquainted with the habit of the plants. Any plants that have been hitherto later in blooming than desired should be kept longer in warmth, for it is in the earlier stages of bud-development that the time of their flowering can be regulated, any attempt at forcing them into bloom by the application of heat through the autumn and winter generally resulting in the loss of the buds. Those that did not flower till late in the spring will now be making active growth; they will be benefited by the application to the roots once a week of a mild infusion of soot-water, say as much soot as can be held in the hand to two gallons of water; this will assist the plants in making growth, will give the foliage a healthy, dark, glossy green colour, and will also help to banish any worms that may have got into the pots. Those plants that make their growth late require more shading than the earlier ones.

**Azaleas.**—Of these the latest flowered should now be encouraged to make growth by keeping the house or pit moist with less air than the generality of greenhouse plants require. All except the small-leaved varieties need little or no shade, save in the very hottest weather, and that for a few hours in the middle of the day. Where Azaleas are much shaded whilst making their growth, the leaves always become weak and so far devoid of substance that they fall off in large quantities in the autumn, which has a correspondingly weakening effect upon the roots. Where a house or pit can at this time of the year be devoted to them and such plants as Camellias that are making their growth, there is little difficulty in giving them the treatment they require; but where they have to be grown in a mixed greenhouse with the usual occupants, there is no alternative but to make a compromise between the several requirements of the various plants; in this case they should be placed at one end of the house where the shading can be regulated as necessary, and the syringe

freely used without wetting those subjects that do not need it, admitting the air that is wanted at the opposite end to where they are arranged.

**Pelargoniums and Fuchsias.**—Those large-flowered Pelargoniums, that were some time ago recommended to have the points of their shoots pinched out so as to induce their flowering after the earlier bloomers were over, should now have weak mature water given them twice a week; if neglected in this respect the lower leaves will assume a sickly yellow condition, and the flowering be proportionately deficient. Fuchsias struck from cuttings in the spring and required to bloom late in the summer should again have the points of their shoots pinched out, and any flower-buds they may have formed pricked off; neither must they have their roots confined in too small pots, as this, more than any other cause, will stop their growth and induce them to form flowers sooner than they are required. The earlier plants that are now blooming should have all dead-pods picked off as soon as the flowers have dropped, as the production of seeds is now exhausting to Fuchsias than flower-bearing. Give them liquid manure every other time they are watered, but it must be in a highly-diluted state, as if given them so strong as many plants will bear it causes the flower-buds to drop off. A free use of the syringe two or three times a week will keep red spider in check.

#### Indoor Fruit Department.

**Vines.**—All young Vines in pots should now be growing freely, and manure water may be given them with advantage at every alternate watering. Red spider is the only pest which is liable to damage them after this time, but frequent and copious syringings will keep the foliage perfectly clean. Those Vines that are intended for planting out when ripe should be stopped as soon as they are 4 ft. or 5 ft. high, as the lower buds will ripen and develop better on a cane of this length than on one a few feet longer. It is of benefit to derive from a cutting a great length of cane for planting, as the top, which is generally the best part of it, is ultimately cut off. Fruiting canes may be allowed to grow until they are 6 ft. and 7 ft. long before they are stopped. The growth which breaks away from the top bud after being stopped should be permitted to make a couple of joints above what will be the principal cane. When free-growing Vines of this kind are kept closely pinched at the end, the buds further down frequently burst and grow, and this interferes with the production of good wood. Never grow any kind of young Vines too closely packed together, or in any position where they are deprived of light, or where the sun's rays cannot get at every leaf. A house with a great deal of fire is unnecessary. The more hardy Vines are grown, especially those for early forcing, the less difficulty will there be found in obtaining the best results. Where mildew has been troublesome an abundance of fresh, dry, warm air, which can now be freely admitted to Vines on suitable days, will check its further progress. To eradicate it thoroughly, damp the affected parts and dust them with sulphur while wet, and this is the best time for doing so.

**Pines**—Where suckers on Queens and other varieties are likely to be very small, when taken off in July, all the leaves should be cut back to within 2 in. or 3 in. of the stock, as soon as the fruit is cut, which enables the suckers to obtain all possible benefit from the pot. This course has also the advantage of letting more light and air about the suckers, and making them more symmetrical in form than could possibly be the case when they are crowded round with leaves. Water sparingly after the leaves are cut, but do not allow the atmosphere to become too dry.

**Peaches.**—Early Peaches are now ripening fast under the present warm and favourable weather, and an abundance of air must be given to flavour and colour the fruit. The trees should still be syringed carefully twice a day, to keep the foliage in good health, and as a preventive of red spider; at the same time, no water from the syringe should lodge in the hollow of the fruit around the stalk, as it will cause decay, and the fruit to drop off prematurely. On no account allow the trees to suffer for want of water at the root; this should be attended to continuously until the wood is ripened, especially in light porous soils. The young wood should now be allowed to grow to the full extent to be benefited by sun-light. When the space between the wires and the glass is filled up with young growth, the under foliage gets too much shaded; it also obstructs a free circulation of air over the fruit. When the latter has been gathered, the trees may be still further thinned of this year's bearing wood, to allow room for laying in the current year's shoots. Attention should be paid to the gathering of the ripening fruit; the experienced eye will readily detect such as are ready to pick.

#### Flower Garden.

The principal operation connected with this department, viz., that of planting the various beds, borders, baskets, and vases with their summer occupants, will now be most easily finished; and it is more than ever necessary that order and neatness should be scrupulously maintained. Lawns at this season are often much disfigured by Daisies, and during dry weather, when Grass does not grow very rapidly, the Daisy rake will be found useful. Plantains and other broad-leaved weeds should now be eradicated, if possible, and this may be done by cutting their heads off with a sharp knife, just under the surface of the soil, when they may be drawn out, and the space they occupied will soon be taken possession of by the finer Grasses of which the lawn should consist. Fox gloves may also be cut. It is seldom that it is so late in this season that any weeds of the present time, as the slightest frost occurring soon after the operation has been performed will inflict so much injury upon them as to make them look unsightly for some time afterwards. Bulbs of Hyacinths and Tulips

may now be taken up and stored away. Peg down the shoots and regulate the development of such plants as Verbenas and Potunias, in order to get the surface of the beds covered as speedily as possible, when less water will be necessary than at present. Regulate also the growth of climbing Roses, Honeysuckles, the new and beautiful Clematises, all of which are worthy of a place in every flower garden. Where a stock of the various kinds of spring bedding plants was not divided or otherwise increased when taken from the beds, that may be done now, or as soon after as possible. Such kinds as the following may be divided if desirable to obtain an almost unlimited extent, viz. *Viola cornuta* and *lutea*, *Aubrieta deltoidea*, *deltoidea variegata*, *Cambellii*, *groca*, &c.; *Mysotis distiflora*, *Omphalodes verna*, *Phlox verna*, *Gentians*, *Hepaticas*, *hardy Primroses*, *Oxlips*, &c. The two last named will now be out of flower; but the best varieties should have been marked, and should now be increased accordingly. All these, together with the various double and single Wallflowers, should have what little attention they may require in the reserve garden, which is also the proper place to test, during the first season, the numerous novelties in the way of bedding plants which are annually introduced, and which are generally sent out in the form of very small plants in May. As soon as they are received they should be re-potted, and have every necessary attention; and, where they have been well treated, such plants will now be sufficiently established to be planted out in this department, in order that they may furnish cuttings at an early period as possible, and also afford opportunities of forming correct opinions as to their merits and adaptability to the purposes for which they are recommended. Wherever rural leaders may exist upon young trees, more particularly upon those belonging to the Coniferae family, the strongest and best should be selected, and all other branches carefully removed. An undue tendency to lateral extension is frequently exhibited by young trees of this description, and this should also be checked by stopping, or slightly cutting back all strong side-growing branches, with the view of directing the energies of the tree to the production of upward growth. Pot off seedlings of perennials raised in pots as soon as they are fit, using for the purpose a sandy compost, and put three seedlings into what are known as thumb-pots, placing them round the edges. In the case of strong-growing kinds, however, one seedling in a pot will be quite sufficient. Seedlings of the common perennials should, however, be pricked out into the open border, selecting a shady spot or one over which a shading may be easily placed, until they have become established. Continue to propagate, by means of cuttings, such plants as it is not practicable to divide. Keep a sharp look-out for the seeds of early-blooming plants, and gather them as soon as ready. In the hardy Fernery many specimens will soon be in their greatest beauty, and should, therefore, have their share of attention. The fresh green fronds of various species, and especially of *Adiantum* sp. and *Smilax*, both of which should be carefully searched for and destroyed, and *Adiantum* specimens of *Osmunda regalis* should have an abundant supply of water.

#### Hardy Fruit.

Apricots are often much infested with a small caterpillar that eats the leaves, and this, if allowed to go unchecked, does serious harm, rolling itself up much in the same way as the Rose maggot; it is, however, easily detected. The grub should be gone over as soon as it makes its appearance, and the invader crushed with the finger and thumb. If the fruit has not been sufficiently thinned, at once remove more, not allowing a greater quantity to remain than the trees can support and mature thoroughly, otherwise the produce will be small and comparatively flavourless. See that no trace of aphides has been left on Peaches and Nectarines, or they will still spread, and inflict serious damage. As regards thinning, the remarks made respecting Apricots apply to these trees also. Let the strength of each individual tree be taken into consideration, such as are strong and vigorous being naturally able to support greater weight of fruit than others in a weaker condition, although the latter generally set the greatest quantity. Over-cropping not only gives inferior produce, but permanently injures the trees if continued for a few years, so as often to necessitate their removal. In many cases the situation is blamed for this state of things, whereas, if they were sufficiently supplied with water and not over-cropped they would live and fruit up to a vigorous old age. Watch closely for mildew; if it makes its appearance on the leaves or points of the shoots it will quickly attack the fruit. As soon as a trace of it is found the affected parts must be dusted freely with sulphur; the old-fashioned sulphur-puff is the best and most simple instrument to use for this purpose. If the weather comes dry and the border in which these trees are grown is cropped with anything else, such, for instance, as Strawberries or summer vegetables, it should not be forgotten that the latter materially assist in extracting the moisture from the soil, and necessitate the application of more water, which must be given without stint. Before it is applied in quantity the surface should be stirred with a spade to a depth of 2 in. to admit of its getting down to the roots. In dry situations, where water has to be given, it is often necessary to repeat this loosening process, as the soil gets baked on the surface and causes the water to run off. Do not allow the leaves to overhang the fruit, which should be fully exposed to the sun; but, in this operation, do not go too far, as the extent to which the leaves of Peaches and Nectarines are often destroyed, where excessive disbudding is practised, renders it utterly impossible that the trees should possess their wonted vigour. It is a good idea to cut out the shoots so that all allowed to remain will have a full share of air and light to strengthen and mature the young wood for next year's fruiting; but all beyond this is injurious, as every leaf removed proportionately curtails the formation and power of the roots.

**Cherries and Plums on Walls.**—These are also very subject to caterpillars, and when they appear in numbers they do much harm, not only disfiguring the leaves, but absolutely injuring the trees. There are no means of destroying them, except by going over such as are affected and crushing them. This should always be done as soon as they are discovered, as the longer they are allowed to remain, the more difficulty there is in their destruction. Cherries are also subject at this time of the year to the attacks of black fly on the young shoots. If this pest be taken in time, before they have become dispersed over the trees, and while confined to a few of the shoots, they may easily be destroyed by dipping those that are affected in Tobacco water. For this aphid it must be strong, as it is much more difficult to kill than the green species.

#### Kitchen Garden.

At this season in many places the kitchen garden is subordinate to the ornamental department, but neglect now, either in keeping down weeds or in performing the necessary operations of sowing and planting successional crops, will certainly entail disappointment in time to come; therefore, make every possible effort to keep pace with the season.

**Tomatoes** should now be planted; they may with advantage be grown wherever there is a small portion of wall at liberty, as is often the case between fruit trees; a south wall is the best, but they will frequently succeed on a western or eastern aspect. On the two latter I should recommend the greater part of the shoots being continually pinched in close, so as to bring them into bearing early. In all cases it is better to confine Tomatoes to a much less number of shoots than is often done, thereby enabling more plants to be grown on a given space. The thinner the shoots are kept the earlier they produce fruit. In warm districts Tomatoes will frequently succeed on a sheltered border fully exposed to the sun. Plant them out singly, using two or three sticks to each plant for support, to which they must be kept regularly tied as the growth advances; otherwise, from their fragile nature, they get broken by the wind. Where they are so grown, the ground is better for being poor, as their natural habit of making too much growth is still further increased where the soil is rich. The plants should stand 3 ft. apart each way, so as to avoid their shading each other.

**Sowing Lettuce.**—Make successional sowings of Lettuce, and at this season it is a good practice to drive shallow drills 12 in. or 15 in. apart, and to sow the seeds in the bottom; if the plants can thus be well soaked with water when they require it; advancing crops will be benefited by the application of manure water. Early crops of the Cos varieties should, as they approach maturity, be tied up with bast, which is of much assistance even in kinds that are the most disposed to burn in their leaves and blanch naturally, and, moreover, it improves the quality. Amateurs who have not had much experience in Lettuce growing are apt to tie the ligatures too tight, which bruises the leaves and causes them to rot. All that is required is to draw the leaves together with the hand and tie them snugly to the centre of the head. Keep the plants between advancing crops frequently stirred with the hoe; and where the soil is of a heavy, retentive nature, and was at all wet when dug, its condition will be greatly improved by forking it over to the depth of 6 in. or 8 in., care being taken not to disturb the roots of the growing crops. Ground so treated becomes pulverised by the action of sun and air, and is in a better condition for the roots to penetrate later on as the different crops advance in growth. Small Salads should be sown every ten days, or, at all events, every fortnight; otherwise, the supply will be interrupted. When the weather is hot and dry, let such plants, and especially Radishes, be watered, or they will be tough and stringy. A small sowing of Walcheren Cauliflower should now be made.

**Planting Brussels Sprouts.**—These should now be planted; and in order to obtain a full crop, the plants ought to be got in when they are large enough to bear the weight of produce which will thus be double what it would be if the plants were being confined to the seed-bed. Brussels Sprouts do not require so much room as winter Broccoli; but they must by no means be planted too closely, or they never attain the vigorous hardy condition which alone enables them to stand a severe winter. The nature and condition of the soil in which they are grown has much to do with the space they should occupy. In good, well-manured land they should be put in 2 ft. 3 in. apart each way; in shallow poor soil, they may be placed 6 in. closer, both in and between the rows. Move them, so far as possible, with their roots entire; and, if the weather be dry, give them a good watering.

#### Extracts from my Diary.

**June 3.**—Sowing Canadian Wonder French Beans. Potting off seedling Petunias. Planting out two rows of Carters' dwarf crimson Celery, and one of Spanish Cardoon. Trimming out Pea sticks. Gathering the following twelve sorts of Peas for exhibition:—Ringleader, Emerald Gem, Maclean's Blue Peter, Maclean's Little Gem, Suttons' Bijou, Carters' White Gem, Carters' First Crop, Dr. Hogg Unicorn, Extra Early Premium Gem, Carters' first crop Blue, and William I., and after a fair trial have come to the conclusion that William I. and Unique are the best flavoured and most useful for an early crop.

**June 4.**—Sowing Calceolarias, Cinerarias, and Primulas. Potting on Begonias and Fuchsias. Pricking off Cauliflower plants. Tying out Tricolor Pelargoniums for exhibition. Turning over gravel walks to give them a fresh appearance. Cutting turf for layering Strawberries. Looking over the Cucumbers and Melons, stopping them, and fertilising them where required. Giving all inside Vine borders where the Grapes

are swelling a good soaking of guano water. Cutting dead branches out of Apricot trees, and spreading out those left to give them a better appearance.

**June 5.**—Sowing Carters' Giant White Cos and All the Year Round Lettuce; also early white Naples Onions for drawing young. Planting Brussels Sprouts, Savoy, and Cauliflower plants. Looking over Peach and Nectarine trees, picking off curled-leaved, and washing the trees with the garden engine. Clearing off Spinach and getting the ground dug up and manured for wicker greens. Weeding and hoeing amongst all growing crops.

**June 6.**—Sowing Chervil, Radishes, and Mustard and Cress. Potting off Tomatoes struck from cuttings. Thinning out and transplanting Parsley; also Spinach and Turnips. Commencing layering Vicomtesse d'Harcourt de l'Herbe Strawberry on pieces of turf 4 in. square. Looking over Vineries, stopping the laterals, and thinning the berries where required. Getting the netting put over late Strawberries. Looking over Apricot trees for snails and grubs. Gathering Gooseberries for bottling.

**June 7.**—Sowing Turnips and Spinach. Planting out Sweet Basil on a south border. Thinning out late-sown Beet and Salsify. Commencing clipping Box edgings. Putting Camellias and other greenhouse plants out under north walls. Nailing in the leading shoots of Plum and Cherry trees, and washing them well with Quassia water to kill green fly. Earthing up late-planted Potatoes.

**June 8.**—Potting off Melons. Tying down the leaders of cordon Apple trees. Getting out trenches for the late crops of Peas; also trenches for Celery, and getting the manure into them. Commencing planting out tender carpet bedding plants. Weeding the Asparagus beds and getting them a good soaking with manure water. Sticking Peas and getting them earthed up. Mowing. Rolling the gravel and all Grass that require it, and giving the pleasure grounds a general clear up. Cleaning up kitchen garden and getting in fuel. Fruit in use for dessert: Pines, Grapes, and Strawberries.—W. G. P., Dorset.

#### IXIAS, SPARAXIS, AND SIMILAR PLANTS.

MAY I ask you to give me the names of the three Ixias which I have sent?—M. F. [Naming Ixias is a somewhat difficult matter, inasmuch as they are mostly garden varieties, and, not being entirely hardy, one has not the opportunity of studying them with the same minuteness as plants which are perfectly hardy and constantly, when in season, under one's eye. What you have sent seem to be (1) I. Buccephalus, (2) I. antiaia major, (3) I. Nord. Ixias, Sparaxis, Tritonias, and Babianas may be grown in this country with considerable success. My first attempt was made by forming a bed close to an old shed. During the winter I protected it with shutters, and I was wonderfully successful. In January, 1877, I planted some bulbs which were left over from the autumn, and they flowered well, but too late, the sun's rays soon driving them out of bloom. I left them in the ground, protecting them this winter with Dutch reed mats (see GARDEN, p. 311). The mats, resting on old railway sleepers, were rolled over the bed during the night and taken off in the daytime. I have had a fine display of bloom; many of the Ixias are 2 ft. high, the Sparaxis about 15 in., and the Babianas I have never seen so fine. My success, however, has mainly been on one-half of the beds, which run up to a drain; on the more distant half the plants are neither so strong nor so floriferous. My advice, therefore, to those who wish to cultivate these plants is first of all to look to the drainage. If the ground be naturally well drained, all well and good; simply raise the beds and take care that there is a good depth of soil; but where the land is not well drained and the substrata naturally porous, then drain thoroughly. The plants evidently like plenty of moisture, but it must pass freely away. Established masses will give finer flowers than freshly planted roots, unless the latter be planted early, which is equal to being established. The foliage comes up in the autumn, and it should be encouraged by allowing the rain to get at the soil, but when severe weather sets in protection should be given; but air must never be excluded, except when the frost is severe. Not only the bulbs I have named, but a great many beautiful Cape and Mexican bulbs could be grown successfully under the same treatment, and I would recommend that the beds be always well raised above the ground level. When the bulbs are left undisturbed, a season of rest should be secured, if possible, by excluding rain till the foliage has begun to grow. I may add that I frequently see stray Ixias flowering beautifully and the plants vigorous in my grounds, where they happen to get into a bit of soil in which they seem at home.

P. BARR.

Portraits of Eminent Horticulturists.—I have read several suggestions respecting portraits of Mr. Marnock and others, and also lives of such men. I should think that a book containing good likenesses and lives of such men as Sir Joseph Paxton, James Veitch, Thomas Rivers, John Keynes, &c., would meet with great favour amongst every one at all interested in horticulture.—E. B.

## GARDEN BOTANY.

(Continued from p. 499.)

ARRANGEMENT OF THE LEAVES.—The position of the leaves of a plant, whether cauline or radical, is in itself a character of no importance in systematic botany, but with the arrangement of the leaves on the stem it is otherwise. Unless disturbed by arrest of growth, the interference of insects, or some accidental cause, the arrangement of the leaves of one and the same species is invariably the same, and frequently the same arrangement obtains throughout a large family. Any point of a stem from which a leaf proceeds is termed a node, and the space between two nodes an internode. Internodes may be long or short; sometimes there is practically no

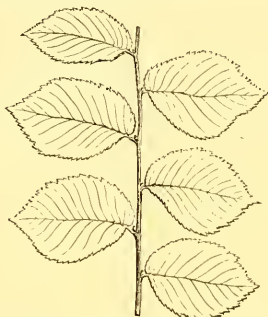

Fig. 176.—Alternate leaves of Elm, with a two-ranked or distichous arrangement.

development of the internodes, and the leaves are crowded together, as in Agave, &c. The number of leaves from the same node may be one, as in the Elm (fig. 176), Oak, Beech, &c.; or two, as in Symphoricarpos (fig. 177), Ixora, Rondeletia, Gardenia, &c.; or several, as in Hippuris (fig. 178), Asperula, Galium, &c. When only one leaf is given off from each node, the arrangement is termed alternate; when there are two from each node or horizontal plane, opposite; and when

Fig. 177.—*Symphoricarpos racemosus*; leaves opposite and decussate.

Fig. 178.—Verticillate leaves of *Hippuris vulgaris*.

there are three or more, verticillate. With regard to alternate leaves, there is a secondary arrangement requiring our attention. At first sight we fail to discern in most instances any fixed order in their arrangement beyond the fact of their being alternate; but if we take branches of, say, *Arbutus*, *Raspberry*, and *Elm*, and try to find, starting from any given leaf, two leaves in a straight line one above the other, we discover that the number of leaves between any two in a straight line is always the same in the same species, though different in each of the plants named. In the *Elm* (figs. 176 and 182) the leaves are disposed in two lines along the branches; consequently, if we number the nodes, as in fig. 182, we perceive that the third and fifth nodes are in a line with the first, and the fourth and sixth in a line with the second. Starting again from the

first node, we have to make only one revolution of the branch before we arrive at another node in a line with the first. This kind of arrangement is called distichous, and may be expressed by  $\frac{1}{2}$ , the numerator indicating the number of times around the branch, and the denominator the number of internodes separating leaves in the same line. This law is practically constant, though liable, as everything else in Nature, to occasional

Fig. 179.—Branch of *Alnus glauca*, in which the arrangement of the alternate leaves is  $\frac{1}{5}$ .

accidental derangements. Tracing the arrangement of the Alder (*Alnus glauca*—figs. 179 and 183) in the same manner, we see that the fourth node is in the same vertical plane as the first, the second, the fifth, and so on. Furthermore, the leaves in the same line are separated by three internodes and, proceeding in a spiral direction, by one revolution of the branch, therefore it may be expressed thus,  $\frac{1}{5}$ . In the Peach (fig. 181) and in the Bird Cherry (fig. 184) the degree of separation is five internodes, with two turns round the branch, or  $\frac{2}{5}$ . The leaves of the Strawberry Tree (*Arbutus unedo*) present a still greater divergence, there being eight internodes, forming a spire of

Fig. 180.—Branch of *Prunus Padus*, showing the two-fifth arrangement of the alternate leaves.

three turns, between two in the same line; and in *Sempervivum tabulare* the arrangement is  $\frac{3}{21}$ . The direction of the curve of the spire is invariable on the same branch, but it is not always the same on a secondary branch as it is on the primary branch from which it proceeds. In the Bird Cherry (fig. 184) the spire turns the same way both on the stem and branches, whilst in the Liquidambar (fig. 185) it turns in a contrary direction. Some-

times the degree of divergence decreases or increases on the same axis. Opposite leaves are usually decussate, each succeeding pair crossing the other at right angles, as in fig. 177, that

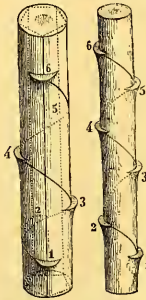

Fig. 181.—Diagram illustrating the arrangement of the leaves of the Peach tree.

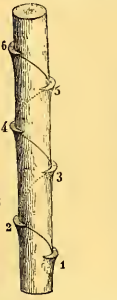

Fig. 182.—Diagram showing the arrangement of the leaves of the Elm.

Fig. 183.—Diagram showing the arrangement of the leaves of Alnus glauca.

is, in four rows, or they are in two rows, distichous.

**DIRECTION OF THE SURFACE OF LEAVES.**—The surface of true

Fig. 184.—Prunus Padus, in which the leaf-spiral of the branches run in the same direction as those of the stem.

leaves is usually spread out more or less horizontally, one side facing the earth and the other the sky; but where the leaves

Fig. 185.—Liquidambar styraciflua, in which the leaf-spiral of the branches turn in a direction contrary to those of the stem.

are reduced to flattened petioles (phylloides), as in most of the Australian Acacias, the surface is vertical. Sometimes true leaves, like those of the Australian Gum trees, have their sur-

face spread vertically, in consequence of a half twist of the petiole. In the same manner the leaves on the horizontal branches of many species of Abies and Picea, which normally would be vertical, become horizontal. The position of the surface of the leaves of some plants is subject to changes due to periodical movements of the leaves themselves or the branches.

W. B. HEMSLEY.

VEGETATION OF SMYRNA AND EPHEBUS.

I LANDED at Smyrna early on the morning of the 27th of April, and proceeded at once by rail to Ayasslook for Ephesus, passing through open undulating plains crossed by isolated ranges of low mountains. The country bordering the railway gives evidence of extreme fertility, though now neglected, the Vine running wild in the broken hedge-rows indicating old culture, overrun by the rich indigenous flora. Amongst the plants noticed by the railway side were one or two very handsome Salvia, Specularia speculum in great profusion, several Echinus, a pink Tragopogon, Asphodelus ramosus, Ornithogalum narbonense, Arum Dracunculus, Tamarisk, Iris pseudo-Acornus, a large handsome Malope, a tall upright purple Linaria, many leguminous plants, and a scarlet Adonis. The vegetation about the ruins of Ephesus was rank in the extreme, in many places almost impeding the passage of the pedestrian, the tall Ferula communis forming conspicuous features in the desolate scene. Asphodelus luteus occurred abundantly on the hillsides, and Cheilanthes odora, Asplenium acutum, and Campanula Erinus on the rocks and ruins.

On the following day I proceeded to Bonjah, a pleasant village situated on the hilly table land four miles out of Smyrna. Here I found Tulipa undulatifolia, which also grows abundantly on the Smyrna racecourse. Bonjah and the surrounding table land of hippurite limestone is the seat of the culture of the seedless Sultana Raisins (Zekirizicidice—Turkish), of which about 10,000 tons are annually produced. The cultivation is somewhat similar to that of the Patras Currant, but the Vines, instead of being trained as a single leader, form a low branching stump from 1 ft. to 2½ ft. high, from which the annual fruit-bearing shoots radiate; no training is required, except an occasional prop under the heavier branches. The harvest commences about the middle of July and occupies about a month, the fruit from the laterals succeeding that on the main shoots. The bunches on being gathered are dipped in a solution of wood-ashes to which a little oil has been added; this is said to expedite the drying, which occupies from five to seven days. As a crop, Sultanas are eminently speculative, the produce of from 7 cwt. to 30 cwt. per acre fluctuating with the season and locality and the price with the crop, and after two or three productive years the value falls below a remunerative rate. They are more costly to cultivate than Currants, and cannot compete with them at equivalent values for general consumption. The demand is therefore limited at remunerative rates. Most of the Vineyards are in the hands of small proprietors; some are absolute freeholds, and others are held under various forms of tenure. They are not found remunerative when carried on by paid labour, and for the most part merely serve as a sort of small savings bank for the spare labour of the working people. Smyrna is also the central emporium of a variety of drugs, both collected wild and cultivated in Asia Minor. Of opium, cultivated in the central districts, from 5000 to 8000 cases of 150 lb. weight each, to the value of about £1,000,000, annually reach Smyrna, and are exported to England, the West Indies, and America. Liquorice, the root of Glycyrrhiza glabra, is also collected from the wild plant growing by moist watercourses a few days' journey east of Smyrna.

Scammony, obtained from the root of the pretty Convolvulus Scammonia, is extensively collected in the neighbourhood of Bonjah and Smyrna. Gangs of peasants are sent out with a good supply of mussel shells, the roots bared and cut, a mussel shell inserted under the incision, and the exuded juice collected from day to day. From the Velonia Oak (Quercus Egilops), and one or two other species, the cups are collected and exported for tanning and dyeing, and the Acorns employed for feeding pigs.

G. MAW, in "Transactions of the Bot. Soc. of Edinburgh."

**Lencojum verum.**—My experience of imported bulbs of the spring Snowflake is that for the first year or two they make little show, but after that time, when established in sandy loam and peat in a somewhat shady border, they flower very freely and regularly. Probably the vitality of the bulbs is impaired by the drying process to which all bulbs are subjected in going through a market, but which has a beneficial effect on some species. I cannot understand the complaint about L. aestivum not flowering freely. It is an excellent plant for the wild garden, and increases as rapidly as the common Daffodil under the same circumstances.—SALMONISSE.

## THE LIBRARY.

## HANDBOOK OF TRAVEL TALK.\*

MR. MURRAY has lately issued a new and carefully revised edition of this handy and excellent book. It is a collection of questions and phrases in four languages—English, German, French, and Italian. The phrases, &c., are such as are really useful and need, and they have been written by professors, viz., German by Professor Buehheim; French by Professor Talandieri, of Sandhurst; and Italian by Signor Genurini. Among the vocabularies is the following one concerning terms used in the garden. (*N.I.*, after certain Italian words, denotes their usage in North Italy, in distinction from Naples. The plural termination of German nouns is, as a rule, given in parenthesis ( ); where no termination is given, the plural is mostly the same as the singular.)

## Vocabulary.

ENGLISH.	GERMAN.	FRENCH.	ITALIAN.
Acanthus	Bärenklau, <i>f.</i>	Acanthe, <i>f.</i>	Acanto
Alder	Eich, <i>f.</i>	Châta, <i>m.</i>	Giunco
Almond	Die Erle (n)	Aune, <i>m.</i>	Ontano. Alno.
—tree	Die Mandel (n)	Amande, <i>f.</i>	La Mandorla
—tree	Der Mandelbaum	Amandier, <i>m.</i>	Il Mandorlo
Anemone	Die Anemone, <i>f.</i>	Anémone, <i>f.</i>	L' Anémone
Annuals	das Windröschen Einjährige (Blumen)	Plantes annuelles, <i>f.</i>	Piante annuali
Apple, —tree	Apfel, <i>m.</i>	Pomme, <i>f.</i> —Pommes, <i>m.</i>	La Mela, il Melomier, <i>m.</i>
Apricot	Aprikose, <i>f.</i>	Abricot, <i>m.</i>	L' Albicocca, l' Albicocco
Artichoke	Die Artischocke	Artichaut, <i>m.</i>	Il Carciofo
Ash	Esche, <i>f.</i>	Frêne, <i>m.</i>	Il Frassino
Asparagus	Spargel, <i>m.</i>	Asperge, <i>f.</i>	Gli Sparagi
Aspen	Espè, <i>f.</i>	Tremble, <i>m.</i>	L' Alberella—trémula
Aster (China)	Aster, <i>f.</i>	Reine Marguerite, <i>f.</i>	Margherita
Balsam	Balsamie, <i>f.</i>	Balsamina, <i>f.</i>	La balsamina
Bean	Bohne, <i>f.</i>	Fève, <i>f.</i>	Le Fave—i fagioli
—, French	Grüne Bohnen—Schneidebohnen	Haricot, <i>m.</i>	I fagiolini verdi
Scarlet Runner	Bunte Bohnen—Feuerbohnen	Haricot d'Es-pagne	I fagioli di Spagna
Bed	Die Beet	Parterre ou lit, <i>m.</i>	Un'aiuola
Beech (Fagus)	Buche, <i>f.</i>	Hêtre, <i>m.</i>	Faggio
Betroot	Rothe Rübe	Betterave, <i>f.</i>	La Barbabietola
Bell-flower	Die Glockenblume	Clochette, <i>f.</i>	La campanella
Birch (Betula alba)	Birke, <i>f.</i>	Blechn, <i>m.</i>	La Betula
Blossom	Blüthe, <i>f.</i>	Floraison, <i>f.</i>	Fiore d' albero, fioritura
Bog-earth	Die Torferde	Terre de bruyère, <i>f.</i>	Melma
Box	Buchsbaum	Buis, <i>m.</i>	Bosso
Branch	Der Zweig, Ast (Aeste)	Branche, <i>f.</i>	Ramo
Broom	Der Ginster	Genêt, <i>m.</i>	Ginestra
Brussels Sprouts	Kohlsprousen, <i>pl.</i>	Choux de Bruxelles, <i>m.</i>	Broccoli
Bulbs — Bulb roots	Blumenzwiebel, <i>f.</i>	Plantes bulbeuses, <i>f.</i>	Bulbi
Bunch of Grapes	Die Weintraube	Grappe de raisin, <i>f.</i>	Grappolo d'uva
Bush	Strauch, <i>m.</i>	Buisson, <i>m.</i>	Cespuglio
Cabbage	Kohl, <i>m.</i>	Chou, <i>m.</i>	Il Cávolo — <i>le verze</i> (N.I.)
Camellia	Camellia	La Camélia	La camelia
Campanula	Glockenblume	Campanule, <i>f.</i>	La campanella
Candytuft	Iberia	Thlaspi, <i>m.</i>	L' Espéride—viola (Ibèride)
Caper (Capparis spinosa)	Kaper, <i>f.</i>	Caprier, <i>m.</i>	Il capperò
Carnation	Garteneulke, <i>f.</i>	Gillet carné, <i>m.</i>	Garofano
Carrot	Die gelbe Rübe—Möhre	Carotte, <i>f.</i>	La Carota
Cauliflower	Der Blumenkohl	Choufleur, <i>m.</i>	Il Cávolo fiore
Cedar	Die Ceder	Cèdre, <i>m.</i>	Il Cedro
Celery	Der Sellerie	Cèleri, <i>m.</i>	Sèdano
Cherry	Die Kirsche	Cerise, <i>f.</i>	La Chriegia
Chestnut	Castanien	Châtaigne, <i>f.</i>	Una castagna
—tree	Der Castanienbaum	Châtaignier, <i>m.</i>	Il castagno

\* Orchidées, famille de plantes. Orchis, plante herbacée.

In the year 1878-77 about 110 acres of new land in Bengal were planted with Red Bark trees.

## TREES AND SHRUBS.

## COLOSSAL FIG TREES.

THE genus *Ficus* is essentially a tropical type. Few of the species are native even of sub-tropical regions, and *F. carica*, the common Fig, is the hardiest of them all. A large proportion of the species—and they number several hundreds—are arboreous, and many of them attain truly gigantic dimensions. They are spread all over the Tropics, but they are especially numerous in India and the Malayan Archipelago, where they constitute one of the most conspicuous features of the arborescent vegetation. In variety of habit, amazing vigour, and rapidity of growth, as well as in size, this genus is unsurpassed. Devoid of showy flowers themselves, Fig trees in

cially in the half desert parts, where it is almost the only umbrageous species. The fruit is edible, though inferior to that of *Ficus carica*.

**The Banyan (*Ficus bengalensis*).**—Assuredly the Banyan tree ranks among the wonders of the vegetable world. Every traveller in India is struck by the peculiar and prominent feature it forms in the landscape in many parts, from Bengal to the foot and on the lower slopes of the towering Himalayan mountains. Brandis states that the Banyan sends down aerial roots from the branches to a greater extent than any other Fig. These roots, which he calls "rootdrops," penetrate the ground and afterwards grow into trunks, which serve as a support for the horizontal branches and as feeders, and thus gradually increase the diameter of the crown. In Bengal there are many specimens with the crown 200 ft. to 300 ft., or even more, in diameter. Colonel Sykes mentions one at Mhow with sixty-eight stems descending from the branches, and capable of

The Sycamore (*Ficus Sycamorus*).

tropical countries support a host of brilliant parasites and epiphytes, such as Orchids, Bromeliads, Loranthus, &c. Some of them, too, are epiphytal or terrestrial themselves, as best suits their purpose, whilst others quickly spread over a large area of ground by means of descending rooting branches. The following are some of the more noteworthy species:—

**The Sycamore (*Ficus Sycamorus*, or *Sycamorus antiquorum*).**—The Sycamore, or Sycamore, as it is sometimes spelled, of the ancients, inhabits the countries bordering the Red Sea, and is equally noteworthy for growing in a sterile soil, where trees are scarce, and for its very large size. Bruce mentions some very ancient and large trees he met with between the Red Sea and the mountains of Abyssinia. It abounds also in some parts of Egypt, and Syria, and Arabia. Hasselquist states that the Sycamore is a "huge tree, the trunk often being 50 ft. thick." The same writer declares that the ancient Egyptians made coffins of the wood of this tree, wherein to lay their embalmed dead, and coffins of it 2000 years old were found. For its shade, this tree is invaluable in the countries named, espe-

affording shade under a vertical sun to 20,000 men. Colonel Drury relates that there was formerly a tree of this kind near Fort St. David, which was computed to cover nearly 1700 square yards. The height of the Banyan tree is from 70 ft. to 100 ft., and the main trunk does not usually grow to a large size, as it is supplemented by so many auxiliaries. In its cooler habitats in Northern India it forms fewer rootdrops, however, and the main trunk is commonly 25 ft. to 30 ft. in girth. Frequently the seeds are dropped by birds in the forks of other trees, and especially in the axils of the leaves of the Palmyra (*Borassus flabelliformis*), where they germinate and send down numerous interlacing roots, embracing and finally choking the unfortunate nurse tree.

**Australian Abbey Tree (*Ficus colosea*).**—This tree inhabits the banks of rivers in Queensland, Australia, and attains more than 100 ft. in height. But it is not remarkable so much for its height as for its widely-spreading branches and the enormous abutments of its trunk, by reason of which the colonists have given it the name of "Abbey Tree." It has ample woolly leaves, which afford a grateful shade in a country where shade-giving trees are not numerous. True,

in Queensland already the Gum trees are to a great extent replaced by trees of a more tropical Asiatic character.

**Indian Caoutchouc Tree** (*Ficus elastica*).—This Fig tree is probably familiar to more persons in Europe than the one which furnishes the fruit of our tables, as it flourishes indoors both in town and country. Its hardness, indifference to the fumes of gas, to dust, to uncertain watering, and, indeed, to neglect in general, entitle it to our highest respect. Few persons who have had it for years in their rooms would imagine that it formed one of the giants of the forest, that it towers above the surrounding trees, or that its trunk sometimes attains the astonishing size of 75 ft. in circumference. Yet Griffith describes such a specimen, the spread of whose branches covered an area of 610 square ft. It is a native of the country skirting the foot of the Himalaya, and, like many others of its genus, adapts itself to circumstances in the struggle for existence, being often epiphytal in the early stage, and subsequently establishing itself in the earth, to the destruction of the tree that nursed it.

**The Peepul** (*Ficus religiosa*).—Buddhists and Hindoos alike venerate this handsome umbrageous tree, and it is said to be peculiarly sacred to the former. In foliage it is not unlike a Poplar with ovate or heart-shaped, long-pointed leaves, borne on long, slender stalks, so that the slightest breeze causes them to move with a rustling noise. It grows 80 ft. or 90 ft. high, and has a short, fluted, and buttressed trunk of most irregular shape, and commonly 25 ft. to 30 ft. in girth. This tree is commonly distributed, particularly in moist localities, throughout India, and is generally planted near pagodas, houses, and other buildings. The natives are all of them most unwilling to cut it down, but, as the wood is perfectly useless, it is undesirable. The seeds of the Peepul, like those of the Banyan and other Figs, are conveyed by birds, and often germinate on other trees or in crevices of buildings, occasioning much damage if not removed in time. In the Himalaya Mountains planted trees are found up to an elevation of 5000 ft., and it is also common in some parts of China. The Chinese use the skeleton leaves for painting, examples of which may be seen in the museum at Kew.

W. B. HEMSLEY.

#### EARLY OPENING OF KEW GARDENS.

A SINGULAR document is being circulated among the members of the House of Commons *apropos* of Sir Trevor Lawrence's motion for the early opening of Kew Gardens. The following are a few extracts from it:—

Having an extensive acquaintance with botanic gardens in various parts of Europe, and being personally acquainted with many directors of such institutions, we may claim to express an opinion on the subject; and we are the more anxious to do so that, having known the Royal Gardens at Kew for the last thirty-five years, and having seen them gradually rise from a condition of inferiority to their present uncontested pre-eminence, we now apprehend that such a measure would infallibly lower their scientific importance and diminish their value to the nation. \* \* \* \* We have more than once had the opportunity of discussing the matter with the Director, Sir Joseph Hooker, as well as with the other officers of the Kew establishment, and, while feeling sure that we are not biased by personal friendship, we have no hesitation in asserting, on grounds of public interest, that it would be impossible to maintain the institution at its existing level if the object proposed by the present agitation should be effected. \* \* \* \* We appeal with confidence to the experience of all who are acquainted with the management of large gardens in saying that the perfection of keep and finished beauty which are unattainable in any country but our own cannot be maintained without an amount of supervised labour which it would be hopeless to attempt to perform in grounds frequented throughout the day by the public. Equally incompatible with the presence of crowds of visitors is the work of the scientific staff, consisting, as it does, in the examination and re-arrangement of the collections, and the revision of the tens of thousands of labels attached to the plants. All this work is now carried on daily from early morning till noon; and it requires not only activity but excellent organisation to complete it within the time available. From the hour at which the general public is admitted serious work becomes impossible. Between the absolute necessity for keeping a watch on the proceedings of the miscellaneous assemblage that resorts to the gardens and the interruptions inevitable from the mere presence and frequent inquiries of visitors, it is not found possible to pursue any but necessary mechanical work arranged beforehand. If the same interruptions are to continue throughout nearly all the working hours, the scientific work of the gardens, in addition to that mentioned above, must also speedily fall into arrear, and the decline of Kew as a scientific, no less than as a first-class horticultural institution,

will at once commence. This may, perhaps, hardly fall within the anticipations of those who are exciting the present agitation, or may be even a matter of indifference to them; but the loss and the discredit will fall on the nation if, having possessed such an unique establishment, it should forfeit its advantages by yielding to a local and temporary outcry. It must not be forgotten that at the present time all persons of respectable character anxious to obtain access to the gardens for scientific or other special purposes readily obtain admission during the forenoon, and it is actually resorted to in this way by artists, as well as by gardeners, horticulturists, and botanists. The proposed admission of the public during the morning hours would greatly interfere with persons of this class, who certainly have more claim to consideration than those who merely seek recreation or a convenient place where to send their nursery maids and children. It would be especially hard upon the two men to whom the nation owes the present condition of the gardens at Kew if the labour and skill that have resulted in making these the most beautiful and attractive of all botanic gardens, as well as the first in a purely scientific sense, were to be the cause of their ruin. If science alone had been recognised, if the gardens had been laid out in ugly square beds divided by straight gravel walks, to which, as in many foreign gardens, the public had been restricted, they would not have supplied a delightful resort to our crowded population, and science would not have been called on to surrender them to mere pleasure-seekers.

There are statements in the above strange document, signed by John Ball, M.A., F.R.S. & L.S., and Robert Hogg, LL.D., F.L.S., which will be most surprising to those who know the gardens and their management best. As usual in documents of this character, it is assumed that only the public are shut out, whereas we have shown that horticulturists have been deliberately shut out, and their recent admission, through some side gate after certain declarations on their part, has been only quite lately conceded, though long called for.

— Having heard much of the terrible results that would ensue were Kew Gardens to be opened to the British public in the morning, I determined to see for myself the present state of things inside the gates between 10 a.m. and 1 p.m. I accordingly disguised myself as a German botanist, stuffed my pockets full of dried herbs, put on a pair of blue spectacles and a stoop, and having obtained a special order from Sir Joseph Hooker, went down on one of the beautiful mornings we had last week nominally to take notes of the "blending of the pistils in the indehiscent varieties of monothalamic fruits." Having carefully brushed my hat the wrong way, and blacklead-pencilled my nails on the journey down, I was received with great deference by two assistant gardeners and directed to the monothalamic fruit house. On my way, I walked all over the open part of the gardens, and the result was that I came across in all forty-one individuals—of whom thirteen were gardeners, or labourers, merely weeding or bedding out, or something of that sort. Of the rest, no less than nine were favoured young ladies—perhaps relations of the director and his staff—who were most comfortably ensconced on snug seats, reading novels from Mudie's, and who, of course, would be very indignant at being interrupted by the public. The number mentioned also included five aged gentlemen, who may have been eminent botanists, but who were most certainly fast asleep in garden chairs; eleven other gentlemen not aged and not asleep, but all apparently engaged in testing the effect of cigar smoke on open-air evergreens; and three foreign savans, sitting in solemn silence round a small shrub, and examining its buds in turn with a magnifying glass. I did not trouble to look into the hot-houses and other buildings, since the rapacious public does not even dare to ask for these to be thrown open all day for its selfish satisfaction. But I had seen quite enough, sir, to feel assured that the unreasonable wish of the four million inhabitants of this great city would never be granted. And should think not, indeed! What, sir! are nine young ladies, accustomed to read their novels in sweet quiet, only pleasantly disturbed by the occasional advent of some of the fumigating young men, to be ruthlessly driven from their seats? Are five aged gentlemen used to bask in the morning sun and sleep, unannoyed by noisy multitudes, to be deprived of their open-air nap? Are thirteen gardeners, who now work in solitude, to be subject to the searching eye of the thousands who help to pay for them? And are the three foreign savans who honour Kew with their presence to be subjected to the noise of a British crowd? Of course, sir, the answer, which I will not delay till next week, is "Never! Never!!! Never!!!" And really, after seeing what I have told you, I am amazed that the public has had the impudence to dare to suggest an arrangement which would result in such wide-spread inconvenience and annoyance.—"Funny Folks."

— The reasons for keeping Kew closed to the public all the morning are more 'Kew-rious than cogent. The assumption that

fect privacy is necessary to enable certain old dry-as-dust professors to watch the Grass grow, or to study the habits of polyandrous Polyanthuses, is simply absurd. If these old boys must botanise alone, let them be locked up in the glass-house with their specimens, and the public forbidden to even stop to stare at them as they pursue their particular task. But to say that thousands of visitors, eager for the fresh air, and pretty sights of the gardens, would interfere with the progress of botany as a science, by quietly walking about in the gravel paths and gazing at the beauties of the scene, is ridiculous. No, no; we must have those gardens opened, Doctor, by Hook-er or by Crook! You really must see what you can do in the matter, Dr. Hooker. We used to take your part in the days Ayrtoun came down on you and your scientific colleagues so heavily, and really you ought to return the compliment by taking our advice in the present instance. You have, believe us, a splendid chance of playing a brilliant stroke if you will only manage your "Kew" property. So go in, Doctor, for a regular "open game!"—"Figaro,"

### ANSWERS TO CORRESPONDENTS.

**Rose Roots and Lead.**—I do not think that the lead can have injured the plant of *Maréchal Niel* (see p. 506). I should rather be inclined to look for the cause in the want of sufficient depth of good soil. I have never found plants of *Rose* to do well for more than two or three years under glass. I generally take them up after that time and plant fresh ones.—R. N. G. BARNS.

**Malformed Fuchsias.**—Herewith I send you a curious deformity in a *Fuchsia*. What could have been the cause?—G. [It is difficult to say; malformations frequently occur in *Fuchsias* bloom.]

**Blighted Roses.**—I know of no remedy for *Rose* trees which are so blighted as "E. J. G." describes (see p. 508). The better plan is to attack blight as soon as it makes its appearance; a few washings with soft soap and water, followed by syringing with plain water, will generally remove the spidings; but the great thing is to encourage vigorous growth from the first, as *Roses* that are growing well seldom suffer much from blight.—R. N. G. BARNS.

**New Zealand Spinach.**—Where can seed of this be got?—J. B. [From any seedsman.]

**Camellias and Azaleas from Seed.**—Will some of your contributors be good enough to inform me if *Camellias* and *Azaleas* can be raised in a greenhouse from seed? If so, what can the seed be obtained? and in what small quantities and price?—A. S. W. [Camellias and Azaleas may both be raised in a greenhouse from seed, but the result would be very disappointing. Four or five years would elapse before the seedlings bloomed, and ninety-nine plants in one hundred would produce flowers not worthy of notice. Seeds of both could be obtained from most Continental seedsman, possibly from Messrs. Vilmorin, Andrieux, & Co., Paris.]

**Insects on Chestnuts.**—W. S. C.—The minute, red-brown objects so closely congregated together in the crevices of the bark of the Chestnut tree are Acari or mites. If you examine them with a pocket lens you will find that they have eight legs and a well-marked proboscis; and if you well rub some of them from the bark on to some white paper you will find that they make free use of their legs and crawl about with ease. They might be easily killed by washing the bark with gas water, but I do not suppose that they are very injurious, if confined to the bark. Are they found on the leaves as well as on the young succulent wood?—W. W. S.

**Insects Attacking Timber Trees.**—I know of no remedy against the attacks of the insects mentioned (see p. 508) which could on a large scale be brought to bear efficiently and prevent further mischief. Picking might be resorted to in the case of young trees, but this would do but little good if larger and unpicked trees were near. The subject has had the attention of many intelligent men both in this country and abroad. I have suffered much myself from the larvae in question. I have tried various remedies, but none but picking, with attention, has come to my knowledge.—W. W. S.

**Names of Plants.**—G. T.—1. Apparently *Begonia Prestoniensis*. 2. *B. nitida* coccoloba. 3. *B. Weltoniensis*. 4. *G. B.*—*Aucus gracillima*, a Swan River shrub.—A. G.—Potato blight, apparently injured by frost.—W. W.—Apply to any of the great London plant nurseries. We cannot recommend any particular house, or give prices.—K.—*Papaver orientale* and *Hydrangea quercifolia* very ornamental as sent. It is quite hardy, but we have not seen it flower so well out-of-doors as your specimens.

**Edible Cucurbits.**—I read in the "Bon Jardinier" for 1876 that *Cucumis arada* and *Benincasa cerifera* are delicate eating. Can any of your readers tell me if they are really wholesome and good, and if they are the same as those mentioned under the above names in Messrs. Henderson's catalogue?—A. SCHRIBER, Co. Clare, Ireland. [Seeds of these Cucurbits can be had from any good seedsman. *Benincasa cerifera*, though largely used in India for carries, is hardly known in Europe as a vegetable. The fruit is intermediate between a Marrow and a Cucumber; it is used as the latter when half grown, but the flesh and taste are not so pungent, and therefore preferable. When young the fruit is green and tender, but when fully grown the rind becomes hard and covered with a waxy exudation. It can be kept from two to three months in a cellar. I have seen it grown in

hot climates, but none thought of it as a vegetable on account of its strong musk scent. *Cucumis arada* produces fruits covered with hard spines, very much like the rough prickly fruit of the Horse Chestnut. They have a long stalk, are produced abundantly, and are used, when half grown, like Cucumbers. Both require the same treatment as that usually given to Cucumbers.—D. GUILENEUF.

**Horse-hoof Parings as Manure.**—In *The Gardener* of last week (see p. 464) are some remarks upon "Buffalo Horn Manure," and at p. 434, Vol. VIII., is a very able chapter on "Bones as a Manure," wherein sulphuric acid is recommended for dissolving them. I have about a bushel of horse-hoof parings from a blacksmith, but am at a loss how properly to apply them to pot plants; they vary in size from  $\frac{1}{2}$  oz. to 3 oz. and less. Are they to be dissolved, or crushed, and how? I find they are powerful stimulants when put up very fine, but that process, with a knife, is very slow and troublesome; they will not grind in an ordinary Coffee mill.—IGNORAMUS. [There is no chemical method of effecting what you require. It would take many weeks to dissolve horn shavings with sulphuric acid even of the strongest kind. A better plan would be to dissolve the shavings by continued boiling in water. When the greater portion of the horn has dissolved, add more hot water, and then allow it to cool. The mass will gelatinise on cooling and may be cut into strips, or by adding about 150 times its volume of hot water a solution will be obtained, with which the roots of the plants may be watered. In this condition it will decompose, and give off its ammonia very rapidly, and therefore should be applied to plants in smaller quantities and more frequently than the undissolved horn, which is slow to produce effect, and equally slow in exhaling itself.—F. W.]

**Soil for Lilies.**—What is the best soil in which to grow *Lilium auratum*? also the size of pots in which to grow it 7 ft. and 8 ft. high? and will the same soil suit all other Lilies, including *Aram Lilies*? I cannot get my plants of *L. auratum* to grow very high. I see in a recent number of *THE GARDEN* that a firm grower of Lilies of the Valley in Cocoa-nut fibre refuse, and that when about to flower they pot them up. Do they pot them in the same material? [No.] Is it a good plan to plunge the pots of Lilies outside all winter? I have done so.—H. S., *Argyleshire*. [The best soil in which to grow *Lilium auratum* is one-half good turfy loam, one-quarter peat, and one-quarter leaf-mould, all well mixed and sharpened with silver sand. With regard to other Lilies, the Thunbergianum group require only one-quarter loam, the Martagon group all loam, speciesum group one-third loam, and *Aram Lilies* the same. As to size, the pots should be as broad at bottom as possible, and 12 in. pots are none too small for Lily culture; there must be good drainage, and above that it is well to place a tuft of Sphagnum, Cocoa-nut fibre, and other fibrous refuse to aid drainage. As to plunging pots of Lilies out all winter, it depends much on the situation. They must have a moderate amount of wet, but anything like saturation from heavy rainfalls will be most injurious. They had better be kept in a shed or out-house, and watered once a week. When *L. auratum* is growing freely it is a good plan to mulch with weak liquid manure twice a week.—W.]

**Coloured Primroses in Woods.**—I was glad to see the remarks of "A. D." (see p. 437) about Primroses in woods. It is somewhat of a relief to me, after being taken to task on the subject by "A. P." Certainly, as "A. D." suggests, such flowers would never be safe from collectors and depredators, and, much as it may be desired, it would take a century to naturalise the coloured Primrose to be anything equal in quantity to the native one. We occasionally meet with a coloured Primrose as a natural sport, and such plants are always brought home, root and all, in triumph; and as to turning it out in thousands, as Mr. Cornhill suggests, that would certainly be the way to cool the ardour and satisfy collectors. I should much wish to hear of some one making the experiment with, say, 100, and plant them in some wild place, say half-a-mile or a mile from a house, and give an account of them at the end of two years.—THOS. WILLIAMS, *Ormskirke*.

**Walling in Firm Tree Roots.**—Allow me to confirm "J. S.'s" statement (see p. 490) respecting the beneficial results arising from this practice. Figs on open walls here do well. In one instance a good-sized bearing young tree had its roots nearly all cut off, and the remainder bricked in to within 1 ft. of the wall, as the root-run was required for an entrance to some deeply-sunk pits. This tree was left only as an experiment, but by keeping it well watered, it not only lived, but is the most prolific, according to size, of any tree here; the growth which it makes is short, hard, and stubby, and it produces fruit as abundantly as those in pots usually do.—J. GROOM, *Henham*.

**The Public Park** at Portsmouth, called the Victoria Park, was opened by the Mayor on Her Majesty's birthday.

## SOCIETIES AND EXHIBITIONS:

## CRYSTAL PALACE.

MAY 24 AND 25.

This exhibition was in all respects a good one, the exhibits consisting chiefly of those produced at the Royal Botanic Society's Show two days previously. The Roses from Mr. Turner and Messrs. Paul & Sons, together with the collections of stove and greenhouse plants from Messrs. Tudgey & Chapman, the fine-foliated plants from Mr. Rann, of Crawley, and the Azaleas, formed its chief features. A collection of Orchids from Mr. Williams, of Holloway, were much admired. It contained a variety of *Cypripedium barbatum* bearing fifty flowers, and the long-tailed *C. caudatum* was in excellent condition. The same exhibitor also sent a miscellaneous group of new plants, in which were noticeable *Microlepis anthriscifolia*, a dwarf hybrid *Maranta Massangeana*, the brilliant crimson-white-edged *Amaryllis* Mrs. Rawson, the new *Dracæna Bausei* and *Goldieana*, and *Croton Queen Victoria*; altogether an effective group. Mr. Wills showed a well-arranged collection of plants, in which were fine examples of new *Dracænas*, rare specimens of *Yucca filamentosa*, large bushes of *Phallis thalictrifolia*, choice *Marantas*, and new *Gloxinias*. Mr. Hooper, of Bath, contributed out flowers of Pansies, which were much admired on account of their varied colours. Mr. Moorman, gardener to the Misses Christy, had very large blooms of *Maréchal Niel* Rose, out from a bush which has borne this year quite 500 blossoms. Mr. Parker, of Tooting, sent an attractive collection of hardy herbaceous plants, in which were examples of *Paeonies*, *Spiræas*, the beautiful *Saxifraga cœchleata* and *S. nepalensis*, *Scaberriflora*, *Globe Flowers*, and the mauve-tinted *Iberis Tenoreana*. Associated with these were also large spikes of the purple *Muscari comosum monstrosum celestinum*, the pink-fringed *Disanthus hybridus floribundus*, and the rose-coloured *Lychnis viscaria rubra* fl.-pl. Messrs. Osborn & Sons, Fulham, had a collection of ornamental plants, consisting of the bronze-leaved Palm (*Stevensonia grandiflora*), flowering plants of *Medinilla magnifica*, well-coloured examples of *Croton Wisemannii*, and the handsome *Adiantum gracillimum*. Messrs. F. & A. Smith, Dulwich, also sent a collection of plants, in which were several new show *Pelargoniums* of an attractive character. One of the best was *Queen of Hearts*, a free-growing kind, bearing large pink blossoms with a clearly-defined white centre, the upper petals being blotched with dark crimson; *Jewess* was the name of a bold dark crimson flower edged with light pink; and a good striped kind was named *Magnificent*. Messrs. Rollison & Sons, Tooting, showed a good collection of plants, in which were examples of new *Dracænas*, the beautiful *Saxifraga nepalensis*, the singular-looking *Brassia Lawrenceana longissima*, and several rare *Lady's-slippers*. Conspicuous in a large group of plants from Messrs. Carter & Co. were several beautiful *Coleuses*, including *Empress of India* and *Duchess of Edinburgh*, and well-grown plants of *Spherygyne latifolia* and the graceful *Casuarina sumatrana*. In a collection of stove plants from Mr. J. Spode, Rugeley, was noticeable a remarkably fine specimen of the well-known *Chorozeema Chandleri*; and from Mr. Peed, Norwood, came a well-flowered plant of the bright purple *Franciscæa calycina*. Messrs. Jackson & Sons, Kingston, showed a collection of Heaths. In a group of plants from Messrs. Laing, Forest Hill, were examples of *Anthurium crystallinum*, *Caladium La Perle*, several new and valuable seedling *Gloxinias* and tuberous-rooted *Begonias*; also some Palms, variegated Pines, and *Pandanias*. Messrs. Rollison had a collection of *Sedums*, *Sempervivums*, and *Echeverias*, which proved to be a source of interest.

## ROYAL HORTICULTURAL SOCIETY.

MAY 28.

In this great four days' show Mr. Turner's Roses formed the chief feature in the principal tent, and a collection of choice plants from Messrs. Veitch & Sons, occupying a central position, proved a source of great attraction. The weather on the first day was unfortunately very unfavorable, which to some extent marred an otherwise successful show. The banks of Orchids arranged in one of the long tents received, perhaps, the greatest share of attention after the Roses, and the fruit, which was very good for the season, was in itself no mean exhibition. Mr. Jones sent from the Royal Gardens, Frogmore, Apples consisting of thirty sorts, many of which appeared almost as plump and firm as when first gathered.

**New Plants.**—In competition for new plants sent out during the last three years, Mr. William Bull and Mr. B. S. Williams had good collections. The former exhibitor had a well-flowered plant of *Pavonia Wiotii*, a finely variegated plant of *Dieffenbachia maculosa*,

*Croton trilobum* Disraeli, *Anthurium Dechardi* (furnished with large white spathes), an excellent specimen of *Dracæna Goldieana*, and the beautiful crested *Lomaria discolor bipinnatifida*. Mr. Williams had a fine panful of the dwarf garden hybrid *Maranta Massangeana*, the graceful *Adiantum princeps*, and finely-coloured plants of *Croton Queen Victoria* and *C. Disraeli*. The best group of plants not yet in commerce came from Mr. W. Bull, Chelsea, and consisted of—

**Dieffenbachia Regina.**—A dwarf-habited plant, the leaves of which are oblong in shape, of a creamy colour, shaded with pale green, and blotched and edged with dark bronzy-green.

**Anthurium insignis.**—A graceful-growing plant, with bright copper-coloured, trilobed leaves, which change to green.

**Davallia fijensis.**—A dwarf species, with finely-cut pinnæ; excellent for culture in pans.

**Croton formosum.**—A compact-growing plant with long, narrow, lance-shaped leaves, marked with rich orange-crimson, green, and lemon colour.

**Dieffenbachia Leopoldi.**—A North American species, apparently of rapid growth, having large, oval-shaped leaves of a velvety-green colour, the midrib being white.

**Philodendron Carderi.**—A strong-growing creeping plant, having large, velvety-green and bronze *Begonia*-like leaves.

**Zamia princeps.**—A graceful Palm, with Pea-green, wax-like foliage.

**Aralia concinna.**—A very ornamental variety, with deeply-cut leaves of a bronzy-green colour.

**Dipteris Horsfieldi.**—A curious Fern from Java. Well worth growing.

Mr. Williams's collection consisted of—

**Dracæna Mastersi.**—A graceful-leaved hybrid kind, of bushy growth, the leaves being of a rich glossy crimson and bronze colour.

**Dracæna speciosa.**—An attractive plant, having glossy, Pea-green leaves, edged and striped with Rose and cream colours.

**Wallichia zebrina.**—Previously alluded to in THE GARDEN.

**Asiophila Macleayi.**—A large-growing Fern, with elegant spreading fronds and finely-cut pinnæ. Well worth adding to good collections.

**Adiantum Williamsi.**—A neat-growing Fern of the omeatum class, having curiously-fringed pinnæ.

**Croton Williamsi.**—A kind from the South Sea Islands, of strong growth, and having leaves beautifully mottled with bronzy-green and fiery scarlet.

**Aralia spectabilis.**—A species closely resembling the one first alluded to, but dwarfer and more compact in growth.

Mr. Williams had also a large specimen of *Encephalartos latifrons*, *Aralia nobilis*, and a golden and green-leaved *Croton* named *Crown Prince*.

First-class Certificates were awarded as follows:—

**Show Pelargonium Fortitude (Turner).**—A free-growing variety with beautifully formed pink blossoms with white centre, the upper petals being blotched with maroon. One of the most showy kinds we have seen for a long time.

**Gloxinia Berkehirei (Fisher, Balham).**—A large drooping flower with creamy-white throat, and delicate violet-tinted petals.

**Dracæna Bijou (Bull).**—A very dwarf, compact-growing kind, with narrow grass-like leaves of a dark bronzy colour, margined with rose-crimson. An excellent sort for small vases.

**Clematis Duke of Connaught.**—A free-growing variety having large double satiny flowers of a rich mauve colour.

**Kentia rupicola (Bull).**—A graceful Palm, with large, feather-like leaves and smooth glossy brown stalks.

**Roses.**—A considerable portion of the large tent was occupied by Roses in pots from the leading growers. Mr. Turner had a grand collection, consisting of fresh, finely-bloomed plants, both in the shape of large and small specimens. Among the larger plants were noticeable *La France* (furnished with large, bold, bright pink blossoms), the beautiful cream-coloured *Madame Villmorez*, and the bright crimson *Paul Verdier*. With these were associated *Beauty of Waltham*, grand plants of the satiny-white *Miss Ingram*, and *François Treve*, a brilliant kind. Amongst the smaller plants we noted remarkably well-flowered examples of *Madame Lacharme*, *Comtesse de Serenyi*, the large pink-flowered *Palm Neron*, the brilliant crimson *J. S. Mill* (one of Mr. Turner's own seedlings), and the maroon *Louis*

Van Houtte. François Michelon was greatly admired, as was also Captain Christy, both being in unusually good condition. Mr. Turner had in all nearly 100 Roses in pots, and all marvels of good cultivation. Messrs. Paul & Sons, the Old Nurseries, Cheshunt, had good plants of Madame Victor Verdier, the flesh-coloured Tea Rose President, Celine Forestier, and the creamy-yellow Madame Margottin.

**Orchids.**—The best collection of these came from Mr. B. S. Williams, and consisted of remarkably well-bloomed plants of *Cypripedium caudatum* and *C. niveum*, *Odontoglossum vexillarium*, and a gorgeously-flowered *Cattleya Mendelli*. Messrs. Jackson & Sons had magnificent plants of *Dendrobium nobile cærulescens*, *Phalaenopsis amabilis*, *Odontoglossum Alexandræ*, and *Oncidium Marshallianum*. Mr. Child, gardener to Mrs. Torr, Ewell, Surrey, had finely-flowered plants of *Oncidium ampliatum majus* and the beautiful *Dendrobium Devonianum*. The best specimen plant in competition for Sir Trevor Lawrence's prize came from Mr. Perry, gardener to J. W. Miles, Esq., Shirehampton. It was a fine example of *Lælia purpurata*; it bore nine flower-spikes, each furnished with four or five gorgeous blossoms. Mr. Child had a plant of *Cypripedium Stonei* furnished with eighteen very large and attractive flowers. From King's Weston, Bristol, came a plant of *Dendrobium thyriflorum*, growing in a basket and bearing six massive, drooping spikes of blossoms. Mr. Douglas, Loxford Hall, Ilford, showed finely-flowered plants of *Dendrobium formosum giganteum*, *D. Dalhousianum*, the beautiful *Cypripedium spectabile*, and brilliantly flowered plants of *Masdevallia Harryana* and *M. Veitchi*. Mr. Ratland, gardener to the Duke of Richmond, had a plant of *Cattleya Mossii* bearing over thirty gorgeous blossoms; also an excellent example of *C. Skiuneri* and an *Odontoglossum Alexandræ* bearing five massive spikes of crisp, violet-tinted blossoms.

**Azaleas.**—These were not so plentiful as in former years, but what were shown were well grown and flowered, and imparted colour to the show. Mr. Ratty, gardener to R. Thornton, Esq., had a group containing good specimens of the large salmon-scarlet kind called *grandis*, the brilliant crimson *Roi de Hollande*, *Souvenir de Prince Albert*, and *Criterion*; also excellent standard plants of the bright rosy-scarlet *Callina* with beautiful imbricated blossoms. The same exhibitor had also a group in which were good specimens of *Grand Crimion*, one of the highest of *Azaleas*; the showy white and salmon-striped *Charlesinks*, and the brilliant orange *Chelston*. Mr. Turner, Slough, also furnished an attractive group of well-grown plants.

**Stove and Greenhouse Plants.**—These were shown in good condition, but, as a rule, too trimly trained. Mr. B. S. Williams, Holloway, had in his collection beautifully-flowered plants of *Erica ventricosa grandiflora*, a fine pyramidal specimen of the white *Azalea Magnificens*, and *Bongainvillea glabra*. Messrs. Jackson & Sons furnished a collection containing fine plants of *Hedera multiflorum*, the bright pink-flowered *Apheloxis sesamooides* Brucei, well-flowered *Heaths*, and fine examples of *Anthurium Schorzerianum*. Mr. Tudgy had splendid specimens of *Allamanda grandiflora*, *Stachys profusa*, and *Bongainvillea glabra*. Among *Heaths* were noticeable fine plants of *Erica obtata*, with very large flowers, and *E. ventricosa nana*, covered with lively pink waxy blossoms. *E. tricolor* Wilsoni, shown by Mr. Tudgy, was in every way perfect, the flowers of this variety being a great improvement on those of the type; and *E. coccinea* minor in several instances served to show it to be still one of the most attractive kinds for exhibition purposes.

**Pelargoniums.**—These made a good display. The best came from Mr. James and Mr. Turner. The former exhibitor had a kind named *Bluebell*, with blue and violet-crimson spotted blossoms, which was much admired; along with it were the bright scarlet *Duchess* of Cambridge and the light-coloured *Snowflake*. Mr. Turner had a variety named *Prince of Prussia*, with very large white flowers tinted with claret colour; also a pleasing kind named *Ruth*, and a rich maroon and crimson-striped variety named *Scottish Chieftain*, with a white centre. Among *Fancy's*, *delicatum* from Mr. Turner was much admired on account of its satiny, white flowers tinted with delicate purple; also *Nelly Fordham*, an elegant kind with white flowers diffused with pink.

**Fine-foliated Plants and Ferns.**—Mr. Bull had a collection of these amongst which were well-grown examples of the glaucous-leaved *Eucaphalarctos horridus rotunda*, the ornamental-leaved *Varia venusta*, a noble plant of *Coccol Weddelliana*, *Dracæna Goldiana*, and fine-leaved *Crotons*. Mr. Williams, Holloway, had a group consisting of well-grown healthy plants of *Cycas media*, the massive-leaved *Verschaffeltia splendida*, elegant lace-leaved *Cnapanias*, glossy-leaved *Dracænas*, and *Yuccas*. Mr. Tudgy, gardener to J. F. Williams, Esq., Henwick Grange, Worcester, had large specimens of the fan-leaved *Latania borbonica*, *Crotons*, and

*Dasylirops*. Mr. Ley, Croydon, had a collection of finely-grown *Palms*. Mr. Rann, The Gardens, Handcross Park, had unusually large specimens of *Stevensonia grandiflora*, *Areca sapida*, and *Lætanian borbonica*; also splendid specimens of *Cycas rotunda*, *C. circinalis*, *Dasylirops glaucum*, and finely-coloured plants of *Croton majesticum*, *C. variegatum*, and the drooping-leaved *C. Youngi*; also the finest seedling plant of *Cibotum princeps* we have yet seen. It was only three years old, and was furnished with massive fronds 14 ft. long. In a collection of fine-foliated plants from the Rev. Canon Bridges were good examples of *Alcaesia marorrhiza variegata*, *Dracæna australis*, and a beautifully-variegated plant of *Pandanus Veitchi*. Messrs. Hooper & Co. had also a collection, in which were well-coloured *Crotons*, *Pandanada*, a good plant of the graceful *Damonopsis trichous*, and the bronze and green *Lætanian rubra vera*. Mr. Williams had the best coloured plant of *Croton undulatum* we have yet seen; also a collection of Ferns which attracted much attention; they consisted of *Cyathea Dregei*, *C. medullaris*, a finely-grown plant of *Davallia Mooreana*, *Gleichenia rupestris*, and *G. Splenula*.

**Miscellaneous Groups of Plants.**—The centre of the large tent was occupied by a magnificent collection of Orchids and other choice subjects from Messrs. Veitch & Sons, associated with Ferns, *Palms*, and similar plants. Conspicuous among the Orchids were finely-bloomed plants of *Cattleya Mossii*, *C. Mendelli*, the bright yellow *Dendrobium suavisimum*, a coloured plate of which was given in THE GARDEN (see p. 166). *D. crystallinum*, suspended among the other plants, was very effective, as was also finely bloomed plants of the golden-flowered *Oncidium concolor*, the chocolate-coloured *O. crispum*, *Odontoglossum Alexandræ*, and *O. cirrhosum*. The new *Hæmanthus Kalbreyeri* formed quite an attractive feature in this group; as did also grand specimens of the *Flamingo* plant, and seedling *Gloxinias* were much admired; also various insectivorous plants under bell-glasses. The beautiful *Phyllanthus roseo pictum*, associated with trilobed *Crotons*, afforded fine colour in the way of foliage. This group also contained new *Begonias* of an attractive character, and beautifully bloomed plants of *Utricularia montana* placed on pedestals. Good examples of the new *Rhododendron Crown Princess* of Germany were well furnished with pleasing orange-coloured blossoms, whilst the curious flowers of *Vanda teres* were conspicuous behind the leaves of *Alcaesia Veitchi* and other plants with handsome foliage. Near this group was one from Mr. Wills, South Kensington, tastefully arranged and composed of miscellaneous flowering and fine foliated plants—averitable miniature forest of ornamental-leaved plants and flowers. It consisted of grand examples of the brilliant salmon coloured *Dracæna majestica*, the black-leaved *Artoocarpus Cannoni*, graceful specimens of *Coccol Weddelliana*, *Thrinax elegans*, *Pandanada*, and other fine-leaved plants, among these were arranged in groups brilliantly-flowered *Cactuses*, *Amaryllises*, *Begonias* of the *Rex* section, and dwarf bright-leaved *Crotons*. The front of the bank was furnished with beautifully flowered plants of *Dendrobium Bensoniæ*, *D. chrysotoxum*, *Odontoglossum*, *Cattleyas*, and choice *Gloxinias*. These were all plunged in a beautifully undulated bed of *Club Mosses*, *Ferns*, *Panicums*, *Panlinias*, and similar subjects. Mr. Aldous, South Kensington, had a good group of plants, consisting chiefly of such kinds as are grown for market purposes. These were edged with small plants of *Caladium argyrites*, *Begonias*, and *Adiantams*. A miscellaneous collection of plants from Chiswick was also shown, and included a quantity of well-grown *Gloxinias* of an attractive character. Mr. William Bull showed an extensive collection of new and rare plants, consisting of *Palms*, *Tree Ferns*, the fine-leaved *Carolinia recurvata variegata*, *Cycads*, and *Dracænas*; grouped among these were new and attractive show *Pelargoniums*, *Amaryllises*, *Hæmanthus cinnabarinus*, and fine pansy of *Bertolonia Van Houttei*. One side of the group was very attractive with masses of *Odontoglossum vexillarium*, *O. Alexandræ* (bearing massive flower-spikes), finely-coloured *Adiantum gracillimum*, and other choice Orchids, placed in a bed of the *Adiantum gracillimum*. From Mr. Williams came a collection containing *Tillandsias* and trumpet-leaved *Sarracénias*, associated with *Amaryllis* Mrs. Rawson, *Oskathe Oranges* full of fruit, the pretty-leaved *Bertolonia marocana*, and the new white *Hydrangea* *Thomas Hogg*. Messrs. W. Rollinson & Sons, Tooting, had an attractive group, in which were good plants of *Cattleya Mendelli*, *Lælia purpurata*, *Sarracénia purpurea* (finely in flower), the graceful *Grevillea filicifolia*, *Damonopsis ornata*, and *Filmy Ferns*; together with fine *Dracænas*, *Crotons*, and several valuable hardy plants. In a large collection from Messrs. Carter & Co. were baskets of choice *Colerases*, *Caladiums*, beautiful cut-leaved *Acers*, and the graceful *Casuarina sumatrana*; altogether a very attractive group. In a collection of plants from Messrs. Cutbush & Sons were good examples of the double white *Azalea* named *Reine de Portugal*, the scarlet *Gompholobium polymorphum splendens*, the pretty blue-flowered *Tetratheca verticillata*,

and the white *Dracophyllum gracile*, effectively interspersed with Ferns, Palms, Araucarias, and other fine-foliaged plants. Messrs. Osborn & Sons had an attractive collection of plants, in which were well-grown examples of *Croton Veismanni*, the dark-fronded *Alsophila Miguelti*, *Stevensonia grandiflora*, finely-coloured plants of *Yucca aloifolia*, and the large green and cream-coloured *Dracaena Regina*.

**Miscellaneous Subjects**—In competition for Mr. Bull's silver cups, Mr. Williams had good examples of *Croton splendidum*, *C. chalcifer*, and *C. Bismarcki*, *Dracaena Robinsoniana*, and *Artocarpus Cannoni*. Mr. Penfold, gardener to Canon Bridge—Brahea filamentosa and the fine crimson-edged narrow-leaved *Dracaena vivicans*. Mr. Rann had *Acaolypha marginata*, finely coloured plants of the twisted-leaved *Croton chrysophyllum*, *Aralia filiofolia*, &c. Mr. Turner, Slough, sent baskets of plants of new Pelargoniums, among which were *Illuminator*, a very brilliant variety called *Forget-me-not*, *Martyr*, *Arthur*, and *Fortitude*, all well worth adding to the smallest collections. Messrs. Osborn & Sons sent out blooms of *Iris Victorine*, *I. sibirica*, and *I. germanica*, all in excellent condition; and Mr. Peacock, Sudbury House, Hammersmith, sent a collection of *Cacti*. Messrs. Barr & Suggden had an extensive and attractive collection of out-blooms of hardy flowers mixed with Ferns. They consisted of beautifully coloured *Iris*es, double-*Ornithogalum*, *Lilies*, and a large assortment of *Pyrethrums*, several beautiful *Alliums*, and a large selection of *Isias* and *Sparaxis*, several beautiful small Alpine plants and *Echeverias*, &c.; all of which combined to make the collection highly interesting. Messrs. F. & A. Smith, Dulwich, had a collection of show Pelargoniums intermixed with Ferns, *Yuccas*, *Caladiums*, and Palms. Messrs. Osborn & Sons sent an attractive collection of hardy Ferns, intermixed with well-flowered plants of *Saxifraga napaulensis*, the blue *Veronica rupestris*, *Scillas*, and other hardy plants. Mr. John Laing, Forest Hill, had a good display of flowering *Begonias*, choice Palms, and *Gloxinias*. A fine bank of *Rhododendrons* was furnished by Messrs. H. Lane & Co., Berkhamstead; the plants had been lifted and potted, the soil nearly approaching clay; yet both foliage and flowers were of the most healthy description, and attracted much attention. Messrs. Veitch sent a remarkably fine collection of *Isias*, *Sparaxis*, and *Tritionias*; the spikes, as well as the blossoms, were large and handsome, almost equal to those of Continental growth, and showed how well these highly attractive flowers may be grown to perfection even near London. Mr. Cannell, Swanley, sent out blooms of *Zonal Pelargoniums*, which made a fine display; they consisted of the best single and double kinds, the colours of which varied from the darkest crimson to the most delicate lilac, pink, and rose. Mr. George, Putney, also sent seedling flowers of Ivy-leaved and *Zonal Pelargoniums* of a meritorious character, many of the colours being new and striking. Mr. Ware, Tottenham, had cut blooms of *Pyrethrums*, fine in form and colour; and Mr. Waterer, Knap Hill, had a fine display of hardy *Azalea* blossoms. Mr. Hooper, Bath, showed choice *Pansies*. Mr. Gallup, Brighton, sent a good display of his new *Mignonette*, which was much admired, and the prizes offered for the best plants of it brought together a number of well-grown examples from other growers. Mr. G. F. Wilson, Heatherbank, sent cut spikes of *Lilium tenuiflorum*, *L. Martagon album*, *L. pulchellum*, *L. elegans*, and *L. Thunbergianum*, all of which were in good condition and were much admired. Mr. Fisher, Balham, sent seedling *Gloxinias* of an unusually pleasing character; the blooms, which were large and delicately coloured, were of good form, and all well worth growing. Messrs. Radcliffe & Co. sent glass window cases, filled with Ferns, Palms, and flowering plants, which attracted much notice, as did also the dinner-table decorations from Messrs. Mortlock, Oxford Street, who showed dessert tables arranged in the oldest style. A Warden Case, filled with much taste and skill, was shown by Messrs. Barr & Suggden.

**Fruit**.—This was fairly represented for the season. Grapes, both black and white, were on the whole good. Mr. Miles, Wycombe Abbey, had excellent examples of Black Hamburg and Forster's Seedling Grapes, Black Crossian Cherries, and Stirling Castle Peaches. Mr. Bannermann, gardener to Lord Bagot, had very fine Brown Turkey Figs, also the best two bunches of Black Hamburg Grapes. Excellent Grosse Mignonne Peaches were shown by Mr. Fry, gardener to S. Baker, Esq., Hayden Hall, Pinner, and Mr. Lovibond, Beckenham, Kent, had well-coloured, large examples of Elrue Nocturnes. Strawberries were well shown by Mr. A. Moss, Chadwell Heath, and Mr. Norman, Hatfield. Mr. Jones, Frogmore, sent fine examples of Smooth Cayenne Pines. Melons were shown in good numbers, the best coming from Mr. Chilton, The Gardens, Tetworth, Oxon. A collection of Strawberries in pots were sent from the Society's gardens at Chiswick, to show the best kinds for pot culture. The collection of Apples from Frogmore attracted much attention. Among the best kinds were noticeable well-coloured plump fruits of Scarlet Golden Pippin, Newtown Pippin, Wellington, and Five-crowned Jack.

**Vegetables**.—These were shown in good numbers. The best collection came from Mr. Miles, Wycombe Abbey, who had excellent Stamfordian Tomatoes, Little Gem Peas, and Asparagus. Mr. Iggaldon, gardener to R. Baker, Esq., and Mr. Pragnell had also excellent collections.

Mowing machines and other garden implements, from the best makers, were shown in large numbers.

**Mr. John Waterer's Rhododendron Exhibition**.—This, which is being held this year in Cadogan Square, Sloane Street, Chelsea, was opened to the public on Wednesday last, and a better display has probably never before been seen in London; the plants, consisting of many thousands, are arranged better than usual, and amongst them are some wonderfully fine specimens. The centre of the tent is occupied by standards, which contribute in no small degree to the effect of the exhibition, and the surrounding beds are so arranged that every variety can be seen to advantage. Amongst the most conspicuous new kinds was especially noticeable one named Countess Cadogan, a variety which has large conical trusses of lively crimson-scarlet blossoms; Princess of Wales, also an excellent kind, has white flowers bordered with deep rose. A variety named Kate Waterer is considered to be one of the best seedling Rhododendrons ever raised at Bagshot; it is vigorous in growth, and bears unusually large trusses of waxy rosy-pink flowers, one of the upper petals of which is delicately marked with yellow. Sir Robert Peel is conspicuous on account of its bright magenta blossoms, and a kind named Princess Mary of Cambridge has white flowers, delicately tinted with rose, in large pyramidal trusses. Mr. Herbert, of Maccross, is a valuable addition to the crimson-flowered kinds, the colour being remarkably bright, and the petals interestingly imbricated. Other good sorts are Mr. Charles Leaf, John Waterer, a well-known variety, and the vivid crimson Duchesse of Bedford. A kind named Lady Olivia Guinness must not be omitted, for it is one of the most distinct of new Rhododendrons; fine standard plants of it bear beautiful white blossoms, delicately spotted with rich crimson. Fred Waterer is considered to be one of the best self-coloured kinds in cultivation, its flowers being of the brightest crimson. Many other valuable new as well as old varieties are also shown, and there are hundreds more to come into bloom.

**Iberis superba**.—In the notice of our *Iberis* (see p. 485) you are under the impression that *I. superba* is like *I. Garreixiana*, and in order to show the difference we send by post flowers of *I. superba*, *I. coreofofolia*, *I. Garreixiana*, and *I. Tenoriana*, all taken from the same rockery, and it will be seen that *I. Garreixiana* is much inferior in quality to any of the others; indeed, though it grows very freely and stands well, it is such a shy bloomer that we never recommend it to any one as being worth growing. On two plants, each as large as that sent last week, there are only six heads of flower, two on one and four on the other. *I. Tenoriana* is very pretty, but only a biennial. Our experience of *I. gibraltaria* is similar to that of "*A. D.*" (see p. 490), as we have not found it hardy, and its flowers are much faded and not pure white, like those of *I. coreofofolia* and *superba*.—DICKSONS & CO., Edinburgh. [The plant that used to be grown at Kew as *I. Garreixiana* flowered in the most abundant manner. Messrs. Dickson's plant is a very good one, and is welcome in a genus already rich in good things. It would, perhaps, be best to give garden varieties in this and other hardy families English names, which would prevent some confusion between varieties and species resulting from the use of Latin names for the varieties.]

**Yellow and Blue Flowers**.—What is the meaning of a note (see p. 485) in which it is said that a yellow *Torenia*, about to flower with M. Lebeuf, will settle the question as to the presence of yellow and blue flowers in the same genus? Can anything be bluer than *Gentiana verna*? and is not *Gentiana lutea* in the same genus? Or if we are to read species for genus, then some of the *Pansies* are nearly true blue (*Gentiana* blue, if we may credit a recent plate in THE GARDEN), and yellows are common enough, while others are dusky crimson.—SALMONIERS.

As regards the yellow *Torenia* settling the question of yellow and blue flowers in the same genus, has not this already been settled in the *Gentiana* family, in which there is *Gentiana lutea*? And is not the truly yellow *Lobelia*, *L. lutea*, somewhat to the point?—I. WILLIAMS, Ormskirk. [The same occurs in various other families.]

**A Blue Bush in May**.—If the plant which I send be *Solanum crispum* it covers, at present, a space of 21 ft. wide and 12 ft. high on a wall in the Vale of Avoca; but for a blue-flowering bush at this time of the year (see p. 489) I prefer *Ceanothus Tomatoes*, which is covered with flowers and quite hardy in this part of Ireland.—F. O. Wexford. [The small specimen sent seems to belong to a smaller species, but you can easily determine this by comparison with the fine bush of *Solanum crispum* in flower at Glasnevin.]

## NOTES FROM KEW.

**Hardy Trees and Shrubs.**—On the wall of the Herbaceous Ground may be seen nicely in flower a near relation of the beautiful *Abelia floribunda*, a coloured plant of which was issued with THE GARDEN of May 18. *Abelia triflora*, the species in question, has flowers (pale yellow, tinged with pink) arranged in threes at the extremity of the branches. A figure of this North Indian shrub will be found in THE GARDEN, Vol. X, p. 58. *Asimina triloba*, a shrub from the United States, has dark brown flowers, and is chiefly remarkable as being a hardy, or nearly hardy, representative of an otherwise exclusively tropical Natural Order—an Order which includes such well-known tropical fruits as the Sour-op of the West Indies, the Sweet-sop of the Malayan Archipelago, the Cherimoyer of Peru, &c. *Caragana arborescens*, from Siberia, is a shrub or small tree, attractive on account of its light-green, pinnate leaves, and pleasing, yellow, axillary flowers. A weeping variety of this, *C. arborescens pendula*, when worked on tolerably high stems will find favour with many. *Cistus Clnsi* is one of the most charming of the South European Rock Roses; it makes a neat bush about 1½ ft. or 2 ft. in height, and has narrow leaves and a profusion of pleasing flowers, snowy white, with the exception of a tinge of yellow at the base of each petal, and measuring 1 in. or more across. *C. corbariensis*, like the last, a native of Spain, has flowers similar in colour, but larger; the leaves, too, are much larger than those of *C. Clnsi*. *Spiraea trilobata* is a beautiful dwarf bush from the Altai Mountains; the large, corymbose racemes of white flowers are very freely produced. *Pyrus arbutifolia* var. *pubens* is a pretty, North American, deciduous under-shrub with Hawthorn-like blossoms.

**Hardy Herbaceous Plants.**—*Castilleja indivia* is a recently introduced Rocky Mountain representative of the Eye-bright of the pastures and heaths of England; the flowers themselves are inconspicuous, but the large bracts subtending them are a most brilliant scarlet. Many extremely handsome species of this genus have not yet found their way to European gardens. *Sarothamnus scoparius prostratus*, a creeping variety of the common Broom, makes a very charming rock or border plant, and has flowers quite as large as those of the type; in a wild state it is only found in Cornwall. Another member of the British flora is the Vernal Gentian, *Gentiana verna*, a native of mountainous meadows in the north of England; few flowers surpass in colour the intensely brilliant blue of this lovely little Alpine. Like many other Gentians, it requires pieces of limestone among the soil in which it is planted; care should also be taken not to have it moved or disturbed in any way. Three of the most desirable Alliums at present in flower are *A. coruleum*, a fine species from Turkestan, with a cylindrical scape 1½ ft. high, crowned by a dense, globose head of bright blue flowers; *A. Clusianum*, which comes from Crete, and has numerous umbels of white, star-like flowers, borne on scapes 1 ft. high, springing from amidst the tufts of Grassy leaves; and *A. subhisutatum*, which hails from the Mediterranean region generally, and is somewhat similar in size and general appearance to the last-named. *Scilla amethystina* is an attractive plant with a scape 1 ft. high, surmounted by a raceme of pretty small blue flowers. *Ornithogalum glaucophyllum* is a most striking and distinct species with very glaucous leaves; the upper surface of the perianth segments is pure white, the under side being green bordered with white. *Centaurea montana*, a dwarf European Composite, has for a long period been an inmate of our English gardens; Gerarde cultivated it, and it is mentioned by him as the Great Curne-flower; the type has large blue flowers, but a variety with white ones is equally pretty. A charming annual, of neat habit and very floriferous properties, is *Lathænia glabrata*, a Californian Composite with golden-yellow flowers. *Pentstemon panicens*, with glossy leaves and bright scarlet flowers, is a very showy perennial of easy culture. *Polygonum alpinum* attains a height of about 2 ft., and its large panicles of white flowers, borne well above the narrow leaves, render it a valuable border plant. *Symphandra Warneri* is a member of the Bell-flower family, from Austria; it hardly reaches the height of 1 ft., and its drooping, pale blue flowers are very pretty. *Vinca herbacea* is also an Austrian plant with smaller and narrower leaves than most of the other species of the genus; as a basket plant this makes a pretty object, its long shoots forming a charming fringe of verdure. *Saxifraga lantoscana* has a small rosette of glaucous, tongue-shaped leaves, from the centre of which springs a shortly-stalked, densely flowered panicle of handsome white blossoms. *Geranium Wlassovianum*, from Siberia, grows 2 ft. high; it has palmately-cut leaves and delicate light blue flowers about ½ in. in diameter. *Erysimum australe* is a Mediterranean Crucifer with somewhat shrubby stems and bright golden-yellow flowers. *Anemone obtusiloba* is a white-flowered Himalayan species, the rarity of which makes up for its lack of show. *Cathoartia villosa*, one of Sir Joseph Hooker's Himalayan discoveries, is a very handsome Poppwort, with lobed leaves, which are clothed with soft yellow hairs and drooping,

golden-yellow flowers. *Erinus alpinus albus* is a white-flowered variety of a most charming Alpine; this, as well as the type, should be in every collection of choice Alpines.

**Greenhouse Plants.**—A very uncommon-looking and handsome plant is the Australian *Elaeocarpus cyanus*; although attaining a large size in its native country, it flowers well in a small state under cultivation, the ends of the shoots being crowded with axillary racemes of beautifully-fringed, whitish flowers, similar in size to those of *Soldanella alpina*. *Andromeda formosa* is a Himalayan shrub, with large, deep green, glossy leaves, and bell-shaped white flowers, where space can be afforded, this is a good plant for the cool conservatory. *Magnolia fuscata*, from China, is well worth growing for its sweetly-scented flowers. In the Glass House Greenhouses Macdonaldie, from Honduras, the largest of the night-flowering Cacti, and the scarlet-flowered *C. Mallesoni* (grafted on the same plant) are in bloom; the contrast between the large white flowers of the one and the brilliant scarlet ones of the other is very fine. *Callistemon salignus* var. *viridiflorus* is an Australian shrub with dense spikes of greenish flowers, the numerous long anthers of which form a brush-like mass. *Melalouca Wilsoni* has needle-like leaves arranged in four rows and clusters of rosy-purple flowers, which spring from the old wood. *Calythrix tetragona*, from Australia, has Gorse-like leaves and white, star-like flowers, clustered towards the extremities of the branches.

**Stove Plants.**—A very beautiful stove shrub is *Steriphosia paradoxum*, introduced to Europe from New Granada at the close of last century. The short, dense-flowered racemes are terminal; the calyx is a bright orange, and the petals a pale yellow, the stamens (3 in. or 4 in. in length) being of the same colour as the petals. A charming Brazilian *Acanthad* is *Arthrostylon formosum* with large, bright scarlet, long-stalked flowers. *Palisota Barteri* has almost sessile heads of brilliant coral-red fruits, and is very showy. *Janoullia parasitica* is a very desirable Peruvian evergreen, having large, handsome, wax-like, deep orange flowers, which last a long time in perfection. Three beautiful *Scotellarias*, worthy of a place in any stove, are *S. pulchella*, *S. Ventenatii*, and *S. Mociniana*; the first has blue flowers, the others scarlet; the last, however, is a larger grower than *S. Ventenatii*.—†

## HARDY WHITE FLOWERS AT BYFLEET IN BLOOM ON MAY 25, 1878.

<i>Andromeda Catesbei</i>	<i>Spimedium niveum</i>	<i>Potentilla rupestris</i>
<i>Anthericum Liliatum</i>	<i>Erinus alpinus albus</i>	<i>Rhododendron rupestre</i>

and nearly seventy sorts of Saxifrages. JOSEPH STEVENS.

## OBITUARY.

We have to record the death of Mr. Jackson Gillbanks, of Whitefield House, Cumberland, which happened on the 19th ult., after an illness of several duration, caused, as he believed, by shock through slipping upon a piece of Orange peel in the streets of Carlisle last autumn. Mr. Gillbanks was educated for the Church, but studied for the Bar. He was very fond of natural history, especially that relating to plants, in which he took a great interest, and concerning which he was a frequent contributor to THE GARDEN.

We learn that H.R.H. the Prince of Wales has appointed Mr. John Wills, of South Kensington, to be one of the jurors of the Horticultural Section of the Paris Universal Exhibition.

**Hair-worms.**—At p. 503 Gouvoins was inadvertently printed for Gordius, the name of the hair-worm sent by Mr. Hobday.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### NEW AND RARE IRISES.

THE following are now in flower in the Kew collection:—First on the list is the new *I. cashmeriana*, which was flowered last year for the first time by M. Leichtlin, of Baden-Baden, and named by Mr. Baker. It much resembles the common *I. florentina* in habit, but its flowers are larger and of a much lighter colour than those of that kind; and, besides, they are deliciously fragrant; it is a native of Cashmere, as its specific name implies. *I. albicans*, of Lange, is a pure white Spanish form of *I. florentina*, but as colour is but of varietal importance, Mr. Baker puts it as merely a variety of *I. florentina*. The beautiful North American *I. tenax*, as seen here true to name, is very unlike the kind generally sold under that name, and which frequently proves to be *I. sibirica* or some other narrow-leaved sort; it is one of the beardless section, dwarf in growth, and bearing tufts of narrow and very tenacious leaves about 1½ ft. long, tinged at the base with a reddish colour, which appears to be a distinctive character; its flowers, which are solitary at the apex of the slender stems, are of a bright lilac-purple, and measure about 2½ in. across. *I. tectorum* (syn.—*I. tomiolopha*) is a charming species, and is flowering very freely; it is a member of the crested group, of which we have but three hardy kinds; it is second to none in point of beauty, and should find a place in the most select collections; its blossoms are large and of a bright purple beautifully mottled with dark purple, and, unlike those of the majority of Irises, all the six divisions are on the same plane, which much enhances its beauty. It was introduced to cultivation from Japan a few years ago by Mr. Bull, of Chelsea. *I. (Xiphion) lusitanica* is a lovely Portuguese kind, bearing flowers in form resembling the common Spanish flag, but of a bright canary-yellow, lasting a long time in good condition. *I. orientalis*, although considered by Mr. Baker to be a variety of *I. sibirica*, is, nevertheless, from a floral point of view, a great improvement on that species. It agrees with it in foliage, but it has much larger and brighter-coloured flowers, and the reddish tinge of the young leaves and spathes—on account of which it has been named by some *I. sibirica* var. *sanguinea*—forms another mark of distinction. The Californian *I. longipetala* is a very ornamental Iris, with large flowers, the inner divisions of which are of a light purple and the outer white and delicately pencilled with purple, thus rendering it a very striking plant. *I. tridentata* is a little known species, remarkable as regards having the inner divisions of the flowers reduced to three teeth, hence its name. Besides these there are many others less rare, such as *I. pallida*, with its large mauve-coloured flowers; the bright-coloured old garden favourites, *I. Swerti*, *I. versicolor*, and its lighter-coloured variety *I. virginica*. The gigantic yellow and white *I. (gigantea) ochroleuca* deserves to be better known, and *I. spuria*, with its dark violet blossoms, is also a desirable kind. Lastly, the charming *I. Ævagata* (Kempferi) may now be seen at Kew in its normal form, and scarcely less beautiful than the many fine varieties which have sprung from it. A.

**Double White Rocket.**—This is just now a grand border flower throwing up noble spikes of bloom 6 in. in length, resembling a pinkish-white Brompton Stock. It makes a fine companion to the old Giant Scarlet Brompton, and if planted in twos or threes along with the Stock in borders the result would be a fine display. The double Rocket is a somewhat difficult plant with which to deal on some soils, whilst in other places it forms stools of great size, but as a rule it should be treated as a plant that requires more than ordinary attention for border growth. Here, because the damp seems to affect the leaves and crowns in the winter, it is necessary to lift the plants, separate the crowns, and plant them singly in a soil bed in a cool house. In the spring these root freely, and are turned out in the open ground

with good balls. Wherever it is difficult to keep the plants over the winter similar treatment should be resorted to. As soon as the flowers decay the stems should be cut away, and thus renewed growth is induced.—A. D.

### HELIANTHEMUMS, OR SUN ROSES.

THE remarks of "A." (see p. 484) in reference to these plants are very *apropos* at this season, when they are ablaze with colours of every hue. The common Rock Rose never varies in colour in a wild state, being invariably of a bright golden-yellow. Few British plants are more handsome than this, covering, as I have seen it, the almost bare rocks in some parts of the kingdom. In a wild state it is truly charming; it grows quite flat on the rocks or walls, but in cultivation it assumes a neat, bushy habit, with an almost endless variety of colour—in fact, every colour but blue; and instead of there being one double-flowered variety, there are several. I myself have three—white, orange, and purple. Why they are called Sun Roses I cannot tell; for, like the flower of the Grass, the sun no sooner rises with a burning heat but it withereth the fashion thereof; and whoever wishes to see these plants in full glory must visit them on a dull day. "A." seems enraptured with *Cistus formosus*. It is, as its name implies, very beautiful, but somewhat straggling, and wants well pinching in to make a good specimen. It is not to be compared with the neat *Chaste C. algarvensis*. *C. Tuberaria*, or the Plantain *Cistus*, is a very singular species. Perhaps the most charming of this very extensive family is the dwarf Gum *Cistus*, simply and truly described by the Messrs. Backhouse as "a gem," a lovely miniature shrub 1½ ft. to 2 ft. high, deep green in foliage, and with flowers as large and similar to those of the Gum *Cistus*. *C. crispus* is a fine rose-coloured species. A reserve of these fine plants should always be kept in pots, and a stony bank or rockery solely appropriated to the various beautiful species of them would be something worth remembering. THOS. WILLIAMS.

*Ormskirik.*

**Primula japonica for the Wild Garden.**—In your list of plants for the wild garden (see p. 488) you omit this. It is one of the best plants for the purpose, and sows itself freely. It has also the valuable quality of being rabbit proof. I have some plants growing at the edge of a wood, and although the Grass around is eaten quite short by rabbits, not a leaf of the Japanese Primrose is hurt. It is difficult to believe that four or five years ago the price of this Primrose was 30s. a plant. It has now become one of the commonest of herbaceous plants. The rich crimson of its flower-heads is most effective in the wild garden.—SALMONCES.

