MASSACHUSETTS  
AGRICULTURAL  
COLLEGE

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED

*W. Robinson, F.L.S., Author of "Alpine Flowers," etc.*

"You see, sweet maid, we marry  
A gentle scion to the wildest stock;  
And make conceive a bark of baser kind  
By bud of nobler race: This is an art  
Which does mend nature; change it rather:  
The art itself is nature."—*Shakespeare.*

Per  
G 16  
1878 v. 13

INDEX TO VOLUME XIII.

- A.**
- Abelia floribunda*, 468
- Abies canadensis macrophylla*, 392; *Douglasii*, 27; *Festoniana*, 134; *polita*, 239; *Regina Amalia*, 172
- Abronia fragrans*, 444
- Abutilon Boule de Neige*, 561; *vestitum*, 59; *Lemoine*, 559; *Lady of the Lake*, 613
- Abutilons*, 97
- Acacia lophantha*, 260, 412; *Riceana*, 239; the best, 32
- Acacias*, 233, 581
- Acer polymorphum stro-purpureum*, 372; *platanoides Schwedleri*, 572; *cineratum*, 620
- Acantholimon glumaceum*, 186; *venustum*, 186
- Acimenes*, culture of, 463; propagating, 505
- Acorns*, germination of, 333
- Adiantum Capillus-Veneris*, 636; *cy-cloclorum*, 569; *Fericyneis*, 343; ditto, in bloom, 182; *Lowestianum*, 402, 455; *Neo-guineense*, 607; *palmatum*, 250; *tetraphyllum gracile*, 377; *Willisii*, 531
- Adeles*, 504
- Agapanthus*, the double, 94
- Ageratum album*, 114
- Ageratum*, new, 616
- Allananda Schottii*, double-flowered, 39
- Allamandas*, double, 112; specimens, 379
- Allium flavum* from seed, 106; *nespolitanum*, 136, 250
- Allonlands*, garden, 610
- Almerian Grapes*, 614
- Alpine Auriculas*, 116; plants, cultivation of, 513
- Alophia plumosa*, 507; *Macleanii*, 631
- Alstromeria hemanthia*, 613
- Alyssum saxatile compactum*, 436
- Amaryllis*, 415
- Amaryllids*, culture of, 345; in London nurseries, 329; species of, 225; new, 220
- Amaryllis Crismum Banner*, 328; double, 637; E. Pilgrim, 377; *formosissima*, 233; Mrs. Rawson, 220; *virginialis*, 415
- American blight*, cure for, 213
- American Fruit*, 674
- Amphoclea Emodi*, 3
- Amphiparsia persica foliis purpureis*, 670
- Andropogon Halepensis*, 305; *muricata*, 229
- Andromeda floribunda*, 186
- Anemone blanda*, 113, 199, 247; *fulgens*, 36; *dividing*, 113, 144, 161, 200, 228; *palmeta alba*, 459; *the Blue Wood*, 344
- Anemones* in June, 651
- Angracum essequipedale*, 26
- Animal food*, preserving, 699
- Annals*, tender, 412
- Antonynton Rollinson*, 39
- Antericum Liliatum majus*, 537; *variegatum*, 316
- Anthurium insignis*, 531; *Scherzerianum*, 354, 459; *Wardii*, 12
- Anthuriums* at Anerley, 277
- Antipathy and sympathy*, 421
- Antirrhinum procmehens*, 176
- Antirrhinums*, 582
- Ants*, 429; in October pits, 693
- Ants' nests*, 533
- Apelandra Boeali*, 3
- Apelonea maculata*, 290
- Aplopappus Fremonti*, 305
- Aponogeton distachyon*, 224
- Apple buds killed on galvanised wire, 352
- Apple trees and *Mistoleto*, 60; caterpillars on, 669, 593