**Bouvardias as Flower Garden Plants.**—Planting out Bouvardias early in summer and taking them up in autumn for flowering in pots in winter is a practice with which most people are familiar, but the method of rendering these plants striking objects in the flower garden during summer is a matter to which little attention has hitherto been paid. Bouvardias may, however, by good management, be made to play an important part in flower garden arrangements. For this purpose old plants require only to be stored away in a cool house during winter, and be kept rather dry at the roots, as is done in the case of Fuchsias. In spring, when they start into growth, a little more water may be given them; and if planted out in beds of good soil in May or June, they will grow and flower profusely all the summer, and will make a much better display than can be made by Verbenas or other plants usually employed for bedding purposes, and they will, moreover, yield an abundance of bloom for cutting. If the surface of the soil be mulched with half-rotted manure or other material during hot weather a great advantage will be gained, and occasional soakings of manure water will improve both the appearance of the foliage and the size of the blossoms.—S.

**Gold-laced Polyanthus.**—My plants of named varieties of these are now in their summer quarters in the open ground, but the bed is so situated that the shade of some neighbouring trees falls across the plants about noon. The sun shines upon them only during the forenoon. In such a position the plants can scarcely fail to do well, provided they are in suitable soil. They are now pushing up their summer growth, and forming side shoots, which give increase of stock by and by. During the summer I top-dress with leaf-mould once or twice, and do not fail to keep the plants well supplied with water. In a few cases, happily very few, I am troubled with the ravages of a fat-looking black grub, which eats through the stems of the leaves just beneath the surface of the soil. They appear to possess a singular capacity for finding out the most valuable sorts, and it is annoying to have one's plants robbed of their leaves just when they are serving an important purpose in the economy of plant life. I think these grubs are the result of using some old cow manure I

employed as a top-dressing for the plants at flowering time. The manure had laid by for a long time, and I took the precaution of either baking it in an oven or sealing it with hot water before using, to destroy any eggs or insect life; above escaped this ordeal, and have lived to trouble me in the way above mentioned. Another time I shall have to be more careful in searching for any harmful subjects of this character. It is grand weather for all kinds of hardy Primulas in the open ground; they are making an enormous growth, and if all goes well, a good head of bloom should be enjoyed next spring. But many risks lie in the way of the unknown path to be trodden during the next ten months.—D.

**Saxifraga nepalensis.**—This is far from being a free bloomer. A year or two ago one of our great plant decorators desired to bespeak 200 plants of it when it flowered. "To get these," replied the grower, "I shall have to pot at least 1000, and perhaps not then get as many to bloom as are wanted." This is an awkward habit, as it leads to disappointment; but it is possible that the true requirements of the plant may not be understood, or else it needs a certain period to elapse before it becomes floriferous. I find its near ally, *Saxifraga pyramidalis*, to be also somewhat shy. I have had a dozen plants of it for two years, and have yet only got one to bloom. *S. nepalensis* in flower is a grand plant, its fine pyramid of bloom being sure to elicit the warmest admiration when first seen.—A. D.

**Adiantum Capillus-Veneris.**—This pretty hardy Fern grows here on the inside of the wall on either side of a cool house, and nearly close to the ground, where it is admired by all who see it. How the plants came to be first fixed there I am unable to say, but I conclude that my predecessor here must have grown plants of it, and that he must have placed them at times beneath the side stages, and that seeds thus became attached to the joints of the brickwork and grew there. That these now increase there can be no doubt, as numbers of minute plants are discernible on the surface of the brickwork. The fronds of Ferns so produced are really charming for bouquets and button-holes, and yet their cultivation is a matter of chance. If the walls of cool houses near the ground were jagged and roughed with mortar, and seeds of this pretty Fern sown upon such surfaces and kept moist, no doubt in time the walls would be covered with lovely green foliage that would be useful in many ways.—A. D.

**Rubus deliciosus.**—I observe in THE GARDEN (see p. 501) Mr. Thompson, of Ipswich, challenging the statement given in "Notes from Kew" (p. 434) that to me "was due the honour of having introduced this fine shrub to English gardens." He asserts that it "was not introduced by Mr. Isaac Anderson-Henry, but by me. Mr. Anderson-Henry simply bought seeds or plants of it of me; I forget which." I certainly neither bought seeds nor plants of it from Mr. Thompson, and I think I can satisfy your readers, as well as Mr. T. himself, of his error. On looking back into my Plant Book for 1866, I find I had, on September 29 of that year, sown seeds I had through a friend of *Rubus deliciosus*, from the Rocky Mountains, lat. 41°, the first of which was through on March 17 thereafter. Now, as Mr. Thompson is good enough annually to favour me with his seed catalogue, not a few of which I find I have preserved, I have glanced my eye over some of them, and find that in the appendix of his catalogue for 1872 he inserts, for the first time, under the heading "New Seeds of the Present Season," "*Rubus deliciosus*, interesting North American species." I had large bushes of it about 3 ft. high in 1873, as Dr. Hooker observes in his notice of it along with the figure which he gives of it in the "Botanical Magazine," t. 6062, of that year. Under these circumstances, I think Mr. Thompson ought first to have made sure of his facts before making the rash assertions which he has done in your columns.—I. ANDERSON-HENRY, *Hay Lodge, Trinity, Edinburgh.*

**Times at which Lilies Bloom.**—I find my own experience in regard to the cultivation of Lilies so very much at variance in several points with what is stated by several of your correspondents, that, without wishing in any way to controvert their theories or modes of treatment, I should like to state a few facts which I have noted as to *L. auratum* and *speciosum* in my greenhouse. "Dunedin" states, in reply to Mr. Harvey, that plants of *L. auratum* will under glass "themselves return to their natural time of flowering." What is their natural time of flowering? One I have blooms every year the first week in May; this year it was out on the 2nd of that month, and the five blooms which it produced lasted, as usual, three weeks. Other bulbs that have not been shifted for three years, in the same sized pots and in the same greenhouse, are all in different stages of growth. One will be open the first week of next month; another rather later, and others are not showing for bloom, though 5 ft. high; whilst imported bulbs of last autumn are only just pushing through the ground, or at most 6 in. high. In short, I have come to the conclusion that *L. auratum* does not observe times and

seasons like *L. speciosum*, which, with me, is as regular as clock-work. In the month of October last I took two bulbs of *L. rubrum* that had bloomed while the flower-stem had scarcely decayed, and potted them in 8-in. pots; also two bulbs of *L. album* and of *album novum*, keeping one pot of each that had bloomed on single stems unshifted. The result shows how much varieties of the same species (if they are but varieties) differ in habit. *L. rubrum* (despite "Dunedin's" theory that the old bulbs decay) has come up in the centre of each pot, a single stem, now over 6 ft. in height, and with from sixteen to eighteen blossom-buds on each. The plant of *L. album* in each case has thrown up two stems, which are from 4½ ft. 5 ft. in height. These unshifted have thrown up from four to five stems, and are dwarf with but few flower-buds. *L. giganteum* has bloomed well with me this year, six very perfect blossoms lasting over three weeks, the large stem and foliage remarkably perfect, as if formed of green glass. As the last bloom is dropping, I have carefully removed the earth round the stem, and find the bulb decayed, the stout stem resting on the stool from which the roots radiate, and on either side a shoot with two large leaves, each of which will form a bulb, and bloom (I presume) the second year. I shall in no way touch it, and see what the result will be.—AMATEUR.

### HERBACEOUS CALCEOLARIAS.

TIME was when large specimen Calceolarias were a leading feature at exhibitions, much as Roses in pots are now, but that on-growth has ceased, and now we see only small but remarkably well-grown and finely-flowered plants. These varieties of Calceolarias were named kinds and propagated by cuttings, and it was from cuttings such large examples were grown. But what has happened in the case of other plants—the *Cineraria*, for instance—has happened also with the Calceolaria; the types raised from seed are now so good generally that little or nothing is gained by naming any of them, and so it has come to pass that named Calceolarias, except of the shrubby and bedding kinds, have ceased to exist. An indifferent strain of seed of Calceolarias is now the exception and good strains the rule. A few days ago I had an opportunity of inspecting a spacious house of herbaceous Calceolarias at the London Road Nurseries of Messrs. Sutton & Sons, at Reading, and here I saw some approach to the fine specimens that used to turn up at the metropolitan and other shows a quarter of a century or so ago. The house was filled with Calceolarias, consisting of plants of varying sizes, but some of the specimens were particularly noticeable, being 3 ft. or so through, dwarf, compact, and vigorous in habit, and densely laden with flowers of excellent quality. Sticks had been used to keep the shoots well distributed, and these arranged from 1 ft. to 1½ ft. in height, the heads of bloom were level and well displayed. The bold deep green leaves hanging about the rims of the pots, showed that the plants had been grown as Calceolarias should be. The seed of these Calceolarias had been sown some at the beginning of June, and the remainder at the end of June, or early in July of last year. It was sown in the usual manner, but thinly, so that the plants might have room to grow into size; they were pricked off as required, and set singly into small pots as soon as possible, and grown on in cold frames. The next shift was into 5-in. pots, and at this stage some of the most forward and strongest plants had the centres taken out to induce the pushing forth of side shoots, as from these large plants had to be made. Some had an intermediate shift into 7-in. pots, and others were not moved till they were put into 9-in. and 10-in. pots in October. The plants hitherto kept in cold frames were continued there, but kept close for a short time to induce root growth, and then plenty of air was given them all through the autumn, even in rainy weather, the lights being well tilted up at their sides on the leeward side. I saw these plants at the end of October, and they then had six or seven shoots each, and they were in the most robust health. The treatment was the very opposite of "coddling"—that unfortunate process to which the Calceolaria is so much subjected during the winter months; and there is no doubt that a well-grown, robust Calceolaria, grown in a cold frame, is as nearly a hardy plant as can well be. In spacious, airy, cold frames, that could be artificially warmed during the winter, if needed, these plants were kept till they began to throw up their flower-stems and till near blooming point, when they were taken to the flowering house and kept well shaded and cool when requisite. A most important point in the case of the herbaceous Calceolaria is cleanliness. Constant fumigation and a free circulation of air are absolutely indispensable, as well as strict attention to watering. Many amateurs fail with the Calceolaria because they keep their plants in too close and dry an atmosphere, and are not sufficiently attended to in the matters of watering and cleanliness. These are first essentials to health, and in so far as they are looked after will be the measure of success reached by the cultivator. D.

## NOTES OF THE WEEK.

**Iris gigantea.**—This tall Iris is now in flower in the collection of the New Plant and Bulb Company at Colchester. It is really a tall and pale form of *Iris ochroleuca*, and therefore valuable for the wild garden, and for moist soil near water.

**Leucojum hyemale.**—I have grown this plant for some years. It is perfectly hardy, but in wet winters the bulb is apt to perish. It is therefore best to grow it planted out in a glazed pit. It never blooms till April or May. I have no doubt the name *hyemale* was given to it from the fact, like *Corbularia Bulboodium*, it throws up the leaves at the beginning of the winter. It is a most elegant and lovely little flower.—HARPUR CREWE, *Drayton-Beauchamp Rectory, Tring.*

**Aquilegia haylodgensis.**—This new hybrid Columbine, which is now in flower at Kew, is apparently identical with *A. cœrulea* hybrida, lately exhibited by Messrs. Veitch, and doubtless the same parents were employed in its production, viz., *A. chrysantha* and *cœrulea*, as it partakes of the colour of both these species. It is needless to add that it is a charming acquisition, and it is to be hoped that more will be done in this way by crossing kinds of weakly constitution with those that are more robust, such as *A. vulgaris*, *alpina*, *glandulosa*, &c.—W.

**Anthericum Liliastrum majus.**—Of this plant there is just now a fine display in the Wellington Nurseries, St. John's Wood. It is planted out in good soil and bears strong spikes of large, snow-white, sweet-scented blossoms, which, in a cut state, are highly esteemed. Planted in masses, together with *Irises*, *Ixias*, and similar plants, this *Anthericum* would, even near London, form one of the most important features in the herbaceous garden.

**Mrs. James Cutbush Tulip.**—Messrs. Van Eden inform us that the Tulip Mrs. James Cutbush, supposed by them to be a new form, has proved to be an old, rather scarce kind, the true name of which is *La Laitière*; consequently they are not entitled to give it a new one.

**Meconopsis aculeata.**—This truly majestic Poppy from the Himalaya Mountains has large blue flowers, which are borne in profusion on a long spike  $1\frac{1}{2}$  ft. to 2½ ft. in height. Unlike *Meconopsis nepalensis*, which is not much more than a biennial, this beautiful species is a true perennial. It is now in full flower on the rockwork in Messrs. Backhouse and Sons' nursery, York.—R. P.

**Cool Orchid House at Drumlarnag.**—There are at present more than 200 blooms of *Masdevallia Harryana* in this house, 97 of which are on one plant; and 20 spikes of *Odontoglossum vexillarium*, 13 of which are on one plant. This fine *Odontoglossum* is kept constantly in the cool Orchid house at Drumlarnag, and is found to thrive vigorously.—C.

**Hardy Plants in Bloom at Tring.**—*Libertia formosa* (alias *pulchella*), which I have hitherto failed to grow, is now in fine bloom with me. It has about twenty spikes of flowers. It has been out the whole winter. *Chrysobactron Hookeri* is also blooming well in the open border for the first time with me, and *Sarasa kamehatchica*, which last year had only one flower, has this year two, so that even if you live on chalk rock with a superstratum of sticky clay you need never despair.—H. HARPUR CREWE, *Drayton-Beauchamp Rectory, Tring.*

**Graceful Basket Plants.**—*Nierembergia*s are highly esteemed in London for furnishing small vases or window boxes, and deservedly so, for few plants are more graceful or better adapted for the purpose. *N. gracilis*, with small blue and white flowers and dwarf habit, and *N. frutescens*, possessing an upright habit, and bearing large white flowers with mauve-coloured eyes, are the chief kinds used, and it is satisfactory to find that by crossing these two kinds intermediate varieties have been raised, which possess a better habit of growth than that of the parents, and by again crossing these with *N. gracilis* the result is good habit, large flowers, and fine blue, white, and mauve colours. We saw lately a quantity of them in the Pine-apple Nursery.

**Hardy Flowers at Tottenham.**—In the rock garden in the Hale Farm Nurseries large clumps of an improved Sea Thrift (*Armeria cephalotes purpurea*), surrounded by dwarf white-flowered Saxifrages, and backed up by white and crimson Alpine Roses, are very effective. The beautiful *Veronica rupestris* is the best dwarf blue-flowered plant at this season, large banks of it here being now a sheet of blossom. A variety of the Rock Rose called *Fireball* is very showy, its flowers being large and of a brilliant flame colour. *Linum luteum* and the drooping *Cyclobothra* furnish abundance of yellow blossoms, and the handsome *Geum coccineum* fl.-pl. is a blaze of scarlet. In other parts of the ground *Iris susiana* bears large and

handsome blossoms; those of the Spanish section, together with the germanica and Siberian varieties, are just now in charming condition. The same remarks also apply to beds planted with the purple-flowered *Muscari conocephalum monstrosum*, amongst which we noticed some beautiful varieties. *Ixias* and *Spiraxias* in sheltered places are in full bloom, also the free-flowering *Brodiaea congesta alba* and the curious *Arum crinitum*. Seedling *Columbines* are remarkably showy, and amongst them are many new and valuable kinds.

**Double Amaryllis.**—A good double *Amaryllis* (*A. equestris* fl.-pl.) is now added to the collection of the New Plant and Bulb Company at Colchester. It is said to resemble a double Rose, and flowering specimens which we saw in a dried state seem to justify this description.

**Xerophyllum asphodeloides.**—This beautiful hardy North American plant is now finely in flower in the nurseries of Messrs. J. Backhouse at York. It has dense tufts of narrow, graceful leaves. The flowers, which are pure white, are borne in a kind of pyramidal panicle on leafy stems 13 in. to 24 in. in height. The whole plant resembles a miniature *Yucca*. It thrives well in deep, rich, sandy peat or leaf-mould in damp positions.—R. P.

**Saxifraga pyramidalis.**—Few people seem to be acquainted with this Saxifrage. There was none at South Kensington last week to be compared to it. My plants of it are upwards of 2 ft. in height, flowering from the rim of the pot, where the diameter is 13 in.—truly a snowy pyramid of bloom—and these are by no means large specimens. Anyone can grow it who has a window or a cold frame.—D., *Ashmore, Dorset.*

**Irises at Fulham.**—There is just now a fine display of the beautiful *Iris Victorine*, a coloured plant of which was given in THE GARDEN (see p. 80), in Messrs. Osborns' nursery at Fulham. Its blooms are larger than we ever remember to have seen them, and their colours are strikingly beautiful. Several other new and valuable *Irises* may also be found here, as well as a good display of the germanica section.

**Orchids in Flower at Clapton.**—One of the most gorgeous displays of Orchids which we have seen for a long time may now be found in Messrs. Low's nursery, Clapton. Hundreds of plants of the showy *Dendrobium swainsonianum* are furnished with gracefully drooping clusters of bright golden-crimson-blotched blossoms. *D. chryso-tectum* is producing blossoms in profusion, and hundreds of the miniature *Vanda corulescens* Boxall, also in flower, may be seen in the same collection. Of this there is a purple-lipped variety named *Lowi*, which is also in flower. Plants of *Dendrobium Bensonianum* are likewise finely in bloom, and amongst them are many highly-coloured and fine varieties.

**Plants in Bloom at Colchester.**—Our *Calochorti* are now coming into bloom; *C. luteus*, *C. elegans*, *C. albus* var. *paniculatus* and *C. Leichtlini* are already out, and, with *Anthericum Liliastrum*, *Camassia esculenta*, and that beautiful and delicate-tinted *Nemastylis geminiflora* brighten our beds. Among the *Lilies*, *Szovitzianum* is just coming into flower with very large and numerous canary-coloured bells, and *tenuifolium* has been out with us for some time, and now the beautiful *pulehellum* has opened. *Arethusa bulbosa*, *Cypripedium parviflorum* and its variety *passerinum*, and *C. pubescens* are fully out. Among the *Irises*, *tripetalata*, *longipetalata*, and a whole host of other beautiful forms are in full beauty. *Hyacinthus candicans* is remarkably strong in growth. *Romneya Coulteri*, a bush with us, now four years old, that grew 6 ft. high last year, promises this year to exceed even that size. For several years past I have not observed a greater promise of strong growth and fine bloom among the *Lilies* than I now see. *L. Hansonii* and *L. dalmaticum* promise to be very fine; on the last I counted over thirty blooms last year.—ALEX. WALLACE.

**Wistarias Run Wild.**—The fine old *Wistarias* in the Fulham Nurseries, to which allusion has been made before in THE GARDEN, are now in full bloom. Climbing unrestrainedly over brick walls, and even trees, their large trusses of blossoms are shown off to advantage. Growing in this way, they are far prettier than trimly trained, and the older they are the better they bloom.

**Choisya ternata a Hardy Wall Plant.**—This, by many, is considered to require protection in winter, but that is by no means necessary, at least near London, for plants of it put out against an open wall in the Wellington Nurseries some five or six years ago have, up to the present time, never failed to yield a profusion of white, sweet-scented blossoms, and that without the least protection. The plants in question have lately been removed, and they are now growing very rapidly against a wall at Pine-apple Place. No one need, therefore, be afraid to plant this *Choisya*, at least, in southern parts of the country; and where it succeeds well it will be surpassed by few other wall plants.

## NOTES FROM KEW.

**Hardy Herbaceous Plants.**—This week the British flora has representatives which vie in beauty with most of their exotic congeners, and are worthy of cultivation in choice collections. The first is the great Irish Butterwort (*Pinguicula grandiflora*), a coloured plate of a near relation of which (*P. vallisneriifolia*) was issued with THE GARDEN of April 13 last. The beautiful blue-purple flowers of this lovely plant are freely produced if the requisite moisture be allowed. *Erodium Manescavi* is a handsome Stork's-bill from the Pyrenees; it attains a height of 18 in., and has umbels of bright magenta flowers about 1½ in. in diameter. *Aquilegia chrysantha* is a splendid Columbine from New Mexico; its fragrant, very long-spurred, yellow flowers are extremely beautiful. Another kind, a European one (*A. pyrenaica*), is much less than the last, but the dark blue blossoms are large; this is, perhaps, the dwarfest of the cultivated Columbines. *Ausome pennsylvanica*, from the United States, is a rather tall grower, with five to seven-lobed leaves and white flowers. Two of the most lovely of the perennial Flaxes are *Linum narbonneense*, a European species, with large bright blue flowers, and the New Zealand *L. monogynum*, with pure white ones; both form very attractive objects in the herbaceous border. *Potentilla nevadensis*, a Spanish Cinque-foil of dwarf habit, bears a profusion of bright yellow flowers. *Onobrychis sativa* var. *montana* is a dwarf form of the common Sainfoin, which it resembles in other particulars; this pretty plant has been distributed as *Hedysarum montanum*. *Astragalus purpureus* is a handsome European Milk Vetch, with rosy-purple flowers, and grows about 18 in. high. The Mexican Tree Lupin is a noble shrub, with flowers which vary in colour from yellow to white with a tinge of rose. *Saxifraga cochlearis* is a Piedmontese species, with compact little rosettes of small leaves and panicles of charming flowers, white spotted with pink. *Patrinia scabiosetolia*, a dwarf member of the Valerian family, which was introduced from Daburia during the first quarter of the present century, has a compact head of yellow flowers. *Saxifraga Maweanae*, recently introduced from Morocco, is a dwarf plant with large white flowers; it is as yet rarely seen in collections, but is sure to become a general favourite with lovers of rock plants. *Senecio Doronicum*, 1½ ft. high, has large heads of bright yellow flowers; this is a very showy and desirable plant, most of the leaves being radical, and the flower-heads, about 2½ in. across, being well borne above the leaves. *Veronica pinguifolia*, from New Zealand, makes a dense, little, cushion-like bush, the white flowers almost hiding the small, rather fleshy leaves. One of the best of the Alliiums not previously noted is *Allium roseum bulbiferum*; its scape is about 1½ ft. high, and the flowers are of a light rose colour. A brilliant-flowered bulb is *Brodiaea coccinea*, discovered by Mr. Lobb in California; the drooping flowers are about 1½ in. long, the lobes of the limb being green, a band of yellow intervening between that and the blood-red of the tube. *Chrysoastron Hookeri*, from the rich plains of the Middle Island, New Zealand, has racemes of golden-yellow blossoms; when in flower it is said to cover the boggy spots in which it grows with a sheet of yellow. *Crinum exense* var. *riparium* is a stately semi-aquatic with broad green leaves and beautiful light rose-coloured flowers.

**Greenhouse Plants.**—A new species of *Aponogon*, *A. spathaceum*, though not so handsome as *A. distachyon*, is well worth growing; the Rush-like leaves are erect, not floating, as in *A. distachyon*, and the much shorter-forked inflorescence is tinged with rose. Another new plant, *Iris spectabilis*, from Hong-Kong, is a pleasing species, but not nearly so pretty as the Chinese *I. fibrinatis*. *Panacratium littorale* is a very elegant *Amaryllid*, with short, stout scapes bearing umbels of the purest white flowers, the segments of which are very narrow, and the corona almost perhaps than in any other species of the genus. *Eliense longipetala*, a relation of the last-named, is a noble plant, with erect leaves and pure white flowers; it was introduced from Lima in 1837. Dr. Lindley called this a splendid species, and stated that it would prove welcome to all cultivators of bulbous plants. *Albucca tenuifolia*, from the Cape of Good Hope, is one of the prettiest of the genus; it has little Grass-like leaves and bright yellow-tipped, green flowers. Where unlimited space can be allowed it, *Passiflora cinnabarina* makes a handsome climber for the cool conservatory. The most lovely of the Australian *Liliaceae* are the *Blandfordias*, and *B. flammea* var. *elegans* is now in flower; it has long, slender leaves and large scarlet and yellow bell-shaped flowers.

**Stove Plants.**—Two of the most striking stove plants at present in flower in the Kew collection are the *Bromeliads* *Bilbergia Portensae* and *Pitcairnia flavescens*. The first-named is a magnificent species with long leaves overlapping each other for half their length (which is above 3 ft.), and a gracefully drooping inflorescence; the large bracts are a brilliant crimson-scarlet in colour. *Pitcairnia flavescens*

has pale yellow flowers with orange-coloured anthers. *Utricularia montana*, a most curious epiphyte from the West Indian Islands, is as interesting as it is beautiful; in a wild state it grows on the wet Mosey trunks of trees on the mountains; the large, drooping flowers are white, with the exception of the yellow disk of the lower lip of the corolla. The *Amboyana Lily* (*Euryclides ambonensis*) is a handsome white-flowered stove bulb. A coloured figure of *E. australasica* was figured in THE GARDEN of November 17, 1877. *Justicia natans*, a tropical American aquatic with Willow-herb-like leaves and showy yellow flowers, is well worth a place in a warm tank.

**Orchids.**—Undoubtedly the prettiest of this week's Orchids is the lovely *Dendrobium suavisimum*, a coloured plate of which was given with THE GARDEN for Feb. 23 of this year; the large, glossy, wax-like, yellow flowers are borne in drooping racemes, the fringed lip being prominently marked with a crimson-black blotch. *Burlingtonia fragrans* is a charming little epiphyte from Brazil; the short, drooping spikes bear several flowers, which are white, except the yellow crest of the large lip; the backs of the sepals and petals are tinged with rose. *Aerides odoratum* and its var. *najus* are no less remarkable for the elegance of their spikes of flowers than for their fragrance; the type, introduced to Kew by Sir Joseph Banks in 1800, has delicate cream-coloured blossoms spotted and blotched with purple. *Epidendrum aromaticum* is a Guatemalan species, having whitish sepals and petals, which are similar in size and form; the lip is marked with very fine purplish lines. *Odontoglossum cristatum*, from Peru, has pendulous racemes; the greenish-yellow and brown sepals and petals are narrow, the column and a portion of the crests of the peculiar lip are white. *Mesospidium sanguineum*, from great elevations on the Peruvian Andes, is a little Orchid with much-branched panicles of rosy-red flowers.—†.

## EARLY OPENING OF KEW GARDENS.

AMONG the various doubtful statements published by the small party at Kew that desire to keep the garden closed till the afternoon, that published last week in THE GARDEN (p. 529) deserves exposure. "We appeal," we read in the memorial signed by Dr. Robert Hogg and J. Bull, F.R.S., "with confidence to the experience of all who are acquainted with the management of large gardens in saying that the perfection of keep and finished beauty, which are unattainable in any country but our own, cannot be maintained without an amount of supervised labour which it would be hopeless to attempt to perform in grounds frequented throughout the day by the public." It is surprising that gentlemen of such reputation, and who presumably know something of the gardens of Europe, should put their names to statements so far from being exact. The presence of the public from early morning till dusk does not in the least interfere with the keep or the high culture of public gardens; as, for example, the Park Monceau and Battersea Park.

**Tropæolum azureum and Jarratti.**—Mr. Cornhill's article on *Tropæolum azureum* (see p. 517) is especially interesting to me for having grown *T. Jarratti* (or what I take to be so) with some success for a small conservatory, which is entirely unheated, I had determined to try *T. azureum* also, until Mr. Hemley's remark on the greater difficulty of growing it discouraged me. I plant one tuber of *Jarratti* in each pot, and almost invariably find two of nearly equal size when I turn them out, but never more. The shape of these tubers is usually round, but sometimes a finger-shaped one occurs. As soon as they are potted I place them in a light window facing the south, where they remain for several months, until they have made considerable growth and show flower-buds. This year it occurred to me to have a small archway of Hazel twigs formed across one of the corners of the little conservatory, with a plant at each side, and since the middle of April the effect has been charming. At present it makes a frame for a large plant of *Hoteia japonica*, which contrasts well with the scarlet wreath of pendent blossoms above it. I failed in growing this *Tropæolum* so long as I tried it in a Vinery, which, nevertheless, is only heated by a stove in very severe winters to keep out frost. The window treatment, however, seems to succeed admirably in a room without a fire. Is *T. azureum* as hardy? If so, there ought to be no insurmountable difficulty in growing it. *Jarratti* seems to me to be impatient of any fire-heat. Would it be troubling Mr. Cornhill too much to ask also what kind of trellis he uses for training *azureum* upon? *Jarratti* has an unconquerable aversion to being trained round and round, as upon a balloon trellis, which is moreover, in my opinion, unnatural, and, therefore, not in good taste.—D., *Ashmore, Dorset.*

ART IN GARDENS.

I NOTICE in a horticultural contemporary a favourable review of "a privately printed essay on the æsthetics of garden art," entitled "Aesthetik der Gartenkunst," by Von Lothar Abel, a garden architect of note in Vienna, which "is essentially a defence of the architectural style of laying out a garden immediately around a castle or mansion, as opposed to the landscape style." The author regards gardening as an art which uses natural materials, but in which scenes other than those which occur in Nature are the most charming; whilst a landscape garden he looks upon as incongruous with a building or with inclosure walls and as being not "æsthetic" or "artistic" but "simply the reproduction of certain scenery." This landscape gardening is alleged to be a peculiarly English error. Would it were more so. The world's greatest thinker—an Englishman—in the words of the motto of THE GARDEN, wrote of gardening—

This is an art  
Which does mend Nature: change it rather: but  
The Art itself is Nature.

In the spirit of this last line, admitting that we may "mend Nature" by adding to the beauties of our native plants those of any other clime; admitting that boundary walls are apt to be unsightly and are unlike Nature's usual landscapes; admitting, too, that buildings of all kinds mar the beauty of views in a natural garden by detracting from its naturalness, I venture to maintain that, as the gardening "art itself is Nature," we are as much justified, as a matter of taste or—if we must use a long word—æsthetics, in following the thoughts of Nature in her landscapes as nearly as we can, as are the painter or the sculptor in not confining themselves entirely to the conventional, but striving after the nearest possible approach to that perfect portraiture to which they can no more attain than can we. We aim at this and at no more. We do not merely re-produce certain scenery any more than the dramatist or the novelist re-produces every-day life. We have to select the pleasing to epitomise. We do more, we add the impossible if only it be beautiful. Plants of another hemisphere are placed side by side with British species, on the sole justification of beauty, in defiance of Nature's laws of geographical distribution.

It is by no means necessary that a garden be enclosed by four unsightly walls, by less than that number, or by more. The rock walls, curtained with Ivy and Virginian Creeper, with Yuccas and rock shrubs in the foreground (engraved on p. 234), the Rose-covered palings of the Waltham Cross Nurseries (engraved on p. 357), a piece of water, which can be so readily made ornamental, a tangled thicket, a Haw-haw, or many a device can be used to avoid this unnatural and, I admit, unbeautiful incongruity, even in small gardens. The same is true to a great extent of buildings. Engravings in THE GARDEN have already shown how tool-sheds or summer-houses may, as Ivy-clad caves and grottos, harmonise with semi-wild surroundings, and how even the house itself, draped with Roses, Ivy, Wistaria, Virginian Creeper, or what not, may not be strikingly inharmonious. It may be illogical, but I have yet to learn that æsthetics, art, or other matters of feeling or imagination are governed by the rules of reasoning or formal logic; even if so, I cannot see the necessity, urged by some, of degrading our gardens, of torturing and clipping the works of Nature into geometrical outlines, straight lines and level surfaces, of treating them architecturally, so that

they may harmonise with an architecture the most destitute of principle and of beauty perhaps of any the world ever saw. But, after all, landscape gardeners recognise two facts; first, that much of the value of a garden depends on its beauty as seen from the house, from which the house itself does not detract; secondly, that a leading charm in landscape is repose, perhaps only another name for harmony, and that this is best secured by as far as possible shutting out the house, however draped, as also anything else obviously artificial, from as many as possible of the natural landscape vistas of the garden. "The highest art is the concealing art." To my mind there can be little or no repose to the eye in a mixture of sculpture, marble, carved stone, stucco, or brick and mortar, with Nature's wildings. Florists' flowers in a conservatory may look well in majolica or terra-cotta. Gilt chairs with blue silk curtains may look well in a drawing-room. To my mind and eye there would be no repose, no comfort, no art, no beauty, in either case.

G. S. BOULGER.

11, Burlington Road, Westbourne Park.

**New Zealand Flax Seed.**—My experience in reference to the growth of imported seeds of New Zealand Flax is entirely different from that of your correspondents "J. S." and Mr. Thompson. Three

years ago I received a packet of seeds by post from Wellington, New Zealand, of the Marsh Flax. I placed them in a shallow pan of black sandy soil; the soil scarcely covered the seeds; they were kept continually wet. A very large number grew and are now fine plants, about 3 ft. high. My success was so satisfactory, that I wrote requesting to have more seed sent me, and last autumn I received another packet by sample post (postal charge 4d.), containing Flax and other seeds. The Flax I now placed in a pot, not a shallow undrained pan. I have already grown a number, also a large number of what I believe to be a species of Veronica, also an innumerable number of plants of a fine long Grass, stated to be very ornamental, and such a quantity of Chianthus that I must either throw or give them away; I cannot use them. Only one packet of seeds failed, which, I am informed, belonged to a plant very much like the Flax;

but of this package not a seed grew. I am convinced that the proper treatment of Flax seeds is to grow them in a shallow pan, in little soil, keeping them constantly wet, and as soon as they germinate to pot them off. Slugs are very fond of them when young, and through slugs I have lost a large number. My object in having a quantity of Flax plants was to place them in my wild garden, in between rocks and in other places. I hope the fashion of bedding out and carpet bedding is on the wane; for years I have protested against it. The latter (carpet bedding) is a perfectly barbarous plan, which no man really liking plants, liking a garden, and with a correct taste, would ever adopt.—K. K., Taddyfords, Devon.

**In the Inner Garden of the Tuileries.**—The annexed illustration shows a glimpse of the effect of this garden in summer, when Cannas, Roses, Gladioli, and Dahlias adorn its Ivy-margined borders. With the Ivy, and the flowers, and "fine foliage," the formal effect of the straight borders is agreeably modified. There are many statues and some good shrubs, which are allowed room to grow without needless mutilation.

**Saxifraga Wallacei.**—In a note in reference to this plant in last week's issue it is stated that it is the finest Saxifrage known to the writer. I think this statement will tend to mislead if such fine species as *S. Maweani*, *pyramidalis lutescens*, and a few others be not excepted, although it is a very fine variety of the group to which it belongs, and it has also the peculiar habit of *S. Maweani*, &c., of developing buds in the axils of the leaves, and which afford a rapid means of propagation. The *Iberis superba* mentioned in the

In the Inner Garden of the Tuileries.

same paragraph is undoubtedly the finest of all the white Iberises. The heads of flower are as large as in *I. gibraltarica*, and it is also very floriferous, thriving either in the shade or in an exposed place. It is proved to be a fine form of *I. Garreziana*.—W.

#### SHRUBS AND FLOWERS FOR WOODLAND WALKS.

ALLOW me to add my mite to what has already been said on this subject. Many years ago I had the management of a large garden, and along with it the woods on the estate. The latter, as usual, comprised sites and soils of many kinds, steep—almost inaccessible—banks, swamps, level tracts partly covered with coarse herbage, as well as now and then tracts where the umbrageous foliage of the trees had destroyed almost all surface vegetation. Such woods are often traversed by footpaths, by the sides of which it is easy to plant a few choice shrubs or herbaceous plants, and I have more than once heard ladies of the highest rank and of acknowledged good taste admit that they enjoyed a walk through such paths more than one through what are called dressed grounds. To plants in such situations rabbits are, however, sometimes troublesome, and therefore they should consist as much as possible of varieties of which they are not fond. Plants newly planted, too, are often attacked where the same kinds that have become established are unmolested. Box is about as safe as anything; for, although it is said that rabbits will not destroy *Rhododendrons*, I have lost hundreds by means of them, and especially of the better kinds. *Berberis Aquifolium* of a dozen or more years' standing has also disappeared where these destructive pests are encouraged in numbers; and amongst deciduous shrubs or trees I know none except the common Elder that escapes their depredations; but even this may not be entirely exempt, for, emboldened by the knowledge of their not touching the common sort, I planted some yellow-berried ones and some of the variegated and cut-leaved varieties, all of which disappeared. Some years ago I was tempted to try some Bitter Willows that were advertised as rabbit proof, but I found, on trial, that these little four-footed depredators preferred them to the commoner kinds. There are, however, many places in which rabbits are not so numerous, and to which many fine shrubs and plants might be introduced with advantage. Even where the herbage had disappeared, in consequence of overtopping trees, I have found Snowdrops and Daffodils to do well, especially the former, and when opportunity offered I have more than once amused myself and others afterwards, I hope, by planting in a good-sized open place some fancy scroll-work with Snowdrops, which are well adapted for that purpose, and here and there a ring of them around a tree about 3 ft. from the collar has looked well and retained its form for several years. Daffodils look best in detached tufts; both produce a fine effect in early spring, and both will struggle with and hold their own amongst ordinary herbage. One of the prettiest displays I ever made with Snowdrops was on a site that was in summer, or rather in spring, covered with a mass of Pile-wort, which died down in autumn, and was bare and unsightly until the Snowdrops made their appearance above ground in December, or sometimes in November, in favourable seasons. Even these two plants alone give to uninviting places a lively appearance, and that at the dullest time of the year. Next to these are Primroses, and of these the greatest favourites with me were the single white and a single mauve-coloured kind. Both these Primroses are very hardy, and they are not at all particular as to soil or situation, provided it be not too dry. Polyanthes may also be introduced. One year I remember saving a quantity of seed from some strong-growing common kinds in the garden. This I sowed in the woods in various places, but as I left before it had time to make its appearance, I cannot say with what result. I have also done the same with Snowdrops, but the seed of these takes a long time to germinate. Monkshood does well in rather damp places, and I have also tried the more refined *Aconitum variegatum*, also the pretty *Dicentra spectabilis*, and, in fact, many other plants that would have been thrown away in other cases, so that no great expense need be incurred in this kind of cultivation, for I will not call it gardening; and to meet with a plant where it is not expected affords more pleasure than to see it in the dressed grounds, or in a beautifully cultivated border. Shrubs, too,

are important adjuncts; many a place has been made highly ornamental by introducing *Rhododendrons* on a large scale, as, for instance, at Cobham Hall, in Kent. These, when planted on suitable sites, seed and reproduce themselves in such numbers as to cover the whole ground, leaving only room for roads or drives. Other shrubs might also be tried, but I have never met with the Holly-leaved Berberry as much at home anywhere as the *Rhododendron* is at Cobham Hall; in fact, I am half inclined to think that B. Darwini will establish itself sooner and reproduce itself better than its elder companion. B. Darwini is, however, difficult to transplant, but it seeds abundantly, and might be sown in quantities where it was wanted to grow. My mode of sowing such seeds was merely to scatter them over the ground and let them take their chance; the wild herbage assisted the germination, especially that of *Rhododendrons*. Box also succeeds very well when transplanted, but I cannot say the same of Aucubas, as rabbits injure them severely. A RETIRED GARDENER.

#### HARDY FLOWERS AT THE REGENT'S PARK SHOW.

CONSIDERING the liberal prizes offered by the Royal Botanic Society at the last show (May 22) for old-fashioned hardy and Alpine plants, I was somewhat surprised to see such a scanty competition in these classes, and the old-fashioned flowers which were staged showed but a poor attempt to represent to the present generation an example of the grand old hardy plants our forefathers loved to cultivate, or even to carry out the object the Society had in view, which was, I presume, to encourage the culture of hardy plants and to rescue from entirely sinking into oblivion plants introduced previous to the present century. The judges wisely withheld the award of the first prize, as, by the appearance of some of the plants, it seemed as if the exhibitors had hurriedly put in pots the same morning the first and most common plants to which they came in their herbaceous borders. I think that an exhibitor of hardy plants ought not to stage for public inspection ungainly or unsuitable plants any more than an Orchid or a Rose grower to stage an inconspicuous Orchid or a monthly Rose, for not only does it not convey an idea of the object in view, but it throws discredit on the name of hardy herbaceous plants; and were it not that it was in some measure compensated by the sight of the lovely hybrid Columbine close by, the uninitiated would have had but a poor idea of the beauty of outdoor garden plants. It cannot be that there is a lack of plants in flower at this season that were introduced previous to the present century, for in my rambles the following day I noticed many fine plants which, if well-grown specimens of them were exhibited, would make a dangerous rival to the choicest collection of Orchids or stove and greenhouse plants. I have jotted down a few of the most desirable plants which I noticed, together with the year in which they were introduced, and no doubt the list could be extended, but these are all readily procurable and of easy culture. They are as follows:—

<i>Aquilegia alpina</i> , 1730	<i>Cypripedium pubescens</i> , 1730
<i>Androsace Lilastrium</i> , 1629	" " <i>spectabile</i> , 1731
" " <i>Liliago</i> , 1698	" " <i>parviflorum</i> , 1769
<i>Iris sasiensis</i> , 1698	" " <i>Calceolus</i> , British
<i>Philox divaricata</i> , 1746	<i>Iberis gibraltarica</i> , 1732
" <i>ovata</i> , 1736	<i>Saxifraga Cotyledon pyramidalis</i> , 1693
<i>Pancreatum maritimum</i> , 1697	<i>Ranunculus acanthifolius</i> (l. pl.), 1696
<i>Ranunculus pyrenaicus</i> , 1731	<i>Trollius asiaticus</i> , 1769
<i>Phlox pilosa</i> , 1759	<i>Sarcocolla purpurea</i> , 1840
<i>Corydalis nobilis</i> , 1783	<i>Anemone palmata</i> , 1697
<i>Aquilegia canadensis</i> , 1840	" " <i>alpina</i> , 1665
<i>Faonia anomala</i> , 1783	" " <i>coronaria</i> , 1698
" " <i>tenuifolia</i> , 1765	" " <i>lortoniensis</i> , 1697
<i>Verbascum phoeniceum</i> , 1698	<i>Hesperis matronalis</i> , 1697
<i>Linum narbonneense</i> , 1759	<i>Ornithogalum pyramidale</i> , 1762
<i>Dodecatheon Meadia</i> , 1744	<i>Sedum Doronicum</i> , 1765
<i>Cortusa Matthiola</i> , 1696	<i>Lupinus arborescens</i> , 1783
<i>Lupinus nootkatensis</i> , 1794	<i>Genutiana verba</i>

In the class for Alpines but one exhibitor appeared, and although the collection contained some well-flowered plants massed in large pots, yet, strange to say, there was not one characteristic Alpine, not a crustaceous Saxifrage or Alpine Dianthus, or any of the true Alpine gems. Moreover, instead of being shown in imitation of growing in fissures of rock, by placing pieces of sandstone round the neck of the plants, they were closely packed round with ordinary Moss, as if they had been taken from a forest instead of the exposed mountain side.

The hybrid Columbines above alluded to were simply magnificent, the pot specimen being a cross between *Aquilegia cœrulea* and *chrysantha*, and partaking of the floral characters of both in a striking degree; it was also a good example of superior culture. The cut specimens represented hybrids of the finer kinds, as *A. californica*, *alpina*, &c.; and, well illustrated, what can be done by judicious hybridising and careful selection? If these were shown in the high state of perfection which we are accustomed to see in the case of other classes, I feel sure that no better step could be taken to popularise these charming plants.

A LOVER OF HARDY FLOWERS.

[We quite agree with our correspondent, and also hope the Royal Botanic Society will do away with the useless separation of hardy plants into "old-fashioned" and the reverse. The prizes given ought to be framed so that people might see at their exhibitions some of the beauty of the rich collections of hardy flowers now in English gardens. We fear this rule about "old-fashioned" plants accounts for the weedy rubbish frequently seen at the Botanic shows.—Ed.]

### STONE LEDGES FOR ROCK GARDENS.

In a paper read before the Botanical Society of Edinburgh on May 3 last I stated that the blooming of the Pasque-flower (*Pulsatilla vernalis*) was greatly enhanced by being planted

within the narrow low stone compartments formed round the base of the larger rough upright stone walls of the rock garden. These upright or back wall stones stand from 1 in. to 2½ ft. above ground, and are generally sunk from 1 ft. to 1½ ft. in the soil, according to their length. Dwarf stones of a uniform

length and depth are also sunk into the ground 6 in. or 8 in., so as to stand 2 in. or so above the surface, and from 1 in. to 3 in. apart from the permanent upright stones, both in high and low situations. These stone ledges are filled with good soil for the growth of dwarf plants. Many of the stones used in the rock garden have been procured from the Hailes Quarry, near Edinburgh. They are generally received in slabs 4 ft. long and from 10 in. to 1 ft. broad, and are readily cut into suitable lengths and easily split into thicknesses suitable for the various places in which they are to be used. These stone ledges, formed along the base of the rockery, are usually filled with prepared soil, and they receive, in addition, the fine particles of earth washed down from the upper parts, and prevent them from coming down upon the gravel walks. These dwarf stone ledges certainly improve the appearance of the rock garden and are capable of holding a large number of plants, particularly bulbous and tuberous-rooted sorts, kinds that are often lost sight of in ordinary open borders and sometimes on rockeries. Most of the description of plants here

alluded to flower early, and their foliage, in many cases, soon dies down; therefore, when in open borders, they are not unfrequently dug over for the reception of scarlet Pelargoniums and other summer bedding plants, unless much care is taken to have them named or otherwise protected, which is not always done. In such stone ledges as are here described all the species of *Erythronium* are quite at home, as well as *Galanthus nivalis* and *plicatus*, *Scillas*, *Muscari*, *Leucocoryne*, *Leucojum vernum*, dwarf *Fritillarias*, *Corydalis*, and a multitude of others. Besides the *Pulsatilla vernalis* already noticed, all other species of dwarf *Anemones* succeed well under such conditions, as do also *Dondia Epipactis*, *Hepaticas*, *Primula vulgaris* and its varieties; likewise *Gentiana gelida*, *septemfida*, *ornata*, &c. The accompanying sketch shows a portion of the higher upright walls of the rock garden 2 ft. in height, with a section of the same, each showing the stone plant ledge at the base. At intervals between the upright stones are masses of dwarf *Phloxes*, particularly of *Phlox setacea violacea*. The various species of *Aubrietia* have also a striking effect under such conditions. Besides these, *Polygonum vacciniifolium*, *Arctostaphylos californicum*, *Cytisus prostratus*, *Parochetus Communis*, &c., are useful pendent plants; also *Daphne Cneorum*, *Dryas Drummondii*, *D. octapetala*, and all the double and single *Helianthemum* when planted near the edge are very useful, while the open chinks in the upright stone slabs are filled with innumerable plants, such as *Alpine Auriculas*, *Primulas*, *Hepaticas*, *Linaria alpina*, various sorts of *Erinus*, and many others suitable for a northern aspect. Mr. Jenner, of Easter Duddingston Lodge, recently presented to the Botanic Garden about 400 *Orchis* roots, chiefly *O. mascula*, to be cultivated in the rock garden. Most of them have been placed in the open rock ledges already alluded to, and if they succeed as well as some *Orchises* previously inserted there they will prove very ornamental. Mr. Jenner has long been celebrated as an Alpine plant cultivator. He is now arranging at Easter Duddingston one of the largest, and perhaps the most artistic set of artificial rockeries to be seen near Edinburgh, and that in addition to those previously described in THE GARDEN, Dec. 6, 1873; one of large size is entirely devoted to the cultivation of Ferns, and the others for the different sections of Alpine, dwarf herbaceous, and hardy formal-growing plants, such as *Yuccas*, *Phormiums*, *Cordylines*, *Bambusas*, &c. This undertaking is being carried out under the superintendence of Mr. Gorrie, whose artistic taste in such works cannot be questioned. J. McNAB.

Royal Botanic Gardens, Edinburgh.

### LILIUM BROWNI v. JAPONICUM COLCHESTERI.

OBSERVING Dr. Wallace's remarks about these Lilies in THE GARDEN (see p. 505), I have again referred to Mr. Elwes' observations, and I have thought that it might interest some of your readers to know what I have to say respecting the history of these Lilies and their allies. About forty years ago there was cultivated with success in my father's garden, under the name of *Lilium japonicum*, a fine and rare Lily. I cannot say whence it was introduced, but it is possible that my father bought it at the sale of the stock of the famous nursery of Voorhelm Schreevoegt in 1837. Of this Lily there were sold annually a few dozen bulbs, especially in Belgium, at a price of 10s. 6d. each. It was then considered to be the true *Lilium japonicum* of Thunberg, and was a form allied to *Lilium odoratum* of Planchon, figured and described in the "Flora dea Serres," t. 876-77. I find *L. japonicum* under that name in the nursery catalogues of our firm in 1850-1855; the last year at a much higher price than before. It had not been offered for a couple of years, as the stock had diminished too much. In 1858 it is again quoted at the former price, with a remark as to its rarity, but in the following year it was omitted, being lost or sold out, and since that time I have never met with this form in any collection. Planchon speaks about this Lily as being figured in *Lodiges' "Botanical Cabinet,"* t. 438, and states that it is in some points different from his *Lilium odoratum*. This is quite true, and both Lilies must be considered as two, perhaps closely allied, but different forms. *Lilium odoratum* was introduced to our nursery in 1854, and in the catalogues of that and the following year it was noted that it was a distinct form of the old *L. japonicum*. Both these Lilies showed, at least from a horticultural point of view, so great a difference from *Lilium Browni*, that, if not considered as distinct species, they at least must be accepted as strikingly different varieties. L. Browni

was once cultivated, too, as *L. japonicum*, and quoted in the catalogues as *L. japonicum* of gardens in contradistinction to the true *Lilium japonicum*, the old sort which was considered to be that of Thunberg. In England at that time *L. Browni* was considered by some to be identical with Thunberg's *Lilium japonicum*. This erroneous impression was, if I remember rightly, first cleared up by Spæe in his "Mémoire sur le genre *Lis*," offered to the Belgian Academy of Sciences in 1845. *L. Browni* was introduced into Holland in 1838 either from England or Belgium. M. Const. Gheldorf, Ghent, in his catalogue (1844-5) writes about the two *Liliums* in question as follows:—"In *L. Browni* the exterior of the petals is white, striped with dark crimson, nearly  $\frac{1}{4}$  in. broad, sepals greenish-white, dotted with crimson, and bordered with clear white. The Japan *Lily* introduced in 1801, which is now very scarce, has only the top petals tinged with crimson." The last is quoted in this catalogue as *L. japonicum verum*, and was the same as that cultivated by my father under that name. As for *Lilium japonicum Colchesteri*, not having been fortunate in its cultivation, I have not yet seen it in flower, but, judging from the figure of it in the "Flore des Serres," I suppose it is nearer to the old *L. japonicum* and *L. odoratum* than to *L. Browni*. As for the true *Lilium japonicum* of Thunberg, I find that the opinion that it is identical with the white form of *Lilium Kramerii* is not contradicted by what is said about it by Planchon in the "Flore des Serres," ix., p. 53. M. Van Houtte, in his article on the Colchester Lily, arrives at no decision on this point, and only puts a (?) after the word *Japonicum* in his name of *L. japonicum Colchesteri*.

As far as I can judge, there are mixed up in this question four different forms of *Liliums*, which I should be inclined to unite in two groups, one consisting of *L. Browni*, the finest of all and the most popular in cultivation, as well as the most hardy and most easily grown when once established. The other group should consist of the three others, viz., the old *L. japonicum*, *L. odoratum* of Planchon, and *L. japonicum Colchesteri*. Being delicate and difficult to manage, the two former are at present probably lost in Europe. These three forms are perhaps very closely allied one to the other, but in various points they seem to differ much from *L. Browni*, especially in the bulbs.

Haarlem.

J. H. KRELAG.

**Aquilegias from Seed.**—A week ago I should have been inclined to agree with Mr. Dod (see p. 515) that any attempt to grow seedlings of *Aquilegia chrysantha* and *Skinneri* was a farce, but on my return home the other day, after two months' absence, I was surprised to find a bed of each variety blooming well, and I was so much struck with the exceeding beauty of *A. chrysantha* and the quaint colour of *A. Skinneri*, that I am most anxious now to continue growing them. The seed was sown in the spring of 1876, and in the autumn the young plants were pricked out on the warm border where they are now flowering; last year they made no growth, and thus it was that I had given up all hopes of success and had almost forgotten their existence. I should be glad if anyone would tell me what is the best thing to do with them, and if it be necessary, as with *A. cœrulea*, to have young plants every year.—E. FARRER.

— I find *Aquilegia chrysantha* to come true from seed and to thrive well, but it does not like frequent removal, and it is well to sow a little seed of it every year. *A. glandulosa* does badly generally; the seed germinates indifferently, and the young plants grow very slowly. I find that seeds of *A. cœrulea* also germinate slowly, and so do those of the new hybrid *cœrulea*, as seed of that and of *californica* hybrids, sown at the same time, showed the latter to germinate in one-half the time required by the other, and the plants are now much larger. I have seeded plants to bloom next year of *A. chrysantha*, *glandulosa*, *cœrulea*, and the two new hybrids, and directly I get seed ripe—which will be in a day or two—I shall sow seed of that earliest of all *Aquilegias*, the dwarf *A. formosa*, and shortly seed of the fine purple *A. alpina superba*. I shall thus be enabled next year to thoroughly test the point as to the truthfulness of varieties from seed. Beautiful as *Aquilegias* are in the open border, I cannot but think that many of the choicest kinds are well worthy of pot culture; indeed, in the fine group of choice plants staged by Messrs. Veitch at South Kensington last week few were more attractive than a well-flowered plant of the new *A. cœrulea* hybrids, which held its own, as regards elegance and beauty, even when associated with *Orchids*, *Gloxinias*, and other richly-coloured flowers. Perhaps some day flower show committees may take *Aquilegias* under their patronage, and offer prizes for plants of them in pots. One of the prettiest kinds, the early dwarf *A. formosa*, is by no means common, but it is well worth a place in any hardy plant house, as it flowers freely through the month of April. That it will invariably come true from seed there can, I think, be little doubt, as it is in bloom so long before other kinds. *Aquilegia* seed should be

sown in pans or boxes under glass not later than the month of April, if possible, as it is then easy to secure good plants to flower the next year. The common garden kinds will germinate anywhere, but my remarks are intended to apply to the choicest species and hybrids.—A. D.

**Coloured Primroses in Woods.**—Mr. Williams (see p. 530) seems to imply that the naturalization of coloured Primroses in woods is a hopeless task, and doubtless it would be if they were to be planted in positions where every one calling themselves "naturalists" had free access to them; but there is no lack of semi-wild gardens as much secluded from "British plant collectors" as are the carpet beds of modern flower gardens. I well remember the lovely effect produced at Cliveden by planting large masses of coloured Primroses, *Polyanthuses*, *Oxlips*, &c., in semi-wild portions of the grounds, and even by sowing the seed of such varieties in borders or margins of shrubberies where they had a chance of perfecting their growth unmolested. I am myself an ardent admirer of our native yellow Primrose, but I certainly think that masses of it would be none the less effective by being intermixed with the bright coloured varieties; they increase so rapidly by division, that hundreds this year might be multiplied into thousands next season.—JAMES GROOM, Wangford.

— Mr. Williams recommends us to plant in a wholesale manner such flowers as Snowdrops, Crocuses, Snowflakes, and Hyacinths in places remote from the garden, but treats as absurd the idea of introducing the coloured Primrose into similar situations. At p. 457, in speaking of *Lilies* of the Valley, he advised us to "plant them in abundance," as they "would not then need to be guarded;" whereas at p. 530 he insists that such a proceeding would merely serve to attract predators. At p. 457 Mr. Williams says: "The fact is, there is too much conservatism as regards these sorts of flowers. Some imagine that flowers of this or any other class never ought to be out of a garden. If all surplus stock of Snowdrops, Crocuses, and Hyacinths were distributed in woods and copses, a new feature would be added to them which they do not at present possess." It appears to me that if such flowers as those enumerated may be planted and preserved in woods, that the Primrose would be equally secure, for I am sure that the *Lily* of the Valley and garden Hyacinths would be equal in value to the Primrose in the eyes of the spoiler. In spite of Mr. Williams' censure, I cannot see that there are such insuperable difficulties in the way of naturalising the Primrose. On most estates there are little bits of shady wood, not necessarily a mile away from the dwelling, where the experiment could be made with a prospect of success. I know of many such in which there is but little danger of flowers being stolen. Owners of property manage to prevent indiscriminate trespassing and pilfering now-a-days, and it must be something a little more valuable than a few roots of flowers that will tempt a person to run the risk of the penalties to which the theft of them would render him liable. There is a wood in this neighbourhood, near a large manor, which is carpeted with the common Primrose and *Ferns* of various kinds. Permission is annually given to the neighbouring population to go and gather the flowers on the condition that no roots are taken up, and I have never known this privilege to be abused. Were other kinds of flowers introduced into such situations, I cannot imagine that the owner would have any difficulty in protecting them. "A. D." suggests the *Polyanthus* instead of the Primrose. If a greater amount of seed can be had of the *Polyanthus*, then that is perhaps the most suitable flower with which to start. Why I suggested the Primrose was because in many districts this tribe of plants do not hold out in beds and borders, whereas in the same places they thrive almost without care when in perpetual shade during the summer. I hope that some of your readers will give them a trial.—J. CORNHILL, Blythe.

— I will use all the spare plants I have to carry out Mr. Williams' suggestion, and they shall be placed in a wood, situated as he describes, where already Snowdrops, Aconites, and Daffodils grow in profusion.—E. FARRER.

**Dicentras.**—It is almost impossible to praise these too highly. Three plants of *D. spectabilis* bought in Covent Garden, in March, 1877, had all their flowers cut off for decorating vases, and their roots, which were afterwards planted in a shady part of my garden, have this year produced enormous clumps of blossoms and foliage. Early this spring I bought two more pots of it, cut off all the leaves and blooms for vases, and placed the pots in a cold, shaded frame. They are now in flower again, and very pretty objects they are. *D. eximium* and *D. pulchellum* used to be considered identical, but a visit to Mr. Parker's nursery grounds at Tooting just now will enable any one to note the differences amongst them.—W. T. T.

**Violas at Swanley.**—The improvements that have taken place in this ornamental class of hardy border plants during the last few years are so satisfactory, that now we have kinds with flowers as large as those of the garden Pansy of a quarter of a century ago, while, as

regards rich and varied colours and profusion of blossoms, they are quite equal to the still beautiful *Viola cornuta*. Mr. Cannell, of Swanley, who has lately planted nearly an acre of ground with the best known kinds, will, in a short time, have such a display of blossom as has rarely before been seen. Grown in good, rich, sandy loam, the plants make rapid growth, and, even in exposed positions, if the soil be deep, they continue to yield masses of blossom from April till October. Although shady places are usually recommended for *Violas*, they will succeed equally well in sunny ones under the conditions just named. Among the sorts which appeared to be the best we selected *V. Admiration*, bright purple; *Mulberry*, dark claret; *Blue Gem*, very large and of a lively blue; *Spring Beauty*, purple; and *Cliveden Purple*. These have large, well-formed flowers, and are in every way well worth culture. *Sovereign* has smaller flowers of a bright golden colour, with a dark eye, and *Queen of Spring* is of a self lemon colour. The best whites were *Vestal* and *Purity*, and *Blue-bell* is a profuse bloomer and very attractive. Some kinds may be found probably with larger flowers than those named, but, for abundance of bloom and good quality, all of them are excellent.—S.

### THE SNOWDROP IN SOMERSETSHIRE.

ANYTHING that throws a light on the native habitats of beautiful plants may be useful to those interested in naturalising them, or in

Snowdrops in "bottom" in Somersetshire.

introducing them to fresh places. The little illustration herewith given shows one of the homes of the Snowdrop in Somersetshire, where it grows in spots that at first sight would be thought unsuitable. It grows in a woody valley with a stream running through its centre, both in places where there is an open carpet of Grass, and also on the margin of the stream, under the shade of bushes, and about the stumps of old Hazel trees and Alders. In a low-lying, damp wood, near the same valley or "bottom," they grow abundantly under deciduous trees and under bushes. In both these places they display great beauty in early spring.

**Double-flowered Eschscholtzia.**—I send you a flower of *Eschscholtzia*, which has come double for these past two seasons, and this is the first flower which it has produced this year. What is your opinion of it? The plant is of a very dwarf habit.—H. D. PALMER, *Noyland, Colchester*. [The flower sent is certainly double, and very pretty.]

**Old-fashioned Flowers.**—I have just now in fine bloom what I may term an intermediate flower garden, consisting of white Pinks, East Lothian Stocks, various kinds of Pansies, Daisies, Carnations, and Pæonies. The better kinds of Pinks, just coming into flower, dressed with *Fyralthrum*, make a fine display, which also includes London Fride, Lilies of the Valley, and Forget-me-nots—together a pleasant sight. Nor must I forget that beautiful spring-flowering plant, *Dicentra spectabilis*, which, being quite hardy, is simply unique.—R. GILBERT, *Burgley*.

## THE INDOOR GARDEN.

### FORCED FLOWERS FOR WINTER.

In addition to the numerous species of tender or exotic plants whose natural time of flowering is during winter or early spring, there are also many hardy or European species which can be induced to unfold their blossoms at a period long anterior to their usual or natural season of doing so; and this result is, of course, accomplished by subjecting such plants to the influence of an artificial temperature. Some species of plants, as well as some varieties of the same species, are more easily started into active growth than others, and are consequently better suited for forcing. As regards the Rose, to which I will first allude, some of the more recently introduced sections, such as the Hybrid Perpetuals, are forced into bloom with greater facility than the old Provins or Cabbage variety (*Rosa centifolia*); and formerly this was almost the only variety which was forced. There is, therefore, now little difficulty in having a display of Roses in bloom during February and March under glass that will rival that of July in the open air. Under proper care, most varieties of the Rose will remain in a healthy condition, although forced, year after year for an indefinite period. A collection near here is now (middle of March) in full bloom, and the plants of which it consists have been forced every season during these last twenty or more years, and have never once failed to bloom profusely, and they are still in perfect health. They are chiefly Hybrid Perpetuals and Tea-scented varieties, and the majority of them are on their own roots, a few upon the Manetti stock, and a few upon the Brier; and of these three methods I am inclined to give preference to the first, viz., on their own roots. The plants were originally potted in light, rich, fibrous loam, and they are re-potted every season about the beginning of January into the same sized pots, *i.e.*, 8 in. and 10 in. in diameter. In doing this the drainage is carefully renewed, the balls of soil considerably reduced, and straggling roots are cut back, so as to admit of the use of a considerable portion of fresh rich soil. The annual pruning of the plants is generally done some time previous to the re-potting, and as soon as the latter has been performed the pots are placed upon a slight bottom-heat, and the atmospheric temperature of the structure is gradually increased, although the minimum or night temperature is seldom allowed exceed 55° with a maximum of 65°. Thus treated, the plants generally commence to bloom about the third week in February, when they are removed from the forcing pit and placed in a light greenhouse, in which they continue to bloom until the middle of April, or even later, and furnish all the time an abundant supply of flowers in a cut state. During summer the plants are placed or plunged in ashes on the north side of a wall, where they are carefully attended to with water, until the return of the season, when they are pruned, re-potted, and again placed in the forcing pit.

The genus *Deutzia* has already been mentioned as comprising plants well suited for forcing. But the well-known, although comparatively recently introduced, *D. gracilis* is well worthy of special notice. It is a dwarf-growing deciduous shrub, and, although sufficiently hardy to be grown in the open air, is, nevertheless, seen to the greatest advantage as a greenhouse plant, and is easily forced into flower at any period during winter or spring, when it forms a decorative object either for the greenhouse or conservatory, and furnishes at the same time an abundant supply of pure white Orange-blossom-like flowers that are useful in a cut state. Plants of this *Deutzia* remain for a considerable time in bloom. Old plants of it may be readily increased by division, or the young unripened shoots from plants which have been forced made into cuttings, will be found to root as freely as *Verbeas*. When plants which have been forced are out of bloom they should have the shelter of a cold pit or frame until about the beginning of May, when they may be more or less cut in and thus induced to assume any form desired, such as that of a standard or a pyramid, and they may either be retained in pots, or planted out in any ordinary rich light soil, where, during the ensuing summer, they will produce and ripen young shoots. The same plant may generally be forced year after year for some considerable time, although, as has been recom-

mended in the case of the Persian Lilac (see p. 518), it is advisable to have a stock of suitable sized plants in reserve from which to select the necessary number required for forcing each season, potting them during October, and transplanting those not intended to be forced, cutting back the roots more or less at the same time, so as to prevent the plants from becoming unduly large. The cutting in of the shoots should be deferred until the spring is somewhat advanced, and all danger from severe frost past. By pursuing this or some similar system it will seldom be found necessary to force the same plants two years in succession.

Among hardy herbaceous plants suited for forcing, the position which is assigned to the Rose among hardy shrubs may be accorded to the various varieties of Pinks. The sorts suited for this purpose are now numerous, and are mostly in the way of the well-known Anna Boleyn, which may be considered as the type of the forcing kinds, many of which are exceedingly beautiful as well as fragrant, and are great improvements upon the original type. The necessary stock of each sort should be annually raised from cuttings, put in early in March. And the earliest batch of forced plants will generally furnish the supply of cuttings. They will strike freely in a compost consisting of about equal parts of sharp river or silver sand and finely sifted leaf-soil, using well drained pots some 6-in. in diameter, placing them upon a slight hotbed, and covering them with a hand-glass. Thus treated, they soon become well-rooted, when they should be potted off singly into 3-in. or 4-in. pots, and be kept in a somewhat close and growing temperature until they have become well established, when they may be placed in a cold pit. When the pots have become well filled with roots, they should be shifted into their flowering pots, which need not exceed 5 in. or 6 in. in diameter, and placed in any sheltered, but open situation in the open air; or the plants, when well rooted, may be taken from the 3-in. pots and planted out in a bed of moderately rich soil in the open ground, and carefully raised with good balls of soil and potted in October, using soil for the purpose of a light rich character. Among the best sorts for the purpose are Lord Lyons, Rosy Morn, Claude, Mrs. Pettifer, Coronet, Most Welcome, The Duchess, Miss Jolliffe, Garibaldi, and Anna Boleyn. The last named is exceedingly fragrant and beautiful, but the pod is liable to burst, a circumstance which detracts from the value of the bloom.

The *Hotesia* (*Spiraea*) *japonica*, as it is frequently called, is an exceedingly useful plant for forcing, on account of its fine foliage and large panicles of leathery-white flowers, which it usually produces in great abundance, and these have also the very desirable property of remaining long in good condition when cut and placed in water, as well as when allowed to remain upon the plants. The latter are naturally of a dwarf and compact habit of growth, and seldom require support in the form of stakes or otherwise; consequently they are well adapted for all decorative purposes. And although no foliage can be supposed to associate better with flowers of any kind than that of the plants which produced them, still it so happens that some plants, such as the Lilac, Ghent Azaleas, Kalmias, &c., when forced into flower, do not produce foliage enough for the purpose, and there are certainly few plants whose foliage is so well adapted to supplement this deficiency as that of the *Hotesia*, which is exceedingly ornamental, and when placed in water keeps long in good condition. In the open air this plant succeeds best in a somewhat damp situation; the soil and climate of Holland are, therefore, admirably suited to its culture, and it is consequently imported annually from that country in small clumps or pieces ready for potting for forcing. It may, however, be successfully grown for that purpose in suitable situations in this country, and the number of plants likely to be required should be potted in October and placed in a cold pit or frame, from which they should be introduced at intervals into the forcing house. A somewhat brisk heat is necessary to induce it to start into growth; but this, at the same time, should be applied gradually, and before the flowers are fully expanded the plants should be removed into the greenhouse, or some other cool structure. As an abundant supply of water is absolutely necessary, the pots may with advantage be placed in pans or saucers, which will retain the water which drains from the pots, and which the roots of the plants will speedily absorb.

The Lily of the Valley is deservedly held in high estimation for forcing, and, like the *Hotesia*, it is annually imported in considerable quantities from Holland in patches of a suitable size for potting, and the imported roots are generally found to succeed better than those produced in this country. After being potted, it should be plunged and covered up to a depth of 5 in. or 6 in. in old tan or cinder ashes. The slight warmth in the plunging material will soon stimulate the roots into activity, and a portion of the plants should be transferred at intervals into the forcing house, in order to keep up a succession; but it is always advisable to remove them into a cooler structure as soon as the blooms begin to unfold.

Solomon's Seal is also a native of Britain, and equally well adapted for forcing as the Lily of the Valley. It seldom fails to produce abundance of shoots clothed with innumerable silvery bell-like flowers, and is altogether more effective when grown in pots under glass than it is when out-of-doors, where it is apt to become somewhat coarse. On that account it should be cultivated for the supply of plants for forcing in beds of light, not too rich soil, in an open situation, and from these beds the portion of plants required for forcing should be annually potted about the end of October, using pots of some 6 in. or 8 in. in diameter. After being potted the pots should be covered with cinder ashes or old tan, and the plants should be introduced at intervals to the forcing house in order to keep up a succession. The leaves (depending of the gracefully drooping blooms) are exceedingly useful, being of a delicate yet rich shade of green, more particularly so when the plants have been forced, and are admirably suited for mixing with cut flowers in vases. The plant is easily increased by division and soon recovers from the effects of forcing, but it is, at the same time, unadvisable to force the same plants two seasons in succession.

*Dicentra spectabilis*, one of the most beautiful of hardy herbaceous plants, is very easily forced into bloom, and forms an exceedingly effective plant for the decoration of the greenhouse or conservatory. When growing in the open air it is sometimes injured by spring frosts, which not unfrequently occur during the latter part of April and early in May, while plants grown under glass appear to possess a delicacy in foliage as well as in flower, which even surpasses that of plants in the open air. The plant requires little or no preparation for forcing; all that is necessary is to pot the desired number of roots in pots of various sizes early in autumn, plunging them in cinder ashes in a cold pit or frame, from which portions of them should be introduced at intervals into the forcing houses, and as soon as they are in flower they should be removed into a cooler structure. It is easily increased by division of the roots, or by cuttings which will root readily if inserted in light soil or sand and leaf-mould under a hand-glass. There is also a white-flowered variety of this plant, which forms a contrast to the original type, but does not surpass it in beauty and elegance. It retains, however, the purity of its colour better when grown under glass than it does in the open air.

The Neapolitan and other sweet-scented Violets are easily forced into bloom during winter and early in spring, and beds of them in the open air should be encouraged to furnish rooted runners as early in the spring as possible. In order to promote this the surface of the beds should be covered with a portion of sifted leaf-soil and sand. As soon as they have become well rooted they should be separated from the old plants and planted out in a bed of rich light soil, and if in a somewhat shady situation so much the better. They should be supplied well with water during dry weather, and any runners which may be produced should be removed. In October they should be potted into pots 5 in. or 6 in. in diameter, and at once placed in a light, warm situation near the glass, where they will soon commence to bloom, and will continue to do so throughout the winter and spring; or a portion of the rooted runners, instead of being potted, may be planted in a frame upon a slight bottom-heat, keeping the plants quite close to the glass, covering well up during frost, and admitting air whenever the weather will permit.

In addition to the plants already named there are many other hardy species, many of which are exceedingly impatient of artificial heat; but they may, nevertheless, be induced to flower at periods much earlier than is natural to them by merely

potting them during the month of October and placing them in a light, warm greenhouse, or similar structure, carefully attending to them as regards watering, and keeping them as near the glass as possible. By this means the beauty and fragrance of such plants as the Jonquil, the various varieties of the hardy Primrose, the Crocus, the Winter Aconite, the Snowdrop, &c., may be enjoyed under glass at times when the state of the weather will not permit this to be done in the open air.

Culford, Bury St. Edmunds.

P. GRIEVE.

### MAMMILLARIA ELEPHANTIDENS.

This is a somewhat corpulent-looking species, each mamma being about  $\frac{1}{2}$  in. long and 2 in. round, terminated by a cluster of from seven to nine pale brown spines. The flowers, which are large for those of a Mammillaria, are straw coloured. Plants belonging to this section of the genus are apt to become affected by red spider; there-

fore they do best in the open air during summer. They only grow about 6 in. high, and are, as a rule, favourites with those who are fond of Cacti.

Sudbury House, Hammersmith.

J. CROUCHER.

### IMPROVED TEA ROSE CULTURE.

The manner of growing these, the only Roses worth calling "perpetual," is destined to undergo a revolution. There has of late years been a great move towards growing, flowering, and finishing with plants in pots in one season—for instance, Fuchsias, Gardenias, Tree Carnations, and many others of less importance—but till within a year or two I had no idea that Tea Roses were amenable to this style of culture. It is, however, proved that they are not only amenable to it, but that grown in any other way they will bear no comparison at all. Our young beax will have to look elsewhere for a supply for their button-holes, for Catherine Mermot and Souvenir d'un Ami 5 in. or 6 in. across will be voted vulgar in the extreme; even in the bud just showing colour they almost look like miniature "Sugar-loaf" Cabbages. Happily our ladies do not object to large Roses, even should they be able to bury their faces in them; therefore I am on the side of the ladies (the next best position to that enjoyed by Mr. Disraeli when he said he was "on the side of the angels"), and shall listen to no one who decries large Roses, unless they are at the same time either coarse or scentless; for remember the words "large" and "coarse" are not synonymous. Anyone who has noticed the natural mode of growth of Tea Roses will have observed that to thrive at all well they must throw up a continual succession of suckers, first weak, then a little stronger, and afterwards, if encouraged, stronger still. This, then, is the key to the only right way of growing them, and to make sure that all the

suckers shall be of the right sort it is necessary to have the plants on their own roots. I know no reason for growing them on Briers or Manettis; it cannot be to make them grow stronger, for it has the very opposite effect in the long run. It cannot be to enable them to withstand winter, because if they are killed down to the ground all is gone but the Brier, whereas Tea Roses on their natural roots down in the ground a foot or two would probably start again from the base in the spring. Nor is it because they are difficult to propagate, for they are as easy to strike as Verbenas. If it be argued that it makes them more floriferous, then remember that, with the exception of one or two sorts not strictly Teas, where there is growth flower will follow as a matter of course, and the finest flowers do not come on the weakest growth.

In July, 1876, I inserted cuttings of the best sorts I then had, including some which are not yet surpassed—viz., Devoniensis, alba roses, Catherine Mermot, and Souvenir d'un Ami. The cuttings were made of the firmest growth of the current year, and placed under handlights on the north side of a wall. They soon rooted and started growing without losing much of their old foliage; they were then potted into 4-in. pots, placed in a cold frame kept rather close and shaded till they started, then gradually hardened, and soon after—probably in September—they were shifted into 8-in. pots and placed outside. They were protected a little during winter, being in a cold house not by any means frost-proof, and during last summer were re-potted into 14-in. and 15-in. pots, using soil such as would grow fruit trees well in pots—viz., fresh rather heavy turfy loam, a sprinkling of  $\frac{3}{4}$ -in. boiled bones, a few pieces of charcoal, and a little decayed farmyard manure of good quality dried and rubbed through a sieve. The loam was rough, many of the pieces being half the size of a brick.

This spring we have had flowers such as I had never seen before, and the plants have kept constantly throwing up suckers stronger and stronger, with flowers to correspond. But the pots are already too small for the plants; they will, therefore, be transferred to the open ground on the north side of the walls of some of the houses, and be succeeded by a fresh batch. It will be seen that the plants now to be turned out are nearly two years old; but from past experience I have no doubt of being able to do them nearly as well, if not quite so large, in one year. It may be said that the same liberal treatment given to plants not on their own roots might have produced equally satisfactory results, but I can say decidedly, no; for I bought some of the best plants procurable, and treated them as well as I was able, and they are simply nowhere in comparison.

Mildew does not often come spontaneously on plants grown thus without a check, but the purchased plants of newer sorts had some and it spread to the others. When such a case occurs I practise and advise no half measures, but gather all expanded flowers, place some sulphur with water in a waterpot, stir well about, and apply with a syringe in fine spray to both sides of every leaf in the house whether affected or not, and the first time the sun shines on it every spore will be killed. This is much easier and a far more effectual plan than dusting. The sulphur can be syringed off in a day or two, leaving hardly a trace behind. I do not think sulphur does much good in dull weather either inside or out; it is not at all easy to kill mildew outside in autumn when the sun has but little power.

So much for Tea Roses indoors. I have said that the plants in pots now will be turned out against the north side of some of the houses. I am fully convinced that Tea Roses do not like extreme temperatures. A south wall is the very worst possible position for them, but the north side of a heated house suits them to perfection. I have all such positions almost covered with them, but some of the sorts will have to give place to their superiors. I should advise friends in a less genial climate to try their Roses on the western or south-western side of a building. Mere garden walls will not do so well as the walls of a building. Tobacco powder is very useful for dusting whenever there is a suspicion of fly. It is certain death to the fly with which it comes in contact, and if applied in the evening when the sun is not powerful it will not injure the foliage even if allowed to remain on next day. Dusted over cuttings closely confined in a hand-light or bell-glass, it will kill every insect whether it touches them or not, but in this case the sun must on no account touch it. The powder I use is prepared by Corry & Soper, London, and is supplied by nurserymen; but I believe there are other manufactures equally to be depended on. It is free of duty, and therefore costs little.

WILLIAM TAYLOR, in "Journal of Horticulture."

Clorodendron Balfourii.—I do not know any stove creeper which can be relied on like this to produce a great quantity of bloom for a long while, unless it be the Bougainvillea; the two would certainly not be easy to match. A plant of this Clorodendron here, which was a small plant about 9 in. high two years ago, was then put into a

14-in. pot, and it now extends one way down the stove path for 20 ft. on a broad trellis, and nearly as far the other way, through a hole made in the glass partition into the intermediate house, which gives us flowers for a much longer period. In the stove the flowers are nearly over, but in the intermediate house they are still in perfection. Possibly this plant has given us about one-quarter of the trouble that an exhibition "specimen" of the same kind would have done, and it has produced more flower in one season than such specimens usually do in half-a-dozen years, judging from the plants we have seen grown by the foremost cultivators. From the base of our plant right to the extremities of the shoots it has been one mass of flower, and I should hardly be believed if I were to state how much flower has been cut from it for indoor decoration. Just at present it seems to have flowered itself nearly to death, having as yet made little growth; but it will recover as it has done before, and finish its growth in good time. It delights in good strong loam principally, and, when once it is established in the pot, it can hardly be too well fed with top-dressings and liquid manure. Our plant has not been shifted for these last two years, but it will receive another shift as soon as it has done flowering, and afterwards top-dressings must keep it going. In a 20-in. pot we expect it to cover a trellis some 60 ft. long and 4 ft. wide; it now covers more than the half of that in its 14-in. pot. This shows the advantage of allowing such plants to grow after their natural bent instead of confining them to a pot, and after years of culture getting a specimen perhaps 2 ft. through, with as much bloom on it as they can ever carry away in his hat, which is certainly as much as the finest specimen I ever saw produced.—J. S.

#### CONTINUOUS FLOWERING OF BOUGAINVILLEAS.

*B. SPECTABILIS* is much more difficult to manage than *B. glabra*; it will never flower satisfactorily, if at all, if kept in a growing state all the year round, nor will *B. glabra* continue to produce its beautiful racemes of flower in the same strength and profusion long without a period of rest. A plant of *B. glabra* covers the roof of a span-roofed house at Court Hill, near here. This plant, which is planted out, always flowered very well under ordinary stove treatment, but in consequence of alterations in the house, the stove was turned into a cool house in winter, and in the summer there was a high moist temperature kept up for general purposes. Under this change of treatment it seemed to be transformed into a huge mass of flower, the racemes being of unusual length, and the colour a richer and deeper purple than usual. Another notable plant of *B. glabra* may be seen at Calderstone. This I have been in the habit of seeing for over seven years. It is trained exactly like a Vine on the "short spur" system, and is supposed by many to be a distinct variety, and the way in which it is treated is attributed the reason why it always flowers so regularly, and so equal in strength. The spurs are about 8 in. apart, and the shoots, which are trained with system and regularity, are cut back to an eye at the base at the winter pruning. It would thus appear that the proper system to pursue in regard to the cultivation of this plant would be to treat it much in the same way that we do the Vine. That the Bougainvillea will flower continually over a short period, more or less, according to its strength, there can be little doubt, but it will soon become a "thicket," and ultimately get flowerless. A neighbour tried the *Allamanda Schottii* on the continuous flowering principle, and success seemed to attend his efforts for a time, but eventually the size of the flowers began to diminish to such a degree that one could hardly have recognised the variety. With regard to *Bougainvillea spectabilis*, it is absolutely necessary to give it a good rest in winter. Twelve months ago I saw this variety in magnificent condition at Kew. It was in luxuriant health, and the flowers were of a rich purplish shade, considerably more striking than that of *B. glabra*. It was growing in a small house adjoining the Victoria house, in which a high summer temperature is kept up, but in winter the thermometer is allowed to fall as low as 40°. In this I was told laid the secret of success. I do not think any one will ever succeed in flowering this variety where it is planted out in a warm moist stove. The best plan would be to grow it in a pot as we do Vines, and rest it in winter.

W. HINDS.

**Ficus repens.**—For covering a bare and unsightly wall, either in a greenhouse or stove, this plant stands unrivalled, owing not only to its rapid growth, but also to the tenacity with which it clings to the wall against which it may be planted. I have seen houses with walls in a wretched condition which one or two of these creepers planted against them soon made attractive, especially if a variegated plant, such as *Cissus discolor*, be allowed to run amongst them. I could point to a number of walls, ranging from 8 ft. to 10 ft. high, where it is impossible to see a single brick.—J. PEAKE, Worcester.

#### PLATE CXXXI.

#### THE EVERLASTING PEA.

Drawn by H. NOEL HUMPHREYS.

NEXT to the Sweet Pea (*Lathyrus odoratus*), the Everlasting Pea (*L. latifolius*) is perhaps the most ornamental of a genus comprising upwards of 100 species, nearly all of which are pretty and many of them very handsome. Although an exceedingly hardy, as well as a showy, plant, it has apparently never before been figured in a horticultural or botanical journal. Both the white and rose-coloured varieties have long been in cultivation—how long it is impossible to say—but the striped variety is of more recent origin. This, some people would say, is the least pretty of the three. Doubtless much more ornamental varieties might and will be raised, and if a variety were raised in which the white and rose were contrasted, as in some varieties of the Sweet Pea, it would soon have many friends. The name Everlasting Pea is in reference to its perennial character in contradistinction to the annual duration of the Sweet Pea. It is readily distinguished from the latter at a glance, in consequence of the racemes being many-flowered instead of only two-flowered. Generously treated, it will grow 3 ft. or 10 ft. high, and bear a succession of flowers. In many country places it is a favourite cottage garden plant, though it has been much neglected by gardeners. A native species, *L. sylvestris*, is a similar, though less showy, plant, smaller in all its parts. This is also sometimes cultivated and mistaken for *L. latifolius*, which has become naturalised here and there in various parts of the United Kingdom. The true *latifolius* has a wide range of distribution in Continental Europe. Before leaving this I cannot refrain from recommending the elegant Grass Vetch (*L. Nissolia*), an annual species with Grass-like foliage and almost crimson flowers. It is a rather rare native plant in Sussex and some other counties of England.

W. B. HEMSLEY.

—The genus *Lathyrus* contains many beautiful plants, as the Sweet Pea, or the Posey Pea, as it is called by cottagers in many parts of England, bears evidence, and even the pretty little blue Tangier Pea must not be overlooked. *Lathyrus latifolius* is not a very happily named plant, but the specific name must only be taken in a comparative sense, as the leaves are not at all broad. It is an old inhabitant of our gardens, and perhaps one of the hardiest and most easily cultivated plants in existence. Thriving, as it does, almost anywhere, even in court-yards, amongst flags and boulders, it may be made to ornament any dead, naked walls, for a few bits of it dibbled in among the stones under a wall will take care of themselves, as the long, leathery roots penetrate to a great depth. The white variety of Everlasting Pea has come into notice during these last few years. Different coloured kinds would look well planted together so as to form one mass. Such plants are peculiarly well adapted for wild, rough, stony places, rambling and scrambling over bushes and stones. Codling, and tying, and training only spoil them. Other Everlasting Peas are *L. grandiflorus*, which is not so rampant in growth, but infinitely handsomer than *L. latifolius*; the stems are weaker, and the flowers twice the size. This I consider the handsomest of all. Another species, *L. rotundifolius*, is comparatively a lower-growing plant than any of the family, having some affinity to *L. latifolius*, but neater in habit, and excellent for stony banks. Another one, *L. pyrenaicus*, is the most rampant of the family, growing 20 ft. in a single season, and bearing a prodigious quantity of blossoms of a yellowish tint, veined with purple. This is a charming kind for running over the trunks of dead trees and similar places. The last which I shall notice is *Lathyrus sylvestris*, which is one of the gems of our native flora, and I have often wondered that it is not more sought after and cultivated than it is. Its flowers are large and greenish, with purple veins, and to see this plant as I have seen it in Wales, festooning the bushes in open places in woods, is a sight worth seeing.

THOS. WILLIAMS.

Ormskirk.

[The specimens from which our plate was prepared were supplied from Mr. Robert Parker's nursery at Tooting.]

VARIETIES OF THE COMMON EVERLASTING PEA (*LATHYRUS LATIFOLIUS*)

## PROPAGATING.

**AZALEA INDICA.**—There are two ways of increasing this fine tribe of plants. The first is by means of cuttings taken off in the following manner:—When the plants have done flowering they will push out a number of shoots at the ends of the branches; press them down gently to the right and draw them off, then cut off any small pieces of bark that may be attached to them, leaving a little heel to each cutting, as shown in fig. 1. Fill some well-drained pots with soil consisting of one-half

Fig. 1.

peat and the other half equal parts of loam and silver sand, making the whole somewhat firm; then insert the cuttings firmly. Give a good watering, and place them on a half-penny manure bed in a frame with closely-fitting sashes. Shade during the middle of the day, and in about six weeks they will be ready for potting off. A second mode by which Azaleas may be increased is by grafting, and in order to have good shapeable plants the stocks should be from 6 in. to 9 in. high, according to the height required. The graft should consist of half-ripened wood, with from three to six eyes; the half-wedge

Fig. 2.

Fig. 3.

graft at the top, as shown in figs. 2 and 3, is a very good method. Bind both stock and scion together with matting or thread, and place a small piece of grafting-wax on the top of each, then set them in a close box on a cool bottom, and give air occasionally if they show signs of damping. H. H.

**Culture of Camellias at Florence.**—One of the most extensive and magnificent collections of Camellias, perhaps in Europe, is to be seen in the garden of the Cavaliere Cesare Franchetti, at Florence. The Camellia was introduced into Europe, in 1730, by the Ven. Father Kamel, and was first cultivated in Florence in the garden of Count Leopoldo Galli about 1794. The rich collection of Cav. C. Franchetti consists entirely of the best varieties, he being a most artistic and enthusiastic admirer of this flower. The following are among the most recent kinds added to his collection: Generalo Pescetto, Luisa Franchetti, Mapino d'Azello, Duchessa del Balzo, Principessa Antonietta Strozzi, Marchese Luisa di Lascio. The variety *Goffredo Odero* merits particular mention. In a plant containing thirty flowers no two are alike, so much do they differ in form and colour. The variety, however, which is decidedly the most remarkable as regards the beauty of its stripes, regularity and fineness of petals, and brightness of colour, is not yet in commerce, and has been named *Engenia Parlatore*. Cav. Franchetti has no fewer than 30,000 plants of all sizes, many of them raised from seed.—“*Bullettino della R. Società Toscana di Orticoltura.*”

## GARDENING FOR THE WEEK.

## Indoor Plant Department.

**Treatment of Orchids when in Flower.**—With such Orchids as succeed under cool treatment there is little drawback to their inspection when in flower on the score of too much heat in the houses in which they are grown, and, to some extent, this holds good with those that thrive in an intermediate temperature; but with such species as are indigenous to the hottest parts of the Eastern and Western Hemispheres, it is anything but an unalloyed pleasure to remain in the house in which they are grown at the season of the year, even for a short time. Where large collections of Orchids are cultivated, it is always advisable to have a small house or a compartment partitioned off for the reception of the plants when in flower. Where a separate house does not exist that can be devoted to this purpose, the best position is to have a division at the entrance end of the Mexican house, where such plants as are in flower can be accommodated for the time with a temperature and condition of the atmosphere such as are most calculated to prolong the bloom for as long a period as possible, and where it can be viewed with comfort to those who are wishful to give more than a passing glance to these most singular and interesting plants. Another advantage in the use of such a house or compartment is, that the plants, even from the hottest houses, can remain here for a reasonable time without suffering any injury; and if a little taste be exercised by the judicious introduction of a few small, elegant-habited Palms, Ferns, Lycopodiums, Bertolonias, and other subjects of similar character, it will result in a combination at once beautiful and effective. One of the first essentials in such a house or division of a house is that the temperature can be kept equable. The best during the night should be as low as the plants grown in the hottest structures can bear, with a considerably less proportionate increase of warmth during the day than is given to them when in their growing quarters. This will have no injurious effect, for the simple reason that the majority of the plants whilst here will not be making growth. Another primary consideration is the state of the atmosphere; it should not be so dry as to completely stop the root extension of such plants as *Aerides*, *Saccolabiums*, and *Vandas*, which, being true air plants, make a good deal of roots completely above the soil, neither must there be sufficient humidity to permit of the slightest condensation of moisture on the flowers, as this especially is fatal to the bloom of those plants that luxuriate in a higher temperature, and more particularly in the case of white flowers such as the greater portion of *Phalenopsis*. Enough shade ought to be used during sunny weather to prevent the temperature rising too high, otherwise it will necessitate giving more air than is conducive to the well-being of the warmer section, as also to the duration of the flowers. A little thicker shade whilst the plants are here and making little or no growth will have no injurious effects upon them, such as the insects which do so much shade which is injurious in its effects, but, although, as I have intimated, it will require to be given in the daytime, still I should advise its admission being confined altogether to the roof ventilators, and under no account given in such quantities as to cause a perceptible current amongst the plants, which would do no harm to the generality of other flowering subjects, but with most Orchids very soon has the effect of drying the air in a way alike detrimental to the bloom lasting and the health of the plants. In such a structure, subjects from the coolest house, such as *Odontoglossum*, *Masclevallias*, *Epidendrum*, *Ruellias*, and similar plants that thrive in a low temperature, may be placed without suffering any injury; and if, as already said, the arrangement be effected with taste, the house will possess a charm such as not to be equalled by a combination of any other plants.

**Orchids for Exhibition.**—Orchids are now so generally exhibited that a few words may not be out of place to those who have not had much experience in the matter. Where it can be avoided it is very much better not to have to subject the plants to any extremes of temperature either by the application of too much heat to force on such as it is necessary to get to open their flowers in time, or by retarding others that may be advancing too quickly, but, of the two evils the former is the most likely to be injurious in its effects, for although the flowers of any species in strong heat will usually open more kindly and grow to a larger size than under cooler conditions, yet the plants when moved from such a temperature to that of an exhibition tent are very liable to suffer severely through the sudden change from a hot to a low temperature. Wherever Orchids are submitted to anything approaching a sudden change from heat to cold they should be as dry at the roots as it is safe to keep them without danger of their being injured by the leaves or bulbs shrivelling, and it must ever be borne in mind that almost all Orchids that consist of leaves, simple stems, and roots alone, with the absence of pseudo-bulbs, are invariably more susceptible of injury from this cause than those that are furnished with pseudo-bulbs; consequently, it is necessary to be more careful in dealing with the former, and wherever under the influence of an excess of heat it is well to give more light, as this will be found to have a favourable counteracting effect. In the case of plants that have to be kept back this, like all other operations connected with retarding flowers, should be done in the early stages of the flower development. If kept too cool when the bloom is made considerable progress and approaching the last stages of growth it is certain to expand deficient in size, and generally in substance and colour; and if subject too long to cool treatment at this stage it will often cause the destruction of the flower-stems altogether. Whilst this retarding process is going on it is essential to be very careful in the application of water to the roots, using no more than is necessary to keep the plants plump, and to duly sustain the advancing flowers; the atmosphere should not be so dry as to induce a shrivelled condition, but

all over-humidity must be guarded against, as it will be very injurious in its effects. The plants must not be kept too dark, neither should very much air be admitted, or it will cause the necessity for more water being applied, both to the roots and in the atmosphere, than is conducive to their well-being.

**Packing Orchids for Exhibition.**—This is an operation that can only be learnt effectually by practice and observation. From the soft fleshy nature of the greater portion of the species they are extremely susceptible of injury from the rubbing and chafing inseparable from the shaking they undergo in transit; this not only results from the flowers individually rubbing against each other, but also through the friction of the various parts of each bloom; for instance, the large-flowered *Laelias* and *Cattleyas* of the Mossin section require most careful packing, otherwise the sepals and petals are certain to chafe against each other or with the labellum, consequently every flower must have all its parts packed with fine cotton wool, so that not the slightest friction can take place, as will the flowers secured so as not to rub one another. *Angulias* again require special packing. It is no uncommon occurrence to see splendid examples of the beautiful yellow *A. Clowesi* or *A. eburnea* with the internal portion of their flowers all blackened through moving only a short distance, as the column and labellum, although entirely enveloped within the cap-shaped petals and sepals, get completely blackened through vibration, unless well packed with cotton to keep them from touching the side of the flower. The chaste white blooms of *Phalaenopsis amabilis* and *grandiflora* require to be protected with cotton, so that there is no possibility of their touching each other. The same is the case with *Odontoglossums*, especially the beautiful *O. vexillarium*, the immense labellum of whose flowers frequently overlap each other in a way that causes their rubbing, to certain destruction if sufficient of the wool be not used to keep their parts separate. The dense spikes of *Dendrobiums* of the densiflorum section are best enveloped in fine tissue paper tied round them so as to prevent the individual flowers moving against each other. The old but beautiful white *Calanthe veratriflora*, from the purity of its colour, shows the effect of the least friction more than most Orchids; with this also thin tissue paper is the best, completely enveloping each head of flower, folding the paper round it and securing it by tying firmly immediately below the head and also at the top of the spike, so that the paper will lay in contact with the whole of the flowers without pressing them too tightly, but so as to prevent their rubbing against each other. In the case of *Vandas*, each individual flower on the spike should be enveloped with as much cotton as will keep it completely away from the others. The spikes of all such plants must be secured by small sticks firmly inserted in the pots, to which they must be tied. It is also necessary to see that the leaves of the plants cannot, even when shook severely, touch the flowers. *Sobratias*, with their immense blooms, are very difficult plants to pack, and should have a petal animal of every leaf of the spike covered with cotton, which material, as in the case of all other Orchids, should be so secured that it cannot shake out. *Acerides*, *Scaccolabiums*, *Oncidiums*, *Epidendrums*, *Cypripediums*, *Barlerias*, *Brassias*, *Lycastes*, *Madevallias*, and *Stanhopes* require to have every flower, or raceme of flowers, tied to a single neat stick sufficiently secured that they cannot touch each other. If these directions are followed out with care and foresight, the disappointment which young exhibitors so frequently experience in finding upon opening their best flowers so disfigured as to be useless, will be avoided.—T. BAINE.

**Stove Plants.**—These, as a rule, are now making free growth, and, consequently, should be kept moderately warm, shaded, and well watered. By running *Dipladenias*, *Stemplantosias*, *Clerodendrons*, &c. and *Allamandas* on threads stretched across the rafters inside the houses, a greater quantity of bloom is produced on them than when their growth is more restricted. If required for specimen plants, the strings may be cut down and drawn out from amongst the shoots, which should be carefully and equally trained around a trellis. Re-pot all young plants as they require it, and by plunging them for a few days afterwards in a gentle bottom-heat the roots are stimulated into action. Attend to staking, tying, and keeping the plants free from insects. Ventilate moderately in the earlier part of the day, and opening in the afternoon; shade from strong sunshine, and with syringings and water sprinkled on the walls and paths keep up a moist atmosphere.

**Ferns.**—These are now growing vigorously, therefore abundance of root and atmospheric moisture is necessary as well as gentle syringings. *Chloridiums*, *Claytonias*, and other ferns, such as *Aspleniums*, *Adiantums*, should not be syringed overhead, such treatment being more injurious than beneficial to them. Sow spores under favourable circumstances, prick them off in little patches about 3 in. or more apart after they appear, and pot all seedlings requiring it, as well as young and vigorous-growing Ferns of all kinds. Thin out any old and decaying fronds so as not to impede the progress of younger ones. Replenish Fern baskets; seedlings inserted between the meshes of wire baskets give a good appearance to all suspended plant baskets.

**Greenhouse Soft-wooded Plants.**—Keep up a succession of annuals, such as *Balsams*, *Cockscombs*, dwarf *Asters*, *Mignonettes*, and others. During all stages of their growth plenty of ventilation must be admitted, and abundance of water given. Than the scarlet *Salvia fulgens* and the blue *S. splendens* plants are more beautiful, free blooming, and satisfactory, either in pots or planted out; they require rich soil and plenty of water, and by cutting off the spent flower-spikes and maintaining a regular supply of young wood they continue in excellent flowering condition until late in the season. Keep *Pelargoniums* and shrubby *Calceolarias* in open houses or frames, and give them plenty of water, but

as soon as they come well into bloom remove them to the conservatory. Discard herbaceous *Calceolarias* when past their best, and if seed be required let it be saved from plants that have borne the finest-formed and best-marked flowers; place them in a cool and light house, and supply them moderately with water. Any suckers of *Cinerarias* ready for potting should now be removed from the old stock, potted singly in moderately rich soil in thumb or 3-in. pots, and put for a time in cold frames, placed so as to face the north. Re-pot *TREE Carnations* as they require it.

**Pelargoniums.**—Some autumn-struck cuttings of scarlet and pink *Pelargoniums* should now be potted for winter-flowering. Amongst the single red varieties I have found nothing better than *Vesuvius*, nor in single pinks the old sort *Christine*; both are short-jointed compact growers, producing their flowers freely through the winter with a little warmth. To prepare them for winter work they need special treatment; the first essential point is not to over-pot, the object being to have the plants in a dwarf, compact, thoroughly ripened condition, consequently the pots used should not be over 6 in. in diameter; ordinary loam, with a little rotten manure and sand, is the best material in which to grow them; press the soil quite firm on the pots, plunge them in a bed of ashes out-of-doors in a situation fully exposed to the sun, stop the shoots as necessary to induce bushy growth, pick off all flowers as soon as they are formed, give water as required; they will need nothing more until September, by which treatment [the plants will be in the hard, stocky condition that enables them when placed in warmth to produce flowers freely instead of pushing off into growth.

**Heliotropes.**—Some spring-struck cuttings of these favourite plants should now be moved into 6-in. or 7-in. pots, plunged outside, kept stopped, and the flowers picked off similarly to the *Pelargonium*. This sweet-scented favourite so managed will produce flowers, with the assistance of a little warmth, all through the autumn up to the end of the year.

**Lilies** in pots will now require more water as the soil gets full of roots, and should be placed in an open airy position, away from the influence of walls or trees to avoid weak and spindly growth; turn the pots round every two or three weeks to prevent the plants getting drawn to one side. The earlier-flowering kinds, such as *L. eximium*, will now be benefited by the application of manure water. See that all are kept perfectly free from aphides, which get down into the points of the shoots on the partially-developed leaves, and in a very short time cause them to become curled and permanently injured. A little Tobacco water syringed into the points of the affected shoots and on the under sides of the leaves will be found effectual in destroying them. The plants will be much better for being plunged in ashes, which will save labour by their requiring considerably less water and greatly benefit them by preventing their thick mass of roots from being affected by the sun. The earliest-flowered kinds should be staked and tied, so far as they require it, before the growth gets too far advanced.

**Deutzias** in pots, that were forced in the winter and have been since kept in a Vinery or other structure where a little warmth could be added, will now have so far completed their growth as to be ready for turning out-of-doors; this is one of the few hardy plants that makes its growth for next year's flowering much better when kept inside than in the open air. A good succession to the above is the double-flowering *Plum*. These should now be plunged during summer.

**Chrysanthemums** that were moved a short time ago into their flowering pots should now be plunged. It often happens that a few of the strongest shoots of these so far take the lead as to deprive the weak ones of their share of nutriment. Where this is the case, pinch out the points and peg them out horizontally to the sides of the pots.

**Petunias and Balsams.**—*Petunias* struck late should also be potted, tying them well out and stopping the shoots to keep them bushy. Many of the double varieties now in cultivation possess a compact habit of growth, and, from their easy culture and free, continuous blooming disposition, they are very useful for growing as decoration during the summer and autumn. Earlier plants of these *Petunias* that have been flowering for some time should be assisted with manure water and kept tied into shape, by which means they will continue blooming for some time yet. The later-sown *Balsams* should be moved out of the small pots they occupy into others 7 in. or 8 in. in diameter. These quick-growing, cross-feeding plants require a rich soil, a light position, and a plentiful supply of water to produce them in anything like condition.

**Centareaus and Coleuses.**—If a few small plants of the different varieties of *Centareaus* used for bedding be placed singly in 6-in. or 7-in. pots, and grown on in a cold frame or pit, they will be found very useful for standing about in the conservatory amongst flowering plants through the autumn; they are useful for window decoration, bearing confinement better than most plants. A few of the most handsome-leaved *Coleuses* should now be put into pots proportionate to the required size of the plants—8 in. will be sufficiently large for general decorative purposes; they should be accommodated in a frame or pit, or they may be kept where they are to remain through the summer in the greenhouse.

**Window Plants and Boxes.**—Windows should now be gay with flowering plants, both inside and out. Such plants as are inside should be as near the glass as possible, regularly and well watered, but they should not be permitted to stand in pans or saucers of water for any length of time; their young growths should be pinched if they become too long. *Myrtles*, *India-rubber plants*, *Callas*, and similar plants that have smooth and thick leaves should be gently sponged; but *Pelar-*

goniums, Heliotropes, most kinds of Ferns, and such plants as have hairy leaves, should be taken out of doore and sponged occasionally, in order to clear them from dust. Window boxes, if well drained, allow superfluous water to pass off freely; water may, therefore, be administered plentifully without any fear of its stagnating about the roots. A good loamy soil, mixed with leaf-mould or decayed manure, makes a good compost for plants in boxes. The beauty of *Calceolarias* is soon over, as is also that of several other flowers; therefore, some preparatory means must be adopted for supplying their places with fresh material, and for this purpose *Pelargoniums*, small plants of *Acacia lophantha*, *Fuchsias*, *Nasturtiums*, *Lobelias*, *Mignonettes*, &c., should be held in readiness. Plants now in the boxes should be induced to display themselves to the best advantage, and for this purpose, if a very narrow strip of wire netting be run along the top of the box and made to lean backwards, and another piece bent downwards in front, and some of the shoots of the plants attached thereto, a large and showy surface is obtained. Brackets and suspended baskets should likewise be well furnished with suitable plants, such as the hardier sorts of *Adiantums*, *Polypodiums*, *Aspleniums*, *Aspidiums*, *Athyriums*, *Pterises*, &c. Ivy-leaved *Pelargoniums*, *Lobelias*, *Petunias*, and the small-leaved dwarf-growing *Ivies* are also very pretty when used as basket plants.

#### Flower Garden.

Look well to such plants as *Verbenas*, *Asters*, and others that are similarly subject to the attacks of green fly; for, if it is allowed to remain upon these plants, it will, in a short time, spoil them for the season. Even when all the necessary care has been taken that they were clean when turned out, it frequently happens that they become affected afterwards, in which case there is no remedy but a thorough washing with Tobacco water, or dusting with Tobacco powder.

**Herbaceous Borders.**—Numbers of plants will now require snipping by sick and tye. This should always be carried out as soon as it is needed, or the plants get broken down and disfigured by the wind. To do the work in a proper manner requires some taste and consideration as to the nature of the plants. Nothing is more common than to see the sticks and matting brought so prominently into view as to make it appear that they, and not the plants, were intended to be looked at; or to see each plant bound up as tight as a Birch broom, with an injurious effect, both as regards their health and natural appearance. Never use more supports than are absolutely necessary, and keep them as much out of sight as possible. There is nothing like getting the seed of such herbaceous plants as are generally raised in this way sown in good time, by which means they get strong before winter, instead of struggling for existence through the dry late summer months, requiring much more nursing than if they had attained more strength early in the season. *Polyanthuses*, *Delphiniums*, *Sweet Williams*, *Aquilegias*, with a host of similar kinds, if sown at once, will make plants by the autumn superior in quality to what they would be if the sowing is longer deferred. Sow on a well-prepared piece of ground, with the surface made quite smooth, and cover the seeds lightly with sifted vegetable mould; if the situation be a little shaded from the mid-day sun, so much the better; but it should not be where the plants will be weakened and drawn up by the too near proximity of trees.

#### Hardy Fruit.

Now that all danger from frost has passed pinch or cut off all superfluous growth from Pears, Plums, and Cherries, and apply the usual remedies for the destruction and prevention of aphides and blight of all kinds. Gordons and espaliers of Apples and Pears should now have the fruit thinned and the leaders tied to supports. Strawberry runners, whether intended for forcing or planting out, should be layered as soon as the young plants are formed. For the former purpose early runners are essentially necessary, that a long season may be had for the full development and ripening of the crowns, without which it is useless to expect successful results. Blackbirds and thrushes attack the fruit as soon as, and sometimes before, they change colour, and it is advisable, therefore, to protect it with netting as soon as it begins to turn. Water effectually when necessary.

**Raspberries.**—There is often a great waste of strength in the canes by allowing them to produce a greater number than can be retained for bearing the ensuing year, and which necessarily have to be cut away. To avoid this and to concentrate the energies of the plants in the production of the present season's fruit and the growth of next year's bearing wood, the young shoots that spring up from the bottom should now be thinned to within something near the required quantity. In the case of young plantations that have not yet attained their strength, two or three bearing shoots will be enough; those that are stronger may have six. In thinning the young shoots it is not sufficient to cut or break them off level with the ground, for if so treated they will quickly spring again. I have found an ordinary planting trowel the best implement to use for the purpose, removing 1 in. or 2 in. of the soil, whereby the shoots can be taken off directly from where they spring, in all cases retaining the strongest. The ground amongst these, as well as Gooseberries and Currants, should be again hoed over. If this be attended to sufficiently, often the weeds can be effectually kept down with comparatively little labour. Delay in this work often causes the part of the garden devoted to these fruits to have an untidy appearance and be a source from which the seeds of weeds of a light character are carried by the wind to the surrounding portions of ground.

#### Kitchen Garden.

**Planting Celery, Sowing Peas, Endive, &c.**—The main crop of Celery should now be planted, choosing showery weather for this operation, should such occur within reasonable time, as when the ground is moist and the weather dull the roots will hold of the new soil more quickly than they could be induced to do by artificial watering. The last sowing of Peas may now be made where these are required as late as they can be had; but, unless in open favourable situations, the produce of such late sowings is precarious. Give them, as previously advised, plenty of room, by sowing thinly and having the rows placed far apart. Where Endive is required early a little of the Green Curled variety may now be sown, but as this early sown crop is liable to rot to seed, it is not well to have too much of it. Where Broad Beans grow strongly when they come into flower they will be benefited by having their tops nipped off. This has the effect of concentrating the efforts of the plants to form pods instead of making useless growth.

**Planting Broccoli.**—Winter and spring Broccoli should now be planted, and if the plants have been treated as advised some time ago, they will now be fit for putting out. In the case of Broccoli, it often happens that with only a moderate frost great quantities of it perish. Except in extremely low damp localities, this is more attributable to the way in which the crop has been treated than to the kinds grown being tender or the situation at fault. In order to impart to the Broccoli that hardy condition of growth which is indispensable to its standing a severe winter, it should be planted widely apart; if planted too close, it is certain to be weak and soft, and almost sure to succumb on the first occurrence of severe weather. If the land on which it is to be grown is of average quality and fairly manured, the plants should stand 3 ft. apart each way. Where ground is limited, this may seem extravagant, but it is false economy to run the chance of losing the greater portion of the crop through an attempt to grow more than the space at command will permit. On poor inferior soils, where the plants will not attain full size, they may stand 2½ ft. apart.

#### Extracts from my Diary.

**June 10.**—Sowing two rows each of the following sorts of Peas—*Ne Plus Ultra*, *British Queen*, *Fortifield*, and *Laxton's Omega*. Potting off Cucumbers and Melons. Planting out Cardoons; also Wheeler's Imperial and Carters' Heartwell Early Marrow Cabbage plants. Thinning Onions and giving them a top-dressing of soot. Making a new Mushroom bed under north wall for summer use. Nailing in and tying Roses on wall and washing them well in the evenings with the garden engine to keep down green fly. Hoeing up weeds and all suckers that are not required amongst the Raspberries. Clipping Box edgings. Hoeing and weeding amongst herbs.

**June 11.**—Sowing early Snowball and American Strap-leaf Turnips. Putting in cuttings of choice *Pelargoniums*. Pricking off *Geranias* and *Primulas*. Planting out another piece of Veitch's Autumn Self-protecting Broccoli. Thinning out Parsley, Spinach, and Turnips. Looking over all wall trees, nailing in leaders, and washing the trees where required with the garden engine to keep down insects. Cutting out all small fruit and late blossoms of President and British Queen Strawberries to make sure of fine fruit, and giving them a good soaking of manure water. Watering all newly-planted fruit trees and bedding plants.

**June 12.**—Sowing Broad-leaved Batavian and Green Curled Endive; also Mustard and Cress. Potting on *Fuchsias*, *Colons*, and *Calandinas*. Planting out Savoy, double Wallflowers, and *Asters*. Layering *Vicomtesse Héricart de Thury* and President Strawberries on pieces of turf 4 in. square, and well watering them every evening when they require it. Looking over Cucumbers and Melons; stopping them and giving them a little earthing where required. Digging out more Celery trenches and getting the manure into them.

**June 13.**—Sowing Scarlet Runner Beans to come in for a late crop. Potting on young Vines; also seedling *Cyclamens*, *Stocks*, and dwarf *Asters*. Planting out Brussels Sprouts, Broccoli, and three more rows of Celery. Giving main crops of Carrots a final thinning and running the Dutch hoe between them. Looking over all Vineries, tying down leaders, stopping the laterals, and taking out all small berries where required. Looking over the Pines, tying them up, and well watering them.

**June 14.**—Sowing Wheeler's Imperial and Carters' Heartwell Early Marrow Cabbage to come in ready for September and October. Potting on Balsams, *Chrysanthemums*, and *Heliotropes*. Planting out *Spiraeas* and *Dentzias*. Drawing drills and planting out Lettuce plants. Staking Scarlet Runner Beans, and nailing the runners round all manure frames. Planting a new Vine border with Muscat of Alexandria struck from eyes the same season. Mulching Peas with rotten manure. Hoeing and weeding amongst all growing crops, and getting the nets put over Cherry trees.

**June 15.**—Planting *Vicomtesse Héricart de Thury* Strawberries that have been forced on a south border for autumn crop; also *Colons*, *Alternantheras*, and other carpet bedding plants. Stopping and nailing in the Vines on walls. Thinning out the Apples on the border trained trees. Stopping the Fig trees and watering the Fig house; also all newly planted *Camellia* and *Lettuce* plants. Hoeing, cleaning, and weeding all gravel walks and Box-edgings in the kitchen garden; also mowing and cleaning up the flower ground, and rolling the grass and turf on which that require it. Fruit in use for dessert—Pines, Grapes, Melons, Peaches, Nectarines, and Strawberries.—W. G. P., Dorset.

## THE KITCHEN GARDEN.

### CULTURE AND WINTER CARE OF COLEWORTS.

NOTWITHSTANDING the popularity to which this vegetable has attained in large towns, and the vast quantities which are grown for the supply of the London markets, the Colewort is far from being so generally cultivated as one might naturally suppose it might be. In large private establishments it is of course well cared for, and is there considered to be indispensable. In smaller gardens, however, it does not appear as a rule to be thus recognised, and I have often felt much surprise that it is so seldom found in good condition therein. In mid-winter, when fresh green stuff is more or less scarce, the Colewort, owing to its tender juicy nature, proves a most delicious dish, and amply recompenses anyone for the little care that is necessary to procure it in good condition. Many who attempt the culture of the Colewort fail, and the reason for this is, I think, easily to be accounted for. The fact is, that great exactitude is required as to the time of sowing; in this particular point lies the main-spring of success, and a little divergence in this respect either one way or the other will suffice to entail disappointment. In Colewort culture there is always a danger of running to extremes; either the plants may not have time to heart sufficiently, or they may run too much to head, in which case they are more susceptible of injury in inclement weather. Now, as the sowing time falls just in the height of summer, when the attention is apt to be distracted therefrom by press of work, it often happens that the proper moment passes unawares. Then, again, the weather being often very hot and parching, the seed, in the ordinary way of sowing, does not germinate quickly, thereby creating such a loss of time as cannot possibly be recovered. The seed should be sown not later than the first week in July, and it is not advisable to be much earlier in so doing, as, if the sowing and planting be done then, there will be just the proper time to bring the heads to the desired substance. The seed should be soaked for forty-eight hours before sowing; in the meantime, let a piece of good mellow soil be prepared, and draw some drills therein about 9 in. apart. If the weather be very dry, water the drills well before sowing the seed in them, which it is not well to do very thickly, as, if the seed be good, nearly every grain will come up. When sown, the bed should be covered with a few boughs, which will exclude birds and help the soil to retain its moisture. In a few days the seed will be coming through, when the shading must be removed. By this manner of sowing success is ensured, even in the most trying weather; in fact, owing to the heat of the soil, germination takes place more rapidly in a dry time. As soon as the plants have acquired sufficient strength, they should be planted out upon a piece of moderately rich ground, in rows about 1 ft. apart and 9 in. from plant to plant. It is as well to make two plantings, drawing out the strongest plants first, and leaving the remainder for a week to gain strength. It sometimes happens, too, that, through press of work, it is hardly possible to attend to them all, but if a portion be thinned out the rest may stand without injury until it is convenient to plant them. A good watering now and then in the earlier stages of growth will be found beneficial, and the soil should be well stirred amongst them, keeping them free from weeds. They are liable to the attacks of a brown grub, which eats them off at the collar. When this is perceived they must be looked over now and then and the maggot destroyed; it will generally be found concealed just under the soil close to the stem. A dressing of soot is of great service in keeping them away. A few plants should always be kept in hand to fill up the blanks thus created. In mild and ordinary winters the Colewort will stand uninjured, and may be cut fresh and tender the whole winter through. There sometimes comes a season, however, when they get entirely destroyed. Those who would like to save their crops which they have been at the pains to grow should endeavour to secure a little protection for them. This is best effected by taking them up and laying them in a sheltered place where they may be covered in very severe weather by a few shutters or some Fern. This really delicious vegetable is worth taking some pains to secure, and it is no small satisfaction in a severe

winter, when green vegetables generally are scarce and of poor quality, to be enabled to keep up a supply of tender Cabbages.

*Dyflcet.*

J. CORNHILL.

**Best Time for Planting Asparagus.**—We have invariably found Asparagus to succeed best if removed while in active growth, say in April and even as late as July. We have never known one-year seedlings to fail, and we have never known perfect success to attend the removal of older plants. Many object to the loss of time caused by planting one-year-old seedlings. To overcome this difficulty, we manure the ground very highly on which the seed is to be sown. It is sown in rows 1 ft. apart, and the young plants are thinned out to 4 in. or 5 in. asunder, by which means we obtain better roots than ordinary two-year-old plants, and from these some heads may be cut twelve months after planting.—RICHARD SMITH & Co., Worcester.

**A Plea for November-sown Peas.**—On the 29th of May I gathered my first dish of Peas outside from plants the seed of which were sown on November 9. The variety is Dillistone's Early William I, sown on the same day and in the same border, will be ready in a few days. I find the former to be much the hardiest, the rows being thickset, while those of the latter are ragged in appearance. William I, sown on the 8th of February, is showing flower, but I hold one dish of Peas in May to be worth three in June. For three weeks past I have been gathering Little Gem, sown in boxes at Christmas, and grown in one of our cool fruit houses.—R. GILBERT, *Burghley.*

**Lettuces.**—Herniman's Lettuce or Royal Albert and Grand Admiral are what are grown here as the best winter sorts. I have had the Grand Admiral in fine condition for a month past, but now the best have bursted. Herniman's or Royal Albert, so named hereabouts, is beautifully crisp, like the Neapolitan. The Grand Admiral is the winter Lettuce with the market and other gardeners here. The Hammersmith never does well with me, and it runs to seed in the spring. The above will be succeeded by Paris White Cos, stout plants of which are now 8 in. high. They were sown amongst Carrots in a frame in January. I get them in June and July from 3 lb. to 4 lb. each; this and the Neapolitan are my summer sorts. All the Year Round I have grown, but it was similar to the Grand Admiral. I make about three sowings in August and September, and the produce of the last will be good for a month to come.—JOHN GARLAND, *Killerton, Exeter.*

**The Potato Crops.**—Seldom have these looked better than during the present spring. A cool, even-tempered winter, with neither sharp frosts nor quick reactions, and not an excessive rainfall, kept seed Potatoes in check, so that they broke later and stronger than they usually do. To plant them about the middle of April with good stout shoots of 1 in. in length, well-seasoned by exposure, is the best possible safeguard against the effects of dangerous spring frosts; but sets planted even a month earlier have this year met with no check, and everywhere the tops look robust and healthy, and in some instances have made a remarkable growth. Those who gave up planting in November have lost one of the best seasons for early winter planting that ever offered, but the risk of average seasons is too great to allow this plan to be recommended. With such a fine promise now it may be thought unreasonable to indulge in fears for the future, but a long continuance of cold, quite unseasonable for the end of May and beginning of June, combined with heavy rains, has hardened and cooled the soil, and induced a somewhat drawn, succulent haulm that would, in the advent of the disease, soon fall an easy prey to its effects. Well as the growths look, there can be no doubt that all prospects of a good healthy crop now hinge upon a change to warm, sunny, dry days. Hot, scorching weather and heavy dews are to be dreaded, as with the mists of night often come the destructive fungus, and the labour of months is thus destroyed in a few hours.—ALEX. DEAN.

**Which is the Earliest Potato?**—I have this day tried a root of each of the following, viz., Extra Early Vermont, Ashtop, Bedford Prolific, Coldstream, and Alpha. The last is at least ten days in advance of any of the others as regards size and beauty, the tubers being egg-shaped, and clean, and as large as good-sized Walnuts. Ashtop comes next; the others are the size of marbles. Bedford Prolific, from Mr. Dean, bids fair to be a good cropper; the top is short, and the leaves lie low down on the soil, which is a good sign in a Potato.—R. GILBERT, *Burghley.*

**Slugs and Zinc Collars.**—Several of your correspondents have mentioned that rings of zinc around a plant will keep off slugs; but, supposing that a colony of young slugs were concealed under the ample foliage of a Polyanthus when the ring was placed round it—slugs so small that old eyes do not find them during the short time that rheumatic limbs allow of the head being so close to the earth—what is to be done then? Will soot entice the plant as well as clothe the slimy victims in a suit of mourning?—W. T. T.

## GARDEN BOTANY.

(Continued from p. 525.)

**MOBILITY AND IRRITABILITY OF LEAVES.**—Both of these phenomena, in some of their most striking exemplifications, are familiar to most people, but they are much more common than is generally supposed. Movements in leaves (and other parts of plants) are due to various causes and circumstances, combined often with a peculiar structure of the organs, or some part of them. To give even an outline of what is known on this subject would occupy more space than we can afford to devote to it. Briefly, the movements we have to consider under this head are entirely distinct from those of growth, and only take place in the fully-

Fig. 186.—A branch of *Mimosa pudica* (the Sensitive Plant); one leaf depressed and its leaflets appressed.

grown leaves. We may distinguish between movements caused by contact or concussion and those caused by alternation of day and night, by alternation of heat and cold, &c. But the influences are too numerous and complicated for definition here. The seat of both kinds of movement (that is to say, sensitiveness to touch and what is called the sleeping and waking of leaves, &c.) is in the joints of the petiole and petiolule, and the mechanism of it is a sort of cushion of contractile tissue. What is termed irritability in plants is susceptibility to touch or shock, the susceptibility being exhibited by move-

Fig. 187.—A branch of *Desmodium gyrans* (the Moving Plant), or Indian Telegraph Plant.

ment. The Sensitive Plant (*Mimosa pudica*—fig. 186) illustrates this remarkable phenomenon in a high degree; but the intensity of the sensibility depends upon the health and vigour of the plant and the temperature to which it is subjected. When touched or shaken, the petioles of the active leaves of the sensitive plant are deflected, the pinnæ converge, and the upper surface of the leaflets on the opposite sides of the rhachis are brought close together by an obliquely upward movement. Thus the movements of each of the three systems, if we may so call them, of articulations, are different, and their combined movements produce the effect described and shown in one leaf of fig. 186. *Dionæa muscipula* (Venus's Flytrap) also exhibits irritability to touch in certain parts of its leaves.

Each of the two halves of the blade of the leaves is provided on its upper surface with three rather conspicuous, slender glandular appendages, arranged in the form of a nearly equal-sided triangle; and any insect or other body coming in contact with them excites the motile mechanism which resides in the midrib, and causes the two halves of the blade to close upon each other. Some time after the irritating agent has ceased to act the leaves recover their normal position, but the duration of the effects of contact or of concussion is governed by a variety of external conditions. Besides the movements in leaves from a diurnal to a nocturnal position, or from the waking to the sleeping condition, there is a periodic spontaneous movement which may be too slow to follow, or relatively rapid, as in *Desmodium gyrans* (fig. 187). This plant has a compound (trifoliolate) leaf, the lateral leaflets of which are comparatively small. The latter are attached by short petiolules, which are the organs of movement, and the motion is of two kinds, a rotatory and an oscillating, so that the leaflets are alternately bent upwards and downwards, and their tips describe nearly a circle. According to Sachs, one revolution takes place in from two to five minutes, when the temperature is above 72° Fahr., and the motion is often irregular, proceeding gradually or by jerks. There is also an oscillating movement of the terminal leaflet. Leaves which exhibit a periodic spontaneous movement, or are irritable to the touch, frequently also assume a different position at sunset, or go to sleep. This phenomenon is strongly developed in the compound leaves of many Leguminosæ, of *Oxalis*, and some others. During the day, or at least during sunshine, the blade is spread out flat, whilst at night it is folded in some way. In Clover, Tares, the Sensitive Plant, and a vast number of others the leaflets are folded upwards, so that the upper surfaces of the opposite ones are closely applied to each other. *Amorpha fruticosa* is an example of a plant with similar leaves, in which the leaflets move in the opposite direction, that is to say, they are bent downwards, and the backs or undersides of the opposite rows of leaflets touch when they are in their natural position. The trifoliolate leaf of *Oxalis acetosa* has the leaflets deflected at night on the petiole, and their backs touching each other; but one of the most singular nocturnal positions is that affected by the leaflets of *Cassia marilandica*. This plant has pinnate leaves, the leaflets of which are bent downwards at night, and by a twist in their petiolules their upper surfaces are brought together beneath the rhachis. The petiole also of some plants differs in its diurnal and nocturnal positions. In *Mimosa*, for instance, the petiole is bent downwards at night, and the leaflets folded together upwards; whereas, in *Phaseolus* the petiole becomes erect, and the leaflets turn downwards.

**THE SIZE OF LEAVES.**—The comparative size of the leaves of closely allied species is taken into consideration in descriptive botany; but the actual size of the leaves of any individual plant of a species is a character of little importance. Leaves vary from a line or two in length, as in some of the Cypressess, to 40 or 50 ft. long and 20 ft. across, as in certain Palms; and the leaves of a given species are often spoken of as large or small in relation to the leaves of its congeneric or allied species, and not to leaves in general. Thus a large-leaved Oak, a broad-leaved Grass, or a small-leaved *Euonymus*.

**ABSENCE OF LEAVES.**—Many of the Cactaceæ and other plants are quite leafless, or the leaves are reduced to small scale-like organs. Generally speaking, plants that are destitute of leaves have green stems or branches, which perform the functions of leaves. Sometimes, as in *Ruscus* (fig. 188), the branches are flattened, and resemble hard, rigid leaves, but their true nature is determined by their being axillary productions. They spring from the axils of small scale-like leaves; and leaves, broadly speaking, do not proceed directly from the axils of other leaves. In the British species (*R. aculeatus*) the flowers are borne upon the flattened branches (cladodes).

**VERNATION OF LEAVES.**—The condition in which the separate leaves are in the bud is called the vernation or prefoliation. They are variously folded and rolled, according to their shape, size, &c., or they are flat, as in *Pinus*, &c. A common form of vernation is that of the Lime, in which the two halves of

the blade of the leaf are simply folded together upwards. In *Richardia aethiopica* the leaves are rolled up longitudinally from one side to the other, or what is termed convolute. There are numerous other modes of veneration, only one of which we will specify, and that is the circinate veneration of Fern fronds, which are rolled up from the tip to the base.

**FUNCTION OF LEAVES.**—In this place it is only necessary to mention the use of the leaves to the plant in a general way, as far as it is known. Everybody, we may say, is aware that leafy plants will not thrive without healthy foliage. Stripping a plant of its leaves as fast as they are put forth will soon cause it to have a sickly appearance, and ultimately kill it outright. Researches and experiments seem to prove that it is in the leaves where the food taken up by the plant in the form of gases, water, and various substances held in solution by water, undergo certain chemical changes, and are transformed into nutrient compounds required for the further growth of the plant. The generally accepted theory is that the food thus assimilated is drawn from thence to any part where active growth is going on, or where it can be stored up for the future use of the plant. There are certainly some

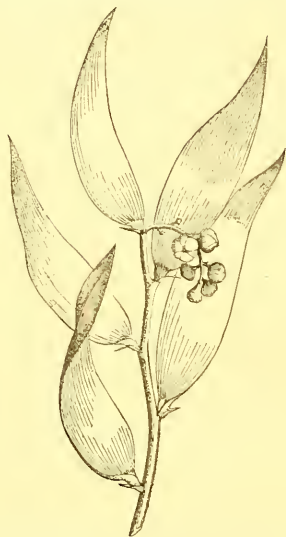

Fig. 188.—Flattened branches (cladodes) of *Ruscus racemosa* proceeding from the axis of the small, scale-like leaves.

difficulties in the way of accepting this theory in its entirety, though it is based upon a number of indisputable facts. But however much future investigations may modify existing notions on the economy of plant life, from a practical point of view we cannot do wrong in assigning a very important part to the leaves.

#### Accessory or Subsidiary Organs.

**DEFINITION.**—For convenience sake a number of organs of quite different nature are included under this head. Some of them are stem structures (caulomes), some are leaf structures (phyllomes), and some are epidermal structures (trichomes) or outgrowths (emergences) of tissue covered with the epidermis. It may be explained here that all parts of plants, excepting true roots, are referred to the three types just named; that is to say, they are metamorphoses of three primary types, all the metamorphoses of each type being of the same nature or morphological value, whatever their final form or function.

**HAIRS.**—The surfaces of leaves and other organs are smooth (glabrous), as in the common Laurel, or more or less clothed with hairs or other excrescences. Mr. Bentham uses the term

"smooth" when the surface is without any protuberance whatever, and "glabrous" when without hairs of any kind; but these terms are generally regarded as synonyms, and a surface is said to be naked (*levis* in Latin descriptions) when it is devoid of hairs and all other outgrowths. In descriptions the absence of excrescences, other than hairs, is understood without being expressed, because they are comparatively rare, and when present they are described. But it is necessary or desirable in most cases to mention whether the surface of leaves is glabrous or hairy; and it is usual to indicate the kind of hairs or degree of hairiness. Hairs of all kinds are trichomes or outgrowths of the epidermis or skin, and are very variable in their structure; but it is only of their outward forms, texture, and density we have to speak now. The kind of hairs is designated by such terms as woolly, as in *Stachys*

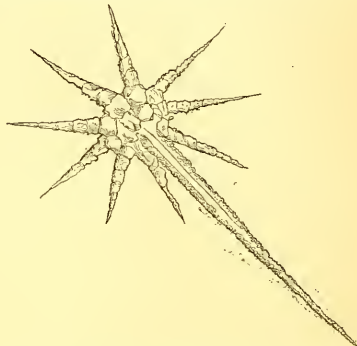

Fig. 189.—Stellate hair of *Onosma tauricum*. Magnified.

*lanata*; hispid, as in Borage, Comfrey, and most of the plants of the family to which they belong; silky, as in *Potentilla anserina*; downy, when the hairs are short and soft; bristly, when they are stiff and erect; glochidiate, when they are hooked at the tip; and sometimes they are mealy or chaffy in their nature. Several other terms are employed by botanists, but not often in a very definite and uniform sense, therefore it would be of little use to particularise them. Of course there will always be more or less vagueness in the use of comparative terms, especially when the characters they are

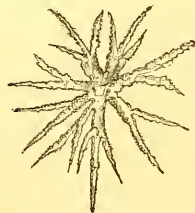

Fig. 190.—Stellate hair of *Alyssum montanum*. Magnified.

intended to express are taken separately; and it is only by an aggregate of characters that it is possible to determine plants from descriptions. Hairs are simple or branched, often in a stellate manner, as in *Onosma tauricum* (fig. 189) and in *Alyssum montanum* (fig. 190). Certain kinds of hairs are characteristic of whole families. The Malvaceæ (Hollyhock, &c.) have usually stellate hairs; most of the Boraginaceæ have harsh or bristly hairs; in the Malpighiaceæ they are commonly attached by the centre; and in the Urticaceæ (Stinging Nettle family) and the Loasaceæ, stinging hairs are frequent.

**OTHER DIVERSITIES OF SURFACE.**—Colour is not regarded as a distinctive character for species, but it is often convenient to mention not only the colour of the flowers, but also the hue of the leaves. Thus, when they are of a bluish-green, as in

the common garden Pea, they are termed glaucous. The surface is sometimes furrowed, or ribbed, or wrinkled, or scabrous (rough to the touch), or viscid, or glutinous, or warty. In many families the leaves, &c., are beset with immersed, sessile, or stalked glands, which contain various secretions. The glandular hairs of some *Pelargoniums* and *Roses* contain an agreeably fragrant secretion. Prickles sometimes occur on the surface of leaves, as in *Victoria regia* and some of the species of *Solanum*. The leaves of *Elaeagnus* and allied genera are clothed with elegant scale-like appendages.

**PRICKLES DIFFERENT FROM SPINES.**—Prickles, like hairs, originate from the superficial tissue, as may be proved by breaking off those which clothe the stems, and more or less the leaves, of *Brambles* and *Roses* (fig. 191); they are therefore called trichomes. But spines have a deeper origin, and are either leaf structures (phyllomes) or stem structures (caulomes). Some of the branches of the *Hawthorn*, *Blackthorn*, and some species of *Elaeagnus* (fig. 192), are aborted and terminate as sharp spines. The common *Furze* has spiny branches, and some of the leaves are reduced to spines. The common *Barberry* (fig. 193) is another familiar instance in which some of the leaves are reduced to spines. Usually it is not difficult to ascertain whether spines are metamorphosed

Fig. 191.—Branch of Rose covered with prickles.

lower part of the shoots, and then usually there are two leaves with tendrils opposite to them, followed by one leaf without a tendril, two with, and again one without, and so on. This order is disturbed only by the bunches of fruit. The strength of tendrils, when fully grown, is prodigious in relation to their size. A remarkable instance of adaptability to circumstances

Fig. 192.—*Elaeagnus*; branches terminating in a spine.

is exhibited by the *Virginian Creeper*, the tendrils of which form adhesive disks at their tips on coming in contact with a wall or rock, &c. Mr. Darwin, in his admirable essay on tendrils, states that a single branch of a tendril, at least ten years

leaves or branches, because we find when the former is the case all sorts of transitional stages may be found.

**TENDRILS.**—Some plants possess slender filiform appendages which have the power of twining round other bodies, and by means of which the plants are able to climb towards the light. These are called tendrils, and they are either reduced leaves or branches. Among familiar foliar tendrils we may name the *Sweet Pea*, *culinary Pea*, and *Everlasting Pea*; the upper part of the leaf is transformed into a branched tendril, the number of branches representing the number of reduced leaflets. The tendrils of *Cobaea scandens* belong to the same category. In *Flagellaria indica* and *Gloriosa Plantii* the midrib is continued in the form of an unbranched tendril; and in *Lathyrus Aphaca* (fig. 194) the whole leaf is reduced to a simple tendril, which is compensated for by the stipules becoming foliaceous. The tendrils of the *Grape Vine*, *Virginian Creeper*, and *Passion-flowers* are arrested or metamorphosed branches. In the *Grape Vine* the tendrils are opposite the leaves, the same as the bunches of fruit, of which they may be regarded as modifications to support the branches. This view is strengthened not only by the position of the tendrils, but also by the fact of their sometimes becoming more branched and bearing a few berries. The production of the tendrils of the *Grape Vine* is very singular. None are formed on the

Fig. 193.—*Berberis vulgaris*, with some of the leaves reduced to spines.

Fig. 194.—*Lathyrus Aphaca*, in which the leaves are reduced to simple tendrils, and the stipules are large and foliaceous.

old, of the *Virginian Creeper*, bore a weight of 2½ lb. without being detached, and he calculated therefrom that the entire five-branched tendril would support 14 lb. or 15 lb., so that the tendrils of a large plant attached to a wall must be able to

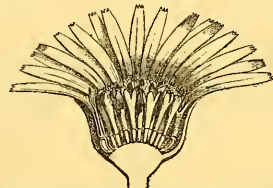

Fig. 195.—Section of a flower-head (capitulum) of the *Corn Marigold* (*Chrysanthemum segetum*), showing that it consists of a cluster of flowers.

support an enormous weight. The position of the tendril in the *Cucumber*, *Melon*, *Gourds*, and other plants of the *Cucurbitaceæ* is below and a little on one side of the insertion of the leaf.

### The Inflorescence.

WHAT IT IS.—The flowers of plants are very variously arranged, and the manner in which they are arranged is the inflorescence. An inflorescence comprises all the flowers of a plant collectively, as of *Agave americana*, *Hyacinthus*, and of all plants which throw up only one flowering-stem above the ordinary foliage leaves; or all the flowers of each separate

Fig. 196.—Section of flower of a single Rose, for comparison with fig. 195.

stem of a plant, as of Foxglove, Lily of the Valley, Aconite, Daisy, Dandelion, &c.; or when stems are branched, each cluster or spike of flowers separated by leaves constitutes an inflorescence, as the terminal clusters of flowers of *Rhododendron* and the lateral spikes of *Lavender*. Sometimes an inflorescence consists of only one flower. *Lysimachia numm-*

Fig. 197.—*Coreopsis aristosa*. (See text under "Difference between an inflorescence and a flower.")

*laria* (Creeping Jenny) and *Anagallis arvensis* (Poor Man's Weather-glass) are examples of this kind of inflorescence, as only one flower proceeds from the axil of each leaf. Before describing the various types of inflorescence it may be well to warn the beginner against falling into the error of confounding an inflorescence with a flower.

**DIFFERENCE BETWEEN AN INFLORESCENCE AND A FLOWER.**—The structure of a Buttercup flower has already been explained, and the names of its different parts given. Now, there are some inflorescences marvellously like flowers in external appearance, and which are popularly called flowers. The *Dahlia*, *Aster*, *Marigold*, *Daisy*, and *Zinnia* are of this class, and the natural order or family to which they belong is the most numerous both in genera and species of any in the vegetable kingdom. Hence the importance of learning their real nature. In cutting longitudinally through an inflorescence of this kind it is easy to see that it consists of a number of small flowers crowded together—see fig. 195, and compare this with fig. 196, which is a single flower of a *Rose*, not differing materially in its structure from that of the *Buttercup*. *Coreopsis aristosa*

Fig. 198.—Inflorescence of *Coreopsis canadensis*. Reduced.

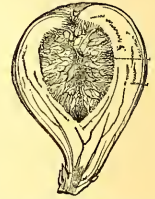

Fig. 199.—Section of a Fig showing the flowers inside

(fig. 197) has heads of flowers remarkably like the separate flowers of some *Anemones*. And, again, the inflorescence of *Coreopsis canadensis* (fig. 198) is not unlike a single flower, as seen in the cut, but it is much larger than here represented, and the separate flowers of which it is composed are conspicuous and evident to the naked eye. There is one more curious inflorescence which should be mentioned here. It is that of the Fig tree. Fruits of different sizes may often be seen on the same tree, but visible flowers there are none, at any season of the year; and it seems to be a case of a tree yielding fruit without producing flowers. But it is not so. If a section of a Fig be made, it will be found to contain a number of small bodies,

Fig. 200.—One female flower of the Fig removed from the inside of the fruit. Enlarged.

which, with the aid of a lens of low power, prove to be flowers (figs. 199 and 200). These inflorescences are more fully described below.

**NOMENCLATURE OF THE DIFFERENT PARTS OF AN INFLORESCENCE.**—Flowers, of course, constitute the most important part of the inflorescence, but the flowers are usually provided with stalks, and the inflorescence itself is often branched and bears other appendages besides flowers. Flowers, like leaves, are sessile, or stalked, and the stalk of a flower is the peduncle in an unbranched inflorescence; but when the latter is branched, many botanists employ the diminutive pedicel to designate the flower-stalk. It should be observed, however, that there is a great want of uniformity in the application of these two terms, one often being substituted for the other. Here they are used in the sense indicated. A peduncle which springs from the crown of the root is termed a scape, whether it bears one flower, as in the *Tulip*, or several, as in the *Hyacinth*; and when the peduncle is enclosed or sheathed by a large leafy expansion (spathe), as in *Arum maculatum*, *Anthurium Scher-*

zerianum, and *Richardia ethiopica*, it is termed a spadix. The ramifications of the inflorescence are usually provided with leafy appendages, more or less like the ordinary leaves, from which they often exhibit a gradual transition, or they assume very different forms. They are called bracts. There is no absolute distinction between leaves and bracts; but if the leaves subtending the flowers differ in shape or other characters from the ordinary leaves of the plant, then they are called bracts. In reality, bracts are reduced leaves, and the ramifications and flowers of the inflorescence have their origin in the axils of the bracts. Occasionally the bracts are very minute, or altogether obsolete, or they fall off as the inflorescence unfolds. Sometimes the ultimate branchlets (the pedicels) of an inflorescence bear small bracts, in the axils of which no further branches or axes are produced. When the bracts on the pedicels are dissimilar to those on the main axis or axes of the inflorescence, they are distinguished in descriptions as bracteoles, otherwise no distinction is made. Some of the most noteworthy modifications of peduncles, pedicels, bracts, and bracteoles will be pointed out in succeeding paragraphs.

**TYPES OF INFLORESCENCE.**—There are two distinct types of inflorescence based upon the mode of branching, but both of these types may be combined in the entire system of the inflorescence of one and the same plant. These types are termed indefinite when the primary axis does not terminate in a flower and when the flowers open successively from the base upwards, or from the circumference towards the centre, that is to say, in centripetal order.

W. B. HENSLEY.

**The Spring Snowflake** (*Leucojum vernum*).—I have noticed in THE GARDEN certain paragraphs concerning this pretty spring flower, which, instead of increasing its popularity, are apt to cause it to be still more rarely grown; therefore I was pleased to see in this week's number that "Salmoniceps" endorses my opinion (p. 251), that until the plant is fairly established judgment as to its merits ought to be withheld. My plants have no extra care bestowed upon them; the soil and situation, to all appearances, are anything but favourable, and yet the result this spring was all that I could desire; and I think if others can be induced to try this Snowflake, they will succeed equally well.—E. FARREK.

**The Root History of Lilies.**—My promised paper, with "photographic specimens of offsets of the first year, bulbules or small bulbs of the second, third, and fourth years, together with fully-developed bulbs," was finished and closed on the day before I had the pleasure of seeing Mr. D. T. Fish's most interesting article on "The Root History of Lilies." As he has drawn my attention to the importance of leaves, and to the feeding of the germ or young Lily bulb through the old bulb, I shall have much pleasure in complying with his invitation in my second succeeding paper; and shall have additional pleasure if I can be instrumental in removing from his mind any doubts on the subject. I may, at all events, be able to lay before him certain facts, which may enable him to settle the matter to his own satisfaction. All I ask is to have what I propound carefully considered, and this Mr. Fish has already convinced me he is quite prepared to do.—DUNEDIN.

**Hardiness of *Lilium auratum*.**—I have been reading and re-reading "Dunedin's" lengthy notes on the tenderness of Lily "germs" until I begin to doubt if what my own eyes have seen of the hardness of the bulbs of, for instance, *L. auratum* is correct. His theory as to the cause of the too frequent death of imported bulbs of *L. auratum* may be correct, but it is at least fortunate that bulbs from home-raised seeds are neither so delicate nor so easily killed. Indeed, I know of no Lily more hardy than this for outdoor cultivation in Britain. Four years ago I raised a large quantity of bulbs from seeds ripened out-of-doors here. For the first two years they grow in the shallow pans in which the seeds were sown, having been exposed to all weathers for two winters. The surface soil got washed out of a few of the pans, thereby exposing the young bulbs bare to their roots. In this condition I found them one morning when the thermometer registered 20° of frost. They had been so injured by exposure to the inclemencies of the weather previously, that the only apparent effect which such severe frost had upon them was that they were reddened, but they subsequently grew as well as any of the others that were not so exposed, and all, I may say, now that they are planted out, are swelling into good-sized bulbs, many of which have already flowered.—GEORGE SYME.

## THE FRUIT GARDEN.

### THE ORCHARDS OF HEREFORD AND WORCESTER.\*

Though differing in many other respects, these two contiguous counties are mostly reckoned as one, as regards their fruit cultivation. Parts of Gloucestershire, Shropshire, and Warwickshire, which adjoin, are also included in this tract of orcharding. Nurserymen are fond of stating in their catalogues that Apples do well in any soil. No doubt by such assertions they gain more orders, but it is a question whether the country has many more Apples. Some are bold enough to add that a deep, friable loam suits them best. No doubt of it; and most other things as well. It is quite certain, however, that the most important condition of the soil for the Apple tree is depth, and this, in the neighbourhood above referred to, it thoroughly enjoys. The formation of the country, too, affords numberless sheltered hills and sunny slopes where fruit trees luxuriate, as if in walled gardens. There is no doubt that Worcestershire was inclosed and highly farmed at a very early period, and the cultivation of Apples and Pears must have been energetically carried on from the first. Herefordshire produces, perhaps, the best Apples, but very few Pears. The latter fruit gives one the best idea of the antiquity of this sort of cultivation. The remaining trees in the celebrated Barland Ferry Orchard at Monksfield Farm, near Malvern, are stated by one writer to be six hundred years old. This is probably an exaggeration, but there are, doubtless, many trees scattered over a large area that must be several hundred years old. An Apple tree would hardly be of any use to the owner after a hundred years, but the Pears above referred to are still, many of them, most valuable. The ground, however, seems tired of them—and no wonder—and the grafts taken from them do no good. Few Worcestershire homesteads do not possess a few of the "Early Jennet" trees, which still bear bountifully, though of an enormous age. This and other descriptions of the earliest Pears ripen about the 1st of August, and in a good year help the farmer very much with his labour bill, so heavy at that time of year. The fruit is shaken down by boys who climb into the trees with long, hooked poles, and picked up by women underneath. Sacks and cider cloths are spread underneath to break the fall of the fruit. These are the Pears that are so constantly seen in the early autumn hawked about the streets.

Hop and fruit cultivation often go hand in hand, the former demanding even more imperatively a deep soil. In the famous Temes valley—one of the richest spots in England—the ground will grow Hops for ever, such roots as die being re-planted. On the uplands, however, it is found necessary to change the Hop-ground every twelve or fourteen years. The effect of Hop-growing on the soil, contrary to what one would suppose, is to render it almost as fertile for a renewal of general cropping as virgin soil. An old writer, indeed, drily remarks that "the greatest profit in Hop-growing is the breaking up of the soil afterwards." Up to the present time, whenever Hops were planted, an orchard was planted at the same time, as an economy of labour and ground. By the time the trees began to be prejudicial to the Hops, it was time to remove the latter altogether. Of course the field remained arable, but that used to be thought no hindrance to the orchard; or rather, the orchard was thought no hindrance to the arable field. When it is considered how much finer the trees grow on an arable field, and that they are thus nearly always out of the way of cattle and horses, it will be seen that the disadvantages are compensated for. These are the spilling of Corn crops by the sun being kept from them (a trifling loss if the trees are not planted too closely), and the difficulty of cleaning the field when encumbered with trees. No difficulty exists as to ploughing, though a slight extra expense is entailed by the necessity of having three men or boys attending to the horses when the tree rows are being ploughed out, and also of having the ground just round the trunks dug with the spade. This is well done by any labourer for a penny a tree.

When orchards are planted in Grass land it is much better to have the young trees dug round for several years. They

\* A paper, contributed to the Annual May Conference of the Vegetarian Society, by Mr. Baron D. Webster, of Nowland Court, Great Malvern.

require to be fenced in on Grass land with great care and expense, and at the time of the ripe fruit everything must be kept out of the field. It is far better, when planting an orchard on the green, to stock it for the first few years with nothing but sheep and young cattle. Horses and full-grown cattle will knock over any fencing, unless made so strong as almost to interfere with the growth of the trees. The best and cheapest fencing for young trees is of this description: Plant firmly in the ground, in the shape of a triangle, three stout Hop poles about as thick as a man's arm, and cut them off to about 4 ft. or 5 ft. high. They should stand about 1½ ft. from the stock, and lean outwards. To these nail wire netting as high as a sheep can reach. You are then safe from sheep and game. If calves and young cattle are to be in the field, protect the wire netting again well with bushes fastened round with wire. If cattle and horses must come in, however, there is nothing for it, but the old-fashioned heavy wooden cribs, which, besides being very cumbersome and expensive, are also very detrimental to the prosperity of the tree. Their great posts make holes for the wet to accumulate and lodge in during the winter, and cracks to let the drought through in summer. Of course, in pruning, the object is to keep the branches growing outwards from a stem about 5 ft. high. Some farmers, who are convinced of the profit of growing fruit, are so particular on these points, that they get slightly eccentric, to say the least, and discharge their men for the slightest infringement of their rules. An Apple tree can hardly become very profitable under fifteen years' growth at least, and it certainly is most aggravating to have a tree, or perhaps an orchard full, seriously damaged by purely avoidable causes after, perhaps, a most careful watch has been kept on them for ten or twelve years. After an orchard is once well started the only expense connected with it is the pruning, and that is about covered by the sale of the "brash." Apple trees in Worcestershire often attain the size of an ordinary Oak, and a tree of a good sort will bear 25 bushels of Apples. One Pear tree will often make as much as 200 gallons of perry.

It is very dangerous to lay down to Grass an orchard that has hitherto been in tillage. It often causes all the trees to die. The ordinary one year's course of seeds does not seem to hurt them, but a two years' ley undoubtedly does. The decrease in the extent of orcharding and the inattention to fruit cultivation is very sad to see, and it will not be amiss for us to look into the reasons for it:—

1. First of all we have the enormous and grossly unfair profits taken by the "middleman." A pot (5 pecks, or 80 lb.) of fruit bought from a farmer for, say, ten shillings, is not sold to the public under twenty shillings or twenty-five shillings. The usual system is for the farmer to take his fruit to one of the merchants in Worcester, who sells it for him on commission, in reality to middlemen in large town; so—at least so he is told—the merchant, in paying the farmer, always professes to be getting only sixpence or so per pot out of the matter. At the same time they carry on the business in other ways, buying fruit in large quantities on the trees or after being picked and keeping it themselves as a speculation. A large farmer with much business to transact cannot be always personally looking after the sale of every load of fruit, and most of them usually sell it in this way. All that the farmer does not want to keep for the winter he sends in as fast as it is picked, and notes the quantity in a book which is taken to the merchant, who signs it and adds the price he means to give for it, or sometimes the price he will give for the previous lot, this being still uncertain. The farmer can, if he is at any time dissatisfied, close up accounts; or, if he goes on all the year, can draw money as he wants it, sometimes drawing more than is due. At Christmas the book will be squared for the season. Sometimes the fruit is sold by auction on the trees, orchard by orchard. In the former way, of course, each individual lot of fruit is quite at the mercy of the merchant, and the farmer loses the full advantage of sudden and spasmodic rises in the market. On the other hand, he never has his fruit refused in a great flush. It is the profit made after the fruit has left the merchant and before it reaches the public that is so unfair. For instance, in one abundant year, when a pot of good fruit did not fetch more than two shillings in Worcester, enough to make an Apple tart cost one and eight-

pence at Malvern. A commodious fruit market has been built at Worcester, but it does not seem to work in any beneficial way to the large growers. Farmers give up the business in disgust at the unfairly low prices they get for their fruit.

2. The next cause that acts so much to check English fruit-growing is the foreign importation. Of course fruit from abroad is landed in large consuming towns, and close to railways, so that it can be easily and cheaply distributed over the country. Nobody would deny that we could produce fruit enough for our own use. And the question arises whether, for the sake of removing a very slight addition to the immediate cost of an article to the public, it is worth while to persistently discourage an excellent industry, pay our money into foreign pockets, and reduce employment for our large population. Depend upon it, the 4d. loaf is well worth 5d. to the English labourer, if entirely grown in his own country. Let us be only reliant and self-supporting. Besides, if English fruit-growers had really a fair chance, English fruit would soon be as cheap as foreign supplies. It is well known that the diseases which foreign cattle bring in with them destroy more English meat than they supply. The importers of foreign cattle possess by their wealth an improper influence, and the importers and dealers in foreign fruit to some extent the same. "Why," says a writer on English agriculture, "do we not turn fruit growers? I was in Covent Garden market yesterday, there was £20,000 worth of fruit, and it was all from abroad." Every year we had articles in the papers on this subject. The chief reason why this cultivation is not increased is because there is no getting a fair price for the produce. When a Worcestershire farmer travels to Manchester or London in the vain hope of selling his large stock of splendid fruit, he is told that foreign fruit can be got so cheaply that he cannot be offered anything worth his acceptance. What is the consequence? The farmer goes home disgusted, five or six extra men hand-picking at 2s. 6d. a day are dismissed, and the fruit is either made into cider or devoured by the sheep and pigs. At rent day, when the farmer meets his landlord, he cannot pay all his rent, his farm being valued at perhaps 10s. per acre all round over its corn-growing value for the fruit that is supposed to be sold off it. Then as to labour. A few years ago there seemed no certainty at all as to where the demands of the agricultural labourer would stop, and farmers all turned their attention to methods of making money without need of labourers. Of course, to market a crop of fruit takes labour, and that of an expensive kind. Had the movement continued, the English labourer might soon have found himself out of employment altogether. And although wages were raised to the highest pitch five or six years ago, Worcestershire farmers have never since reduced them; still the attitude of the labourers caused terrible mischief, and has in these counties conduced to the present lamentable state of agricultural affairs. No doubt we have improved, and that enormously, in our stock-raising. But, alas! for the ploughed land. Will anyone look at our fruit-growing districts and say if there is any improvement there? Where are the crops of Wheat and Beans that were grown forty years ago; where is the workman-like, clean appearance of the land, and where are the workmen? We must be growing less and less Corn every year.

3. And this brings us to the last cause we will mention of the deterioration of our fruit growing. Generally in this district all farming, except stock raising, is going backwards, and at the same time we are trying to make ourselves believe it is quite the contrary. Landlords in this neighbourhood have determined to have the land farmed on what is called the "high" system, and they want to help both themselves and the farmers by reducing labour. Trees, wherever planted, are of course an obstacle to the use of machinery; but the system of farming which, no doubt, answers well in the Lothians of Scotland and on the broad plains of Norfolk will never succeed in such a neighbourhood as this. The whole formation of the country and the character of the soil are against it. No greater mistake is being made than that of the landowners in discouraging fruit cultivation, or, perhaps, rather, not exerting themselves to interest and improve it. Every farm should be well inspected with regard to its fruit-growing capabilities. Orchards that are half-stocked with trees should be planted up and kept planted up. Tenants

should be bound to plant a new tree for each one that comes to an end. The green orchards which are almost worn out should be either entirely planted up or entirely rooted out. A farmer is often losing weekly five pounds worth of dairy or other produce for the sake of a pound's worth or so of fruit that is not fit to be gathered. An orchard should be well worth shutting up altogether when necessary, and by taking care no inconvenience will be occasioned. It is easy to eat down the orchards bare and let the open land grow up till the middle or end of August. Straggling trees all over the farm are a great nuisance on this account also. Cattle thus get a chance of tasting the fruit, and they often, especially in a dry season, get such a hankering after it that they cannot be safely confined in any field by any fence. A dairy of cows turned into a field of splendid keep, after being brought back from their "fruiting," will not put their heads down to eat for hours together. Why we bring our Wheat from Russia and our fruit from America, leaving agriculture in our own land to go down hill, and the country generally to be ruined, is a question to which economists might well apply themselves. Our soil is probably not above the European average, but, on the other hand, we have more capital than any other country, and we have far more knowledge of how to apply this capital to agriculture. Were this surplus capital put into our own soil, and those branches of agriculture encouraged which feed most, and employ most, we should find ourselves at times like the present in a very different position. Why, it is said that the troublesome little state of Servia can put more men into the field than we. Vegetarians will be interested to know that the only branch of industry in that country is Plum growing. There can be no doubt that by increased attention to fruit growing in England a great deal more useful, wholesome food would be produced, and many more people employed. Of what use would be tons of gold and silver in the Bank of England if foreign produce were prevented, by any reason, reaching our shores?

It is satisfactory to turn for a moment from the Apple and Pear cultivation of this district, which is certainly either at a standstill or going down hill, to that of Plums, Gooseberries, and Currants, carried on so extensively in the neighbourhood of Pershore. Enormous plantations of the white *Magnum Bonum*, commonly called the Pershore or Egg Plum, are there to be seen, and it is difficult to know where market gardening ends and farming begins. One holding of 200 acres is entirely devoted to Plums and Gooseberries, with the exception of a few Pears, and is well worth going a long way to see. On an average, this garden is very profitable, but the losses some years are, of course, very great. It was planted by Mr. Varden, an engineer, who was employed in the construction of the Great Western Railway, and who was so much struck with the Pershore system of cultivation, that he devoted himself to it on this scale. Since his death it has been bought by Mr. Bomford, who farms about 3000 acres besides. Along the Teme valley are many valuable Cherry orchards, some of which bring from £10 to £15 per acre annually to the farmer without expense on his part, the crop being sold on the trees by auction or otherwise. Cherries should invariably be planted together, and as thickly as possible, as it is necessary for some weeks before they are gathered to have a man living in the field to scare the birds. Damsons would be more cultivated were it not for the difficulty of getting women to pick them. A woman must work hard to pick a pot in a day, and there are fewer women to do to work now than formerly. Damsons fetch as much as 3s. a pot in some good years, and are always saleable on account of being used for dyeing purposes. Plums here in a very abundant year can hardly be got rid of at all. Damsons, of course, do better on light soils, but they thrive well along with the Apples and Pears.

#### THE RIPENING OF MELONS.

MORE Melons are wrecked at the finish than through all the preliminary stages of culture; in fact, there may be said to be but two crucial stages in the growth of Melons—the set and the finish. Secure a simultaneous set of, say, six fruit to a plant, and see that they all start abreast, and the Melons are sure to swell under ordinary treatment. An average temperature of 75°, a moist atmosphere, a fair amount of moisture, and

sundry stoppings of the lateral shoots in advance of the fruit to prevent overcrowding, and the fruit swells rapidly and well. But as it nears the finish, difficulties and dangers multiply in the ratio of ripeness. First, there is the danger of fruit splitting—the result generally of an excess of water at the roots. The plan of growing Melons on manure beds has many advantages. Prominent among these are a genial atmosphere and a warm soil enriched by the escape of ammonia from the manure. One great drawback of a manure base for the soil of Melons is, that the roots escape into the manure, and often imbibe far more food and moisture than is good for the fruit. It is difficult, if not impossible, to curtail or regulate the supply of either with the roots free to roam through several square yards of manure. The manure is apt, also, to become too dry as well as too wet. What with the heat of fermentation running to excess, and so burning the manure as dry as chaff, and the roots absorbing all the moisture applied to the surface soil, the bottom roots very often suffer much from drought, the plants show signs of distress, the fruit stops growing, when suddenly the entire bed is saturated through with manure or other water. The sudden transition from dearth to plenty of food and water gives such a stimulus to the plants, as to furnish the leaves, stems, and fruit with so much sap, as to split the fruit. It is impossible, in fact, to be too careful in watering Melons during their later stages of growth. Another source of danger is leaving the fruit to lie on the damp soil. This rather helps than hinders Melons to swell the faster through their earlier stages. To such an extent do some carry this, that they even bury the fruit for the first few weeks of its life. The young fruits swell very rapidly treated thus, and, if carefully exposed afterwards, take no harm from being buried; but contact with the soil is dangerous as the Melons approach maturity. It not seldom causes blotches on the rind, which speedily advance into absolute rottenness of the flesh and decomposition of the sweet juices of the Melon. All the fruit should, therefore, be elevated above the ground, and also more or less above the leaves. The commonest modes of elevating Melons are those of placing one or more tiles, bricks, or pots under them. Most of these modes are faulty; the best plan is to raise wire or wooden cradles, 6 in. or so square, on two or more pots or cleft sticks, and place the fruit on the latticed or reticulated cradles. Light and air have thus free access to all parts of the fruit, which is by no means the case when the lower portion of it lies on a solid or opaque base. Next to these open rests for ripening Melons, glass rests are the best. These, though shutting out the air from the lower portion of the fruit, admit the light to most of it. A good deal also depends on the height of these Melon-rests not only above the soil, but in relation to the leaves and stems of the plants. In the case of weak plants, the fruit should be under the line of the stems and leaves, and the fruit be permitted to pull slightly on the branch that carries it. In the case of strong plants the fruits should be elevated as much as possible above the line of the bearing branches. The sap will thus have to run uphill—an unnatural course for the fruit food of Melons—and, consequently, less of the sap will find its way into the elevated fruits. In cases of abnormal luxuriance the supply of food to the fruit through its last stages may be further limited by cutting the stem of the Melon, or the branch on which it is growing, partly through. This checks the flow of watery sap into the fruit, hastens maturity, and heightens quality.

These cradles or Melon-rests are as useful to Melons on trellises as to those grown on manure beds in pits or frames. On trellises, the weight of the Melon during its later stages endangers its safety. The stalk either gives way, and lets the Melon fall with a crash that breaks it in pieces, or the mere weight of the fruit cuts the branch through, or partially or entirely hinders the passage of fluids through it. The simplest cradle for Melons on trellises consists of two wide, strong strands of Russian matting brought to a point at both ends and open in the middle, something in the form of a canoe. The Melon lies in the middle, and is thus upheld in safety. A dry atmosphere is as essential for the development of flavour as the regulation of the supply of fluids through the roots. But this is another rock on which many promising Melon crops are annually wrecked. It is

vitaly important in horticulture to discriminate wisely and well between the relative and absolute meaning of words. Dryness, aridity, wet, heat, cold, ventilation, &c., all have different meanings only. A dry atmosphere, for example, means only such a degree of aridity as shall preserve the Melon leaves in health. This is too often lost sight of. As soon as the Melons begin to ripen, all root waterings, surface sprinklings, &c., are at once withheld. The natural consequence is, the leaves either wither up prematurely or are devoured by red spider. The fruit, deprived of the leaves when it needs them most to change the crude juices of the soil and the plants into lusciousness and sweetness, either fails to ripen at all, or ripens of very inferior quality. It is, however, just possible to maintain a temperature sufficiently dry to develop the highest flavour, and yet to keep the roots, stems, and leaves of the plants healthy to the close. This feat is the perfection of Melon culture, and hardly ever fails to finish fruit of the highest quality. The exact time to cut Melons is another difficult and delicate point in their cultivation. The majority of Melons are left too long on the plants. It is no uncommon thing to find crops of Melons half roasted into ripeness without leaves, stems, or roots. The pit or frame bakes them into maturity as a baker's oven does alike the tops and bottoms of loaves brown. This is bad enough, but the Melons are more like burnt bread than that done to a turn. They are left on the plants far too long. Melons ought to be cut as soon as they begin to swell. It is a grave mistake to leave them swelling in hothouses, pits, or frames for days until they become full to overflowing of odours rich and sweet. The more aroma escapes from a Melon the less flavour remains in it; therefore, husband aroma as you would treasure gold, and, in nine cases out of ten, Melons would be far higher flavoured when they came to table. Some cultivators, not content with semi-roasting their fruit into maturity, lay them up on shelves or on the hot soil of pits and frames to heighten their maturity after they are cut. All this is wasteful and ruinous to the highest flavour. The scent of Melons, instead of being thus scattered broadcast on the wings of the air, to the attraction of all vermin to prey upon the fruit, and the reckless loss of its choicest elements, should be jealously preserved thus: Cut the fruit carefully as soon as it begins to swell and the stalk is seen to have almost severed its vital connection with the fruit; wrap it round carefully in several folds of tissue paper or fine cotton wool, and lay the Melon aside in a cool, dry fruit room till wanted. From three to five days after it is cut it will, as a rule, have reached its highest flavour. Melons, thus carefully finished and preserved, have a vinous richness and a delicious coolness which render them perfect and as different as well can be from those that are left after they are ripe in the sweltering atmosphere of hothouses, pits, and frames until they are placed on the table. Much of the unpopularity of Melons arises from their being thus emptied before eaten of their best qualities. Good Melons are second to no fruit; and as considerable skill and capital are expended on their cultivation, it is to be regretted that their quality should so often be spoiled through lack of attention to a few trifling matters at the finish. London never wrote a truer sentence than that "good gardening consists in attention to trifles;" and this is emphatically true in regard to the ripening, cutting, and preserving of Melons. D. T. FISH.

*Hardwicke House, Bury St. Edmunds.*

**Fruit Prospects in Durham.**—In looking over my own and some of my neighbours' fruit trees and orchards, I find that the crops of fruit in this district (North Durham) are not quite so promising as they were in the early part of the year. On Apricots there is a good crop, but Peaches are scarcely up to the average, except where they have been protected with tiffany or good copings. In many low-lying places Peaches and Nectarines are an entire failure, owing to the immature state of the wood, the excesses of rainfall last autumn preventing its proper maturation. Plums are, generally speaking, a good crop, and the same may be said of Cherries. Apples and Pears are not quite set yet, and should the present dull damp weather and low temperature continue, I am afraid that the result will not be satisfactory, although I notice that Jargonelles are pretty well set in most places, as are also the Keswick Codlin and Lord Suffield Apples. Gooseberries we must

regard as a failure, but Red Currants are an abundant crop—greater, in fact, than we have had in this district for many years. Black Currants were injured by the sharp frost which we had on May 19, and the cold easterly and north-easterly winds that followed it have, to all appearances, ruined the crop, the ground being literally covered with fallen half-set fruit. Strawberries are a mass of bloom, and the same may be said of Raspberries. On the whole, I think, in spite of the dull outlook at present, that we will have a crop of fruit equal at least to that of average years. I notice, too, that Hollies are again full of blossom; therefore we are likely to have another heavy crop of Holly berries. The common Laurel is also producing plenty of flowers, but we never see any berries here. The Mahonias are plentifully covered with fruit, except *Berberis Darwini*, which is still in flower.—TYNE DALE.

**Fruit Crops near London.**—Whilst we have been comforting ourselves that the effects of the hard March frosts on fruit trees were but partial, and that some kinds would produce heavy crops, subtle influences have been at work to destroy our hopes. The Apple bloom was so fine and so abundant, and as there was no frost during the time when it was expanded, we naturally looked for a heavy crop, and such a crop has generally been anticipated. Some keen observers, however, did not fail to remark that the flowers fell early, and that at no time did the trees present those rich garlands of flowers that in some seasons characterise our Apple orchards, and now, when it is seen that there is not half a crop of Apples on the trees, the speedy falling of the blossom is explained. The early frosts did the mischief even whilst the flower-buds were almost dormant. The Black Currants are in a similar condition. A heavy crop of fruit set, but two-thirds of it have fallen, and the bushes present but a barren aspect. Red Currants are little better, and we have known all along that the Gooseberry crop was but a light one. Plums and Cherries are the best crops so far, but should the present cold weather continue, much of the fruit will become stunted and will presently fall. Thus we are again brought face to face with another indifferent fruit season, and growers see but a poor prospect of recouping the losses incidental to the past two years.—A. D.

**Fruit Crops in Cleveland.**—In this district the fruit crops are somewhat better than was expected after the severe frosts that were experienced in March and April. Gooseberries are, however, hardly to be called a crop this season. At Egglecliffe, Yarm, about two acres are planted with Gooseberries, and the variety called *Industry* is the only one that carries anything like a crop. This is remarkable, considering that such fruitful sorts as Whitesmith and Aston are berries. In the same district I examined carefully many acres of Gooseberries, but saw nothing to compare with *Industry* as to crop. Red and Black Currants are a fair crop, as are also Raspberries, with a few exceptions. The Strawberry crop is likewise very promising, especially at Egglecliffe, where Strawberries are grown extensively. Pears, with a few exceptions, are a light crop. Apples appear to be a poor crop. Cherries are a fair crop. Plums are fair crops on walls, but poor on standards; *Victoria* is the best Plum in Cleveland.—CHAS. McDONALD, *Stokesley*.

**Brown Dead Spots on Peach Leaves.**—Will some of your correspondents tell me the cause and cure for brown dead spots and subsequent holes in Peach leaves? Only two of the trees in the house seem really injured; one is an old tree trained on the wall (inside), the other a young plant trained under the opposite glass on wires. Some of the fruits are affected with brown spots, which appear to be but skin-deep at present. I am consulted about it because I am interested in insects and plants, but I am unable to detect any insect or fungus as the cause of the mischief.—F. N.

**Apple Tree Caterpillars.**—I should be glad if any one would inform me what remedy I should employ to prevent small grobs or caterpillars infesting my Apple trees. I hand-pick them to the best of my ability, but when they enter the bloom the damage is done before their presence can be detected. On some trees I have had every bloom in past seasons destroyed, and this year I was beginning to flatter myself that the trees were going to be spared, but they have re-appeared, though later than usual, and the bloom, I am in hopes, is setting well. I may mention that there are three different kinds of grub—one almost black or dark brown, another green, and the third yellow, but the two former are the most common.—W. B.

**The Strawberry Crop of 1878** bids fair to rival that of any year within my recollection. The crops on Sir Charles Napier and Amateur—two especial favourites here, planted last August with runners layered in small pots—are enormous. I counted 328 fully expanded flowers on one plant, and I fully believe those on each plant would average 300, while two and three-year-old plantations close by are most satisfactory.—R. GILBERT, *Burgley*.

## ANSWERS TO CORRESPONDENTS.

**Pruning Roses.**—I have some Roses on their own roots in pots. How short should I prune them so as to have plenty of bloom? Should the shoots be tied down to make them push out the whole length of the shoot? My Roses are the Provence (Moss and plain) and Devoniensis.—H. S., *Argyloshire*. [Neither Tea nor Moss Roses will bear hard pruning. It is a good plan to tie the shoots down so as to make them break at all the eyes.—R. N. G. BAKSA.]

**Coverly Plants.**—What are the best plants for covers that will grow under trees?—F. W. [Common Bracken and other strong-growing hardy Ferns make excellent cover for pheasants, and St. John's-wort (*Hypericum calycinum*) will thrive under trees and forms capital shelter for game; when once established in small patches it soon spreads over a large area of ground.—G. B.]

**Double-flowered Rhododendrons.**—I send you some blooms from a Rhododendron truss, in which every flower is more or less double.—H. TAAZ, *Bushy Grove, Watford*. [Double and semi-double flowers amongst the common kinds of Rhododendrons are not uncommon. That figured at p. 517 is an Indian one.]

**Cucumbers (K).**—Your Cucumber seems a good one, and is very large, but we never can see what the public gain by these new and enormous Cucumbers, which is not so useful for general purposes as those of ordinary length.

**Melons Splitting.**—I have seven Melons consisting of different sorts, the fruit of which averages from 4 to 7 lb., and I fear they may split. How is this to be prevented?—NOANON. [Cesse watering at the roots, ventilate freely, leaving a little air on all night, and keep the temperature of the house dry.—S.]

**Swamp Gum Tree.**—Can seeds of the Tasmanian Swamp Gum Tree (*Eucalyptus viminalis*) be procured in England? and if so, where?—C. B. [We fear you will be unable to get seeds of it in England, but it may be obtained of Vilmorin-Andrieux et Cie., 4, Quai de la Mégisserie, Paris.]

**Caladiums and Gloxinias.**—What amount of heat is necessary to start Caladiums into growth in the spring? and what heat is necessary to grow Gloxinias and Dracenas successfully?—K. B. [A bottom-heat of from 60° to 65°, and a top-heat of from 55° to 60°, or they may be started well enough without bottom-heat. Gloxinias will grow well in a temperature of 60°, also Dracenas; but some kinds will succeed in a much lower temperature, whilst some of the choicer kinds are benefited by one a little higher.]

**Thuja gigantea.**—Is this as hardy as the common American Arbor-vitæ? Would the Arbor-vitæ family be generally likely to succeed under tall trees, there being no low branches or undergrowth to interfere with them?—R. [Thuja gigantea is quite as hardy as the common Arbor-vitæ, and is at the same time a much faster grower. It will thrive well enough amongst tall trees, provided the soil be not too much impoverished by trees, such as the Beech, Ash, &c., whose roots run on the surface. When planting, fresh soil should be given to each plant so as to ensure a good start.—G. B.]

**Herbarium Paper.**—Can you inform me what is the best way of fastening dried plants to paper? What is the best paper for the purpose? and where is the best place to get it?—S. M. M. [The best paper on which to mount dried specimens is plain white cartridge, and the most convenient sized sheets are those which measure about 15 in. in length and 10 in. in width. Gum the whole specimen over on one side, and press it down upon the sheet. Both sides, however, must be shown if this method be adopted; some simply strap down the main stem with gummed paper.—W. H. G.]

**Moss on Lawns.**—What is the cause and remedy for Moss in a Grass plot. I have had for some years past a very good piece of Grass, but for the last year or two Moss has made its appearance, until now it half covers the plot.—H. K. [The superabundant growth of Moss on lawns is frequently caused by imperfect drainage, and often also through poverty of soil brought on by repeatedly cutting with the scythe or mowing machine, and clearing away all growth without returning anything to the soil for the encouragement of the finer Grasses. Scarifying with a sharp rake in February or March, and applying a good dressing of lime, will kill the Moss, after which some good lawn Grass seeds should be sown and covered with fine rich soil. Then roll down firmly, and otherwise treat as in the case of newly laid down sward.—J. G.]

**Names of Plants.**—E. 1. Rhododendron arboreum album. 2. R. argenteum. *Bolton*.—We have received a few young leaves apparently of a *Daphne*; from such materials it is difficult to name plants. M. C.—1. *Pittosporum tobira* (hardy in southern counties). 3. *Rhynchospermum jasmoides*. The other is a very imperfect specimen; a shoot with flowers should be sent if you require the name. H. J. *Ross, Italy*.—1. *Sarcanthus* species; cannot say which. 2. *Dendrobium*, probably crassinode, but must see a piece of bulb to be sure. 3. *Dendrobium Pierardii*. W. C. *Frimley, Londoners tatarica*. W. T. P.—We do not name varieties of florists' flowers which should always be sent for naming to the grower of a collection of the same plants. Never pack flowers in cotton wool, as it is one of the worst materials for the purpose.

**Propagating Stove.**—In answer to "J. P." (see p. 506) allow me to say that a span-roofed house 8 ft. high and 12 ft. wide outside, with bars fixed to the top rafter and a plate on the brickwork, will answer perfectly. It should have a door at one end with a ventilator over the top, and one in the brickwork at the other end. Inside

there should be a path down the centre, with a platform on one side and a bed on the other, constructed by running up a 4-in. wall to the height required, and bottoming with slates. Lynch White's No. 2 cast-iron conical boiler and stand for use without brickwork will heat about 200 ft. of 4-in. piping. The boiler would be best placed at the end outside, with a flow and return under the platform and under the bed, with an air tap at the highest point.—H. H.

**Gorse Covert.**—I want to get up a Gorse covert on a piece of dry granite soil. The land, about eight acres, has a southern aspect, and is now producing bunches of short mow Furze, with coarse Grass in the intervals, which together make a rough surface. What is the best preparation for the land, the proper time for sowing, and the quantity of seed per acre?—A. K. [The land should be ploughed up at once, and allowed to remain fallow during summer; but if it is urgent to have the seed sown this season, the surface-soil should be well broken up by means of a grubber several times over the whole pieces in opposite directions, and afterwards repeatedly harrowed. The present is a good time to put in the seed; about 16 lb. per acre is sufficient; it is worth from 1s. 6d. to 1s. 8d. per lb. It would be a good plan to divide the eight acres into six or eight quarters (or blocks), leaving a space of 24 ft. or 30 ft. between, which should be sown down with Grass seed, so as to supply food for rabbits. Moreover, a covert, with open spaces and glades, so as to admit the sun, is preferable to one continuous mass of covert, either for vermin or game.—G. B.]

**Visiting Paris Gardens.**—I purpose going to Paris for a week or so soon. I shall, of course, be very busy, and will, I fear, not see one-third of the places named in the "Gardens and Parks of Paris." I should esteem it a great favour if you would mention a few of the most noteworthy. I shall try and see the Argenteuil Asparagus, Montreuil Peaches, Versailles, and the Municipal Gardens and Mushroom caves. I shall be located in the Avenue Bois de Boulogne. My chief business will, of course, be with the Exhibition.—HORRUS. [Among gardens worth seeing are the Parc Monceau, Bois de Vincennes, as well as the Bois de Boulogne; the Parc des Buttes Chaumont, several of the best squares—a little one Montrouge, a big one Batignolles—and Versailles. The "florists" in the Little Trianon, which means the gardener's garden. For a winter garden properly arranged, if possible see that in the garden of Madame Fould, at St. Germain. The School of Horticulture, or old Imperial Kitchen Garden, is distinct from the ornamental garden of Versailles, and certainly ought to be seen. For an example of a neat little fruit garden, although a nurseryman's, M. Jamin's, at Bourg-la-Reine, will do. There is a very good example of tropical plant culture at M. Truffaut's, at Versailles. If possible, see the way in which people grow the outdoor Pines at Thomery; the culture also of Asparagus at Argenteuil (in the fields as well as in the gardens), and when there also have a look at the Fig trees, which are cultivated in a very curious and instructive way. The little market gardens near Paris are exceedingly well worth seeing; you ought to get into one or two of them, but it would be worth while to get an idea of their general aspect by riding round Paris on the railway (Chemin de Fer de Ceinture), and from the carriages you can see a good deal of them. Probably the quickest way you could see a Mushroom cave would be about Montrouge. Make a point of seeing the flower markets; early in the morning, of course. Your guide-book or the journals in Paris will tell you the days. The Cité and Madeleine are two of the best, and worth going to look at.]

## Questions.

**Roses not Opening.**—Amongst my pot Roses on cultivated seedling Briers in a greenhouse I had six fine blooms on *Comtesse de Serenye* which did not open, but appeared as if an insect was eating them away, although I could not find one upon them. The tree was in a most healthy state. Can any of your readers inform me the reason? Is this Rose in the habit of not opening?—ANT.

**Roots of Fruit Trees too Deeply Buried.**—I have fruit trees about twenty years old. Gradually the roots have been buried by the ordinary operations in a kitchen garden. Soil and manure have been placed on the ground, and thus the surface has been raised. For the last two years I have had no fruit. Can I improve the trees by lowering the surface and partially exposing the roots?—AN AMATEUR.

**Colourless Marechal Niel Roses.**—Mr. Dean says (see p. 495) that he has no reason to complain of his Roses as regards colour. What is the nature of the manure required for the cultivation in which he has been apparently so successful? I have been so disappointed by the absence of the grand tint of this splendid Rose, that I am endeavouring to grow plants of it entirely on their own roots. My blooms have in bud shown some colour when looked into, but when they have opened the colour has entirely gone, so that they more resemble Lamarque or some equally pale Rose than Marechal Niel.—E. A.

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 4.

THE exhibits at this meeting were limited to small collections of plants from Messrs. Veitch and Sons, Mr. B. S. Williams, and a few miscellaneous subjects.

**First-class Certificates** were awarded to the following plants:—

**Adiantum cycloosorum** (Veitch & Sons).—A graceful Fern, the plants of which resemble those of *A. Capillus-Veneris*, and which in a young state are of a beautiful silvery-venerous colour. Its fronds are light and graceful, and it is altogether a valuable Fern either for culture in pots or pans.

**Xeromea Moorei** (Veitch & Sons).—A curious Iridaceous plant, having short, stiff, and sword-like leaves, and bearing flower-spikes 2 ft. to 3 ft. long, terminating with a cluster of crimson flowers, the stamens of which form the chief part.

**Platycoerium Hilli**.—An ornamental species of the Stag-horn Fern, from Queensland; well worth attention.

**Gunnera manicata** (C. Green).—A gigantic-growing variety of the well-known *Gunnera scabra*, distinct in habit and general outline; well worth planting in ornamental grounds.

**Lathyrus Drummondii** (R. Dean and C. Green).—An old but useful species of the Everlasting Pea, bearing a profusion of red blossoms; excellent for pot or border culture.

**Miscellaneous Subjects**.—Messrs. Veitch & Sons had in their collection of plants well-flowered examples of the Cinnamon-flowered *Rhododendron Crown Princess of Germany*, the scarlet-flowered *Hemantthus Kallreyrii* (from the West Coast of Africa), a specimen of the Peruvian Daffodil (bearing flowers of a bright yellow colour), and a finely coloured plant of *Croton Hanburyanum*, the leaves of which are large and graceful, and beautifully mottled with orange, crimson, green, and rose. This collection also contained a painful of *Nertera depressa*, covered with bright orange-coloured berries, and a flowering example of *Lilium coloratum*. Mr. Williams had *Asplenium horridum*, a strong-growing, *Blechnum*-like plant having brance-coloured fronds; *Eranthemum variabile*, a useful plant for pan culture, with lance-shaped, white, green, and rose-blotched leaves; also plants of *Phoenix canariensis*, *Maxillaria grandiflora*, and the useful table plant *Panax elegantissimum*. Mr. Green, Bletchingly, sent a interesting group of plants, in which were noticeable the curious *Carolina insigula*, *Gardonia Stanleyana*, the curious *Aristolochia orithocarpala*, and the long, white-flowered *Posequeria longiflora*, also out sprays of the snow-white *Libertia formosa*. Mr. Kingsbury, of Bevis Valley Nursery, Southampton, sent a new Colens named *Empress of India*, which appeared likely to prove a valuable kind; also a finely-colored tricolor *Pelargonium* named Mrs. Russell Gurney, and a silver-leaved kind named *Florence*. The same exhibitor likewise contributed several single-flowered *Patnias* of an attractive description. From the Society's gardens, Chiswick, were beautiful flowering plants of *Saxifraga nepalensis*, *Orchis foliosa*, and the useful white-flowered *Veronica pinguifolia*. Mr. Donald, Lea End, Alvechurch, near Redditch, sent blooms of a seedling *Piotee* named Mrs. James Birchley, resembling *Princes of Orange*, of a meritorious character. Mr. R. Dean contributed blooms of *Antirrhinum* with rich and varied colours, and which were much admired. Messrs. Paul & Sons, Chesnut, showed a curiously-shaped Strawberry named *Pauline*, the flavour of which was not good. Several seedling Melons came from Mr. James Manderson, Ottershaw, Chertsey, and Mr. Atkins, Wantage; and a bundle of fine Asparagus came from Mr. Allan, Gunton Park. A commendation was awarded for 'Tobbs' universal travelling pot, which is made of stiff paper and pitched inside. It is made in such a form that mousing is not required in packing, and the weight of the plants is reduced considerably—altogether a good idea.

## SCOTTISH HORTICULTURAL ASSOCIATION.

JUNE 4.

MR. HUGH FRASER gave a short account of the history of the *Rhododendron* and of some of the more striking hybrids that have been raised from it. Mr. Jas. Spiers, Haddington, next read a paper on the "History of the Haddingtonshire Ancient Fraternity of Free Gardeners." Mr. Spiers said that the minutes, proceedings, and competition of this fraternity are correctly recorded since Aug. 16, 1676, and there are traces on the minutes that this body must have existed for a much longer period. It is thus established that the Haddingtonshire Association is one of the oldest

horticultural institutions in the country. As far back as 1774 monthly meetings have been held, previous to one meeting a year, and four times a year. In 1671 prizes were offered for the Carnation, and regular competition has taken place each year since. The enthusiasm of this ancient body, and the public spirit which has always characterized it, were abundantly proved by Mr. Spiers quoting extracts from the minutes of the resolutions passed from time to time. Messrs. Dicksons & Co. exhibited *Rhododendron Broughtoni* superbum; Messrs. Mithven & Sons, *Rhododendron cinnabarinum*; Mr. John Carson, Miles' spiral *Aligouette*; and Mr. Mark King, *Scarlet East Lothian Stock*. The following awards were made on the occasion: *Gloxinia* Mrs. Smart (commended); *Patunia Craigleigh Beauty* (certificated); both from Messrs. Ireland & Thomson. *Fancy Pansy Hugh Fraser* (certificated), *Empress* and *Memento* (commended); these three were shown by Messrs. Dicksons & Co. From Messrs. Downie & Laird came *Fancy Pansies Lady Clerk*, *Lady Falmouth*, and *Mrs. Wolfe Murray* (to which certificates were awarded); and *Lady Hay* and *A. McLeod* were commended.

## LAW.

**Removing a Greenhouse** (*Moss v. James*).—This was an action of trover for a greenhouse. The facts, which are somewhat peculiar, were as follows: James had let a house and premises to one Hargrove, and permitted him to put up a greenhouse, which he was to be at liberty to remove at the expiration of the tenancy. Jackson assigned all his goods and chattels, and among them the greenhouse, to one Hargrove by a bill of sale. Hargrove enforced the bill of sale and sold the greenhouse to the plaintiff for a sum of £20. This occurred on June 7, on which day the plaintiff attempted to remove what he had purchased. Jackson's solicitors, with the knowledge of Hargrove, on May 14, had surrendered the lease of the premises to the defendant, who refused to allow the plaintiff to remove the greenhouse on the ground that they had no right to do so after the surrender. At the trial before Mr. Justice Denman it was admitted that the plaintiff had a right to move the greenhouse within a reasonable time after the surrender, and the only question to be decided was whether the time which had elapsed between May 14 and June 7 was a reasonable time or not. This question was left by consent to the learned judge, who decided that the greenhouse had not been removed within a reasonable time, and gave judgment for the defendant. On appeal, their lordships thought it was a severe finding on the part of the learned judge, but could not say, upon the evidence, that it was wrong. They therefore dismissed the appeal.

**Alleged Wrongful Exhibiting**—(*Edwards v. Cooke*).—This was an action to recover damages for an alleged libel in the "Wandsworth and Battersea District Times," of which the defendant, who is also a chemist, is the proprietor.—Mr. Wright appeared for the plaintiff; Mr. Lyon was counsel for the defendant.—The plaintiff is one of the parochial officers of the district, and the libel complained of imputed to him that a Cabbage exhibited at the flower and vegetable show last summer at Battersea, which gained the third prize, had not been grown by him, but purchased of a neighbouring market gardener. In consequence of this imputation he had been forbidden by the committee, the vicar, and churchwardens to exhibit any more till his character was cleared. The letter was signed "Observer," and the plaintiff had endeavoured in vain to obtain the name of the anonymous correspondent. Thereupon this action was brought. It appeared the plaintiff had written to the defendant complaining of these aspersions on his honesty, and that the following footnote, commented on strongly by Mr. Wright in opening the plaintiff's case to the jury, had been appended to his letter:—"Our correspondent would have been wiser if, instead of writing threatening letters, he had given proofs that the assertions of 'Observer' were untrue." At the conclusion of Mr. Wright's opening address, Baron Huddleston asked the learned counsel for the defendant if some apology would not be made, and Mr. Lyon said he should certainly advise his client to make one. The name of the writer would probably have been given up had it been asked for sooner. But it had not been demanded till long after the action was brought.—Mr. Wright said he would be content with a verdict for 40s. and all costs, with an apology published in the paper, and these terms were accepted.—Baron Huddleston remarked that no doubt the defendant would withdraw the imputation, express his belief that the plaintiff had not purchased the winning Cabbage, and regret that such a document should have appeared in the paper. There was certainly a point of honour among newspaper proprietors, who invited the public to contribute on matters of general interest, to shelter those who wrote for them; but whether this was right or wrong he would not express an opinion.—Verdict for the plaintiff—Damages, 40s. and costs.

**Crimum capense**.—A grand specimen of this noble plant may now be seen in good bloom in the Fulham Nurseries. It is growing in front of one of the glass houses, and bears six or seven strong flower-spikes, each of which is surmounted by at least ten large handsome blossoms and buds. Isolated in front of shrubberies which would form shelter from cold winds and frosts, such plants as this would do well, and if planted with care at first they would never fail to yield abundance of blossoms early in summer.

**Scarcity of Laburnum Bloom**.—It is somewhat singular that the *Laburnum* should be an exception to the general abundance of flower on trees and shrubs this season, but it is so. Is this failure local, or has the same occurrence been noted in other places?—J. G., *Zenkon*.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

**Romneya Coulteri in Essex.**—This fine plant, recently figured in THE GARDEN, proves quite hardy in one of the gardens of the New Plant and Bulb Company, at Colchester. It forms a luxuriant bush, the shoots of which die back a little, but break again vigorously. The soil is dry and good, and the position somewhat elevated. Many of our readers will be pleased to know that the genial climate of the southern and western coasts is not essential for the successful growth of this plant.

**Tritonia crocata.**—This fine showy bulb, sometimes seen as a spring-blooming plant in the conservatory, is now bearing numerous blossoms in Mr. Barr's grounds, grown along with the *Ixias*, *Sparaxis*, &c., in the open air in sheltered beds in light, well-drained soil.

**Iris Darius.**—Among the beautiful Irises now in flower is *Darius*, a variety raised by Mr. Brown, manager at the Exotic Nursery, Tooting. It is novel in colour as well as large and free in habit, and should be noted as an acquisition by all interested in these beautiful hardy flowers—the Orchids of the north.

**Echium vulgare.**—This is a charming plant in certain positions, its long racemes of blue flowers are even handsomer than those of the Italian *Anchusa*. Against a hot wall, where nothing else will grow, in the Grammar School at Colchester, Dr. Acland planted some which have increased, and now furnish a beautiful display of bloom. It is most valuable for similar positions, particularly on hot gravelly or chalky soils.

**Cyananthus lobatus.**—This very interesting blue Himalayan rock plant is now in flower in the Exotic Nursery at Tooting, and is likely to continue a long time in bloom. It was protected during the winter by a shallow frame, but is, we believe, quite hardy in rock gardens. When plants are rare, however, it is often desirable to protect them as far as possible against accidents and changes, even if able to resist cold.

**Blandfordia nobilis grandiflora.**—This is one of the most useful of the *Blandfordias* for pot culture. It grows well, has long, grass-like foliage, and flowers freely. Plants of it in Mr. Williams' nursery at Holloway, growing in 6-in. or 7-in. pots, are furnished with four or five strong flower-spikes, each of which is surmounted by at least a dozen finely-coloured bell-shaped blossoms. These, associated with *Liliums* and similar plants, have a fine effect.

**Lilium Szovitzianum and its Varieties.**—Our plants of *Lilium Szovitzianum* are now finely in flower, and amongst them I have marked the following distinct forms:—1. The unspotted form, a rich canary-yellow. 2. A nearly allied form, with a very few small dots and richly tinted. 3. A very rich-coloured and regularly and numerously dotted form, with fine petals. 4. A pale whitish form. 5. A form with rich central yellow streak and white edges. 6. A form with light-coloured anthers, generally deep-tinted, and regularly spotted with larger dots than usual. *Xiphion filifolium* is now out—a most beautiful lilac-purple and fine flower.—ALEXANDER WALLACE, Colchester.

**Bollea celestia.**—This rare Orchid is now blooming freely in the York Nurseries, and it is, even with single flowers, a striking and beautiful plant. The idea of its being either difficult to cultivate or shy to bloom must surely vanish now. Several of the crowns have two and three, and one four, blooms. One plant with two new growths has eight grand buds all nearly ready to expand. The flowers vary much in colour. In some the ground colour is very pale—almost white; in others a decided blue-lilac; in others downright purple. All are more or less heavily blotched in the upper portion of the petals with deep and rich or very dark purple. The labellum is bright yellow, and marvellously plumed. Even yet the full beauty of this plant is probably not gained, as a single shoot (imported) had the remains of eight flower-stems on it.—P.

**Anemones in June.**—Large beds of *Anemones*, from French and Dutch sources, in Mr. Barr's grounds at Tooting, are just now in fresh flower, and many buds are coming on. They are of the *A. coronaria* section and are mixed varieties, among which are some possessing beautiful and distinct colours, well worth being permanently named. Striped flowers, scarlet with white edge, pure white, and all shades of blue are here represented. The curious fact about these

plants is, that the roots were kept for two years in the shop without being planted, which no doubt accounts for their lateness in blooming, and this shows that, under certain treatment, a display of *Anemones* may be kept up for a long time. *Ixias*, *Tritonias*, and *Babianas* are also still very showy, as are likewise *Lilium umbellatum*, the lemon-coloured *L. Szovitzianum*, and *Gladiolus Colvilei*.

**Iris sibirica orientalis.**—Messrs. Barr and Messrs. Hooper have what appears to be a fine large variety of the well-known Siberian *Iris* under the name *orientalis* and other names. It seems to differ only from the species in its larger flowers.

**Passiflora vitifolia.**—This beautiful Passion-flower, so seldom seen, is now finely in flower in Mr. Parker's nursery, at Tooting. Its blossoms are of the most brilliant scarlet. The plant is a free grower, and well worth planting in any warm house.

**Hardy Lady's-slippers at Chester.**—Our bed of *Cypripedium* spectabile has now several hundreds of blooms fully expanded, and is very effective. We consider the plant to be perfectly hardy, as no protection, except a few leaves, has ever been put upon the bed, and we do not think these even necessary.—JAMES DICKSON & SONS, Chester.

**Primula sikkimensis at Kew.**—In order to form an adequate idea of the beauty of this charming Primrose, such specimens should be seen as are now in flower on a rockery at Kew. The flower-stalks are over 2 ft. in height, each bearing at their points an umbel of from thirty to forty beautiful lemon-coloured blossoms, borne on slender drooping pedicels, contrasting agreeably with the bright green foliage. It is perfectly hardy in the neighbourhood of London, provided its position be elevated and it is afforded thorough drainage. It succeeds well in a compost of good fibrous loam and a small quantity of well decomposed manure or leaf-mould. Partial shade is indispensable to its successful culture, and also a plentiful supply of water during the growing season.—A.

**Tree Lupin.**—A large good yellow variety of the Tree Lupin is a most precious plant now in great beauty. One can imagine nothing more beautiful than this for rough rocky banks or slopes. It flowers most profusely, and the scent of a single bush of it reminds one of that of a field of Beans. The purplish variety of the same plant, though good, is not nearly so valuable, and there are also inferior yellowish varieties. The best variety which we have seen is in Mr. Barr's trial ground at Tooting, and is, indeed, the best of all yellow Lupins with which we are acquainted. The bluish variety of the Tree Lupin is not so good, because there are good blue herbaceous Lupins, whereas there is no other good yellow.

**Symphyantra Wanneri.**—This beautiful hardy plant is a member of the Bell Flower family, and is one of the only two species of the genus which we have in cultivation. It differs but slightly from *Campanula*; in fact, it is as well known under that generic name as under the one above mentioned. It is of dwarf habit, rarely exceeding 1 ft. in height, rather narrow toothed and hairy leaves. Its flowers are borne very copiously on branching racemes, and are of about 1 in. in length by  $\frac{3}{4}$  in. in breadth, and of a deep mauve colour. It differs from *S. pendula* in its corolla being very slightly lobed, and in the colour of the blossoms, which in *S. pendula* are white. It succeeds well in company with the majority of the Bell-flowers, but it is one which is apt to be short lived, therefore a duplicate should be kept at hand. It is a native of Austria, whilst *S. pendula* is a Caucasian species.—W.

**The Paris Exhibition.**—M. Godfroy-Lebon, of Argenteuil, requests us to inform visitors to the Paris Exhibition who may wish to visit his Asparagus grounds that they can always do so on Saturdays, and, indeed, on all occasions on any other day, by giving previous notice to him of their intention.

**Royal Horticultural Society.**—In addition to the prizes gained by Mr. Turner, of Slough, for his beautiful Roses exhibited at the Royal Horticultural Society's great show on May 23, the Council have specially awarded him the Lindley Medal of the Society.

**Scottish Fanny Society.**—This holds its meeting in Edinburgh on the 21st inst. The schedule contains fifty-seven classes, so arranged that the smallest growers have as good facilities for exhibiting as those having large collections. As it is an open show, cultivators from all parts of the country are invited to send blooms for competition.

**Preston Show.**—A deputation from the local committee, consisting of three members and the hon. secretary, had a conference on Tuesday last with the Council of the Royal Horticultural Society at South Kensington, at which they reported progress. Arrangements were stated to be far advanced towards completion, and there is every reason to expect that the show will be a success,

## NOTES FROM KEW.

**Hardy Trees and Shrubs.**—Conspicuous for the fine tint afforded by the golden-yellow foliage, and on that account worthy of special mention, are the three following: *Quercus coccinea*, *Neillia opulifolia* aurea, and *Ptelea trifoliata* aurea. The first is a variety of our common English Oak, and, unlike many variegated trees, is a vigorous grower; its yellow leaves, too, do not scorch. The next-named is a sport from the North American type *Neillia*, or, as it is sometimes called, *Spiraea opulifolia*, the clusters of white, Hawthorn-like flowers contrast well with the large leaves (which resemble those of the Gaelder Rose) of the green kind, though they do not show off so well with the yellow foliage as a background. *Ptelea trifoliata* aurea is a very pretty variety of the Hop Tree of the Eastern United States. *Pieris ovalifolia* is a Nepalese shrub with bronzy-red leaves and shortly-stalked white flowers, pendulous from the underside of the branches. The peculiar colour presented by the foliage at the present time, very like the autumn tints of some trees, renders this shrub a valuable one for effective grouping; for the flowers alone it is scarcely worth growing. *Rosa rugosa* is a handsome Japanese species, with large deep rose-coloured flowers; it forms a compact bush about 3 ft. high, and, even when the blossoms have fallen, is very striking with its large orange-red fruits. This has been blessed with a variety of names, under which it has been distributed at various times as new. It is certainly one of the most distinct of the Roses which have not been created, as it were, by the hybridist. *Rosa chlorocarpa* is a native of Siberia, and has rosy-pink flowers nearly 3 in. across, followed by very peculiar spiny fruits.

**Hardy Herbaceous Plants.**—*Lilium monadelphum*, one of the Martagon group, is a noble Lily about 3 ft. high, having numerous, rich yellow flowers, spotted with black; it is a native of the Caucasian region. *L. tenuifolium*, a very beautiful Siberian plant, belongs to the same section as the last-named, its flowers being rich scarlet in colour. *L. concolor*—scarlet, slightly spotted with black—comes from Japan and China, and belongs to the set with erect, bell-shaped blossoms. The most noteworthy of the kinds of *Oxalis* at present in flower are *O. latifolia* spectabilis, a dwarf sort with manure-coloured flowers and prettily marked leaves; *O. odorata*, with magenta flowers; *O. floribunda*, a very floriferous Brazilian perennial, with blossoms a shade deeper in colour than those of *O. odorata*; and *O. Smithi*, with rose-coloured flowers. *Tropaeolum polyphyllum*, recently figured in THE GARDEN, does well in the open border at Kew, and its brilliant yellow blossoms last some time. *Medicago mariana*, a creeping plant from the south of Europe, has silky leaves and branches, and heads of golden-yellow flowers. *Allium Murrayanum* is one of the finest of the Alliums; it grows 1 ft. or more high, and has heads of large, rose-coloured flowers. *A. polyphyllum*, a Siberian kind of graceful habit, grows to a height of 2 ft. or 3 ft., and has reddish flowers. *A. paradoxum*, from the Caucasus, has heads of golden-yellow blossoms, as rich in colour as those of the South European *A. Moly*; the habit of the plant, though, is totally different from that of the last named.

**Greenhouse Plants.**—In the Winter Garden may be seen a large specimen of *Convolvulus canariensis*, the blossoms of which are mauve-coloured and have white centres. As a corridor plant, this free-flowering, strong-growing, woody climber can be highly recommended. *Phyllocactus crenatus*, from tropical America, has large flowers, the sepals of which are greenish, and the petals white. For brightness of colour and for easy culture few plants surpass the Fig Marigolds or Mesembryanthemums, and yet they are not nearly so much grown as they were many years ago; the most striking of those now in flower are *M. aurantiacum*, a shrubby kind with deep orange-red flowers, which grows to a height of 2 ft.; *M. cespitosum*, a stemless species, with large, beautiful, lemon-yellow flowers on stalks about 3 in. high; *M. roseum*, a dwarf, shrubby sort, with large rose-coloured blossoms; and *M. spectabile*, of similar habit to the last, and having rosy-purple flowers 2 in. across. *Swinosia elegans* is a fine Australian shrub, with snowy-white, Pea-shaped flowers. The Peruvian *Dafodil* (*Ismene Amancebes*), with its golden-yellow, very fragrant flowers, is a charming bulbous plant, worthy of general cultivation. The Scarlet Trumpet Honeysuckle, *Lonicera sempervirens* and its variety minor make two of the most beautiful corridor or pillar plants possible. Although introduced to English gardens more than 200 years ago, these charming North American climbers seem little known. *L. sempervirens* minor, being a native of Carolina, would only prove hardy in favourable conditions. *Hedychium Gardnerianum*, a Brazilian giant flower, planted out in a cool house, makes a very charming object.—†

**Rubus deliciosus.**—In reference to Mr. Anderson-Henry's note on the subject of the introduction of this plant, I have to express my

sincere regret that I should have fallen into the error of supposing that he obtained his plants or seeds of me. On the question of the priority of introduction I have, however, nothing to retract, the seeds having been received by me in January, 1863, and raised by me the following spring, since which period it has been uninterrupted in my possession. In evidence of this I have forwarded to Mr. Anderson-Henry a copy of my seed catalogue for the year named, and you will doubtless receive from him an acknowledgment to that effect. I do not possess a copy of my seed catalogue for 1872, referred to by that gentleman, but the Rubus seed there offered was no doubt that first saved from my own plants. Your readers will therefore doubtless exonerate me from the charge of rashness for having claimed that such merit as may be due—and I do not by any means desire to exaggerate it—to the first introduction and raising of the plant in question, should be placed to my credit.—W. THOMPSON, Ipswich.

— I have some seedlings of this Rubus about 7 in. high. The seeds sent me by Mr. Thompson, of Ipswich, were sown early in the spring of last year, and did not germinate till they had been in the mould twelve months. I have lately sown some of the seed in a small pot filled four-fifths of its height with rich earth, into which the seeds were firmly pressed and covered with the earth about  $\frac{1}{2}$  in. The pot was then filled to the top with silver sand and immersed in mould in a larger pot, in which it will be allowed to remain till next spring, and kept moderately moist. The pot will then have to be removed, the sand shaken out, and the seeds, if necessary, stimulated with a gentle heat.—B. S.

## OPENING OF KEW GARDENS.

ONE of the statements in the recent controversy is not true. The Jardin des Plantes is open, but the botanical division in the garden is not, and admission can only be obtained by tickets, while it is said that the botanical garden of Paris is open all day.—A. BOTANIST. [There is one division of the Paris garden shut off, but it is only separated from the rest of the garden by a low railing. This fact has more than once been stated in THE GARDEN. This is a very different thing from shutting the garden altogether. The portion alluded to is laid out in narrow beds, and is out off by a low railing in the interest of the student no doubt. We believe it to be, like many such restrictions, needless, and one of many in the Garden of Plants which might be changed with advantage.—Ed.]

— The fitness of Whit Monday morning tempted thousands out early, destined for the parks, the river, and Kew Gardens. The District Extension ran one train per hour extra, and the whole of the Kew and Richmond trains were crowded, while the Metropolitan Company also conveyed many thousands in the same direction. Kew Gardens, for the second time, were opened at ten instead of one o'clock, and as soon as the gates were opened the grounds were besieged by an orderly crowd, who distributed themselves over the various paths and walks, and went through the museums and glass houses. The new regulation for earlier opening did not appear to act prejudicially; indeed, there were at least 25,000 persons admitted, and they were widely dispersed over grounds which cover several hundreds of acres. The police bore testimony to the fact that the earlier opening of the gardens had a beneficial effect, inasmuch as the people passed quickly into the grounds, instead of congregating and drinking at the public-houses.—"Daily News." [So far, it will be observed, the recent agitation has done good, even carried on as it has been, according to some writers, by persons actuated by selfish and unworthy motives. It has been argued that the agitation was "local," but who so likely as local gentlemen to see and deplore the scenes that used to occur on Kew Green before the gardens were opened at 10 o'clock on bank holidays?—Ed.]

**Antirrhinums.**—Plants of these from early-sown seed put out now will bloom in August and September, and succeed the plants raised from seed in August last. In this way the pretty homely Snapdragon can be had in bloom throughout a good part of the summer. A good strain only should be grown, as it is a waste of time to cultivate inferior forms; and now that a preponderance of striped flowers is certain to occur in a good strain, that is an additional reason for having a plantation in a garden. The cold wet spring has had an injurious effect on some of the old plants kept over from last year, and many that were in a cold wet soil have died away altogether. On the other hand, plants in a light drier soil have done wonderfully well; and really very fine specimens can now be seen in gardens in full bloom. Those who have a wet, cold, uncongential soil will do best to raise plants in the autumn, winter them in store boxes in cold frames, and plant them out in March and April, when the weather is favourable.—D.

PROPAGATING.

ROSES.—Cuttings of these should be made of half-ripened wood in March and April, as shown in fig. 1. A compost consisting of equal parts of loam, well-decayed manure, and leaf-mould, to which a little sand has been added, will answer the purpose. Sift it fine, and fill well-drained pots with it; insert the cuttings, fasten them well in, give a good watering, and

Fig. 1.

place them on a gentle bottom-heat in a hotbed; look them carefully over from time to time, removing all decayed leaves that may be seen on them; they will soon emit roots, and will be ready to pot off in about six weeks. Roses may be grafted indoors in January and February. One of the best and most successful modes I have found is to get the stocks (Manetti) in and laid in by the heels for a week in some old tan or Cocoanut refuse; cut the scion either as shown in fig. 2 or fig. 3, make the incision in the stock as in fig. 4, and fit in the scion;

Fig. 4.

Fig. 2.

Fig. 3.

tie firmly with worsted, and place them in rows in a gentle bottom-heat, covering up with the plunging material just above the ties. It is best to place glasses or lights over them, which must be opened every morning to allow all excess of moisture to escape. In about three or four weeks they will be ready for potting. They must still be kept in warmth for a short time, so as not to give them a check. H. H.

**Darlingtonia californica Hardy in England.**—This very interesting plant has proved hardy at Tooting. Having seen the plant growing wild in the mountains of California, and gathered it where it was making very great efforts to hold its own amongst the Common Rush in small bogs covered with Sphagnum Moss and deeply covered with snow in winter, I always felt that the common way of growing this plant could only lead to failure. Many thousands of imported plants have died owing to their being treated like exotic Orchids. Mr. Parker put out a small plant in his arti-

social bog; it has come through the winter quite fresh, and is now growing well. Failing a bog, the best place for the plant is a sunny shelf in a greenhouse, or a place not shaded in a pit or frame, with its pot standing in a saucer of water.—V.

THE KITCHEN GARDEN.

KITCHEN GARDEN CROPPING.

Plot No. 1.—Well trenched for Onions last year, pulled and carried off the ground to dry under our south walls; ground cultivated and planted the same day with little Pixie Cabbages 15 in. apart, all out, and cleared off by April 8. The ground was then manured with a few loads of old rotten sawdust, and again cultivated, and planted with show Potatoes, the produce of which will probably be exhibited at the Crystal Palace for Messrs. Sutton and Sons' prize.

Plot No. 2.—Potatoes last year. Well manured and dug for Cabbages, every alternate row being planted with Scarlet Runner Beans. Just now, June 7, Cabbages all out, Beans staked, and a row of Brussels Sprouts planted between each without any digging whatever. In fact, summer digging in my opinion, is a waste of time.

Plot No. 3.—Trenched and well manured for Strawberries. These are allowed to stand two years; the Strawberries are chopped off with a spade and Broccoli planted, in the crowbar fashion, without any digging. After Broccoli, Celery, with two rows of Lettuces, planted on each ridge. Ten years' experience here and twenty-five at other places tell me too truly that too much digging is a great mistake. R. GILBERT.

Burghley.

**Asparagus Culture.**—Reading the remarks on this subject in last week's GARDEN, I thought it would not be out of place to state what came under my notice last week. I was invited to spend a day at Forrby, a sandy desert-looking place at the mouth of the Mersey, between Liverpool and Southport, on the Lancashire and Yorkshire Railway; and there, to my surprise, amidst the surrounding desolation of sand-hills, spotted here and there with the coarse Star Grass, I came upon a field of Asparagus sown in drills about the same distance apart as Potatoes. The soil is nothing but sand, to which I could see a little manure had been added. The field was surrounded by wire netting to keep off rabbits, and I was told that it was bringing to its owner, Mr. Forrby (after whom the place is named), a large amount per week for Asparagus sent to Liverpool market, and that his was the best sent to that market. I did not see fully the extent of ground under cultivation, but the thought that struck me was that here is a new source of wealth to those who own these hills or who can rent them cheaply, for there are thousands of acres in the neighbourhood all along the coast that might produce similar results, and, as the subject is one of food for the people, it is for the public good that this should be made known.—THOS. STUDD, *Heaton Mersey.*

—With all due deference to the perhaps deserved criticism on my little article on the growth of Asparagus, I must still think my plan a good one, and in confirmation of which I can appeal, if need be, to Mr. Radclyffe, one of our greatest amateur gardeners in Dorset. On light, or very rich loamy soils, Asparagus may and can be grown on a perfectly even surface, but in my deep-blue clay soil the plants would rot in a short time, except as I treat them. As to 19 in. being too close, I have in light soil seen good crops on a bed sown to raise plants; but of course I do not advocate the plan. By my plan I cannot get the heads of the Asparagus much more than 3 in. to 4 in. in girth, but I am satisfied.—EUGENE P. LEGGEE.

—I send a few specimens of our Asparagus cut from single lines. It is not so fine as it was a fortnight ago. We have had a great fall of rain for the last four weeks, with a low temperature; consequently, the ground is cold and wet, and the growth of the Asparagus at a standstill. Our Asparagus is not large, as our soil is not all that can be desired for its growth; still we have always an abundant crop, which is of excellent quality.—D. LUMSDEN, *Bloxholm Hall, Lincolnshire.*

[Very good Asparagus, but a little too bitter for some tastes, owing to its greenness. The question of blanching, however, or not blanching is quite apart from the question of culture. We believe the happy medium will be found in partial blanching, as is the practice of the London market growers.]

**Early Peas.**—Like Mr. Gilbert (see p. 550), I still retain a liking for the oldest of all practices, that of sowing Peas in November for

a first picking; and in localities not too wet, where they can be grown profitably, they, as a rule, come in the earliest. Sweet Peas for cut flowers are by some had very early by sowing in November. Where mice and other vermin are troublesome the seeds may be sown on the flat surface; cover them first with chopped Furze, and then mound the earth over the rows, using a covering of soil over the young tops when they begin to show their green points through the ground. A good dusting of sifted ashes or chaff from Barley is used by some for the purpose of preventing the depredations of slugs. This system of raising early Peas was at one time largely practised, and I have observed good results from it, both as regards quantity and earliness, in Scotland, and near Dublin especially. For the sake of having a double chance of an early crop, I always sow a number of boxes with early kinds of Peas some time in January, only using protection for them against severe frosts and heavy rains, and if they are not required for podding under glass they are planted out in a sheltered border in March and staked at once for protection. Extra caution did not act as a specific against frost this season. Even those planted late in March suffered severely from the frosts which occurred early in April, of which we had one night 15°. We thought at one time that our Peas were entirely destroyed, but they afterwards branched out and enabled us to pick a dish on May 27; the kind was Dillestone's Early. I find that the dwarf Pea named Blue Peter bears very early, and is of good flavour and a capital cropper. Sangster's No. 1 was in good bearing condition the first week in June, and, though they were severely injured by frost early in April, they have branched out with great vigour and require topping. Rich and deeply-trenched ground changes the character of Peas materially, and under such circumstances they should be planted as thins as French Beans.—M. TEMPLE.

#### NOTES ON TULIPS.

THE Royal National Tulip Society held its annual exhibition at Manchester on May 25, and the Northern Counties Tulip Show at Gorton on May 30. These are the leading Tulip shows held in the north of England. It is not my intention to give any report of these exhibitions, but briefly to indicate a few of the leading flowers, and more especially some of the newer ones that were exhibited at these shows. Bizarre Sir Joseph Paxton, an old standard variety of great merit, was in fine form, especially as a flamed flower, and some feathered forms were also remarkably good. Dr. Hardy, flamed Bizarre, was also very fine, and remarkable for its bright colouring. John Morris, feathered Bizarre, was not much shown, but generally in rare condition. Slater's Masterpiece is fine always whether feathered or flamed, but on this occasion it amply justified the encomium passed upon it of being the best feathered Bizarre that has yet been raised. Headley's Demosthenes, though worthless as a flamed flower, was thoroughly good in its feathered character; it is in the way of the old Royal Sovereign, and very often seen in winning stands. How good Willison's Sir Joseph Paxton is, and how constant its fine character, may be properly inferred from the fact that for the past nine years it has won the premier prize as the best flamed Tulip at the Royal National Tulip Society's Show. It should be included amongst the most select collection of florists' Tulips. Hardy's Ajax, which is regarded as a seedling from and a great improvement on Polyphemus, was, as usual, fine as a flamed flower, and this is invariably its best character; and when it comes feathered the markings are very fine. Lawrence's George Hayward is a fine old Bizarre, which is always best in the feathered state; it is unfortunately somewhat inconstant and uncertain. Hardy's Lord Delamere is a new and scarce variety, and comes very fine both in the feathered and flamed state; it always takes high rank, and is characterised by great refinement in the marking. In the class of Roses, Annie Macgregor was an exceedingly fine-flamed flower, the pencilling of the feather being of the most refined and delicate character possible, although firmly laid on and carried well around the edges of the petals. This and Lady Sefton were raised by Martin, the latter being a flamed Rose of the highest quality; and both are regarded as the two best flamed Roses in cultivation. They are as yet quite scarce, and those who are looking after them will have to patiently wait till the overflow of stock reaches them. Martin's Mabel is also a charming flower as a flamed Rose, and is identical with Mrs. Lomax. The old Triomphe Royale was also in good character as a flamed flower. The most attractive feathered Roses were

Hepworth's Nancy Gibson, very beautiful and very handsomely marked; Modesty (Walker), a finely-marked flower with a pure white ground; Charming (Martin), a useful flower in the way of Mabel, but scarcely so refined; Industry (Lea), regarded as the finest feathered Rose in cultivation, the colour being a bright carmine-scarlet on the palest of white grounds; and Heroine, a fine old variety, and a favourite old flamed Rose, and, being plentiful, is generally shown; in its flamed character it is known as the Triomphe Royale, referred to above. Aglaia and Madame de St. Arnaud are old varieties of considerable merit, still much grown for show purposes.

Of Byblomens, Headley's Adonis is always good; both in the feathered and flamed state it is a fine variety, and well deserves to be grown. Hepworth's Bessie is a noble feathered flower when well grown, and though it sometimes comes flamed, it is decidedly best when feathered. Mrs. Cooper is a very fine feathered flower, and when in good character not surpassed by anything; it is also known under a later name of Rutley's Queen. Martin's 101 is a very useful flower in its feathered state, and though not perfect, is always a great favourite. Mrs. Pickerrill was also good in its feathered character, but it is an old variety gradually being displaced by newer introductions. Adonis was also good as a flamed flower; and Hardy's Talisman showed the refined marking, for the possession of which, when in good character, it is so famous. It is the finest flamed Byblomen in cultivation, and sometimes in finely feathered condition; but the feathered breaks, so far have shown no stability, but have passed into flamed flowers. Slater's Friar Tuck was fine in the flamed character; it also comes good as a feathered flower, and has won the premier prize. Brown's Salvator Rosa is a first-class uncertain flower, and because it is uncertain is seldom seen in good character; much, however, depends on having a good strain of it. A few of the newest and scarcest flowers were found in Bizarres William Willison, a very useful flower, both feathered and flamed; Byblomens David Jackson, fine, both feathered and flamed, and Hardy's Nimbus, supposed to be a seedling out of the same pod which produced Talisman, and grand in any form; and Rose Mrs. Barlow (Hepworth), a very fine flamed flower, and exceedingly beautiful in the Breeder form. The Breeder Tulips, in their beautiful and delicate self-coloured and splendid forms, are always objects of great interest. The most attractive were Bizarres Sir J. Paxton, Willison, Dr. Hardy, and William Lea; Byblomens Glory of Stakehill, Talisman, delicata, and Martin's 117; and Roses Mabel, Annie Macgregor, Mrs. Barlow, and Olivia.

**Auriculas.**—At no season of the year does green fly more persistently congregate on Auriculas than at this season of the year. They cluster about the hearts of the plants and on the undersides of the leaves, and their presence in force is detrimental to the well-being of the plants. A good fumigation with Tobacco smoke is the best and most thorough eradicator, applying it strongly too, for it will not injure the plants, and following it up with a good brushing by means of an artist's brush. If the plants be looked at daily, and the brush applied for a few minutes, the enemy is soon routed. There is a small green caterpillar also that needs to be sharply looked after. He gets into the heart of a plant, and feeds on the tender leaves, and soon eats away the heart. A good Auricula cultivator makes a constant practice of looking over his plants, and he soon detects if anything is wrong. If, on the other hand, Auriculas are neglected, insidious foes soon storm the citadel. Auriculas bearing seed are best left in their blooming pots till the harvest is gathered, but as the soil at this time of the year, through frequent waterings, is apt to become sour on the surface and covered with Moss, it should be frequently stirred. The plants that have been re-potted, if kept cool and shady, will not require much water, and root action goes on merrily in a moderately moist soil. The young stock is now growing fast, and should be shifted into larger pots as required. Over potting in the case of the Auricula is a great mistake, and especially is this true of small plants, for when overdone with pot room beyond their requirements, the plants will decline and die outright. Seedling Auriculas raised from seed sown last autumn, and already pricked off from the seed-pans into store pots, will soon require another shift. The largest plants can be placed singly into thumb-pots; but it is a saving of time and labour to put three or four plants into small 3-in. or sixty-sized pots and allow them to flower in them.—D.

## THE FLOWER GARDEN.

## HARDY ORCHIDS.

Few classes of hardy plants afford more interest than a well-grown collection of hardy Orchids. Although their flowers are not so gorgeous as those of some of their epiphytal congeners of the Tropics, yet they are extremely beautiful both in colour and form; indeed, language fails to convey an idea of the subtle tints belonging to some of them, and it would be equally

difficult to describe, without the aid of drawings, the many singular forms which they assume. In them we find mimic representations of insects, birds, reptiles, &c., although it must be admitted that in some the similarity to the objects which they are supposed to represent is somewhat vague. Notwithstanding all this, they are, however, but seldom seen in gardens, or if so, but rarely in a thriving condition, and doubtless the reason why so few attempt their culture is, that they are reputedly difficult to cultivate; the failure, however, may in the majority of cases be attributed to either an improper mode or time of transplanting them, or in placing them under unnatural conditions. Perhaps the following remarks may tend to induce those who have not yet attempted to grow them to form a collection, and also encourage those to persevere who have hitherto had but ill success with this interesting tribe of plants. The best way is to begin with the kinds that are the most readily procurable, and after gaining experience with these, rarer kinds may then be taken in hand without fear of failure. Even our British Orchids have amongst their number some really beautiful kinds, and open a wide field for experience in culture; for instance, those who can keep in a thriving condition the bee or fly Ophrys need not hesitate to try the rare, and even more beautiful,

South European kinds of Ophrys; and at this season, when the indigenous species are in flower, a word on the mode and time of transplanting them may be useful, though I should be sorry to see it carried to such an extent as to endanger the extermination of these gems of our native flora. After success depends greatly, as I have said, on this operation, and the time at which it is usually performed is altogether wrong. The usual plan is to do it just when the first or second flower has opened, so as to enjoy the remaining few in the garden, and, this done, the cultivation has in most

cases begun and ended. To show how mischievous such a course of procedure is, I may state that at this period of growth the plant is forming a new tuber for the following year, and if this is in any way injured, it shrinks and dies, thus oftentimes causing disappointment at its non-appearance in spring. If, instead of this, the plants were marked when in flower and allowed to remain until August or September, when the newly-formed tuber will be thoroughly matured, the risk of transplanting it is considerably lessened, provided it be taken up with a good deep sod. It is advisable to take from the sod

the roots of other plants, though some allow them to remain to spread over the Orchid border, thus imitating natural conditions by protecting the roots in winter and preventing evaporation in summer. In a garden, however, this presents an untidy appearance, besides the risk of cutting away the Orchids as well as the Grass, &c., in the flowering season. In this matter we can be aided by such plants as the pretty Balearic Sandwort (*Arenaria balearica*), Lawn Pearlwort (*Sagina glabra*), the mossy and tufted section of Saxifrage, and many others, which are at all seasons very beautiful and interesting, and serve the purpose equally well. The next thing to consider is a place in the garden best suited to their requirements. Doubtless many have grown and will continue to grow the more robust kinds successfully in mixed borders or amongst the denizens of the rock garden, or in a detached portion of it; but, where space is no objection, a place set apart for a collection is by far the best plan, and, in lieu of a more appropriate term, it may be called the "Orchid garden," though in such a small space as a garden can afford the natural condition of each kind cannot be very minutely imitated, some being shade-loving, others delighting in sunshine; so experience has shown that partial shade is most congenial to them when under cultivation, such as

The Wild Garden in Early Spring.

may be obtained with an eastern or western aspect, with trees or, less preferable, a high wall as the means of affording shade. The Orchid garden should consist of a raised portion, from 5 ft. to 6 ft. at the highest parts, with a gentle slope outwards and a more steep slope inwards (towards the trees or wall). Thorough drainage by means of rubble is indispensable, the importance of which cannot be too emphatically impressed, as it is in the neglect of this precaution to which one of the chief causes of failure may be attributed; so to whatever height the border is raised the soil should not be more than 15 in. in

depth, the rest being taken up in drainage material. On the outer slope should be planted those kinds that are found in pastures and exposed places, &c.; on the inner slope those whose wild haunts are in woods and thickets, &c., therefore requiring more shade. For the kinds that inhabit bogs, swampy and other wet places, an artificial bog may be easily constructed at the base of the raised portion, by sinking troughs or large glazed earthenware pans, so that the rims are within 2 ft. of the surface, and then filling them with water and large stones, and on these placing the peat or other soil; the water will then rise in it by capillary attraction, thus rendering it a good spongy bog, in which *Cypripediums* and other bog-inhabiting kinds will thrive. It will be necessary to have a pipe to each pan or trough in order to refill it, though this is but seldom needed, except in hot weather. The soil for the slopes should consist of three kinds—A, equal parts of good sandy loam and chalk from under trees, which, being mixed with decomposed leaves, &c., is preferable to any other soil. To those who reside in a chalk district this is a simple matter, but if this be not obtainable, old mortar, or sandstone broken finely, is the best substitute. Nearly the whole length of the outer and part of the inner slope should consist of this compost, and a lesser portion should consist of peat mixed with the above (B) and on a small portion of the inner slope a compost consisting of (C) peat with chopped *Sphagnum Moss* and sand in small quantity; in this the kinds of *Goodyera*, &c., delight to creep. The artificial bog should be extended half-way round each slope with a compost 2 ft. in depth of two parts of fibry peat D, one part of well-decomposed leaf-mould, and half part sand; the remaining portion of the base should consist of a deep, rich loam, with an admixture of limestone E, but should be also well drained; in this the more robust kinds should be planted. The surface of the slopes should be undulated; but straight margins should be carefully avoided, and by forming here and there little nooks, wherein many kinds would delight to nestle, it would greatly enhance the utility of the place. Large stones should be placed half-buried on the slopes to serve as stepping-places, and the roots of many will be benefited by being in contact with stones; some may be placed at the base also, to serve as stepping-stones across the bog. Now for a word on the exotic kinds of hardy *Orchids*, which may be obtained at any of the large nurseries where hardy plants are treated as a speciality. Taking first the *Lady's Slippers* (*Cypripediums*), which bear the largest flowers, we have about a dozen species introduced to our gardens, all deserving of cultivation, but I need scarcely say much about these, as the faithfully-coloured illustrations, lucid descriptions, and excellent cultural notes that have appeared from time to time in *THE GARDEN* have brought them very familiarly before us; suffice it to say, that they will all thrive in the bog in the compost D, with the exception of our English *Lady's Slipper* (*C. Calceolus*), which requires a clayey loam and leaf-mould, in a well-drained situation. Taking next the genus *Ophrys*, we find in it the gems of the family, for we have in them strange forms and indescribable colours, especially in those that come from the Mediterranean region. As an instance of this, I quote the words of a distinguished botanist and traveller when speaking of *Ophrys Speculum*, the Looking-glass *Ophrys*, which inhabits the Grassy hill-slopes of Greece, &c. "The brilliant polished surface of the disk of the lip shines like a blue steel looking-glass edged with gold, and that, again, set in a rich maroon-velvety frame, presents a combination of colours quite unlike anything known to me in the vegetable kingdom;" and those who saw the fine collection exhibited a few years since at some of the metropolitan shows by the Comte de Paris, an ardent lover and cultivator of these plants, can corroborate this assertion, and also the amount of interest and admiration that was evinced by all who saw them. All the kinds must be planted on the outer slope of the *Orchid Garden* in the soil A, and by carefully watching for their live enemies, and perhaps using an inverted pot to protect the more southern species from too much wet and cold in winter, success will be inevitable. The greatest number of kinds belong to the genus *Orchis*, and amongst these are many beautiful sorts, perhaps the handsomest being *O. foliosa*, a native of Madeira, but quite hardy in the neighbourhood of London. I have seen magnificent specimens of this fine species at exhibitions

staged with a collection of its tropical associates and yet out-vying many of them in beauty. The indigenous species of this genus are also numerous, the best being *O. hircina*, *O. mascula*, *O. militaris*, and the beautiful Channel Islands species *O. laxiflora*.

The genus *Satyrium* affords two lovely species—*S. aureum*, with flowers of a bright golden-yellow colour, and *S. carneum*, with large flowers varying from white to deep rose. Both are natives of the Cape, and therefore require slight protection in winter. The position best suited to them is in the artificial bog at the base of the inner slope. The beautiful *Goodyera pubescens*, with its velvety green leaves and silvery veins, is quite a rival to the tropical *Naectochili*; it will succeed in the soil C, on the inner slope, in company with our native species *G. repens*. It seems needless to comment more on the beauties of these plants; I will now append a list of the best kinds, of which many may be obtained at nurseries, whilst others are very rare; but some of your readers may have correspondents or other means of obtaining the South European and other kinds, or perhaps some of our enterprising nurserymen will undertake their introduction in quantity, as they have in the case of those from the Tropics. Unfortunately, we cannot look to our National Botanic Garden for their introduction, or to see them in a living state there under the most approved mode of culture.

**COLUMBINES AND THEIR CULTURE.**

My experience of the finer kinds of *Aquilegia* differs greatly from that of Mr. Dod (see p. 515). Possibly this high situation—720 ft. above the sea level, and a consequently cool climate—may be suitable to the growth of these beautiful plants, which are worth any amount of trouble expended on their culture. I began about five years ago with *A. canadensis*, an old friend, with which I first made acquaintance on the rocky banks of Niagara. It grows like a weed in this garden, and seeds itself pretty freely. This year, for the first time, I notice signs of deterioration, and shall therefore raise a new stock. Since then I have had *A. Skinneri*, *glandulosa*, *corules*, *chrysantha*, and *Wittmanni*, all of which have done well, though in different degrees. *Skinneri* is a luxuriant bush, 2½ ft. high, with more than 200 blossoms on it of exceeding elegance. Most of last year's seedlings of *A. glandulosa* are blooming well, with very large individual flowers, but it is a somewhat shy bloomer, and looks best in tolerably large clumps. This species seems to me to be biennial. *A. chrysantha*, on the contrary, is a good perennial. Here it is not yet in bloom, but looks promising, with strong-flowering shoots. *A. corulea* I find to be the most difficult to manage, and it seems to require more shade than the others; but I have several plants of it in bloom, and do not despair of growing it better in the future. *A. Wittmanni*, a hybrid, is not to be despised as a substitute for it. I believe most people would prefer it from its much greater luxuriance, while in colour it is almost identical with *A. corulea*. The long spurs which add so greatly to the beauty of the latter species are wanting in *Wittmanni*, and its whole growth is less elegant, but as a decorative border plant of

strong constitution and an undoubted perennial I should think it could hardly be surpassed. It grows about 3 ft. high. I should add that I obtained my seed from Mr. Thompson, of Ipswich, who has done so much for our gardens in introducing these amongst many other valuable hardy plants, and every variety that I have flowered has come true to its name without a failure, which is very remarkable. I know other gardens in the south of England where *Aquilegia* grow more freely than with me, and a relative in Devonshire keeps them in pots in a cold frame, for the decoration of an open verandah, being afraid to trust them in the thick clay and slug-infested soil of that neighbourhood, and who blooms them with very fair success.—*D., Ashmore, Dorset.*

— I think Mr. Farrer (see p. 542) is in error about having a bed in bloom of *Aquilegia Skinneri*. This variety is a very late bloomer. I never have it till July, when the others are over, and in all probability the one Mr. Farrer has is *A. californica*. Both *A. Skinneri* and *A. chrysantha* do perfectly well in beds, but to get good blossoms of the latter the plants should be grown under glass, as the weather impairs their beauty. I have three and four-year-old plants blooming well, but it is better to keep them only for two years if fine flowers are required. The small seedlings should be kept under cover the first winter. I find *A. corulea* a miffy plant to grow in the open ground, but there is no difficulty with it under glass. *A. glandulosa* does not do at all well in the south; it wants a damp climate. It is almost impossible to get the seed of *Aquilegia* true unless a single plant is kept perfectly apart from all other varieties. It is surprising

*Aquilegia chrysantha.*

that florists do not carefully cross some of the better varieties. If Mr. Farrer will look at vol. iii., part 18, of Henderson's "Illustrated Bouquet" for 1864, he will see a plate of some beautiful hybrids which I raised between *A. fragrans* and *A. Skinneri*. He will in the same place find some hints as to their culture. The germination of the seed varies. I have at this moment hundreds of *A. chrysantha* seedlings coming up in the open air as thick as Mustard and Cross sown in April, and sometimes they take a year to vegetate. I think it does best if sown as soon as the seeds are ripe.—*A. R., Bromley.*

**Columbines in the Isle of Wight.**—I cannot think that the deterioration of *Aquilegia* is altogether due (see p. 516) to locality. I believe that they can be grown as well in the south of England as in the north, with the single exception that some of them are not worth much after the first year. There is, however, something very puzzling about *Aquilegia glandulosa*. Some four or five years ago I raised three of these fine plants from seed, which were as beautiful as anything could be. They acquired quite a reputation in the place, and several persons visited my garden to see them. I fondly imagined that *Aquilegia glandulosa* would be permanently established here, and I looked for it the next year as a matter of course, but it never came again, though I have grown scores of plants from the best seeds I could get. I never have been able to make out why success was so easy at first and has never since been obtained. I can only suppose that there must have been some great difference in the seeds themselves to cause results to be so different under the same conditions. I was fortunate, I fancy, in the first instance with the seeds, but unfortunate afterwards. *Aquilegia corulea* and *A. chrysantha* are, in my experience, much more to be relied on than their

very beautiful congener, and they do hold on fairly well from year to year.—H. EWANK, *St. John's, Ryde.*

#### SEDUM MAXIMUM.

It seems strange that the genus *Saxifraga* should engross so much attention while the *Sedums* are, in a degree, kept in the background. There is certainly more diversity of beauty and form among the *Sedums* than among the *Saxifragas*, from the minute *S. brevifolium*, with its turgid leaves, like small pearls, and the delicate sea-green *dasyphyllum* up to the arboreous *S. populifolium*. There is every conceivable form of outline and colour in this tribe. The plant under notice (*S. maximum*) is one of the finest and most distinct of the family, unique in colour, being a rich chestnut-brown. It is a most telling plant, nor can I at this moment call to mind a hardy plant of the same colour—just one of those plants that every one stops to ask what it is. The plant is of bold, stately growth, grows about 1½ ft. high, and is admirably adapted for massing; and, if better known, would, I believe, find its way into every park and public garden. A bed of this mixed with *Cineraria maritima* or *Centaurea candidissima*, and edged with Golden Feather *Pyrethrum*, would be very effective. To have this plant in perfection, it should be planted in the poorest, stony, gravelly soil, and smoke will not injure it. On rockwork of a white calcareous nature, it is all that can be desired. The term *maximum* is not a very appropriate one, as there are several more robust species than this, notably *S. latifolium*. In conclusion, I may say no plants want less care than *Sedums*; they do not even care about being planted—you may lay them down on the ground where wanted, and go and find them rooted and growing in a few days.

*Ormskirck.*

THOS. WILLIAMS.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Rate of Growth in the Lichen geographicus.**—Can any of your readers tell me what the rate of growth is of this Lichen? It will soon be a year since I placed a piece of flint, picked up on Sea Fell, in Cumberland, in a shady window of my house, and I cannot say that the Lichen on it has extended a hair's breadth during that time. It is difficult to tell whether a plant, which grows so close to the stone as to appear to be painted on it, is dead or alive; but my specimen, examined through an ordinary microscope, seems to-day just as fresh as the day it was picked up. Judging from its apparent rate of growth, the specimen, which covers about a couple of square inches, must have taken 100 years or more to grow.—J. S. W.

***Eremurus robustus.***—As I was told when I bought this plant from Mr. Ware last autumn, that there were not six flowering specimens of it in the country, some particulars about it may be interesting to readers of THE GARDEN. I planted it in ordinary soil under a cold frame in autumn, and in February, finding that it was growing, I planted it, as I was recommended to do, in a well-drained, sunny position. The roots were large and pushing actively. It grew quickly, and I protected it during frosts with a bamp. Large leaves measuring 3 in. across were produced, and towards the end of March the scape began to appear. At the present time (June 7) it measures a little more than 6 ft. in height, and it is 2½ in. in circumference at 3 in. from the ground. The spike is 2 ft. 1 in. in length, and as only a few of the lower whorls of the flowers are expanded, it will probably grow longer. The blooms are of fair size, and of a delicate pale rose colour, with orange-coloured anthers. A frost in May has, I think, touched the apex of the spike, which might otherwise have grown more. The plant seems impatient of drought at the flowering time, as a few dry days caused the spike to droop, and watering the root did not perfectly straighten it. My impression is that I did no good by coddling it in winter. I may add that beside it is a good bloom of *Iris asiatica*, which I have never before succeeded in flowering.—FREDERIC CLOWES, *Widdermere.*

***Saxifraga pyramidalis.***—Why this *Saxifraga* (see p. 537) is so little known is, because it is often confounded with, and sold for, *S. Cotyledon*. The latter, though handsome and having a more dense inflorescence, with curving racemes, is still inferior to *pyramidalis*, which has a more diffuse, branched panicle of flowers, and makes a very fine conservatory plant. In order to grow this plant to perfection, a single strong crown or rosette should be aimed at by keeping the plant clear of suckers. I need scarcely add that *pyramidalis* is not a species, but a variety of *S. Cotyledon*. The fine *Saxifraga*, too, from Nepal, *S. nepalensis* of many, is the *S. ligulata* introduced nearly sixty years ago. While on *Saxifragas*, let me add that, take it for its all in all, I consider *S. ajacifolia* one of the handsomest *Saxifragas* grown, certainly so in the section to which it belongs—the Cassian or Mossy group.—THOS. WILLIAMS, *Ormskirck.*

#### A RURAL VILLA GARDEN.

THE rural villa garden, of which the following is a description, possesses many good points, although it may not embrace what may be termed the "latest improvements" which usually figure conspicuously in the decoration of suburban villa gardens. The extent of ground, too, is larger than that attached to most villa residences near thickly populated towns; but in rural districts, where land is of less value than near towns, and the houses in many cases built specially for the owner, a considerable amount of land is often enclosed and divided into pleasure grounds and kitchen gardens, and in most cases a small meadow or paddock is added. In the case to which I am about to allude the property is under two acres, yet I doubt if many owners of fifty times that extent derive more pleasure from their estates than the occupier of this well-managed garden and grounds. The house stands just far enough back from the high road to be partially concealed from it by a belt of evergreen Oaks that flourish amazingly near the seacoast, and afford a grateful shelter to tender vegetation from the rough blasts that prevail in the locality. A verandah covered with Roses and other climbers runs the whole length of the house, and forms both shelter and shade, while a quantity of that excellent seaside shrub, the Golden *Buonnyms*, in a contiguous plantation, is effective at all seasons of the year. A half-circular Grass plot in front of the entrance is bordered with herbaceous plants, and even under the deciduous trees a beautiful display of early spring flowers is obtained by naturalising hardy, bulbous, and other early flowering plants that flourish under semi-wild conditions. Folding glass doors separate the drawing-room from the plant house and Vinery combined, which is interesting the whole year through, the owner knowing what plants to grow and how to grow them. Hotbeds are extemporised for propagating and raising seeds of tender plants, and sheltered nooks and corners are made available for raising successional stock up to the period when it becomes available for decoration. A few Ferns and fine-foliated plants, such as the hardiest Palms, *Dracænas*, *Ficuses*, and succulent plants, contrast well with the flowers of any season of the year. From this house a flight of steps leads to a lawn, consisting of mossy turf, that answers at once for pleasure ground and orchard combined, as nearly all the trees on it are fruit-bearing ones. The central one, a fine Mulberry, is a beautiful object, and a Medlar and several fine Apples and Pears grow wildly and mingle with good effect with evergreen trees. In autumn the trees are literally loaded with fruit, while in spring the blossoms are most effective. No regular bedding out is attempted, but large, irregular masses of Roses, mixed with *Gladioli*, *Stocks*, and showy-flowered and scented annuals, ensure a continuance of bloom both early and late. I am aware that a certain degree of prejudice exists against the employment of useful fruit-bearing trees in positions that are supposed to exclusively belong to the ornamental department. This may be a very good arrangement in large gardens where ample scope is allowed. But why amateur gardeners with a limited area at command should devote two-thirds of that space to purely ornamental subjects while they have scarcely enough vegetables, and little or no fruit, passes comprehension, except on the plea "that it is the fashion." In this case, however, the owner has reason to congratulate himself on being an exception to the rule; consequently, his fruit room is every year abundantly supplied, as, owing to the trees being sheltered, I have seen good crops of Apples when trees more exposed were bare. The kitchen garden, which is well sheltered on the north and east by lofty trees, is enclosed by a good high wall on the north, and by a low one on the south, and thus a good south aspect is secured for Apricots, Plums, Figs, &c. Figs are especially prolific, and require no protection in winter, owing to their proximity to the coast. The north walls are devoted to Gooseberries and Currants—a useful and certain crop on such aspects. One walk, 10 ft. from the wall all round, leaves a good border for the roots of wall trees, and for early crops of vegetables and salads. Two narrow central walks in the form of a cross divide the main portion into four equal compartments. Pyramid fruit trees, closely spurred in, are planted at the corners, and espaliers by the sides of the walks. Good beds of Strawberries, Asparagus, and the more permanent crops occupy a quarter by themselves for a term of

years consistent with a proper rotation of crops, by which means the whole is kept in the highest state of productiveness. Rough, strong-growing vegetables are grown in the paddock that was formerly devoted exclusively to the production of Grass for hay, but during the last few years better results are obtained by breaking up a portion, cropping it for a few years, and then relaying it with Grass seeds. Some may contend that this is not an ordinary villa garden; but what is done in one case may be done in another. The owner does all the sowing, gathering, pruning, and training himself, merely employing a day labourer occasionally for digging or other laborious work.

J. GROOM.

## THE INDOOR GARDEN.

### MASSANGEA HIEROGLYPHICA.

A FINE specimen of this plant, according to the "Revue Horticole," has lately been imported from Brazil to the Jardin d'Acclimatation, at Neuilly, under the name of *Tillandsia musaica*. It is well worth attention on account of its incomparable beauty and gracefulness. It measures about 6 ft. 7 in. in diameter, and 3 ft. 3 in. in height. Its habit and general aspect resemble those of a strong *Tillandsia musaica*, but it is

*Massangea hieroglyphica.*

larger, lighter, and more graceful. The stem is thick and has a swollen appearance, caused by the sheathed base of the leaves. The latter are bright green in colour, marked, as will be seen by the annexed woodcut, transversely with irregular zones (thicker on the inside than on the outside) of violet-black. The extremities of the leaves become slightly narrower and suddenly round, the ends turning under. The marks towards the points become more and more irregular, and have the appearance of Hebrew characters or hieroglyphics, hence the specific name *hieroglyphica*.

### EPACRISES AND THEIR TREATMENT.

THESE indispensable plants for greenhouse decoration have a strong objection to artificial heat during certain stages of their growth, while at others it is highly beneficial and even necessary. Although the flowers do not fall off, like those of Camellias, forcing causes them to come small and puny and without their proper colour, and not only this, but it endangers the health of the plants; and yet, strange and paradoxical as it may appear, at certain times, as just remarked, a little warmth does good. This is after they are cut down and have begun to break again, and from thence onwards till they have made

plenty of young wood, after which, the cooler and more airy they are kept the better and finer will the individual blooms be. The minia type or section, however, will bear closer confinement than any of the others, and, from their more continuous blooming habit and generally graceful appearance, are of greater value than most of them, and are just the plants for those who wish to make a fine display. The treatment requisite for these differs somewhat from that required by the more upright-growing kinds, inasmuch as they should only be thinned out, and not pruned hard in after they have done flowering in the way that is customary with most cultivators who grow the other varieties. All the different sorts of *Epacris* delight in fibry peat, which should be chopped up moderately fine and have a portion of the earthy matter sifted out by using a small-meshed sieve, and as this will carry away any grit the peat may contain, the loss must be made good by adding a heavy sprinkling of sharp silver sand, and mixing the same well up before using. One of the most important things to attend to is to see that the pots are properly drained, as nothing is so inimical to the welfare of the plants as water-logged soil. A single crock over the hole, placed so as to fit and prevent the ingress of worms, is a good practice, and over this about 1 in. in depth of others broken about the size of a nut. If on these a little *Sphagnum* or common Moss be scattered, it will keep the interstices clear by preventing the finer portions of the peat from running amongst them, which it is otherwise sure to do, and thus impede not only the percolation of the water, but also interfere with a free circulation of air through the soil, by which alone roots can be kept in health. These being of a hair-like nature, the potting should be done firmly by ramming the peat well down with a blunt stick made for the purpose. The great mistake many make when shifting *Epacris* and other hard-wooded plants is in filling the pots too full, by doing which sufficient room is not left to hold enough water to thoroughly moisten the ball through; and this is a frequent cause of plants dying or getting stunted in their growth when, to all appearance, the soil is quite wet enough, if judged by that on the top. Even with the smallest pots, the space left should not be much less than 1 in., and for others of larger size nearly double that is necessary; and, with this much allowed, it is advisable, when watering has to be done, to go over the plants twice, so as to ensure a thorough soaking, for in this way alone can *Epacris* be kept in perfect health.

S. D.

### DOUBLE AZALEAS FOR CUT FLOWERS, &c.

As a rule, double or semi-double flowers last longer in a fresh condition, either when the flowers are left on the plant or when cut, than do single flowers of the same species. This is very strikingly exemplified in *Azaleas*; and though it cannot, perhaps, be said that double *Azaleas* are more beautiful or generally effective than single ones, neither can it be said that they are less so. The doubles very far surpass the singles in the length of time they remain in bloom, as well as for their endurance when cut for bouquets and vases. On this account the culture of a fair proportion of them is very desirable both as decorative plants and for affording sprays of bloom for mixing with other flowers in vases, and for wiring in single blooms for bouquets. Indeed, very few plants excel them for these purposes, especially when it is considered that their flowering period can be extended from October to June, and that the colour of their flowers ranges from the purest white to nearly crimson. The whites are especially useful for bouquets, from the fact that some of them, such as *Maria Waterougl*, are small.

To all who have a supply of flowering plants and cut flowers to keep up in the autumn and winter months as well as early spring, double *Azaleas* are most useful. The length of time they remain in bloom is remarkable. On the 3rd of April we had a plant of the semi-double and charming *Souvenir de Prince Albert* in bloom that has outlasted several sets of single varieties growing in the same house. The same may be said of the following selection, which can be strongly recommended for the qualities and purposes we have referred to:—

**BORSIC.**—Pure white, medium size; can be had in bloom by the end of October.

**CHARLES LEIRENS.**—Very dark salmon, with crimson blotch on upper petals; blooms in October.

**FLAG OF TRUCE.**—Splendid large pure white, vigorous habit; excellent for February and March.

**IBERICATA.**—As double as a Balsam—said to be the finest of its class. We can only speak of a small plant that bloomed in February; appeared not so pure a white as it has been described.

**MARIA WATERBOUGH.**—Pure white, flowers small and neat, and valuable for bouquets; can be flowered in winter.

**NARCISSIFLORA.**—White, and the earliest of all the double varieties; can be bloomed easily in October.

**SOUVENIR DE PRINCE ALBERT.**—In every respect a charming variety, and can be flowered in winter; a beautiful rosy-peace, broadly margined with white; lasts a very long time in bloom.

These eight varieties are well worthy of special culture for winter and early spring decoration; and, for cutting at a season when white flowers are scarce, the whites are invaluable.

At no other season are Azaleas more enjoyable than in winter and early spring, when they last longer in bloom than later in the season. By growing a few of President Van der Hecke, a single variety, and Narcissiflora, to come into bloom early in October, there is no great difficulty in prolonging the Azalea season to eight months of the year. Of course, for this purpose it requires that a growth should be forced on different sets of plants in succession, so as to be easily got into bloom at their respective seasons. D. T., in "Gardener."

**Camellias in Winter.**—With Camellias and their culture all are familiar, but, valuable as they are for blooming during the winter and easily as they may be grown, many fail in producing them at that season through want of knowing how to grow and prepare them to come in a month or two earlier than they will do under ordinary treatment. The practice with many is a few weeks before the flowers are wanted to place the plants in heat with a view to force them, when after a short time, to their amazement, off come the buds, or if by chance they should remain on, the blooms when they come are never anything like the size or substance they would be if the plants were kept in an unheated structure. The only way Camellias can be forced successfully and get into flower early is by inducing them to make their growth early, which may be done by subjecting them to a moderately warm temperature, where they can be screened from the sun's rays, and afforded plenty of atmospheric moisture by giving them copious syringings, and keeping the floors and other available surfaces well damped. Managed in this way, they make vigorous young shoots and set their buds long before they otherwise would, and these keep on gradually increasing in size till they expand before the end of the year. When once they are got into this early blooming habit, it is an easy matter to keep it up, as it is also to bring them to it; but to do this, no time must be lost in getting them into gentle heat after the flowers have fallen. Another frequent cause of bud-dropping is through allowing the plants to become dry at the roots; and any sudden change in this way, as well as undue excitement, Camellias are very impatient of, but if attended to properly with water and kept cool during the autumn and early winter without any attempt at forcing, there is nothing more easy to grow.—S. D.

### MAY FROST IN NEW JERSEY.

WHEN in England I expected to experience frost as a matter of course from May 1 to 21, and to see fruit crops destroyed from that cause; but for the first six or seven years after coming here I considered myself safe from frost after the first week in May. We frequently had quite severe frost at intervals during April, and it was seldom out of the ground till after the middle of that month, a circumstance which prevented vegetation from making much progress before the middle of May, and then trees previously bare would be in full leaf in a few days; but during the last two years matters have altered. Last season we had cold nights and frequent frosts until the end of May, and this year, after an unusually mild winter and very hot April and beginning of May, we are now (May 16) having frost every night. In April there were only two nights on which the thermometer fell below freezing, and then not more than 3°. On the morning of May 14 everything outside was covered with white frost from eleven on the previous evening until 6 a.m.; and as the thermometer had ranged each day during the previous week from 75° to 85° for several hours in the daytime, and from 50° to 60° at night, vegetation had progressed at a tropical speed. Shoots, therefore, from 1 ft. to 1 ft. long are killed back to the old wood, not one green leaf remaining. *Deutzia gracilis* and *Spiræa japonica*, just opening their flowers, are in the same condition. Weigelas and wild Ferns look as if a fire had passed over them. Strawberries, which had just commenced to ripen in this district, are all frozen through. Asparagus is killed to the ground, and any of the tender vegetables which the long term of hot weather had

tempted people to plant were completely destroyed. The few newspaper accounts as yet published report the total loss of the fruit crop, which was previously promising. If the frost was general the damage must amount to many millions of dollars. JAS. TAPLIN.  
South Amboy.

### VEGETATION ROUND CONSTANTINOPLE.

A LONG drive through the suburbs of Pera and over the bare, undulating downs separating the Golden Horn and Bosphorus, brought me, on the afternoon of my arrival, to the Sweet Waters of Europe, a pleasant valley at the head of the Golden Horn, with long reaches of quiet waters and pretty groves of trees, interspersed with a few handsome buildings, including one of the Sultan's numerous palaces, and environed by steep bare hills on all sides. Lencocium æstivum formed large tufts in the bottom of the valley, and the hill slopes were covered with *Poterium spinosum*, one or two species of *Erica*, and several *Ornithogalum* and other bulbous plants. On the evening of the following day I availed myself of an invitation from my friend Mr. Millengen, of the Imperial Ottoman Bank, to visit Buyukderé, or the Bosphorus. The Judas Tree (*Cercis Siliquastrum*) was in full spring glory, its brilliant rosy-crimson flowers contrasting with the dull masses of Cypresses rising out of the almost continuous bordering of white marble palaces, barracks, and villages which line the Bosphorus on both shores. The hills between Buyukderé and the Black Sea, attaining a height of 500 ft. or 600 ft., are, for the most part, covered with scrub of *Erica arborea*, *Cisti*, *Arbutus Andrachne*, and several small evergreen and deciduous Oaks, with occasional patches of taller trees, including the Velonia Oak, Chestnut, Beech, Horse Chestnut, Plane, Poplars, Elm, and Stone Pine; but there is no extent of wood till the Belgrad Forest is reached, a few miles inland on the European side. *Crocus pulchellus* is most abundant amongst the underwood, varying occasionally with white flowers; and Mr. Millengen informs me that a variety with double flowers is sometimes met with. The shady dingles running down to the Bosphorus abound with herbaceous and bulbous plants, including *Lilium martagon*, which here occurs within 100 ft. of the sea-level. *Fritillaria pontica*, several *Ornithogalum*, a *Geranium*, *Epidemium pubigerum*, *Hellebore orientalis*, *Hypericum calycinum*, *Colchicum byzantinum*, and several species of *Muscari* and *Bellevalias* also occur about Buyukderé.

On the slopes and summit of Chamlijah I found a second annulate *Crocus* out of flower, with narrow leaves, probably *C. biflorus*. This was accompanied by *Colchicum variegatum* and a very small *Iris*, with the habit of *Iris pumila*, but with much narrower leaves; also many leguminous plants, one or two *Ericas*, *Poterium spinosum*, *Muscari*, *Ornithogalum*, and other bulbous plants. The public garden of Pera is of very limited extent and poor in arrangement and detail, but the standard Roses were exceptionally fine. Small *Platanus* trees planted in winding avenues are extensively used, and yellow *Banksian* Rose intermixed with *Wistaria* had a remarkably good effect. *Ligustrum japonicum* is planted in masses bordered with *Yuccas*. The *Loquat*, *Wellingtonia gigantea*, and *Cedrus Deodara* also thrive, but the attempt at flower gardening everywhere is poor in the extreme.—G. MAW, in "Transactions of the Bot. Soc. of Edinburgh."

### THE SMYRNA SEEDLESS GRAPE.

IN Mr. G. Maw's interesting note on the "Vegetation of Smyrna and Ephesus," read before the Botanical Society of Edinburgh, and quoted in THE GARDEN of June 1 (p. 525), he gives a strange mixture of "z" and "f" for the Turkish name of the Smyrna Seedless Grape. Mr. Maw has evidently been misled by some Greek friend, who, like most of his race, is incapable of pronouncing Turkish words, and, in addition, maltreated by the printers of the Edinburgh "Transactions." The proper Turkish name is *Chekirtekis üzüm*, *chekirtek* meaning pip, *siz* less, and *üzüm* Grape, literally the pip-less Grape. It is also called *Soultaneh üzüm*, literally the Sultan's Grape, being so luscious as to be thought worthy of gratifying the palate of the Commander of the Faithful. Our corruption of *Soultaneh* into *Sultana* is doubly incorrect, the word *Soultan* being applied equally to males and females. Can any of our Grape-growing readers tell me if the cultivation of this most delicious Grape has ever been attempted in England? It would well repay a trial, for the best Boujah qualities when eaten fresh can hardly be surpassed for lusciousness and delicacy of flavour. Should any one like to try the experiment, I should be most happy to put them in the way of obtaining plants. C. W. QUIN.

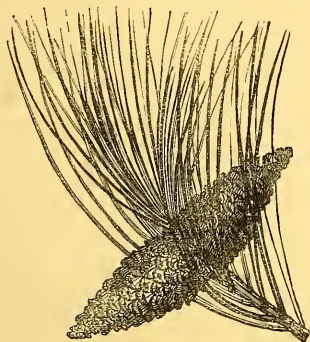

Imported Cherries.—Hundreds of baskets of these have lately been sold by auction in Covent G den. They came from Algiers, and realised from 4s. to 6s. per basket of 15 lb. or 20 lb.

## TREES AND SHRUBS.

## THE CORSICAN PINE.

(PINUS LARICIO.)

THIS Coniferous timber tree was first discovered in the island of Corsica, where it grows abundantly on the summits of the highest mountains, forming large woods and forests. It is also indigenous to the uplands of Spain and other countries bordering on the Mediterranean. It is said to be a lofty tree, attaining a height of from 120 ft. to 140 ft. This valuable Conifer was introduced into England about 1759; it cannot therefore be called a modern introduction, but, so far as I am aware, it has not been planted extensively until comparatively lately, as there are but few large specimens of it to be found in this country. It is now, however, well known amongst experienced planters as the best of all the Conifers for planting as a forest tree in poor soils and on exposed sites, and it even thrives well on the seacoast. It forms the best substitute for the Larch where the latter does not succeed well; we have examples of it here growing on an exposed plain in a thin poor sandy soil where the Larch has in many cases failed. Thus situated, *Pinus Laricio* is shooting up and growing at a rapid pace, quite over-topping the Scotch Fir, Austrian Pine, and other Conifers with which it is associated. It seems to shape itself at once, even in a young state, into a timber tree by forming a round, straight, clean stem; the branches, too, are not only few in number, but are small and

Cone and young shoot of *Pinus Laricio*.

less woody than those of any other Conifer, except the Larch. In habit it is quite distinct; its branches grow in regular whorls horizontally from the stem, and the terminal shoots turn upwards. In all stages of growth this Conifer presents a thin and bare appearance with little to recommend it as an ornamental tree; but, on the other hand, for planting extensively on sites and in soils not suited for the healthy growth of profitable hardwoods or the Larch, it is the tree above all others to introduce with a view to a profitable outlay. Its timber will most probably prove to be of about the same value as that of the Scotch Fir, and possibly, like the latter, vary in quality according to soil and situation. It is a more rapid grower, and does not take up so much room as the Scotch Fir; hence, a greater number of trees may be grown on a given space, and, consequently, I may safely assert that it will yield a more profitable return as a timber tree. During the last ten or fifteen years the good qualities of *Pinus Laricio* have become better known by landed proprietors and foresters than hitherto, and it has been planted out in great numbers; indeed, during the last few years nurserymen have hardly been able to keep up a stock of it equal to the demand. The consequence is that it is difficult to procure, at a moderate price, good-sized plants of it well rooted and fit to plant out. Possibly another reason why it keeps scarce in the trade is it being a difficult tree to transplant, and unless great care and attention be given to it when moved in the nursery lines large quantities of it often die. It should be

moved in the nursery every year in order to check its rapid top growth and to induce the formation of fibrous roots. The system which I adopt here is to buy from 5000 to 10,000 two-year bedded seedlings every year, and to grow them on in our nursery in a light kindly soil until they are from 2½ ft. to 3 ft. high. They are shifted in the nursery lines every year until they are finally planted out in the woods. By following this plan I have always a good stock with excellent roots and moderate top-growth, and the result is but few deaths. There is this advantage, too: they are lifted one day and carefully "heeled" in and planted out the next; their roots are not allowed to be exposed long enough to the air to become dry. From much experience with *Pinus Laricio*, I have found it quite necessary, in order to ensure success, to use these precautionary measures, or I am quite sure disappointment and loss would be the result. We have planted out many thousands during the last six or eight years with the greatest success; they are mostly planted in large masses on exposed situations, and where the soil is not deemed good enough for the profitable growth of hardwoods. In such positions this Pine flourishes, and I have no doubt that it will prove successful in a pecuniary point of view. I should not omit to mention that *Pinus Laricio* is practically a hare-and-rabbit-proof plant; at least I have found it to be the tree of all others least relished by ground game. Of course I cannot say that I have never known it to be injured by these troublesome and mischievous depredators, for what Coniferous tree will they not nibble and bark when their natural food is covered up by snow for several days? Nevertheless, the fact remains the same, that, under ordinary circumstances, it is better calculated to resist the attacks of hares and rabbits than any other Coniferous tree with which I have had experience in planting amongst game coverts. GEORGE BERRY.

Longleaf.

## TWO NEW JAPAN QUINCES.

THIS species of shrub possesses many qualities which well fit it for frequent use in lawn planting. We have known it so long and become so accustomed to its presence everywhere that we hardly realise the superior advantages it undoubtedly offers for every purpose required of a flowering shrub. Hardy, compact, and vigorous of growth, its bright glossy leaves and numerous richly-coloured flowers, clinging closely to the stem, would certainly call forth rapturous expressions of delight were they presented as a new introduction from foreign countries. As it is, every one enjoys the early beauty of the glowing flowers formed before the leaves are developed, and no group of deciduous shrubs that pretends to offer a series of blooms extending throughout the spring and summer can dispense with its rich colours. The Japan Quince is a large-growing shrub, and hence should occupy positions in the centre or rear of the mass, unless some prominent point of a peculiar character requires a larger growth than is ordinarily used. It should be set out early, although, on the whole, it is quite easy to transplant. Years ago it was considered somewhat difficult to propagate, but now it is grown readily from root cuttings. As already intimated, the foliage constitutes one of its great charms, and a thorny habit has caused its successful employment for ornamental and impassable hedges. To sum up its advantages, it has nearly everything necessary to the character of a perfect hardy deciduous flowering shrub. Although the general appearance of the foliage of the Japan Quince in its many varieties is much the same, the colour, size, and shape of its blossoms form a very distinctive peculiarity. Distinguished chiefly by the appearance of the flowers, there are at least a dozen varieties common in nurseries. Their colours range all the way from scarlet or crimson to white, with some varieties striped in a very attractive manner. The red and white are, of course, most popular because most distinct. Almost the only accusation that can be justly made against the Japan Quince is that it grows too large for some positions. My object, however, in calling attention to the Japan Quince is not only to offer a brief tribute to its many choice qualities, but to describe two distinct varieties that are really very fine and quite unknown to the lawns of America. They come from Mr. Thomas Hogg, as do so many other good plants, and have now attained a size which very fairly indicates their nature at maturity. The first is a strong-growing kind, with leaves of a more oval form than usual and very large flowers of white, touched on the upper edge with rose colour. The flowers are well formed and clustered in the usual way about the stem. Their size is very striking, and the habit of the entire shrub decidedly attractive. It will undoubtedly be found a great improvement and addition to the present list of Japan Quince varieties.

The other variety of *Pyrus japonica* is still more remarkable than the last. I have already noticed that for some positions the heretofore known varieties of Japan Quince were too large. Nature has apparently become cognizant of the fact, and therefore has sent us from Japan this little gem of the species. Dwarf enough to occupy any position near the house where small plants would be used, it has, in addition, literally masses of pretty salmon-coloured flowers and a most lovely variegation of the leaves in red, white, and green. The flowers rest like a rich crown on this compact little plant. It may be readily seen how charmingly adapted such a plant would be to a group of low choice shrubs near the house, a place from which the common Japan Quince is perforce excluded. The great value of the introduction of such new deciduous shrubs lies in the increased beauty and variety of foliage and flower afforded at a particular season by groups arranged for continuous blooming. It is not easy to speak too strongly of the importance of deciduous shrubs on a lawn, and, in order to increase the list of materials to be combined by the landscape gardener, it affords a pleasure to present two new Japan Quinces for consideration.—"Rural New Yorker."

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Crimson-leaved Japanese Maple** (*Acer polymorphum atropurpureum*).—There is in the grounds here a plant of this Maple 8 ft. in height, and as much through the branches, which reach almost to the ground. It is now densely yet elegantly clad with its pretty palmate leaves of a bright, almost dazzling, crimson. It is a living wonder amongst the various green tints surrounding it. Seen near or far from it, it is the one object that arrests the eye. Compared with it, the purple Beech is sombre. As the growth matures the colour of the leaves becomes subdued, until about the end of June a second growth of fiery foliage is added to the first. The Japanese Maples are generally considered to be tender, and better adapted for conservatory decoration than for out-door planting in Britain. This may be true of some varieties, but surely not of this one. The plant I have mentioned has been out-of-doors for four years, and although it had commenced to grow this spring at the time of the late severe frosts, which blasted so many of the early fruit tree blossoms throughout the country, the only effect which they had on this Maple was to discolour the leaves a little; but it soon recovered, and is now the glory of the nursery.—Geo. SYME.

**Purple-leaved Peach** (*Amygdalus persica foliis purpureis*).—This, though less effective than the crimson-leaved Japanese Maple, is also very ornamental. The young leaves are reddish-crimson, deepening with age to a coppery-brown, with somewhat of a metallic lustre on the upper surface. It is of free growth, but, like ordinary Peaches when grown in the form of bushes out-of-doors in Britain, it shoots do not get fully matured; therefore it is necessary to prune the young wood rather severely, by which, however, the colour of the leaves the following season is heightened. It is very effective in a mixed shrubbery.—Geo. SYME, *Elvaston Nurseries, Borrowash*.

**Catalpa Wood**.—The wonderful durability of the wood of the American Catalpa has long been known; but Mr. E. E. Barney, of Dayton, Ohio, has done an excellent work in collecting together several letters written by him at different times to the "Railway Age" in regard to the economical value, especially with reference to the employment which can be made of it, for railway sleepers. To these letters are added satisfactory evidence of the astonishing durability of the wood of this tree, its adaptability to many useful purposes, besides some excellent suggestions as to the best methods for cultivating it. The whole forms a neatly-printed pamphlet of twenty-six pages, under the title of "Facts and Information in relation to the Catalpa Tree (*Catalpa bignonioides*)," which can be procured from the author. Mr. Barney calls attention to the fact, which has heretofore escaped our notice, that in some of our Western States a variety of the Catalpa is found in cultivation with very large white blossoms, appearing two weeks earlier and much more abundantly than in the common form. Experiments, too, show that this early blooming variety is of more upright, rapid growth and considerably hardier, and so more valuable for forest planting; a fact well worth bearing in mind. To all with whom the question of a supply of fence posts is getting to be a serious one, and especially to the managers and owners of railroads, Mr. Barney's pamphlet will be found useful and instructive reading.—"Gardeners' Monthly."

**Acer platanoides Schwedleri**.—This hardy, free-growing, purple-leaved Maple should not be lost sight of by planters. It is a real acquisition, as far as effective contrast is concerned, amongst trees of light green foliage. The leaves of this beautiful Maple are bright reddish-purple when newly unfurled, very brilliant and glossy, and as large as those of the common *platanoides*, or Norway Maple.—G. B.

#### PLATE CXXXII.

#### MAGNOLIA HALLEANA.

Drawn by Miss DUFFIELD.

With reference to this valuable addition to our hardy flowering trees, Mr. S. B. Parsons, of Flushing, U.S., obliges us with the following note:—"Regarding this Magnolia, some time prior to 1862 I had been much interested as to the best mode of getting access to the flora of Japan. I knew no one who possessed the tact and perseverance requisite at that time for such an undertaking, and for want of such an one my enterprise languished. In the darkest hour, however, the man appeared. One day in 1862 there walked into my office a gentleman with a frank and pleasant manner, who introduced himself as Dr. G. R. Hall, of Japan, who had for some years been making collections of plants in that country, and who had with him in Wardian Cases the whole collection. He desired to know whether we would take, propagate, and distribute them. We consented at once, and the cases came. Did you ever see a connoisseur unpack a fine painting or litterateur open a case of books? Or can you dream how Schliemann felt when he unearthed the treasures of Priam's palace? You can thus fancy the enthusiasm of our *employés* when these cases were opened. I cannot tell you at this date what plants made their appearance, but I recollect the Japan Maples, the Yeddo Grape, *Thuopsis dolabrata*, *Deutzia crenata* flore-pleno, and a few bulbs of *Lilium auratum*, which we sold to a firm in Europe for 80 dollars each. From the seed then sent we grew *Sciadopitys*, *Abies polita* and *Alcocquiana*, *Hydrangea paniculata*, *Planera Kaki*, and others. From the seed of *Retinospora obtusa* we grew many thousands. Among the plants were two Magnolias, one of which we named Halleana, after Dr. Hall, and the other Thurberi, after Dr. Thurber. The former proved a gem, but for various reasons our propagation of it was small until 1869, when its merits, clearly displayed in large plants, induced us to extend its cultivation by all the means in our power. A large number near our office are now in bloom while I write, and their general effect is like a mass of Water Lilies. The plant is dwarf, and will probably not attain a greater height than 6 ft. or 7 ft. Its flowers appear much earlier than those of *M. conspicua* or *M. Soulangeana*, and when fully opened will often measure 4 in. in diameter. The individual petals are  $\frac{3}{4}$  in. wide, and  $1\frac{1}{2}$  in. to 2 in. long. When fully expanded they do not lie close together, and the sunlight between them gives to the whole flower a very unique appearance. It has a delicate fragrance, and is in all respects very charming. When well known it cannot fail to be a general favourite."

The drawing for our plate was made from a specimen that flowered in Messrs. Veitch's nursery at Coombe Wood.

**Hardy Geraniums in Flower**.—In the Kew collection some good specimens of the finest kinds of this handsome genus may now be seen in flower. The lovely *G. arvense* is flowering very freely; its blossoms are of a bright magenta with a jet black centre, from which radiate delicate black lines to the margin. One detractive point is, that its flowers are very fugitive, but this is in some measure compensated by the profusion in which they are produced. It is still but little known, although it was described and figured in THE GARDEN last year (Plate 77, p. 478), and various other notes in reference to it have appeared from time to time. Amongst the indigenous kinds are some which are very ornamental, the best being the dwarf magenta-coloured *G. sanguineum* and its beautiful Lancashire variety with rose-coloured blossoms finely pencilled with dark lines; *G. pratense*, a tall-growing kind, with large purple flowers, and its pure white variety, are very desirable. There is also an intermediate form with white and purple flowers. The Caucasian species, *G. gymnocaulon* and *ibericum*, with rich purple blossoms 2 in. across, delicately pencilled with black, are strikingly beautiful. *G. eriostemon*, much resembling the preceding, and *G. Wassouianum*, with pink flowers, are the best of the Siberian kinds. The most desirable of the South European sorts are *G. sabaucalense*, from the mountains of Greece, a lovely dwarf plant not more than 1 ft. high, with finely streaked pink flowers. It is admirably adapted for the rock garden on account of its compact habit. *G. Endressii*, a tall-growing kind with rose-coloured blossoms, is also very attractive. All the above are perfectly hardy, easily cultivated, and should be in every collection of hardy flowers.—A.

## GARDEN DESTROYERS.

## ELM TREE BEETLES.

(OTIORHYNCHUS NOTATUS.)

IN THE GARDEN for May 25 (see p. 503) is an excellent article by Mr. Fred H. Pearson, of the Chilwell Nurseries, on the depredatory habits of a species of Otiorhynchus which he calls *O. notatus*, but which, by his own inadvertent showing, is probably *O. notatus*. He says, "to find it on the soil is nearly like 'looking for a needle in a bush of hay,' as its colour so much resembles the soil." The foregoing fits *O. notatus*, but not *O. silvaticus*. Before me is a letter, dated April 29, 1876, from the late Mr. A. Murray, thanking me for what he was pleased to call "original notes," which I had previously sent him on the habits of a beetle, to which, from specimens that I had admitted to him, he gave the name of *O. notatus*. In the letter which I sent to him I remember saying that I knew more of its natural history and habits than was good for me, and that my great object in writing to him then was to get the name of the beetle, that I might the better deal with it, for if there lives a beetle more deserving of destruction I should like to know, at least, its name. The *O. notatus*, according to the same author, is black and at least three times the size of *O. notatus*, being quite  $\frac{1}{2}$  in long. Like *O. notatus*, it is a general feeder, but by no means so common, at least, in this district. Unfortunately, what I know of the habits of *O. notatus* enables me to endorse all that Mr. Pearson has timeously said about it, and I am also prepared to prove that of all the secret enemies of the out-door propagator this is the king. Here we annually graft a large quantity of the different varieties of Elms and other hard-wooded ornamental trees. Of these a certain percentage die, and the death rate I have found is mainly traceable to the pernicious habits of this insect. In the dusk of the evening it sallies from its hiding-place, beneath the surface of the ground near the root of the tree, and travels to the top of the stock, where it may be seen gouging out the buds of the scion, and eating the bark off in irregular flakes and patches until there is not a chance left for the scion to live. With this in view, and the widespread distribution of the species, I have sometimes thought that it would be well if nurserymen were not too hasty in condemning their propagators from want of success in grafting such subjects as I have mentioned. This beetle is too common an enemy, but, being somewhat secret as regards its operations, it is not generally known. Mr. Pearson has given us his *modus operandi* of collecting the beetles, but as our plan differs slightly from his, it may bear well to give it. Two men are each provided with a light board about 2 ft. long by 1 ft. wide, on one edge of which is cut a half-moon-shaped notch sufficiently large that when the two boards are brought together they will clamp the stem of an ordinary sized nursery plant. A third party, a lad, carries a lantern and a tin bucket. All three quietly approach the plant, the men with the boards from different directions, and when the boards are met together they gently tap the plant two or three times, and the "bugs" as they fall are caught on the boards and conveyed to the bucket. By this means we have sometimes got as many as fifty from one plant.

GEO. SYMIE.

*Testacella halotidea*.—This is most likely to be the name of the slug which "W. J. T.," Brixton, mentions (see p. 504) as having been found in his garden looking like a slug with a horny substance like a shell; this is a true shell. The wearer of it belongs to the extensive family Helicoides, and differs from all others of our British land Molluscs in being entirely carnivorous, its food consisting of earth worms, which during the greater portion of the year, I am inclined to think, they hunt underground, but late in spring I have seen them seize their prey above, as also more rarely in the autumn. They have been accused of devouring slugs (*Limax agrestis*), and even of cannibalism, from the fact of the shell of small individuals having occasionally been found in their intestines. Owing to the peculiar construction of their dental and digestive organs, it is impossible they can devour any vegetable substance; they may therefore be looked upon as a true gardener's friend. There are too species of *Testacella* found in this country. The one just named which is indigenous, and is also certainly found in some parts of Germany; in fact, Albers gives the west of Europe. The other species, *Testacella Maugei*, is said to be a native of Portugal and Teneriffe, and supposed to have been imported somewhere about the early part of the present century, and, I believe, first discovered by Mr. Miller of the eminent firm of nurserymen, Miller & Sweet, Durdham Down, Bristol; and I remember one of the firm showing it to my father and myself (a child) nearly sixty years ago. A good account of these interesting creatures is to be found in Jeffrey's "British Conchology," vol. i. pp. 140—148.—JOHN E. DANIEL, 6, *The Terrace, Epsom*.

—The slug with a small shell on its tail is, I presume, *Testacella*

*Maugei*. In 1843, the late Prof. Lindley offered one guinea for 100 of them, and I had the good fortune to obtain it. At that time it was considered to be of use in gardens. I have frequently seen it with half a worm protruding from its mouth, the other part being in course of digestion.—JAS. WEGLEY, *Henbury, Bristol*.

## THE FRUIT GARDEN.

## NEW DISEASE IN YOUNG VINES.

NEXT to the Phylloxera, I am not aware that the Vine is subject to the attacks of any other pest or disease of so irremediable a character as the one which is about to form the subject of my remarks. I have not any specific name for the disease, so that the best that I can do is to lay before your readers the symptoms by which it will be easily discovered. Until recently, I attributed it to a sort of fungus, but I am now convinced that there is a very minute insect at work, a white spider, much smaller than our common enemy the red spider. It requires the assistance of a powerful lens and a keen eye to be able to discover it, for, unlike red spider, it is not easily seen by the naked eye. Whether the fungoid appearances on the leaf of the young Vines owe their origin to the presence of this insect, or whether the insect is the natural companion of a fungoid disease, I am not at present in a position to state. Is it possible that the Vine, constitutionally speaking, is becoming less hardy, or is the disease the result of atmospheric conditions, or some other local cause? In its first stages the disease somewhat resembles what is commonly known as warts on the back of the leaf, which is purely the result of a saturated atmosphere and a low temperature. The leaf becomes narrower and pointed at the extremity of the lobe, gradually assumes a black, contracted appearance, and eventually becomes covered with a fungoid-like excrescence, which seems to arrest further expansion; indeed, the Vine is practically at a standstill so far as leaf development is concerned. I have seldom, if ever, seen the disease attack old Vines or young ones that are planted out and growing with vigour. It seems to make the greatest havoc with young Vines of the current year's growth. The reason of this I think is obvious. The young Vine is raised from an eye, which produces a shoot with from three to four leaves, the result of sap already stored up in the bud. After this is used up roots begin to form slowly, and the Vine rapidly extends itself, say from 2 ft. to 3 ft. in length. When the disease appears at this stage it becomes most dangerous; the young Vines, unlike those that are established in borders, or that have already become well furnished with roots, are brought to a premature standstill immediately the leaves cease to act, and the insect thus becomes the conqueror. The point of the young Vine gets destroyed, every leaf vanishes, as if it were scorched or burnt with sulphur, and quantities of laterals take their place.

When I had but a very imperfect knowledge of the pest a few years ago I had a smart attack of it in a house of young Vines which were in a vigorous condition, and which had made canes from 6 ft. to 9 ft. long. The second year I got rid of it by pinching out the affected portions, taking care not to cut back into the hard wood; the lateral growth was removed, and the roots being in full action, the bud at the base soon pushed away, and the stopping of course only helped to thicken the young canes. From the success of this experiment I looked upon the disease as one of little moment until last year, when I decided (instead of growing pot Vines) to plant them out in pits on either side of a little span-roofed house. Several of the Vines were slightly attacked with the disease before they were planted out, but, trusting to previous success, I thought that the Vines when planted out in a rich border would soon grow out. We kept them in a steady temperature for a time, and hoped against hope, but all to no purpose, as the disease seemed to grow worse instead of better. I then pulled the Vines out of one side of the pit, and re-planted it with clean healthy young ones, but in a fortnight or so they looked nearly as bad as those that were taken out. Several other Vines badly effected were also pulled out, and their places were filled up with healthy stock, but the result of all our

efforts was, that all ingress as regards the house was stopped, and the Vines were left to take care of themselves. A crop of Melons in a house adjoining was also lost through the same cause, the communication between the two houses not being cut off in time to save the latter crop. More than one good cultivator said the best plan would be to destroy the Vines altogether, and a recurrence of the disease this season was predicted, but I am glad to say the reverse is just the case, for finer or healthier young Vines no one could wish to see. They were, of course, cut down to two or three buds at their base last winter, and have had every attention in the way of a steady temperature and careful ventilation.

The lesson, therefore, to be drawn from the case is this, that young Vines from eyes should, where possible, have a house exclusively to themselves, where their wants can be attended to as necessity indicates; secondly, that on the first appearance of the disease the affected Vines should be immediately destroyed; and, thirdly, that there is no use in attempting to "patch up" as long as a particle of the disease is left.

Our Vines from eyes this year are quite as badly affected as they were last, and will therefore only make "cut backs" for another season. The best remedy for keeping the pest in check next to destroying the Vines is to maintain a comparatively low dry atmosphere and to ventilate freely, but carefully avoiding all checks or extremes. I have heard cultivators say that the disease was caused by lack of vitality, inaction of the roots, &c., which is, in a sense, true, but the origin of the inaction begins with the leaf, and he who can propound a remedy for the utter annihilation of the insect will be doing good service.

W. HINDS.

—*Otterspool.*

#### WIRING GARDEN WALLS.

REFERRING to some recent objections to this practice, Mr. J. Sheppard, of Woolverstone, writes to the "Gardeners' Chronicle" as follows:—"As I have perhaps been foremost of late in advocating the wiring of walls for training fruit trees, and finding that doubts exist in the minds of some as to the desirability of doing this, I should like to have a little further say in the matter. I may remark at the outset that I have had many years' experience with the use of galvanised wire for the above-named purpose, both indoors and out, and I have never yet seen a single branch or shoot injuriously affected by coming in contact with it, unless where they have been tied too tightly, thus causing a pressure on the underside of the bark. Gross unripe wood is subject to causer under any circumstance, and it is generally this that suffers from being pinched, owing to the rapid rate at which it swells, and from having an insufficient amount of room in the ties. Some years ago I had a young vigorous tree on a painted wire trellis almost spoiled through tight tying, but since I have insisted that every shoot shall have room enough to grow to at least double its size, I have had no further trouble with gumming or causer. It is a well-known fact that Apricots are more liable to these maladies than any other trees; but, from close observation, I am convinced it is more the result of cold and sudden transition of temperature than anything else, and last season helped to confirm my opinion, as they were worse then than I ever remember. I can, however, just now point to some trained on a galvanised wire trellis on a south-east wall in the most perfect health that were so full of blossom as to be quite a sight, and on the whole of these I do not think a diseased branch could be found. Besides this stretch of Apricot wall we have nearly 300 ft. done in the same way for Peaches and Nectarines, and we intend to continue on as rapidly as possible till the whole is finished, so as to entirely do away with the nuisance of nails and shreds and their attendant evils. The least of these are red spider and earwigs, which are fostered and encouraged by the innumerable perforations made for them to lay their eggs and secrete themselves in, but if this were all it could be readily got over. Unfortunately, however, this is not the case, for the bricks and joints in course of time become so ruinously defaced as to be let in wet, which lowers the temperature considerably, and impairs the wall as a means of protection. Frost, too, acts rapidly on them when in that state, and soon brings about their ruin, so that there is every reason why wiring is so much to be preferred to nailing, but so tenaciously do some cling to old customs that it is hard to convince them. The mistake many make in wiring is in having it placed too far from the wall, thus allowing a draught to get behind the trees, which, acting on the tender blossoms and shoots, has a most injurious effect. I fell into the same error at starting, but since I have had it placed close to the bricks, the results have been as satisfactory as I could possibly wish.

The way we manage here is to drive in studs at about 8 in. or 9 in. apart so as to work the trellis into squares standing on end, as I find the training can be done much more expeditiously and neatly than is possible when the wires are simply strained horizontally. In this latter fashion it often becomes necessary to run a strand of matting across to secure the point of a branch or shoot. A trellis formed as above is much neater and better in every respect. Instead of tying, the young shoots may be quickly made secure in their places during the summer by the use of a few small twigs—such as the clippings of Privet edges or anything of that kind—which answer every purpose, and this is a great saving of time. Under the old system this would have to be done by nailing, and that at a busy season, so that here again the trellis has the advantage, as it has likewise in other respects. That tying may involve an equal amount of labour at the final winter training I am free to confess, but much depends on the activity of those engaged at the work, and the amount of practice they have had at it; for my part, I would much rather tie a tree than nail one, and I am sure this would be the choice of most others. Although wiring walls is an innovation here, it has been in use on the Continent for many years, and if it produced any unfavourable action on the bark of trees the mischief would not have escaped notice, but would have been reported long ago. That it has no injurious effect on any of ours is certain. I shall have great pleasure in showing them to any one interested who may favour me with a call. I am of opinion, therefore, that your correspondent, Mr. Hudson, will find the disease of which he complains lies in the roots, or that it is brought about by the particular kind being on an unhealthy stock, or growing in a wet, cold border; and if not this, possibly it is the effect of the sharp frost that occurred in May last, the shock from which was so great as to disorganise the whole system of such tender fruit as Peaches, and the wonder is that many of them ever recovered. Looking at them in the condition they were last June, one could not have expected to see them in the satisfactory state they now are; indeed, so great is the promise that, should the weather be anything like favourable, the fruit harvest will be an unusually abundant one. As wiring walls, although not costly, is a work that partakes of a permanent character, it will be well if those who have had a lengthened experience of it will say how they have found it to answer, as the subject is a most important one, seeing there must now be many walls in the country that are so damaged that they will scarce hold a nail. Such was the condition a large portion of ours was fast getting into, but with the joints neatly stopped with cement, and the fruits wired, they will now last sound for generations to come."

#### AMERICAN FRUITS.

THE "Proceedings of the American Pomological Society" have just reached us, and, as usual, they are well printed, well arranged, and full of valuable matter. Amongst other things they contain an interesting list of native and introduced species of fruits and nuts growing or cultivated in the open air in the United States and Canada, which we subjoin. Those marked with an asterisk (\*) are of native origin. To avoid unnecessary detail, the States lying between latitudes 42° and 49° are termed the Northern Division; between 35° and 42°, the Central Division; and between 28° and 35°, the Southern Division.

ACHRAS SAPOTA (Sapodilla Plum)—grown in Florida.

\*AMELANCHIER CANADENSIS (Service)—Nova Scotia, New Brunswick, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, Wisconsin, Pennsylvania, New Jersey, Delaware, Maryland, and D. C., Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Illinois, Iowa, and Missouri.

ANANASSA SATIVA (Pine-apple)—Florida.

ANONA CHERMOLIA (Cherimoyer)—Florida.

ANONA SQUAMOSA (Sweet-sop).

ANONA MURICATA (Soursop)—Florida.

\*ASMINA TRILOBATA (Papaw)—Pennsylvania, Virginia, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, Missouri, South Carolina, Georgia, Alabama, Florida, Indian Territory, Arkansas, Mississippi, and Louisiana.

BERBERIS VULGARIS (Barberry)—Massachusetts, Rhode Island, Connecticut, and New York.

CACTUS OPUNTIA (Indian Fig)—Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, Missouri, Nebraska, Kansas, Indian Territory, Arkansas, Mississippi, Texas, New Mexico, and Arizona.

CARICA PAPAYA (West Indian Papaw)—Florida.

\**CARYA ALBA* (Shell-bark Hickory)—Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, Wisconsin, throughout the Central Division, except Colorado; Utah, Nevada, California; also in South Carolina, Georgia, Alabama, Indian Territory, Arkansas, Mississippi, and Texas.

\**CARYA OLIVEFORMIS* (Pecan)—Indiana, Kentucky, Tennessee, Illinois, Missouri, Florida, Indian Territory, Arkansas, Mississippi, Louisiana, and Texas.

\**CARYA SULCATA* (Large Shell-bark)—Kentucky, Illinois, and Missouri.

\**CASTANEA VELOCA* (European Chestnut).

\**CASTANEA AMERICANA* (American Chestnut)—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, New Jersey, Delaware, Maryland and D. C., Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Tennessee, and Illinois.

\**CASTANEA PUMILA* (Chinquapin)—Pennsylvania, New Jersey, Delaware, Maryland and D. C., Virginia, North Carolina, South Carolina, Georgia, Alabama, and Florida.

*CITRUS AURANTIUM* (Orange)—California, Georgia, Alabama, Florida, Mississippi, Louisiana, and Texas.

*CITRUS LIMONUM* (Lemon)—Florida.

*CITRUS LIMETTA* (Lime)—Florida.

*CITRUS MEDICA* (Citron)—Florida.

*COCOS NUCIFERA* (Cocoa-nut)—Florida.

\**CORYLUS AMERICANA* (American Hazel)—Ontario, Indiana, Illinois, Missouri, Nebraska, and Kansas.

*CORYLUS AVELLANA* (Filbert).

\**CORYTHUS ROSTRATA* (Beaked Hazel-nut)—New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut.

*CYDONIA VULGARIS* (Quince)—Rhode Island, Connecticut, New York, Ontario, Pennsylvania, New Jersey, Maryland and D. C., Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, Missouri, and New Mexico.

*CYDONIA SINENSIS* (Chinese Quince)—South Carolina, Georgia, Alabama, Florida, Arkansas, Mississippi, Louisiana, and Texas.

\**DIOSPYROS VIRGINIANA* (Persimmon)—Pennsylvania, Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, Missouri, South Carolina, Georgia, Alabama, Indian Territory, Arkansas, Mississippi, Louisiana, and Texas.

*DIOSPYROS KAKI* (Japanese Persimmon)—South Carolina.

\**DIOSPYROS TEXANA* (Black Persimmon)—Texas.

\**FAGUS FERRUGINEA* (Beech)—Nova Scotia, New Brunswick, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, Wisconsin, Pennsylvania, New Jersey, Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, Missouri, South Carolina, Georgia, Alabama, and Indian Territory.

*FIGUS CARICA* (Fig)—South Carolina, Georgia, Alabama, Florida, Arkansas, Mississippi, Louisiana, and Texas.

\**FRAGARIA VESCA* (Alpine Strawberry)—Minnesota, Dakota, Montana, Wyoming, Idaho, Washington, and Oregon.

\**FRAGARIA VIRGINIANA* (American Strawberry)—throughout the Northern Division, except Montana, Wyoming, Idaho, Washington, and Oregon; throughout the Central Division, except Colorado, Utah, Nevada, and California; throughout the Southern Division, except Florida and Arizona.

\**FRAGARIA CHILSENSIS* (South American Strawberry)—Oregon and California.

\**GAYLUSSACIA RESINOSA* (Black Huckleberry)—California.

\**GAYLUSSACIA FRONDOSA* (Blus Dangleberry).

*GHIAS CALIFORNIA* (Anchovy Pear)—Florida.

\**JUGLANS CINEREA* (Butternut)—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, Pennsylvania, New Jersey, Maryland and D. C., Virginia, North Carolina, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, and Missouri.

\**JUGLANS NIGRA* (Black Walnut)—Rhode Island, Connecticut, Ontario, Michigan; throughout the Central Division, except Utah, Nevada, and California; not at all in the South.

*JUGLANS REGIA* (European Walnut)—Connecticut, Pennsylvania, and California.

*LAURUS PERSEA* (Avocado, or Alligator Pear)—Florida.

*MESPILUS GERMANICA* (Medlar).

\**MORUS RUBRA* (Red Mulberry)—Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, Wisconsin; throughout the Central Division, except Colorado, Utah, Nevada, and California; not at all in the South.

*MORUS NIGRA* (Black Mulberry).

*MORUS ALBA* (White Mulberry).

*MUSA PARADISIACA* (Plantain)—Florida.

*MUSA SAPIENTUM* (Banana)—Florida.

*OLEA EUROPEA* (Olive)—Florida.

*PHENIX DACTYLIFERA* (Date Palm)—Florida.

*PROTINIA JAPONICA* (Loquat)—Florida.

\**PODOPHYLLUM PELTATUM* (May Apple)—Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan; throughout the Central Division, except Colorado, Utah, Nevada, and California; not at all in the South.

*PRUNUS [AMYGDALUS] COMMUNIS* (Almond)—Nevada, California, and Arizona.

*PRUNUS [AMYGDALUS] PERSICA* (Peach)—Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, Oregon; throughout the Central Division, except Colorado; throughout the Southern Division.

*PRUNUS ARMENIACA* (Apricot)—Oregon; throughout the Central and Southern Divisions.

*PRUNUS DOMESTICA* (Garden Plum)—throughout the Northern Division, except Minnesota, Dakota, Montana, Wyoming, Idaho, and Washington; throughout the Central Division; not at all in the South.

\**PRUNUS MARITIMA* (Beach Plum).

\**PRUNUS AMERICANA* (Wild Red and Yellow Plum)—Michigan, Wisconsin, Minnesota, Dakota, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Illinois, Iowa, Missouri, Nebraska, and Kansas.

\**PRUNUS CHICASAW* (Chickasaw Plum).

*PRUNUS CERASUS* (Garden Red Cherry, Morello, &c.)—throughout the Northern Division, except Minnesota, Dakota, Montana, Wyoming, Idaho; throughout the Central Division; not at all in the South.

*PRUNUS AVIUM* (Bird Cherry, Heart, &c.)—Vermont, Massachusetts, Rhode Island, Connecticut, New York, Washington, Oregon; throughout the Central Division; not at all in the South.

\**PRUNUS PUMILA* (Dwarf Cherry)—Oregon.

*PSIDIUM PYRIFERUM* (Guava)—Florida.

*PUNICA GRANATUM* (Pomegranate)—throughout the Southern Division, except Indian Territory and Arizona.

*PRUNUS COMMUNIS* (Pear)—throughout the Northern Division, except Nova Scotia, New Brunswick, Montana, Wyoming, and Idaho; throughout the Central Division; throughout the Southern Division, except Florida and Arizona.

*PRUNUS MALUS* (Apple)—throughout the Northern and Central Divisions; not at all in the South.

*PRUNUS PRUNIFOLIA* (Siberian Crab)—throughout the Northern Division, except Montana, Wyoming, Idaho, Washington, and Oregon; throughout the Central Division; not at all in the South.

\**PRUNUS CORONARIA* (American Crab)—Michigan and Wisconsin.

\**PRUNUS RIVULARIS* (Oregon Crab)—Idaho, Washington, Oregon, and California.

*RIBES CROSSULARIA* (English Gooseberry)—Nova Scotia, New Brunswick, Washington, Oregon.

\**RIBES HIRTELLUM* (Houghton Gooseberry, &c.)—throughout the Northern Division, except Wyoming and Idaho; throughout the Central Division, except Utah, Nevada, and California; not at all in the South.

\**RIBES RUBRUM* (Red Currant)—Nova Scotia, New Brunswick, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, and Wisconsin; throughout the Central Division, except Nevada and California; not at all in the South.

\**RIBES NIGRUM* (Black Currant)—same as Red Currant.

\**RUBUS OCCIDENTALIS* (Black-cap Raspberry)—same as Red Currant.

*RUBUS IDREUS* (European Raspberry)—Nova Scotia, New Brunswick, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Ontario, Pennsylvania, and New Jersey.

\**RUBUS STRIGOSUS* (Wild Red Raspberry)—Nova Scotia, New Brunswick, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, and Ontario.

\**RUBUS VILLOSUS* (Blackberry)—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, Ontario, Michigan, and Wisconsin; throughout the Central Division, except Kansas, Colorado, Utah, Nevada, and California; throughout the Southern Division, except New Mexico and Arizona.

\**RUBUS CANADENSIS* (Dewberry)—Massachusetts, Rhode Island, Connecticut, and New York; throughout the Central Division, except Kansas, Colorado, Utah, Nevada, and California; not at all in the South.

\**SHEPHERDIA AROBENTEA* (Buffalo Berry)—Minnesota, Dakota, Montana, Wyoming, Idaho, and Washington.

*TAMARINDUS INDICA* (Tamarind)—Florida.

\**VACCINIUM PENNSYLVANICUM* (Dwarf Early Blueberry)—throughout the Northern Division, except Canada, Wyoming, Idaho, Washington, and Oregon.

\**VACCINIUM CANADENSE* (Canada Blueberry)—same as Dwarf Early Blueberry.

\**VACCINIUM CORYMBOSUM* (Swamp Blueberry)—same as Dwarf Early Blueberry, except Minnesota, Dakota, and Montana.

\**VACCINIUM TENELLUM* (Southern Blueberry) — Virginia, North Carolina, and South Carolina.

\**VACCINIUM MACROCARPA* (American Cranberry) — Connecticut, Michigan, Wisconsin, and New Jersey.

*VITIS VINIFERA* (European Grape) — Utah, Nevada, California, New Mexico, and Arizona.

\**VITIS LABRUSA* (Northern Fox Grape, Concord, &c.)—throughout the Northern Division, except Nova Scotia; throughout the Central Division; not at all in the South.

\**VITIS ÆSTIVALIS* (Summer Grape, Hebeumont, &c.)—throughout the Central Division; throughout the Southern Division, except South Carolina, New Mexico, and Arizona.

\**VITIS CORDIFOLIA* (Winter Grape, Clinton, &c.)—throughout the Northern and Central Divisions; Georgia, Alabama, Florida, Indian Territory, and Arkansas.

\**VITIS VULPINA* (Bullace Grape, Muscadine, &c.)—throughout the Southern Division, except New Mexico and Arizona.

*ZIZYPHUS SATIVUS* (Jujube) — Alabama, Florida, Mississippi, Louisiana, and Texas.

The above "Catalogue of Native and Introduced Fruits and Nuts" was a favourite idea with Mr. Flagg, the late lamented secretary of the Society, and was prepared by him just previous to his decease.

### ROOTS OF FRUIT TREES TOO DEEPLY BURIED.

ONE would like to know a little more about "An Amateur's" fruit trees (see p. 559) before framing an answer to the question asked by him. There is no doubt that the ordinary manuring and cultivating operations carried on in a combined kitchen and fruit garden during a period of twenty years or less will drive the roots too far from the surface, and, consequently, induce the production of watery spray that cannot properly ripen or produce fruit spurs. But in this case the remedy should be sought not in removing the good surface-soil, but in pruning the roots that are descending, and, by discontinuing deep digging close to the trees, permit the roots to again occupy the upper soil. Of course, if at any time fresh soil has been brought in, so as to raise the surface round the stems of the trees, burying the collars and literally suffocating them, then the soil should be removed immediately. But the probabilities are that the cause of barrenness may be ascribed to deep rooting, which may be traced generally to two main causes, viz., injudicious pruning and digging too much over their roots, accompanied by the use of rank manure. Root-pruning has often been described in the columns of THE GARDEN, and need not be fully entered on here further than to say that such work is always best done tentatively, beginning at a good distance from the stem, and, after digging a deep trench, working up towards the trunk with a fork, carefully turning back all healthy horizontal roots and severing only those that are going down perpendicularly. When the ball has been worked under as far as can be done, the earth can be replaced, or, what is better, changed for fresh material from another part of the garden where no trees are growing, and the roots that have been saved laid in a horizontal direction, making the earth beneath them firm, in order to prevent them from their being ruptured, or their course altered by much settling. The best season for root-pruning is from the end of September to the beginning of November, but, like transplanting, in careful hands root-pruning may be done at almost any time of the year, except in winter. If I had a quantity of trees that I was sure required a check, I should have no hesitation in gently repressing some of the worst cases now. The only difficulty is in knowing the amount of check to give, as the only danger to be apprehended is in growing too much, but roots severed when the foliage is in full activity soon heal, and throw out fibres from their extremities which will not be without effect upon this season's growth; and as the trees in question are bearing no fruit there will be no crop to sacrifice; and if the trees, or some of them, could have a careful root-pruning, say on one side, and be encouraged by the addition of a little fresh loamy soil laid in immediate contact with the roots, a season might be gained. In dealing with large old trees, open the trench 5 ft. or 6 ft. from the trunk of the tree, deep enough to reach the perpendicular roots, and gradually undermine and work out the soil with a fork. A good deal of the success of root-pruning depends upon the care exercised in its performance.

E. HOBDAV.

## THE LIBRARY.

**First Principles of Agriculture.**\*—Mr. Tanner's little volume, which forms the latest addition to Messrs. Macmillan's excellent series of Science Primers, although written specially with a view to the instruction of agricultural students, may, nevertheless, be read with profit by those amateur and professional horticulturists who are desirous of knowing the scientific principles involved in the growth of plants. The book is written in a plain, clear style, all pedantic epithets being carefully avoided. The chapters on manures are the ones which will most interest our readers; and amateurs, who are often too fond of loading their garden plots with every description of fertiliser—animal, vegetable, and mineral—will do well to read Mr. Tanner's warnings on this subject in the chapter in which he describes the effects of over-maturing on cereal crops. The remarks, too, upon the treatment that different kinds of soil should receive will also be of great use to the amateur gardener. Mr. Tanner's method of conveying instruction to his readers is evidently the result of long experience in teaching, for he never makes a statement or lays down a principle without giving abundant reasons for so doing, a duty only too often neglected by popular instructors. We cordially recommend this little work to our readers.—C. W. QUIN.

**Hints on the Culture of Ornamental Plants.**†—A third edition of these practical hints, by Mr. John Adair, of Dublin, is welcome as a useful local effort. Mr. Adair has done much to increase the knowledge of tropical plants in Ireland. Written in an easy discursive style, with frequently a touch of history or anecdote, the author gives us some sound practical information and hints, in a small compass, upon a somewhat extensive field for observation, the eleven principal heads dealing respectively with plants for dwelling houses, including window gardening, table decoration, gardening in yards, areas, &c.; town gardening, viz., in city squares, &c.; rock gardening, street planting, churchyards and cemeteries, botanic gardens, people's parks, and gardening for villas and country seats. To town dwellers the work most appeals. We have some doubts, however, about flavouring an Apple pie with *Pyrus japonica* (see p. 25).

**A Monograph of the Vine Fungi.**‡—This monograph of the fungi of the Vine is a work of interest not only to the scientific botanist, but also, though perhaps in a lesser degree, to all our cultivators. It contains an enumeration of some 220 species of fungi which occur upon the Vine, its leaves, fruit, stems, branches, and roots, in various parts of the world. It treats of the fungi found upon the following nine species of *Vitis*, viz.:—*V. vinifera*, *Labrusca*, *æstivalis*, *vulpina*, *riparia*, *cordifolia*, *rotundifolia*, *candicans*, and *sylvestris*. Of the nineteen fungi affecting the Grape itself, *Oidium Tuckeri* is of course the most important in a practical point of view. Baron Thumen appears to follow Pöckel in regarding it as the conidial form of *Sphaeroteca castagnei*, and therefore distinct from the American *Erysiphe necator*, which species does not seem to have been recorded since Schweinitz's time; while it is classed by Dr. Cooke, in the "Erysiphe of the United States," with the species *dnica*. The author also considers it unconnected with a variety of *Uncinula spiralis* that occurs sometimes upon the Grape in the United States. Amongst the great number of fungi upon the living and dead Vine stems and branches are many new species. The Spheria are designated by their new generic appellations—*Cryptovalsa*, *Ectrospheria*, *Bertia*, *Teleospora*, *Anthostomella*, *Rebentiochia*, *Valsaria*, &c., names much more familiar to Continental botanists than to us in this country, who are somewhat slow in appreciating the advantages of this system of nomenclature. Of the Hymenocytetes fungi twenty-two species are mentioned, mostly on the dead stems, including a small *Agaric* from the Cape of Good Hope, *A. proteus*, allied to *A. variabilis*. Of the fungi on living Vitis leaves one of the most interesting is a new species of *Uredo*, *U. vitis*, which, like *Peronospora vitis*, is of Transatlantic origin. The difference between the American and European Vine flora is very striking; so many fungi occur in America that have not been met with in Europe, where Vines form such an important industry and mycologists are so much more numerous. Many of the old species of Schweinitz have never been met with here. A figure is given of the curious mould which grows parasitically upon *Oidium Tuckeri*, the *Cicinobolus Cesatii* of De Bary, a plant apparently common enough on the Continent, but as yet unobserved in Great Britain. Baron von Thumen is to be congratulated upon the exhaustive manner in which he has compiled this monograph.—C. B. BLOWRIGHT, in "Journal of Botany."

GARDEN BOTANY.

(Continued from p. 555.)

**INDEFINITE INFLORESCENCES WITH SOLITARY FLOWERS.**—Flowers are termed solitary when only one is borne in the axil of each ordinary leaf, or at the extremity of each branch.

Fig. 201.—*Vinca herbacea*; flowers solitary and axillary. Fig. 202.—*Fabiana imbricata*; flowers solitary and terminal.

In *Vinca* (fig. 201) they are solitary and axillary, and in *Fabiana* (fig. 202) they are solitary and terminal.

**INDEFINITE INFLORESCENCES WITH AGGREGATED FLOWERS.**—Of this class there is a great variety, the principal modifications of which we will review. They may be divided into two groups—a spicate group and a paniculate. In the spicate group the lateral axes of the first order do not branch and all bear flowers, and the primary axis or peduncle (rachis of some botanists) terminates with or without a flower. To this group belong—

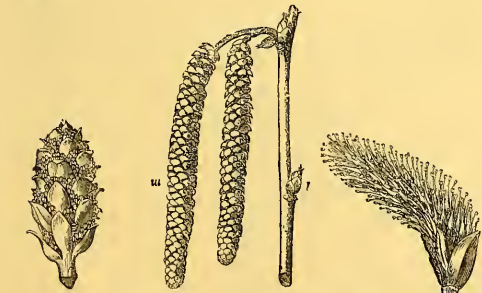

Fig. 203.—Catkin of flowers of *Fothergilla amifolia*. Fig. 204.—A branch of Hazel bearing both male catkins, *m*, and female catkins, *f*. Fig. 205.—Catkin of female flowers of a Willow.

**THE SPIKE.**—The peduncle is elongated and the flowers are sessile upon it, as in *Plantago*.

**THE CATKIN.**—This is distinguished from a true spike in being deciduous, that is, falling bodily, and in bearing unisexual flowers which are destitute of true floral envelopes. The male and female catkins are borne on the same plant, as

in the Hazel (fig. 204), or on separate plants, as most Willows. The male and female catkins of the Hazel are very dissimilar, whilst those of the Willow (figs. 205 and 206) are not unlike each other.

**THE SPADIX.**—A spike with a more or less fleshy axis, usually sheathed by a large bract (spathe), and the flowers unisexual or bisexual, but on the same spadix (fig. 207—spathe removed), or on different spadixes.

**THE RACEME.**—Here the flowers are distinctly stalked (pedicellate), as in the Red Currant (fig. 208), Laurel, Berberis, Deutzia, &c., and there is a small bract at the base of each pedicel, and the pedicels are nearly all of the same length. This

Fig. 206.—Catkin of male flowers of a Willow. Fig. 207.—Portion of spadix of *Arum maculatum*; *m*, male flowers, *f*, female flowers.

kind of raceme is usually pendent, though sometimes the peduncle or main axis of the inflorescence is stout and nearly erect, as in *Berberis Beali*. The flowers of most Cruciferae (Wallflower, Shepherd's-purse, and Cabbage, for example) are racemose, but the racemes are erect and destitute of bracts

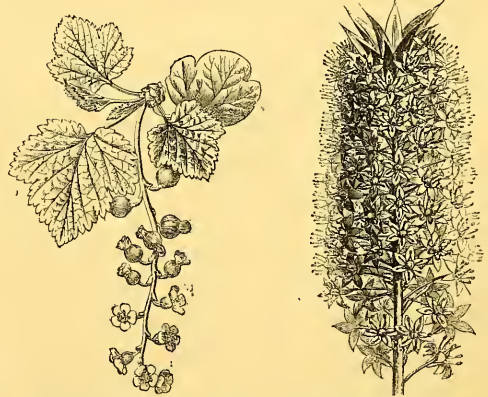

Fig. 208.—*Ribes rubrum*; flowers in a raceme. Fig. 209.—*Eucomis punctata*; flowers in a raceme.

(ebracteate). Another kind of racemose inflorescence is offered by *Eucomis punctata* (fig. 209), also sometimes called scapose, with a many-flowered scape. It is erect, and has a long naked peduncle (scape), and terminates in a tuft of bracts.

**THE CORYMB.**—This kind of inflorescence differs from a raceme in the lower pedicels being longer than the upper, so that the flowers are nearly all on the same level, as in the Bird Cherry (*Prunus Padus*—fig. 210). An inflorescence which ultimately grows out into a raceme is often corymbose in an early stage—the Wallflower, for instance.

**THE SIMPLE UMBEL.**—In the simple umbel the main axis is arrested, and the pedicels are crowded together at the end,

proceeding, as it were, almost from one point, as in figs. 211 and 212. The bracts form a ring around the base of the pedicels, and when bracts are thus arranged they are termed, collectively, the involucre. The bracts of the involucre over-

Fig. 210.—*Prunus Padus*; flowers in a corymb.

Fig. 211.—*Prunus Cerasus*; flowers in a simple umbel.

top the flowers in *Astrantia* (fig. 212), whilst they are much shorter than the pedicels in the *Cherry* (fig. 211).

THE CAPITULUM.—Here not only the main axis is undeveloped,

Fig. 212.—*Astrantia major*; flowers in a simple umbel.

as in the simple umbel, but likewise the secondary axes (pedicels), so that the flowers are sessile on the expanded apex of the floral axis or flowering branch, as seen in fig. 213, &c. In

Fig. 213.—Section of a flower-head of *Aster grandiflorus*, showing the flat receptacle.

English descriptions these inflorescences are called capitules or flower-heads, and sometimes composite flowers, and the separate flowers florets, but the two last terms should be re-

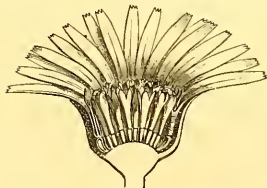

Fig. 214.—Section of a flower-head of the *Corn Marigold*, showing the convex or hemispherical receptacle.

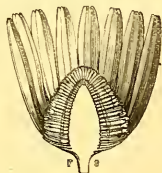

Fig. 215.—Vertical section of a flower-head of *Matricaria*, showing the conical receptacle.

garded as the remains of an inappropriate set of terms, because misleading. The largest family in the vegetable kingdom, the *Compositæ*, numbering some 10,000 species, are so named in consequence of the arrangement of the flowers in heads or

capitules; but the *Dipsacæ* (*Teasel*, *Scabious*) and several genera belonging to various families have capitulate flowers. A capitulum is really nothing more than an abbreviated spike. The expanded portion upon which the flowers are seated is the receptacle, which is flat in *Aster grandiflorus* (fig. 213), convex or hemispherical in the *Corn Marigold* (fig. 214), conical in *Matricaria* (fig. 215), and concave in *Centaurea Fontanesi* (fig. 216). The flowers, or florets as they are commonly called, of

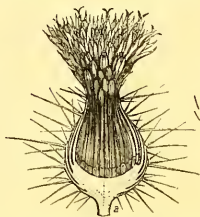

Fig. 216.—Section of a flower-head of *Centaurea Fontanesi*, showing the concave receptacle, and flowers all of the same shape.

Fig. 217.—Flowers in a capitule or head (*composite flower*), in which the flowers of the centre (*disk*) are different in shape from those of the circumference (*ray*).

a capitule are all of the same shape, as in *Centaurea* (fig. 216) or those of the centre (*disk*) and circumference, as in figs. 217, 218, &c., and as in the *Daisy* and *Chamomile*, are dissimilar. Where there is a distinction in the ray and disk flowers, the latter are split open nearly to the base on one side and flattened out, as

Fig. 218.—Disk flower of *Helianthus*; corolla tubular.

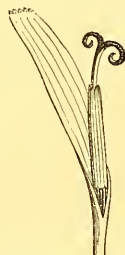

Fig. 219.—Flower of *Dandelion*; corolla ligulate.

Fig. 220.—Inflorescence of the *Fig* (*Ficus carica*).

in fig. 219, and the disk flowers are tubular, as in fig. 218. In the large sub-order of the *Compositæ* to which the *Dandelion* belongs all the flowers of a capitule are alike in shape (fig.

Fig. 221.—Inflorescence of *Doretenia contrayerva*.

219), and are what is termed ligulate. Such are the chief modifications of the capitulum. There is one other character which may be mentioned here. Besides the bracts forming the involucre, there are in some *Compositæ* chaff-like bracts intermixed with the flowers called pales. The Fig fruit, the nature of which we have already explained, may be regarded as

an extreme modification of the same type of inflorescence as the capitulum, in which the receptacle is hollow enclosing the flowers (fig. 220). In *Dorstenia* (fig. 221), a plant allied to the Fig tree, the receptacle is irregularly spread out. The foregoing are the principal modifications of the spicate group of

Fig. 222.—Compound spike or spicate panicle of *Panicum Crus-galli*.

Fig. 223.—Compound racemes or racemose panicle of *Ligustrum vulgare*.

inflorescences; and we will now examine those of the paniculate group, which differ essentially only in the lateral axes or branches again branching once or more.

**THE SPICATE PANICLE OR COMPOUND SPIKE.**—This differs from a simple spike in the flowers being sessile upon the lateral axes of the first order instead of upon the main axis (fig. 222). The ears of Wheat and the inflorescence of *Spiræa Aruncus* and *Veratrum* are spicate panicles, but it is very dense in Wheat.

**THE RACEMOSE PANICLE OR COMPOUND RACEME.**—Distinguished from a compound spike by its flowers being pedicellate.

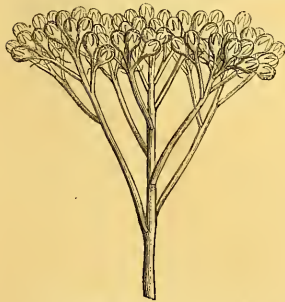

Fig. 224.—Compound corymb of the flowers of *Pyrus torminalis*.

Fig. 225.—Compound umbel of flowers of *Cheroxyllum temulum*.

The Common Privet (*Ligustrum vulgare*—fig. 223) is an example of this kind of inflorescence.

**THE CORYMBOSE PANICLE OR COMPOUND CORYMB.**—The Wild Service (*Pyrus torminalis*—fig. 224) differs only from the corymb of the Bird Cherry (fig. 210) in some of the outer and lower lateral axes of the first order bearing axes of the second order.

**THE COMPOUND UMBEL.**—In by far the greater number of the Umbelliferae the umbel is compound, as in fig. 225, and

in the Carrot, Parsnip, and Parsley the presence or absence of involucre should be noted. An involucre of bracts at the base of the primary ramifications of a compound umbel is the general involucre in contradistinction to the partial involucre at the base of the secondary ramifications. *Cheroxyllum temulum* (fig. 225) has no general involucre; in the Carrot it is very conspicuous; and in the Parsnip there is neither general nor partial involucre. For the sake of brevity they are sometimes spoken of simply as bracts and bracteoles, or the general involucre simply involucre, and the partial involucre involucrel.

**DEFINITE INFLORESCENCES.**—These include all inflorescences of the cymose class in which the primary axis or peduncle

Fig. 226.—Chickweed (*Stellaria media*); flowers in a dichotomous cyme.

terminates in a flower, and branches below this flower, each successive order of axes terminating in flowers and ramifying in the same manner. In this class of inflorescences the flowers expand in centrifugal succession, or from the centre towards the circumference.

**DEFINITE INFLORESCENCES WITH SOLITARY FLOWERS.**—There are two modifications of this type. The main branches of the

Fig. 227.—*Nemophila atomaria*, with solitary flowers opposite the leaves.

Chickweed (fig. 226), and many other plants of the same family, terminate in flowers, from below which, proceeding from the axils of the last pair of leaves, which are opposite, two opposite branches are produced. These secondary axes terminate in flowers, and in their turn branch in the same manner as the primary axis. Although the flowers are solitary and terminal, the whole system of ramifications, after the plant begins to bloom, forms what is called a forked or dichotomous cyme. In *Nemophila atomaria* (fig. 227) the development of the flowers is very curious. As may be seen in the cut, they are solitary and opposite the leaves, which are alternate. In this case also the flower is at first terminal, but as a branch grows out from the axil of the uppermost leaf of the axis which terminates in a flower, the latter then appears to be a lateral production. The succeeding leaf is on the same side as the first flower, and the

next flower is on the same side as the leaf, which is opposite the first flower. The second flower is soon overtopped by an axis of the third order, and so on until the plant ceases to flower. Now let us compare this inflorescence with that of *Vinca* (fig. 201), and we shall be in a position to perfectly understand the meaning and application of the terms definite and indefinite. In *Vinca* the primary branch or axis continues elongating and producing flowers, consequently the number of flowers which each branch or axis will bear is uncertain and indefinite; whereas in *Nemophila* and Chickweed each branch terminates in a flower, and a succession of flowers is only maintained by the development of branches of the second, third, and successively higher orders, from the axils of the leaves borne by

Fig. 228.—*Gypsophila paniculata*; flowers in a dichotomous cyme.

the older branches. As we know beforehand that each successive axis or branch will bear only one flower, the inflorescence is determinate or definite. A careful comparison of living examples of the plants named in illustration will enable the student to comprehend not only the differences between definite and indefinite inflorescences, but the general laws of branching.

Fig. 229.—*Hyoscyamus niger*; flowers in a scorpioid cyme.

Fig. 230.—*Alstromeria versicolor*; flowers in a helicoid cyme.

**DEFINITE INFLORESCENCES WITH AGGREGATED FLOWERS.**—The distinction between these and definite inflorescences with solitary flowers is not very obvious, and is really nothing more than the replacement of ordinary leaves by bracts, as a comparison of figs. 226 and 228 will show. It is a distinction without any fundamental difference, but, nevertheless, useful in descriptive botany.

**THE DICHOLOMOTUS CYME.**—*Gypsophila paniculata* (fig. 228) has a dichotomous cyme, differing only from that of Chickweed

in not being leafy; the mode of branching is the same, but the successive ramifications have their birth in the axils of bracts, or foliar organs different from the ordinary leaves.

**THE SCORPIOID CYME.**—The inflorescence of *Hyoscyamus niger* (fig. 229) is simply a modification of the same type as *Nemophila*. The uppermost leaf of the first axis, which terminates in a flower, gives birth to a leaf and a flower, the new

Fig. 231.—Simple umbels of *Hedera Helix* in a raceme.

leaf being at right angles to the last; and the same mode of branching is repeated throughout the inflorescence.

**THE HELICOID CYME.**—A glance at fig. 230 will be sufficient to enable one to understand how a helicoid cyme differs from a scorpioid cyme, as exemplified in *Nemophila*, *Hemerocallis*, &c. The successive branches of a helicoid cyme are all developed in the same direction as the primary one, and not alter-

Fig. 232.—Flower-heads of *Petasites sibus* in a raceme.

Fig. 233.—Inflorescence of Horse Chestnut; in which scorpioid cymes are arranged in a racemose manner.

nately right and left, so that they form one or more coils in a young state with flowers in a line on the outside of the coil and bracts on the inside (see fig. 230).

**OTHER DEFINITE INFLORESCENCES.**—A few other modifications of this group deserve mentioning, though the distinctions are rarely observed in descriptions of plants. In the Meadow Sweet and some Rushes the pedicels from the base of the inflorescence considerably overtop the succeeding ones, and the inflorescence is then termed an anthela. The axillary cymes characteristic of so many of the Labiatae (for example, the white Dead Nettle) are verticillasters, or false whorls.

**SECONDARY ARRANGEMENT OF INFLORESCENCES.**—The arrangement of such inflorescences as the capitulum and the simple umbel may be scapose, spicate or racemose, corymbose or paniculate, cymose, &c. Compare Dandelion, Butter Bur (fig. 232), Golden Rod, Yarrow, and other native Compositæ. The umbels of Ivy (fig. 231) are arranged in racemes. W. B. HEMSLEY.

## GARDENING FOR THE WEEK.

### Flower Garden and Pleasure Ground.

Where the planting out of bedding plants is quite finished, which will generally now be the case, little will require to be done for some time except attending to routine operations, such as mowing, cleaning, and the staking and tying up the various sorts of plants which require that attention. Copious waterings should, for some time to come, be given to the flower beds and borders whenever the state of the weather renders that attention necessary. Wherever the embroidered or carpet style of work is attempted, this must have unflinching attention in the way of regulating the different sorts of plants employed, an operation which involves stopping and pinching back throughout the greater part of the season. Carpet bedding, as a rule, should be effected without the aid of flowering plants. It should, in fact, be confined to plants possessing remarkable foliage, and of this class there is a considerable variety suitable for the purpose, hardy as well as tender, such as Ajuga, Antennaria, Echeveria, Sempervivum, Saxifraga, Veronica, Sedum, Cerastium, Cineraria, &c., most of which are indigenous to Britain or the south of Europe, and perfectly hardy; together with the highly-coloured tender species from Brazil and Peru, such as the Alternanthera, Coleus, Iresine, &c.; and lastly, but by no means the least useful, is the Golden Fether Pyrethrum, now so well known and so extensively used for this and other purposes, such as marginal lines to beds and borders. Sub-tropical plants, such as *Cycas revoluta*, Palms, Musas, and similar material, should be transferred to their outdoor quarters, giving them positions in which their beauty will be set off to most advantage; yet they must be sheltered, and not too confined with surrounding vegetation. *Monstera deliciosa* does well in a warm place under the shade of trees, and forms a good companion to tender Ferns, which may also be accommodated there. Plants of the green and also of the variegated leaved New Zealand Flax look well planted out, or plunged as centres to small flower beds, or used as specimens for conspicuous places, such as vases on terraces. American Aloes and Yuccas may likewise be used in the same way.

### Indoor Plant Department.

**Stoves.**—Fine-leaved plants now form a chief feature in stoves; every encouragement must, therefore, be given them, in order to promote the proper development of the foliage. They should have a moist, warm, and steady atmosphere, plenty of tepid water at the root, and daily sprinklings overhead with the syringe. The young leaves of the finer *Anthuriums* must be kept clear of foliage, which should be put aside, so as not to impede their growth. Some plants will require stakes, which should be neatly and sparingly applied. Remove such plants as are in flower to the coolest end of the house, if practicable. The propagation of stove plants from cuttings should, as a rule, be suspended for a time, until the wood becomes a little firmer than it is at present, but such as were propagated earlier should be potted as they become well rooted. *Coincettias*, however, are an exception, and the sooner good cuttings can be obtained from them and rooted the stronger the flowering plants will be. The young shoots nearest the end of the branches may be removed for this purpose, and about four or six of the lowermost left on the old plant if it is to be retained.

**Conservatories.**—*Passiflora*, *Bignonia*s, *Kennedya*s, *Hibbertia dentata*, *Lonicera sempervirens*, and similar plants, must now be regularly thinned, taking care to preserve a large quantity of young wood as possible, without overcrowding, and permitting the shoots, after they reach a certain height, to hang down in graceful festoons. Keep up a good accession of flowering plants from greenhouses and frames, and replace those going out of flower. *Acacias*, *Rhododendrone*, *Heaths*, and other hard-wooded plants will now be contributing to the beauty of indoor structures. Any appearance of mildew on *Heaths* should be immediately checked by dusting with sulphur; in the centre of large plants mildew often develops itself unnoticed.

**Greenhouses.**—These, being now clear of bedding plants, may be filled with annuals (*Pelargoniums*, *Fuchsias*, *Hydrangeas*, *Begonias*, &c.), in order to forward them for the decoration of the conservatory. *Hydrangeas* are now coming into bloom, and require some assistance in the way of manure water; any shoots not furnished with flower-buds should be removed and used for purposes of propagation. By means of plenty of ventilation—complete exposure, in fact, during fine weather—retard the show *Pelargoniums*. Old roots of *Cyclamen* not bearing seed-pods may be transferred to a frame having a north and shady aspect. The young ones must be kept in a good growing state. Plants of *Spiræa japonica* that have done flowering should be transplanted into a plot of ground that is rich, moist, and warm.

**Primulas and Cinerarias.**—Both *Primulas* and *Cinerarias*, if sown as advised, will shortly be fit for placing in thumb-pots in soil consisting of three-fourths good loam and one-fourth rotten manure and

leaf soil in equal quantities, with a good sprinkling of sand. When potted, put them into frames facing northwards, as these plants cannot bear exposure to full sunshine, to break the rays of which, when very bright, shade with a piece of netting or thin canvas. *Cinerarias* should stand on a bed of ashes that will hold moisture and maintain a humid atmosphere about the plants; they cannot endure being placed on shelves exposed to dry currents of air. Place *Primulas* on inverted pots, so as to keep them up near the glass, or they will become drawn and long in the leaf-stalks. After potting, keep the lights closed about dusk at night with only a little air on during the day until they have commenced to grow freely, after which give air plentifully night and day.

**Pinks.**—Cuttings of Pinks for forcing should now be put in and potted on singly in each separate row. They are easily managed, do not occupy much room, and, with a little warmth, afford a succession of elegant-scented flowers alike suitable for bouquets or vase decoration. They are not much subject to insects, though green fly sometimes attacks the young leaves; its presence, however, is easily detected by the leaves beginning to curl up. Dipping and syringing with Tobacco water will be found the best remedies. The plants must always be sufficiently supplied with water, or they get into a stunted condition, from which it is difficult to induce them to emerge.

**Salvia generosefolia.**—Cuttings of this put in some time ago will be ready for moving into 6-in. pots. This most useful winter-flowering plant naturally assumes a bushy habit, but to furnish the plants with plenty of shoots near the base the position of the leading growths should now be checked. These ought to be at once plunged out-of-doors in a sunny sheltered situation. It is a free grower and makes roots rapidly. In the course of six weeks' time the plants will require moving into 10-in. or 12-in. pots for blooming, keeping them outside till the beginning of September.

**The White-flowered Abutilon Boule de Nègre** is deserving of a place in even the most select collection of greenhouse plants. It blooms nearly during the whole year, producing in succession its beautiful drooping flowers, alike suitable for display on the plant or for cutting. It is of the easiest possible management. Cuttings of the half-ripened shoots, 5 in. or 6 in. in length, inserted singly in 3-in. pots in sand, moist, shaded, and covered with a propagating-glass in a little warmth, will strike in a few weeks, and make nice small specimens that will bloom through the autumn and winter. *A. vexillarium* and *A. vexillarium igneum* are equally worthy of cultivation, flowering freely in small pots with ordinary greenhouse treatment. The two latter, grown with single stems 12 in. or 18 in. in height, and then stopped so as to form a bushy head, make beautiful miniature standards suitable for table or window decoration, or for placing in the greenhouse, where, if raised on inverted pots, they greatly relieve the even surface of dwarf-growing subjects.

**Acacias and Cytisus.**—*Acacia Drummondii* and *A. armata* are the two best varieties for pot culture, as when placed in a little heat they can be brought into flower early in the winter. They are of easy growth, and not liable to die off suddenly through either a superabundance or long stay of water like many hard-wooded plants. Young plants of these *Acacias* that have been grown on from a small state, and others that are larger and have been cut back and re-potted after blooming, will, in most cases, have made sufficient growth, and should be exposed in the open air; this is necessary to fully harden and mature the growth and to induce the formation of flowers, for if the plants be kept under a glass in a growing state all the summer they will not produce flowers in such profusion as if thus exposed. By getting them out-of-doors in good time they will be in a condition to bloom earlier through the winter. The very useful winter-blooming *Cytisus racemosus superbus*, which is much better than the common *C. racemosus*, requires to be similarly treated. If a few examples of this free, delicate, yellow-flowering plant be grown, a succession of its highly-fragrant flowers may be had through the winter.

**Boronia serrulata** is another highly-fragrant subject, as a small plant in 6-in. pot will fill a large house with perfume. Any one with a moderate knowledge of general plant-growing may venture to cultivate it, as it is not liable to die off; it is of dwarf compact habit, and grows freely in sandy peat. When it has ceased flowering cut back the shoots to within 6 in. of where it was stopped last year; if this be omitted the plant soon gets into a straggling condition. It should be kept in the greenhouse for some time yet, exposed to full light and syringed overhead every afternoon; this treatment is necessary in order to keep down red spider, a pest to which it is somewhat liable.

### Indoor Fruit Department.

For Pines maintain a strong, moist, and steady heat; avoid draughts, and give just sufficient air to prevent too great a rise of temperature. Remove all strong suckers, pot, and start them in bottom-heat. Gradually lessen moisture, both in the air and soil, where Pines are ripening fruits. Notwithstanding many instances of badly ripened Vines last year, through careful treatment, and slow and not too early forcing, the plants are bearing well this season. Thin the shoots and berries as required; only allow one bunch to each lateral, and pinch the shoot at the second eye beyond the bunch. If the borders are indoors, see that they are thoroughly moistened. In the Peach house border watering must also be attended to, and liquid manure supplied now and then. Disbudding, syringing, and other daily operations will require attention. Top-dress Cucumber beds immediately the young roots are seen to be protruding above the surface, thin out superfluous laterals and decaying leaves, and always maintain a regular supply of young and good bearing wood. Never permit too many fruits to be on one plant at a time, as they only prevent

each other's development. Springs both Melons and Cucumbers twice a day with clean tepid water; but if mildew be suspected, mix with it a little flowers of sulphur. Strong and healthy plants militate against red spider; therefore manure water must be freely applied to Cucumbers. Melons ripening require to be kept a little on the side of dryness. As the frames are now cleared from bedding plants the latest-sown Melons should be put in them; these will come in late in the season. The beds need not now be made so substantial as was necessary earlier in the season; if a good supply of late autumn's leaves are at hand, they may be used; and not one-half of this and well-prepared manure. Three feet in depth will be enough now; beds of this description will be sooner cool enough to receive the plants than those recommended earlier in the season. In localities not favourable to the growth of Tomatoes, or where a difficulty has been experienced through attacks of the disease with which this vegetable has of recent years suffered, it would be advisable to grow some in frames. If the plants are put into 12-in. pots and plunged in the ground, and the frames elevated on bricks so as to give increased heat room, good crops may be secured. The principle thing to be observed in their culture is to keep the plants sufficiently thinned and well tied out, not allowing them to suffer for want of water, and giving enough air to induce stont growth. In Pine stoves or other forcing houses near the glass have a successional supply of French Beans; they require plenty of water, as well as liquid manure, also syringing twice a day, and the minute red spider is discerned, let the plants affected by it be immediately discarded.

**Vines.**—Encourage free growth in the case of all young Vines planted out this season by closing the ventilators early in the afternoon, so that the temperature may remain about 90° for an hour or two at that time. Damp all bare surfaces and use the syringe freely where the slightest indication of the presence of insects can be detected. Do not let the growths on one-year-old spring-planted canes become crowded, which they are apt to do early in the time. The leading rods, which may have been allowed to grow to make quantity of foliage for forming pots, should never be permitted to come nearer than 1 ft. of each other, and the lateral growths produced on these must be kept in to the first leaf. Where only one or two canes have been taken from each root, the secondary growths may be left longer, their length being regulated by the space there is around them. Vines planted last season and brought into growth early without forcing will now be getting well established. Bunches will be appearing on the strongest rods, and the number left on must depend on the capabilities of the Vines. Some may be allowed to bear two and others four and five, but it is always best to crop lightly when at this age, or the Vines will be liable to become prematurely impaired in health. No bunch should be left on the leading shoot, the great object being to get that as perfect as possible for next year's supply. Those who have plenty of Grapes on older Vines will lose nothing by not fruiting young Vines of this age till next season, but temporary ones planted along with them may be cropped heavily, as some of them may have to be dispensed with next spring. Those planted two years ago should produce some fine Grapes this season. The size of the bunch and strength of the Vine should determine the weight. When well regulated, a bunch on every alternate shoot on the lower portion of the rod is an average crop for ordinary Vines.

**Peaches.**—To prevent ripe fruit falling to the ground and getting spilt a good plan is to suspend a herring-net under the trees, or a series of flosses or doubles, so as to catch the falling fruits and yet not allow them to fall too far and perhaps knock against each other, as they would do if all fell into one part of the net. Succession houses may be kept closer and warmer than those in which the fruit is ripening, and syringed more liberally. Houses in which the fruit is stoning should be carefully attended to during bright hot weather, giving abundance of ventilation early; a slight shade would also benefit the trees at mid-day during hot weather. At this stage, at which an overstrain would have the tendency to cause the fruit to drop, see to the gradual thinning of the fruit in orchard houses, and take care that the borders are abundantly moist as a precaution against red spider and blight; for, sure enough, those enemies will at once attack a tree in distress. The crop must also suffer if the roots be dry, and if the fruit gets stunted from dryness now no front management will bring it up to the required standard. The fruit ventilators may be kept open day and night when the wind is south or south-west.

#### Kitchen Garden.

Whenever a crop is done with manure and dig the land on which it grew, in order to have it in readiness for something else. Nothing impoverishes ground so much or looks more untidy than runaway vegetables. Peas in windy places are sometimes apt to partially escape from the sticks which support them; when this tendency is first noticed, if a strand of rope yarn is run along the rows on the level and hooked here and there to the sticks, it will turn the back to the right direction and prevent them from being blown down. Make a further small sowing of Early Horn Carrots; there is a frequent demand for small young Carrots, which it is always best to anticipate. Sow Spinach once a fortnight in cool damp-bottomed land that has been deeply worked; in dry weather it is sometimes a disappointing crop. Sow Turnips to succeed those just up; burnt earth or ashes from any substance except coal has an invigorating influence upon the growth of Turnips in dry weather. The Red American Stone and Orange Jellies are the best Turnips for sowing at this season. Avoid, if possible, the necessity for sowing in freshly-dug land. If the land has been prepared a week or so, the moisture, even in dry weather, will have risen by what is termed capillary attraction, and by drawing the drills rather deeper than necessary or desirable early in the

spring, the seeds may be laid in moist soil, and germination thereby assisted. Continue planting, as opportunity offers and space becomes vacant, such crops as Brussels Sprouts and early Broccoli. A sufficient breadth of spring-sown Cabbages should also be planted, giving them room according to their kinds; small varieties, such as Cocco-nut or Little Pixie, will do if they be placed 15 in. apart each way, whereas those of the English Market class should stand 18 in. asunder in the rows with 2 ft. between. Savoys should have a similar space allotted to them, according to the small or large variety grown. A few spring-sown Red Cabbages should also be planted 18 in. from plant to plant, and the rows 20 in. apart. With the large number who cannot find room until something that has preceded them is cleared off, there is no chance but keeping the plants until the required space is at liberty in the nursery beds in which they were recommended to be pricked out a short time ago, from which they can be removed with very much less check than if allowed to remain in the seed-bed until permanently planted. The main crop of Celery may now be planted, choosing the first favourable opportunity when the weather is showery, for although the plants may not be so large as to be taking any harm in the nursery bed, they will receive less check from moving than if planted later when they are larger. Treat as to water as recommended for the earliest planted.

#### Extracts from my Diary.

**June 17.**—Sowing Parsley in cold pits for winter use. Potting off seedling Campanas. Planting out Wakeham, Snow's Winter White, and White Cape Celery. Preparing the soil and getting the Early Exhibition Celery earthed up. Cutting up small pieces of turf for layering Strawberries on. Clearing off Cabbage stumps, manuring the ground, and getting it dug up ready for another crop.

**June 18.**—Sowing Carters' Giant White Cos, the Favourite, and All the Year Round Lettuce. Potting on Cinerarias and Primulas. Putting out Celery plants. Raking down and levelling all flower borders and beds, and pegging down all plants that require it. Layering Vicomtesse Héricart de Thury and President Strawberries on pieces of turf 4 in. square. Watering all newly-planted bedding plants. Looking over Pines and watering them.

**June 19.**—Sowing Canadian Wonder and Long-podded Negro French Beans. Potting on Chrysanthemums and Pelargoniums. Cleaning out Potato frames and getting them ready for Melons. Sticking Peas and getting them earthed up. Looking over all Vinerias, tying down leaders, and stopping the laterals where required. Thinning Turnips and Spinach. Watering all newly-planted Cabbage, Cauliflower, and Lettuce plants.

**June 20.**—Sowing Coleworts and Little Pixie Savoys. Planting out another row of Peas. Dividing and planting out double Daisies. Thinning out Peas where hanging too thickly. Clipping Box edgings. Mulching Peas with rotten manure. Tying in all the leading shoots in Peach houses and watering the borders where required. Clearing off Lettuce stumps and Spinach. Giving all Vinerias as they require it a good soaking of guano water. Gathering Strawberries for preserving.

**June 21.**—Sowing Silene pendula and Forget-me-nots. Potting on large Colenases and Cockscabbs. Putting sticks to Fuchsias and Phloxes and tying them out. Turning gravel walks to give them a fresh appearance. Nailing in all the leading shoots of Plums, Apricots, and Peaches, and giving the latter a good washing with the garden engine every evening to keep down red spider and other insects. Putting back Ivy where overgrowing windows. Gathering Green Currants for bottling. Watering newly-planted Strawberries.

**June 22.**—Sowing Snowball, Veitch's Red Globe, and American Strap-leaf Turnips. Planting Grange's Autumn Cauliflower and Purple Sprouting and Adams' Early White Broccoli. Sticking two rows of Peas. Looking over Cucumbers and Melons and topping them where required. Clearing off Pea-sticks from early border and putting them round Asparagus beds to protect them from the wind. Planting six lights with Melons after Potatoes. Watering all newly-laid Strawberry runners. Fruit in use for dessert: Pines, Grapes, Melons, Peaches, Nectarines, Strawberries, Raspberries, and Cherries.—W. G. P., Dorset.

**Bone Dust as Manure.**—I find this invaluable both for flowers and fruit, especially pot Vines and Strawberries, and it is not only a rich, but a lasting manure, which I consider better than bones in a rough state. The latter are, however, best adapted for Vinery and fruit tree borders. For pot plants, such as Fuchsias, that bloom nearly continuously, if sufficient food be supplied to insure fresh growth, a liberal sprinkling of this kind of manure will be found to be of the greatest service. In vegetable culture, a sprinkling in the drills with Turnips and crops that are best pushed rapidly into full leaf beyond the attacks of fly and other insect pests, I have found bone dust most satisfactory.—JAMES GROOM.

**Garden Cats.**—I should like to add my testimony to the great utility of cats in gardens under certain circumstances. I am a great lover of animals, but still I dislike to see Peas or other seedlings destroyed by mice. I have about my premises some out-door cats, and two indoor ones. I thankfully give my scraps to the former, the latter being of course provided for, because I know their real value. True, I may find borders occasionally slightly deranged, but this only causes a little work; and how small is this in comparison with an

almost entire absence of mice from the garden. I have recently had two cats with one kitten in a conservatory, and have not received the slightest harm from their presence. It is no biased testimony which I give, but one resulting from an experience of some years. I can easily imagine a large number of cats to be a great nuisance, but the number in the country is more limited than near towns, and to a lover of a garden I cannot but recommend them as a certain cure for rats, mice, and too many birds, all of which so often disturb one's peace of mind.—A CONSTANT READER.

### ANSWERS TO CORRESPONDENTS.

**Italian Tulips.**—Can you inform me whether the Red and White Italian Tulip (T. Clesiana) will grow in this country?—**TURT.** [These grow perfectly well in light well-drained soil in England.]

**Ants in Cucumber Pits.**—How can I get rid of ants in a Cucumber pit? They make their hole within a few inches of the plants, which keeps the earth very loose and dry. I have tried paraffin and water, but without effect.—**E.** [Sprinkle guano about their holes and runs. If it does not destroy them, they will soon desert such unpleasant quarters.—**W. H. J.**]

**Weeds on Gravel.**—Can any of your correspondents inform me how to get rid of weeds in a yard covered with gravel? I have heard of arsenic boiled in water as a remedy, but do not know in what proportion to mix it.—**X.** [Have no dealings with arsenic. Hand-weeding is the best plan, but if very bad, give a rather heavy dressing of common salt, taking pains to keep it off Box, turf, or other edgings, as it is certain death to them. Such a dressing, repeated annually, will effectually rid your yard of weeds.—**W. W.**]

**Binding Gravel.**—Can you tell me any way of making loose gravel bind properly together? We have had some put down that does not get hard, though it has been down a good long time.—**T. M. PIRK.** [Before putting on the upper or final coating of gravel, apply a thin layer of fresh slaked lime; on this spread the fine gravel, and roll at once; some walks served thus are equal to asphalt.—**W. W. H. J.**]

**Morello Cherries Shedding their Fruit.**—Will some one kindly inform me whether any artificial means can be taken to bring Morello Cherries to perfection? My trees (on walls) blossom profusely, but each year at stoning time the young fruits all drop off.—**F. W. P.** [This the blossom previous to expansion. Morello Cherries always bloom profusely, and it is well that not more than half the fruit sets, or we should have poor samples indeed. Surely all the fruit does not drop? If so, examine the roots in the autumn to see that the drainage is effective; then dress with a compost with which lime-serape or chalk have been freely mixed.—**W. H. J.**]

**Wash for Fruit Buds.**—What are the proportions in which lime, soap, sulphur, Tobacco, and red lead should be mixed as a wash for the protection of fruit buds?—**J. J. M.** [We presume you mean orchard trees; if so, the following makes a good wash for keeping off both birds and insects. With each bushel of soot and lime mix, to the consistency of thin paint, water, in which has been previously dissolved 4 lb. of soft soap. Some fresh cow manure mixed with it will help to make it plastic, and prevent the dressing from being washed off by rain ere it has had the desired effect. Sulphur, Tobacco, or red lead, are not necessary.—**H. W. W.**]

**Insects on Melons.**—What kind of insects are those which I send on a Melon leaf? and what are the best means of destroying them? They are very numerous, both in the Melon and Cucumber pits, round the stems of the plants. Can you also tell me what the insect is which is on the back part of the Daisy or Pyrethrum leaf I send, and how to eradicate it?—**G. J. J.** [The Melon insects are mites, and should be got rid of. The way in which red spider is destroyed will put an end to their ravages. On the Pyrethrum leaf sent I find the operations of a small mining larva causing a bladdery appearance on the upper surface. Picking the injured portions off and destroying them is the most efficient way of preventing further injury.—**W. W. S. J.**]

**Paint for Hot-water Pipes.**—What is the best paint for hot-water pipes? Would the fumes arising therefrom affect any plants in the same house? Would Brunswick Black answer the purpose?—**DISQUIRER.** [Lamp-black, mixed with boiled oil and turpentine, is usually applied to hot-water pipes, and is perfectly harmless to plants. Our painter says if turpentine chine is used, and only a little oil the pipes will not smell so strongly nor be so long in drying.—**J. S. J.**]

**Mildewed Grapes.**—I have sent you a part of a bunch of Grapes for inspection. Would you kindly inform me the cause of the nasty appearance on the berries, and whether I am likely to lose any bunches through it? The Vine appears otherwise in good health, and on the average the bunches will run, if they ripen, about 2 lb. in weight. [Your Grapes are evidently attacked with mildew. Cut out what berries are worst affected, and paint the pipes with sulphur; keep them warm day and night, and the atmosphere of the house dry for a week or so. Afterwards ventilate freely during fine weather, but avoid draughts.—**S.**]

**Ribbed Glass.**—I am building a small house, and want to know the best sort of glass for the top, as I am away all day, and cannot depend upon anyone at home doing any shading. Will rough plate be of any use? If so, which side should I put out? The house will lie north and south, with an east front, and is span-roofed.—**J. E. W.** [Ribbed or obscured glass should not be used for plants that like plenty of sunshine, such as Peaches and Melons, for example,

Vines and most other subjects will do well enough under it, but it will not obviate the necessity of shading shade-loving plants occasionally. A good deal, however, depends upon ventilation: The rough side of the glass is usually placed outdoors.—**J. S. W. J.**]

**Ants' Nests.**—What will destroy these round Rose trees without injury to the roots?—**J. B. B. Bromley.** [We have found scattering guano about their runs the best antidote. A slight sprinkling daily soon disperses them.—**W. W. J.**]

**Apple Tree Caterpillars** (see p. 653).—We know of no plan better than hand-picking. As a preventive, will dress the trees in winter with the wash recommended below.—**W. W.**

**Dissolving Bones.**—Can you tell me how to dissolve bones for the purposes of manure? and, when dissolved, should the fluid be evaporated or used in the liquid state?—**J. W. N. N.** [Crush the bones, moisten with a quarter of their weight of hot water, and then pour over them half their weight of oil of vitriol. Stir with an old rake till gas ceases to be given off, and allow them to stand for a few days. If not sufficiently dry; add peat, sawdust, or anything else free from lime, for the purpose. The operation is best carried on in a leaden or earthenware vessel, or on the ground within a ring of ashes. Boiled bone or bone ashes answer better than raw bone, being more soluble. 2. Make them into a heap, and keep them moist, and cover with mould or manure. They will ferment and dissolve of their own accord.—**F. W. W. J.**]

**Disease in Pelargoniums.**—The accompanying leaves are from a garden near Winchester, in which neighbourhood the disease has been noticed in several places, and seems to have been increasing for the last three years. It is confined to plants in pots, and the only cure for it yet found none is to turn out the plants into the borders or beds, when in from two to three weeks the diseased leaves fall off and the plants assume a natural healthy appearance. What is the cause of it? and how can it be prevented?—**W. T. T.** [I have carefully examined the Pelargonium leaves for insects, but can find none. The small brown spots with yellow margins, which eventually decay in the centre and leave an opening through the leaf, may arise from insect action, but about this I cannot speak with certainty. The disease, if I may call it so, commences with a small, round, yellow, pellucid spot, which, extending, becomes a brown spot in the centre. This brown spot is the desiccated substance of the leaf, through which all nourishment has ceased to pass. When the brown spot gets much extended, it appears to crack and leave an aperture through the leaf. Was the uninjured leaf from the same plant as the injured one?—**W. W. S. J.**]

**Names of Plants.**—**Equisetum.**—1. The Orchid flowers sent are all forms of the common Orchis maculata. It is well worthy of garden culture, though rarely seen in gardens. 2. We have seen it thrive well as a border plant, growing into large tufts in moist loamy soil; such success was secured by some little care at first. 3. A greenhouse would not be the place for it. Wrapping plants in cotton wool is not a good way to send them. *J. E.*—We cannot undertake to name more than four plants at a time. 1. Indeterminate, from no leaves being sent. 2. *Fumaria officinalis* (Common Fumitory). 3. *Silene inflata* (Bladder Campion). 4. The Wood Moneywort (*Lysimachia nemorum*). *Sanguinea.*—*Hemerocallis flava.* *J. E.*—We cannot undertake to name Roses. They should be sent to some Ross grower who has the means of comparison at hand. *C. Fison.*—The shrub, as well as can be judged from the piece sent, is *Philadelphus hirsutus*, from North America. *Z. G.*—*Echinum vulgare*. *P. and M.*—The names of the Pelargoniums figured in THE GARDEN (see p. 550) are as follows:—The orange-coral variety in the centre is Earl Zealand (Pearson); the ocellate one on the right hand side is Evening Star (George); the salmon one on the left hand is Miss Strachan (Pearson); the magenta-coloured flower on the right hand top corner is Louis (Pearson); and that on the left hand bottom corner is Lais (Denny). *M. W.*—Apparently Common Ragwort (*Senecio Jacobaeae*); *M. M. C.*—Some species of *Pitheopogon* and *Dolichos ligulosus* from the East Indies.

**Vine Insects.**—I enclose two insects which were a great trouble to me when my Vines were first started, as they disfigured the leaves as soon as they opened. Can you give me any information respecting them?—**J. G.** [The long-snouted insect sent is, no doubt, *Hylobius abietis*. It is an insect usually found in Fir plantations, not infrequent in the south of England, but abundant in the northern parts of the country. It would be well if it were shown how this and the following insect injured the Vines by sending an illustration of the mischief done. The expression that the insects disfigured the Vine leaves is very vague. The other insect is one of the spring or click beetles. The larva of some of the species are most destructive to plants, and are well known as wire-worms. The specimen was much crushed, but by carefully examining the pieces I believe they belong to *Athous niger*.—**W. W. S. J.**]

**Dutch Bulbs.**—*Cymro.*—One is about as good as another. We cannot, for obvious reasons, recommend dealers:

### Question.

**Culture of Asparagus.**—I have read with much interest what has been lately written in THE GARDEN on this subject. I have a bed of about twenty-five years' standing, which has this year failed, and my gardener proposes trenching it 2 1/2 ft. deep with layers of manure 6 in. or 8 in., and then transplanting the old plants, after the decayed roots have been removed. He says he has seen it tried, and it gave the greatest satisfaction. Perhaps some of your correspondents can enlighten us as to their treatment.—**A.**

## SOCIETIES AND EXHIBITIONS.

## ROYAL BOTANIC SOCIETY.

JUNE 12.

This, the second summer show of this Society this year, was in every way a good one. The principal features were the banks of Orchids and the miscellaneous collections of new and rare plants from the leading nurserymen, together with well-grown Pelargoniums—both above and below—and there were several fine collections of stove and greenhouse plants.

**Stove and Greenhouse Plants.**—These were on the whole in excellent condition. The best group in the open class came from Mr. Tudgey, gardener to J. G. Williams, Esq., Hawick Grange, Worcester, which consisted of twelve even and well-grown plants, among which were especially noticeable remarkably well-flowered examples of *Allamanda Hendersoni*, *Dipladenia amabilis*, and a plant of *Anthurium Scherzerianum* bearing upwards of thirty large and brilliant blossoms. With these were associated a grand specimen of *Ixora Willmami*, one of the best of *Ixoras* for exhibition purposes, and one which was greatly admired. In the same class Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, Essex, showed a magnificent specimen of *Hedera macrantha*, which was, however, too trimly trained to beset to the best advantage; also fine examples of *Aphexis macrantha* purpurea, and the white and pink *Erica Easoniana*. Messrs. Jackson & Sons, Kingston, had a good plant of *Pimelea mirabilis*, but its blooms were hardly open, and a healthy specimen of *Hedera fuchsoides* well bloomed. In the smaller collections of stove and greenhouse plants, Messrs. Jackson & Sons had a good example of the pink-flowered *Erica kingdonensis*, a garden variety admirably adapted for exhibition purposes; the finest plant of *Clerodendron Balfouri* which we have seen this season, and a good *Flamingo* plant. Mr. B. S. Williams, Holloway, sent a remarkable plant of *Pimelea densata* and a beautiful pink-flowered *Erica*, the name of which did not appear. Mr. Tudgey had a well-grown plant of *Allamanda grandis* beautifully in flower. Mr. Hennell, gardener to F. A. Davis, Esq., Anglesea House, Surbiton, had an excellent plant of the magenta-flowered *Phanocoma prolifera* Barnesi, one of the most difficult of plants to cultivate, but one of the most beautiful when seen in perfection. In the class for groups of stove and greenhouse plants arranged for effect, the competition was not so great as might have been expected, and the plants shown, though well arranged, were mostly of an ordinary character. The best came from Mr. Wheeler, Regent's Park, and consisted of healthy well-flowered plants of *Clerodendron Balfouri*, *Heaths*, &c. Interspersed among these were *Fuchsias*, *Colenses*, and *Dracenas*, the whole being backed up by healthy *Palms* and edged with *Begonias* and *Maidenhair Ferns*. Mr. Ford, gardener to J. G. Meegaw, Esq., Norwood, had an equally good collection in the same class; the plants were all well grown, and not quite so closely crammed together. Among them were noticeable fine specimens of *Dieffenbachia picta*, *Crotoms*, and *Caladiums*, backed up by column-like plants of golden-leaved *Fuchsias*, and edged with *Mosses*, *Grasses*, *Fittonias*, and other fine-foliated plants.

**Orchids.**—These occupied a prominent position in the show, and proved the greatest source of attraction, the finest display of the year being here on this occasion. The best groups in the nurserymen's classes came from Mr. B. S. Williams, who had finely-flowered plants of *Laelia purpurata*, *Odontoglossum vexillarium*, associating effectively with the brilliant scarlet *Epidendrum vitellinum majus* and the white-flowered *Calanthe veratrifolia*. The same exhibitor had also a healthy plant of the beautifully-marked *Cypripedium superbiens*, bearing twenty large flowers, and the curious *Nanodes Medusa*, which is seldom seen in flower. In the amateurs' classes, the best groups came from Mr. Denning, gardener to Lord Lonsborough, Norbiton, who had a plant of *Anguloa Clowesi*, furnished with over twenty large, golden, cup-shaped blossoms; *Odontoglossum Alexandræ*, with eight spikes of large, delicately-tinted flowers; and the gorgeously-flowered *Cattleya Warneri*, bearing nine remarkable blossoms. With these were associated grand examples of the beautiful *Vanda Boxalli*, *Dendrobium Bensoniæ*, and *Laelia cinnabarina*. Mr. Douglas, gardener to F. Whitbourne, Esq., Loxford Hill, Iford, had magnificent plants of *Madeoella Harryana*, *Odontoglossum Alexandræ*, the beautiful white-flowered *Thunia Marshalli* bearing over thirty waxy blossoms, and a specimen of *Cattleya Warneri* with nearly twenty unusually large and gorgeously-coloured flowers. The same exhibitor had also well-bloomed examples of *Dendrobium formosum giganteum*, *Cypripedium spectabile*, and *Odontoglossum crispum*. Mr. Salter, gardener to W. Cabb, Esq., Silverdale Lodge, Sydenham, had a grand example of the chocolate-flowered *Oncidium*

*crispum grandiflorum*, *Odontoglossum vexillarium* with nearly forty large delicately-tinted blossoms, a made-up potful of *Dendrobium anavisium* containing several dissimilar varieties, and *Odontoglossum Alexandræ* furnished with fourteen spikes of flowers. Mr. Heims, gardener to F. A. Philbrick, Esq., Regent's Park, had fine plants of *Sobralia macrantha*, *Aerides Schroderi*, and *Saccolabium Holfordi* furnished with long racemes of well-coloured blossoms. The same exhibitor also sent out blooms of the curious *Stanhopea tigrina*, which attracted much attention. Mr. Child had a remarkable plant of *Cypripedium Stonei* and *Oncidium ampliatum majus*.

**New and Rare Plants.**—Excellent groups of these were shown by the leading nurserymen. Messrs. Veitch & Sons had a collection which attracted much attention. Noticeable among other fine plants were good examples of *Adiantum Luddeemannianum*, the showy-leaved *Abutilon Sellovianum marmoratum*, finely-coloured examples of *Phyllanthus roco-peto*, plants of *Hemantthus Kalbreyeri* (bearing noble heads of scarlet blossoms), remarkable plants of *Acalypha muscica*, the brilliant-flowered *Scutellaria Moccasinæ*, choice *Crotoms*, *Begonias*, insectivorous plants, and the yellow-flowered *Madeoella Davisii*. Opposite this collection was one from Messrs. Laing & Co., Forest Hill, and consisted of new *Begonias* (with marvellous flowers), *Gloxinias*, variegated *Crotuloids*, and *Colenses*, backed up by graceful *Palms* and fine-leaved *Dracenas*. Mr. Bull had a very attractive group, consisting of finely-flowered plants of *Odontoglossum Alexandræ*, *O. vexillarium*, *Cattleya Mendellii*, fine-leaved *Anectochilus*, *Hemantthus cinnabarina*, and *Colognyne corymbosa*, tastefully disposed among light *Ferns*, and backed up by noble-leaved *Palms*, *Dieffenbachias*, *Alocasias*, and *Crotoms*. Mr. Williams had a collection which attracted much notice. In it were Pitcher-plants, fine-leaved *Yuccas*, well-flowered plants of *Blandfordia grandiflora*, new *Colenses*, *Dendrobium Galdieannum*, the silver-leaved *Nothochloa Eckloniana*, *Clerodendron Falax*, and *Liliums*.

**Pelargoniums.**—These were both numerous and good, and formed one of the most showy banks in the exhibition. Mr. Turner, of Slough, had well-grown plants of the choicest kinds, among which were the white *Clarel*, Prince of Prussia, the rosy-coloured *Ruth*, the rich dark crimson *Senator*, and the brilliant rose-pink *Ambassador*. Mr. James, gardener to F. Watson, Esq., Redles, Isleworth, had very large and well-flowered fresh specimens of *Bine Bell*, *Snowflake*, *Statesman*, and *King Charles*. Mr. Bones, gardener to D. McIntosh, Esq., Romford, had likewise excellent plants, but their blooms were hardly open enough. They consisted of the dark *Chieftain*, *Victory*, *Maid of Honour*, and other good kinds. The best *Fancies* came from Mr. Turner, in whose collection were noticeable *delicatun*, *Nelly Fordham*, the beautiful lavender-pink *Lady Carington*, and the magenta-coloured *Shah*—excellent kinds for show purposes. Messrs. F. & A. Smith, of Dulwich, sent baskets of plants of seedling show *Pelargoniums* of an attractive description, many of the kinds being beautifully striped, and possessing colours rarely seen in *Pelargoniums*. Mr. Turner also sent several new and attractive kinds, among which were noticeable—*Silvio*, a brilliant crimson flower, the upper petals being blotched with dark crimson; *Captivation*, a very dark kind named *Devastation*; and a kind having unusually large flowers with bright pink, recurved petals, the upper ones being of a rich velvety-crimson, the centre being pure white. All these were much admired, and are well worth adding to any good collection. Mr. Levesley, Isleworth, also sent several attractive striped kinds likely to be valuable for market purposes. The Rev. A. Matthews, Gunley, Leicester, also sent a magnificent kind named *Henry*, the flowers being very large and well formed, and of a brilliant crimson color, the centre being white; the same exhibitor also sent other good kinds. Mr. William Bull likewise sent a show *Pelargonium* named *Triumphans*, which attracted much attention on account of its ornamental, deeply-cut foliage, and its purple and magenta-coloured blossoms; quite a new colour in *Pelargonium*. Zonal *Pelargoniums* were well shown by Mr. Catlin, gardener to Mrs. Lermite, Finchley. The plants were nearly 6 ft. in diameter, and full of bloom. The best scarlet was *Corsair*, the best rosegay *Thomas Adams*, and a good salmon-coloured flower was *Band*.

**Heaths.**—These were well shown by Messrs. Jackson & Sons, who had a fine plant of *Erica verticosa Bothwelliana*, furnished with remarkably large clusters of waxy pure-colored blossoms; *E. tricolor rosea* and *E. ampullacea obtusa* were also in excellent condition. Mr. Tudgey had an unusually bright-flowered young specimen of *E. verticosa grandiflora*, and Mr. Child had a well-flowered young specimen of *E. odorata rosea*. Mr. Hennell had an excellent specimen of *E. verticosa magnifica*, and a vigorous healthy young plant of *E. Cavendishi* furnished with long racemes of brightly-coloured blossoms. Mr. Donald had excellent examples of *E. Candolleana* and *E. tricolor Lindeni rosea*.

**Fine-foliaged Plants and Ferns.**—These occupied the recesses in the tent, and effectually toned down the bright colours of the stove and greenhouse plants, near which they were arranged. Mr. Rann, Handcross Park, had remarkably fine specimens of *Croton undulatum*, C. Weismanni, and *Dasylirotum glaucum*, backed up by gigantic specimens of *Cycas circinalis* and C. *revoluta*. Mr. Donald, gardener to J. Barclay, Esq., had fine examples of the Weeping *Croton angustifolium* and a well-grown *Yucca aloefolia*. Mr. B. S. Williams had well-grown specimens of *Pandanus Veitchii*, *Dasylirotum acrotrochium*, and *Cocos Weddelliana*. Mr. Child had fine examples of *Geonoma Verschaaffii*, *Latania borbonica*, and *Croton Weismanni*. Messrs. Hooper & Co., Covent Garden, had a fine plant of *Dracaena Shepherdii*, the most beautifully-coloured plant of *Croton undulatum* which we have yet seen, and *Matepe odulia*. Mr. B. S. Williams sent a much admired group of Ferns, consisting of healthy examples of the Australian Bird's-nest Fern (*Asplenium Nidus*), *Todea africana*, and *Trichomanes radicans*. Among these were fine Tree Ferns, consisting of *Cyathea Burketi* and other valuable kinds, also *Gleichenia Spelunca*, and *rupestris*. Mr. Douglas had an excellent group of Ferns, in which were beautifully fresh examples of *Todea pelucida* and *T. superba*, *Gymnogramma Sauchiana*, *Gleichenia Spelunca*, the bronzy-green *Davallia divaricata*, and the lace-like *Pteris acubarda*. Mr. Rann had large specimens of *Cyathea dealbata*, C. *Dregii*, and *Gleichenia Spelunca*. Mr. Donald showed well-grown specimens of *Alouphia exelsa*, *Diokomia antiochia*, and an elegant example of *Davallia Mooreana*. Mr. Tudgey had *Cyathea dealbata*, *Cibotium Regeli*, and C. *medullaris*.

**Miscellaneous Plants.**—Messrs. Carter & Co., High Holborn, had an extensive and attractive group of miscellaneous plants edged with boxes of coloured-leaved plants used for carpet bedding. In this group were good examples of *Casuarina sumatrana*, *Adiantum Farleyense*, Bird's-nest Ferns, tuberous-rooted *Begonias*, finely-coloured *Crotone*, *Dracaenas*, and cut-leaved *Acers*. Messrs. Low & Co., Clapton, sent baskets of Orchids, which were much admired. In them were remarkably well-coloured varieties of *Dendrobium Bensoniae*, D. *suavisissimum*, and *Vanda cerculescens* Boxalli. Messrs. E. G. Henderson & Sons, Pine-apple Place, sent cut blooms of *Antherium Liliarium majus* of great beauty, also blooms of *Pyrethrus* and *Irises*. Messrs. Osborn & Son contributed a collection of Palms and other fine-leaved plants, among which were finely-coloured *Acalyphas*, *Marantas*, and *Pandanias*. Messrs. Wm. Paul & Sons sent blooms of old-fashioned Roses, which attracted much attention; and Mr. Parker, Tooting, showed an extensive collection of cut blooms of *Irises* and *Paeonies*. *Paeonies* of a meritorious description were sent by Messrs. Laing & Co. Mr. Cannell had brilliant blooms of *Zonal Pelargoniums* and *Verbenas*, and Mr. Douglas sent a dwarf *Ageratum* named J. Douglas; the plants were not more than 6 in. high, bushy, and covered with bright blue blossoms. Mr. Marchant, Isleworth, sent very attractively-striped single *Petunias*.

Messrs. Carter & Co.'s exhibition of annuals proved a source of interest. The plants, consisting of many thousands, are arranged in the glass corridor adjoining the conservatory; they are not so well grown as could have been wished, but their flowers are bright and effective, and well worth inspection.

Mr. Anthony Waterer's annual show of *Rhododendrons* was also at its best on this occasion. The plants, which are well bloomed, are admirably arranged, and form a source of great attraction.

**Certificates of Merit** were awarded as follows:—

Mr. W. Bull, for *Bowenia spectabilis serrulata*, *Adiantum tetraphyllum gracile*, *Doodia aspera multifida*, *Aralia venusta*, *Coffea liberica*, *Macrozamia Mackenziei*, *Echinocactus cylindraceus*, *Zamia Lindenii*, *Kentia rupicola*, *Coccoloba corymbosa*, *Croton Rex*, *Dracaena vivicans*, *Dieffenbachia Cordieri*, *Cibotium chamissoi*, *Gloxinia Duc de Cazes*, and G. *Mdlle. Angelina* Martin.

Messrs. Veitch, for *Cyrtipedium superciliosum*, *Aloesia Thibautiana*, *Begonia Daviei*, B. *Duchess of Teck*, B. *Symetry*, *Croton Challenger*, C. *Hanburyanum*, *Macrozamia Mackenziei*, *Davallia elata*, D. *fijensis*, *Sarracenia Chelsoni*, *Xerozema Moorei*, *Bollea colostis*, *Cattleya tricolor*, C. *Mardelli*, *Zygopetalum Lindenii*, and *Gloxinia Unique*.

Mr. B. S. Williams, for *Areca lapa*, A. *purpurea*, and *Nephrodium exensum*.

Messrs. E. G. Henderson & Son, for *Dactylis glomerata longissima* anrea and *Saxifraga valdensis*.

Mr. E. Holmes, Wellington Nursery, for *Juniperus virginiana* albo spica.

Messrs. Rollison and Sons, for *Erica obtata* exposita.

Rev. A. Mathews, for Show *Pelargoniums* Douglas, Osman, and Henry.

Mr. C. Turner, for Show *Pelargoniums* Illuminator and Criticron.

Mr. J. Levesley, for *Pelargonium Rose* Levesley.

Messrs. J. Laing & Co., for *Begonia* Baron Leguay and *Pierceli vitellina*.

Mr. Robert Parker, Tooting, for *Iris Darius*.

## MANCHESTER HORTICULTURAL EXHIBITION.

JUNE 7.

THE Manchester Society has again reason to be well satisfied with the exhibition brought together under its auspices this season, collectively, it is a fine one, though perhaps not quite equal to some that have preceded it as regards extent. It however possesses the essential feature of an absence, with few exceptions, of inferior productions. It is not to be wondered at that the large shows throughout the kingdom do not come up, as regards the quality of the exhibits, to what they once did, for although the numbers of plants grown now are no doubt greater than formerly, yet exhibitors of plants have not increased in proportion to the increased number of exhibitions. The exhibition house and the new annex had both a fine appearance on this occasion, and there was a large display of horticultural requisites in the shape of greenhouses, boilers, and almost everything required for garden purposes, the merits of which were closely scanned and commented upon. It is impossible within our prescribed space to notice all the fine plants and flowers shown; consequently, we have been obliged to confine our remarks to the most meritorious, and to give a list of the prizes in our advertising columns. Stove and greenhouse plants were well represented; the flowers were all fresh and beautiful, and the plants had that healthy appearance which is the best characteristic of good cultivation. Mr. Shuttleworth, Howick House, Preston, took a decided lead with plants not over large but generally well flowered and possessing the variety of colour indispensable to effect. Amongst them was a noble *Anthurium Scherzerianum*, bearing nearly forty very large blooms; *Statisia profusa*, some 4 ft. across, densely ornamented with its beautiful bluish-lilac flowers; two plants of *Ixora coccinea*, well bloomed; a grand *Primula mirabilis*; the glowing crimson *Azalea Holfordi*, profusely flowered; *Alamanda nobilis*; and *Franciscoa confertiflora*. Mr. E. Pilgrim, Cheltenham, also had a fine example of *Anthurium Scherzerianum*, a very large and finely-bloomed *Dendrobium* noble, *Azalea Souvenir de Prince Albert*, a strikingly handsome kind; and *Pimelea decussata*. In the amateurs' class for sixteen plants, Mr. Pilgrim stood in the foremost rank with plants profusely flowered and in unexceptionable condition, the most meritorious being *Erica tricolor impressa*, the orange-red *Ixora Williamsii*, *Hederaea tulipiferum*, well bloomed and finely coloured *Stephanotis floribunda*, and one of the best forms of *Pink Everlast-ing*. Amongst his fine foliaged plants were a grand *Pritchardia pacifica*, one of the finest of all Fan Palms; *Cycas circinalis*, and the variegated New Zealand Flax. Mr. Samson, Bowdon, had larger plants, but they were not so even in quality. In the nurserymen's class for fifteen stove and greenhouse flowering plants, Messrs. Cole, of Withington, showed much smaller plants than they usually exhibit; *Azaleas* Charmer and *Duc de Nassau*, both deep crimson, were the best examples, both being unsurpassed by any other varieties of the same colour. Mr. T. A. Bircley exhibited a varied and well managed group of fine foliaged plants. This exhibition is always noted for its Ferns, but on no occasion here or elsewhere do we recollect seeing such a splendid group as that shown by Mr. Hubberstey, gardener to O. O. Wrigley, Esq., Bury; his *Gleichenia Spelunca*, G. *flabellata*, and the scarce G. *Mendellii* were not less than from 6 ft. to 8 ft. through, by 6 ft. high, and alike remarkable for their clean and faultless condition; *Davallia polyantha* was 7 ft. across, and *Cibotium princeps*, C. *Schiedei*, and *Cyathea dealbata* were fitting companions both in size and condition to the foregoing. Mr. Lingard showed comparatively small, but really well grown plants. Palms were well shown by Mr. Smith and Mr. Corfield. The groups of miscellaneous plants well exemplified the better effect that can be produced by associating flowering and ornamental leaved plants together than by keeping them in distinct classes. Mr. Smith staged a good collection, conspicuous in which was one of the finest specimens of *Nepenthes Hookeri* that has yet been produced. It bore some thirty large, highly-coloured pitchers, and was otherwise in excellent condition. This group also contained other equally good fine-leaved subjects. Mr. MacKellar, gardener to Jas. Watts, Esq., Cheshire, had, amongst others, a very handsome *Acrophylum venosum*, and several grand plants of the beautiful *Yucca filamentosa variegata*. Three pots of *Lilium auratum* were shown by Mr. Fildes, Stretford. Heath and *Pelargoniums* were shown in considerable numbers, the latter being much better grown and flowered than such as are generally met with. Roses in pots were not nearly so good as those shown lately by Messrs. Turner & Paul, the weather having rendered it impossible to keep the plants back for this exhibition. In the amateurs' class were good examples of *Mario Baumann* and *Baroness Rothschild*. The prizes for hardy *Rhododendrons* were well contested, and the plants good and well flowered. Those who have never seen a Manchester exhibition can form little idea of its extent. As regards Orchids, it is no exaggeration to say that all those shown at metropolitan exhibitions during a season would not equal the

display here. In the class for 15 (amateurs) Mr. Hubberstey had some fine plants, uniformly large in size, and profusely flowered. *Masdevallia Harryana*, 2½ ft. across, bore some 120 large, highly-coloured, fully-expanded flowers; *M. Lindenii* was equally large and perfect; *M. sanguinea* was furnished with eighteen fine blooms, indescribable as regards colour; *Dendrobium Schroederi* had fourteen large drooping spikes; *Anguloa Clowesi* bore forty open blooms and A. Turneri thirty-four; *Odontoglossum vexillarium* was furnished with ten or twelve racemes; *Cattleya Warneri* with thirteen gigantic blooms, the petals of one, which was measured, being 3 in. across; *Vanda swavis* (Veitch's variety) had twelve spikes; *Thunia Marshallii* had eight spikes, and *Cypripedium Veitchii*, *C. niveum*, and *C. villosum* were all good; and last, but not by any means last in merit, was the old *Calanthe veitchii*, crowned with some thirty-five panicles of snow-white flowers. Mr. Mitchell, gardener to Dr. Ainsworth, Manchester, was second, and there also were good plants in the other collections. Of single Orchids Mr. Bolt contributed a grand example of *Saccolabium premorsum*, bearing six spikes, the largest 2 ft. in length. In the classes for nurserymen Mr. B. S. Williams was first for both twenty and ten, the two collections forming together such a group as one rarely sees from one establishment. Of *Filmy Ferns* Messrs. Standish & Co., Ascot, showed a grand group, in which *Todea superba*, *T. pellucida*, *Trichomanes radicans*, and *Hymenophyllum domissum* were large and fine. In the open class for Nepenthes, Sarracenias, &c., Mr. Hubberstey was deservedly first. Collections of plants arranged for effect were shown by Messrs. Caldwell and Messrs. R. P. Kerr & Sons, Liverpool. Messrs. Rollison contributed eighty Alpine and herbaceous plants, the whole making an admirable group in fine condition. Mr. B. S. Williams and Messrs. Rollison showed new and rare plants, and both exhibited large collections of miscellaneous flowering and fine-foliaged plants. Mr. Boller had a collection of Succulents similar to that for which he lately received a Banksian Medal at South Kensington. Fruit was fairly well shown in moderate quantity. Mr. Miles, gardener to Lord Carington, had a collection in which were good Foster's Seedling and black Grapes, a Queen Pine, very fine Black Circassian Cherries, a beautiful dish of Brown Turkey Figs, Peaches, Nectarines, and a couple of Melons; Mr. Banerman, gardener to Lord Bagot, was second. The best two bunches of white Grapes came from Mr. Banerman, who showed Backland Sweet-water. Mr. Green, gardener to J. Warrington, Esq., Barnsley, had Tynninghame Muscat. The best two bunches of black Grapes came from Mr. G. Smith, who had well-coloured Black Hamburgs. Twelve excellent pots of Strawberries were shown by Mr. Hinds, Otterpool; the sort was Sir C. Napier. Mr. Smith had President.

### ROYAL HORTICULTURAL SOCIETY.

JUNE 10.

The idea of holding a show on Whit Monday for the poorer classes of London was a good one, and, as far as can be judged, answered the expectations of its promoters. The wet weather no doubt kept many people away, but during the afternoon thousands of visitors entered the gardens. The exhibits were arranged in the Society's large tent, and although it was not filled, it nevertheless contained a large number of plants. The best collection of plants in the market growers' classes came from Mr. John Reeves, Acton, and occupied a prominent position. It consisted of well-grown pot Roses, Fuchsias, show Pelargoniums, blue and pink Hydrangea, *Lilium candidum*, *L. longiflorum*, and fine, dwarf, well-flowered plants of *L. aratum* and *Saxifrage nepalensis*; these were intermixed with Palms, Japanese Acera, *Ficus elastica*, *Dracaena*, and other fine-foliaged plants, all of which combined to make a very attractive group. The same exhibitor also showed baskets of plants of the dark crimson semi-double-flowered Pelargonium Dr. Masters in order to show its suitability for market purposes. It has an excellent habit, and its flowers last for a longer time in perfection than those of any other show Pelargonium grown for market. Messrs. Hayes, Edmonton, contributed banks of scarlet Pelargoniums and a fine group of miscellaneous flowering plants, in which were remarkable examples of Hydrangeas. Masses of *Calceolarias*, Fuchsias, Musk, and similar subjects were also shown by other market growers, and the brilliancy of so many plants in flower was toned down effectually by means of groups of ornamental-leaved plants from Messrs. Osborn & Sons, Rollison & Sons, and Mr. B. S. Williams. Messrs. Radclyffe & Co. sent examples of window boxes, Fern cases, and a rockery furnished with Ferns and miniature fountains, &c., all of which attracted much attention. Messrs. Barr & Sugden showed out blooms of Irises, and Messrs. Smith, Dulwich, seedling Pelargoniums. Spaces which would otherwise have been vacant were filled with plants from the Society's garden at Chiswick. The number of visitors was 15,763, of whom 15,558 paid for admission.

### HORTICULTURAL PROGRAMME FOR THE PARIS EXHIBITION.

JUNE 1 to 15.—3rd of Series of Horticultural Shows, viz.:—Orchids and Pelargoniums, Hothouse and Greenhouse Plants, Open-air Ligneous Plants, Roses, Forced Vegetables and Fruits. June 16 to 30.—4th of Series of Horticultural Shows, viz.:—Roses, Palms, and Pelargoniums, Orchid, Hothouse, and Greenhouse Plants, Open-air Herbaceous Plants, Vegetables of the Season, Exotic and Indigenous Fruits, &c., &c.

Trial of Agricultural Implements (3rd Series), viz.:—Machines and Implements for dealing with Hay. Trials of Agricultural Implements (4th Series), viz.:—Machines and Implements used for Harvesting, in June and July.

July 1 to 15.—5th Series of Horticultural Shows, viz.:—Pelargoniums, Gloxinias, &c., Hothouse and Greenhouse Plants, Orchids, Open-air Plants, Vegetables of the Season, Fruits, &c. July 16 to 31.—6th Series of Horticultural Shows, viz.:—Hothouse and Greenhouse Plants, Gloxinias, Open-air Plants, Ornamental Ligneous Plants, Fruit Plants, Vegetables of the Season, &c.

August 1 to 15.—7th of Series of Horticultural Shows, viz.:—Fuchsias, Gladioli, Hollyhocks, Climbing Plants, Dahlias, Phloxes, Fruits, Vegetables in Season, &c. August 16 to 31.—8th of Series of Horticultural Shows, viz.:—Arads and Ferns, Hothouse and Greenhouse Plants, Annuals, Bulbous Plants, Vegetables, Fruits, &c.

Trial of Agricultural Implements (5th Series), viz.:—Machines and Apparatus for decorating Cereals and other Plants, and for the Preparation of Food for Domestic Animals, in August.

September 1 to 15.—9th of Series of Horticultural Shows, viz.:—Dahlias, China Asters, Hothouse and Greenhouse Plants, Tea Roses, Fruits, &c. September 16 to 30.—10th of Series of Horticultural Shows, viz.:—Aralias, Dracaenas, Large-foliaged Plants, Fuchsias, Chrysanthemums, Cut Roses, Vegetables, Fruits, &c.

October 1 to 15.—11th of Series of Horticultural Shows, viz.:—Fruits of all kinds, Chrysanthemums, and Vegetables of the Season, &c. October 16 to 31.—12th of Series of Horticultural Shows, viz.:—Vegetables, Shrubs, Chrysanthemums, &c.

**Rooting Banyan Trees.**—The mention of the Banyan of India (see p. 528) reminds me of the noble tree which I remember admiring so much in the Calcutta Botanical Gardens. It was, indeed, a sight to see; but I believe that it was fearfully reduced and injured by the cyclone of (I think) 1867. I saw it some ten years before that date, and, when speaking admiringly of it to an old Indian acquaintance, he told me that a root-drop can be produced in the Banyan tree by suspending a "chatti" (an earthen vessel) full of water close beneath one of the branches. Can any of your readers corroborate this? My informant seemed to have no doubt whatever of its being a fact.—*ASHLEY LATOUCHE, 63, Warwick Street, Liverpool.*

**Laburnum Bloom.**—In reference to Mr. Groom's note on this subject (see p. 560), allow me to say that with us the Laburnum bloom is this year unusually abundant, although it is suffering considerably from the excessive wet weather that we are experiencing. Indeed, most of our lardy trees and shrubs have bloomed well this year; the Yew was literally a mass of bloom. Genas were also full of blossom. The Lilac was a complete sheet of flowers, which were, however, quickly wrecked by the frosts in the latter end of May, and the subsequent want of sunshine. Rhododendrons have also bloomed well, but from the causes just named their blossoms have never been seen to advantage.—*TYNEDALE.*

**Late Apples.**—As Mr. Groom and Mr. Fish have spoken so highly of the Norfolk Beefing, it may not be out of place at this season of the year to name a few others that are keeping equally well here, viz. Hanwell Souring, South Carolina Pippin, Harrison's Anne Elizabeth, and last, but not least, a kind unnamed, but which I believe to be "Enameled." Be that as it may, it is the best keeping serviceable Apple with which I am acquainted, and one which should be made known to all lovers of late-keeping fruit.—*T. SHINGLES, Tortworth Court, Gloucestershire.*

### OBITUARY.

Mr. George Wheeler, of the Warmister Nurseries, well known throughout England for his knowledge of hardy plants, expired at his residence on Friday evening last, June 7. He was in his eighty-seventh year, and till recently, though much enfeebled, led a very active life. His loss will be sincerely felt, for he was a good master and altogether an excellent man, as all who ever had business transactions with him will aver.

**Coluseses Out of Doors.**—Amongst soft-wooded plants now being speedily planted out, few deserve more attention than the Coluseses, owing chiefly to their rich and varying colours, which contrast so strongly with either white or green-foliaged plants. Some few varieties, such as Duchess of Edinburgh, Jewel, Bausei, &c., require a little more care than the others; but, when fairly established, nothing can look more lovely than the different tints of Coluseses, which, as regards softness and beauty, are unrivalled. For a dark variety, Napoleon III. stands unsurpassed, its leaves being nearly black, whilst it grows as freely as *C. Verschaffeltii*.—*J. PEARCE, St. John's, Worcester.*

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### EARLY PEACHES.

THERE is at present a great advance in so-called early Peaches, that is, Peaches ripening some three or four weeks before the old representative sorts, to wit, the Noblesse and Royal George. One of the finest of these early varieties is Hale's Early, of which I send you a specimen gathered from a tree forced by artificial heat and ripe, while the Royal George, and others under the same conditions are still hard and very faintly tinged with colour. The importance of this attribute of early ripening cannot be well over-estimated, as a great saving of fuel is effected, and thus one of the principal sources of expense in forcing is lessened. Hale's Early originated in America, and is included in Downing's "Fruits and Fruit Trees" of that country, edition 1869, but it is not mentioned in the edition of 1850. It was first distributed under the name of Early German. Whether forced or grown on walls it has here always proved a good and profitable sort, although not what is called a free bearer; the fruit is handsome and good flavoured, and has the merit of being very equal in size, colour, and taste.

The Early Rivers' Peach is, I think, perhaps the finest early Peach in existence when in perfection, but, unfortunately, the fruit has a tendency to crack at the stone, and when this defect occurs all flavour departs. I have thought that, as this evidently is produced by imperfect fertilisation, that a remedy may be found by using the pollen of those sorts which produce it more abundantly, and, to a certain extent, I think I am right; but I must add that the remedy is not complete, as this season almost every stone is perfect, although not artificially fertilised, and I am quite at a loss to account for this fact. Of one thing I am sure, and that is, that when bees are plentiful and at work in early spring—the time during which Peaches are in bloom—a heavier crop of stoned fruit may be expected; for, when not thoroughly fertilised, more fruit will drop during stoning; the fruit will drop, to speak practically, not because of the inability of the tree to ripen it, but from the fact that the blooms have not been perfectly fertilised. All the early Peaches, in which I include Early Beatrice, Early Louise, Early Rivers, Hale's Early, Early York (Rivers), Early Victoria, Early Alfred, Condor, and the Early Grosse Mignonne, may be grown in pots in an orchard house, and moved out to ripen their fruit, the removal to the open air being deferred until the weather is thoroughly settled, warm, and genial, and they should be carefully returned to their glass home in October. In order to give strength I should advise perforated pots being used, and the trees plunged in a border of light, well-drained soil, the perforations in the pots being covered by the soil. A light wire framework should be attached to the orchard house, to prevent the trees being injured by birds, and also to break the force of the wind. A wire house of this kind, which will not cost more than a poultry-pen, will make a pleasant promenade, and may be used not only for Peaches, but for Plums, Pears, and Apples, which, when sheltered in the spring, will amply repay the cost of their shelter four years out of five.

T. FRANCIS RIVERS.

*Sawbridgeworth.*

### VINE GROWING IN POTS.

WHAT becomes of the thousands of Vines grown in the London and provincial nurseries is a wonder even to the trade itself. Having the accommodation, I grow my own, very much like cutbacks, as the nurserymen term young Vines from eyes. My Vines for fruiting in 1880 are from 12 in. to 15 in. in height; these we shift out of 8-in. pots into 6-in. ones. They are grown without bottom-heat on the curb-stones of Pine and Cucumber pits, well ripened and cut back when the foliage drops. Those

for fruiting next season are now full grown (about 7 ft. high), and are ripening their wood. We commence forcing early in October, without any bottom-heat, and very steadily, the thermometer never being over 43° or 50° during the night until the young canes break. These, in consequence of being early and well-ripened, break with as much regularity as permanent Vines in the Vineries. Disbudding begins almost as soon as they break; at least, one-half of the buds are removed at once, and then we wait until we can see which are going to be the best bunches, when we thin them until about six bunches are left on each plant. Black Hamburgs, Foster's Seedling, and Trebbiano are the varieties chiefly grown here, on account of their being both good growers and also good setters. I see no reason why bunches not required should be allowed to set and grow. When thinned a top-dressing of rich soil is given them enclosed in a narrow strip of turf, which is put round the pots. We have this season fruited several plants of Golden Queen, and a very good pot Grape it makes, much better than when grafted on Hamburgs or other permanent Vines. The true Trebbiano is my especial favourite for pots. It has not the flavour of a Muscat, nor the size of berry of a Gros Colman, but it has a true amber colour and the freshness of a Sir Charles Napier Strawberry. Just now (June 11) I have grand examples of this variety. Two houses are yearly occupied with Vines in pots, and these, besides giving us our first ripe Grapes, are afterwards utilised for the growth of Melons, Cucumbers, and Tomatoes.

R. GILBERT.

*Burghley.*

**The Weather and the Fruit Crops.**—The rainfall here in May has been excessive; the rain gauge registered 5.33 in., which is more than that which fell during January, February, March, and April. Since June has come in, and up to this date (the 17th) 2.18 in. more have fallen, making the rainfall in forty-eight days 7.51 in. All strong soils are therefore soddened with water, and the temperature, being very low for the season, vegetation has made but slow progress, and, unless dry warm weather sets in soon, the season will be a late one. Conditions like these have had an unfavourable effect on the fruit crops, for aphides, blights, and other diseases have injured the foliage and young fruits, especially those of Apples, Plums, and Cherries. The tips of the young shoots on Gooseberries and Currant bushes are likewise curled through the attacks of aphides, and unless clipped off the fruit will be blackened with honeydew. The prospect of a good fruit year is not likely to be fulfilled, but there will not be such a scarcity of some kinds as last season. The Strawberry crop is making very slow progress in swelling and ripening, and warm dry weather is now much wanted to give the fruit colour and flavour. I have about 500 plants in pots in frames where they have not been forced, and they are now yielding good dishes. The sorts consist of British Queen, James Veitch, Dr. Hogg, and President, and the berries are of good size and flavour. I am afraid, should summer heat set in with the present saturated state of the soil, that the fungus will be developed on the early Potato crop. It is generally about the middle or end of July before it appears virulently in the early sorts in warm, wet summers, but this year, the weather being so exceptionally wet, it may appear sooner.—W. TILBERT, *Walbeck.*

**Roots of Fruit Trees too Deeply Buried.**—If "An Amateur" is disinclined to follow Mr. Hobday's advice (see p. 576), he might try the effect of merely removing the whole of the soil down to the level of the highest principal roots at the distance of, say, 1 ft. from the collar, and then filling in with 4 in. or 5 in. of earth taken from another part of his garden where ordinary vegetable crops only have been grown. If the whole, or a part of it only, could be obtained from a Grass field, all the better. The effect of this would probably be considerable for a few years, unless the evil complained of arises from over-insurance, in which case Mr. Hobday's remedy should be applied at once; and perhaps if only half of each tree had its roots pruned now, and the operation on the other half deferred for a time, that might suffice. It would certainly have the effect of restoring partially the productive element, and might, in "Amateur's" case, be a safer course.—B. S., *Uppingham.*

**Fruit Prospects in North Durham.**—Since I last wrote on this subject (see p. 558) our prospects of an abundant crop of fruit have sadly diminished. The long continuance of dull, cold, and rainy weather has prevented the general crop of Apples and Pears from setting, and those which did appear to be set have, from some cause or other, mysteriously dropped off. This may have occurred from the soil being cold and soddened, or through the great want of sunshine last summer and autumn preventing the buds from

being properly developed. However that may be, the fact remains that the apparently perfectly set fruits drop off without any warning. Plums, however, on walls appear to be going on all right, but the critical time for them has not yet arrived; on standard and pyramid trees they are not such a heavy crop as I thought they would have been. Cherries, particularly Morellos, are a good crop. Black Currants have further suffered since my last note on this subject. Nothing looks so well at present as Strawberries and Raspberries, and should the former not "go blind," there will be an abundant crop. It would, I think, be useful if cultivators would take notes of such Apples and Pears as have withstood the present unfavourable season; such notes, if made public, would be productive of good results. In reference to Apples, I may add that in our district, where the soil is suitable, no Apple appears to do so well, and bear such good, continuous crops, as the Hawthoruden.—TYNE-DALE.

**Lilies in the Wild Garden.**—Mr. G. F. Wilson, long known for his successful cultivation of Lilies in the garden, is now making a very interesting experiment with them in the wild garden. He has enclosed a piece of wood in which vegetable soil, the accumulation of ages, is deep, and in it planted a variety of Lilies without any preparation beyond that of digging up the natural soil. They are planted in groups and masses, and, so far as can be yet judged, they are doing very well indeed. There is no doubt that many Lilies will succeed better under such conditions than in bare borders, in which they are often planted. The effect also will be very fine when the plants flower amongst the Braeken and trees. This is one of the many ways in which hardy plants can be shown to greater advantage than in the mixed border.

**Trapa natans.**—This interesting aquatic is growing and fruiting freely in the Victoria tank at Kow. Cultivated in the open air the radiating clusters of triangular, toothed leaves assume a deep coppery colour, and the plants rarely flower, or if they do produce flowers the fruits do not come to perfection. At Glasevine, however, it succeeds admirably in the open air, but the water in which it grows is slightly heated by the overflow from the Victoria tank. Figures of a plant of this species and its fruit will be found in THE GARDEN, Vol. III., pp. 209 and 211, whilst an illustration representing the Chinese gathering Ling (*Trapa bicornis*) is given on p. 214 of the same volume. The stalks of the leaves are each furnished with a float-like swelling (much resembling that seen in many sea-weeds), which serves to buoy up the plant. It has been stated that a large portion of the food of the ancient Thracians was furnished by *Trapa natans*, and *T. bispinosa* (the Singhara Nut) is at the present day a most important food plant to the inhabitants of Cashmere. Dr. Royle affirms that it yielded as much as £12,000 a year revenue to the Government of Runjeet Singh, the tax being levied upon from 96,000 to 128,000 ass-loads from the great lake of Ooller.—N.

**Pansies from Bath.**—That the climate of the north suits Pansies best most people will agree, but that they can also be grown well in the south is proved by the fact that Messrs. Hooper, Bath, in competition with northern growers, carried off the first prizes at Manchester the other day. We have before us a boxful of their blooms, consisting of both show and fancy kinds, all very perfect in form and beautiful in colour. Amongst large-flowered striped kinds are John Cranston, bright crimson and maroon, very fine; E. B. Forster, rosy-scarlet, traversed with dark purple veins, blotched with maroon-crimson, and having a bright yellow eye; William Ogg, a fine dark self; and G. L. Brown, a good, rich plum-coloured self. With these came several excellent blue Violas, the flowers of which are large and fine. Amongst them we may mention V. Blue Bonnet and V. Lord Beaconsfield. It must be admitted that the present has been an unusually favourable year for Pansies and Violas, as far as southern growers are concerned, but in even dry seasons and in the warmest parts of England no one need despair of being able to grow these popular flowers to perfection, provided they give them proper treatment, which consists chiefly in planting them in deep, rich, well-drained soil, and in giving heavy mulchings during summer, and copious waterings.

**The Edelweiss at Dangstein.**—I am not surprised that the Edelweiss is cherished so much by the Swiss, for it is as beautiful as it is peculiar. Last year (see p. 105, Vol. XI. of THE GARDEN) I gave an account of Lady Dorothy Nevill's success with it at Dangstein. Her ladyship, through her precaution, in the first instance, of saving the seed from a small bouquet which had been given her by a friend, is now rewarded with scores of plants in her Alpine beds and other parts of the garden. In spite of the very mild winter which we have had and the excessive rainfall, the young seedlings are looking remarkably well, and are producing strong branching heads of bloom, finer, indeed, than I ever remember to have seen them. I am glad to find that within these last twelve months the Edelweiss is better appreciated by lovers of Alpine plants than it

has been, and that it is now considered to be a valuable addition to an Alpine garden. Lady Dorothy Nevill receives many congratulations respecting her success with this plant, and which she richly deserves, for I doubt if there can be found anywhere in England as large a quantity of such healthy plants flowering in such abundance as at Dangstein.—L. J. V.

#### GRAVEYARD GARDENS.

THE idea of turning disused graveyards into gardens for the use of the public is highly commendable; for open spaces in thickly populated districts in large towns is desirable, as much from a sanitary as from an ornamental point of view. But on visiting such graveyards in London as have been converted into gardens, and in some cases at great expense, one cannot help thinking that too much has been done in imitation of our public parks. We know of more than one churchyard in which the turf has been cut to pieces in order to make provision for long beds, which during summer are planted with long lines of Beetroot, Golden Feather Pyrethrum, or the white-leaved Centaureas; other round and oblong beds are filled with Coleuses, Pelargoniums, Alternantheras, and similar plants, the duration of which, especially in cold seasons, is indeed but short. These beds, for the greater part of the year, simply remain bare spaces, which form anything but a pleasing contrast to the green sward. Between the trees and shrubs, many of which have died through being planted late in spring, the ground is also bare, and until the shrubs are large enough to cover the soil is likely so to remain. Although a graveyard may be divested of its tombstones and its formal hillocks of earth, yet one cannot forget that it is still a graveyard. People planting individual graves generally aim at using such flowers and plants as are unobtrusive in appearance and devoid of glaring colours. Why, then, should this not be the case when embellishing a whole churchyard? The hundreds of easily cultivated, really good hardy flowers which we now possess afford a selection of suitable subjects, even for the most smoky parts of London; and whilst the garden may be made beautiful with plants which bloom naturally at all seasons of the year, the green turf may remain undisturbed, and no bare unsightly places need be observable. Then, again, the plants now in use involve a great expense yearly, and, in some cases, even hot-houses are built to propagate and protect them during winter; whereas, if a good selection of hardy plants were employed in the first place, no protection or further expense would be needed, which, in poor neighbourhoods especially, is an important advantage. Experience will, however, in this matter, as in others, no doubt lead to improvements; but there is still no reason why a pleasant, unpretentious, and enjoyable garden should not be made in the first place. One of the best graveyard gardens which we have seen in London, considering the limited means at command and the space occupied, together with an unfavourable locality for the growth of plants, is that attached to St. John's Church, Waterloo Road. Shady places near the building have been planted with British Ferns, wild flowers, and other shade-loving subjects, whilst the walls will be hidden by *Ampelopsis Veitchii*, Ivies, and other rapid-growing creepers. Several clumps of shrubs and trees have been planted, among which we noted the spring-flowering Almonds, silver-leaved Poplars, and other plants suitable for the situation. There is a good breadth of beautifully green turf, and a total absence of ill-formed flower beds. The ground is slightly undulating, and not a straight line or edging can be seen anywhere; although the borders round the groups of shrubs have this year been partly filled with common bedding plants, the contributions of people interested in churchyard gardens, it is proposed, as soon as suitable means can be obtained, to fill up the shrubberies with good hardy plants. People having a surplus of such hardy plants as will succeed in London would do well to give them for such a purpose, thereby encouraging a taste for true gardening in the heart of London.—S.

**Pelargonium Monstrosum.**—Mr. Gilbert, of Burghley, has sent us blooms of a seedling *Pelargonium*, which show a peculiar kind of monoströphy. The trusses, which are large, consist of flowers piled one above the other, house-hose fashion, for quite 1 in. in length, rendering the head of blossom not unlike cluster of Hope.

## NOTES OF THE WEEK.

**Oxalis floribunda.**—The masses of bright flowers now shown by this plant are quite remarkable for their beauty and abundance. It is an excellent plant in all ways, and quite easy to grow in most soils.

**Goat's Beard** (*Spirea Aruncus*).—This is by far the most valuable herbaceous plant now in flower, being beautiful in foliage and habit, as well as in its flowers, so freely produced in large, gracefully-drooping plumes. It should, however, be noted that there are inferior green varieties of this plant, and that they are not worth growing. In its best forms it is as good in midsummer as the Pampas Grass is in autumn.

**Lewisia rediviva.**—Large numbers of this singularly beautiful Rocky Mountain Alpine plant are now finely in flower in Messrs. Backhouses' nursery, York, where they make quite a display. Their blooms are of a lovely soft rose or pink, resembling those of a small Cactus, and they are produced close upon the ground. The plant appears to thrive best when planted in about half loam and half peat.—R. P.

**Genista virgata.**—This, the Twiggly Broom, as it is generally called, is now beautifully in flower in Messrs. Osborns' nursery at Fulham. When we state that it forms a plant 8 ft. high and 10 ft. through, one mass of bright yellow blossoms, and feathered all round quite to the ground, some idea may be gleaned as to the effect which it produces. *Magnolia Thompsoniana* is also just coming into flower in the same nursery.

**A New Yellow Torenia.**—Mr. Godefroy-Lesneuf, of Argenteuil, sends us a bloom of a yellow species of this popular genus, which seems as ornamental as it is interesting. If it prove as graceful in habit as the other *Torenia*s it will be a very welcome addition to our gardens.

**A New Variegated Cockfoot Grass.**—Messrs. E. G. Henderson showed recently in the Regent's Park a variety of *Dactylis glomerata* with very long leaves handsomely variegated. It seems distinct from the old variegated sorts of this plant and likely to be useful from its drooping habit and long leaves.

**Hardy Flowers at Tottenham.**—In addition to many well-known and popular flowers now in bloom in Mr. Ware's collection, we noticed the white *Brodiaea*, the light crimson *Bomarea oculata*, the elegant white *Hesperocordium lacteum*, several handsome varieties of *Papaver nudicaule*, three varieties of the Japanese *Rosa rugosa*, *Habenaria fimbriata* (a pretty hardy Orchid), and the double *Geum*, a bright flower of a fine orange-scarlet colour.

**The Large Thrifts.**—The seedling forms of the great Thrift are now very beautiful in the gardens round London, particularly in Mr. Ware's collection. Their rose and pink varieties especially are very handsome, and we cannot have too many of them so long as they are distinct, but we hope that no one will add to our sufficiently numerous collection of names by giving them separate ones.

**Stephanotis floribunda in Covent Garden.**—Neat little plants of this, loaded with blossoms, are now being offered for sale in Covent Garden Market. They are grown in 6-in. pots, and trained round a few slight stakes. Plants of this description are exposed during summer and autumn to plenty of air and sunshine, in order that the wood may get thoroughly ripened. They are shortened back and brought gently on in spring, and nearly every break produces a flowering shoot.

**Habrothamnus fasciculatus in Cornwall.**—I herewith send you flowering branches of this *Habrothamnus*, but it is not nearly so good as I expected on account of the continuous floods of rain and cold winds to which it has been fully exposed during the past fortnight. The plants have stood out as standards for several years without the least protection. It is a grand plant for a south wall, and enables us to cut from it large quantities of blossom for indoor decoration.—SANGUINEA, *Truro*. [Common as these *Habrothamnus* are, we had no idea of the great beauty of this species until we received these fresh and vigorous shoots of it grown in the open air, and laden with myriads of coral-coloured blossoms, of which there were 300 on a small twig 1 ft. in length. We should have had it drawn for a coloured plate had it not been so old a plant and already figured.]

**A Blue Bush.**—The best example of this which I have ever seen is *Ceanothus divaricatus*, now in full flower here, a condition in which it has been for a month or six weeks. It was planted about seven years ago, a small plant from a pot, and now it measures about 15 ft. high, about 18 ft. wide, and the stem near the ground girths close upon 2 ft. It is a mass of pale blue, and fills the air with an odour

like that of Hawthorn. Your Wexford correspondent must, I think, have been in error (see p. 533) when he stated that he had *C. azarvus* in flower in May, as this species does not usually come into bloom before August, and it continues here in full beauty until stopped by frost, but this for that season is far surpassed by *C. Gloire de Versailles*.—T. SMITH, *Nevry*.

**Orchis foliosa.**—A batch of this noble hardy Orchid, now in fine bloom, passed part of the spring under water, owing to floods—another proof of its hardiness, if any were wanted. It seems to grow, flower, and increase without any of the accidents or weaknesses which seem common to other hardy Orchids.

**Speckled Gloxinias.**—One of the best of these which we have seen is named *Papilion*. Its flowers are well formed, borne in an upright manner, white, and beautifully speckled with small bluish-purple dots. The plant grows freely, and is in every way a desirable one. It is now in flower in several of the principal London nurseries.

**Abutilon Lemoine.**—This lemon-coloured *Abutilon*, now flowering in the Holloway Nurseries, forms an excellent companion for the white *Boule de Nègre* and *rosafleur*. In habit it is similar to the white-flowered kind. Any one having well-grown plants of the three *Abutilons* just named will have no difficulty in securing abundance of yellow, white, and rose-coloured blossoms nearly every month in the year.

**Iris Ganymede.**—This beautiful variety of the Germanica section is now blooming freely in Mr. Parker's nursery at Tooting. Its body colour is yellow, irregularly margined with dark purple, the fall petals being suffused with crimson. It is in every way well worth having in any collection of hardy Irises.

**Royal Botanic Society's Evening Fete.**—At the evening fête of the Royal Botanic Society, which will be held on the 27th inst., prizes will be offered for dinner-table, sideboard, and buffet decorations, table and hand bouquets, hanging and standing baskets, groups of plants arranged for alcoves, fire-places, and balconies, and for flowers, in a cut state or otherwise, which only expand at night.

**Begonias at Forest Hill.**—A fine display of tuberous-rooted *Begonias* may now be found in Messrs. Laing & Co.'s nursery, Forest Hill. The plants, which are of good size, are unusually well grown, and free from that peculiar curl in the leaf to which, in some cases, they are subject, and which amounts to quite a disease. They are arranged in a light airy, span-roofed house in such a way that they can be seen to the best advantage, and, being now loaded with blossoms, present a sight, the brilliancy of which is surpassed by but few plants. These *Begonias* have been obtained from all available sources, both in England and on the Continent, and, by careful cross-fertilisation, remarkably distinct kinds, both as regards habit of growth, foliage, and flowers, have been obtained. Among the most useful sorts now in bloom, we selected the following, viz., Baron Hornby, a free-growing kind with large leaves, and bearing flowers of a bright ruby crimson, measuring nearly 5 in. across the petals; Coltoni, a large orange-crimson flower with broad stiff petals; W. E. Gumbleton, one of the best of the upright-flowered kinds, dwarf and bushy in habit, and producing abundance of flower-spikes from the root-stock, the blossom being of a vivid scarlet; White Queen, a good white-flowered kind of the *hollensis* type, bushy and compact; and Queen of Whites, of the *Roseflora* type, also excellent. *P. Lecontei* is a remarkably floriferous sort, having large drooping spikes, each of which produces seven to ten clear rose-coloured blossoms. Other good single kinds are delicate, of quite a new colour, and with flowers round and well formed; John Laing; Cornelles, rose colour; and Oriflamme, carnine. Excellent double kinds may also now be found, but only a few of them are at present in flower. Two good ones now in flower are President Burrole, brilliant scarlet, equal to a Carnation in appearance; and a delicate pink, Balsam-flowered kind named B. Calypso. Hundreds of plants of the older kinds are here planted out in the open air, and appear to be growing remarkably well, and it is probable that the day is not far distant when *Begonias* will play an important part in hardy flower gardening.

**National Rose Society.**—The second exhibition of this Society will take place at the Crystal Palace on Saturday, June 29, and the last day for forwarding entries is Saturday, June 22.

**Calcot Gardens, Reading.**—It will be seen by an advertisement in another column that these gardens, the property of the late Mr. Webb, are to be sold at the Mart, Tokenhouse Yard, on Wednesday next. They are famous for fruits, and especially for Nuts, of which Mr. Webb possessed several new and improved varieties.

**Papaver nudicaule for Cutting.**—This Poppy keeps fairly well in a cut state in rooms. The white, rich yellow, and orange forms are very handsome.

## NOTES FROM KEW.

**Hardy Shrubs.**—Perhaps the most interesting, as well as the most beautiful, of this week's hardy shrubs is the Mexican *Ilabrothamnus corymbosa*. This charming species is a near ally of the deservedly popular *H. elegans*, one of the most useful of pillar plants for the cool conservatory or greenhouse; it is, however, a much stronger and more rapid grower than *H. elegans*. Towards the extremities of the main branches short, leafy ones are freely produced, and each of these is terminated by a cluster of deep rose-coloured flowers; as a wall plant in sheltered situations this makes a fine object. *Ceanothus integriramus* is a very desirable kind, with a profusion of white flowers. *Raphiophloeum japonica*, a handsome shrub, belonging to the Rose family, has leathery, dark green leaves and panicles of white flowers. The Jerusalem Sage (*Phlomis frutescens*), with its Sage-like leaves and whorls of large, golden-yellow blossoms, is the most showy, yellow-flowered shrub to be seen at present in the Kew collections. *Rosa Brunoniiana*, a rampant grower from the Himalayas, has large heads of pure white flowers, and is very conspicuous in the tall shrubs, amongst which it has been planted. For similar situations this is almost unsurpassed, and there is not much fear of its being crowded out.

**Hardy Herbaceous Plants.**—*Dolichnum casbmerianum* is a desirable perennial Larkspur; it is not a strong grower (scarcely attaining a height of 2 ft.), but its large light purple flowers are very pleasing. *Arenaria loricifolia*, one of the most easy plants to grow, is worthy a place in the front row of any flower border; its large flowers are so abundantly produced as to present the appearance of a sheet of white. *Spiraea pubescens* is a pretty, dwarf, herbaceous species from Siberia; it has large clusters of white flowers, and grows about 6 in. high. One of the most handsome of the evening Primroses is (*Oenothera marginata*, from the United States; it has very large white flowers, slightly tinted with rose; 9 in. is the full height to which this plant grows. *Scabiosa caucasica* is a fine Scabiosa, with pale blue flowers more than 2 in. across; the root leaves are quite entire, but those on the stems are much cut. The Blue Daisy of Morocco (*Bellis rotundifolia* var. *corculascens*), though hardly deserving to be called blue, is a pretty plant which was introduced to English gardens a few years ago during Sir J. Hooker's Moroccan expedition. It appears that in various parts of Morocco it is one of the commonest spring flowers, abounding in fields with a rich soil near Tangier, and occurring in great profusion by the watercourses of the valleys of the Greater Atlas at elevations of from 4000 ft. to 11,000 ft. *Edrianthus* (or *Wahlenbergia*) *Pumilio* is a charming Alpine recently introduced by Messrs. Backhouse; it forms a dense perennial tuft of small silvery leaves and sheets of large, purple, bell-shaped flowers; to grow it successfully it requires rather sunny chinks in calcareous rockwork. *Phytanum Scheuchzeri* is a pretty rampant which grows about 1 ft. high, and has blue flowers. *Solidago pumila*, a beautiful little Golden-rod, only attains a height of a few inches and is a mass of bloom. *Galax aphylla*, a perennial from the United States, has stalked, glossy, kidney-shaped leaves and dense spikes of pure white flowers on stems from 1 ft. to 1½ ft. in height. *Amsamia angustifolia* is an elegant North American Dogbane with narrow, Willow-like leaves and heads of very pretty pale blue flowers. *Eriogonum nubbellatum* has yellow flowers which are red in bud; the leafy portion sits close to the ground, but the flower-stalks are 1 ft. high. A Spanish *Digitalis* (*D. Thapsi*) with soft, rosy-red flowers, is a charming border plant, much dwarfier than the English Foxglove. *Hypicum ciliatum* is a compact, pretty perennial with small narrow leaves and showy yellow flowers. *Pentstemon Wrightii* var. *angustifolius* is a charming plant with rosy-pink flowers. *Kniphofia caulescens*, a striking species of sub-tropical aspect, approaches in habit some of the Cape Aloes; the flowers are deep blood-red when young, but after expansion a light yellow. *Sisyrinchium convolvulum* has densely-tufted, Grass-like leaves and bright yellow blossoms. *Ornithogalum narbonneense* has long-stalked, pure white flowers on stems from 1 ft. to 1½ ft. high. *Allium Macleanianum* is a beautiful and distinct Californian species with deep rose-coloured flowers. *Bloomeria aurea* and *Brodiea congesta* are very pretty bulbous plants, the former having umbels of golden-yellow blossoms, the latter heads of fine blue ones.

**Stove Plants.**—A Brazilian climber, *Ipomoea bonariensis*, is especially worth of mention; it has beautiful, rosy-red trumpet-shaped flowers, the inside of the tube being much deeper in colour. Two other tropical American climbers, which, however, require considerable space in which to develop and show their full beauty, are *Stigmaphyllon ciliatum* and *S. littorale*; both have handsome yellow flowers. Two of the most lovely tropical Water Lilies are *Nymphaea dentata*, from Sierra, Leone, with fine leaves and pure white flowers 8 in. in diameter, and the garden hybrid *N. Devoniana*,

a very free-flowering kind with leaves like those of the last-named and brilliant red blossoms.

**Orchids.**—*Cypripedium superbum*, a native of Java and Assam, is one of the best of the barbatum group; it has splendidly variegated leaves, remains a long time in bloom, is a free grower and of good habit. *C. Dayanum*, from Borneo, has large flowers, the sepals being white, with green veins, and the petals purplish, tinged with green. *Hartwegia purpurea*, from Guatemala, is a pleasing epiphyte with rather thick, fleshy, spotted leaves and long, thread-like curved flower-stems bearing numerous small purple flowers. *Cattleya Mendellii*, a magnificent species, the sepals white, tinged with rose, white petals, and a large, much waved, and crisp lip, richest purple in its broadest part, and yellow upwards. *Dendrobium chnummii* has wax-like flowers, pure white with the exception of the lip, which is marked with reddish-orange towards its base. *D. nodatum*, from Moulmein, has whitish sepals and petals, and a orange lip bordered with white, and bearing two crimson-purple blotches at its base. *Oncidium longipes* is a compact little species, attaining a height of about 6 in., and bearing a profusion of brown and yellow flowers. The Mexican *Epidendrum rariferum*—something like *E. nutans*—is a pretty plant with greenish sepals and petals, marked with rich purplish brown spots and a whitish lip.—†

## DARLINGTONIA CALIFORNICA FROM SEED.

This singular member of the so-called "carnivorous" class of plants ought now to be regarded as hardy, since it has withstood the last two winters unprotected in various parts of the country, and doubtless it would stand even more severe winters, seeing that it inhabits high elevations on the Sierra Nevada Mountains, where at times intense cold prevails. Nevertheless, should cultivators not feel inclined to risk it in the outdoor garden in consequence of its comparative rarity, they will, at all events, doubtless now discontinue coddling it in a high temperature. Plants of it which I have seen outside are very robust, with stout and very highly-coloured pitchers, whilst those under glass, in a more equable temperature, have uncoloured thin pitchers, far exceeding in length those that I have seen on native specimens, thus showing that the plant is not living under natural conditions. As I consider that I have been successful in its culture, perhaps a few remarks on my mode of procedure may be of interest. I prefer raising it from seed to investing in imported plants of it, which rarely live more than a year or two. Seeds can be obtained at a cheap rate from most seedsmen, or direct from any of the San Francisco firms. They should be sown in well-drained pans, filled to within 1 in. of the rim with a compost consisting of one part fine peat broken into pieces about 1 in. square, one part finely cut live Sphagnum Moss, half a part sharp silver sand, and half a part broken charcoal; a layer of finely-cut Moss should be laid on the top, and on this sow the seeds; then cover them with a flat piece of glass and keep the pans always moist. In about a month or six weeks they will germinate, and after the seed leaves have become fully developed, the young plants should be pricked off into pans about 1½ in. apart, using the same compost as before. The second season they should be potted in small pots, taking care not to injure the tender roots, and a layer of live Sphagnum should be placed on the surface, as it retains moisture and is a material in which the roots delight to creep. All the preceding operations will, of course, apply to cool frame culture, but the four-year-old seedlings should be gradually inured to the full rigour of the climate. A permanent place should be selected for them by the side of a stream, in an artificial bog or in any moist place, and they should be fully exposed to direct sunlight, but sheltered from the cold winds of early spring, when they are throwing up their young leaves. The plants will require frequent watering in dry seasons. When they have attained a large size, they have a tendency to develop side shoots, which, if taken off and potted, make by far the strongest plants in a comparatively short time. If culture under glass be preferred, the house or frame should be kept as cool as possible, but not shaded. W.

**Diplacus glutinosus.**—This, though an old plant, is not grown so much as it should be, considering how easily cultivated it is and the profuse manner in which it produces its orange, Mimulus-like blooms. It is easily propagated by means of cuttings made of the half-ripened shoots taken between April and August and inserted in sandy soil. When struck, it should be potted off in a compost of good fibry loam, peat, and sand; it may then be placed in a cool frame and kept close until started, when it should have abundance of air. In autumn it should be removed to a greenhouse, where it can be protected from frost. Thus treated, it should bloom well the following spring, and have the coolest end of the conservatory allotted to it, when it will produce a fine display all summer.—T. W. S.

## THE FLOWER GARDEN.

### GROUP OF YUCCAS.

IN the dawn of anything like real perception of the way in which to arrange vegetation in gardens, we have often tried to point out the disadvantages of dotting plants about so as to destroy all good effect. This dotting may be equally wrong in two ways—where it consists of all different plants or of many specimens of a few kinds. Thus, one who collects many kinds and dots them about singly may produce as bad an effect as one who selects and dots about favourite kinds everywhere. It is not well to follow any one plan for gardens generally, but we are convinced that grouping is much the most artistic and in all ways most satisfactory way. By this we mean irregular, but carefully considered, massing in one place. The illustration shows the effect of this as regards Yuccas and allied

remarks on the subject in reply to Mr. Groom; but as Mr. Fish has since (see p. 514) expressed his agreement with Mr. Groom "in all that relates to the importance of leaves," and has requested from me an explanation on certain points, I propose now to deal with the subject at somewhat greater length, for the special benefit of those who attach so much importance to the preservation of the leaves.

On Saturday, June 30, 1877, as related by me in *THE GARDEN* of October 20 (see p. 375), I lifted several clumps of the White Lily (*Lilium candidum*) when they were in full bloom, for the purpose of proving that this Lily was not an evergreen. Among the bulbs so lifted I found some interesting specimens, and as I was desirous of further examination, I placed them in a small basket in my tool-house, and shut down the lid, as I had to leave home on the Monday for six or seven weeks. The remainder of the bulbs taken up I re-planted on the same day, namely, June 30. Those that were re-planted succeeded so

A Group of Yuccas.

plants. It is equally applicable to every hardy plant worthy of a place in the garden. Even in the smallest places a carefully composed group of a favourite flower would afford a much more satisfactory effect than dotting the same number of plants at irregular intervals about the garden, while it would allow of a far greater variety in the aspects of vegetation.

### CUTTING DOWN LILIES JUST AFTER BLOOMING.

MR. GROOM says (see p. 252, March 23): "The only point to which I took exception was that of cutting down the flower-stems before the leaves had faded." . . . "If 'Dunedin' will illustrate the totally distinct character of Lily bulbs in such a manner as to prove that neither directly nor indirectly is the succeeding year's flower-stem affected by cutting down the leaves while they are yet green he will confer a boon on many cultivators, who up to the present time have attached great importance to retaining the foliage in health as long as possible." I have already (see p. 451, May 11) made some

well, that in the first week in May last they were among the most promising I had in the garden; so much so, indeed, that I decided on lifting one of them, from which to cut out a specimen for photographic illustration hereafter, which will be given in my next paper. As this is bringing us face to face with facts, will any one venture to say that the stem I cut off from the bulb in May last was in any way affected by the loss of the stem and leaves that were cut down on June 30 last year when the parent plant was in full bloom?

Mr. Baines remarked (see p. 349, Oct. 13, 1877), that at that time "All herbaceous plants should be removed or divided that require it, except such plants as the common white Lily, which will now be making active growth, and if the roots be disturbed, it will have the effect of wholly or partially preventing its flowering next year." Now many of us can bear witness to the correctness of this statement. But what of that? A great deal. In such cases the tufts of leaves which appear fresh and green above the ground fade and die through the checking of the roots; the bulbs also, instead of sending up

stems, die before the ensuing spring, there being no such thing as dormancy in the Lily. The seed-buds, however, which would have been liberated and vegetating during the middle of the previous summer would go on growing, though slowly at this time, drawing nourishment from the food which had been laid up in the parent bulb. On the return of spring, however, the seed-buds would then go on growing with great rapidity, in an increasing ratio, up to the blooming season, when they would be fully developed bulbs, having by this time, with the additional aid of their own roots, completed their first twelve months of existence. As yet, they would be incapable of sending up flower-bearing stems, but would be capable of doing so the second year, the first year being a blank, as Mr. Baines remarks, in consequence of the check to the roots of the bulbs and the death of their predecessors. This is no mere theory, but is in accordance with experimental facts. Then, what aid could these bulbs or their stems have had from any stem-leaves whatever? About the end of February, 1877, I procured some bulbs of *L. auratum* for the purposes of dissection. Among them was one which appeared to me to be in better condition than the others. I therefore planted it in a pot and placed it under a glazed verandah. During the latter part of the summer I placed it out-of-doors. In course of time it showed for bloom, but one night I found that the early frost had touched the leaves, and I brought it in again to its old place under the verandah. The leaves, however, I found had been severely injured and were turning yellow, while the flower-buds (nine in number) were grown like large Beau-pods. The leaves now began to drop off one after the other. The flowers, however, all opened fully and bloomed beautifully, measuring from tip to tip of the petals 11 in. and 12 in. Before the half of the flowers were done blooming, not a single leaf was left on the stem. By the time the last flower was beginning to fade the stem itself was getting yellow; so I cut away the greater part of it, and left the plant as it was in the pot during the rest of the winter. In the spring not one but two strong stems shot up, showing that the successional bulb had thriven, notwithstanding the loss of the leaves, and had liberated two germs, which had produced twin bulbs. I put them out-of-doors, and the stems this season are actually double the thickness of their predecessor, with a little offset growing beside them. How, then, could Mr. Groom's exception apply here when the leaves had all fallen before the parent plant had done blooming?

We have been considering whether the growth of the new bulbs or their stems can be affected by cutting down the stems of the parent plants immediately after they are done blooming. Let us now turn the tables, and ask: "Can the growth and blooming of the stems be affected by cutting off the bulbs?" I reply: It cannot. I have a bed of Lilies, consisting of *Lilium bulbiferum*, *candidum*, *croceum*, *longiflorum*, *pyrenaicum*, *speciosum*, and *umbellatum*, some of which have bloomed and others are in bloom, and there is not a bulb among them. How can this be? In taking up the bulbs in the beginning of May, for the purpose of making specimens for THE GARDEN, I cut off the stems about 2 in. above the bulbs, and these stems I planted out in a bed on the same day, the stems being from 1 ft. to 18 in. in length. I watered them thoroughly, and all continued to grow and bloom well, though not so long, of course, as if they had been feeding on the nutriment specially stored up for them. Almost all true Lilies have a tendency to throw out roots under certain circumstances, more or less, from the stems above the bulbs, and these would tend to keep the leaves green for a length of time without having the slightest connection with either the new or the old bulbs. These stems, without bulbs, that I planted out in the beginning of May have continued not only green, but have actually increased in growth and bloomed; and yet there are many cultivators who, up to the present time, have attached great importance to retaining the foliage in health as long as possible." Why? Because those who have gone before them have left it as a traditional relic that "the succeeding year's flower-stem is affected by cutting down the leaves while they are yet green." Green leaves on the old stems are, as a fact, no criterion whatever that those stems and leaves have any connection at the time with the new bulbs, or the stems within the new bulbs. If all that I have written fails to remove what I believe to be

erroneous impressions, let any one who is interested dig down near a clump of Lilies just as they have gone out of bloom, and carefully cut away a bulb, without in the least disturbing the stem, and then replace the soil again. He will find that the stem and the leaves will continue green quite as long as those that have not been moved; and if he will at once re-plant the bulb in congenial soil, he will find that next season it will bloom better and continue longer in bloom than those that have been left in the ground undisturbed.

I propose now to adduce some collateral evidence in support of what I have stated by touching lightly on the structure and functions of the roots, bulb, stem, leaves, and flowers.

**THE ROOTS.**—In growing downward the roots continually renew the tender tissue through which the absorption required to restore what is lost by evaporation or consumed in growth is principally effected. The idea that all the underground portion of a plant belongs to the roots is by no means correct. The roots give birth to no other organs, but themselves directly perform those functions which pertain to the relations of the plant with the soil; their ramifications bind the plant to the earth; their newly-formed extremities or rootlets imbibe nourishment from it. The roots lengthen by continued cell-multiplication mainly at their lower extremities, the parts once formed scarcely, if at all, elongating afterwards, the growth taking place continuously at the tips alone, so that the tips of the growing roots always consist of the most newly formed and active tissue. Hence the danger of disturbing active roots during the season of growth, as they cannot be removed from the soil, as Mr. Baines has remarked, without great injury to the plant, a most reprehensible practice on the part of those who transplant late in the season.

**THE BULB.**—Some Lily growers call the bulb "the root of the matter," but this is incorrect. The bulb is not the root. It is a permanently abbreviated stem clothed with scales, which are imperfect and thickened leaves. The new bulb does not send up a stem during the first summer, but elaborates what it receives from the roots into organic or nourishing matter, and stores it up for future use in the core and in the cells of the scales borne on the core, which enlarge or become more fleshy as the nourishing matter accumulates. When vegetation becomes active in the following spring the new stem and the successional bulbule within the new bulb, fed by this stock of nourishment, grow with great vigour, and the stem produces leaves and at last flowers. When the plant has continued in bloom for some time—longer or shorter, according to the quantity of nourishment stored up—the stock will then become exhausted, and, by using the microscope, it will be seen that the cells in the scales have become emptied of their contents and are now soft and flabby, the old roots being dead or dying. The scales then dry up, and the parent bulb entirely perishes, leaving it to the successional bulb to go through the same course the next season.

**THE STEM AND THE LEAVES.**—The aboveground functions are carried on not so much by the stem itself as by the organs which it bears, namely, the leaves. Hence, the production of leaves is one of the characteristics of the stem. It is essential to the plant that there should be evaporation from the leaves, as it is the only method by which its excessively dilute food can be concentrated. Some arrangement is therefore requisite that shall allow of sufficient exhalation from the leaves while the plant is freely supplied with moisture by the roots, but restrain it when the supply is deficient. It is clear, then, that the greatest demand is made upon the leaves at the very period when the supply through the roots is most likely to fail; for the summer's sun, which acts so powerfully on the leaves, at the same time parches the soil upon which the leaves, through the rootlets, depend for the moisture which they exhale. So long as their demands are promptly answered, all goes well. The greater the force of the sun's rays, the greater the speed at which the machinery of the plant is driven. But whenever the supply at the roots fails, the foliage begins to flag and droop, as is so often seen under a sultry meridian sun; and if the exhaustion proceeds beyond a certain point, the leaves inevitably wither and die. Some adaptation is therefore needed, analogous to a self-acting valve, which shall regulate the exhalation according to the supply. Such an office is actually fulfilled by the stomata, or breathing pores.

The number of these breathing-pores on a square inch of surface of a leaf of the White Lily is from 20,000 to 60,000 on the lower surface, and somewhere about 3000 on the upper surface. In this plant, and in all other true Lilies, they are so remarkably large compared with some other plants, that they may be discerned by a simple lens of 1-in. focus. Mr. Fish has remarked "that nothing has yet been proved by me to show that Lily leaves are of less moment to Lily bulbs than Potato haulm to Potatoes." I reply that there is no similarity whatever between the organic structure of a true Lily and that of a Potato—the same may be said of the Gladiolus, to which he refers—and, therefore, had it even struck me, no comparison could have been made one way or the other.

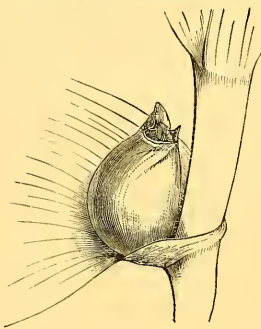

**THE FLOWERS.**—We now come to the flowering of the plant; and this, to Lily growers, is the most important point which we have to consider. Lilies begin to flower at a nearly determinate period for each species, which is dependent partly upon constitutional causes, and partly upon the requisite supply of nutritive matter in their system; the experience, therefore, of cultivators under glass—as recently noted in THE GARDEN—is very much calculated to mislead amateur cultivators in the open ground. The flowering of the Lily draws very largely upon the powers and nourishment of the plant, while—unlike the leaves—the flowers yield nothing in return. The food which the roots absorb, after having been digested and elaborated in the leaves, is all expended in the production of flower-buds and flowers, for as they seldom show for seed, unless in pots under glass, it is unnecessary here to take this point into consideration. Flowering is, in fact, an exhaustive process, drawing out to the last the whole of the nourishment that has been stored up in the cells of the scales, and consequently a most liberal supply of food is requisite to maintain the flowering for even a moderate time. The actual consumption of nourishment in flowering may be shown in a variety of ways; but without going into lengthened illustrations, which would be inconvenient at the present time, it may be stated as a positive fact that it is while flowering that the plant actually consumes the most; and when the flowers have all faded, it is a true sign that the nourishing powers of the leaves are gone; and as they now cease to perform their functions, nothing remains for the parent plant but to decay and die—and so it perishes.

Mr. Fish says: "The question that 'Dunedin' has failed to answer is, When does this vital connection between the new germ bud and the old Lily terminate?" It can hardly be said that I have failed when I have had no cause to allude to it. It is said by botanists, "That plants, like animals, are organised and living beings." This being so, part of the answer to Mr. Fish is found by studying the animal creation. The lamb at first will seldom venture to leave its parent; all the feeding it gets comes through her. By-and-by it ventures to taste the green herbage; the taste for stronger food gains upon it as its constitution grows stronger, until at last it ceases altogether to visit its parent. So it is with the new germ bulb or bulbule, which at this stage I prefer to call it. As the bulbule has no power of locomotion, it follows that its food must be near at hand. At the beginning, and until it has sent forth its roots into the soil, it must be nourished and grow by means of organised matter supplied by the parent. This supply is deposited in the cells of the fleshy core to which the bulbule is attached, and also in the cells of the scales, which, like miniature storehouses, are seated on and around the core. The ample store of nourishment thus provided enables the bulbule in the early spring to grow with remarkable vigour, and send down its roots through the core; for we know by experimental facts that the roots begin to protrude into the soil some five or six weeks before the parent plant begins to bloom. We know, also, by the same facts, that as soon as the bloom is over the supply from the parent bulb ceases, and that by this time the new bulb is well able to live and grow solely by the aid of its own roots. Knowing all this, namely, the time when the roots begin to protrude into the soil and the time when the supply of the parent ceases, I must leave it to Mr. Fish and other intelligent horticulturists, who are as well able as I am, to decide at what moment or time the connection between the new and the old terminates. The connection must cease when the supplies cease, but it may be terminated before that time, as experimental facts have proved.

DUNEDIN.

STEM-BULBS IN TULIPS.

We have received from Mrs. Passingham, of Milton, near Cambridge, a Tulip stem with a young bulb on it, of which the accompanying woodcut is a representation. Bulbs, as is well known, are usually underground or close to it; but occasionally buds in the axils of the upper leaves become transformed into bulbs, which is what has happened in this case. Instances

of similar growths, not only in Tulips, but also in other bulbous plants, are not uncommon.

OPEN-AIR VEGETATION IN MAY.\*

MAY commenced with fine dry weather and a west wind which changed to the east about the 7th, and continued more or less to blow from that quarter till the end of the month. Showers were frequent, but generally of short duration. Now and then some rough gales were experienced, which greatly damaged the young leaves of many trees. Occasional hot sunny blinks brought both foliage and blossoms of many trees forward rapidly. The following varieties came into bloom in the order here given:—

- |                               |                                  |
|-------------------------------|----------------------------------|
| May 2. Perfumed Cherry.       | May 30. Scarlet-flowering Thorn. |
| " 4. Gean tree                | " 21. Large-flowered Medlar.     |
| " 6. Double-flowering Cherry. | " 23. Common White Hawthorn.     |
| " 12. Purple Lilac.           | " 23. Bird Cherry.               |
| " 15. Scotch Laburnum.        | " 24. Yellow-flowering Pavia.    |
| " 18. White Lilac.            | " 27. Mountain Ash.              |
| " 19. Common Horse Chestnut.  |                                  |

Of the above the double-flowering Cherry has been remarkably fine. With the exception of the perfumed Cherry, double-flowering Cherry, and Gean, none here mentioned were in flower last year till June. The early flowering this season is probably owing to the fact that only 2° of frost were indicated during the whole month of May, while last year 36° of frost were registered. Although the early part of April was very frosty, no frost occurred after the 9th, which also accounts for the early flowering of certain trees. The scantiness of bloom, however, observed on some trees has evidently been caused by the immature state of the wood during the last two seasons. Some of the peculiarities now observed on ornamental and forest trees, as well as shrubs, are worthy of record. Rhododendron blooms have been particularly scarce this spring; Lilacs in general have produced but very few flowers, and the same may be said of the Scarlet Hawthorn, while some trees of the White Thorn have been tolerably floriferous. Blossoms on the English Laburnum are also scarce, as well as on some of the Scotch variety (Cytisus Laburnum alpinus). Some trees, however, which produced little or no flowers last season are quite covered with bloom. The Scotch Laburnum was in full flower last year on June 30; although the first flowers were noticed on May 15, it was not in perfection till May 28. Mountain Ash, although in flower, is very scanty, and the same may be said of many Service trees, kinds which annually produce flowers and fruit in abundance. The common Horse Chestnut showed its first flowers this year on May 19, but generally very poor, except some in very favourable situations. No flower-buds are observable on any of the Scarlet Horse Chestnuts, and but few on the Pavia flava as compared with former years. The Norway Maple has shown but little flower, and the common Sycamore, Elm, and other forest

\* Read by Mr. James MacNab before the Botanical Society of Edinburgh, June 13, 1878.

trees promise no better. The Gean, which was in full blossom on May 10, does not show much signs of producing fruit.

Many American trees, as usual, are late in coming into leaf, notwithstanding the recent open weather; this is particularly observable in the case of the Liquidambar, Tulip tree, scarlet American Oaks, deciduous Magnolias, *Ostrya virginica*, *Celtis occidentalis*, various *Robinias*, *Taxodium distichum*, and the *Catalpas*.

During May the thermometer was only once at or below freezing point, viz., on the 10th, when it indicated 2°. Since the year 1854 190° have been registered during the May month; the greatest amount was in 1877, when 36° were recorded; in 1863, 1864, 1866, and 1875 no frost was registered. The six lowest markings this year were on the mornings of the 10th, 20th, 21st, 25th, 26th, and 27th, when 30°, 36°, 35°, 36°, 36°, 35° were indicated, while the six highest were on the 1st, 4th, 7th, 15th, 16th, and 17th, when 47°, 48°, 47°, 48°, 48°, and 49° were indicated. The thirteen species of hardy herbaceous plants noticed in my report for May last year as showing no open flowers during that month have this year all been in bloom during their usual period. On the 31st of May 295 species of plants were counted in flower in the rock garden. The following is a list of some of the most conspicuous then in bloom:—

*Andromeda fastigiata*, *Anemone alpina*, *Arnebia echinoides*, *Anubria* (of which many varieties are now in bloom, the most conspicuous being *A. Hendersemi*), *Chlorogalum Browni* and *Leichtlini*, *Cyclobothra coerules*, *Daphne Cneorum*, *Darlingtonia californica*, *Draba triopsideata*, *Dryas Drummondii* and *otopetalata*, *Erigeron alpinum* and *Roylii*, *Erinus alpinus* and hispanicus, *Fragaria lucida*, *Fritillaria kantschobiana*, *Gentiana verna*, *Gemm coccoineum fl.-pl.*, *Hellephantemum* (the earliest and most conspicuous being *Bride*, *Royalty*, and *Queen of Spring*), *Helonias asphodeloides*, *Hippocrepis helvetica*, *Hutchinsonia alpina*, *Iberis corifolia*, *Iris cristata*, *Sedum buxifolium*, *Linaria alpina*, *Linnaea borealis* (American and Scotch), *Menziesia Drummondii* and *polifolia versicolor*, *Meconopsis aculeata hybrida* and *nepalensis*, *Myosotis alpestris*, *Narcissus triandrus albus*, *Pentstemon humilis* and *procerus*, *Pernettya angustifolia spinosa*, *Phlox Nelsoni* and *setacea violacea*, *Polemonium humile*, *Potentilla alpestris*, *dubia*, *lupinoides*, and *peduncularis*, *Primula capitata*, *cartusoides amena*, *luteola*, and *sikkimensis*, *Rhododendron lepidotum*, *Rubus arcticus*, *Saponaria ceymoides major*, *Sarothamnus scoparius pendulus*, *Saxifraga peltata* and *pyramidalis*, as well as a host of others, *Silene acaulis*, *Smilacina bifida*, *Symphandra Wanneri*, *Uvularia stellata*, *Veronica Guthriana* and *rupesstris*.

### SEEDLING COLUMBINES.

I was interested in reading a letter from Mr. Dodd, of Eton (see p. 515), concerning raising the species of *Aquilegia* from seed. Till then I almost fancied I had the enjoyment of that little farce to myself. It is very amusing to be taken round the garden and be shown quaint and often pretty varieties of the common Columbine bearing the names of the finest and most distinct species. While one may not be surprised at this in inexperienced growers of hardy plants, it is, however, rather unpleasant to see leading firms sending out new hybrids, seedlings that may have been noticed cropping up in gardens where the American species may have been grown, seedlings, moreover, which are of far inferior beauty to the species. Haylogicalness and the seedlings sent out by Messrs. Veitch belong to this class. Some recent correspondents of THE GARDEN who say they have flowered certain rare species would do well to ascertain that they really possess the species in question. What we want in *Aquilegia* is to procure the distinct species and keep them distinct, and not raise endless useless hybrids of far less beauty and value than many of the varieties of the common Columbines now in our gardens. AN HERBACEOUS MAN.

***Aquilegia chrysantha*.**—With me this is one of the finest Columbines among some hundreds in all stages of growth. Its spurs measure 2½ in. in length. I have about fifty plants of it all in fine bloom, and have been gathering their beautiful straw-coloured flowers for several weeks past. The plants vary in height from 3 ft. to 3 ft. 10 in., and will probably get higher yet. They have stood in their present position in an open border all the winter, and all come quite true from seed. In order to raise seedlings I find that the seed must be sown under glass, and the plants pricked off when large enough to handle. Some which I sowed in the open ground on a south border never germinated, not a single plant came up; whereas the same seed sown in a little heat grew freely. My plants of *A. chrysantha* have been greatly admired by all who have seen them, and their distinct colour, peculiar shape, and usefulness in the form of cut flowers make them quite acquisitions.—JOHN GARLAND, *Killerton, Ebezer*.

**Hardy Orchid Garden.**—The interesting account of hardy Orchids (see p. 535) has made me wonder whether I could make an

Orchid garden in a triangular piece of wood, where the trees are principally Oak, growing upon a soil of good Hazel loam. I have enclosed, at small distances from each other, a space for a wild garden and Fernery, and another for an American garden, the latter being partly formed from an old tract of peat, in which the Beg Myrtle found a happy home, but where, since being drained and cultivated, I now have American plants, Lilies, and *Cypripedium* spectabile growing. After reading the above-mentioned article, why, thought I, should there not be a third space taken from the old wood? Neither garden would be visible from the other, and woodland walks would connect them; and with a foundation of light earth and also peat to commence with, an Orchid garden would be most interesting. I wonder whether your correspondent would consider it very troublesome if I asked him to have the kindness to furnish me with a rough pencil sketch of what he thinks would be the best arrangement of an Orchid garden under similar circumstances. It would greatly assist an amateur in following his other very lucid descriptions.—M. L. W.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

***Myosotis semperflorens*.**—Under this name a so-called new Forget-me-not has been put into commerce, but I incline to the belief that it is but the well-known semi-aquatic *M. palustris* under another designation. It is very robust and spreading, has stout hirsute stems, and flowers exactly resembling those of the wild kind. It thrives well in the open ground during the present moist weather, but at no time does it produce a good head of flower, or is it effective. No doubt it is worth growing by the side of tanks or ponds, but for beds or borders it is comparatively valueless.—A. D.

***Lilium Thunbergianum*.**—Surely there can scarcely be a more gorgeous pot or border plant at this season of the year than this richly-coloured Lily. Its flowers are so erect, of such a brilliant hue, and so abundantly produced, that a mass of it would be one of the most effective objects to be found in a garden. This Lily can be easily grown, and is rapidly propagated, young bulbs being produced freely. Mr. Hayes, of Edmonton, sends it in large quantities to market, and one is led to wonder what becomes of all the bulbs thus disposed of. Lilies are seldom found in gardens of the average kind, and Lily fanciers are few indeed compared with the mass of persons who profess to grow flowers. The old white *Lilium candidum* is, perhaps, the most common; then come the Tiger and Martagon Lilies, but these are still comparatively rare. Gardeners commonly grow the varieties of *Lilium lancifolium* and *auratum* in pots, and these not always successfully; but, still, at times they are found in good form. Both *Thunbergianum* and *longiflorum* are robust border kinds, and singularly effective, though so very distinct. They should be as eagerly sought for and as freely cultivated as *L. candidum* or other border kinds. Probably the Lily has materially suffered from too much coddling. Treat it as a hardy border plant, with good culture, and the majority of kinds will do well.—A. D.

***Coronilla iberica*.**—This pretty little plant is one of the brightest and most valuable in a very ornamental family. It is quite small and prostrate, and the bright yellow coronas comparatively large. It is a precious little rock plant, and does quite well on the margins of borders.

**Thrift as an Edging.**—Where Box does not succeed, this old garden favourite makes a neat and compact edging with a minimum amount of labour. It will grow in any soil, increases readily by division of the roots, and at this season, when covered with pretty heads of bloom, it adds greatly to the effect of a garden.—J. GHOSE.

***Pentstemon Wrighti angustifolius*.**—This variety, although not different from the type, except as regards its narrow leaves, is, nevertheless, a very pleasing addition to this beautiful genus. It is very floriferous, and its blossoms, which are of a magenta colour outside and of a lighter hue within, are borne on long branching racemes. It is a native of Texas, and was, I believe, introduced to cultivation by Mr. Thompson, of Ipswich.—W.

***Thalia dealbata*.**—Notwithstanding the remarks made at various times in reference to this noble aquatic not being hardy, we have noticed for the past three years a specimen planted in the shallow pool in the herbaceous ground at Kew, and totally unprotected in winter. It is now in a scarcely less thriving condition than specimens in the tropical heat of the stoves, considering the widely different circumstances under which each is placed.—A.

**The Lily of the Nile at Valencia.**—Through the kindness of Dr. Moore, we have been favoured with the perusal of a communication which he had from the Knight of Kerry with reference to the remarkable development of the Lily of the Nile (*Richardia atropurpurea*) at Valencia, that it has been growing almost wild for several years. So floriferous is it, that at times as many as 115 flowers have been counted on a single plant. As regards individual blooms, the Knight of Kerry states that he never before remembers seeing them so fine as they are this season. Of some individual flowers taken round the edge, the spathe measured 36 in.; longitudinally across the throat, 10½ in., and transversely, 8½ in.—"Irish Farmers' Gazette."

## TREES AND SHRUBS.

## THE WEeping BEECH.

AMONGST weeping trees, of which there are now many different varieties in cultivation, a full-grown Beech is one of the most striking and effective. In a young state it is perhaps less attractive than other weeping trees, and it is too often grafted on a short stem, on which its true pendent habit is not seen to the best advantage, but when worked on a tall clean stem and has attained mature age, a Weeping Beech is an object of great beauty, particularly so when in suitable positions and associated with trees of a light airy habit, such as the Birch and Willow. A Weeping Beech is one of the most persistent of weepers; its branches and even spray hang vertically one over the other in massive flakes or layers, giving it a distinct and singular appearance; and whether viewed in spring, when clothed with luxuriant pale green foliage, or in autumn, when it has assumed a warm brown colour, it forms a noble and picturesque

A Weeping Beech.

object in the landscape. It is perhaps seen to the best advantage when planted on the verge of a stream, pond, or lake; but on a steep sloping bank in pleasure grounds, where ample room is given it, or on a rocky eminence in a wild ornamental wood, it forms a telling feature of great interest. Weeping trees should, however, be planted sparingly and not near one another, and carefully selected and suitable sites must be chosen for them, or half their charms will be lost; when met at every turn or too often repeated, their interest and attraction are greatly diminished.

G. B.

## BRAMBLES AND BRIERS.

To the botanist the intricacies of the genera *Rubus* and *Rosa* are indeed beset with thorns. With a little pains, however, the gardener may select those forms best suited for his purpose, not troubling himself whether they are varieties, subspecies, or species. I propose describing those suited to the tangled thicket, or for clumps in the park or long-grassed wild garden, speaking mainly of our native forms.

**Rubus Chamæmoris** (The Cloudberry).—This grows wild in peaty moors of the north, and, being under 1 ft. in height, can only be grown on the outskirts of the thickets. Its large white flowers and delicious orange-yellow fruit, built up of a few large drupels, render it worthy of such a situation; but as the sexes are on different plants, care must be taken to procure fruiting plants and pollen-bearing ones.

**R. saxatilis**.—By the stony banks of streams from South Wales and West Gloucestershire northward may be found this bright little bramble, almost thornless, its barren stems 2 ft. or 3 ft. in length and trailing, whilst its insignificant flowers are borne erect on stems about 1 ft. high. Its leaves are a bright green, and its fruit a handsome scarlet. In wild gardens autumnal beauties must be considered as well as those of other seasons.

**R. Ideus** (The Raspberry).—A shrub by no means to be despised. Its tall erect canes look well amid other Brambles and Roses; its foliage is really beautiful; whilst the berries, red and golden, need no praise of mine.

**R. suberectus** (Anderson), **R. umbrosus** (Lees).—The first of the many forms of the common Bramble (*R. fruticosus*—L.) is most prevalent in the north. A sub-erect form, its barren shoots not rooting at their tips, its stem with very few prickles, no hairs or bristles, its leaves large and bright coloured, generally slightly hairy beneath. The flower is a good size, clear white, with the petals well-shaped and distinct, and the sepals white-edged, whilst the fruit consists of numerous claret or black drupels. The stem is round in section.

**R. rhamnifolius** (W. & N.).—A generally distributed form. Stem pentagonal, with few large prickles, no hairs or bristles, the barren shoots rooting at the tips, and so arching over in a manner suited to the sides rather than the centre of a clump; leaves often white and downy on the under surface; flower not so fine as in the last, the sepals not clearly white-edged; fruit large, black, and juicy.

**R. corylifolius** (Smith), **R. subulstris** (Lees).—Also general in England; has less decidedly angular stems, with more numerous, but much smaller and more slender, prickles than the last. The barren shoots root at the tips and lie almost prostrate, being, therefore, suitable for the outer ring of a clump. The leaf consists of five overlapping, hazel-like leaflets; the sepals are very downy, and the petals broadly egg-shaped, so forming a finer diec of white than *R. suberectus*. The fruit consists of a few large black drupels.

**R. cæsius** (the Dewberry).—A well-known and distinct prostrate form, with stems set with needle-like prickles, and covered with a glaucous bloom. The leaves are green on both surfaces; the flower is not striking; the sepals are downy, but the large drupels of the fruit, "shining dim—powdered with a downy blue," render this form well worthy of a place among the wild Anemones and Violets of the coppice, or outside the Bramble clump, which I hope may soon form part of many a garden.

**R. discolor** (W. & N.).—An abundant form, well known by its delicate pink flowers (as large as any British species) and downy stem set with strong, short, and stout prickles. The stem is roundish, arching, and rooting at the tip. The sepals are white covered with a thick down, and are always reflexed.

**R. leucostachys** (Smith), **R. vestitus** (Weihe), and **R. Leightonianus** (Bab.).—A common sub-prostrate form, with a pentagonal stem and fine panicle of flowers, often of a deep red. The prickles are large and tolerably numerous, and the whole stem is covered with spreading hairs, a few of which are sometimes round-headed or glandular. The name is taken from the dense white hairs on the stalk of the panicle, which may be compared, on a small scale, to that of the Horse Chestnut in its branching. The under surface of the leaf is often white. The flower is very regular and well-formed, the petals standing apart being narrow at the base, but, from their general outline, forming a complete ring of colour; whereas the petals of *R. discolor* represent ellipses with their long axes arranged radially. Those of *R. leucostachys* are ellipses with their short axes so disposed. This is, perhaps, our finest native Bramble.

**R. Sprengeli** (Weike), **R. Borreri** (Salter), and **R. rubicolor** (Bloxam).—A distinct but local form, with round, slender, trailing stems, with few hairs and pink flowers in a loose almost unbranched panicle, the stalk of which is downy with a few prickles on it. Suitable for situations where *R. discolor* or *R. leucostachys* would be too high-growing, but by no means so fine a form as either of those more common ones.

**R. Kehleri**.—A local form, perhaps worth growing for its fine trailing stems, which are sub-angular and covered with irregular, strongly-hooked prickles and numerous bristles. The leaves on the barren shoots consist of five leaflets, which do not overlap and are slightly downy. The flower is insignificant.

**R. glandulosus** (Bell), **R. Bellardi** (Weihe).—A form which might very probably improve under cultivation. The rounded, trailing stem is set with long, straight, awl-shaped prickles, bristles, and copious glandular hairs. The leaves of the barren shoots consist of three brightly-coloured leaflets, and the inflorescence is as large and as much branched as that of *R. leucostachys*, though the indi-

vidual blossoms are not so attractive. The flower-stalks and sepals are thickly bristled, and, though the petals are rather small, the sepals are very beautiful, ending in a leafy, tapering point.

Though, perhaps none of these Brambles are to be had at an ordinary nursery, the characters I have given are almost sufficient to enable any one to be his own collector, and we may hope to see some day free-growing Brambles, with luxuriant foliage and large double white and red blossoms, in every garden.

I need say little as to the foreign Brambles. *Rubus biflorus*, with its fine white stems and erect habit, is a white-flowered species from Western America, suitable for rocky banks in the sun. *R. nutkanaensis*, from Nootka Sound, California, is a splendid plant. Its fine, Raspberry-like foliage and large white blossoms may be seen in the flower-walk, Kensington Gardens. *R. odoratus*, another North American kind, with purplish blossoms, should be grown with it and *R. deliciosus*, that splendid Rocky Mountain species, which I hope soon to see as much of in many a garden as there is now in the Herbaraceous Garden at Kew. *R. spectabilis*, a dark purple-flowered species, also North American, is valuable as a spring-flowering plant, and *R. australis* should also be grown.

Next, as to British Roses, more showy, no doubt, than their cousins the Rubi.

*Rosa pimpinellifolia* (the Barnet Rose).—A small, erect, bushy shrub growing in dry places, especially on sand, under 4 ft. in height, crowded with straight prickles of various length, stiff bristles, and glandular hairs. Its leaves are small, and the flowers solitary, white, from 1 in. to 1½ in. in diameter; the fruit almost globular, and of a dark purple colour.

*R. Sabini* (Woods).—A common form, similar to *R. pimpinellifolia*, but having generally two or three blossoms together, the calyx tubes of which are bristly, and the fruits red, and therefore valuable in autumn, if mixed with the preceding form.

*R. gracilicens*.—A closely-allied form from Co. Antrim, has a smooth calyx tube and from three to six blossoms together.

*R. hibernica* (Smith). *R. pubescens* (Baker).—A form that ought to be prized by Englishmen, since, like very few of our natural productions, it is unknown on the Continent. It occurs in Ireland, the north of England and Scotland, and, though resembling *R. canina* in having stout curved prickles, its habit and other characters ally it more closely to the two preceding forms. It sometimes has as many as from four to twelve blossoms together, and plants having such a prolific tendency should be sought after.

*R. tomentosa*.—A large common form well worth growing. Its branches are long and arching, reaching even 8 ft. or 10 ft.; its prickles are all the same size, and generally, but not always, straight; its leaves consist of fewer and larger leaflets than the four preceding forms, and are very downy, whilst its globular fruit, covered with prickles, distinguishes it from *R. canina*.

*R. rubiginosa* (L.). *R. Eglanteria* (Woods). (Sweet Brier).—A well-known form, wild on the chalk downs of the southern counties, very sweet-scented, with a compact, erect habit, a few stout hooked prickles, intermixed with bristles and glandular hairs, and two or three flowers growing together on very bristly flower-stalks.

*R. micrantha* may be worth introducing in such a tangle as would smother *R. rubiginosa*, since, though it has a fainter odour, its branches are long and arching, so that it can hold its own in a struggle for existence.

*R. canina* (Dog-rose), so called, no doubt, from its not being fragrant, has been split up into some thirty varieties, between which there is little to choose, they all having their more prominent characters in common. They form large straggling bushes with long arching branches armed with stout hooked prickles, uniform in size. Their stems and leaves are generally smooth and inodorous; the styles of their blossoms are not united, and their fruit is rather odder than globular. Two closely allied varieties are noteworthy, viz. :—

*R. lutetiana* (Leman). *R. sericeolosa* (Woods).—Both have smooth leaves and flower-stalks, and in both the sepals fall off before the late ripening fruit changes its colour. *R. lutetiana* produces from one to four pink flowers from one stalk, each about 2 in. in diameter, and is a very common form; but *R. sericeolosa* produces as many as from ten to thirty, and is, therefore, highly desirable for our purposes. Another variety, *R. Reuteri* (Godet), the sepals of which do not fall until after the early ripening fruit has changed colour, is like *R. lutetiana*, but is valuable from the large bracts (as long as the peduncles), the stipules and the branches all turning red in autumn. It is common in the north of England.

*R. stylosa*, recorded from Sussex, is a tall bushy form with long arching branches, strong hooked prickles, leaves hairy all over their under surface, and from three to six white flowers in a cluster, having markedly divided sepals, pinnate, and the protruding styles united into a column.

*R. systia*.—A commoner form than the last, being frequent in Midland and Southern England; only differs from it in having hairs only on the nerves of the under surface of the leaf and usually pink flowers.

*R. Monsoniae*.—Another closely-allied form, from Herefordshire. Is a low-growing, erect bush, with very large red flowers, a shorter stylar column, and sub-globular orange-red fruit. It is obviously one of our most valuable varieties.

*R. arvensis* (L.). *R. repens* (Scopoli).—A common southern form; is a bush from 2 ft. to 3 ft. high, with purple, glaucous, trailing branches. Its prickles are often very large, its leaves quite smooth and glaucous on the under surface; its flowers white with a yellow throat and a purple calyx and the styles united.

For much of the nomenclature and technical characters of both the British Brambles and the British Roses I am indebted to the works of Mr. J. G. Baker, F.R.S.

Of foreign Roses I would mention *R. bracteata*, the large single white Macartney Rose from China; *R. Lyelli*, a double white Rose from the Himalayas; *R. punicea*, the Austrian scarlet, or rather orange, Brier; *R. pyrenaica*, *R. alpina*, and *R. rugosa* alba.

These Roses and Brambles with Honeysuckle and Clematis would make a medley as charming in autumn as in summer.

11, Burlington Road, Westbourne Park. G. S. BOULGER.

## CREEPERS.

THE Rev. Henry Ward Beecher is an enthusiastic gardener, and writes as follows concerning some of his experiences to the "Gardeners' Monthly":—

1. Every creeper, shrub, or tree that approaches the condition of evergreen is valuable for its winter beauty. Hall's Japan Honeysuckle is the most valuable of all the family of hardy Honeysuckles. It is hardy, luxuriant, a real ever-bloomer the summer through, of fine green leaf, and, except under long-continued severely cold weather, it is evergreen. Under my window is a plant of it spread upon the ground as green as in midsummer. *Lonicera flexuosa*, or Chinese, is near by, quite shrunk with cold, and will do no more till spring. If one can have but one, that one should be Hall's. If suffered to grow along the ground, it will root at almost every joint, and furnish abundance of new plants without trouble. I have enjoyed a method of treating Honeysuckles on the lawn, viz., putting about a vigorous root five or six stakes, say 4 ft. high, surrounding them with twine, about three hoops at equal distances, and allowing the plants to cover them. By the second year an altar of green will be formed, most comely to the eye. If *L. aurea reticulata* be used, it will give a splendid golden effect. Golden kinds should not be suffered to twine with others, as the appearance will be that of a sickly Vine mixed with a healthy one; but, kept separately, the effect is admirable. The *Lonicera fragrantissima* is a shrub that comes very near being evergreen. In sheltered places it will hold its leaves till after Christmas. At Peekskill, forty miles north of New York, on the flanks of the Highlands, it is yet (Jan. 4) in good condition, though it has passed through several severe freezings. Its perfume in spring is delicious.

2. Why has not the *Styrax* been brought into notice? It has gone through last winter, at Peekskill, without being harmed. There are few shrubs that can compare with it for beauty in its blooming season, and it ought to be in every garden. I can get it only by sending to England for it. It is finer than *Andromeda arbores*, which with me is not hardy enough to flourish, or I am not skilful enough to make it live, except as an invalid. I do not know the specific name of my *Styrax*, but I think it is *Styrax japonica*. There are several native species that deserve to be introduced to our nurseries, to say nothing of scores of other plants unknown and unobtainable now. I know the reply. Nurserymen cannot afford to cultivate stock for which there is no demand. True, in large quantities; but American nurseries have now reached a degree of development that will enable many of them to bring forward unknown plants and give them such publicity as shall create a demand.

Some agreement might be had by which one would fill out a special department, another a different one, so that out of six or eight nurseries a gentleman might secure what he wished. I cannot secure from any or all American nurseries the hardy Pines. Even *Pinus mitis*, so abundant in the fields, is a

stranger to most nurseries; but not to catalogues. Oh, no; the catalogues are all right, but orders come back unfulfilled in a manner that leads one to think that catalogues are copied from European lists, or are made up as fancy work.

3. Speaking of Conifers, much is written about transplanting. My experience is, that evergreens may be transplanted at any time of the year when the ground is open and workable. I do not lose the half of 1 per cent. of the hundreds that I annually move. If they are ripped up and jerked out of the ground, laid in the sun, and, worse yet, in the mud, until others have been slaughtered, and then hauled in an open cart, stuck into a cramped hole, lumps of soil thrown in and trodden down by one's feet, no wonder they die. It would be a shame if they did not. Take up the roots carefully, cover them from the light as you would your children's bodies, plant them in a larger hole than that which they have left; take time; press the roots as if you were combing your own hair for a party; see that they are not planted 1 in. deeper than they stood before moving, and then—mulch—mulch—mulch—them. After that you may whistle at summer droughts or winter freezings. I have had as good luck in orders from nurseries in September and October as in March or April. I lost some—I always do, for the most careful nurserymen are careless, judged by my standard. I had as lief transplant in July as in May, in November as in June. It only requires a little more care. In that murderous season, four or five years ago, I had planted many scores of Coniferous evergreens, but did not lose 1 per cent.—on the windy hills and sharp climate of Peekskill—and all because the plants were abundantly planted and abundantly mulched. Mulching, summer and winter, is supreme safety for ornamental trees and for fruit trees. I have saved a Pear orchard by a system of mulching in summer as well as in winter.

4. I mean to write you by-and-by of my mistakes and blunders; successes are all very well; everybody likes to narrate them. But there is great instruction in well-considered blunders; only, men are ashamed to relate them; and so much knowledge is lost. There is hardly a department of culture, esculent vegetables, ornamental trees, fruit trees, flowers, Vines, &c., &c., in which I have not been rich in mistakes. Ought they to die unrecorded?

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Privet Hedges.**—As a division between compartments in kitchen gardens or allotments there are few more serviceable hedges than those made of Privet kept cut down tolerably low, say to 3 ft. or 4 ft. They are much used in Suffolk, and if clipped early, say in the first week in June and again in August, they become densely furnished with young spray-like growth, and remain quite covered with green leaves the whole season, but if left uncut until the end of the summer, the whole of the undermost leaves are lost, and after cutting, a bare stubby aspect is the result, altogether spoiling the general appearance of the hedge.—J. Groom.

**Catalpa speciosa.**—About thirty years ago my brother and myself starting in the nursery business in this country, heard of a new and superior variety of Catalpa at Dayton, Ohio. We sent to Mr. Haines for seeds, from which we grew quite a number of trees. I do not know its earlier history or origin. We have grown this variety more or less ever since, always having it for sale, and never until quite lately finding any demand for it. Soon after our first trees began to bloom, Dr. Warder, then residing in Cincinnati, saw them, and named it *C. speciosa*, from the grand appearance of tree, foliage, and flowers. The tree is quite upright, nearly as much so as the Carolina Poplar, and a very rapid grower. The foliage and flowers are much larger than the common *C. bignonioides*. I have measured seed-pods 26 in. long and  $\frac{3}{4}$  in. in diameter. Along the streets of Dayton I have noticed both varieties side by side, and the difference in habit and growth is quite marked. Most of the Catalpa trees planted along the avenues in Indianapolis within fifteen years are *C. speciosa*, and I believe it is pretty well disseminated. The wonderful durability of the Catalpa timber should, and probably will, cause it to be largely planted.—(The Cultivator and Country Gentleman.)

**Laburnum Bloom** (see p. 569).—We notice that Mr. Groom refers to the scarcity of Laburnum bloom this season. In this district there is very little, and what there is poor. This also applies to the Hawthorn. The latter was very early this year, being in flower on the 15th of May.—BALLANTYNE & SON, Dalkeith.

—In this locality the bloom on the Laburnum has been most abundant, therefore I think the failure noted in Mr. Groom's case must be purely local. The Wistaria has also been singularly beautiful this season.—A. D., Bedford.

**Forests in Japan.**—The Japanese Government has just awakened to the necessity of preserving its forests, and stringent regulations have been passed, which shall not only hinder the too rapid destruction of the forests, but increase the area covered by woodlands.—"Nature."

## THE KITCHEN GARDEN.

### THE PRESERVATION OF MUSHROOMS.

THE oldest and most generally adopted method with Mushrooms is to dry them by natural or artificial heat. For this purpose a large gathering of Mushrooms, both large and small, is made during the height of the season. They are first cleaned and skinned, and the stumps are removed as if they were going to be cooked at once. They are then stirred up several times in boiling water, to which a little vinegar or Lemon-juice has been added to prevent the Mushrooms from turning black. Some say that perfectly plain water is to be preferred. In any case any admixture of salt should be scrupulously avoided, otherwise the dried Mushrooms will attract moisture from the atmosphere. The Mushrooms, on being taken out of the boiling water, are drained on a sieve, threaded on strings, and hung up festoon fashion in a well-ventilated shed or room. In favourable seasons and dry localities the preparation described above is sufficient, but in damp districts or during rainy weather the drying process should be completed in a slack oven, one, for instance, from which a batch of bread has just been drawn. This method of drying applies to all edible Mushrooms, such as the Boletus, the Morel, &c. All of them, however, lose much of their odour and flavour in the desiccating process, but they are still of a sufficiently good flavour to be of great use in the kitchen when the fresh Mushroom is not to be got. For use, the dried Mushrooms are first thrown into tepid water or milk until they are sufficiently swollen, after which they are treated like the fresh vegetable. For use as a condiment, the dried Mushroom must be reduced to powder. It is dried very quickly, and then grated on a very fine grater. The powder must be preserved in a well-corked bottle or jar. Equal proportions of powdered Mushrooms of different species, with a tenth or a twentieth of powdered truffles prepared in the same way, form a condiment which is greatly appreciated. The preservation of Mushrooms in oil or butter is a much more expensive process, but the Mushroom preserves a much larger proportion of its perfume and flavour than when simply dried. The best method is the following: The peeled Mushrooms, prepared as in the last receipt, are blanched in boiling water, and then drained on a sieve; they are then placed one by one in a wide-mouthed jar or bottle until it is full. Warm melted butter or pure Olive oil is then poured over them, and the whole is allowed to become perfectly cold, after which the mouth of the jar is tied over with an air-tight parchment or gutta-percha cover. The jars must be kept in a cool place, especially if we have used butter, which is very liable to turn rancid if kept in a warm place. The method of preserving Mushrooms by drying or by immersing them in oil or butter is specially adapted for households or where only small quantities are required, but for commercial purposes on a large scale the Appert process is always used. The Mushrooms and even their fragments are cleaned, peeled, and thrown for a few minutes into water slightly acidulated with vinegar. After they have been well drained, they are tossed in butter until they are half cooked, after which they are packed into wide-mouthed bottles. Every bottle is only three-quarters filled, closed with a good cork, and well tied down with string. The bottles are then placed in a cauldron full of cold water, the bottom of which is covered with a layer of straw or a straw mat, each bottle being surrounded by a packing of hay, in order to prevent breakage. The cauldron is then placed over the fire and allowed to boil for about six minutes, after which it is taken off and allowed to cool gently, and after that the mouths of the bottles are dipped into melted bottling wax.

The use of ketchup as a condiment has become much more frequent in French kitchens and at French tables of late years, more especially with boiled fish. The following is the French method of preparing it, which differs somewhat from that given by English authorities:—Take a kilogramme of very fresh cultivated Mushrooms, and after having carefully peeled them, cut them into very thin slices and strew a layer on the bottom of a deep dish or tureen; sprinkle the first layer with fine white salt, over this spread another layer of chopped Mushrooms and salt, and so on till the dish is full. On the top

of all strew a layer of fresh Walnut rind cut into small pieces. Allow the whole to macerate in a cool cellar for four or five days. When the whole mass has become nearly liquid, pass it through a cullender or a new piece of linen. Boil down the strained liquor to half its bulk, add its own weight of calf's-foot jelly, season with Alspice or white Pepper and Bay leaves, and boil down to the consistence of jelly. Pour into porcelain or stoneware jars, and keep in a cool place. LACHAUME.

### EARLY PEAS.

NUMEROUS are the expedients resorted to in order to hasten the growth of early Peas, there is no way, except growing the very dwarf sorts under glass, that has yet produced Peas in quantity more than a few days in advance of those sown in well-sheltered positions in November, and protected from mice, birds, and slugs—not a very easy task—for during the present season I have seen many crops that were sown at the most favourable season for ensuring rapid growth entirely spoiled by slugs, and that, too, in spite of many precautions taken for their security. Like Mr. Temple (see p. 563), I, however, see no reason for discarding the old system of making a sowing in November, but as a precaution against failure I have usually sown a good quantity during January on strips of turf cut 1 ft. long and 3 in. wide. These, turned Grass side downwards, are packed closely together on stout planks; the middle of each turf is then scooped out, and the Peas sown, and lightly covered with fine soil. A cool Vinery suits them admirably until the shoots are 2 in. or 3 in. high, when they should be transferred to cold pits and hardened off by exposure, so as to be fit for planting the first week in March. As the roots will be found hanging through the turves in quantities, wide drills should be drawn, and each turf should be carefully re-planted. The rows should then be staked at once, and light evergreen branches should be placed a short distance from each row, for the purpose of breaking the force of the rough winds that usually prevail at that season. On a south border, thus planted, Peas in quantity may be generally gathered about the last week in May. J. GROOM.

### ASPARAGUS ON SANDY SOILS.

THE interesting note from Mr. Studd (see p. 563) respecting Asparagus culture on almost barren sandhills recalls to my mind several instances of very old, but yet productive, beds somewhat similarly situated in this neighborhood, the produce of which is quite equal to the ordinary run of that grown in far richer soils. Therefore there does not appear any insuperable obstacle to the universal culture of Asparagus in this country, as when the soil is not naturally of a sufficiently open texture to suit the requirements of a plant that evidently delights in a loose, porous soil, the old plan of mixing sand, ashes, or shingle at once engenders a remedy that may be easily and nearly everywhere applied. From my own experience, I should say that the plants would prove longer lived in loose soil moderately manured than in highly enriched ground of closer texture, as I have observed, a greater percentage of plants go off during wet seasons under high culture than when growing under more natural conditions. Nevertheless, where the object is to get the finest growth possible, sufficient nutriment must exist in the soil, or be artificially supplied to it, in order to promote full development. A light deep loam resting on gravel, so as to insure perfect drainage, is a good soil for Asparagus. Thus planting, and a good long season of growth by discontinuing cutting early, and protection of the tops from being broken by wind-waving, would also be attended with good results. JAMES GROOM.

**Asparagus at Chester.**—We have recently seen samples of excellent Asparagus grown at Chester by Messrs. Francis and Arthur Dickson in some land of theirs that has been reclaimed from the sea. It is of a very light sandy description, and Messrs. Dickson state that it has been under cultivation for about 100 years. The 3 acres of it devoted to Asparagus are laid out in beds 4 ft. wide, and each bed contains three rows of plants, which stand about 6 in. or 8 in. apart in the row. The beds have been planted about ten years. Each winter the surface soil is drawn off them, and a good application of stable manure and potash salt is given to them; the soil which has previously been removed is then spread over the manure on the top of the bed, and no other cultivation is necessary beyond keeping down weeds. Cutting usually begins early in April and ends about the beginning of July. Last year forty-three heads weighed 8½ lb. To us this Asparagus seems different in flavor from any we have tasted, and it would be very interesting to taste it blanched as the London and Colchester growers blanch Asparagus.

### PLATE CXXXIII.

#### FRITILLARIA PUDICA.

Drawn by MRS. DUFFIELD.

THIS charming little plant was described long ago (1814) by Pursh, in his "Flora Americae Septentrionalis," as *Lilium* (♀) *pudicum*, with the remark that it appeared at first sight more related to *Fritillaria* than *Lilium*; and, as these genera are now defined, it is a true *Fritillaria*. In the colour of its flowers this species is variable, but the variety here depicted is the most showy one known. Pursh gives a figure of a pale yellow, taller variety, such as one would expect to find in half-shaded situations; and the late Andrew Murray found varieties in which the flowers were tinged with brown or wholly reddish. *F. pudica* is a native of the Rocky Mountains and the Sierra Nevada of California, where it grows in a dry, barren soil, and is one of the principal spring ornaments of the scanty flora. It is perfectly hardy, ascending to an elevation of from 5000 ft. to 6000 ft. or more. In many places it is exceedingly abundant, but it does not appear to have been introduced into Europe before Roez sent it to M. Max Leichlin, of Baden-Baden, about the year 1870. Two or three years later Mr. Murray brought it from Utah to this country. Among hardy dwarf bulbous plants it is undoubtedly one of the most valuable of recent acquisitions, surpassing even the *F. dasyphylla*. Another very beautiful dwarf *Fritillaria* is *F. armena*, of which two varieties—a yellow and a deep purple—are figured in the current number of the "Botanical Magazine." W. B. HEMSLEY.

[This is one of the most valuable hardy plants introduced to our gardens for many years. We look to its taking a similar place among yellow flowers to that of the Snowdrop among white ones. For the specimen from which our plate was prepared we are indebted to Messrs. Backhouse, of York.]

**Tropaeolum tricolorum.**—The addition of the name "Jarratti" to the long-shaped tubers of this *Tropaeolum* is absurd, as even round tubers will sometimes throw out kidney-shaped ones. All the forms are those of *T. tricolorum*, and in no way do the plants differ either in foliage or flowers. This plant is much harder than is generally believed. Some years ago it used to be grown in great abundance in the kitchen garden at Hurlingham House, Fulham, and I grow my plants here in a cold frame through the winter, planting the roots in the soil and allowing the bine to trail over some spray, as the production of tubers is my only object, and in this way they do better than in pots in the greenhouse. The tubers increase but slowly, as a rule, but sometimes they may be produced more rapidly by laying the young growth beneath the soil before allowing it to reach the supports.—A. D.

**New Method of Preserving Animal and Vegetable Food.**—Dr. Campbell Morfit has lately patented a process for preserving animal and vegetable alimentary products, which promises to be of great service. Dr. Morfit's investigations seem to prove that if gelatin is thoroughly diffused through an animal or vegetable substance and dried in and with it, all danger of decomposition is avoided. Some Lime-juice biscuits, which Dr. Morfit sent for trial, are perfectly good and sweet, although some of them are more than a year old, the peculiar flavour of the Lime-juice, so different from that of the Lemon, being thoroughly preserved. Dr. Morfit's process consists in getting rid of nearly the whole of the natural water contained in the substance and replacing it by gelatin. Plums, for instance, may be preserved by reducing them to pulp, mixing them with gelatin dissolved in water or their own juice, and beating the mixture so as to ensure thorough incorporation of the ingredients; the gelatinized juice is then poured into coolers. The biscuits sent contain 40 per cent. of pure Montserrat Lime-fruit juice, and have a refreshing acid flavour. They are made by mixing the gelatinized Lime-juice with the proper proportion of biscuit powder and baking. The process is, of course, capable of great extension, and if Dr. Morfit can give us biscuits tasting of the Pine-apple, Peach, Strawberry, and a dozen other fruits, he will have conferred a benefit on the community.—C. W. QUINN.

**Japanese Bamboo Shading.**—The best shading which we have noticed in use for hot-houses is one composed of very large Japanese mats formed of Bamboo. They are in use shading the houses of the New Plant and Bulb Company at Colchester. They are also efficient as a protection from hail, and very strong and lasting.

THE GOLDEN FRITILLARY. (FRITILLARIA AUREA.)

## ROSES.

**BUDDING.**—Roses will be in a condition for budding sooner this season than usual; in fact, in the south I noticed that some amateur growers began with standards and half-standards on Brier stocks the first week in the month. So far as my own practice goes, I have found it the best to perform the operation as early in the season as the buds and growth of the stocks would permit, or to defer it till considerably later on in the summer. The earliest-budded plants push their eyes and commence growth as soon as the buds have fairly taken, and in this way make good the first season. Those that are budded sufficiently late take, but the buds remain dormant until the spring; but if the budding be carried out in what may be termed mid-season, the buds, in place of starting into growth and having time to fairly mature the shoots they make, or, in the case of the later, remaining quite dormant through the winter, form shoots that have not time to get enough solidified before the autumn frosts are upon them, and in this way the tenderer kinds are liable to perish. This is more particularly the case in the northern parts of the kingdom. As to the stocks employed, only such at the present time can be used as have already been provided. The difference in opinion as to the superiority of Brier or Manetti evidently arises through the different effects that soils of various descriptions have upon these stocks. Where the soil is so light as to be naturally unsuitable for the free vigorous development of the Brier, Manetti is no doubt preferable, but where the land is of that strong heavy description congenial to growth, the ordinary Brier is in many ways to be preferred; consequently, those who have at hand a choice of stocks will do well to rely principally upon that which is found by experience to do the best in the immediate locality where the Roses are to be grown.

**REMOVAL OF SUCKERS.**—Constant attention should now be paid to the removal of suckers from Rose stocks. Where the plants have been allowed to remain for a considerable time without removal these suckers are usually a source of continual annoyance, especially in such stocks as support the weakest-growing varieties of Roses, as in their case the heads of the plants are not sufficient to draw the full quantity of sap which the roots provide, hence the disposition to break out into this underground growth. In the case of stronger-growing varieties, where the heads have been let to attain a large size, there is generally a less inclination to throw up suckers. Even where standard Roses are grown by the sides of walks with their roots under the turf, and where the suckers run underground for a considerable distance before appearing above the surface, it is always the best to trace them right to the base from where they proceed, removing the soil with a planting trowel or similar implement, so as to admit of this being done, in which case the operation will be effectual until fresh suckers are formed; whereas if the shoots are simply broken off at the point where they appear above ground they keep on repeatedly making fresh growth, which, so far as diverting the strength of the plant from its legitimate course the support of the head, involves a loss little less than if the suckers were not removed at all.

**THINNING OF THE BUDS AND REMOVAL OF DECAYED FLOWERS.**—Large Rose flowers, for filling vases, baskets, and the like, are now held in very much greater estimation than they used to be, consequently upon a taste acquired through the large perfect individual blooms that are seen at the exhibitions of Roses; but these large flowers can only be obtained by thinning the buds on the strong shoots, which alone are able to produce such; and where there is a disposition to sacrifice, to some extent, quantity to quality, the strong shoots should have the buds thinned, particularly where the plants are grown on their own roots and pegged down, under which system the later growths made from the base of the plants are generally very strong and calculated to produce large, fully-developed bloom. To assist the formation of young wood that will give a succession of flowers through the summer and autumn, the first blooms, immediately they decay, should have the seed vessels removed, which will greatly promote second growth. The time employed in this—where, as in most gardens, a great number of plants require attention at this season—can often

ill be spared, yet it is only by attending to such details that the best results are attainable, and a moderate number of plants, where they meet with sufficient care, will reward the cultivator better than much larger quantities when left to themselves. This has seldom been further exemplified than in the present season, when the Rose maggot, where not diligently sought for and destroyed, has effected such havoc, that five-sixths of the flowers are so deformed as not to be presentable for ordinary decorative purposes, although they may be fairly effective when seen on the plants from a distance.

**INSECTS.**—With a like object continual efforts should be made to keep down aphides, which, despite the long run of wet, showery weather, are yet more numerous than usual. Regular use of clean water without stint, applied with the springe and garden engine, will effect the object; their numbers may be reduced in the ordinary way by brushing with the fingers or the small sugar-tongs-shaped brushes, made for the purpose; but in thus crushing them on the buds the matter from their crushed bodies tends to injure the character of the flowers, unless they receive a good washing immediately after the insects are destroyed.

**MANURE WATER.**—In soil, where there is any deficiency of enriching elements in the shape of solid manure, either incorporated with it or laid on the surface in the shape of mulching, the ability to produce flowers later on will be very much increased by the application of manure water, which in the case of Roses, as other plants, is much quicker in its effects than through any other means by which manure can be applied. There is no time through the whole spring or summer when it can be used with so much advantage as the present, when there is a conjoint vigorous extension of both roots to absorb and shoots to assimilate it. To Roses on walls it will be especially beneficial, and in their case it hardly can be given in too large quantities. Roses in all positions will bear manure water applied stronger than most plants.

**INDOOR CLIMBING ROSES.**—Vigorous-growing varieties of Roses, especially such as *Maréchal Niel*, *Gloire de Dijon*, or *Lamarque*, that do not flower freely if pruned to any great extent before growth commences in the spring, will now, after the principal flowering is over, require attention; whilst the plants are young, and before they have filled the space which their heads are destined to occupy, they need not be much reduced, but when they have filled anything near all the room available, if cutting back is not carried out some time in the year they get crowded with useless, weak wood, little able to produce handsome, full-sized flowers. To avoid this, now that the spring blooming is over, a portion of the large, strong, old branches may be cut out near the point on the main stem from which they spring, leaving a stump, the latent eyes of which may be expected to immediately break into growth. These will form strong, vigorous branches, which will produce the best flowers next season. This removal of a portion of the old wood annually, to be replaced by new, may be carried to the extent of one-third or one-fourth the entire plant, which, so treated, will always contain a sufficient quantity of young, vigorous flowering growth, and will not attain a dimension beyond that which there is space for, and that profusion of weak, useless shoots that results from insufficient pruning will not exist. The plants at the same time should be thoroughly well washed, so as to free them from insects. If there is any mildew upon them, a liberal application of water impregnated with sulphur will be found useful. Where planted in inside borders, or in a position where the root space is confined, manure water, given so as to soak the whole mass of soil as far as the roots can extend, will be of the greatest possible use. This may with advantage be repeated from time to time for the next two months whenever the soil requires moisture. T. BAINES.

**Maréchal Niel.**—"B. A." asks (see p. 495) as to the nature of the cultivation given to my *Maréchal Niel* Roses, the flowers of which have been so good in colour. In truth, they thrive under a comparative absence of cultivation, as the dressing given is of the most meagre description. The plants are on their own roots; they are planted in a soil bed about 5 ft. across and 2½ ft. in depth, placed in the centre of a cool span-roofed house. One plant is trained to

the end wall and the other up a supporting column and then along wires at the top of the house. Both make moderate growth, and just now, after the blooms have been taken off, are pushing freely in all directions. There are no unusually vigorous shoots, and I do not desire to see them, as they are often the precursors of canker and decay. The bed is rather dry than otherwise, but when not occupied with seeds or other things (I have a crop of seedling Potatoes growing on it just now), I make a boy fork up the soil, and give a good soaking of water. At other times the surface is simply kept as moist as the plants growing upon it require. About once a year the surface is given a coat of manure, but the roots of the Roses can get but little of it. An aphid is rarely seen on either plant.—A. DEAN, *Belfont.*

#### RULES FOR JUDGING ROSES.

The Committee of the National Rose Society have been engaged in drawing up some rules for judging Roses at horticultural exhibitions, and as they are likely to be instructive to our readers, we subjoin them. In regard to the "Method of Judging," it is recommended that the judges first cast out all bad boxes, that is, those having blooms of inferior quality. Then the remainder are to be compared, and it is recommended that three judges work together in the case of Rose shows, and that each judge in turn shall count and designate the good blooms, the other two standing behind and stopping their colleague when they do not agree with him. In every difference of opinion as to what constitutes a good Rose, a majority of the judges shall decide, and the result of counting the good blooms shall form the decision ultimately reached. In estimating the points in a box of Roses, it is suggested they be recorded by means of "marks," and that these marks be allotted as follows:—"Three marks shall be given to every perfect bloom; two to one not quite so perfect; and one mark only to a moderately good one. One mark shall be taken off from the box for every case of decided badness. As some judges of Roses are apt to show a decided preference for Tea and Noisette kinds, it is recommended that they have no especial favour shown to them as such. Marks to be given for evenness, variety, and general arrangement of the boxes, at the rate of one mark for each of these especial excellences. As Roses are shown in boxes, it is set forth that the flowers must be judged as they are in the boxes at the time of inspection; no other consideration of any kind is admissible. Where stands are equal in respect to flowers, the judges shall proceed to consider the general evenness, variety, arrangement, and setting up, the boxes being placed side by side and in the same light for that purpose. The boxes should be of the regulated size and shape, and set out with Moss, unless otherwise specified. And as certain definitions are employed at Rose shows, they have been set forth as clearly as possible to prevent misapprehension. A bloom or truss should be taken to mean a Rose, with or without buds and foliage, as cut from the tree. As to what constitutes a bad Rose under this heading will be included all that have a faulty shape, confused centre, a faded colour, and which are either undersized or oversized to the extent of coarseness or overblooming. On the other hand, a good Rose must have form, size, brightness, substance, foliage, and be at the time in the most perfect phase of its possible beauty. Form will imply abundant petals of good substance, regularly and gracefully disposed within a circular and symmetrical outline. Brightness shall include freshness of colour, brilliancy, and purity.

**Bougainvilleas at Nice.**—In THE GARDEN (see p. 546) I find an article on Bougainvilleas. Having lately returned from Nice, where I spent the whole of last winter, I had several opportunities of seeing this beautiful plant, which in its habit and growth resembles the Wistaria. I should hardly imagine a stove house to be a suitable quarter for it. The first time I had ever seen it was at Monte Carlo, where there are three or four beautifully-trained specimens of it on a pigeon house. These plants were in good leaf in December, and were still so on the occasion of my last visit, the second week in May; during the latter part of January it appeared to me to be in its greatest perfection. That it will bear a moderate amount of frost is undoubted, for during the earlier part of January we had several frosts in succession, ice forming to about the thickness of a five-france piece, and I was informed that Bougainvilleas would stand from 5° to 10°. I purchased a small plant, the only one I could get, which I have planted at Chaville, and hope that it will make some little growth this summer (if we are to have any), so as to make it worth while to prolong its existence through the next winter with the aid of matting, &c. When established, the Bougainvilleas are rapid in their growth, a single plant covering a large space of wall in about two years.—W. ELLIS, 28, *Rue Bassano, Paris.*

## GARDENING FOR THE WEEK.

### Indoor Plant Department.

**Orchids.**—The different varieties of *Calanthe vestita* and the hybrid *C. Veitchii* will now be making active growth, and must be plentifully supplied with water, keeping the plants as near the glass as convenient. If grown in baskets or pots that can be suspended near the roof over the paths, in this way space can be economised, and they are in the best position for securing stout substantial foliage that will remain fresh and green upon the plants through the autumn and winter much longer than when grown under conditions that favour long growth at the expense of solidity. There are no more useful plants than this section of *Calanthes*, but, unless they are treated through the growing season in a way to impart vigour to the leaves, these often are so far decayed as to necessitate their being cut away when the plants are in bloom; and although the flowers in themselves are always handsome, they have a much better appearance, if even a portion of the leaves can be kept green and living, than when nothing is to be seen but the naked pseudo-bulbs and the flower-stems, and by treating them as recommended there is the additional advantage that the bulbs will attain so much larger size with a correspondingly increased ability to produce flowers.

**Broughtonia sanguinea.**—Although individually not so imposing in appearance as many Orchids of larger growth, still, on account of its colour (deep red), it is a growing of plants that to the extent of a dozen or more plants of a collection, the colour of the flowers contrasting so well with almost everything else. I have found it to succeed well on a block of wood or a piece of cork with a little Sphagnum attached. In this way, suspended from the roof, the plants occupy very little room, and they have a most telling effect when in flower, a consideration worth taking into account, but which is perhaps less studied in connection with the cultivation of Orchids than that of any other plants.

**Mesospindium sanguineum and vulcanicum.**—For the purpose of giving contrast in colour, these are also worthy of a place. Like the *Broughtonias*, they occupy little room, and their rosy-crimson flowers are comparatively large for the size of the plant. Coming into bloom, as they usually do, earlier than the highly coloured *Mastelias*, they are a similar offset on all light-coloured flowers that are near them, and, as they succeed in a cool or medium temperature, they can be grown where there is not the means for cultivating such as require strong heat. They do best in pots, in material like that which answers for *Oncidium* and *Dendrobium*.

**Cattleyas of the Mossin section.**—*C. Warneri*, *C. Skinneri*, and also the different forms of *C. intermedia*—where they require potting should be immediately attended to, as they go out of bloom before much or any growth commences. These, in common with all other Orchids, should never in any case be overpotting, yet they ought not to be allowed to remain in pots where the young growth extends beyond or outside the rim, as, when the roots which the young growth forms cannot take hold of the material within the pots, but, in place of this, grow to the outside, they meet with nothing to sustain them, and are in the worst position for being injured when the plants are moved about in the operation of cleaning, and the growth made under these conditions, instead of getting stronger, usually is smaller than that from which it proceeds, a state in Orchid growing which always, so far as possible, should be avoided, as the stronger the pseudo-bulbs of such plants as these get the greater disposition they have to break double, which is the most effectual way of increasing the size of the specimens, or permitting of division where this is desired. In moving them let it be effected with the least possible mutilation of the roots, which, if the plants are in a healthy vigorous condition, are sure to be actively at work. Do not, after potting, give more water for a short time than is absolutely necessary to keep the bulbs and leaves plump and fresh and to enable the buds to swell, as if the material in which the broken fibres of these plants are placed is made too wet they are very liable to rot, as they, more than most Orchids, are at all times impatient of much moisture.

**Lælias.**—The different forms of *L. purpurata*, *L. elegans*, *L. Schilleriana*, *L. Turneri*, &c., also should, where required, have immediate attention in potting as soon as they are out of flower; they, like the *Cattleyas*, commence growth directly the blooming is over. The potting and material in which they are grown, as also their general treatment, requires to be in every way similar to that recommended for the above-mentioned *Cattleyas*.

**Cattleya Trianae.**—These most beautiful winter-flowering plants should now be making considerable progress in their growth, and will require more water, but when grown in pots care must always be taken that the material is not made too wet, especially in houses where the plants, through any unavoidable cause, do not receive enough light, for it may be taken as an invariable rule that the most stout and sturdy growth they make, consequent upon plenty of light with enough air to sufficiently dry the atmosphere during the day, they will always bear more moisture at the root than when these conditions are wanting.

**Cattleya superba.**—As these commence growth they must be placed under conditions of more warmth than almost any of the others. The best position I have found for this difficult-to-manage plant, where not suspended near the roof, is immediately near the upright glass as the frost or end of the house where the East Indian plants are grown; here it receives somewhat less heat than those that occupy the more central part of the house, and also gets more air, a matter of equal importance to

this, one of the finest of the whole family, yet rarely seen in a state such as it can keep on improving for any considerable number of years.

**Dendrochilum filiforme and glumaceum**.—These elegant-flowered, compact-growing plants will mostly now have done blooming, and where it is deemed advisable to divide them, or they require larger pots, these should be supplied without delay. They succeed well in a mixture of equal parts fibrous peat and chopped Sphagnum, to which is added a liberal sprinkling of broken crocks and a little sand. The coolest end of an East Indian house will be found the most suitable place for them.

**Cyclopogon cristata**.—This most useful of all winter-flowering Orchids will now be pushing freely both root and leaf growth. It is a thirsty subject at the roots, requiring much more water than many plants. Anything approaching a dry condition of the soil, accidentally or otherwise, now, when growth is in full progress, is fatal to the bulbs ever attaining their wanted size, without which many will fail to produce flowers, and those that do bloom will bear them few in number. But though a moisture-loving subject at the roots, it cannot bear a stagnant atmosphere, nor too much heat.

**Cypripediums**.—*C. caudatum*, *C. Stonei*, *C. Fairrieanum*, *C. hirsutissimum*, *C. villosum*, *C. Schlimi*, *C. Lovii*, and the earliest-flowered variety of *C. barbatum*, as soon as done blooming, should at once be placed under conditions of heat and moisture that will assist them to push their growth up and get it completed before winter. *C. Schlimi* and *C. Fairrieanum* are somewhat shy growers, and generally succeed better with a little cooler treatment. All require plenty of water at the roots whilst growing. Any re-potting or division requisite through the crowns getting overcrowded should be carried out immediately the flowering is over.

**Dendrobium nobile**.—Where this serviceable Orchid is grown in quantities to give succession through the winter, portions of the plants should be pushed on into active growth at different times so as to complete their growth in succession, for though they may be retarded for almost an indefinite length of time, still it is better for the health of the specimens to let them come on into flower when they are ready than to grow the whole stock on at once, and have to resort to too long a drying ordeal for such as are wanted to bloom the last.

**Epidendrum cinnabarinum**.—This is a plant that, from its distinctly-coloured orange-red flowers and the length of time it lasts, deserves to be more generally grown than it is. From its very erect close habit of growth it requires much less pot room than many species, but, where potting is required, this should be done immediately the flowers are decayed. I have found it to succeed better with less Sphagnum added to the peat than most plants. Intermediate house temperature will suit it best; it likes plenty of light.—T. BAINE.

**Stoves**.—Ventilate, more or less, according to the state of the weather, and shade from strong sunshine. Keep the atmosphere moist by syringing not only the plants, but the stages and walls, and likewise by sprinkling the floor with water. Plants of *Euphorbia jacquiniiflora* must be kept growing, and also near the glass, so as to ripen the points of the shoots. Pot on young plants of *Sanchezia nobilis*, *Stenotaphrum Mocciniana* and *Ventensii*, *Pentas carnea*, *Linum trigynum*, *Monochatum ensiferum* and *Sericum multiflorum*, *Centradenia*, *Eranthemums*, and others, using a compost of loam, thoroughly-decomposed manure, and a little peat. Increase the stock for *Achimenes* by means of cuttings; *Gloxinias*, by using good and well-developed leaves as cuttings; the fine-leaved *Begonias* in the same way as *Gloxinias*, and also by placing a whole leaf flat on the surface of a pan filled with silver sand and peat, and surfaced with sand, affixing the leaf therein with pegs, cutting or breaking the ribs at intervals, and sprinkling some sand over the surface of the leaf; if kept damp and shaded, leaves treated in this way soon form buds at every break. The herbaceous kinds are best increased by means of cuttings. Keep *Epiphyllums* in a well growing temperature, and *Eucharis amazonica* in a moist stove. Keep the *Dracenas*, *Crotons*, *Ananassas*, and other fine-leaved plants near the glass, in order to bring out their colours, but preserve them from strong sunshine.

**Conservatories**.—Plants under glass are now growing vigorously, therefore cold draughts must be avoided as much as possible; there must, however, be plenty of ventilation, abundance of water, and shade given, and shade of some kind provided as a protection to plants in bloom, the weak of which soon becomes impaired if exposed to sunshine. Give weak manure water to cross-feeding plants, and from specimens planted out in borders, remove all superfluous shoots and suckers. *Fuchsias* trained to rafters require thinning, and *Clematisses* tying to trellises. Do not allow deciduous climbers to intertwine with evergreen ones, as they are apt to spoil the latter. Keep up a succession of *Hydrangeas*, zonal, show, and sweet-scented *Pelargoniums*, *Fuchsias*, *Coluses*, *Lobelias*, *Salvias*, *Cockscombs*, *Balsams*, *Schizanthuses*, and similar plants, and transfer to frames or the greenhouse such plants as have done flowering. Heaths and some other early-flowering hard-wooded plants may now be set out-of-doors on a bed of ashes.

**Greenhouse Plants**.—Old plants of *Azaranthus umbellatus* should have plenty of water and a sunny position. Plants of *Hebeclinium lanthum* should have been cut down after flowering, and should now be kept moderately dry for a time, unless it be necessary to force them early. Out in hard-wooded *Veronicas* that have done blooming, so as to encourage fresh growth. Keep plants of *Lisianthus Russellianus* in a warm, moist place, and re-pot them as often as they require it. Pot off seedlings of *Primula japonica* and keep them out-of-doors, where they form stronger

plants than if nursed under glass. Plants of *Kaloesantas* should now have some assistance in the way of stimulants, as should also *Liliums* that have formed their flower-buds, and some other soft-wooded plants. *Erythras* in pots should be grown in a cool and light house near the glass; they require plenty of water, and their main branches should have supports of some kind to keep them in proper position. *Bouvardias* that were cut back after flowering should now be making good wood; they must, therefore, be kept moist and warm for some time set. Persian *Cyclamens* should be kept in cool and shady frames, or against north walls; they should receive a little water during the summer months. *C. Coum* and similar kinds should be kept moderately dry, but not too much so. *Azaleas* that have done blooming and which have had their seed-pods picked off should be re-potted, if necessary, and put into a warm pit, where heat, moisture, and shade can be given them. *Camellias* also make good growth under similar conditions, as do also *Citrons* of various kinds. Pinching in should be practised freely until the plants have attained the form it is desired they should assume.

**Suspended Baskets**.—Remove any plants that appear to be exhausted and replenish with fresh material; rather, however, than lift out many of the plants, plant the basket afresh, retaining such as are in good condition. Ferns, *Selaginellas*, *Tradescantias*, *Begonia scandens*, variegated *Panicum*, *Asystasis*, *Achimenes*, some of the creeping *Ficuses*, &c., do well in baskets kept in stoves; and for conservatory and balcony baskets take Ivy-leaved and sweet-scented *Pelargoniums*, brilliantly-coloured *Lobelias* of the *Erius* section, *Petunias*, *Mosembryanthemums* of different sorts, *Tropeolums*, *Isoplepis gracilis*, *Gazania splendens*, *Lysimachia nummularia*, *Ivies*, *Musk*, *Convolvulus mauritanicus*, and many kinds of Ferns and *Selaginellas*.

#### Indoor Fruit Department.

**Pineas**.—Water abundantly and sprinkle the plants overhead either with a syringe or through a watering-pot rose. Remove all suckers, except such as are required for purposes of propagation. In the latter case they should be taken off and potted when strong enough. Plants ripening fruit should be kept rather dry, and, in order to keep them as long as possible in good condition, remove them to a cooler house.

**Vines**.—Fruit on late kinds should now be set and ready for thinning. As late Grapes are ripe at a date when they are subjected to damp, the berries should be thinned out more than is necessary in the case of Grapes that are to be eaten as soon as ripe. No rule, as regards distance between each berry, can be laid down, as the same variety does not swell equally everywhere; but most people are more apt to err in thinning too little than too much. Black *Alicantes* must be thinned as soon as the berries can be seen, for when left for a few days after this the bunches generally become a solid mass, which cannot be conveniently operated upon. *Lady Downes* should not be thinned so early, as many of the berries are imperfectly set, which, if left to form a bunch, come to nothing. The berries of the black *Lady Downes* are also liable to become more deformed than any other kind; and, to obtain them of a perfect and uniform shape when matured, the worst-looking must be removed. Scalding of the berries during the stoning period is an evil which this variety is very subject to, and, in those places where every means have failed to check it, the bunches should not be thinned so much at the present time as they will ultimately require, in order that there may be a reserve to take the place of those which may decay. Vines setting and swelling their fruit at an early stage should not be kept closer during the heat of the day than those colouring. They should, however, be shut up early in the afternoon, and a little air should be given in the evening and throughout the night. The atmosphere in houses where the fruit is ripe or ripening must not be kept too dry on hot days, or the foliage, which is always of much service, even after the fruit is cut, will be injured. To prevent this, damp the pathways and surface of the border at midday and in the afternoon when it seems necessary.

**Peaches and Nectarines**.—Where these have been gathered given the trees a good syringing, the borders a thorough watering, and continue a little dry until the wood becomes perfectly ripe. Give up syringing in cases in which the fruit is beginning to colour, but until then syringe daily; tie in and thin the shoots, and put aside any leaves that happen to overlap the fruit, so as to give it a chance of becoming well coloured.

**Figs**.—As soon as the first crop has been cleared off much the soil with manure, water freely, and maintain a warm, growing, moist atmosphere.

**Cucumbers and Melons**.—Give Cucumbers a good supply of manure water, stop laterals, and only retain as many fruits as the plants can well bear. Keep *Melons* ripening fruit rather dry, but water abundantly those swelling. Use tiles or slates for putting under the *Melons* if they are grown in frames. Prepare plants to take the place of those now ripening fruit, or after the fruit has been cut away cut down the old plants to two or three eyes of the stem; apply a dressing of fresh soil over the old material, give a thorough watering, and increase the temperature, when the plants will again start freely into growth.

#### Flower Garden.

After the flower and sub-tropical gardens have been furnished there will probably remain many odds and ends that will prove useful for the decoration of herbaceous and shrubbery borders, and which should now be planted in such positions in them as will set them off to most advantage. Peg down *Petunias*, *Verbenas*, old and "leggy" *Pelargoniums*, *Tropeolums*, &c., so as to render them as effective as possible. Broken

or small Beech pegs are excellent for this purpose. Have a stock of Lobelias in reserve to take the place of inferior kinds, which often appear where seedlings are used. Edgings of Cerastium should be gone over weekly and all flowers cut off with a pair of shears; flowering shoots should likewise be picked off all plants of the variegated *Polemonium cornutum*, golden *Feverfew*, variegated *Spiraea Ulmaria*, and other plants grown only for the beauty of their leaves. A good supply of reserve plants for future stock should never be secured—for instance, Centaureas kept in pots during the summer time are better for propagating from than plants lifted out of the soil. *Solanums*, *Wigandias*, and various other sub-tropical plants kept in pots during summer are also very useful for affording cuttings for the next season.

**Dahlias and Hollyhocks.**—As Dahlias advance in growth, see that they are kept regularly tied up. They should have three or four sticks to each plant, so as to keep them open and allow the sun and air to get to the centres. The practice of tying these plants up to a single stick is bad and unsightly; it causes them to run up tall, and affords little security against strong winds. To induce the plants to throw out strong side-shoots, pinch out the points of the leading growths. See that they are quite free from aphides, and, if any are detected, syringe with Tobacco water. Hollyhocks must be well secured to stout sticks as they increase in size, for if they get blown over it spoils them. They do not require the sticks so long as those sometimes used, unless grown in very exposed places, in which they should not be planted. If the sticks are 4 ft. out of the ground after being firmly driven down, they are high enough. Do not tie them so tightly as not to allow sufficient room for the stems to thicken. On the other hand, they must not be left so loose as to chafe with the wind against the supports.

**Herbaceous Plants.**—These being now in great beauty, a little extra care should be bestowed on them. Lift such *Hyacinths*, *Tulips*, and *Crocuses*, as interfere with them, and spread them out to dry without removing any of the leaves. Cut over the decaying stems of *Verbena* and similar early flowering plants. Gather seeds of *Scillas* as soon as they are ripe, and sow them at once. Plants that require support, apply strong stakes, but *Campanulas*, *Delphiniums*, *Penstemons*, *Antirrhinums*, *Pyrethrums*, and some others of a similar character look best when unsupported in that way. Transplant *Primulas* kept in pots on a shady border, where they should be kept clean and secure from slugs; *P. japonica* always grows better when planted out of doors than when grown in pots. A mulching of rotten manure, spent Hops, Cocoa-nut fibre, or leaf soil should be spread over the ground, and its appearance on the surface is objectionable, cover it with soil. *Phloxes* like plenty of nourishment, consequently a little manure water should now and then be given them. Everlasting Peas, wintered in pots, may now be planted out. *Viola cornuta* and other bedding *Pansies* should be kept well furnished with young shoots by occasionally cutting out the old ones, and the beauty of both English and fancy sorts will be greatly prolonged if they are grown in a moist and partially shaded situation. Train *Clematis* in such a way as they will look best. Such herbaceous plants as have been wintered in frames may now be planted out, but in the case of *Dodecatheons*, &c., intended still to be kept in pots, a shady position on a bed of ashes is best for them, and upon no conditions should they become at any time perfectly dry. Remove decaying flowers, except in cases in which seeds are to be sown. Transplant biennials and perennials, and as soon as they come into flower rectify the nomenclature of *Iris*es, *Lilies*, *Pyrethrums*, &c., the names of which are apt to get misplaced during the operation of transplantation. Double *Rockets*, which have bloomed profusely this season, should have their shoots layered—an operation which will soon induce the production of shoots in abundance; and these, when they have attained a length of 2 in. or 3 in., may be taken off and made into cuttings. *Pyrethrums* for late blooming, if cut down and allowed to grow afresh, will come into bloom during the later summer months. Hardy perennials generally, which bear division, may still be multiplied in that way; and, where that is not applicable, cuttings should be inserted as soon as possible, in order to ensure their becoming well established before winter. Hardy annuals for late blooming should be sown in shady spots to be transplanted however to the positions in which they are to flower. Seeds of *Brompton*, *Emperor*, and *Queen Stocks* should also now be sown for flowering next spring. Continue to prick off perennials as soon as they are ready for removal. Plants in pots will require plenty of water at this season; and specimens of such plants as *Phloxes*, *Paeonias*, *Pyrethrums*, &c., will need attention in the way of staking and removing dead blooms. If not already done, lose no time in plunging the stock of plants in store-pots in wood-ashes or sand.

#### Kitchen Garden.

*Asparagus* beds, now that cutting is over, will be much benefited by a good soaking of manure water; this, being a marine plant, enjoys salt, which, if it be added to the liquid at the rate of 2 oz. to a gallon, will materially assist *Asparagus* beds, especially such as have been long in bearing. Keep the beds quite free from weeds, which it is necessary in this case to remove by hand, as the use of the hoe would interfere with the plants. Beds that have been much out should, at the present time, be encouraged by every means to make good growth, for in this depends their ability to keep up, in years to come, their producing powers, both as regards quantity and quality, in a satisfactory state. *Asparagus* often gets worn out much sooner than it is otherwise would through an arising neglect after cutting has ceased. Advancing crops of *Carrots* should be looked over to see that they are not left too thick, especially the main sowing. Turnips also will require attention in this respect; there are few crops suffer so much as this if allowed to stand too close together, as when in this state they

run to leaf, forming bulbs that are not only small, but very poor in quality. Beet.—Thin the main crop before the plants get so large as to interfere with the growth. Coleworts.—Some seed should now be sown; these will be useful for planting thickly late in the season after other crops are cleared off. In respect to this vegetable it is necessary that amateurs should make sure that they get the seed true, and not some small kind of Cabbage which is sometimes substituted for it, as the Colewort will turn in its leaves and make useful heads when planted later than any variety of Cabbage; it also may be planted under fruit trees when these are not grown too close. Of course they will not produce anything like the crop they will in an open situation; nevertheless, what they do yield is so much gain, and they help to keep down weeds. Beans.—Where dwarf French Beans are held in particular estimation a few more may at once be sown; these should occupy a south border, under the shelter of a wall, where, by a slight additional protection from September frosts, they will frequently go on bearing longer than those grown in more open situations. Autumn-planted Cabbages that have been out and the stools left to produce a crop of Sprouts should, where the land is at all poor or of a light nature, have a good soaking with manure water, by which, in addition to thinning out the shoots to some two or three to each stool, they will make small useful heads, that will come in through the autumn. Keep the hoe going on all favourable occasions amongst advancing crops of every kind.

#### Extracts from my Diary.

**June 24.**—Sowing Snowball, Veitch's Red Globe, and American Strap-leaf Turnips. Planting out *Capsicums* in open spaces against south walls. Fodding *Balaams* and *Paeonias*. Giving early exhibition Celery a little earthing. Putting sticks to dwarf Peas. Hoeing and weeding shrubby borders, and putting sticks to all flowering plants that require it. Clearing off Spinach; manuring and getting the ground dug up ready for other crops. Layering Strawberries for forcing on pieces of turf 4 in. square, and also a large quantity, three in a bunch, on pieces 6 in. square for making new plantations.

**June 25.**—Sowing two rows each of the following sorts of Peas: Laxton's Omega, Ne Plus Ultra, and British Queen. Planting out *Borecole*, *Brussels Sprouts*, and late Broccoli. Putting in cuttings of choice sorts of *Pelargoniums*. Giving all newly-planted bedding material a good watering, and pegging down any plants that require that attention. Looking over Globe Artichokes, and cutting off all stems and heads not required for use. Looking over Cucumbers and Melons and stopping them. Watering all newly-laid Strawberry runners.

**June 26.**—Sowing Wheeler's Imperial and Carters' Heartwell Early Marrow Cabbage; also red and white Turnip Radishes. Planting out Lettuces and Endive. Potting on a batch of Queen Pine suckers. Cutting back Laurels encroaching on walks. Pegging down and stopping Vegetable Marrows. Thinning Turnips and giving them a good watering. Gathering Grove End Scarlet and Keen's Seedling Strawberries. Hoeing and weeding amongst all growing crops. Putting strings round Peas that are forcing their way through the sticks.

**June 27.**—Sowing Giant White Cos, the Favourite, and All the Year Round Lettuces. Planting out Celery and Cardoons. Picking flowers off and tying out Fuchsias for exhibition. Finish clipping all Box edgings. Looking over all cordon-trained Apple trees, tying down leaders, and loosening any that require it; also all young trees tied to stakes. Looking over all Vineries, tying down leaders, stopping the laterals, and giving the borders a good soaking of guano water inside and out.

**June 28.**—Sowing Frazer's Broad-leaved and Green Curled Endive; also Canadian Wonder Beans, Spinach, and Mustard and Cress. Stopping and nailing in Tomatoes. Thinning out Parsley and Spinach. Watering all newly-planted fruit trees. Putting loose ties round all young Raspberry canes, to protect them from the wind. Pinching back the breast wood of Cherry, Pear, and Plum trees and nailing in the leaders. Watering Pines and putting sticks to any that require it.

**June 29.**—Potting Stocks, Heliotropes, and Carnations. Putting first batch of *Chrysanthemums* into their flowering pots. Thinning out Lettuces and Endive; also late-sown Carrots. Nailing and tying in all Roses, Creepers, and Ivy on walls and trellis work. Clearing off another border of early Peas. Placing sticks round *Asparagus* beds to protect the young growths from wind. Watering all newly-planted Celery. Mowing and cleaning in the pleasure grounds and rolling down all gravel and Grass that require it. Fruit in use for dessert: Pines, Grapes, Melons, Peaches, Nectarines, Strawberries, Raspberries, and Cherries.—W. G. P., Dorset.

**Hardy Ferns and Scarlet Pelargoniums.**—One of the most effective combinations that I have seen for some time consists in inserting large specimens of *Vesuvius Pelargonium*, at irregular distances apart, on a bank covered with a luxuriant growth of hardy Ferns, the verdure of the latter forming an admirable groundwork for the brilliantly coloured *Pelargoniums*. Where the latter were not of sufficient stature to show well up above the Ferns, old tree stumps were inserted and covered with a large thick turf into which the *Pelargoniums* rooted freely, and by careful watering looked as if they would maintain a good display during the whole season.—JAMES GROOM.

GARDEN BOTANY.

(Continued from p. 581.)

MIXED INFLORESCENCES.—By mixed inflorescences is meant such as display both indefinite and definite branches in their composition. Thus the inflorescence of the Horse Chestnut (fig. 233) consists of a raceme of scorpioid cymes, which

Fig. 234.—*Chionanthus virginica*; raceme of dichotomous cymes.

is indefinite as to the number of cymes, whilst the cymes themselves belong to the definite type. In *Chionanthus virginica* (fig. 234) we have an example of an inflorescence consisting of a raceme of dichotomous cymes; in *Sparmannia*

Fig. 235.—Inflorescence of *Sparmannia africana*, an umbel of scorpioid contracted cymes.

*africana* (fig. 235) the contracted cymes are arranged in an umbellate manner; in *Datisca cannabina* (fig. 236) the inflorescence consists of a spike of contracted cymes; in *Vernonia centriflora* (fig. 237) the capitules are arranged in a branching, scorpioid cyme; and, finally, in the *Laurusinusus* (fig. 238) the dichotomous cymes are grouped in umbels. In each and all of these inflorescences there is a combination of the definite and indefinite types of branching.

ABNORMAL INFLORESCENCES.—By abnormal in this, as in all instances of its use in these paragraphs, is meant something unusual or out of the ordinary way; but there are two distinct significations to the word. As employed in this place it has a

Fig. 236.—Inflorescence of *Datisca cannabina*; contracted dichotomous cymes in a spike.

general application, that is to say, the inflorescences described are abnormal as regards plants generally, but not as regards each of the particular species. Branches, whether they bear leaves or flowers, usually arise in the axils of the leaves or bracts, and are mostly free from them; but in the Lime (fig. 239) the peduncle of the cyme of flowers is adnate, or adheres to the large bract, from the axil of which it proceeds. Sometimes the peduncle adheres to an ordinary leaf, and the flowers appear to spring from the centre of the leaf itself. *Erythrochiton hypophyllanthus* is a remarkable example of this kind of adhesion, the flowers being borne on the under surface of the leaf. In *Helwingia* (fig. 240), on the contrary, they appear on the

Fig. 237.—Inflorescence of *Vernonia centriflora*; flower-heads in scorpioid cymes.

upper surface. The leaf-like branches of *Butcher's Broom* (fig. 241) have been explained. As the leaf-like expansions are true branches, the abnormality of their bearing flowers is only apparent; as also in *Xylophylla* (fig. 242), in which they are

borne on the margin of the flattened branches. It not unfrequently happens that the peduncle of an inflorescence is adnate to the branch for some distance above the axil which gives it birth, and thus it appears to be an extra axillary production. In *Asclepias floribunda* (fig. 243) the peduncle adheres the length of one internode, hence it seems to spring

Fig. 238.—Inflorescence of *Laurustinus*; an umbel of dichotomous cymes.

from between the pair of leaves next above its real point of origin.

**UNUSUAL MODIFICATIONS OR COMBINATIONS OF BRACTS OR BRACTEOLÆ.**—The involucre (made up of bracts) of the *Compositæ* and *Umbellifera* has been explained under the definitions of the capitulum and the umbel, but the term is commonly employed to designate some other very different combinations of bracts, the nature of which it is important to know.

**THE CUPULE.**—There is a particular combination of bracts termed a cupule which invests the fruits of some of our most

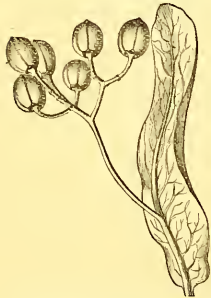

Fig. 239.—*Tilia europæa*; peduncle of cyme adnate to a leafy bract.

Fig. 240.—*Helwingia rusciflora*; bearing clusters of flowers on the leaves.

important forest trees which is likely to puzzle the beginner. Starting with the Acorn (fig. 244), the fruit of the Oak, the involucre consists of numerous very small bracts consolidated into a cup containing a single fruit. The cup of the Acorn in English Oaks is rarely more than half as long as the Acorn, but in some exotic species it almost completely encloses the Acorn. In the Hazel (fig. 245) the involucre consists of two

or three deeply cut leafy bracts covering at the base, and as long or longer in some varieties than the single fruit; and in the Beech (fig. 246) the bristly bracts of the involucre meet at

Fig. 241.—Flattened leaf-like branches of *Ruscus aculeatus*, bearing flowers in the centre.

Fig. 242.—Flattened branch of *Xylophilla obovata*, bearing flowers on the margin.

the edges and quite enclose the fruit, with the exception of a small aperture at the top. When the fruit is ripe the involucre separates into four valves and frees what look like two or three shining triangular seeds, but which in reality are separate fruits. The involucre of the Sweet Chestnut (fig. 247) is similar to that of the Beech, but very prickly, and it also contains two or three fruits.

**THE SPATHE.**—The spathe or large sheathing bract of the *Aroidæ* (*Arum*, *Anthurium*, &c.) has been referred to. Occasionally the spathe is double (fig. 248), but this is an abnormal

Fig. 243.—*Asclepias floribunda*; flowers in interfoliar cymes.

condition for the plant in question. The flowers of Palms are borne on a spadix, often very much branched and sometimes of enormous dimensions, enclosed in a spathe consisting of one or several valves.

**INVOLUCEL.**—This term is given by some botanists, as already mentioned, to the bracteoles or partial involucre of compound

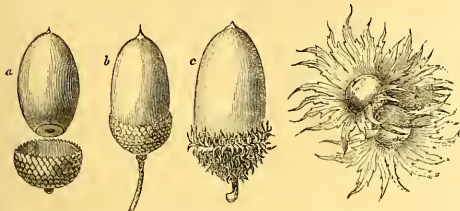

Fig. 244.—Fruits of Oak, with a cupulate involucre; a, fruit removed from cupule.

Fig. 245.—Fruits of Hazel, with large, lacerated involucre.

umbels. It is also applied to the cup-like involucre which encloses each separate flower in the capitules of the Dipsacæ

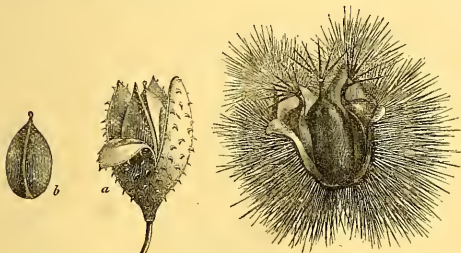

Fig. 246.—a, cupule or involucre of Beech, which contains two or three fruits; b, one of the fruits removed.

Fig. 247.—Fruits of Chestnut enclosed in a prickly cupule or involucre.

(Teasel, Scabious, &c.). It is one of the essential characters of this small family, and is easily seen in the Purple Scabious

Fig. 248.—Richardia ethiopia with a double spathe.

(fig. 249), where it is spread open, showing the fruit inside.

**THE EPICALYX.**—Immediately beneath the calyx of some flowers there is a kind of second calyx formed by the bracteoles.

It is called an epicalyx or involucre, or in descriptions the parts constituting it are called bracteoles. It is a common character of many genera of Malvaceæ (Malva, Althæa, Hibiscus, &c.) to have an epicalyx, and the number and degree of cohesion of the bracteoles afford generic distinctions. The Strawberry flower (figs. 250 and 251) has an epicalyx. Sometimes the bracteoles are entire, but usually more or less deeply cleft. Something of the same sort occurs in Dianthus (fig. 252), where the bracteoles cohere in opposite pairs.

**COLOUR OF BRACTS.**—Bracts and bracteoles are usually inconspicuous as regards colour, but in Bougainvillea, Poinsettia, and some other genera they are far larger and more brilliantly coloured than the flowers themselves. Many of the Bromeliaceæ, too, have very showy bracts, as also have some of the Salvias.

Fig. 249.—A separate fruit of *Strawberry* crowned with the calyx; the involucre cut down one side and spread open.

Fig. 250.—Flower of *Strawberry*, in which the bracteoles forming the epicalyx are deeply cleft.

Fig. 251.—Flower of *Strawberry*, in which the bracteoles forming the epicalyx are deeply cleft.

**GLUMES.**—The outer chaffy envelopes of the flowers of Grasses (figs. 253 and 254) are termed glumes, and the parts corresponding to the calyx and corolla of other plants are absent, or very small. Grass flowers are described and illustrated in a paragraph under the next section.

Fig. 252.—Flower of a *Dianthus*, showing the epicalyx of closely imbricating bracteoles.

Fig. 253.—Spikelet of *Rye*, with the glumes in position.

Fig. 254.—Spikelet of *Rye*, with the glumes separated at the base.

**The Flower.**

**THE COMPOSITION OR STRUCTURE OF THE FLOWER.**—Having examined the principal types of inflorescence, we may now advance a step further, and take the separate flowers constituting the inflorescences. As the various modifications of the flower afford most of the essential characters by which natural orders and genera are distinguished, it is of importance to become acquainted with their principal types. Leaves and inflorescences, and even stems, often vary very much in the same order and in the same genus, though in some cases one particular type of leaf, or arrangement of leaves, or kind of inflorescence, prevails throughout an order or genus. As we shall constantly have reason to speak of natural orders and genera and species, a general definition of what constitutes an order, &c., will render these allusions more intelligible. In the paragraphs relating to the seed, one of the characteristics of each of the two large classes of flowering plants—monocotyledons and dicotyledons—is pointed out; and in treating of leaves we incidentally mentioned the prevailing type of leaf of each of these two classes. Each of these classes includes a number of natural orders, sometimes called families. Under

the head devoted to a definition of the capitulum, it is noted that this kind of inflorescence prevails throughout the largest natural order—the Compositæ—in the vegetable kingdom. By this kind of inflorescence, associated with certain peculiarities in the structure of the flower, the order is characterised and its members distinguished from those of all other natural orders. Natural orders consist of few or many genera, each genus having the essential characters of the order in some of their numerous modifications. We may again refer to the paragraph on the capitulum and figs. 213—217 for some idea

perianth. The floral envelope of whatever kind, even when it consists of calyx and corolla, is really a perianth; but in practice this name is only given to the floral envelope when it is single, or the parts are similar in shape and colouring, in contradistinction to distinct calyx and corolla. This distinction

Fig. 255.—Dichlamydeous flower of Wallflower.

Fig. 256.—Dichlamydeous flower of Tobacco.

of generic characters. The form of the receptacle, the presence or absence of pales between the flowers, the bracts of the involucre, &c., &c., furnish characters upon which genera belonging to the natural order Compositæ are founded. Genera comprise one or more, often very many species, differing from each other in minor particulars. For example, the Apple and Pear are both species of the genus *Pyrus*; the former has corymbose flowers, and a more or less globular fruit, with a depression where the stalk is inserted, and the latter has subumbellate flowers, and a top-shaped fruit tapering towards the stalk end. Each of these species includes a number of varieties, dissimilar in shape, size, flavour, &c., though always preserving the essential characters of their species. But leaves and inflorescences of the same type occur in quite distinct natural orders, and therefore afford characters only of secondary value. A complete flower consists, as in the Buttercup

almost limits its application to the floral envelope of monocotyledons and such dicotyledons as have only a single envelope.

**DICHLAMYDEOUS FLOWERS.**—The flowers of all dicotyledonous plants having a distinct calyx and corolla, as the Wallflower (fig. 255) and Tobacco (fig. 256), are dichlamydeous.

**MONOCHLAMYDEOUS FLOWERS.**—When the floral envelope of the flowers of dicotyledonous plants is single, they are mono-

Fig. 261.—Hermaphrodite flower of Passiflora.

chlamydeous, as in Rhubarb, Daphne, Grevillea, and Aristolochia (fig. 257).

**ACHLAMYDEOUS FLOWERS.**—The flowers of some plants are entirely destitute of a perianth or achlamydeous, as the common Ash (fig. 258).

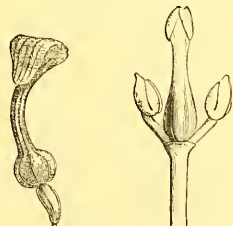

Fig. 257.—Monochlamydeous flower of *Aristolochia cle-matidis*.

Fig. 258.—An achlamydeous flower of the Ash.

Fig. 259.—Hermaphrodite flower of *Hypericum*.

Fig. 262.—Female flower of *Buxus sempervirens*.

Fig. 263.—Male flower of *Buxus sempervirens*.

Fig. 264.—A female flower of a Poplar removed from the catkin.

(figs. 14 and 15), of calyx, corolla, stamens, and pistil; but one or more of these organs, or sets of organs, is often absent, and then the flower is incomplete. The enlarged apex of the floral axis upon which the parts of the flower are inserted is termed the receptacle, which must not be confounded with the receptacle of flowers of an inflorescence. The calyx and corolla form together the floral envelope, and the stamens and pistil are the essential organs of reproduction. We have already mentioned (see *Tritelcia*, fig. 13) that when the parts of the floral envelope are similar in shape and colouring, it receives the name of

**HERMAPHRODITE AND UNISEXUAL FLOWERS.**—When a flower contains both fertile stamens and pistil, as in Ash, *Hypericum*, *Alchemilla*, and *Passiflora* (figs. 258 to 261), it is termed hermaphrodite; but frequently they are in separate flowers. When the stamens are wanting, or only rudimentary or barren, the flower is a female; when the pistil is wanting, or only rudimentary, the flower is a male (figs. 262 to 265). The

Cucumber, Melon, Hop, Hemp, and Red Bryony are familiar plants in which the sexes are thus separated. Both unisexual and hermaphrodite flowers may be destitute of perianth or monochlamydeons, or dichlamydeons (figs. 258 to 268). If the

Fig. 265.—A male flower of a Poplar removed from the catkin.

Fig. 266.—A male flower of a sinuous Willow and its subtending bract removed from the catkin.

Fig. 267.—A longitudinal section of the same.

male and female flowers be borne on the same plant, as in the Cucumber, Hazel (fig. 269) and Arum (fig. 270), the plant is monoecious; if they are borne on separate plants, as in *Acubata*,

Fig. 268.—A female flower of a Willow and its subtending bract removed from the catkin.

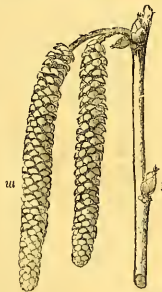

Fig. 269.—Branch of Hazel, bearing both male catkins (m) and female catkins (f).

Fig. 270.—A spadix of *Arum maculatum*, with male flowers (m) and female flowers (f).

*Garrya*, Hop, and Willow (figs. 271 and 272), the species is said to be dioecious. It is not unusual for a plant to bear male and female and hermaphrodite flowers intermixed, and then it

Fig. 271.—Female catkin of a Willow.

Fig. 272.—Male catkin of a Willow.

is polygamous. The Ash, Maple, and Asparagus are polygamous.

W. B. HEMSLEY.

THE exportation of Potatoes from North Germany to England last autumn and winter considerably exceeded, according to the "Farmer," that of any previous year. In Hull alone 91,351 tons were landed between October and the middle of May, of which 43,068 tons came from Hamburg and 32,890 from Stettin. Twenty-five per cent. of the Hamburg export were bought up by an agent in the South Liegnitz district, where, in consequence of his activity, the local price of Potatoes rose from ninepence to a shilling per cwt. above the average.

## THE INDOOR GARDEN.

### MEDINILLAS AND THEIR CULTURE.

MEDINILLAS rank amongst the finest of evergreen stove shrubs, alike handsome in foliage and flowers. The latter are arranged in gracefully drooping panicles, unlike anything else to which they can be compared, and the plants themselves are amongst the freest of free growers. They may be cultivated with success even by those who have not had much experience in plant growing; still, although deserving of general cultivation where sufficient room exists in which to grow them, they are hardly suitable for small houses, for, though their natural free disposition to flower is such that they will bloom in a small state, still the grand appearance possessed by a fully developed specimen cannot be realised in the shape of a small plant. Being indigenous to hot countries, it is useless attempting the cultivation of *Medinillas* where a sufficiently high temperature cannot be maintained. To do full justice to them, they require a good light house, where the growth, as it is formed, is of such a character as to promote the natural free development of flowers; for although they need a process of ripening the wood by means of dry treatment in autumn, still this will not bring out the full disposition to flower to the extent that results from the growth being made under the gradual solidifying process effected in a house under a maximum amount of light. Another great advantage arising from their being cultivated under the conditions here recommended is, that the wood produced is short jointed and the foliage comparatively small, a state that admits of the plants when in flower being much more profusely clothed with bloom than they otherwise would be.

Cuttings taken off in April, or as soon as young growth is produced and half ripened, strike readily inserted singly in 3-in. or 4-in. pots drained and half filled with finely-sifted sandy soil. The upper portion, which should be all sand, must be kept moist and covered, but not too closely, with a bell-glass. Cuttings thus put in in a night temperature of 70°, and proportionately higher in the daytime, will root in three weeks or a month; then gradually tilt the glasses and ultimately dispense with them altogether, inuring the plants by degrees to the ordinary atmosphere of the house. By the time they have made one pair of young leaves they will require more root room, and should have their points pinched out to cause them to break. *Medinillas* are free-rooting subjects, and will bear moving into pots 4 in. or 5 in. larger than those in which they are growing. They will succeed in either peat or loam, but I prefer the latter, though in it the foliage will not possess quite so much of the generally prized dark green tint that it will acquire in peat. This is, however, counterbalanced by the habit being made more sturdy and close. Through the summer they will bear as high a temperature as most stove plants receive—say 75° at night, and from 80° to 90° by day during sunny weather, syringing them freely at the time of closing the house in the afternoon, and giving plenty of water at the roots. In very bright weather they will require a thin shade for a few hours during the middle of the day, but on no account should they be subjected to the darkening process to which stove plants, collectively, have often to submit. An impression prevails that it is necessary to keep out a portion of the light; whereas all that is wanted is simply to break the sun's rays. *Medinillas* should, therefore, always be at that end of the stove wherein are placed such plants as require the least shading. Their natural habit is such as to require but little support; a stick to the centre shoot and one to each of the side branches will be quite sufficient. The shoots will very likely again require stopping at the end of July or beginning of August. It is necessary to attend to this in the first stages of the plant's existence, so as to furnish a sufficient number of shoots near the base. By the end of August shading should be dispensed with altogether. In the following month give more air and cease syringing overhead, which will gradually induce a state of rest. A night temperature of 60° through the winter will answer with a little more warmth during the day, and just sufficient water at the root to keep the soil from getting too dry. By the end of February the temperature should be raised 5° at night and 10° or 15° by day, with sun-heat. Commence syringing again as soon as the plants exhibit signs of growth, when they may be potted; a 6-in. or 8-in.

shift will not be too much if they are plentifully supplied with roots, at this time the loam may be used in a more lumpy state than hitherto. Put plenty of crocks in the bottom of the pots and secure them well from soil getting amongst them, as these plants, with their large amount of leaf surface, require a copious supply of water during the growing season. Owing to the natural disposition which they have to ramify, there will be, as a rule, no further necessity for stopping, except in the case of any shoots that are taking the lead too much. Raise the temperature as solar heat increases, keeping the plants up near the glass, and in syringing see that the water regularly reaches the whole of both upper and under surfaces of the leaves. Shade as before during the brightest portion of the day, and give the necessary support by sticks and ties to the branches, without which sometimes the weight of water in syringing will cause them to split off. Treat as in the preceding summer, dispensing with shade, and syringing as the sun's power begins to wane, together with the admission of more air.

Winter as before, giving no more water at the root than is requisite to keep the leaves plump. This dry condition of the soil is necessary to the free production of flowers, but it must not be carried so far as to cause the leaves to flag, or they will fall off prematurely. Again raise the temperature in spring, when the first efforts of the plants will be directed to the formation of flowers, which will make their appearance at the points of the branches. Whilst these are in course of development too much atmospheric moisture should be avoided, and it is not advisable to syringe them overhead, as any excess in this way frequently leads to the blooms falling off before they expand. The flowers will last for two or three weeks, during which time they have a grand appearance. After blooming any strong growths may be cut back, and as soon as shoot growth commences another shift of 2 in. or 3 in. should be given, getting away some of the old soil from the upper portion of the ball as far as it can be done without disturbance of the roots. Treat them generally as recommended during the preceding summer, giving manure water once a week, and their winter management should also be the same as before. It frequently happens that plants in the second and subsequent years of flowering bloom more profusely than during the first, as, in addition to the bunches at the points of the shoots, quantities of flowers are often emitted from the hard wood of the branches or main stem, in which state they have a most singular, yet beautiful appearance. *Medinilla* may be retained for years, so as to occupy a moderate space, by having their branches shortened freely after flowering, and in potting shaking out a portion of the old soil and replacing with new material, supplying the requirements of the roots by the liberal use of manure water in place of giving them inconveniently large pots.

*M. magnifica*, a native of Java, is a magnificent species. Its leaves measure from 10 in. to 12 in. long, and 7 in. or 8 in. broad. The flowers, which are produced in large, drooping, branching panicles, are of a rosy-pink colour, and the unopened buds are of the same shade, and are almost as handsome in the advancing stages as when expanded. *M. amabilis* is a native of Java, and may be said to be almost an exact counterpart of the preceding, except that the panicles are borne perfectly erect instead of pendulous. Though thus nearly alike, the contrast between the plants when in flower side by side is most remarkable, each enhancing the beauty of the other. *M. Sieboldi*, from Montmeim, is a handsome plant, but inferior in that respect to both the above. It has rosy-white flowers.

All the species of *Medinilla* are somewhat liable to the attacks of red spider, unless the syringing recommended in their cultivation is regularly attended to. Mealy bug and brown scale will also live upon them; for these, sponging the leaves and a strong application of insecticide in the case of old plants that, in cutting back, have been denuded of their foliage will be found the most effectual remedy.

T. BAINES.

*Cistus cypricus*.—I have growing against a somewhat shaded west wall in my forecourt garden a plant of the common Gum *Cistus* that in the course of three years has made a very fine growth, and during June and July blooms with great freedom. The flowers are

not very durable, but they are produced successively for a considerable period, and are objects of great beauty when fully expanded. The fine rosy-purple *Cistus creticus*, which I saw in full bloom in Mr. Parker's nursery at Tooting a few days ago, would make a capital companion for the common form, the flowers being nearly as large and bright, and effective in colour.—D.

#### WINTER AND AUTUMN PELARGONIUMS.

Now is the time to pot and push on plants for autumn and winter decoration, a time when the Pelargonium will be found among the most useful of subjects—I mean the zonals and similar sorts. The varieties now-a-days are almost too numerous to mention, but one cannot go wrong, when ordering such plants, to procure all shades of colour, combined with a free-flowering habit and good flowers. When well grown there are hardly any of the varieties inferior. Plants that have been struck this spring or last autumn will be in 6-in. and 7-in. pots respectively by this time—at least they should be—and they will need no further shift this season. Like other plants, they only begin to flower abundantly under glass late in the season when the pots are full of roots. During summer, when there is plenty of light and sunshine, they flower well when making their growth, but it is different when the short dull days arrive—they need the assistance then which is afforded by mature growth and a potful of roots. Pelargoniums are not particular as to soil, but they prefer good friable turfy loam to any other. If anything then is added it may be well-rotted cow manure or sand, according as the loam is light or heavy. The pots should be carefully drained, the compost should not be rammed in potting, and sufficient room should be left for watering,  $\frac{1}{2}$  in. at least. The plants should be grown on in a light airy greenhouse or pit, be copiously watered, and have as much air as possible day and night. Anything like forcing in the least must be avoided. During the summer the flowers should be picked off, but the practice must not be continued till too late in the season. We just like to have the flower-buds well up and the most forward expanded when the plants are needed in autumn, with, of course, plenty of buds showing and coming on. When the plants are in this condition they come on without forcing and the flowers last longer, but it is necessary, during the dull days of November and December, to give the plants a little heat, but no moisture, just to keep them growing apace. Cold and damp are the ruin of both the buds and flowers, and consequently it is necessary to be very careful in watering, as there is then little demand upon the roots by the leaves. J. S.

**Experiences with the Slug Pest.**—Slugs are assuming something of the character of a plague this season. Cultivators who have never known what it is to have losses in their crops to any extent from vermin cannot this year save even the most ordinary vegetables from these little depredators. Beet, Parsley, Parsnips, Carrots, and several other crops, which I never remember to have suffered from any cause before, are this season being started under the greatest difficulty. Raising them in boxes and planting them out seems to be the only alternative, for as soon as the young seedlings vegetate they are cleared off, notwithstanding all ordinary precautions to the contrary. We have tried as preventives ducks, fresh lime, red lead, soot, and sifted ashes. The first were allowed to run freely amongst Lettuces, Endive, and other crops during the winter, but as the Endive and Lettuces were gradually becoming smaller, we found that, besides searching diligently for animal food, they were also feasting on the hearts of the young plants. Batavian Endive, consisting of many hundreds, had all their hearts eaten out entirely, and every tender leaf was nibbled. They seemed, indeed, to like the flavour of this Endive more than that of any of the other crops. We found applications of lime to be useful, but lime soon becomes inert, and then the slugs creep over it uninjured; red lead and soot were also temporary preventives. Small ashes have been all along and are still the most useful barriers to slugs, though the battering rains which we have had have, to some extent, made them smooth enough to allow mischief to be done. A slight sprinkling acis as an effectual remedy, and a store of them should be kept ready for any emergency.—M. TEMPLE.

#### OBITUARY.

On the 10th inst. there died at Lyddington, near Uppingham, the Rev. B. H. Margetts, curate of that place, at the early age of thirty-one. He was an occasional contributor to THE GARDEN on matters relating to *Chrysanthemum*, of which he was an excellent cultivator and successful exhibitor at the shows of the Northamptonshire *Chrysanthemum* Society when curate of Finedon, Wellingborough. His favourite flower, however, was the *Auricula*, of which he grew a small and select collection; and at the *Auricula* show at the Crystal Palace in April last he was a successful exhibitor. D.

ANSWERS TO CORRESPONDENTS.

**Burning Bush.**—Is there such a plant as the Burning Bush? and what is its botanical name?—W. LIVINGSTON, *Ball's Bridge Nursery, Dublin.* [Burning Bush is an American name for *Euonymus atro-purpureus* and *E. americanus*; it is also sometimes applied in gardens to the Artillery plant (*Pilea serpyllifolia*.)]

**Double-spathed Arums.**—I have sent you a photograph of a sport on the flower of an Arum, which is at present in bloom in the conservatory of the Deaneary, Clogher, Co. Tyrone, Ireland, and I wish to know if such a sport is common.—B. [The photograph sent shows an example of *Richardia* (*Calla*) *ethiops*, with a double spathe, a not very uncommon occurrence in the case of this Arum. A similar case is illustrated this week under the head of "Garden Botany."]

**Large Roses.**—I send you a bloom of Paul Neron, which measures over 15 in. in circumference.—ANNIE TRAVELL. [Large and showy, but that is all that can be said in its favour, as it is faulty in shape and comparatively scentless.]

**Re-planting Old Asparagus Roots.**—"A." (see p. 683) could not follow a worse plan with his Asparagus than re-planting in any way the old roots. In such cases the best way to success is planting one-year-old plants in spring or early summer.—V.

**Vine Insects (H).**—I have carefully examined the portions of diseased Vine sent, and I can find no white spider nor any other living creature; in them, except one minute pale yellow thrip. The Vine appears to be in poor condition to produce such weak wood.—W. W. S.

**Maidenhair Ferns.**—What is the treatment of a Maidenhair Fern which is gradually decaying? I have tried heat and plenty of water, but they do not answer.—T. T. [Shake the soil from the roots and re-pot, not too deeply, in well-drained, light, turfy loam, leaf-mould, and silver sand, and place the plants in a moist, warm temperature.]

**Vine Leaf Excrecences (L).**—We cannot assign any cause for the holes in your Vine leaves; the little green excrecences on the back of them are the result of deficient ventilation and too much moisture in the atmosphere.

**Rose Blooms for Exhibition.**—What is the best way in which to prepare Rose blooms (cut) for exhibition? Would they be best cut the night before, or on the morning of the show.—H. [If there be little or no dew, roses may be cut on the morning of the show, but there is nothing so dangerous as cutting them during a heavy dew, as, unless the best blooms are marked on the previous evening, it is simply impossible to distinguish them; neither do they travel so well when cut wet. I generally commence cutting as soon as the sun has left the blooms, and have always found them, cut at that time, to retain their colour and freshness wonderfully well. A great deal of judgment is required in cutting Roses for exhibition, as some varieties must be cut much younger than others. Considerable experience and close attention to results can alone teach an exhibitor this.—R. B.]

**Names of Plants.**—Correspondents wishing plants to be named will oblige by complying with the following rules: To send the specimens of complete as possible, i.e., both stem, leaves, and flowers, and fruit, when possible. We cannot attempt to name plants from single leaves. To carefully pack them in gutta-percha tissue, or other impervious material which will prevent evaporation. Not to send varieties of popular flowers, such as *Euchias* or *Ponies*, which are best named by experienced growers of such plants, who have the means of comparison at hand. Not to send more than four plants or flowers at a time. Always to send, in addition to whatever pseudonyms or initials they may desire to use in the paper, their full name and address. To pre-pay all packages containing plants or flowers.—W. C.—The white and the ordinary form of *Dictamnus Fraxinella*, an old-fashioned border flower. *W. J. F.*—Potato-stem tubercurs; they are not uncommon, especially when anything arduous grows underground. *Glanschein*.—The leaf we cannot determine without knowing something of the flower. Many plants belonging to widely dissimilar Natural Orders have leaves the exact counterpart of the one sent. Is anything known of the country from which it comes? *Messrs. B.*—A well flowered specimen of *Ceanothus velutinus*. The other is a *Pittosporum*, probably *P. Mayi*. We have seen the same plant in various gardens both in the United Kingdom and in California, where it forms a tall pyramidal evergreen of great beauty. It was introduced here from New Zealand. *L.*—The parasite on the leaves sent is a *Puccinia*, probably *P. malvacearum*. *J. E.*—1. *Stellaria graminea*, 2. *Silene conica*, 3. *Stachys sylvatica*. *W. E. R. Clonnet*.—The Orchid is a species of *Rodriguezia*. You might try some of your seedling *Acacias* out of doors. *Dealtha* succeeds against a wall in some parts of England. *J. W. V.*—*Ceanothus rigidus*. *H. M.*—*Aster alpinus*. *Ceranium*, apparently *G. Endressii*; but it had fallen to pieces when it reached us.

**The Glastonbury Thorn.**—What is the true history of this Thorn? I am told that there is but one plant of it known, which is growing on a steep hill at Glastonbury, and that it has the mysterious property of coming into bud, leaf, and blossom from a perfectly dormant state in a single night, the particular night being Christmas Eve, and that on Christmas Day the tree is perfectly bare again. My informant vouches for the truth of it, having, he asserts, seen it himself.—R. L. TRANTON, *Beeston Fields, Notts.* [This remarkable Thorn, with which so many superstitious legends are connected, is merely a precocious variety of the common Hawthorn. Tradition says that the original

tree was the staff of Joseph of Arimathea, who came over to Britain, along with twelve companions, to found the first Christian Church in this island. As a proof of his mission he stuck his staff in the ground, which, after he had had a night's sleep, was found to be in leaf and flower in the morning. Joseph seemed to have inferred from this that it was an omen of good; so he made this his resting-place and built a chapel, after which it became by additions and improvements the magnificent Abbey of Glastonbury. Another tradition tells us that, until the time of Queen Elizabeth, the Glastonbury Thorn had two trunks, one of which was cut down by a zealous Puritan. It is said that in the time of Charles I. the remaining trunk was cut down, but a publican of the place, "out of pure devotion," as the writer has it, secured a slip, which, being set in his garden, flowered on December 25. There are still two venerable Hawthorns near the Abbey, which probably sprang from the veritable tree which blooms during mild winters early in the year. There is a tradition, I know, that this Thorn comes into leaf and flower on Christmas day, and that it withers the next day. This, of course, is pure superstition, for its blooming period is ruled by the weather. It is, nevertheless, an early-flowering variety, which, during unusually mild winters, has been known to be in blossom in January and February, and even as early as Christmas when the weather has been exceptionally mild, and growing. The Glastonbury Thorn is worth cultivating for the sake of its early blooming in mild seasons.—G. B.]

Questions.

**Sub-tropical Plants for Cornwall.**—I shall be glad to know if any of your readers have had experience with the following planted out of doors, viz., *Araucaria excelsa*, *Cycas revoluta*, *Cyathus excolata*, and *Dicksonia antarctica*? and whether there would be any chance of their withstanding the cold of our usually mild winters.—SANGUINA, *Cornwall*.

**Gas-heating and Inside Blinds.**—Would any of your readers inform me which is the best kind of gas-heating apparatus for a conservatory 15 ft. by 9 in., and rather high in proportion? I require it only of sufficient heating power to keep out frost. Also if I can use inside blinds with spring rollers; and, further, the most useful material for the blinds? I should like to place the boiler on the other side of a brick wall, so as to heat at the same time an adjoining room.—C.

**Barren Fruit Trees.**—Can any of your readers give me advice in the following case? My Pear trees blossom well, and so do Plums, but thirty or forty trees for eleven years never bear fruit, though I have been which fertilise the trees. They make much wood, my soil being in every way excellent.—T. B. B.

NOTES—VARIOUS.

**Fabiana imbricata.**—It is much to be regretted that this hardy shrub is not often met with than it is. It has been in great beauty here for some time past, and is just now past its best. Cuttings made of the firm young shoots, and put under a bell-glass in a cold pit or frame, soon form good plants. It does well in a south or south-east aspect in common garden soil. *Habro hamnis elegans* is also in bloom in the open air.—W. DIVINE, *Winton Maidstone*.

**Zygopetalum Sedeni.**—In the report of the Royal Botanic Society's Show (see p. 685) I notice a small error. Your reporter mentioned, amongst the first-class certificates obtained by Messrs. James Veitch & Sons, *Zygopetalum Lindleyi*; this ought to have been *Z. Sedeni*, a hybrid, obtained by Mr. Sedeni, the foreman (Orchid department of the firm), by crossing *Z. maxillare* with *Z. Mackayi*. Its petals and sepals are dark brown, and the labellum violet veined with white, and the flowers are beautifully scented. In habit and foliage it resembles *Z. Mackayi*, and is altogether a very good plant.—ERNEST BERGMAN, 69, *Farnborough Road, West Erompton*.

**Horticultural Education in Switzerland.**—The Canton of the Grey League first set (according to the "Farmer") the example in Switzerland of giving the inhabitants gratuitous instruction in the rational cultivation of vegetables. For this purpose teachers of approved merit travel from valley to valley of the canton during the winter months, and instruct classes of all ranks of society who may choose to attend their lectures in the theoretical part of the subject. In summer time the same teachers again go their rounds, and demonstrate practically the theoretical lessons enforced during the previous inclement season. Of the 95,000 inhabitants of the canton some thousands of all ages and classes have availed themselves of the opportunities thus afforded them since the establishment of the lectures in 1874. The good effects of this system are everywhere visible. In hundreds of places vegetables of many kinds and of excellent quality are now grown at altitudes where formerly no attempt at cultivation was ever dreamed of, and, where some notion of gardening may previously have existed, the various improvements since introduced have effected marvels of late years. The good example thus set by the Grey Leaguers was quickly followed by the Canton of Zürich, and last year Argau, Lucerne, and Berns heartily adopted the same system with a zeal which will doubtless bear fruit in due season.

## GARDEN ALLOTMENTS.

It is an undoubted fact that more than half the population of England are living deprived of pure air, of clear sunlight, and of the opportunity of tasting the pleasures derived from simple natural objects. The desire for them is not yet dead. I have known of people in the east of Manchester cultivating a Nettle in a back yard with the greatest care, as it was the only plant that would grow where they were forced to live. On holidays their case is no better, for the high moorlands which border the most thickly peopled parts of Lancashire are closed throughout the whole year by the successful shoddy manufacturers who have taken to game preserving. Real physical health is impossible, and moral health proportionately difficult. Education no doubt spreads a desire for natural beauty, but the satisfaction of that desire is beyond the power of the masses, whose minds and eyes we are cruelly endeavouring to open, so that they will be more conscious of wants which they may not satisfy. An educated man, unless living in a purely abstract world or absorbed wholly in his success in active life, must of necessity be miserable if forced to live in a hideous street of small brick houses, where nothing will grow and were sunlight never penetrates. A weekly tenant in such a place is scarcely likely to devote his mind to beautifying his home, or surrounding it with the simple marks of his industry and skill which render it a place he loves for its own sake. His leisure must almost of necessity be spent in the public-house, where his cost must be paid for at the expense of his health, his prospects, and his family. These are the evils which we are now forced to check unless our town population is to sink into utter misery and degradation, and our country districts are to be a desert, entered only for a month or two every year that the sacred birds which are their only inhabitants may be duly sacrificed at the appointed time. Where is the remedy to be found? If not in general legislation, we may perhaps look to local effort put forth either by co-operation among workmen themselves, by the benevolent wisdom of wealthy individuals, or by special action of municipal bodies who are acquainted with the wants and capabilities of the district whose affairs they administer. There are indications that if the course which would really conduce most to the benefit of the most thickly populated districts of England were once clearly recognised, and reasonable means for accomplishing the desired end were pointed out and generally known, societies or persons who would provide the necessary organisation would not be wanting.

The evils to be overcome are clear. First, it is obvious that it is impossible and probably undesirable for the majority of the poorer classes in England to obtain their sustenance from agriculture or even market gardening. It is possible that nearly half the population of the country will be dependent on the earnings of the head of the family to which they belong, derived from manufacturing or mining. Secondly, if any health of body, any feeling of patriotism, any enjoyment of the externals of home life are to be possible for this section of the people, the conditions under which they now live must be altered. How is the necessary alteration to be brought about? Already the suggestion of a solution of the difficulty has been indicated. More than thirty years ago William Howitt, in "Tait's Magazine," gave a glowing picture of some of the districts round his own town. He calculates that in 1835 about 420 acres of land near Nottingham were divided into small plots let as gardens at low rents, and furnishing a healthy and inexpensive means for about 5000 factory workmen and small tradesmen to occupy their leisure. Mr. Howitt speaks enthusiastically of the benefits and pleasure derived from this system by those who availed themselves of it. Even as a speculation on the part of the landowner it was then considered successful. It was to this system, so useful in his own town, that Mr. Howitt looked as capable of aiding most effectually the establishment of the ideal Christian state of which he dreamed. Thirty years, however, have made little change in this direction. The Nottingham gardens are slightly more numerous now than they were when William Howitt wrote, but their number has not increased in proportion to the growth of the town. The gardens, too, are less convenient than formerly, as the town has extended, and their distance from the factories and the homes of the workmen is greater than it was formerly. About 8000 allotments, varying in size from 200 square yards to 600 square yards, are now held by the town-people of Nottingham. Most of the tenants of these plots are engaged as workmen in the lace or hosiery factories, and have some distance to walk from their homes in the town to their gardens in the suburbs, as it is only in a few exceptional cases that cottages have been built on the allotments. In 1872 the average rent was about one halfpenny a square yard, so that until the plots are required for building the system is one eminently advantageous to the landlord, and would be still more so to any co-operative society of workmen who could venture together to buy larger plots and lay them out with a special view to their being used permanently as

gardens. At present the landlord does little besides mark out the plots and some sort of pathway to each. Even when the hours of labour were longer than they are at present, the privilege of possessing one of these gardens was highly prized by many, although much of the short space of daylight which remained after working hours was consumed in the walk from the factory to the cottage and from the cottage to the garden. Generally both flowers and vegetables are cultivated, and most of the tenants have some special hobby in horticulture, and each takes a particular pride in rearing the finest vegetables or flowers of the kind which accords with his own taste. In the summer months the gardens afford an attraction against which the public house cannot compete. The whole Sunday is often spent by a workman and his family in his garden, where some kind of summer-house is frequently built as a temporary shelter and adorned with flowers. From the testimony of those who have lived long in Nottingham, it seems that the system even on its present limited scale has done much to diminish drunkenness and improve the health of those who avail themselves of its advantages. It cannot be said, however, that the circumstances under which it has been at work are very favourable. The land is not exceptionally fertile and the rents are high. I have known a working gardener near Nottingham to pay £6 10s. for a small market garden for which he would probably not have paid more than £3 a little farther in the country, if the landlord would have let a small holding at all. The distance of the garden from the home is a second disadvantage of the most serious character, which would not affect the system if properly carried out and the cottages were placed on the allotments, or, if that were impossible, built in rows very near to lands which had been divided thus into gardens. Probably, too, it will be felt that as the hours of labour are now shorter than formerly, the need for such an employment as the cultivation of these gardens will be greater, and at the same time more opportunity will be given for carrying that cultivation to perfection and making it productive, even from a purely economical point of view. The diet of an English working man and his family would probably be more wholesome if it consisted to a larger extent of fresh vegetables. In the north of England at present fresh vegetables are considered a luxury, and not one of the staples of ordinary diet. If a workman, however, grew them himself, he would prize them more, use them with more care and greater pleasure, and possibly find that the cost of production was a little pleasant labour, which would be a healthy recreation, and a few pounds, which would otherwise have been unprofitably spent.

Attempts on a small scale to introduce the Nottingham system in other towns have at times been made, but suitable land near to the workmen's houses is generally too dear. If the plan is ever to work successfully, it must either be tried on a large scale or in some new place. Workmen change their habits and notions very slowly, and the change advocated is a very radical change. It is not merely an attempt to improve the dwellings of the working classes, but to make the artisan a food producer also, to break down to some extent the hard line of division between town life and country life. We are producing more coal, iron, and calico than we can sell, and the failure of a market means starvation for a whole district. It is time that an effort should be made to render our country more self-sufficient, and that workmen should have it within their power to produce some at least of the necessities of life for themselves. So many persons are engaged in the production of articles of mere luxury or of tools, and so few in using the tools, that articles of necessity are dear and luxuries cheap. So much thought has been spent in trying to manufacture as many things as possible, that the question, "What is the good of the article manufactured?" is seldom considered. All classes buy things because they happen to appear cheap rather than because they really want them. If in the theories of economists and in the practical activity of the nation it could be remembered that the real aim of the ceaseless industry of the nation is to provide food, health, and wise recreation for all classes of the people, according to their several stations, and not to produce as much as possible of every commodity which clever contrivances may find a sale for, the country would be infinitely happier, and free from the dangers which are every day becoming more threatening. At present the old sentence is only too true of us: "Ye have spent your money for that which is not bread, and your labour for that which satisfieth not."

ALFRED HOPKINSON, in "Fraser's Magazine."

**Potato Disease.**—This appeared in the garden here on the 12th inst., and since then it has spread considerably. The kinds first attacked were Porter's Excelsior and Alpha; Late Rose and Veitch's Ashleaf have followed. In cottage gardens in this neighbourhood the Potato crop is very luxuriant and strong this season, but the soil is completely saturated and chilled with so much wet and absence of sun; the disease is therefore likely to be destructive; unless we get a favourable change soon.—W. DRYER, Wierton, Maidstone.

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 18.

By combining the Society's Rose show, which was held on this occasion, with that of the Pelargonium Society, and holding the usual fortnightly meeting on the same day, an attractive exhibition was the result. The chief features of interest were the noble groups of plants from Mr. John Wills, Messrs. Veitch, and Mr. B. S. Williams, and the large collections of Roses from Waltham, Cheshunt, Slough, and Salisbury.

**First-class Certificates.**—These were awarded as follows:—

**Lilium Hansonii** (G. F. Wilson).—A tall-growing species bearing a profusion of half-drooping, golden-yellow, medium-sized flowers having recurved petals spotted with dark crimson.

**Begonia Calypso** (J. Laing & Co.).—A dwarf-habited kind having erect spikes of partially-drooping, semi-double, pink blossoms, very floriferous, and highly ornamental.

**Dracena vivicans** (W. Bull).—An elegant decorative plant having long, narrow, graceful leaves of a glossy bronze colour, edged with bright rosy-crimson.

**Rose Countess of Rosebery** (Wm. Paul).—An English-raised Hybrid Perpetual with well-formed flowers of a rich rosy-crimson colour.

**Erica obbata expolita** (Rollisson & Sons).—A free-growing plant with large, white, waxy flowers borne freely in terminal clusters, and a great improvement on the type.

**Dactylis elegantissima aurea** (Cannell).—A free-growing ornamental Grass, beautifully striped with green and golden-yellow, suitable for baskets or borders.

**Clematis Viticella Earl of Beaconsfield** (Cripps & Son).—A free-flowering kind, having brilliant purple, well-formed blossoms of a striking and highly ornamental character.

**Rhododendron The Tocsin** (Noble).—A kind having noble trusses of large bright rose-coloured flowers with imbricated petals, the upper one being beautifully spotted with golden-yellow.

**Potentilla Prince Arthur** (E. & J. Perkins).—A variety of great beauty, with double lemon-coloured blossoms.

In connection with the Pelargonium Society first-class certificates were awarded to:—

**Pelargonium Insulaire** (Turner).—A fancy kind, having flowers with white centre, the petals being striped with claret and white, the top petals rich crimson.

**P. Titania** (Dr. Denny).—A zonal compact in habit, and bearing lively crimson blossoms, with clear white eye.

**P. Amethyst** (Turner).—A distinct show kind, the lower petals of which are purplish-magenta, traversed with dark markings, the upper petals being black edged with purple.

**P. Invincible** (E. B. Foster).—A large-flowered show kind, with bright crimson and maroon-coloured blossoms.

**P. Symmetry** (Foster).—A show variety with remarkably attractive pink and maroon blossoms.

**P. Dauntless** (Foster).—A show kind having flowers of a bright pink, the top petals being blotched with maroon.

**P. Marmion** (Foster).—A show variety, with well-formed pink flowers and white centre, the top petals being velvety-crimson.

**P. Criterion** (Foster).—A dark crimson show flower, with white centre, and very distinct.

**P. Janette** (Turner).—A fancy kind, with round flowers of rosy-crimson, the centre and edges of which are white.

**P. Placidum** (Turner).—A fancy kind, having bright rose-magenta flowers, with white edges and centre.

**P. Fanny Catlin** (Catlin).—A robust-growing kind of good habit, with dark zonal leaves, and large trusses of perfectly formed orange-salmon blossoms.

**P. Manfred** (Dr. Denny).—A good-habited kind, having finely-formed, smooth-petalled flowers, of a brilliant orange-scarlet colour.

**P. Sunbeam** (Dr. Denny).—A well-formed, bright scarlet-flowered zonal.

**P. Madonna** (Dr. Denny).—A zonal, with deep rose-coloured flowers, of great substance, and very attractive.

Messrs. Veitch & Sons showed a collection of new plants, consisting of *Begonias*, *Dipladema Crossiana*, a garden hybrid, having medium sized flowers, elegantly tinted with pink; *Oroton Hanburyanum*, a graceful-leaved kind, from the South Sea Islands, beautifully mottled with green, gold, rose, and crimson; *Davallia elata*, a showy Fern, with finely-cut bronze pinnae. From Messrs. Laing & Co. came several fine new *Begonias*. Mr. Bull contributed *Cœlogyne corymbosa* in good condition, also several new Palms, *Dracenas*, and a show *Pelargonium* named *Princess of Wales*, with beautiful striped, rose, purple and white flowers. Messrs. E. & J. Perkins, Leamington, sent a fine double *Petunia* named *Madame Van Merton* and several new *Potentillas*. From Messrs. Cripps & Son, Tunbridge Wells, came new *Clematises* and Mr. Cannell showed a fine basketful of *Dactylis elegantissima aurea*. Messrs. Wm. Paul & Sons sent blooms of English-raised seedling *Roses*, among which were several promising kinds, such as *Duchess of Bedford* and *Countess of Rosebery*. The Rev. A. Rawson, Bromley Common, contributed remarkable blooms of the hardy *Lady's-slipper*, *Cypripedium spectabile*, several fine *Lilies*, and a beautiful new seedling *Iris*. Mr. R. Dean sent fine blooms of a new strain of *Canterbury Bell*; they were large in size, and in some cases had double cups, while in colour they varied from cream to the deepest azure-blue.

**Fruit.**—An interesting exhibition of fruit trees in pots came from Mr. Rivers, Sawbridgeworth; it consisted of *Cherries*, *Peaches*, and *Nectarines*, all loaded with ripe fruit. Fine *James Veitch Strawberry* came from Mr. Lane, gardener to Lieut.-General Tyche, Pyrgie Park, Romford; and Mr. Hinds, Otterpool, sent good *Melons* and *Tomatoes*.

**Miscellaneous Collections of Plants.**—A group of *Orchids* and other plants from Mr. Roberts, gardener to Baron Rothchild, Gunnersbury, contained a plant of *Odontoglossum vexillarium* bearing more than a dozen graceful flower-spikes and from sixty to seventy handsome blossoms. This occupied a raised position in the centre of the tent, and was surrounded by *Palms* and *Ferns*, from amidst which, in form of a circle, sprang fine spikes of *Odontoglossum Alexandræ*. An attractive group of new and rare plants was contributed by Mr. Bull, Chelsea. In it were noticeable elegant plants of *Cruniglo recurvata variegata*, the white and green-leaved *Phyllanthus nivosa*, pansful of the brilliant *Pelargonium triumphans*, and well-grown examples of *Dracena Goldieana*. In a bank of plants of *Adiantum gracillimum* were inserted examples of *Odontoglossum vexillarium*, *O. Alexandræ*, finely-flowered *Masdevallia*, *Catleyas*, and the brilliant orange-scarlet *Epidendrum vitulinum*. Associated with these were also fine-leaved *Bortolonias*, *Lady's-slippers*, and similar plants. From Mr. Wills came the most attractive collection in the tent. It consisted of a background of *Giant Tree Ferns*, *Palms*, *Cordylines*, &c., under which, tastefully arranged, were *Liliums*, *Spiras*, and brilliantly-coloured *Dracenas*, &c.; the foreground, and of which sprang well-grown plants of the graceful *Cocos Weddelliana*, *Geonoms*, *Caladiums*, choice *Orchids*, *Water Lilies*, and *Gloxinias*. This group occupied altogether several hundred square feet of space. Mr. B. S. Williams had, as usual, an excellent collection, in which were well-grown *Pandanads*, fine-leaved *Crotons*, *Yucca aloifolia variegata*, new and attractive *Dracenas*, &c. Amongst these were arranged fine specimens of the *Flamingo* plant, *Amarylises*, *Fitcher* plants, well-flowered examples of *Dendrobium Benaonia*, and *Odontoglossum Alexandræ*; fine-leaved *Bortolonias*, new *Colouees*, and *Ferns*. Adjoining this group was a bank of tuberous-rooted *Begonias* from Messrs. Veitch & Sons, which was much admired; the plants were well grown and abundantly flowered, and were set off to advantage by being intermixed with *Ferns*, &c. The same exhibitors also contributed a collection of insectivorous plants, which were very interesting, also brightly-flowered *Gloxinias*, *Hydrangeas* *Thomas Hogg*, and fine potsful of *Blandfordia aurea*, backed up by *Acalypha Maccleana*, the leaves of which were unusually bright and well coloured. Messrs. Laing & Co., Forest Hill, showed an attractive group of plants, amongst which were well-grown examples of the graceful *Cruniglo recurvata variegata*, variegated *Pines*, finely-coloured *Colouees*, and a boxful of exquisite *Roses*. A beautifully-flowered plant of *Dendrobium Falconeri* came from Mr. Fisher, gardener to F. Williams, Esq., Balham. Messrs. Carter & Co. had a noble collection of *Palms*, *Pandanads*, *Dioffenbachias*, choice *Ferns*, &c. Messrs. Rollisson & Sons had an interesting group of *Cycads* and *Palms*, associated with which were specimens of the finely-coloured *Dracena salmonea*, the green-leaved *D. fragrans*, the graceful *Grevillea filicifolia*, and *Crotoms*. These were relieved by finely-flowered plants of *Cypripedium spectabile*, a brilliant blue-flowered *Iris*, *Anthuriums*, *Pimeleas*, *Ericas*, and a fine variety of *Dendrobium Falconeri*. Pyramidal plants of *Ivy-leaved Pelargoniums* came from the Society's gardens at Cliswick; also an extensive collection of

zonals and nosegay kinds. A group of miscellaneous plants was contributed by Messrs. Hooper & Co., Covent Garden; noticeable in it were finely-coloured examples of *Croton Hookeri*, *C. undulatum*, *Pandanus Veitchii*, and the bronze-leaved *Lantana rubra vera*. These were effectively edged with well-grown *Achimenes*, *Begonias*, *Gloxinias*, the pretty *Torenia Fournieri*, and similar plants. Mr. J. Marcham, Springfield Nursery, Isleworth, furnished single-flowered *Petunias*, many of which were unusually large and beautifully striped. Messrs. Hayes, Edmonton, contributed an excellent bank of *Liliums*, coloured-leaved and other *Fuchsias*, beautiful show and zonal *Pelargoniums*, intermixed with *Ferns*, *Calceolarias*, and similarly attractive plants. From Messrs. Cutbush & Sons came a collection of New Holland plants and *Heaths*, intermixed with *Palms*, *Ferns*, and *Aralias*, and edged with small-growing *Ferns* and beautiful panfuls of a *Pink* doubtfully named *Dianthus indicus nanus*. Mr. Bolter, Kenel New Town, sent a collection of miniature succulents. Mr. John Reeves, Acton, contributed a collection of decorative plants consisting of well-grown examples of *Lilium longiflorum*, *Hydrangeas*, fine-leaved *Crotons*, *Adiantum gracillimum*, *Fuchsias*, and show *Pelargoniums*. This group occupied one of the circular banks near the entrance to the tent, and, being backed up with *Palms*, *Cannas*, and other fine-leaved plants, had a fine effect. Messrs. Osborn & Sons showed miscellaneous plants, amongst which were finely-coloured *Crotons*, well-grown *Dracænas*, *Bertolonias*, *Pandanads*, *Ferns*, and *Palms*. From Messrs. F. & A. Smith, Dulwich, came show *Pelargoniums*, small *Ferns*, *Grevilleas*, *Palms*, *Yuccas*, and similar subjects. Messrs. Dick Radclyffe & Co. had miniature rockeries, fountains, &c., ornamented with *Ferns*, *Palms*, and other fine-leaved plants; also *Fern* cases and rustic stands filled with flowers for prominent positions on lawns. Mr. Cannell, Swanley, showed stands of brilliantly-coloured *Verbenas*, large both in truss and flower, and in some cases new in colour.

**Hardy Flowers.**—Messrs. Barr & Suggden exhibited an extensive and excellent collection of cut blooms of hardy herbaceous and bulbous plants arranged amongst British *Ferns*. The background consisted of masses of *Lilies* of the umbellatum type, the beautiful white *Gladioli Colvillei*, *Anthriscum Lilifolium*, finely-coloured Spanish *Iris*es and *Pæonies*, &c. The foreground was effectively furnished with flowers of *Tritonias*, *Ixias*, *Sparaxis*, good potfuls of *Allium neapolitanum*, *Alstromeria arnon*, and other choice flowers. The same exhibitor showed, on behalf of Dr. Wallace, a new *Freesia*, the flowers of which were as white as those of *F. odoratissima alba*. From Mr. Parker, Tooting, also came an attractive collection of cut blooms of hardy herbaceous and bulbous plants, among which were noticeable good examples of the white *Martagon Lily*, choice *Iris*es, finely-flowered branches of *Tropeolum polyphyllum*, richly coloured spikes of *Delphinium magnificum* and *formosum*, *Verbascum Chaxii*, and several finely-coloured varieties of *Tradescantia virginica*. With these were associated double *Potentillas* and *Pyrethrums*, a beautiful *Dianthus* named *D. hybridus floribundus*, unusually large spikes of *Orchis foliosa*, and improved *Foxgloves*. In front of this group were stands containing magnificent blossoms of *Pæonies*, among which were especially noticeable *Decandolle*, a very large conical double flower of a rich rose colour; *Eugene Verdier*, a silky white semi-double flower, with deeply imbricated petals slightly tinted with pink; *Madame Furtado*, a rosy-pink; *Mons. Rousselon*, of very double creamy-white colour; and *Gloire de Douai*, rich magenta, the centre consisting of showy golden stamens.

**Roses.**—These were shown in far greater numbers and in much better condition than might have been expected, considering the backwardness of the season. In the class for forty-eight blooms, Messrs. Keynes & Co., Salisbury, had the best blossoms, which were remarkable both as regards size and colour. Among the most prominent kinds were the pink-coloured *Edward Morren*, fine conical blooms of *Marie Baumann*, the rich, dark velvet-crimson *Duke of Edinburgh*, *Exposition de Brie*, the salmon-coloured *Mlle. Eugénie Verdier*, and the finest blooms of *General Jacquemont* which we have ever seen. In the same class Messrs. Paul & Sons, Cheshunt, had remarkable examples of *Sultan of Zanzibar*, *Madame Hippolyte Jamain*, *Duke of Edinburgh*, and *Mons. Gabriel Fournier*. Mr. Turner, Slough, had good blooms of *Victor Verdier*, *Miss Hassard*, *Souvenir d'un Ami*, and the dark-coloured *Horace Vernet*. In the class for twenty-four single trusses, Messrs. Paul & Son, Cheshunt, had the best collection. It contained excellent blooms of *Madame Victor Verdier*, *Souvenir d'Almaison*, and *Miss Hassard*; and Mr. Turner had fine blooms of *La France*, *Louis Van Houtte*, *François Michelin*, and *Magna Charta*. Fine boxfuls were also shown by Mr. George Cooling, Bath. Mr. Hollingworth had excellent *Tea* and *Noisette* kinds, consisting of *Madame Villermoz*, *Marie Van Houtte*, *Devoniensis*, and the pure white *Madame Bravy*. In other classes, Messrs. Keynes & Co. showed a remarkably fine collection of well-

formed, brightly-coloured blossoms, among which were noticeable grand blooms of *La France*, *Charles Lefebvre*, the rich rosy-crimson *Marie Baumann*, the dark maroon *Louis Van Houtte*, and the brilliant *Duke of Wellington*; *Madame Charles Wood* and *Duke of Edinburgh* were also very fine. Messrs. Paul & Sons, the Old Nurseries, Cheshunt, had very fine blooms of *Sultan of Zanzibar*, *Abel Grand*, *Duchess de Valombrosa*, *Charles Lefebvre*, and *La France*. In a collection from Messrs. Curtis & Co., Torquay, were excellent blooms of the pink *Madame Nachury*, *Madame Lecharme*, and *Duchess of Wellington*. Mr. George, Cooling, Bath, showed well-coloured examples of *Marséchal Niel*. Mr. Hollingworth, Turkey Court, Maidstone, had well-formed blossoms of *Beauty of Waltham*, *Fishes Holmes*, the white *Jobnine Malton*, and *Captain Christy*. Messrs. Wm. Paul & Sons, Waltham Cross, contributed an extensive collection, in which, in addition to large and fine blooms of the best hybrid kinds, were numerous sorts of old-fashioned *Roses*, consisting of the white and pink *Damask*, *Harrison's yellow*, the striped *Gallica Perle des Panachees*, the beautiful white hybrid *Damask Madame Plantier*, and *Moss Roses*. The latter were represented by the pink *Prolific*, the common *Moss* grown so largely for market, and several white and rose-coloured varieties. Among other *Roses* were fine examples of *Senateur Vaise*, the scarlet *Charles Turner*, the deep rose *Magna Charta* and the white *Boule de Nègre*. Mr. W. Rumsey, Waltham Cross, had small, but finely-coloured blossoms of some of the best kinds in cultivation.

**Pelargoniums.**—These, both zonal, show, and fancy kinds, were shown in fairly large numbers, and their bright colours imparted a wonderfully gay appearance to the exhibition. In the class for six large-flowered show *Pelargoniums* Mr. James, Isleworth, showed well-grown plants of the dark crimson *Scottish Chief*, the lively rosy-pink *Isabella*, and *Magnificent*. Mr. Charles Turner, Slough, furnished an extensive collection of show varieties, among which were conspicuous *Virgin Queen*, white with purple blotches on the upper petals; *Prince Leopold*, brilliant crimson top, petals maroon; *Gipsy*, a wonderful dark variety; *Cicely*, bright salmon with crimson top petals; *Vesuvius*, brilliant scarlet, with purple-shaded centre, the upper petals being marked with dark maroon; one of the most attractive kinds in the show. The best *Fancies* also came from Mr. James, who had profusely flowered plants of *Mrs. Alfred Wigan*, the *Shah*, and *Princess Tack*. Mr. Weir, gardener to *Mrs. Hodgson*, Hampstead, had smaller plants of *Lady Carington* and *Duchess of Somerset*. Messrs. Hayes, of Edmonton, had a collection of attractive and valuable kinds for market purposes. Among them the best were *Digby Grande*, *Duchess of Bedford*, *Magenta Queen*, *Dr. Masters*, and a beautiful imbricated white-flowered kind named *Bridal Bouquet*; the same firm had also new kinds named *Sultana* and *Prince of Orange*, both well worth growing. *Mons. V. Lemoine*, Nancy, sent several attractive new kinds, which, however, were unnamed. Among seedling show varieties from Mr. Turner were several attractive kinds; *Captivation* was a bright orange-scarlet; *Amethyst* dark purplish-crimson. In a collection of seedlings from Mr. E. B. Foster, Thunderser was an attractive brilliant crimson flower of good form. *Red Gauntlet*, *Invincible*, and *Magician* were also well worth adding to good collections. Mr. Brown, Hendon, sent a bank of beautifully grown plants of show *Pelargoniums*, which were much admired on account of their dwarf habit, and their abundance of healthy green foliage and bright and varied flowers.

Zonals were admirably shown, in the shape of large specimens, by Mr. Catlin, gardener to *Mrs. Lemitte*, Finchley. In the florists' class, the best plants were *Ellen* (salmon), *Agnes Emily* (flesh colour), *Oneida* (scarlet), *Heather Bell* (rose); and in the decorative class the best were *Rebecca* (scarlet), *Rev. Atkinson* (crimson), *Charles Burrows* (pinkish-salmon), and *Mrs. Turner* (rose). In the class for eighteen plants of any class (zonal), the same exhibitor had well-bloomed examples of *Lizzie Brooks* (scarlet). The best four zonals (decorative class), not yet in commerce, came from Mr. Catlin; they consisted of *Nancy Lee* (salmon), *John Tullett* (scarlet), *Edith Mary* (orange), and *Fanny Catlin* (orange-salmon); and the best of the florist class came from Dr. Denny, who had *Scarlet Sunbeam*, *Manfred*, *Madonna*, *Coreggio*, and other beautiful kinds. Mr. Cannell, Swanley, exhibited a collection of cut blooms of zonals, among which were good examples of Dr. Denny, the brilliant crimson *H. Jacoby*, the pink-coloured *Mrs. Keeley*, and the large scarlet *Mrs. Newdegate*. Among doubles were *Victor Lemoine*, *J. Sommen*, *E. Louth*, and *Montesquieu*, all excellent kinds. A good collection also came from Mr. Burley, Brentwood. Mr. Catlin had good plants of *Wonderful* (double scarlet), *Neomis* (pink), and *Eugene Bandouin* (deep rose).

Messrs. Carter & Co. showed a collection of hardy annuals, which proved a source of interest to many.

[For a list of the prizes awarded on the occasion, see our advertisement columns.]

No. 345.]

SATURDAY, JUNE 29, 1878.

[Vol. XIII.]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

**Sub-tropical Plants in Cornwall.**—In answer to "Sanguinea" (see p. 609), I beg to say that in the year 1849 or 1849 I planted a good plant of *Araucaria excelsa* in the open air at Tregothnan. It lived for three years, but, although well protected, died the fourth; that year the winter was an unusually severe one. *Cycas revoluta* I have more than once tried out in Cornwall, but failed to grow it for more than one or two years. *Cyathea excelsa* I have never tried; I have heard, however, of its being grown out in Cornwall near the sea. *Dicksonia antarctica* was grown in the open air at Pencarrow by the late Sir William Molesworth, but I ascertained last year that it was dead. Mr. Jones, however, had, I believe, planted some others out which were living. I have myself tried this Tree Fern, but found that an unusually severe winter killed it. I recently saw at Mount Charles, near Truro, three plants of *Dicksonia antarctica* out-of-doors doing well, and was told that one plant had been out three winters. There are places in Cornwall close to the sea on the south coast where all the plants named above grow well and are not killed, owing to the Gulf Stream; but elsewhere I have never known these plants stand the severe winters we have at times in Cornwall.—J. T. BOSCAWEN.

— I fear "Sanguinea" will not succeed with *Araucaria excelsa* out-of-doors, as I fancy it was well tried at Tregothnan some twenty-five years ago, and, with all the protection afforded, the results were anything but satisfactory. I believe "Sanguinea" is not in a position to give it a more favourable chance, as both places are familiar to me. *Dicksonia antarctica* will do very well in many positions which he can offer it, and very possibly *Cyathea excelsa* may do equally well, but I fear *Cycas revoluta* cannot succeed.—S. GARLAND.

**Leptospermum bullatum Hardy in Kent.**—This New Zealand shrub, generally found in catalogues amongst greenhouse plants, having resisted the effects of the winters of 1875, 1876, and 1877 in our nursery here, planted out in a Pinetum, the soil of which is a cold, stiff clay, I think may be now claimed as a gain to us in the class of hardy evergreen flowering shrubs, and it is in this point of view I wish to bring it before your readers. The genus, of which there are at least fifteen or sixteen species, all natives of New Zealand, New Holland, and Tasmania, receives its name, according to Lindley, from the extreme tenuity of its seed. Most of the species are sub-shrubs, but one or two attain to large-sized trees. The natives call it *Mannk*, and the shrub itself is used by them, and also by the settlers, largely for firewood, and containing, as it does, so large an amount of essential oil in its leaves, stems, and berries, it can be used for fire-lighting immediately after it is cut. The arborescent variety is used for turnery purposes, the wood being very hard and agreeably fragrant; and it is also employed for stuffing mattresses or beds, a purpose for which its elasticity and agreeable fragrance well fit it. But it is as an addition to our ornamental flowering shrubs I wish to bring it under notice, and all who have seen the plant in our Pinetum here agree with me that, when covered with its unique and pretty white flowers, supported on the extremely slender branches, it is very elegant, and worthy of far greater attention than it has hitherto received.—T. BUNYARD, *Rose Nursery, Ashford.*

**Double-flowering Sweet Brier.**—I send you some out blooms of my double-flowering Sweet Brier which, after much time and trouble, I have succeeded in bringing to its present state; you will see that an exceedingly pretty Rose is joined the scent of the Sweet Brier. Both the plant and its bloom are now in perfection.—JOSEPH BANNISTER, *Hillside Nursery, Ventnor, I.V.*

**Abutilon Lady of the Lake.**—Owing to the improvements lately effected in this useful genus of plants we have now colours hitherto unknown in it. Under the above name we have a kind the habit of growth of which is dwarf and stocky. Its leaves are of a pleasing shade of green, whilst its well-formed, large blossoms are of a clear pink colour. We lately saw a number of plants of it in Messrs. Osborn & Sons' nursery at Fulham; it is without doubt the best kind in its way which has yet been raised.

**American Columbine.**—We have received fine blooms of some of the larger Columbines, including the handsome *Aquilegia chrysantha* and *corallina*, from the Rev. Mr. Ewbank, of Hyde, with the view of showing that these plants, true to name, thrive freely with

him. The large and handsome *A. chrysantha* would appear to be the finest of the easily-grown Columbines; it seems more disposed to become a true perennial in some of our cold soils than the Californian or Canadian Columbines.

**Chrysanthemum arcticum.**—This beautiful and rare Alpine is now in flower with me; it is not more than 6 in. in height, is very floriferous, and its blossoms, which are about 1½ in. across, are of a pale rose colour. It appears to delight in a fully exposed place on a rockery in a compost of strong loam and grit. It is a native of Siberia.—W.

**Alatroemeria hæmantha.**—This charming species is now in flower in the Kew collection. It is distinguished from the other kinds in cultivation by its dwarf habit, which seldom exceeds 1 ft., and by the ciliated margins of the leaves. Its blossoms are borne freely on short flower-stems, and are of a deep rose colour, with the two posterior divisions marked with chocolate-coloured stripes on a yellow ground. It is a native of Chili, and was introduced about fifty years ago, but is still rare in cultivation. There is a faithful illustration of it in the 2nd vol. of Sweet's "British Flower Garden."—A.

**Phyllocactus grandis.**—Though an old friend, I have been unusually well pleased with this plant this season, producing, as it has done, such grand creamy-white blossoms, much resembling those of the night-flowering Cereus. Like, it too, it opens its blossoms in the evening, but they continue expanded for about two days. It is in every way an excellent plant, and one which is not particular as to the position in which it is grown. A plant of it in an 8-in. pot is bearing eighteen flowers, each about 12 in. in length, and very sweet-scented.—J. CROUCHER, *Sudbury House, Hammersmith.*

**Gardeners' Benevolent Institution Dinner.**—This takes place next Wednesday, under the presidency of Mr. Marnock. A most successful and pleasant meeting is expected on this occasion. We shall be glad to receive subscriptions to this excellent institution, which has so many claims on the sympathy of all who derive pleasure from gardens.

**London International Horticultural Exhibition.**—This exhibition is now definitely fixed for 1880. The "International" Committee (Sir D. Cooper, Bart., chairman), appointed a short time since to make the necessary arrangements for holding the show, met Lord Aberdeen and some members of the Council of the Royal Horticultural and Royal Botanic Societies on Tuesday last in conference, when, in view of the present depression in trade, the counter-attraction of the Royal Agricultural Society's show in 1879, and the fact of the Antwerp show falling also in 1879, it was decided by a large majority that the London show should be deferred till 1880, the committee in the meanwhile to take such preliminary steps in reference to securing a suitable site as might seem desirable, with a view to more energetic action in the ensuing spring. Mr. T. Moore is honorary secretary for the exhibition; and Dr. Masters was appointed honorary secretary for the congress which it is proposed to hold, as before, in connection with the show.

**Hardy Flowers at St. John's Wood.**—Seedling and named Larkspurs are exceedingly gay just now in the Wellington Road Nursery; some of their flower-spikes have attained a height of 8 ft. or more, and well show the advantage gained by planting in masses. *Lychnis Bungeana* also bears fine coral-coloured, smooth, round blossoms as large as a crown piece; and the beautiful *Gladiolus Colvillei* and its white variety are very attractive, as are also the stately white-flowered spikes of *Ornithogalum pyramidale*. Plants of *Delphinium cashmerianum* are furnished with a profusion of blue nodding flowers, and in a bed of the *Centaura Cyanus*, the flowers of which are just now so extensively used in bouquets in Covent Garden, we noticed a beautiful delicate pink variety, which, if it keeps constant, will be very useful. Improved kinds of *Potentilla* may likewise now be found in full flower here, some of the blossoms being almost as large as those of a *Quelder* Rose, and beautifully striped with gold and crimson. The Japanese *Veronica Hendersoni* is just coming into bloom; it grows about 2 ft. high, and bears large branching heads of blue blossoms. *Rodgersia polyphylla*, just going out of flower, is also well worth culture on account of the beauty of its foliage alone.

**Plants in Flower at Colchester.**—Our beds of *Lilium Szovitzianum*, numbering several thousands, have been a grand sight the last fortnight; on some stalks we have counted twenty large yellow bells; but the heat of the present week is beginning to spoil their beauty. *Lilium Martagon album*, *L. dalmaticum*, and *L. Hansonii* are now out, and form a striking contrast. The last named Lily, *L. Hansonii*, we had over from Japan in the winter of 1869-70, and offered three bulbs of it for sale at Stevens', one of which was purchased by Mr. Wilson, another by Mr. Barr, and the third by Mr. Bull. No one then knew what it was, but our drawings showed it to

be a yellow-flowering Martagon, and it was described to us as one of the first Lilies to flower in Japan. Till this year we have never succeeded in flowering it. It is a perfectly distinct kind. Lillium Browni is now out in full beauty. *L. japonicum* Colchesteri will not be in bloom for another month. All those who have seen the two plants growing side by side have at once declared that they are totally distinct. The graceful, tall-growing *L. columbianum* and *L. parvum*, with several of the Thunbergian group, notably Alice Wilson and Prince of Orange, are now out. Amongst the Irises the English Xephons are noticeable for their beauty; a pretty and quaint little Australian terrestrial Orchid, *Diris lilacina*, is now out. It is of a purplish-lilac tint, and each flower has two long tails. We do not think it has been before flowered in this country. *Freesia refracta* alba is most charming, rather larger and more erect than *F. Leichtlini*, but it has the most delightful concentrated perfume of Primroses possible. *Cypripedium spectabile* is unusually well coloured this year.—A. W.

**Escallonia Phillipiana** is the name of a new white flowered species now in bloom and both distinct and pretty. The flowers are open like those of a Hawthorn, not tubular, clear white, and produced in abundance. It seems to be quite hardy, and may be seen in Messrs. Veitch's Coombe Wood Nurseries.

**Coarse French Forcing Beans.**—A correspondent writes to complain of the flavour, or rather the absence of fresh and agreeable flavour, in the large, fat, and coarse Kidney Beans now obtainable in our markets, and which have been the rule in them for many weeks past. He thinks the culture of such, a step in the wrong direction.

**Orchis latifolia.**—There is a very fine showy variety of this now at Kew. We believe Dr. Moore has observed and collected certain very fine varieties of this plant, which should be looked after by cultivators.

**Almerian Grapes.**—The Phylloxera has found its way into the Vineyards in Almeria, and is causing serious damage. This may serve to check, to some extent, the exportation of the green, insipid Grapes which are sold in London at nearly every season of the year. Should their price become increased, some inducement may be offered to English growers to further extend Grape culture at home; there is no good reason why English Grapes should not be obtainable at a price as reasonable as that paid for Almerian produce.

**Gunnera manicata.**—This fine plant may now be seen in a thoroughly developed state in the Pine-apple Nursery of Messrs. E. G. Henderson & Son. Near it is a specimen of the older *G. scabra*, so that the two species can be conveniently compared. *G. manicata* has a rounder, smoother leaf, and seems to grow quite as large as the old kind. Both are fine plants for the picturesque garden, especially where there is moist and deep soil.

**Premium for a Report on Insects.**—We observe, that the Highland and Agricultural Society have offered a premium of £ 20 for a report "on the insects which prey upon agricultural plants, the diseases occasioned by them, and the best means of prevention." The report to be lodged by November 1 next, and is to be accompanied, when practicable, by specimens of the insects themselves.

**Todea superba.**—Judging by a fine batch of this graceful Fern in the Pine-apple Nursery, it is quite possible to grow it without the great shade that is usually given it. Here the sun often shines on it, and yet it seems to thrive without flinching. It is of course kept very moist, and watered overhead twice a day.

**The Mulberry in London.**—It is worth noting that the Mulberry is one of the trees that do well in London, and even in its central districts. We noticed a fine specimen of it, in an enclosed court in the West Central District the other day, and we have seen fruit of it from trees growing in the garden belonging to the Charter-house. There is no need to add that it is one of the most beautiful of trees, though perhaps people may as well be reminded of the fact, as comparatively few seem to be planted now-a-days.

**Orchids at Chelsea.**—There is now a good display of Orchids in Messrs. Veitch & Sons' nursery at Chelsea. Large plants of *Aerides Lobbi*, virens, and Warneri are furnished with massive racemes of blossom. *Vanda Parishii* is finely in flower; also the curious *V. teres*; *Cattleya Mendellii*, and Warneri are unusually well-flowered, and a fine variety of *Madeoallia Harrayna* is also remarkably attractive. The miniature Japanese *Angreorum falcatum* bears abundance of small wax-like white blossoms, which are agreeably scented. *Angulos uniflora*, also finely in bloom, has flowers large in size and of the purest white, delicately tinted with rose. *Zygopetalum Sedeni*, a hybrid raised in the Chelsea Nursery by Mr. Seden, bears several spikes of finely-coloured flowers, and the beautiful cinnamon-

coloured *Saccolabium carvifolium* is well furnished with handsome spikes of flowers. To these may be added *Disa grandiflora*, *Dendrobium Devonianum*, *D. Jamesianum*, and *D. Bensoniæ*; together with a fine display of *Lady's-sippers*.—H. S.

**Mutisia decurrens.**—This showy and curious plant is about to flower against a wall in the Pine-apple Nursery. We do not see why suburban gardens should not more frequently afford a home for interesting plants of this sort. The shade and shelter in such small gardens, often suit such plants as this, the Flame Nasturtium (*Tropaeolum speciosum*) and the hardy climbing *Lygodium*, a North American Fern. Such plants would scramble through *Rhododendrons* and other choice shrubs, and thrive well in the soil usually given to these.

**The Mammillarias and Echinocacti** in Mr. Peacock's collection, at Sadbury House, Hammersmith, are, we learn, now finely in flower.

**Two Good Hardy Orchids.**—The most conspicuous pair of hardy terrestrial Orchids in flower at the present date are *Orchis foliosa*, always welcome on account of its easy culture, and *Cypripedium spectabile*, a well-known kind, which is highly prized on account of its delicate rose-colored labellum and pure white sepals and petals. Both have fine, striking foliage, and succeed well under the same conditions, viz., a partially-shaded, moist border of peat and leaf-mould, and they are best left to grow undisturbed.—J. G.

**Spargax pulcherrima** in Ireland.—Those who know this plant and its varieties will be interested to hear of the way in which it thrives in Ireland in Mr. Gumbleton's garden at Queenstown. The tufts grow about 6 ft. high, and from these are gracefully suspended in profusion the lovely bells which make this one of the most beautiful of all hardy plants.

**Funkias as Edging Plants.**—The bold and striking foliage of some of the strongest, plain-leaved section of Funkias renders them very effective as edging plants for large beds, while the several kinds that have variegated foliage, such as *F. undulata* medio-variegata, make fine beds or masses, or are suitable for edgings in smaller arrangements. As flowering plants, too, they ought not to be disregarded, and as pot plants they may be usefully employed during the early part of the year. They are not fastidious as to soil; on the contrary, they will grow well in almost any kind of material. Funkias constitute a class of plants that are calculated to reduce the demand for tender exotics that require the protection of glass for nine months of the year, and they are equally effective.—J. G.

**Planting at Kew.**—We observe with pleasure that a great number of trees and shrubs—new, rare, or otherwise interesting—have been planted in the pleasure grounds at Kew. Such planting is very much more important than any work that can possibly be done in glass houses, which has long absorbed so much attention at Kew. The arrangement of these trees and shrubs is not all that could be desired—the masses being stiff and formal in many cases, and the trees very closely placed in certain avenues (*Horse Chestnuts*, for example, about 12 ft. apart)—but to have a really good collection of trees and shrubs, and to have every obtainable species and variety of woody plants hardy in our climate represented would be a great boon to the country.

**Names of Plants.**—Correspondents wishing plants to be named will oblige by complying with the following rules: To send the specimen as complete as possible, i.e., both stem, leaves, and flowers, and fruit, where possible. We cannot attempt to name plants from single leaves. To carefully pack them in gutta-percha tissue or other impervious material which will prevent exsiccation. Not to send varieties of popular flowers, such as *Fuchsias* or *Panicles*, which are best named by experienced growers of such plants, who have the means of comparison at hand. Not to send more than four plants or flowers at a time. Always to send, in addition to whatever pseudonyms or initials they may desire to use in the paper, their full name and address. To pre-pay all packages containing plants or flowers.—J. K.—1. *Vanda limbalis* (rare). 2. *Dendrobium navissimum*. 3. *Dendrobium* (too imperfect for recognition). *W. R.*—1. *Polystichum aculeatum*. 2. *Lastrea filix-mas*. 3. *L. dilatata*. 4. *Athyrium filix-femina* Fieldii: *H. P.*—*Betonica grandiflora*, a free-growing and showy perennial excellent for the wild garden. *W. A.*—It is *Stanhopea insignis*. *G. C. C.*—Seed pods of *Honesty* (*Linaria hians*).

**Re-planting Old Asparagus Roots.**—I do not think that planting old Asparagus roots is such a very bad plan as it is represented to be (see p. 609). I have re-planted Asparagus roots of more than twenty years of age, and the results answered my expectations.—J. M.

—I hope "A." will not give up his trial of old Asparagus roots under "V."s' advice, as I have been told by an old gardener who knew what old Asparagus meant, that some of the finest he ever cut was from old roots which he had replanted, in order to see if it could not be done.—S. GARDNER.

\* \* \* Owing to our Index occupying so much space, a variety of communications are delayed till next week.

## THE FLOWER GARDEN.

### HARDY PLANTS FOR CASCADES, &c.

In the few gardens where pretty cascades are seen, advantage is not always taken to group near them suitable plants. Evergreen herbs and evergreen trailers and bushes are here particularly desirable, because, as a cascade is an object that strikes the eye at all times, so its vegetation should be such as does not lose its charms in winter or any other season. In addition to dwarf shrubs, there are numbers of herbs which lend themselves well to such situations, particularly the large-leaved Saxifrages, *Cornus canadensis*, *Dryas octopetala*, *Epigaea repens*, *Gaultheria procumbens*, *Genista prostrata*, *Iberis* (evergreen kinds), *Linnæa borealis*, *Polygonum vacinifolium*, *Salix lanata*, *Vaccinium macrocarpum*, *Arenaria balearica* (to creep over stones), *Aubrietia* in variety, *Campanula hederacea*, *Convolvulus Soldanella*, *Phlox* (dwarf kinds in variety), *Saponaria*

*ocymoides*, *Saxifrages* in great variety, *Selaginella denticulata*, *Sibthorpia europæa*, *Arabis alba*, *Arbutus Uva-ursi*, and *Lysimachia Nummularia*.

### NOTES ON HARDY PLANTS.

A WALK through Mr. Parker's nursery, Tooting, during the month of June is sure to bring under one's notice many things in the way of hardy plants of a particularly interesting character. There is something in the fine, light, sandy loam—one, however, that does not succumb to drought, as it might naturally be supposed it would do—that appears to suit the circumstances of the plants which flourish in it most satisfactorily. A fortnight ago an opportunity was afforded to look over the plants, and the following were noted as most desirable subjects to cultivate. Let us mention *Phlox ovata Livistona* first; it is about 12 in. in height, erect growing, something resembling *P. verna*, and bearing numerous trusses of rosy-purple flowers. Mr. Barron also has this in fine condition on the new rockwork at Chiswick, where it does remarkably well. *Æthionema grandiflorum* has a rather straggling growth, but makes a capital rock plant, bearing many clusters of lovely pink flowers, changing to white. *Menziesia polifolia bicolor* well deserves attention; it has a dwarf spreading growth, and bears white and reddish-magenta flowers. What a pleasing plant *Silene quadridentata* is, with its dwarf growth and pretty snowy-white flowers produced with great freedom! *Phyteuma comosum* is a rare and somewhat remarkable plant, found growing in the vertical fissures of limestone cliffs; it reaches a height of about 9 in., and bears purplish-blue flowers of large size. Quite a different plant is found in *Linum narbonneuse*, with its erect growth and numerous flower-stems loaded with pale blue blossoms; this should find a place in every border suited to its well-being. The double form of *Geum coccineum* is a capital plant remarkable for its brilliancy of colour, but

with a rather spreading growth. *Ranunculus acris* fl.-pl. is another useful plant with golden-yellow flowers, which make a conspicuous feature in a raised border. The *Lavateras* are really imposing border plants, because they form such dense bushes of flowers. Mr. Parker has the old red and white, and a newer form of the red, which is of a much deeper colour, and therefore much more showy. The two last originated as sports from the former. The *Thalictrum* are perhaps more deserving of cultivation for the elegant character of their foliage than for their flowers. They make fine border plants. *T. aquilegiforme* has trusses of white flowers; and *P. purpureum* lavender-purple. *Erigeron purpureum* is a fine plant growing some 2 ft. in height, and bearing rosy-purple flowers; it is very free and pretty. *Lychnis viscaria splendens* is another taking plant, very pretty, and bearing rosy-pink flowers. Those who have a liking for species of *Pentstemon* will be much pleased with *P. gracilis*; it has a somewhat spare growth, and bright bluetubular flowers edged with white. The pretty *Fuchsia thymifolia* was growing in the border among hardy plants; it appears to be a larger form of *T. microphylla*, and Mr. Parker said it had been flowering all through the winter in a cold frame. One of the varieties of *Dianthus hybridus*, named *floribundus* well deserves the name, for plants of it are blooming with great freedom, and it well merits a place in gardens because it is so valuable to cut from. *Veronica Teucrium* is another capital plant, growing about 18 in. in height and throwing up numerous spikes of bright blue flowers. Then there is the pretty *Dicentra eximia*, with charming red flowers, very free, and blooming continuously for a long time. The yellow-flowered prostrate *Tropæolum polyphyllum* was very effective in several parts of the nursery, growing strongly and throwing up a large number of flowers. The white *Veronica gentianoides* is a most valuable garden plant, as it flowers early and with great freedom; well-established clumps produce a large number of spikes of bloom. What showy masses the *Tradescantias* make! Mr. Parker has quite large masses of them. There are *T. virginica* and *virginica alba*; *rubra*, reddish-purple; *rubra pleno*, very good; and a few more besides. The various *Geraniums*, also, make good and showy clumps, *armenum* in particular being a very vigorous and handsome species, with fine magenta-purple flowers. Then there is the singularly beautiful *Lithospermum petraeum*, enjoying the seclusion of a cool frame, and with it were the delicate blue trailing *Omphalodes Luciliae*, *Iberis gibraltaria*, and the charming *Androsace lanuginosa*, very dwarf, and having pretty pale pink flowers. *Cyananthus lobatus*, with its large, pale bluish-purple, *Campanula*-like flowers, is another most desirable subject, very pretty indeed; and *Delphinium nudicaule* is so dwarf, bright, and free, and so distinct, as to prove welcome in every garden. How fine and even imposing the red and white *Faxinellas* are, and what excellent subjects for the background of a mixed border! *Trollius japonicus* fl.-pl. has fine, deep orange, double flowers; and the yellow-flowered *Coronilla iberica*, with its spreading growth, is well adapted for rockwork. Another allusion to the *Geraniums* is necessary for the purpose of calling attention to the pretty *G. lancasteriense*, the white flowers being pencilled with pink lines; and *G. dabricurum* has striking pale bluish-purple blossoms. Lastly come some of the pretty dwarf *Dianthus*es, and the following were especially striking, viz., *suavis*, *arenarius*, *cœsius*, and the curiously fringed *corizus*. These want to be grown in pots with some pieces of limestone mingled with the soil, and, with a little attention, they can scarcely fail to do well, and become sources of great pleasure to those who cultivate them. D.

**Hardy Flowers at Gunnersbury Park.**—A long wide border here is devoted to a well-named collection of choice, hardy, herbaceous plants. This is decidedly a step in the right direction, as it illustrates the floral wealth of temperate climes, and serves the purpose of bringing young cultivators into direct contact with hardy flowers, which otherwise could be seen only at a few nurseries or in the gardens of amateurs, for it is but too evident that the idea of herbaceous borders in the minds of the majority of young cultivators is associated with such subjects as *Ring* Flags, straggling *Michaelmas* Daisies, or uncouth *Aaron's Rods*. Besides such borders as these, which occupy comparatively but little space in a large garden, serve

a useful purpose in affording cut flowers at a season when indoor flowers are somewhat scarce. I therefore hope that the example set at Gunnersbury will be followed both in large and small gardens, that all rubbish may be discarded from herbaceous borders, and that ere long it will be the new fashion to have "old-fashioned" borders stocked with a selection from the host of beautiful hardy flowers which have of late years been introduced to cultivation.—VISITOR.

#### GRAVEYARD GARDENS.

ALTHOUGH "S." (see p. 558) is perfectly right in his condemnation of the bedding system in graveyards, yet I see no reason why the beds ought to remain so many bare spaces the greater part of the year, since to have a garden as beautiful in spring as it is in summer is about as easy as it is to have a good patch of early Cabbages. However, instead of cutting up the turf into ugly contortions under the name of flower beds, it is far better to have borders and clumps of shrubs judiciously planted and intermixed with suitable flowers. In making a selection of trees and shrubs for graveyard decoration the architecture of the building—be it a church or chapel, or both—ought to receive consideration. Where there is a spire, tall, tapering trees ought to be planted, and for this purpose I know of nothing so suitable as the Irish Yew. Let me not, however, be understood to say that this is the only suitable plant. By no means. Among other evergreens we have the Lawson Cypress, and others of that type, Biotas and Arbor-vitæ, and amongst deciduous trees the Poplars. In association with a building having a tower I would plant something more bush-shaped, as the common Yew, and its congenere Taxus adpressa, common Laurel, Bay, and other evergreens, the number of which is legion. Amongst deciduous trees I would use Weeping Willows, Elms, and Ash; while to give variety I would plant the Copper Beech and other ornamental-foliaged trees. What seems strange to me is the almost universal absence of flowering trees and shrubs in graveyards. Why not introduce the Laburnum, Lilac, Ribes sanguineum, and its white variety, the Laurustinus, various kinds of Berberis, particularly B. Darwini, and Rhododendrons? These would produce a good effect without being too public-parade like. The trees just named, judiciously planted with regard to size, whether in borders or clumps, or intermixed with flowers of suitable sorts, such as Wallflowers, Forget-me-nots, and other spring flowering subjects, could not well fail to give satisfaction. As to the church or other buildings, I see no reason why they should not receive their quota of the gardener's art. Why not cover our churches and cemetery chapels with Ivies, Pyracantha, Cotoneasters, Virginian Creeper, Clomatises, Roses, and Honeysuckles? What could be more interesting than an old church porch covered with Clematis Jackmanni and C. montana, intermingled with the old pink China Rose? or at the entrance of a cemetery to find the superintendent's cottage enveloped in similar drapery? On the whole, I see no good reason why our graveyards generally should not be turned into places of quiet beauty and repose instead of being, as they generally are, dreary wastes. If the authorities would do something towards keeping up the general tidiness and good appearance of the place, the keeping of individual graves would doubtless become much more universal than it now is. "S." says many shrubs and trees died through being planted late in the spring, but more die through bad management both at the time of planting and afterwards. It is generally thought that anyone can plant a tree, but such is not the case; and by employing practical men for such work, the results would, as a rule, be more satisfactory. Many of the trees are also often misplaced owing to their being planted in what one might term the "architectural style," that is so that they may not hide the dull, gray-looking stone of the mason. This is obviously a mistake, as the building, seen through a delicate, ever-moving tracery of foliage, has a much better effect than it otherwise would have. The question of graveyard gardening is one on which a good deal might be said, but from any point of view the system of making our graveyards beautiful with Nature's choicest subjects has advantages which cannot be gainsaid. T. NEDDALE.

**Tree Ferns Out-of-doors in Ireland.**—The increasing interest which is generally apparent about Ferns for ornament out-of-doors, as well as under glass, suggests the mention of *Dicksonia antarctica*, which thrives all the year round outside in some parts of Ireland without artificial covering. We see Tree Ferns out in summer in Battersea Park and elsewhere, in sheltered nooks, and as if enjoying the prospect of making permanent their temporary abodes. Last summer, a newly imported stem of this *Dicksonia*, about 4 ft. long, and with a few (and but few) freshly-grown fronds, was planted in a well-chosen spot, open above, but surrounded with trees and shrubs, Camellias, &c., not many miles from Dublin. At the end of May I saw it, with the fronds of last year's growth, crowned by more

than a dozen new ones, which seemed to luxuriate in the subdued light and moist atmosphere of a lovely spring day. In the autumn of 1874 I also noticed at Fota, in Co. Cork, well sheltered by Bamboos, in what is called the Bamboo Island, two young plants of the same Fern, which had thriven there for above two years. The Bamboos, I understand, have all died, whilst the Ferns continue to prosper, and are now luxuriant. Other species, and other genera of various character and habit, are undergoing trial in different parts of Ireland, but neither so many, nor of so different kinds, as Nature invites us to enjoy.—JOHN ADAIR, *Dublin*.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Yellow Irises.**—Two excellent and true yellow species of Iris are now in flower, I. Monnierii and I. aurea, the first being the largest. Both seem to belong to the group that thrives best in moist earth, or near water.

**Helianthemum rugosum.**—A very beautiful low bush bears this name at Kew, where it is now sparkling with many rich yellow flowers with black centres. It is neat and interesting in habit from a curious difference in the growth and hue of the flowering and non-flowering shoots. This plant is a real treasure for the rock garden, or for stony or chalky banks in the wild garden.

**New Ageratum.**—Two new Ageratum have recently been put into trade, the Queen and Cupid. The first named can hardly be termed an acquisition, as it has a tall habit of growth, and the flowers are of a dull, pale, mauve tint. Cupid, on the other hand, does seem to be of considerable value, as in that not only are the trusses of flowers larger, but the colour is much deeper than is seen in any other kind. It has a dwarf compact habit, dwarfer even than that of Countess of Stair, but the latter throws up its trusses on rather longer stalks, and is altogether the best kind for cutting from. Both kinds are interesting grown in pots. The deeper tint found in Cupid fully justifies the belief that a real blue Ageratum may doubtless eventually be found.—A. D.

**Seedling Pentstemons.**—A large bed of seedling Pentstemons here is just now so gay and beautiful that it is difficult to withhold a strong expression of admiration for this most useful, hardy border plant. No hardy perennial seeds more freely, none are more easily raised from seed, and here at once are conditions of success in culture that merit the attention of all who have gardens. Those who prefer the beautiful to the mere botanical will find in a bed of seedling Pentstemons raised from any good strain (and it ought to be difficult to get a bad strain just now) much variety in colour, and such grand spikes of flowers as will be productive of great satisfaction. During the past few years the named kinds of the Pentstemon have almost disappeared, for the simple reason that seedlings are as good as the parents, and therefore it is useless to propagate by cuttings, and at considerable trouble, sorts that can be almost duplicated from any packet of seeds. Having got some of the latter that is good, sow in a box or pan in a frame or greenhouse during the month of April, and when the seedlings are a few inches in height plant them out in the borders (if to be grown in them) or in a mass in a bed. No matter in what position they may be they are gay, but if a bed can be devoted to them to flower the next year instead of scarlet Pelargoniums, the grower will find, I have every reason to believe, that the sacrifice (if sacrifice it be) has been more than amply repaid.—A. D.

**Hybrid Columbines.**—"An Herbaaceous Man" alludes to these (see p. 594) as being chance hybrids. He also says that it is best to procure distinct species, and to keep them distinct. Now, in regard to the first accusation, that the seedlings raised by me, and to which first-class certificates were awarded both by the Floral Committee of the Royal Horticultural Society and by the judges at one of the Royal Botanic Society's Shows, the hybrids were not chance seedlings, but were raised by crossing distinct species to obtain definite results, which more than justified my expectations; the flowers have been seen by the public, and have been much admired. The second assertion is a matter of opinion, and it is to be hoped that very few admirers of flowers are of the same mind as "An Herbaaceous Man." It is to the intelligent crossing of distinct species of Orchids that we owe such grand plants as *Cattleya exoniensis*, *Cypripedium Harrisonianum*, *Calanthe Veitchii*, &c. Was it wrong in Mr. Dominy to attempt crossing the species of Orchids? and did Messrs. Veitch do wrong in sending them out? There are some, myself included, who believe that *Calanthe Veitchii* is one of our most useful flowering stove plants, either for cutting from or for decorative purposes in winter, and *Cattleya exoniensis* is one of the best Orchids in existence. Messrs. Veitch will be long remembered for their hybrid Orchids, and the new *Aquilegias* will bring no disgrace on that firm.—J. DOUGLAS.

ROSES.

BORDERS OF ROSES.

AMONG the various ways of making the Rose much less objectionable as regards its mode of growth and habit in gardens, one of the best is that of making fringes of them round masses of flowering shrubs and the like. In such positions Roses should be pegged down, and in that way, instead of naked and far from ornamental stems, we have the graceful foliage of the Roses springing directly from the turf. The flowering shoots of the current year that spring from the pegged-down shoots are, of course, free, and, when laden with flowers, toss about gracefully, the growth from Roses on their own roots treated thus being vigorous and the foliage ample. In all cases the Roses should be trained so near the edge that when in full growth they may conceal the dug surface and appear to spring from the turf. Such borders need not be mere lines, but might be allowed to spread into little bays here and there; and they might also be agreeably varied with suitable kinds. Such might well replace many of the stiff ribbon borders round shrubberies made up of any common bedding plants that happen to

A Border of Roses.

be at hand. These are as short-lived as ugly, and have to be renewed yearly, whereas fringes of Roses, once well planted, would last for years with ordinary care.

ROSES AND ROSE STOCKS.

WILD BRIERS are nearly always fit for budding before (except by severely pinching back and thereby often losing the best shoots) the buds are sufficiently developed. The difficulty is that the bark, especially in a dry season after the month of June, does not rise; this can be remedied by the constant use of water, liquid manure being preferable. As to dormant buds, I find that the red spider quile relieves me of the trouble of planting those stocks out, though if one does escape it is an advantage. As for soil interfering with choice of Brier or Manetti, provided the climate be good, the soil can, at a small cost, be made, and the wild Rose is not very particular in that respect. As to the removal of suckers, nothing need be said, nor upon removal of Manetti shoots; both are nearly fatal under any circumstances, and the idea of budding a sucker is absurd. The only difference of opinion as to thinning of buds must lie in a nutshell. Does the grower wish to exhibit for a prize, or to ornament his drawing-room? the excision must, in the latter case, be used with discretion, for the second flowering does not always come to much in dry seasons. Aphides do great injury; the worm in the bud often puts in an appearance; lightning blasts; disease in the leaf is as common as in the Potato; casualties happen. As to removal of decayed or spent blossoms, every plant ceases to produce as soon as seed begins to ripen; as to the removal of all decayed foliage it does injury to the parent plant, though of value to the manure heap when well rotted; as to insects, my gardener keeps a small machine by which he dusts his flowers with some preparation that causes insecticide. Even Tobacco water does not quite improve the health of the green aphid or the bug on the Pelargonium. As regards manure water, I have

this year made a three-hogshead tank to receive the drainings from my cow house, and I am convinced by the use of it in a diluted state, say half-and-half to either fruit or flowers, I gain more than is possible from guano, and run no risk. As to climbing Roses, Gloire de Dijon and Lamarque in good positions do best out-of-doors; Marechal Niel cannot be relied on. With Mr. Baines' idea of pruning my Tea Roses I cannot agree; the only times a knife should be used is to remove dead wood or too luxuriant growth; for many, such as improved Devonensis, die back from the out. Of the two or three dozen new Roses I have this year bought, none can rival Boule de Neige, Madame Victor Verdier, the Empress of India, and perhaps Henri Lafayette. In spite of a bad spring, from cold and rain causing great blight, those Roses which I have named are good.

EUGENE E. P. LEGGE.

**Rosa rugosa.**—It would, I imagine, be folly to speak of a single Rose, after the manner of our Wild Dog Rose, as a beautiful object, when the acme of perfection is to get everything as large and double as possible. Nevertheless, my own opinion is that *Rosa rugosa* is a most lovely object on a bank, its large, dark green pinnate, glossy foliage, and flowers of a bright rosy crimson being quite unique in their way. *Rugosa alba* and *rugosa fl.-pl.* form good companions to the type; and, in addition to the lovely summer effect which they produce, their beauty is enhanced in autumn by clusters of large red berries.—J. GROOM.

**Marechal Niel Rose.**—A small misprint in my remarks upon this Rose inserted last week (see p. 599) makes the point urged so dissimilar, that I wish to correct it. In the paragraph in question I am made to say, "Make a boy fork it up." What should have been said was, "Make a bay and then fork it up," by which I meant to convey the fact that the water given to the plants was no mere surface soaking, but a thorough flooding. The surface-soil was drawn off to form a bank all round the margin, and then about twenty pails of water were poured into the bay. Such a body of water as this would doubtless get well to the roots.—A. D.

CHURCH DECORATION IN CALIFORNIA.

You may like one or two bits out of the subjoined letter, from a lady in San Francisco, which was sent me this morning to read:—"San Francisco, April 25, 1878. Easter morn was very bright and sunny. We went to early service. The church was most beautifully decorated. They do this much more all over America than we have been accustomed to, except in High Churches, and the Advent Church is not High. The decorations were confined to the chancel, except a beautiful large cross of Galla Lilies (Arms) in front of the organ loft. The font, which is placed in a corner on the right side of the chancel was crowned with a pyramid of flowers. In the opposite corner was a large cross of white and pink Roses. On the Communion Table were choice bouquets, the centre one in the form of a cross. In front of the table was a beautiful device, a cross of pure white flowers, before which was placed a large Fern, so that you saw the cross through the graceful green fronds. The reading desk, lectern, and pulpit, or rather preaching desk, were all wreathed with exquisite flowers. The Communion Table was prepared for the Sacrament, and lovely flower wreaths bordered the white cloth. The rails were adorned with the Galla Lily; there must have been several thousand blossoms. But I must return to Easter Day, for I wish to tell you of the Sunday-school festival in the evening. The children carried banners with mottoes, and the head of each class carried some emblem: First, a crown in beautiful flowers; second, an open Bible; third, a Bible and lantern (the latter of flowers and the candle lighted); fourth, a shield; fifth, a lighthouse (of flowers); sixth, a harp (of flowers); seventh, a sickle and sheaf; eighth, a star (of flowers); and, ninth, a cross of bright flowers with a dove resting on it. A large cross was placed in the chancel, and each class carried beautiful flower wreaths which were hung on the cross until it was quite covered, and then the principal class brought a splendid crown of flowers, which was placed on the top. All this was new to us, and, I believe, gives intense delight to the children. Most of the churches here are decked with flowers every Sunday." O. M. B.

**The Official Rhubarb.**—*Rheum officinale* should be noted by all who desire bold and striking effects from hardy plants. It is the most effective hardy plant as regards foliage that has been introduced for many years. All the old Rhubarbs are insignificant beside it. It produces a fine effect early in the year.

## NOTES FROM KEW.

**Hardy Shrubs.**—Amongst Escalloniae now in flower the finest are *E. pterocladon*, from West Patagonia, a compact-growing bush, with small leaves, and *Epacris*-like spikes of fragrant white flowers; *E. peppigiana*, or, as it is sometimes called, *E. rubra*, a very graceful and beautiful plant from Chili, the red flowers being very numerous; and *E. Ingrami*, a variety of the last named, and a more robust grower, with larger leaves and flowers; as a bush among other shrubs in the open ground it seems, however, to be less charming than the type. *Philadelphus speciosus*, a North American shrub, has large ivory-white flowers, about 3 in. in diameter; the scent which characterises so strongly the common *Syringa* of gardens; *I. coronarius* (a native of Europe), being absent from its North American relative. *Zenobia speciosa*, and its variety *pulverulenta*, are handsome shrubs, with large, *Andromeda*-like flowers; the former has large, light-green leaves, the latter smaller, greyish-green ones. *Spiraea betulifolia* merits mention as one of the prettiest of all the shrubby *Spiraeas*; it grows to a height of about 2 ft., and the heads of fine rosy-red flowers are very pleasing. *Wistaria frutescens*, as well as the last named plant (a native of North America), has pretty flowers, darker in colour, and borne in shorter, denser racemes than those of the Chinese plant, *W. sinensis*.

**Greenhouse Plants.**—*Anralta* furnishes the only greenhouse shrubs we note this week. *Oxylobium Callistachys*, a fine leguminous bush with short, dense spikes of deep orange-yellow flowers, is a good-habited and useful plant. *Calothamnus quadrifidus*, a member of the *Myrtle* family, produces its scarlet flowers from the old wood; the long, narrow, almost needle-shaped leaves are fringed with fine hairs. *Callioma serratifolia* has pretty leaves and dense globular heads of whitish flowers with long filaments of the same colour. *Zephyranthes carinata*, from Mexico, a dwarf bulbous *Amaryllid*, with narrow leaves and large pink blossoms borne singly on the flower-stems, is the prettiest of the family at present in flower at Kew, excluding those previously noted.

**Hardy Herbaceous Plants.**—*Cephalaria Balanœ* is a very distinct *Teaselwort*, with Elder-like leaves and heads of straw-coloured flowers, the row of outer florets being very large. Three of the prettiest of the Evening Primroses are (*Knothera pumila*, *C. rosea*, and *C. glauca*, all North American kinds. The first grows about 12 in. high, has narrow little leaves and small bright yellow flowers; the second grows to about the same height as the last and has rose-coloured blossoms; while the third (18 in. high) has large yellow flowers. *Gillenia trifoliata*, a *Spiraea*-like member of the *Rose* family, grows about 3 ft. high, and the flowers have long red calyxes and pure white corollas. *Lobelia littoralis*, a native of New Zealand, is a charming rock plant when allowed to grow in a somewhat damp place; the little branches creep along close to the ground and the white flowers are about as large as those of the white bedding *Lobelias* which have sprung from the South African *L. Erinus*. *Lindelia spectabilis*, a handsome Himalayan perennial with deep blue flowers, is an ally of *Anchusa* and *Omphalodes*; the branches grow about 2 ft. in length, and are somewhat prostrate, not erect. The new *Pentstemon Clevelandii* has small magenta flowers, but is much inferior to many other species in point of beauty. *Baptisia leucophœa* and *B. australis* are beautiful *Lupin*-like perennials from the United States; the first named, which is of comparatively recent introduction, and which was figured in the "Botanical Magazine" a few years ago, has white flowers, the latter deep blue ones. Either for pot culture or for the open border, few members of the *Iris* family surpass in beauty the lovely little Cape bulb, *Romulea* (or *Trichosoma*) *speciosa*; it is of dwarf habit, in that respect resembling the *Crocuses*, and has large, rich carmine, yellow-centred flowers. *Orthosanthus multiflorus*, from Australia, is a very desirable border plant; it has long grassy leaves, and flower-stems 2 ft. high, bearing numerous very pleasing blue blossoms. *Sisyrinchium californicum* is a beautiful species with bright yellow flowers, in size and shade much resembling those of *S. convolutum*, noticed last week. *Homeria collina* var. *ciliata* and *Morphixia paniculata* are two charming Cape bulbs, the first with salmon-coloured flowers, the second with long-tubed, pale salmon, star-shaped blossoms. *Gladiolus Colvillei* also is a splendid plant, the large flowers being pure white, with the exception of a greenish stripe on each of the three lower divisions. *Zygadenus Nuttallii* and *Z. canadensis* have flowers very similar in size and colour, whitish, with a blotch of green at the base of each segment; the first-named attains a height of 3 ft., the other only about half that height. *Milla laxa*, a Californian bulb, has heads of finely-coloured flowers, purple, with a darker stripe to each division.—†

Brems have built their nests and brought forth young during the present season in a tuft of *Hepatica* in Mr. Wilson's garden at Heatherbank, and in an *Aubretia* at Mr. Ware's at Tottenham.

## THE KITCHEN GARDEN.

## TOMATOES TRIED AT CHISWICK.

THE following received First-class Certificates:—

## 1.—Fruit Red.

**Little Gem** (Bliss & Sons).—Fruit similar to the *Round Red*, borne on large clusters very profusely, the later fruit larger, more flattened, and obtusely angular. Plant of dwarf but free growth, the leaves of a light green. Ripens early. A profuse bearer and first-class hardy sort.

**Criterion** (Carter).—Synonym—New Improved (Viok).—Fruit of large size, ovate, perfectly smooth. Colour deep carmine, of excellent quality and very distinct. Plant of strong vigorous growth. Leaves slightly curled. A profuse bearing sort, the fruit borne in large clusters. Ripens early and freely. A novel and most distinct variety.

**Large Red** (Vilmorin & Co.).—Fruit very large, broad, flattened, somewhat corrugated, of a bright red colour. Plant of dwarf free growth. Leaves narrow, slightly curled. A most profuse bearer, the fruit produced in very large clusters. A larger and somewhat later form of Orangefield. Excellent.

**Hathaway's Excelsior**.—Synonyms—Cook's Favourite (Bliss & Sons); Red Apple (Vilmorin); Charter Oak (Veitch).—Fruit large, round, quite smooth and even, or seldom corrugated. Plant of remarkably free growth. Leaves deeply out, deep green in colour, and seldom curled. A free and most abundant bearer. Mid season. One of the best Tomatoes grown.

**Trophy** (Veitch, Carter, Wheeler).—Fruit very large, broad, flat, deeply ribbed or corrugated. Plant of dwarf robust growth. Leaves deeply cut, dark green. A wonderfully profuse bearer, but very late in ripening. A splendid sort for cultivation in heat, but, except in warm seasons, worthless in open air.

## 2.—Fruit Yellow.

**Green Gage** (Carter & Co.).—Fruit of medium size, roundish, of smooth even surface, not corrugated, of a fine clear orange-yellow colour. Plant of free growth. Leaves slightly curled. A very profuse bearer, the fruit produced freely in large clusters. Ripens early. The best yellow Tomato.

**Radish Pods.**—Although these are commonly used in mixed pickles, it is rare that they enter into the ordinary pickling concerns of the domestic household. At this one might well marvel, as they are singularly pleasant eating even in a raw state, and might be well mistaken for crisp young Radishes, as they have the flavour and gentle stimulating heat of that root when in its young state. The seed pods of the long white Californian kind are peculiarly good, and would make, if served up when young, a useful adjunct to the breakfast or tea table. To have these in abundance at this time of the year need of this Radish should be sown in a drill about the middle of September, and the plants will get large enough to stand the winter well. In good ground the produce of pods in the spring will be so considerable that it may with frequent gatherings be extended over several weeks, whilst the plants will need *Pea* sticks or cords for their support. In picking nothing further is necessary than to strip off the points of the pods, and then treat them as *Gherkins*, *Onions*, or other subjects are prepared. To get good roots of the white Californian Radish, seed should be sown at midsummer, as it will then be found that large fleshy roots for winter consumption can be had in abundance. Grown quickly, it is very crisp and pleasant, and makes a capital winter salad.—A. D.

**Mulgedium Plumieri** as a Wilderness Plant.—This is a little-known, somewhat gigantic Composite, having when young somewhat the appearance of a *Sonchus*. Its leaves are sea-green in colour, and have a broad midrib, runcinate at the lower part, something after the way of a *Lactuca* or *Leontodon*, often attaining as much as 4 ft. in length. The flower-stems grow from 7 ft. to 8 ft. high, and bear very large, racemose panicles of blue flowers. A great portion of the stem is leafy, the foliage becoming smaller as it ascends. Altogether a very stately plant and well suited for wild, bushy places. It is, I believe, a biennial, but when once planted it will take care of itself.—THOS. WILLIAMS, *Ormskirk*.

**Lobelia littoralis.**—A delicate little creeping white *Lobelia*, a native of New Zealand, is now in flower at Kew, and promises to prove an interesting plant for Alpine collections.

## TREES AND SHRUBS.

## OLD OLIVE TREES.

In the neighbourhood of Beaulieu may be seen an Olive tree which as far back as 1515 was already noted for its extreme age. Its trunk measures 12½ metres in circumference at the base, and more than 6½ metres at a height of 40 in. above the ground. This tree, called "Pignole," is the only one that survived the terrible hurricane of 1516, since which time it has yielded on an average about 100 kilogrammes of oil a year, and sometimes, in good seasons, as much as 150 kilogrammes. Still more celebrated are some trees growing in the Garden of Olives at Jerusalem. They are eight in number, measure about six metres in circumference, and, according to Bové, must be at least twenty centuries old. On the banks of Lake

Old Olive Grove.

Trasimeno, too, there are other veterans, some of which may doubtless have witnessed the expedition of Hannibal.

## THE COPPER BEECH.

TREES are undoubtedly far too often planted haphazard. Little regard is paid to their grouping, even if a thought is given to soil or to the danger of overcrowding. The consequence is that we have many well-grown specimen trees, whilst we seldom see an effective tree group. Beautiful in itself, no tree can more readily have its beauty enhanced by judicious arrangement than the Copper Beech. I have no more pleasing recollection of a sense of colour than one of the sun shining on a well-shaped tree of this species, on which hopped an escaped canary. In happy proximity to this same tree was a Laburnum, and this is a much-to-be-commended coupling. The homely white clusters of the Snowball tree (*Viburnum Opulus*) have their beauty much intensified by a background of Copper Beeches, adding richness to their own bright green foliage, as a velvet mount sets off the grace of a Wedgwood plaque, and if it be not gilding refined gold, I may even add that the queen of the woods herself, the Silver Birch, seems to have an added glory even from a copper frame. For a neighbouring large tree nothing can surpass the common green Beech, simply on account of its spring-tide verdure. Near at hand may also be with advantage the delicate foliage and grandeur of Violet bunches—like Grapes of Eschol—of *Wistaria sinensis*; and it is to be hoped that we may soon have this splendid plant growing as a perfect standard, as Mr. Meehan describes it to be in his Transatlantic gardens. As accompanying underwood, I will only mention the Broom, the Furze (double), and the Bracken; and I mention so many bright flowers because, though bright enough in itself in sunshine, sunshine is unfortunately so rare in England, that there might otherwise be a danger of my favourites being malignèd as sombre. It occurs to me that few herbaceous plants would benefit more from the proximity of such a background in a landscape than a bed of many-hued Irises, whose abundant glaucous foliage might, under other circumstances, have too pallid an effect.

Speaking of the Copper Beech reminds me of that little knock tree, or rather, let us say, shrub, the Copper Hazel. Neat in habit and iron in constitution, it is, in my opinion, an admirable variation on the Holly, Laurel, and Hornbeam fences one sees often enough. Pleading as these latter are, variety is so also, and I never remember seeing but one hedgerow of Copper Hazel. How would our tall white and crimson Foxglove spires, which I often see standing in all the magnificence of one of our finest British plants against a Laurel fence in a garden at Ealing, look in front of such a hedgerow? or what say you to a group of Ferns, *Polypodium Dryopteris* and *calcareum*, with *Orchis latifolia* and *Cypripedium spectabile*, such as we have now by the rockery at Kew? G. S. BOULGER.

11, Burlington Road, Westbourne Park.

## THE RHODODENDRONS AT COBHAM PARK, KENT.

I SHALL not attempt to describe the magnificent effect produced by the thousands of Rhododendrons in the woods and pleasure grounds at Cobham, the impression created by which, when once seen, is not easily effaced from the mind. They are growing in the natural soil, which seems to be composed of a deep bed of peat or vegetable soil, the accumulations of ages. I have seen the Rhododendron at home (*ie.*, naturalised in the woods) in many places; I have seen gorgeous displays of these and kindred shrubs in the large nurseries devoted to their culture, as well as the unique exhibitions of new and choice varieties at the Royal Botanic Gardens, Regent's Park; but I never remember to have seen greater luxuriance of growth and redundancy of blossom than was presented at Cobham a short time back. Much of this exuberance of growth is no doubt due to the shelter imparted by the proximity of trees of larger growth, and this green framework, if I may so term it, tends to set off and bring into greater prominence the matchless beauty of the Rhododendrons. And all this sylvan beauty, accompanied, as it is, by the music of innumerable feathered songsters, is freely and liberally thrown open to the public by its owner, the Earl of Darnley. On the day of my visit the roads and woods were thickly lined with excursionists, and on the previous Sunday 2500 people visited this unique flower show. The late Canon Kingsley said in one of his works that his thoughts and feelings were often more reverent and devotional in the woods than they were in church. The late Charles Dickens, who, during the later portion of his life, resided in this neighbourhood, speaks in one of his letters of the Rhododendrons of Cobham Park as one of the sights of the district. In the private grounds, most delightfully situated, surrounded by waving foliage, stands the Swiss Châlet in which the great author loved to write, and which was removed and re-erected here after his death. It is a two-storied building, of elaborate and elegant workmanship, bearing in all its details the impress of a cultivated mind. Dickens, referring to it in one of his letters, says:—"My room is up among the branches of the trees, and the birds and the butterflies fly in and out, and the green branches shoot in at the open windows, and the lights and shadows of the clouds come and go with the rest of the company." And all this is equally true of it now, for the site has been most happily chosen. I have, I fear, wandered somewhat from the Rhododendrons, but the Swiss Châlet naturally calls up Gad's Hill Place, and in the long vista of years that are past a still greater name than Dickens was associated with this neighbourhood, for Shakespeare must have been familiar with it, as his references to Gad's Hill and the old inn at Rochester in *King Henry the Fourth* abundantly prove. In connection with the Rhododendrons at Cobham the only subject for regret is that they are all, or at least nearly all, confined to the varieties of ponticum. If a few groups of brighter and better varieties were introduced here and there, not only would a great present advantage be gained, but the future effect upon the character of the seedlings that are continually springing up and establishing themselves would be beneficial, even if the fertilisation of the flowers were left altogether to insect agency. There are hundreds of ancient woods in the country where old trees are only sparsely scattered about that might be immensely improved, by planting Rhododendrons, both in appearance and also for sheltering game and rabbits or hares seldom bark

this shrub, although in severe winters few other plants escape. It has been said that in any neighbourhood where the common Foxglove abounds in the hedges and on the banks by the wayside that there the *Rhododendron* may be safely planted; but given a good deep soil, enriched, if necessary, with leaf-mould, plenty of shelter, and partial shade—such as is usually to be found in almost any old wood—and the *Rhododendron* will thrive and flower well. A soil containing an excess of lime is not suitable, nor yet a very dry soil, as *Rhododendrons* are moisture-loving plants; and any one planting them in these woods should have the ground trenched up deeply, burying any old turf, leaf-mould, or vegetable matter that happens to be comestable, and after the planting is done some attention should be given to them for a few years to keep down weeds and rubbish, and maintain a loose, healthy, friable surface over their roots. A few of the choicer hybrids should be planted along with the ponticums in order to furnish a greater range of colour and to improve the character of any seedlings that may hereafter be produced. E. HOBDAY.

#### METHODS OF MEASURING THE HEIGHTS OF TREES.

FIRST. To measure the height of an object by means of two poles: The one pole should be at least double the length of the other. Fix the long pole perpendicularly at any convenient distance from the tree or object; then, taking the short pole, move backwards till the top of the two poles and the top of the tree coincide. Then as the difference in height of the two poles is to the distance between them, so is the height of the object to the distance from the object to the pole at the level of the observer. SECOND. To measure the height of an object by means of its shadow: Fix a pole in the ground in a vertical position, and in as level a situation as possible. Measure the length of the shadow of the pole, likewise the shadow of the object; then, as the height of the pole is to its shadow, so is the height of the object to its shadow. THIRD. To measure height by means of a triangle: Dress a piece of board exactly square, and not less than 6 in. on the side; divide the square with the saw diagonally, from corner to corner. This transforms the square into two right-angled triangles, either of which may be used for ascertaining the height of any object. For convenience the triangle may be fixed to a staff or stake. One side of the triangle should be kept perpendicular, the other horizontal, which is easily done by means of a small plummet. In making an observation with the instruments look along the sloping side and move backwards or forwards till the sloping side coincides with the top of the object, the distance from the observer to the object being equal to its height. The part of the tree or object below the level of the observer's eye must be added to the observed height, which gives the full height of the object. FOURTH. A 2-ft. rule, with a small level fixed in one of the limbs, and the circumference of the joint divided into degrees, is a convenient instrument for measuring the angle or dip of rock formations, height of trees, and various other purposes. To measure the height of a tree, the rule is opened till the limbs stand at an angle of 45°. The limb with a fixed level is held horizontally. Then move backwards or forwards till the sloping side of the rule coincides with the top of the object, the height of which is equal to the distance of the object from the observer, as in the last method. FIFTH. An optical instrument, termed "the Apomecometer," was produced in 1869 by the well-known instrument maker, Mr. W. F. Stanley, the invention of Mr. R. Millar. The instrument is founded on the same principles as those which govern the sextant. It is 1½ in. long, and 1 in. wide at the broadest part, and ½ in. thick, and weighs little more than 1 oz. Mr. Millar says, "I never went astray with me during six months' travel on the Continent, though I invariably kept it in my pocket, where it required no small amount of knocking about." I may here remark that in measuring the height of an object by means of the "apomecometer," or by means of any fixed angle, the observer requires to be at a distance equal to the height of the object to be measured. For isolated objects this is no inconvenience, but in the case of measuring the height of a tree in a forest or plantation is a very different thing. In nine cases out of ten the observer would find that at a distance equal to the height of a tree to be measured some intervening tree or object would be in the way of his vision. Therefore, in order to obviate the difficulties referred to, I may here state that I have constructed a simple instrument for measuring the height of trees or any object at any convenient distance, no calculation being required. Paradoxical as it may appear, the height of the object is measured before the observation is taken.—J. KAY, Forester, *Bute Estate, Rothesay*, in "Gardeners' Record."

**Seaside Shrubs.**—The following may just now be seen at Weymouth, close to the beach, in full bloom, and bidding defiance to the saline withering breezes, viz., *Escallonia macrantha*, *Cistus ladaniferus* (Gum Cistus), and *Medicago arborea*. The last forms a pretty hedge from 3 ft. to 4 ft. high, covered with showy, deep yellow blossoms, toned down with an intermixture of that fine feathery seaside plant *Tamarix gallica*. Gum Cistus bushes flourish beautifully; they are covered with flower-buds, and as only a few unfold every day, a succession of large showy white flowers will be kept up for several weeks to come. This is one of those good old-fashioned shrubs that are not seen half so often as they should be. Its flowers, seen amidst the dark green foliage, are conspicuous and striking, even at some distance off. *Escallonia macrantha* does well as a shrubby plant; its handsome foliage looks thick and glossy, and its red, waxy-like flowers give to it a rich appearance. *Escallonia Ingrami* is another good variety that should be planted plentifully near the sea; its foliage is not so large and showy as that of *E. macrantha*, but it is a far more profuse and persistent bloomer; it keeps up a succession nearly all summer and sometimes even into autumn, whereas the flowering season of the former is comparatively of short duration. The foliage of *E. Ingrami*, too, has a strong aromatic scent.—G. B.

**The Willows of Babylon.**—Prof. Asa Gray, commenting on an article by Prof. Northrop in the "Boston Journal of Chemistry," says: "Prof. Northrop may safely venture the assertion that this tree 'is now commoner in almost every country than in its native habitat, near Babylon;' for it is probable that it never grew there at all. Although it has over and over been said, up to within a few years, that there can be little doubt that the trees upon which the captives of Israel hung their harps belonged to the species named *Salix babylonica*, yet the hardness of this tree, betokening a colder climate, should have awakened suspicion. And it is now, on good evidence, concluded that this tree is a native of China or Japan, and that, although it may have been brought across the country to Persia and Assyria, in comparatively modern times, it was not there in the days of the captivity. The Willows which Bochart refers to as abounding on the Euphrates are probably the same as those mentioned by the Rev. Mr. Porter, who found there only a low shrubby species. Upon the ancestors of these Willows the Jews could have suspended only the diminutive harps which are nowadays associated with their names. The trees referred to in the noble psalm, and called Willows, were probably Poplars (*Populus euphratica*)." 

---

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Asara microphylla.**—A good hardy shrub is worth a score of the choicest tender exotics. This shrub, introduced by Messrs. Veitch, is not only a good hardy one, but it also possesses a beauty of form quite apart from anything else that we know of. Usually our evergreens are close and formal in outline. This breaks into the most charmingly diversified surface; in fact, established bushes of it, as well as the branchlets, remind one of some beautiful glossy Ferns.

**Acer circinatum.**—This Californian Maple is very distinct from all other varieties; its foliage is nearly round and cut into nine lobes, but not so deeply as to destroy the outline. Its leaves are pale green, and when newly opened yellowish-green. This tree, when planted near A. Schwedeler, forms a pleasing and charming contrast, as regards foliage, both in form and colour.—G. B.

**Concreting Wounds in Trees.**—We find the following note under "Botany in the Academy": "It is said that the Board of Works intends to plug with concrete the wounds of the old trees in Hyde Park." This would be amusing if it were not sad to think of what must become of the sylvan beauty of our parks when such ideas are printed in "leading" and scientific journals.

**Shrubs in Flower at Newry.**—*Adenocarpus frankenoides* is now covered with lovely yellow flowers; *Ozothamnus rosmarinifolius* in a few days will be perfectly beautiful, literally masses of snow; and *Leptospermum bullatum* is also very fine on a wall, a condition in which it has been for near two months.—F. SMITH.

**Ascent of the Sap in Trees.**—M. Böhm's theory offers perhaps a more satisfactory explanation of this phenomenon than any that have hitherto been published. It is based, like the osmotic theory, on the cellular structure of all sap-conducting plants, and it attributes an important rôle to the elasticity of the cells. "When the surface-cells of a plant," says M. Böhm, "have lost a portion of their water through evaporation, they are somewhat compressed by the air-pressure. Like elastic bladders, however, they tend to take their original form. This of course is only possible by their drawing in either air or water from without. Since, however, moist membranes are little penetrable by air, the cells draw from cells further in a portion of their liquid contents. These again borrow from their neighbours further down, which contain more water, and so on, either to the extreme root-cells, or to those parts of the stem which are supplied with water from below through root-pressure."

## THE INDOOR GARDEN.

### CAMPANULAS FOR BASKETS.

CAMPANULA FRAGILIS, as will be seen by a glance at the accompanying woodcut, makes a most charming basket plant. We hardly know one of the many lovely plants belonging to the genus Campanula, which excels the present species in beauty. In its native haunts—Italy, and one or two other countries of South Europe—it hangs over limestone cliffs, and forms quite a sheet of soft blue blossoms. In the open border in this country it does not live long; the cold, damp winters soon kill it. As a frame plant, however, or grown in baskets for greenhouse or conservatory decoration, it is one of the most charming objects imaginable. In habit it is dense and compact, and the very numerous, delicate blue flowers (which are more expanded and star-like than those of most Campanulas), combined with the bright green of the foliage, render this a very desirable plant, and worthy of general cultivation. It delights in a well-drained, open loam, to which must be added

Hanging Basket full of Campanulas.

a little decayed leaf-mould and a few broken pieces of limestone. Not much water is required, except during the growing season, and a full exposure to light is necessary if perfect success be aimed at.

*Campanula garganica*, another South European species, is also a pretty plant, but, not making such long shoots as the last, it is only suitable for smaller baskets. The flowers, which are smaller and more bell-shaped than those of *C. fragilis*, are most freely produced, and are somewhat similar in colour. *C. muralis* also deserves mention; in general habit it is somewhat like *C. garganica*, but the flowers are rather deeper in colour. N.

*Croton mutabile*.—As its name implies, this species assumes innumerable variations of character. The leaves in some instances are lanceolate, entire, from 12 in. to 15 in. in length and 1½ in. broad; in others they are interrupted about 6 in. from the base, and are enlarged towards the apex into a broad, cup-like termination, which is continued with a thread-like midrib for 2 in. or 3 in., when a second leaflet is formed, varying in size from 1 in. to 2 in. in length, having a peltate base, the midrib being continued from the upper surface in a

spiral twist. The ground colour of the leaf is dark green, beautifully marbled with various shades of yellow and pink in the young state, which, as the leaf becomes matured, assume bright shades of magenta and orange. It is a plant admirably adapted for table decoration.—B. S. WILLIAMS, *Holloway*.

### ORCHIDS AND FILMY FERNS IN THE YORK NURSERIES.

THE first house which I entered contained Mexican plants principally. Its roof is glazed with Hartley's rough plate glass, and is never shaded. Here I found *Odontoglossum* well elevated up to the glass, and with much more air admitted than most people give. The plants were, however, in good health; even the usually warmer grown *Odontoglossum citrosum* was in the finest condition. One of by no means the strongest plants had as many as thirty-three flowers on a spike; it was the rose-coloured form, and *Cattleya maxima*, *Laelia superbiens*, and *Oncidium Rogersi*, were equally good. *Laelia anceps* and *L. autumnalis* were also growing freely. Those who require to have their Orchids always deep green looking, both as regards bulbs and leaves, might say the growths made here are not to their liking, but there is no mistake in the way in which they flower, increase in size, and keep on in healthy vigour. *Pleiones*, in the same house, do equally well, and *Vanda Cathcarti* looks quite at home; as does also *Epidendrum nemorale*, which has flowers not unlike *Barkeria spectabilis*. In the next division, similar in size to the preceding house, are the *Cattleyas*, &c. Here all that require ordinary treatment are to be found along with *Vanda teres*, *Dendrobium Wardianum*, *D. Cambridgeanum*, *Coleogyne barbata*, and *Dendrobium Falconeri*. This last is kept through the winter at a temperature only a little above freezing in severe weather. *Cattleya Gigas* and *C. Aclandii* were remarkable for the progress made by imported plants. The singular *Coryanthes macrantha*, which is seldom seen in bloom, was just coming into flower. In another span-roofed house was a quantity of *Bolles*, *Aerides*, *Cypripediums*—young thriving stock. A plant of *Stephanotis* grown along over the path bears a fruit that has been on it eighteen months and not yet at maturity. Another house, similar to the last, is mainly filled with *Odontoglossum* vexillarium, consisting of about 400 plants, on which were some 200 spikes of flower; amongst them it would be a difficult matter to find two exactly alike, although there is not one that can be termed indifferent. The extremes of heat kept within so far as possible in this house are 55° in winter and 70° during summer. *O. Phalaenopsis* does well so treated. The true *Trichopilia fragrans*, one of the sweetest of winter-flowering Orchids, was growing in this house; as was also *Bollea celestis*. Here, too, was the singular old *Maxillaria venusta* with eight blooms from a single bulb; it is an elegant flower for bouquets. In a lean-to house with a north aspect, the occupants are mostly *Odontoglossum Bluntii*, *O. Pescatorei*, *O. triumphans*, and *Masdevallias*; the grotesque *M. Chimera*, was represented by a number of stout, vigorous plants, some of which were in flower.

Of Filmy Ferns this establishment has long been celebrated for its unique collection. In the department devoted to the warmer section was a grand example of *Trichomanes Luschathianum*, 4 ft. high, *T. auriculatum*, the transparency of which is like nothing else in the vegetable kingdom; *T. meifolium*, besides which for ethereal elegance, the most beautiful of the *Todeas* is far in the rear. In a cavern-like, underground house—which, by the way, is a treat to enter on a hot day—was a charming display of Ferns all turned out into interstices between the rocks. Pot-grown plants are insignificant in comparison with these. Of *Trichomanes radicans*, one mass has covered a space quite 12 ft. across. *Hymenophyllum cruentum*, another gem, is in the most perfect condition. *Hymenophyllum demissum* measures 10 ft. over, and *Hymenophyllum candiculatum* is one of the most elegant drooping plants in existence. *Trichomanes exsectum*, from the dripping roofs of underground caverns in Chili, necessarily likes a dark situation. *Trichomanes radicans dilatatum* is in form almost like *Lycopodium africanum*. *Hymenophyllum pectinatum* is another little gem, and *H. attenuatum* is distinct and beautiful. These are only a few of the plants which a hurried visit of an hour altogether permitted me to notice. This house teems with beautiful forms of these fairy-like Ferns. It is a horse-shoe-shaped niche, from 8 ft. to 12 ft. deep, varying in width from 4 ft. to 8 ft., and covered almost on the ground level with large slabs of rough plate glass. It can be just slightly warmed in the winter during severe frost. There are some half-dozen specimens of *Chamaerops Fortunei* planted about the ground some fourteen years ago; they have never been protected, and do not suffer in the least. A handsome pair near Messrs. Backhouses' offices are now finely in flower. T. BAINES.

## IVY-LEAVED PELARGONIUMS.

ONE of the most interesting features of the Pelargonium show was one that perhaps did not attract one-half the attention which it deserved, viz., the collection of Ivy-leaved Pelargoniums from Chiswick. All the plants were well and carefully grown and in an excellent stage of development. What a wealth of double forms of the Ivy-leaf Pelargonium met the eye, and for these, we are mainly indebted to M. Victor Lemoine, of Nancy, and M. Jean Sisley, of Lyons. Mr. Barron had grown all the trailing or climbing types in a way calculated to show off their qualities to the best advantage by adopting the conical form. The largest and freest flowering plants were two years old and had not been cut back. The plan adopted is to grow them strongly into size, and when they begin to get a little pot-bound they put forth their blossoms. The double forms were flowering as freely as could be expected, quite freely enough to give them a claim to be regarded as very useful decorative plants, and they must prove useful to cut from, for the flowers are large and of good shape, and borne on long stiff stems. The next thing to do is to endeavour to vary, and especially to intensify the colours. The prevailing tints are blush, delicate pink, the softest lilac, and a just sufficient dash of purple to make one heartily desire a greater depth of it. The darkest coloured double Ivy-leaf I take to be *Elfrida*, which has flowers perhaps as fully double as others, excepting perhaps those of A. F. Barron, one of Victor Lemoine's latest seedlings; this has flowers of a delicate lilac-blush tint, the blossoms very fine, and fully double; König Albert has very pretty rosy Lilac flowers, with small dark blotches, and is very good and double; Lucie Lemoine is a little loose, but pretty, the colour of the flowers blush, flushed with delicate pink; it is a variety well worth growing for its charming delicacy of tint. *Mdlle. Adrienne Barat* is a little deeper in colour, but more fully double than the preceding, but quite distinct enough to make a variety. *Sarah Bernhart* is a double form of the ordinary white Ivy-leaf, double, very pretty and good. Next comes *La France*, which is also very pretty, and something like A. F. Barron, but with more distinct markings, and rather more colour in the centre, but not so double. *Madame Perle* is of a pinkish-lilac tint, very delicate, pretty, and fully double. *Madame Emille Gallé*, delicate blush, with slight purple markings, is a little thin in the flower, but very pretty and distinct. The most fully double of all the new forms is A. F. Barron, one of the latest of M. Victor Lemoine's seedlings.

When we come to examine the single-flowered, Ivy-leaved Pelargoniums, we are at once face to face with two distinct types; one of these is the old trailing Ivy-leaf, the single counterpart of the foregoing, with their olive-green, leathery, downy leaves, and the hybrid Ivy-leaf forms, that have the habit of growth of the zonal section. While the former are fitted for hanging baskets, trellises, &c., and for training in cone-shaped and pyramidal forms, the latter can be grown as flat or bushy specimens similar to the zonals. Let us take the old Ivy-leaf first. The best of the varieties—that is, having the broadest petals and the largest flowers—are *pictum*, bright blush tinted with lilac, very good; *album grandiflorum*, blush; *Innocence*, flesh-coloured, petals good; *Angelo*, the very best, bright pinkish-lilac, the upper petals pencilled with crimson-purple lines; *Captive*, which appears to be the same as *Innocence*; *Fairy Belle*, pallidum, and *petatum elegans*, pale lilac, very pretty; *Duchess of Edinburgh*, deep pinkish-blush, very pretty indeed; and the variegated *L'Elegance*, which is in all probability the variegated form of *album grandiflorum*.

Turning now to the hybrid Ivy-leaved varieties, it must be admitted that the two which lead the way in point of time, viz., *Willis* and *Willis roseum*, are yet able to hold their own, and probably there is nothing superior to the last named. *St. George* is of a pale rosy-magenta colour, very pretty, and of fine shape, and is one of the best; *Gem of the Season* has a fine habit, the colour of the flowers pink, dashed with salmon-orange, and is very pretty; *Argus*, pale magenta, very pretty and of excellent habit; *Favonius*, very rich deep magenta, dashed with crimson, very fine in colour, but with small flowers, but a decided gain in point of hue; *Alice Lee*, deep bright magenta, good; *pseudo-zonale*, orange-salmon, attractive in colour, but with loose flowers, a variety of Continental origin; *Dr. Schomburger*, pale magenta with orange-salmon centre, very good; *Camballo*, the petals pinkish-magenta, with a kind of pink flame up the centre, and rather more colour in the top petals, very pretty and distinct; *Gem*, delicate lilac suffused with pink, very pretty and good, and of capital habit; *Bridal Wreath*, pure white, with slight purple lines on the upper petals, very pretty and good—sharing with *Willis roseum* the highest honours in this interesting class—and excellent in habit; lastly, there is the variegated *Duchess of Edinburgh* with pale pink flowers and very free, and as it comes from France under the name of *variegatum*, it is, perhaps, not an English sport or seedling, as some have supposed.

"Gardeners' Chronicle."

## PLATE CXXXIV.

## TWO NEW PELARGONIUMS.

Drawn by Mrs. E. M. Wood.

THE annexed plate represents two seedlings raised by the Rev. A. Rawson, of Bromley. The lower one, named *Queen of Stripes*, is a seedling from an old variety called *Mrs. Newman*. The upper one, the *Maid of Kent*, is from the well-known variety *Empress*, upon which it is a great improvement. The trusses are large and often as round as a ball, the fringed petals giving it a beautiful appearance. It is extremely floriferous, and the habit dwarf, like that of its parent. Mr. Rawson states that he has had nine trusses of bloom on a small plant. Apart from its beauty, it will make a valuable sort for market purposes. The *Queen of Stripes* speaks for itself, its drawback being that occasionally it throws up a truss of plain flowers, a defect to be guarded against by using poor soil. Fortunately the first truss came striped, or it would inevitably have been discarded. Frequent use of it for hybridising has produced nothing of any value, a result which has also occurred in the case of *Queen Victoria*, *Beauty of Oxtou*, and others, when used for breeding purposes. The aim should be to get the rosy flake on a pure white ground, like *Claribel*, and this will, no doubt, some day be accomplished. The *Queen of Stripes* is in the hands of Messrs. Henderson, of the Fine-apple nurseries; the *Maid of Kent* is not in commerce.

## CYCLAMENS IN THE WILD GARDEN.

This little sketch of *Cyclamens wild* in Grass was from a group allowed to run wild in this way in Mr. Barr's trial ground at

Tooting. Right bravely they held their way among the Grass and weeds, and carpeted the ground with their glossy leaves, and flowered freely in winter and early spring. Although mostly a South European, North African, and Western Asiatic family, various species grow on the hills, and they are, with very few exceptions, thoroughly hardy. There should be no difficulty in naturalising *Cyclamens* in copses and half shady places, where the surface vegetation is not too rank. We believe they would grow in many of the places for which people so often seek for "plants that will grow under trees." The Mossy floor of many a grove where Grass will not grow may be enamelled with the Ivy-leaved *Cyclamen*, with *C. europæum*, *C. vernum*, and, in fact, most of the species and varieties, with the exception of the Persian *Cyclamen*, which we do know not to be hardy everywhere.

**Thalictrums for the Wild Garden.**—Those who are fond of cultivating almost all kinds of plants with which they may meet most find it very advantageous to have what may be called the rough or wild garden as a kind of receptacle for plants which they do not like to discard, but which are totally unfit for a well-ordered garden—plants that seem determined to grow in their own way, and which, if inadvertently introduced into a garden will bring a person to repentance, such as the *Budweed* and its varieties and many of the *Campanulas*, such as *Rapunculus*. The *Thalictrums* are handsome plants, but many of them, such as our native *T. flavum*, are great pests; many of them, such as *spicuosum*, *aquilegiaefolium*, *glaucom*, and *purpurascens* are very stately plants. These will grow anywhere,

TWO NEW PELARCONIUMS

and open spots in woods are just the places for them. Many of them delight in growing amongst stones, rocks, &c., such as *T. minus*. To say nothing of their yellow, feathery, inflorescence, the foliage of many of them is simply elegant, almost rivaling that of some of the *Aralias*.—THOMAS WILLIAMS, *Ormskirck*.

## PROPAGATING.

**COPROSMA BAUERIANA VARIEGATA.**—This is considered by some to be a difficult plant to increase; but that is only the case when cuttings taken in autumn from plants out of doors are employed. When put in, the leaves often drop off in a few days, and the cuttings frequently never make a start. The best way is to take them in March from plants that have been kept in the greenhouse since the previous October. Make the cuttings as shown in the annexed illustration, and insert them not too thickly in cutting pots, well drained and filled with finely-sifted soil, consisting of yellow loam, peat, and sand in equal parts. Fasten them well in, give a good watering with a fine-roset watering-pot, and plunge the pots half-way up in a brisk bottom-heat, but do not cover them with glasses or lights; shade with sheets of paper during midday sunshine, and they will emit roots freely, and will be ready for potting off in about six weeks. Cuttings taken off outdoor plants in autumn should be treated in the same way as far as soil and mode of preparation are concerned. When ready they should

Cutting of *Coprosma Baueriana variegata*.

be put into a half-spent manure bed, over which the lights should be kept close for the first fortnight, and water should be given very sparingly until they are rooted. After that they may be removed to the greenhouse and wintered in their cutting pots. H. H.

## GARDENING FOR THE WEEK.

### Flower Garden.

**Re-potting Auriculas.**—I have usually done this early in May, and have even sometimes made a start the last week in April, but it is now the third week in June, and not a plant has yet been re-potted. Perforce we will have an opportunity of testing late potting this year, sorely against our will. The plants are certainly looking well, and are forming good crowns, as well as producing a goodly number of offsets. They have required a little attention in the way of picking off withered leaves, and stirring the surface soil in the pots a little. A celebrated grower told me quite recently that July and August were the best months in which to pot Auriculas, and the reason he gave was this: that the offsets were formed by that time, and that the operation of re-potting afforded an excellent opportunity to remove them. It is very desirable to attend to the offsets. I try to get them off close to the stem, and, if possible, with a little bit of root attached to them. I pot these small offsets in very small pots, and place them at once in hand-lights, from which the air is very nearly excluded. The lights should also be put in a shady place.

**Carnations and Picotees.**—When I last wrote about these they were progressing favourably. Since then, however, dull wet weather and cold nights have sadly crippled the more delicate sorts, and only a change to warmer and more genial weather will bring out in all their beauty the more robust varieties. Tying the spindles to sticks, disbudbing, and destroying green fly have been the work for the last week or two. Arrangements must now be made to get a place ready in which to bloom the plants. The best is a light airy greenhouse; ours is span-roofed, and it answers admirably. There must of necessity be movable shading to place over the glass when the sun's rays are too powerful. Those who have not a house to spare, may have some spare glass-lights from frames not in use. A light railing may be erected high enough to clear the heads of bloom; on this the lights may be placed, and, as a further protection from cutting winds and

driving rains, some shading may be nailed round the sides. If any of the flowers are likely to burst the calyx, a strip of matting should be tied round it.

**Pinks.**—These are all planted in beds, and the season seems exactly to suit them, as we never had a finer bloom, and all the flowers are well laced. The object of the Pink grower is to get good, regular plants into the flowers, where size and quality are nothing. It is very desirable to get the plants into their flowering quarters, say, by the end of October. Just previous to writing this I was looking over a good collection, and was much disappointed to see that not half of the varieties were laced, and rightly conjectured that the plants were not put out into the bed until the spring. If the plants are strong and healthy not one of them will suffer in the winter, but if, through any untoward accident, any of them should die, it is easy to keep a reserve from which to draw, in order to fill up their places. Like the Carnation and Picotee, those flowers that are too full for the calyx can be tied in the same way. See that the beds are quite free from weeds, and that all the flowers are tied to neat sticks.

**Gladioli.**—These are looking well so far, but will flower late; what they want now is plenty of heat. If hot, dry weather should set in, I would immediately manure the beds with rotten manure, and apply water freely if thought needful. It is also necessary to place sticks to the plants in the earliest stages of the spikes, as the broad leaves are much set on by gales of wind, and if the roots get loosened the plants soon fall over.

**Tulips.**—The roots of these ought to be lifted at once and stored in a dry place until planting time. Regular Tulip growers have drawers fitted with boxes divided into compartments, into which each variety is placed and numbered. I simply lift the roots and clean them, placing each variety in a small flower-pot, which is stored in a dry loft, and thus managed they keep in good condition until planting time. Before this is published I hope to have ours stored, as the foliage is quite dead.

**Pansies.**—This has been a glorious season for Pansies. We have a bed of seedlings 60 ft. long, the plants in which have bloomed continuously since March, and each plant has at present from twenty to fifty flowers fully expanded upon it. The bed has been no trouble to us, as the plants have fully covered the surface, quite choking any weeds that dared to appear above ground. To all who do not care to incur the expense of cultivating named sorts I recommend seedlings. If the seeds be obtained from the best flowers a large proportion of the produce will be as good as the parents.—J. DOUGLAS.

### Indoor Plant Department.

**Stoves.**—Gloxinias now full of flower will be appreciated by an occasional application of manure water. Keep them near the glass, so as to induce a stout, robust habit, without which the blooms are soft and useless. A shelf over the paths is a good situation for these plants. Achimenes in pots and baskets should have their stems supported by small sticks neatly tied thereto. It is not good practice to give all the plants an equal amount of shade. Allamandas, Bougainvillias, Ixoras, and Dipladenias will succeed better with much more sun than many plants will bear; consequently they should be placed at the warmest end of the house, and only receive a slight protection from the sun in the middle of the day. Climbing plants that are grown in pots and upon trellises should, when they have set a good crop of flowers, be trained over the trellises, but not too closely. Subjects of the above character that are grown permanently as roof climbers should not be allowed to go too long without training, or they become an impenetrable thicket of shoots, and necessitate much cutting away. Do not allow plants grown for this purpose to become too much crowded, or they suffer themselves, and injure everything grown under them.

**Greenhouses and Conservatories.**—Every means should now be employed to prolong the blooming of such plants as are at present in flower in greenhouses and conservatories, as well as to encourage such as are progressing for that kind of decoration. Owing to the greater number of conservatories being usually much loftier than ordinary houses for plant growing, a much greater surface is exposed to the action of the sun; consequently, the atmosphere is much drier, so much so, indeed, during the long summer days, as to make short work of the greater number of blooming plants available at this season. The borders that usually exist for climbers should be kept as moist as is consistent with the well-being of the plants growing in them; the moisture given off from them will, in some measure, counteract the dryness of the atmosphere, and on available occasions, especially early in the mornings and in the evenings, water should be applied under the stages, where such exist, and on the tables, yet not so plentifully as to occasion the unsightly inconvenience of wet paths to walk upon. Moisture applied in this way has not only the effect of benefiting the blooming plants, but tends to keep down red spider, which generally has a particularly genial feeding ground on conservatory climbers. The latter should have forcible applications of water from the syringe or from the garden engine occasionally. This should be necessary in all cases movable should be used not only for the roof, but for the sides of the house next the sun, if the house be lofty. Assist by all necessary attention *Fuchsias*, *Liliums*, *Amarantus*, *Balsams*, *Pelargoniums*, *Vallotas*, *Cassia corymbosa* (yellow), *Witensia corymbosa* (blue), two plants of easy culture, but not nearly so often met with as they deserve. *Achimenes*, *Genera Cooperi* and *Docklaeri*, *Tydeas*, and *Gloxinias* should be properly and carefully hardened by giving them plenty of light and placing them near where air is admitted in the stove before

their introduction to the conservatory, where they should be placed in such a position as to be so far removed from draughts as possible; by such means such plants may be made to last in good condition for a considerable time; and it is necessary to employ plants of this description during the next two months, when there is a greater scarcity of blooming subjects for conservatory decoration than at any other time during the year. And when to all autumn and winter-blooming plants, the first batch of Hydrangeas should now be potted, using pure peat and sand for a portion, and loam and sand for the rest of the stock; by this means, in all probability, both the blue and pink colours will be secured. Attend well to indoor Ferns in the way of water, especially such as have filled their pots with roots; any inattention to this matter results in the destruction of that healthy green appearance of the foliage which is the most prominent characteristic of well-grown plants. Do not maintain a higher temperature than is necessary for healthy development, such being the usual necessity of the conservatory to its endurance if required for cutting. Keep down insects by repeated light fumigations in preference to performing that operation seldom and severely. Azaleas should now be making active growth, which should be encouraged by syringings overhead every afternoon, shutting up early, and keeping the plants thoroughly free from their two great enemies, thrips and red spider. Plants that require re-potting, if their roots are active, should be shifted at once, using nothing but good peat and sufficient sand to keep the soil sweet. Hard-wooded plants that have been potted some time, and that are growing freely, should now be no longer shaded in bright weather; but, on the contrary, should be fully exposed to the sun, throwing water liberally about under the stages amongst the pots, so as to counteract drying influences. Young stock that was potted early, and that is growing vigorously, may be benefited by a further shift. Some growers of Heaths re-pot such as require it about this time, when the plants have done flowering; but it is much better to defer the operation until the autumn, when the weather gets cooler. Pick off all seed-pods, if seed is not wanted, as soon as the flowers are decayed, as the production of seed greatly exhausts the energies of plants.

**Asters and Stocks.**—Successional plants of these may be planted out, and by pits and in batches the bloom may be kept up further in the season. Asters, especially, are so useful for cutting that it is desirable to have them as late as they can be had.

#### Indoor Fruit Department.

If not very carefully looked after now, red spider will quickly multiply, for no kind of weather is more favourable to its increase than that which usually occurs in June and July. Dryness at the root often assists its development more than dryness in the atmosphere, and Vines on light soils are more liable to be affected than those in moist, stiff loam. It is, however, bad management to allow the pest to develop from excessive dryness; and unprotected outside borders, filled with roots, must be well watered, for, where the bottom rests on plenty of drainage, the soil here will quickly get red hot. Where roots are not required and, on the other hand, the surface of the border may receive a coating to the depth of 6 in. or more of this material in a moist state; and the soil may then be forked over and laid rough, water being applied plentifully after the manure has been laid on. This may be done with advantage to all Vines bearing fruit, excepting those upon which it is ripe, or nearly so. When the soil is somewhat exhausted, the manure is of assistance in perfecting the crop, especially where it is at all excessive. All young Vines, planted at any time this season, will have their roots very near the surface. The slightest check in any form will be injurious to them for years to come. Pot Vines intended to supply the earliest fruit next spring should now be widened out, and placed in a position where they will be fully exposed to the sun throughout the greatest part of the day. It must not be thought, because the growth of the Vines is perfected, that insects may do as they like, for to neglect them now is to undo what has already been done. On very hot days it is often necessary to water Vines having their pots well filled with roots twice or three times a day. The foliage should never be allowed to flag for want of water.

When the Grapes are all cut in the earliest houses, every attention should be paid to getting the wood ripened thoroughly, and trying to get the Vines into a state of rest by taking the lights off when it can be done, or exposing them to the air as much as possible. Give abundance of air night and day, and gentle fire-heat in dull weather to Grapes in late Vineries. All Grapes intended to be kept late in bottles of water should be well thinned, and, if possible, got thoroughly coloured and ripened by the end of September. As Peach houses are cleared of fruit, give the trees a good syringing to clear them of dust collected when the fruit was ripening. In houses where the lights can be taken off, it is a good practice to expose the trees to the air, as they will make firmer wood and buds under its influence for next year's forcing. In the late houses syringing the trees and sprinkling the paths once or twice a day will all help to keep up a moist atmosphere and to keep down red spider and aphid. The stopping and thinning of the shoots of Fig trees bearing the second crop must now be attended to. Keep a moist atmosphere by frequent syringings and sprinkling the paths with water to keep down red spider. Still maintain a steady bottom-heat to Melons by means of flues or hot-water pipes if in houses or pits. Mulch the surface of the beds with well-fermented horse manure, the same as for a Mushroom bed, and keep this well watered till the fruit begins to ripen. Melons when swelling require plenty of water at the roots, not dribbles on the surface, but a good soaking to reach the bottom roots. Sow seed now for the autumn supply of fruit, and if the plants are to be grown in pits heated with hot-water pipes, the supply of late fruit will be more certain than when grown

in manure frames. This is a good time for setting and marking the fruit of any good sort of Cucumber that it is desirable to keep for seed. Some grow their plants in large pots to seed from, and after carefully fertilising the flowers, leave only from three to four fruit on a plant. By this mode success is more certain as to getting plenty of seed true to the sort than by trusting to fruit from plants exhausted by cropping.

#### Hardy Fruit.

**Peaches and Nectarines.**—Go over these, and if the fruit is still too thick remove more, as also superfluous shoots, but on no account take away too much leaf, for, in the season, this is worse in its effects upon the trees than the opposite extreme of neglecting to disbud them. Continue to use the garden engine or syringe regularly two or three times a week, wetting the undersides of the leaves. If this is attended to little injury will be done by thrips and red spider, the worst enemies these fruits are affected by, and which not only materially injure the present crop but weaken the trees, thereby seriously affecting them in after years. These fruits will be benefited by mulching the ground with half-rotten manure. This is easily applied where the borders are not cropped with anything over the roots. Where Strawberries are grown on a Peach border the mulching they have received will assist to keep the soil moist.

#### Kitchen Garden.

Keep the hoe at work amongst bush fruits, so as to destroy weeds as they appear. It sometimes happens that there is negligence in this respect, under the impression that the bushes do not suffer from the presence of any ordinary vegetable weeding. As far as immediate effects go, this may be the case, but, wherever they are allowed to grow, they exhaust the soil much more than ordinary cultivated plants do; and to let any part of a garden become foul is simply a direct waste of the manure used, of which even bush fruit stands in need, although not to the same extent as vegetables. It is well to observe that if any portion of their garden, however small, be allowed to become a nursery for weeds, the seeds will be scattered by the winds in all directions, and will cause endless trouble afterwards, whilst the pleasure derived from the appearance alone of an orderly well-kept garden is worth consideration, and all the care that can be bestowed upon it. A clean garden, where every operation is carried out as soon as it requires attention, takes much less labour in the aggregate than one where things are continually behind; and in the operation of weeding this is more than usually apparent. It frequently happens that at the time of preparing the ground there may have been a scarcity of manure, of which some crops have not received a sufficient quantity. Where this has been the case, make up the deficiency by the timely application of liquid manure. This should take place at the middle stages of growth, after the plants have taken a fair hold of the soil and are growing away freely, and when strength will be imparted at the time it is most required. It is, however, necessary to be cautious in the use of manure water; it must not be applied too strong, for plants, unlike animals, have not the power of rejecting the food that is given them, which, in a liquid state, goes direct to the roots, and is of necessity absorbed by them, even if their destruction be the result. If manure of a solid character—such for instance, as that of fowls in a crude state, or guano that is lumpy and insufficiently broken—be dug into the soil, the case is somewhat different; the roots will not enter it, but will run in other directions to escape, as it were, the dangerous diet set before them. A little reflection upon the nature of the particular plant to which manure water is to be applied will, in a great measure, be a safe guide as to the strength of the solution it is able to bear. As a rule, rampant-growing subjects will stand a much stronger mixture than will weak growers—Rhubarb, for instance, being benefited by it at a strength that would injure Peas. Runner Beans may receive it stronger than the weaker-growing dwarf varieties; but, in all cases, it is better to be on the safe side and rather make the solution too weak than too strong.

**Parsley.**—A late Parsley should now be sown on well-prepared rich ground; sow in rows 15 in. apart. This will not be disposed to run to seed so soon in the spring as that which was put in earlier. Thin out the early-sown plants, leaving them 9 in. or 10 in. asunder. If this is attended to in time there will be little to fear from canker at the root, which usually occurs when the plants are overcrowded. Where Parsley is given sufficient room it can be kept through the winter with half the trouble and much greater certainty than where it is starved and weakly.

**Seakale.**—Seakale can be grown either from pieces of the whipcord-like roots, cut in lengths of 6 in. or 8 in., which is the best method, or from seed sown early in April. If, by the latter method, the seeds are, as usual, put in four or six together, in rows at intervals of 1½ ft. apart in the rows, and a like distance between rows, they will require to be thinned to a single plant in each place, and the ground between should be kept well hoed, so as to destroy weeds. By this method, in good, deep, well-enriched soil, a portion of the plants will be strong enough for taking up to force during the coming winter, the weaker ones being allowed to remain for another year. The great advantage in growing Seakale from root cuttings is that the plants have the start of those grown from seed, the greater part making strong roots the first summer. Nearly all that are allowed to stand a second season will throw up flowers, which must be cut away, or they completely prevent the growth of the strong crowns; and under any treatment, these plants that have so thrown up a flower-stem are not so good as they otherwise would be; even when cut out as soon as it makes its appearance it causes the root to form several crowns, which are individually weaker, and not so good for forcing as a plant with a single strong crown. The old system of growing Seakale in rows 3 ft.

apart, the plant being the same distance asunder in the rows, and forcing it in the bed under pots made for the purpose and covered with leaves or ground it occupies, the cost of pots, and the amount of labour, involved. Forced in this way, it also often has an earthy taste. In the cultivation of this vegetable it should be remembered that it is a marine plant, and, like its congeners, is fond of moisture and manure of a saline character. Those who reside on the coast cannot do better than dig into the soil, where it is grown, plenty of rotten sea-weed; where this is not at hand a good dressing of refuse salt—4 oz. or 6 oz. to the square yard—applied through the growing season, but not so as absolutely to touch the plants, will be found highly beneficial to the crop.

#### Extracts from my Diary.

**July 1.**—Sowing Canadian Wonder and Long-podded Negro French Beans. Pricking off *Violas*. Planting out Ten-week Stocks and *Asters*. Thinning out Spinach and Turnips. Stopping and nailing in Tomatoes. Taking up an early border of Ash-leaf Kidney Potatoes and spreading them out in the sun to ripen well for early crops next season. Levelling flower borders and looking over carpet bedding. Mulching Morello Cherries and watering them. Gathering Strawberries for preserving. Watering all Celery and Cauliflower plants.

**July 2.**—Sowing Early Horn Carrots and red and white Turnip Radishes. Potting off herbaceous Calceolarias, Primulas, and Cinerarias. Mulching late Peas with rotten manure and well watering them. Thinning out Chicory, Dandelion, Salads, and Scorzono. Planting out Lettuces and Endive; also Marjoram and Sweet Basil. Watering all newly-planted Broccoli and Brussels Sprouts. Taking nets off early Cherries and putting them over Currant bushes to protect them from birds. Turning over gravel walks where covered with Moss in pleasure grounds to give them a fresh appearance.

**July 3.**—Sowing All the Year Round, the Favourite, and Carters' Giant White Cos Lettuces; also Green-curl'd and Batavian Endive. Potting first batch of Strawberries for forcing. Planting out Celery and Cardoons. Giving Asparagus beds a light dressing of salt. Mulching and watering Peach trees on walls. Staking Peas and getting them earthed up. Watering Pines all through and putting sticks to any that require it. Thinning Early Horn Carrots. Sticking Peas and getting them earthed up.

**July 4.**—Sowing Omega and Ne Plus Ultra Peas. Potting on small plants of *Dracenas* and *Pandanus Veitchii* for table use. Planting out Cauliflowers and late Broccoli. Giving early Celery a little earthing, also first planted Leeks. Gathering Raspberries for preserving. Clearing off Cauliflower stamps, mauling the ground, and getting it dug up ready for other crops. Looking over Cucumbers and Melons, stopping them, and giving them a little earthing where required. Nailing and tying the leaders of Peach trees. Watering all Tomatoes, and mulching them with rotten manure.

**July 5.**—Sowing late crop of Broad Beans and Mignonette for autumn flowering. Putting in cuttings of choice *Pelargoniums*. Potting on Balsams. Gathering Apricots for bottling. Drawing drills for Turnips, and well watering them previous to sowing. Renovating linings round all manure frames. Looking over *Victories*, tying down leaders, and stopping the laterals where required. Nailing in leading shoots on Apricot and Plum trees. Giving Peach trees in early house a good washing with soft soap, sulphur, and Quassia-chin water, to keep down insects. Hoing amongst Gooseberries and Currants.

**July 6.**—Sowing Early Snowball and American Strap-leaf Turnips. Planting out a four-light pit with Tender and True Cucumbers. Sticking late sown Scarlet Runner Beans. Forking and Dutch-hoing amongst all growing crops. Gathering Laxton's Unique Peas for seed. Salting walks to keep down weeds. Turning manure, and mixing it with salt and soot. Watering all the newly-laid Strawberry Runners. Mowing and cleaning up the pleasure grounds, and rolling down gravel and turf that require it. Fit in use for dessert: Pines, Grapes, Melons, Figs, Peaches, Nectarines, Strawberries, Raspberries, and Cherries.—W. G. P., *Dorset*.

**Vesper's Insect-destroying Powder.**—This has effectually cleared our kitchen of cockroaches and black beetles, and we recommend it to all similarly plagued. It is perfectly harmless to human beings and domestic animals, and is clean and inoffensive in use, which is more than can be said of some of the evil-smelling compounds we have lately been trying. Unless we are mistaken, it is a preparation of Pyrethrum roseum, or Russian Tansy—a plant which is well known abroad for its deadly effect on insects, but which, when grown in England, loses its properties. Whether our surmise be correct or not, the value of the powder is beyond question. Having disposed of the beetles, it occurred to us to try it on some Rose trees badly infested with green fly. We applied it liberally—until the trees looked as if it had been raising Scotch snuff—and awaited the result. One of the heavy downpours we have been favoured with recently came down in the night, and in the morning the trees were clear alike of powder and green fly, and the latter had not been seen since. We are assured that it is equally efficacious with ants, fleas, and other tormentors of the tribe, and have little doubt that such is the case.—"English Mechanic."

## SOCIETIES AND EXHIBITIONS.

### ALEXANDRA PALACE ROSE SHOW.

JUNE 22.

THE exhibits on this occasion were arranged in the Concert Room, a capital place for a Rose show, which was, however, not so good as usual, owing, we understand, to a heavy thunderstorm which occurred in some districts a few days previous to the show, and which destroyed the blooms. Such Roses as were shown, however, were considered to be very good. The principal collections came from Waltham, Chesnut, Salisbury, and Devon. Messrs. Paul & Son furnished banks of miniature Roses in pots, which attracted much attention on account of their dwarf and healthy character and the profusion and quality of their blossoms; plants not more than 6 in. or 8 in. high bore from five to seven well-formed, handsome flowers.

**Nurserymen's Classes.**—In the class for seventy-two blooms there were four competitors, the most successful one being Messrs. Paul & Son, the Old Nurseries, Chesnut, who had excellent blooms of Duchesse de Vallombrosa, the dark crimson-coloured Sultan of Zanzibar, Mrs. Charles Wood, the beautiful flesh-coloured Mlle. Eugénie Verdier, and the maroon-crimson-purple-shaded Duke of Edinburgh. With these were associated the white Madame Lacharme, the bluish Madame H. Jamain, the Tea Rose Devoniensis and Madame Villermoz, and the scarlet bloom of Madame Prosper Mangier and H. Ledechaux gave colour to the collection, which was in every respect a good one. Messrs. Keynes & Co., Salisbury, had also a good collection, in which the best blooms were Madame Villermoz, Beauty of Waltham Sir Garnet Wolsley, Horace Verret, and Alfred Colomb. In other collections were admirable blooms of Marie Baumann, Countess of Oxford, Mons. E. Y. Teas, Madame H. Jamain, and Xavier Olibo. In the class for forty-eight Roses, five blooms each, there were only two exhibitors. The best collection, which came from Messrs. Keynes & Co., contained fairly good examples of Sir Garnet Wolsley, Marquis de Castellane, the dark crimson Lord Macaulay, the bluish Captain Christy, and the dark maroon Horace Verret. In Messrs. Paul & Son's collection were good blooms of the crimson Camille Bernardin, Duchesse de Vallombrosa, and finely-coloured examples of the scarlet Alfred Colomb. The best twenty-four Hybrid Perpetuals came from Messrs. Cranston & Co., King's Acre, Hereford, who had good even blooms of Marie Baumann, the velvety-maroon Prince Camille de Rohan, the bluish M. de St. Amand, and Louis Van Houtte. Messrs. Paul & Son showed in the same class well-formed blooms of the bright pink Madame Therosa Levst, Sultan of Zanzibar, and Madame Lacharme. In other collections, the most noticeable were Madame Marie Rody, Star of Waltham, Countess of Oxford, and small, but well-formed, highly-coloured examples of Fisher Holmes. In the class for twenty-four Roses, single blooms, the best came from Messrs. Cranston & Co., in whose stand were perfect blooms of Charles Lefebvre, the dark crimson Exposition de Brie, Madame de Castellane, and Marquis Bernardin. These were shown off to the best advantage by being associated with good blooms of such light kinds as La France, the Tea Souvenir de Elise, and Souvenir de la Malmaison. In the same class, Messrs. Curtis, Sanford, & Co., Torquay, had fine blooms of the white, pink-flushed Madame Hippolyte Jamain, the deep rosy-pink François Michelin, highly-coloured examples of General Jacqueminot, Dupuy Jamain, and Mons. Gabriel Fournier. Selecting from other stands were good blooms of Eugénie Levst, Duke of Edinburgh, Devoniensis, and Marguerite Brasseur. The best twelve single trusses of Tea-scented and Noisette Roses came from Messrs. Mitchell & Son, Uckfield, who had fine examples of Souvenir d'un Ami, the beautiful silky-white, bright pink-flushed Josephine Walton, the beautiful lemon-yellow Bliza Savage, and Comte de Paris. Messrs. Paul & Son had good blooms of the white Niphotos, Catherine Marnet, the deep rosy-magenta Chesnut Hybrid, and the golden Perle de Lyons. The best in other collections were alba roses, Devoniensis and its climbing variety, Madame Caroline Kuster, and the pure white Marie Guillot.

**Amateurs' Classes.**—In the class for forty-eight single trusses, the best came from Mr. Baker, Heavitree, Exeter, who had exquisite blooms of Marie Baumann, the bright pink Madame de Diesbach, the white pink-tinted Marquis de Montemar, Mons. E. Y. Teas; to these may be added the maroon-crimson Auguste Neumann, the pinkish-salmon Marguerite de St. Amand, and Madame Victor Verdier. Conspicuous in other collections in the same class were examples of the creamy-violet-tinted Marie Van Houtte, Marquis de Castellane, Abel Grand, and Madame Cass. Wood. In the class for thirty-six blooms, Mr. L. J. Curtis, Chatteris, had the best collection, the most prominent kind in it being, the scarlet-purple-shaded Thomas Mills and Marie Rody, the dark-maroon Jean Chirpin, and the pink Miss Hassard. Mr. Baker, who had the next best group, showed good

blooms of Marie Baumann, Mdls. Eugenie Verdier, and Charles Lefebvre. The best blooms in other collections were Countess of Oxford, Comte de Paris, Fisher Holmes, and Madame Chas. Wood. The best twenty-four single trusses came from Mr. Gravelly, Cowfold, Sussex, who had good blooms of Rubens, Senateur Vaisse, and the purplish-crimson Maréchal Vaillant. The best twenty-four Roses three trusses of each, came from Mr. Hollingworth, Turkey Court, Maidstone, who had amongst others Duke of Edinburgh, white Comte de Paris, and Dr. Andre. Mr. Davies, Wilton, Wilts, had good examples of Senateur Vaisse, and small but well formed examples of Louis Van Houtte. In the class for twelve single trusses there were eleven exhibitors. The best blooms came from Mr. Edwards, Stisted Rectory, Braintree, and M. Ridout, the best in the two collections were Marquis de Castellane, Charles Lefebvre, Marie Baumann, rose-scarlet Thomas Mills, Niphetos, Maréchal Niel, finely-coloured Senateur Verdier, pink Charlea Lefebvre, large rosy-crimson Madame Victor Verdier, Ami Madame Theresa Levet, and the bright rose Countess of Oxford. Mr. Wakely, Church House, Rainham, had beautiful blooms of Duke of Wellington, Xavier Olivot, the magenta Hippolyte Jamin, Prince de Porcia, Jules Margottin, and very fine blooms of Captain Christy and Paul Nercin. In the class for twelve Tea-scented Roses, Mr. Hollingworth had five half-expanded blooms of Madame Villermoz, the creamy-white Perle de Jardins, and the white Madame Bissy. Mr. Rueshmore, gardener, Tendring Hall, Stoke, Colchester, had good examples of Rubens and the flesh-coloured Bougère; other collections contained good buds of Adam (a flesh-coloured kind), climbing Devonensis, the rosy-tipped Homer, and the salmon-fleshed President.

**Open Classes.**—In the class for twelve Roses of 1876-77-78, Messrs. Paul & Son, Cheshunt, showed the dark crimson-purple-edged Robert Marnock, the rosy-crimson Mdls. Marie Louise Vernet, large blooms of Gabriel Fournier, Mrs. Laxton, and Oxonian. Messrs. Curtis, Sanford, & Co. had the dark maroon Jean Lisbaud, Madame Prosper Sangier, and Magns Charta. In other collections the best were Abel Carrière, Triomphe de France, and Mrs. Baker. For six trusses of any Rose, Messrs. Paul & Son had the best, the kind being Mrs. Laxton, which was globular in shape and bright rosy-crimson in colour. Mr. Piper, nurseryman, Uckfield, had good examples of Duke of Connaught, a fine Rose of a rich bright velvety crimson and perfect in shape, and Mons. Gabriel Fournier, a good show Rose, conical in form, and of a deep rosy-crimson colour, was exhibited in good condition. Mr. Cooling, Bath, sent twelve of the largest blooms of Maréchal Niel, perhaps ever exhibited; they were fine in colour and perfect in shape. Messrs. Paul & Son showed twelve fine trusses of La France, as did also Messrs. Keynes, English-trained Roses were well shown by Messrs. Paul & Son, who had Duke of Edinburgh, the bright pink and carmine Magns Charta, Miss Poole, Devonensis, and John Stuart Mill. With these were also Charles Darwin, the cherry-rose-coloured Annie Laxton, the white globular-shaped Miss Ingram, and the fine double clear rose-coloured Marchioness of Exeter.

A first-class certificate was awarded to Rose Dr. Hogg (Paul & Son), a magenta-coloured flower of fine form, and quite distinct from any other Rose with which we are acquainted.

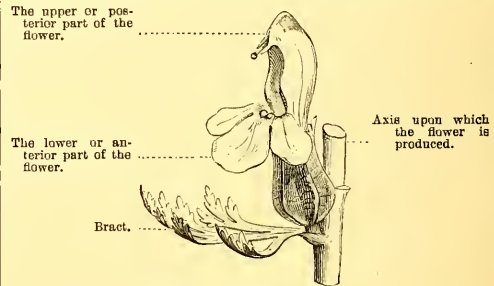

Fine blooms of Marie Baumann were shown by Messrs. Paul & Son and Messrs. Keynes & Co. Mr. Rumsey, Waltham, contributed stands of Tea Rose buds useful for bouquet making, which were much admired on account of their varied forms and rich colours.

Messrs. W. Paul & Son, Waltham Cross, showed an extensive collection consisting of new English-raised seedling Roses. One, named Countess of Rosebery, promises to be a grand Rose of a fiery rosy-scarlet colour, good in form, and well worth a place in any collection. Duchess of Bedford is also a kind likely to become popular; it is darker in colour than the one just alluded to. From the same firm also came a large mixed collection, consisting of Tea and Moss Roses and Hybrid Perpetuals, among which were noticeable magnificent blooms of Duke of Edinburgh, Duke of Wellington, Fisher Holmes, Marie Baumann, and Gabriel Fournier. Mr. Cannell, Swanley, sent fine boxes of Verberas and Pelargoniums. Mr. Ware, Hale Farm Nurseries, Tettenham, exhibited a fine collection of Pansies and Violas, also Pinks and Picotees, among the latter of which may be mentioned P. Newmarket, a beautiful deep rose-coloured variety, previously alluded to in THE GARDEN, and which is likely to be valuable for forcing for market as well as for general decorative purposes. Pink Derby Day is a beautiful double purple flower edged with rose; P. Early Blosk has a beautiful delicate pink flower with imbricated petals; and a white kind named Lady Blanche is smooth petalled and well worth notice. Show Pinks, with smooth white petals edged with deep rose, magenta, and crimson, were also shown in good form. Mrs. Hodgkins exhibited an interesting collection of skeleton flowers and Ferns, which were much admired.

## GARDEN BOTANY.

(Continued from p. 607.)

**THE POSITION OF THE FLOWER IN RELATION TO THE AXIS FROM WHICH IT SPRINGS.**—The part of a flower facing the axis which gives it birth is the posterior or upper side, and that facing the bract or leaf the anterior. Often the anterior and posterior halves of a flower are very different, whilst a section through the median plane, that is, vertically through the middle of the flower in the direction of the mother axis, would give two halves, each similar to the other reversed (fig. 273). The position of the parts of a flower with regard to each other and the main axis affords important characters. For instance, in the Leguminosæ (Pea, Bean, Vetch, &c.) the odd sepal (of five forming the calyx) is anterior, whereas in the Rosaceæ (Apple, Rose, Cherry, &c.) the odd sepal is posterior, or next to the axis. Usually in dicotyledonous plants the sepals constituting the calyx form a whorl; in other words, they all spring from the same horizontal plane; the petals are also whorled, and the stamens, and the carpels forming the pistil are arranged in one or more whorls. In some cases the sepals or petals are in two or more whorls, as in the Mæragriaceæ and Cruciferae, where the calyx consists of four sepals in two whorls of opposite or decussate pairs. The arrangement of some of the parts of the flower of Magnolia, Nymphaea, &c., is spiral. When the number of sepals, petals, stamens, and carpels is the same, the petals are usually alternate with the sepals, the stamens alternate with the petals, and the carpels alternate with

Fig. 273.—Flower of *Pedicularis palustris*.

the stamens; but the greatest diversity exists in the position of the parts of one whorl in relation to those of another, and likewise in the numbers of parts in the different whorls. It is not difficult to express the structure of a flower in words, but it is now becoming a common practice to show diagrammatically the number and position of the parts of a flower, whether it be of a particular species, or the typical arrangement of a given natural order or genus.

**CONSTRUCTION OF FLORAL DIAGRAMS.**—A floral diagram is a horizontal projection or plan of the disposition and number of the parts of a flower. All the diagrams employed to illustrate these paragraphs are real projections of the parts as they exist in the flowers, and must be distinguished from the theoretical diagrams to be found in some books. The latter are constructed upon a general typical plan, and indicate the places of suppressed parts as well as those actually developed, thus representing an imaginary rather than a real condition of things. After studying the structure of a number of different flowers the student will be better able to comprehend what is meant by suppression of parts and a theoretical diagram. Common flowers, in most instances, are chosen for illustration, and we here urge upon the learner the desirability of procuring and examining as many of them as possible, because the most carefully-worded definitions illustrated by accurate figures sometimes fail to convey exactly what is intended. Moreover it adds to the interest of the study to have the living plants before one, and many little points left unexplained by the teacher explain themselves. We would also repeat that, although there is a certain order in Nature, there is no such

thing as mathematical precision, and the student must be prepared to find all sorts of deviations from the general rules laid down here; but these deviations are themselves restricted within certain limits. Let us now examine a flower of *Crasula lactea*, or some other species (fig. 274), and a diagram of it (fig. 275). The mother axis of the flower is indicated by the small circle above the diagram, the bract from the axil of

Fig. 274.—A flower of *Crasula lactea*. Fig. 275.—Diagram of the flower of *Crasula lactea*.

which the flower proceeds below, and two lateral bracts are shown, one to the right and the other to the left of the flower. The parts of the flower are represented by conventional signs, explained under fig. 278. The signs are somewhat slightly modified to indicate certain characters in a flower. Thus, on

Fig. 276.—Diagram of Strawberry flower. Fig. 277.—Diagram of *Pedicularis*.

comparing the diagram of *Crasula* with those of the Strawberry flower and *Pedicularis* (figs. 276 and 277), it will be seen that we have in the former some suggestion of the thick, fleshy sepals, and of the thick petals with a keel running down the middle inside. Besides the sepals, petals, stamens, and

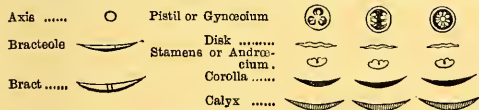

Fig. 278.—Explanation of the parts of a floral diagram.

carpels, another whorl of organs is represented in the diagram of *Crasula*. To this is given the collective name of disk, and it may consist of a continuous ring or of separate bodies, as in *Crasula*. Some of the more striking forms of the disk are described in a succeeding paragraph.

Fig. 279.—Section of a flower of *Crasula lactea*; the two halves alike.

**SYMMETRICAL AND UNSYMMETRICAL FLOWERS.**—When the parts of each whorl of a flower are equal in number, as in *Crasula*, the flower is symmetrical, as it also is if the members of the androecium or gynoecium exceed in number the sepals and petals, or *vice versa*, providing always that the excess is a

multiple of the smaller number. But when the numbers of the different parts are unequal, and are not multiples, the flower is unsymmetrical, as in *Pedicularis* (fig. 277), where there are five sepals, five petals, four stamens, and two carpels forming the pistil. Some botanists attach a somewhat different meaning to these terms, and any flower that can be cut vertically in two halves which are alike (as in fig. 279) is called symmetrical. The direction in which the flower must be cut for the halves to be alike is its symmetrical plane; but in some flowers no symmetrical plane exists, on account of the unsymmetrical insertion of the parts. *Canna* (fig. 280) is an

Fig. 280.—Section of a flower of *Canna*; the two halves unlike.

example of a flower which it is impossible to divide into halves which shall be alike.

W. B. HEMSLEY.

**Eradicating Sorrel.**—The presence of this may be credited to the existence of too much acid in the soil. This undue sourness arises from an excess of moisture in the soil, from too frequent freezings and thawings, which kill out other crops in winter, and probably from other causes. The remedies, if it arises from excessive moisture, are, in the first place, to give thorough drainage, and then the application of alkalies, which will neutralise acid and make the soil sweet and productive of sweet herbage. Sixty years ago, much of the land, especially in orchards in our vicinity, was scourged with a vile sour weed known as "Yellow Johnswort." The acid principle in it was so strong, that animals feeding among it in rainy weather, or when the dew was on, were sure to be afflicted with sore noses in consequence of coming in contact with it when wet. Thorough tillage, with the application of plaster and Clover stocking, runs it out, and at present it is rare to see it in the most minute quantities. Lime and ashes are excellent neutralisers. This I have found by experience. Some years ago I had a piece of land overrun with wild Wormwood. The next year I put spring Wheat on the ground, and from a limekiln near by drew a load of refuse lime, which probably contained some ashes, and spread on the surface of a portion of the Wheat after the last harrowing at the rate of twelve loads to the acre. The result was, not only an increase of the Wheat crop where the lime was applied, but the ground was left free of the Wormwood and all foul weeds, while in other portions of the ground it continued to grow in wild luxuriance. The result of these experiments taught me, that for soils producing sour weeds like Sorrel, or wild Wormwood, &c., the first remedy is thorough tillage—a full exposure of the soil to the atmosphere—and the application of alkaline substances to neutralise what acid remains in the soil, and to convert it into plant food.—W. B., in "The Cultivator and Country Gentleman."

**Dried Fruits.**—Here in Germany, especially in the country, most families lay up a store of dried Apple slices for winter. Any Apples, those that fall or are blown down, are peeled, any bruised or grubby spots cut away, then cut into slices and strung on a thread by help of a thick needle. This fustoon is hung in the sun, or in wet weather on the kitchen ceiling or walls. Mushroom-rooms are done in the same way, and if used in hashes, stews, &c., impart a most excellent flavour. Pears may be treated in the same fashion as Apples. Bilberries and Plums are also dried. These require daily turning.—N. STARR, in "English Mechanic."

## ORCHIDS.

**AERIDES.**—The kinds of *Aerides* that require the highest temperature in which to grow, such as *A. maculosum* and its still finer variety *Schröderi*, the different forms of *A. virens*, and also the varieties of *A. odoratum*, with *A. Lobbi* and *A. Larpentæ*, as soon as they have done flowering should, if any require potting, either on the score of insufficient root-room, or if there be any doubts of the *Sphagnum* below the surface having become so far decomposed as to retain too much moisture in a way not conducive to the health of the roots, be at once attended to. It sometimes happens that, through repeated top-dressings, the material near the surface is fresh and sweet, whilst that lower down in the pots gets into the state described, in which case the plants by no means should be allowed to remain through the season undisturbed, as the heat and moisture to which for some months now they will require to be regularly subjected will tend to still further decompose the *Sphagnum*. In all cases use it in a fresh, healthy state, or, at all events, such as has not been allowed to lay together for a long enough time before being used as to render it incapable of lasting as long as it ought to do; for these, like other Orchids, should never be subjected to the root disturbance inseparable from re-potting oftener than is absolutely necessary. See that the crocks used in all cases are perfectly clean and free from all green vegetable matter. In removing the plants from the pots use all the care possible so as to break the roots that adhere to the sides no more than unavoidable. In potting press the material in firmly, and stake sufficiently to support the plants in an erect position. Previous to potting they should be gone carefully over, so as to effect a thorough cleaning, especially if there is any scale upon them, particularly the white species, which not only establishes itself on both upper and under sides of the leaves and down in the axils, where it is most difficult to get to, but also on the roots that are out of the potting material. Where ever so little of it exists, the opportunity should be taken of the plants being turned out to make a thorough riddance. Nothing is so good as an ordinary tooth-brush for cleaning the roots. After potting they should at once be placed at the warmest end of the growing house, and kept well up to the light. Do not crowd them too close together, nor place them so that the tallest plants will obstruct the light from those that are shorter. If the house is so constructed that the stage or table on which they stand is far away from the glass, loose shelves on inverted pots high enough to elevate them sufficiently should be brought into requisition. The kinds of *Aerides* that will do with a somewhat lower temperature, such as *A. affine roseum*, *A. crispum*, *A. cylindricum*, *A. rubrum*, and *A. Fieldingi*, should be treated in like manner as to potting, &c., but ought to occupy the coolest end of the house, having an equally light position. The beautiful *A. Fieldingi* is especially liable to that most fatal disease, spot, if grown under conditions of too much heat and moisture, with insufficient light and air. The sweet-scented *Aerides suavissimum* and *A. quinquevulnerum*, which generally flower later in the season, should be encouraged to make growth similarly to those which have already bloomed.

**SACCOLABIUMS.**—Most of these now done flowering should be treated like the earliest-flowered *Aerides*, according as they may require it. It is a general remark amongst Orchid growers that these distinct, handsome, and valuable plants are not nearly so well grown as they once were; many of the species, such as *S. ampullacea* and the varieties of *S. Blumei*, *S. præmorsum*, *S. retusum*, and the forms of *S. guttatum*, will need as strong a heat as any Orchids in cultivation, but if grown as they require in a high temperature, and stood where they receive an insufficiency of light, they soon get spotted and unhealthy. The best position which I have found for these, which are collectively dwarf-habited plants, is, if grown in pots, near the front upright glass, shading them no more than is necessary. If grown in baskets composed of wire or wood, there will be no difficulty in getting them sufficiently close to the light; if suspended over the paths near the roof they will be in the best possible situation, and as these are amongst the most costly of the Orchid family, it is well to so far consider them, and give them the best place in the house.

**PHALÆNOIDS.**—*P. amabilis*, *P. grandiflora*, *P. rosea*, and *P. Luddemanniana* will, in many cases, have completed flowering; and where grown on blocks, baskets, or pots, should, if they require it, be placed on fresh ones; or if the whole of the material in which they are growing has become far decomposed, it should be replaced. The roots of these also are very susceptible of injury in removal, and the greatest care ought to be taken in separating them from whatever they have clung to. When on blocks, use no more wire than is absolutely necessary to keep them in their position until the roots lay hold of the wood themselves, using as much *Sphagnum* as will retain the requisite moisture and furnish support to them. These free-flowering, highly-esteemed plants should likewise have a good situation afforded them in the house. They will succeed far the best when hung up near the glass, as here they not only are placed under the most suitable conditions for making thick stout leaves capable of enduring their wanted length of time, but they are also the furthest out of the reach of the insect pests, such as slugs and cockroaches, which, despite the greatest watchfulness, usually exist in most Orchid houses to a greater or lesser extent.

**PHAIUS.**—These stately plants are frequently discarded by Orchid growers on the plea of their being of a coarse habit of growth; yet where cut flowers of an enduring character are required for filling vases and large stands, they are very effective; and when well managed, so as to preserve their leaves in a healthy state, they form most imposing objects when in bloom in Orchid houses, or moderately warm conservatories, for which latter, from their considerable size and the fact of the flowers lasting in good condition on the plants for several weeks, they are especially adapted. I am now speaking more particularly of the species *P. Wallichii*, *P. grandifolius*, and *P. maculatus*, and not of the nearly allied or synonymous *Thunias*, which, being from hotter parts of the world, require considerably more heat both to grow and to preserve them in a healthy state when in flower. *P. grandifolius* is a Chinese plant; the other two from the cooler regions of India. The temperature of an intermediate house suits them the best, with more air than the generality of Orchids receive. With ordinary treatment, they will now have finished flowering and be about to commence growth. These plants are often allowed to suffer through insufficient pot room, for which there is not the reasonable excuse that there is with many Orchids, whose growth during the first season after removal is often a good deal interfered with through the operation, as the roots of *Phaius* do not adhere to the pots to anything near such an extent as do the epiphytal species; consequently they can be turned out without the fibres being much mutilated. When division becomes necessary the plants should be turned out of the pots, the whole of the soil being carefully shook away and the roots completely disentangled. In this way the crowns or pseudo-bulbs can be separated with little or no injury to the roots. They are best divided into portions consisting of the last and two or three preceding years' growths, putting two, three, or four such pieces in pots from 8 in. to 10 in. in diameter, according to the size of the plants required; from 2 in. to 3 in. of crocks in the bottoms of the pots will be sufficient, laying over these a little *Sphagnum*. I have found them succeed the best in good, yellow, turfy loam, to which has been added as much sand as would be considered necessary for ordinary stove or greenhouse plants that thrive in a loamy soil. A handful of moderate-sized crocks or broken charcoal intermixed with the soil will be an advantage; put moderately firm and keep the divided pieces well to the centres of the pots, as they soon make growth towards the outsides. Do not give much water until the roots have had time to get into motion, when they must receive a liberal quantity. The great thing with these plants is to give them a good, light position, where they will get a fair amount of air daily in mild weather with just sufficient shade during bright sunshine to keep the foliage from scorching. In this way the leaf-growth made will be of a thick leathery texture, not attaining near the objectionable size that it does when treated with too much shade, heat, and moisture. The foliage, under the conditions I have advised, will always be found less subject to decay at the points, which is a great disfigurement to the plants when in flower.

T. BAINES.

## ANSWERS TO CORRESPONDENTS.

**Mushrooms in Pastures.**—Can Mushrooms be made to grow in a new permanent pasture just laid down in Grass by introducing spawn? and if so, how ought I to proceed?—J. M. [Yes, doubtless. The spawn should be broken into pieces about the size of a hantam's egg and dibbled in at once; say a piece at intervals of 4 ft. or 5 ft. all over the dried portion of the pasture.—W. W. H.]

**Mildewed Grapes.**—My Grapes are badly mildewed and I have cut the bunches off. Have I done right?—V. *Brenford*. [Yes; they would never have ripened; and it is better to get the Vines in order by next year to bear good Grapes than to ruin them this season with bad ones.—S.]

**Mulberries.**—Wishing to make a plantation of Mulberry trees, I should be much obliged if you could tell me the best way to set about it; I mean how to raise the plants myself, when to sow the seed, or plant the cuttings as the case may be.—R. [It is too late in the season to do anything towards a Mulberry plantation. You could sow the seed in February, or plant young trees in October or November; the latter is the quickest mode and that generally adopted. As the White Mulberry (*Morus alba*) and its varieties are the best for silk culture, you had better procure three to four-year-old plants for your plantation. Seed may be got from the New Plant and Bulb Company, Colchester, who supply everything requisite for silk culture in Great Britain and her Colonies.—A. W.]

**Small Strawberries.**—I have Keen's seedling Strawberries, which always bear a profusion of fine blossoms, but the berries turn out small. What is the cause of it? Should I thin the berries? The stalks are long. The soil is sandy, but good. Is there a better sort to grow? and what kind? I want to keep to one good kind only.—H. S. [I fear you have not got the true "Keen's Seedling," for though occasionally it fails to set, or is what gardeners terra "blind," it never fails to produce good fruit. If you must grow this variety, obtain a fresh stock and plant on fresh ground. Taking all points into consideration, Vicomtesse Héribert de Thury is the best Strawberry in cultivation, and next to that is President; try these against Keen's Seedling.—W. W.]

**The Tamarix in French Gardens.**—I have lately been over some of the French gardens, and I saw a plant I do not remember ever having seen in England covered with small pink flowers; they called it Tamarix. I never saw so pretty a shrub. I suppose it would not grow in English pleasure grounds.—O. M. B. [The Tamarix does well in England, but is little planted, though so elegant in habit and form. The one commonly grown with us is less ornamental than the one grown about Paris, and which bears the name of T. indica. Cut down annually, this throws up long, vigorous, feathery shoots, which are as beautiful as they are wholly distinct from anything else grown in gardens. As is well known, these plants thrive by the sea-shore on the south coast. The fact that they do so well in Paris proves that the vicinity of the sea is not a necessity to their culture. They are a family that any one interested in improving our collections of hardy ornamental shrubs might take up with great advantage.—En.]

**Genetyllis fuchsoides.**—I. I recently bought a large plant of this in full flower. My gardener a month ago cut off the flowers, as he said the plant was delicate. He then potted it and put it into a close hot greenhouse to make it grow; but, instead of growing, it died. Being a New Holland plant, should he not have put it into a cold pit or cool shady greenhouse, or even out on a north border to make it grow? Kindly say who is right; also, is the treatment which the gardener adopted in the case of this plant suitable for hard-wooded Heath?—C. S. K. [Had the plant not been delicate, the treatment would have answered; but, being in an unhealthy state, it succumbed to the warmth and moisture, to which may be added probably dryness at the roots; a light airy greenhouse is the best place for hard-wooded Heaths.—S.]

## Questions.

**Viola altaica.**—Can any of your readers inform me where I can obtain this plant true? or if it be in cultivation?—V.

**Trees Killed by Field Mice.**—Can you help me? I have been endeavouring for several years to raise young trees in a situation exposed to the ravages of rabbits and to the blasts of a cutting sea wind. By dint of the greatest care and constant re-planting I was beginning to get up a very creditable show when a new enemy appeared. He is the field mouse. During the last winter he has most effectually spared me the trouble of thinning by eating off—2 in. or 3 in. below the ground—about 30 per cent. of my plants, generally selecting those of about 1 in. in diameter. I should have been in doubt as to the depredator, the "cut" being as clean as if done with a sharp knife, but for the teeth marks, which are perceptible on close examination, and from seeing the great number of mice and their holes in the plantation. This mouse does no mischief in the summer time, having no doubt plenty of his natural food, but I

fully expect him to favour me again during the autumn and winter, and I should be glad, with someone's help, to try a return match with him.—R. F.

## HEADING DOWN WEAKLY PLANTS.

I AM not an advocate for the indiscriminate and undue use of the knife; but in the case of weakly plants, with long, thin, naked stems, amputation is often necessary. Hundreds of instances might be given where the simple process of cutting off a plant's head has been the means of prolonging its life, and enabling it to attain to a much higher state of development than would have been possible if it had been compelled to draw its supplies through the old narrow channel; and, of course, the treatment that opens up a new life to the stem and branches of a plant calls for and encourages renewed activity at the roots, and so every part of the plant feels the impetus of the new outlet, and the stimulus imparted by increased activity in the circulation. The best time to head down any plant that may require it is just before the flow of the sap commences in spring. If bleeding takes place, the wound must be cauterised, or be coated with some kind of styptic. The liquid substance called knotting by painters is a very simple remedy in most cases, and easily applied; and wherever there is a likelihood of this being required, it should be applied at the time the wood is freshly made, and not deferred till the sap begins to exude, or it will be more difficult to stop it. Some judgment is necessary in selecting the subjects to be operated on, as the measure of cutting off a plant's head is a drastic one, and should only be applied to very young plants to strengthen their base, or to old sluggish specimens whose channels of communication and circulation have lost their elasticity. In either of these cases heading down will be beneficial. The Clematis or Wistaria on the wall or trellis will start with renewed vigour after being cut back. The old Grape Vine will, by the same process, be brought into a more active state of existence; and the same means will in like manner invariably produce like results, always provided the necessity for its application exists. No one, of course, would expect to gain anything by heading down a plant in vigorous health, and much harm might be done thereby. E. HOBDAV.

**Note from the Royal Academy.**—In the picture by W. J. Mueckley, No. 117, in the second room, entitled in the catalogue "The Night-blowing Stock," there is evident, to any horticulturist who may take the trouble to examine it, a curious series of errors resulting from ignorance of the most ordinary nomenclature of common garden flowers, which should not exist in any one who attempts to paint them, or exhibits his portraits of them in public. In the first place, there is no such plant as the Night-blowing Stock, that which approaches nearest to that description being *Mathiola tristis*, the Night-scented Stock, which, though its blossoms are fully expanded during the daytime, does not begin to exhale its delicious perfume till the close of the day, and continues to do so during the night. Next, the picture in question does not contain any representation of this plant, the flowers portrayed therein being those of the common double white Rocket, the large single orange-scarlet Poppy, and some purple flowers whose identity it is difficult accurately to determine. Hence, then, the singularly inappropriate title?—"Field."

**Skeleton Leaves.**—At a recent meeting of the Scientific Committee of the Royal Horticultural Society, Mrs. Cussons, of Southport, exhibited some skeleton leaves, and along with them sent the following note:—"For the dissection of leaves I find the process of maceration too long and tedious, to say nothing of the uncertainty as to the results; I have therefore adopted the use of alkali in saturated solution, the specimens to be introduced while the liquid is heated to the boiling point. The time of immersion to be regulated by the character of the various leaves, and the nature of the epidermis to be removed. When the specimen is freed from epidermis and cellular tissue, it must be subjected to the action of chlorine to destroy the colouring matter. The introduction of peroxide of hydrogen serves not only to render the lace-like specimens purer in colour, but also preserves it. In destroying the colouring matter in Ferns this also is invaluable; added to the chlorine, it gives a solidity to the bleached fronds, and appears to equalise the action of the chlorine. For skeletonising capsules the slow process of maceration by steeping in rain-water is alone available—a moderate heat may be applied to hasten the process, but alkali is useless. The only known flower which can be dissected is the *Hydrangea japonica*. The fibrous nature of the petals renders it easy to skeletonise in the perfect truss in which it grows. Skeletonised leaves and capsules appear to gain in the process a toughness and durability not possessed by them in their natural state."

## THE FRUIT GARDEN.

### APPLES ON THE PARADISE STOCK.

ONE of the greatest drawbacks to the planting of abundance of fruit trees has been the erroneous idea that many years must elapse before any fruit would repay the labours of the planter. If any one needs the fallacy of this impression to be proved beyond a doubt, more especially as regards that king of hardy fruits, the Apple, I would recommend a visit to be made at once to the principal nursery grounds round London in which fruit trees are made a speciality, and the most approved system of culture adopted to ensure early fruitfulness, combined with a dwarf habit of growth to fit the trees for positions where large, wide-spreading branches would not be admissible. A few days since I saw at Messrs. Veitch & Sons' Fruit Tree Nursery, Southfields, Fulham, several very large breadths of all the best free-bearing kinds, both early and late, so loaded with fruit as to need considerable thinning—Lord Suffield, Keswick Codlin, Cellini, and Hawthornden being already quite large enough for culinary purposes. I need scarcely remark that in a season like the present, when Gooseberries are, as a rule, a thin crop, early Apples will prove a welcome addition to the list of culinary fruits. The Paradise Stock appears effectually to moderate over-luxuriance of wood-growth, and to concentrate the energies of the tree on fruit and fruit-buds. I need scarcely enumerate the advantages of planting this class of fruits in gardens of all kinds, more especially in those of limited extent. Even a good selection of kinds for various seasons may be accommodated in the smallest of gardens, for, if kept closely spurred in they may be planted as closely as Gooseberry or Currant bushes and kept down to nearly the same size. A row of trees as a background to central flower borders, or as an avenue through the kitchen garden, would prove a profitable investment. The flowers in spring and fruits in summer and autumn would hold their own against any ribbon border in existence. Abundance of wholesome fruits would be secured from positions that are in many instances producing nothing. There is no good reason why we need import such quantities of hardy fruits as we do, as I feel confident that all our wants might be supplied at home, and amongst the first considerations of consumers should be to see if they cannot at least partially supply their own wants. A few dwarf Apple trees on the true Paradise Stock as single specimens on Grass or as centres to beds might be tried in even the smallest of gardens.

J. GROOM.

**The Frogmore Golden Peach.**—This handsome Peach, as its name implies, originated in the Royal Gardens, Frogmore, a few years ago, and is the result of a cross between the Bellegarde Peach and Pitmaston Orange Nectarine, from which latter parent it inherits its yellow flesh. The fruit is of the medium size. It is evenly shaped, having a shallow suture, and is but slightly indented at the crown. The skin is of a dark brownish-red when fully exposed to the sun, fading off to a golden yellow when shaded. The flesh is tender, fine-grained, and of a yellow hue, except near the stone, where it is tinged with red. It parts freely from the stone,

and is of good quality, with a fine Peach flavour. The trees are of a free and healthy habit, and not at all subject to mildew. It belongs to the section producing large flowers, and is provided with smooth leaves, having globose glands. The flowers are of a deep pink colour, so that when in blossom the tree forms an object quite worthy of admiration.—"Florist."

### THE APPLE CROP.

APPLE trees generally are again this year fruiting so indifferently, and from many the early fruit has dropped so much, that I fear it will be found at gathering time that not more than a very moderate quantity has been left to store. In my ground here I have a row of over sixty trees, chiefly of bush growth, and including fifty sorts. It is, therefore, a matter of interest in such an uncertain season as the present to go over these, and note what kinds are carrying fruit and what are not. As all the trees are fully exposed to the winds and frosts, all have the same opportunities and the same dangers to share; and when I find that not more than a dozen trees have anything like a crop, and but a few more carry just a sprinkling, I cannot but conclude that, great as the opportunity may have been, the dangers have undoubtedly been greater, as few of the trees did not bloom freely in the spring. The first fact that presents itself is this, that the less robust kinds are the only free fruiters, whilst the coarse growers have few or none. Had all the trees been of the dozen good-fruited kinds only I should have had a large crop. The sorts in good fruit are the Hawthornden, Lord Suffield, Mother Apple, Cellini, Holland Pippin, King of the Pippins, Sturmer Pippin, Downton Pippin, Warner's King, Winter Peach, Petworth Nonpareil, and the Seraphoffe Apple, a kind that nearly resembles King of the Pippins, but is smaller, handsomer, and of richer flavour. Nearly all of these kinds are free fruiters, that is to say, they do not expend their strength in riotous shoots, that have to be cut away from year to year, but rather produce good fruit spurs and well-seasoned woody shoots that will be properly fruitful in years to come. The result thus seen would serve to show that the early frosts were not responsible for all the present deficiency of Apples, but that much was due to the excessive and unfruitful vigour of the trees engendered by a previous free-growing season. All of my trees are on the Crab stock, and this is found to suit only the weak-growing kinds. If all the coarse sorts were on the Paradise stock, no doubt these would be fruiting as freely as are their weaker brethren. Some sorts even on the Crab stock do not make quite such a robust growth as could be desired, and therefore it might be worth trying in their case the process of double grafting, working first, say, Blenheim Orange, and then on that the weaker kind. As a reverse case, it may be worth a trial, whether, by first working some weak kind, such as Hawthornden or Downton Pippin, on the Crab stock, and then Blenheim Orange, Reinette du Canada, and others on to these, it would be possible to reduce the tendency to make wood and induce early fruitfulness. This is a subject well worthy the attention of fruit growers, and I trust that some one will give us their experience in the matter.

A. D.

**Apricots in Covent Garden.**—Large quantities of Apricots from Spain are now sold by auction in Covent Garden Market; they are of medium size and of better quality than they were last year.

END OF VOL. XIII.