- Apples, *Albemarle Pippin*, 93, 134; *Callville blanche d'Eliver*, 258, 257; *Hochkin Pippin*, 112; imported Newtown Pippin, 197; *Jolly Beggar*, 308; *London Pippin*, 245; late keeping, 559, 586; *Newtown Pippin*, 139, 436; *Norfolk Beefing*, 439; *Ohio*, 462; *Oregon Crab*, 492; *Rainette de Caux*, 269; killed by *Mistoleto*, 12; two species of, 492; distances apart, 453; from cuttings, 290; *Lichen-covered*, 274; ornamental, 454; and *Pears*, grafting, 218; in *Covant Garden*, 153; on *galvanised spalliers*, 332; on *Paradise stock*, 630
- Apricot bloom*, 213, 246, 302
- Apricot branches* dying, 21
- Apricots*, on spurs, 401; in *Covant Garden*, 630
- Aquaria*, cement for, 189
- Aquilegia alpina superba*, 455; *chry-diflora*, 397; *Haydockensis*, 537; *viridiflora*, 397
- Aquilegias*, culture of, 687; from seed, 516, 532
- Araucaria conchina*, 651; *pyrifera*, 109; ditto, propagating, 490; *spectabilis*, 631
- Araucaria imbricaria*, 92
- Arbutus Andrachne*, 28; *tomentosa*, 383
- Arches*, fruit trees on, 66
- Armeria juncea* and *A. setacea*, 612
- Archiea schidoides*, 407
- Arctichokes*, Jerusalem, 373
- Arums*, double-spathed, 609
- Arundo conopsea*, 34
- Asparagus*, at *Chester*, 538; at *Ganton Park*, 569; culture of, 267, 609, 583; *Dutch and Argenteum*, 371; *French*, 612; earthing up, 219; forcing, 45; gathering, 218; in *English gardens*, 350; large, 493; hardy climbing, 186; on sandy soils, 599; paper from, 23; planting, 217, 559; plough culture of, 217; prices for, 355, 452, 612; procuring, 409; season, lengthening the, 413, 453; white, 494; replanting old, 609, 614; culture in *France*, 455
- Aspects*, value of, north, 492
- Aspen*, 393
- Aspidistra diphytus*, 308
- Asters*, annual, 364; dwarf *Peony*, 117; in masses, 283; seed, 284
- Athens*, Botanical Garden at, 418
- Athyrium Filix-foemina* *Elwirthii*, 210
- Aucuba berries*, 393
- Auricula*, popularity of, 250, 274, 296; *Sivria*, 458
- Auricula Society*, 3, 493
- Auriculae*, *Alpina*, 116, 403; and *Poly-anthusa*, 156, 402; as table plants, 365; culture of, 294, 344, 425; double, 187; in open ground, 197; notes on, 197, 241; old and new, 45; top-dressing, 123; treatment of, 499, 664
- Australia*, *Loranthus* from, 187
- Azalea*, a good, 155; buds drying up on, 112; abnormal bloom of, 484; *Flambeaz*, 433; *imbricata*, 316; *Indian*, hardy in *Ireland*, 445; *Mdmn. C. V. Eckstone*, 455; *Mdmn. Lefebvre*, 454; *Molls*, 94, 176; *Narcissiflora*, 94, 165; *Rollinson*, 27, 224; *Wm. Carmichael*, 220; indica, propagating, 567
- Azaleas*, 293, 492, 455, 609, 632; after flowering, 454; at *Clapton*, 459; double, for cut flowers, 569; at *Chel-sea*, 407; from seed, 530; notes on, 186
- Azara microphylla*, 620
- B.**
- Balsams*, 239, 414
- Balsam seed*, 285
- Bamboo stems*, seedlings in, 202; shading, Japanese, 699
- Banyan trees*, the, 596
- Barbarica*, culture of, 397
- Basket plants*, *Sweet Peas* as, 394
- Dark and timber trade*, 504
- Beach*, a Tropic, 347
- Beak*, *White Runner*, remarks on, 373
- Beans*, coarse *French forcing*, 614
- Beech*, the *Copper*, 619; the *Weeping*, 695
- Beches*, species of, 331
- Bees and Mignonette*, 36
- Beetles and cochineals*, 404; and *Cucumbers*, 604
- Begonia Frobeli*, 198, 250; from seed, 24; in *America*, 35; *Calypso*, 611; insignis in winter, 72; *manicata* in ditto, 79; *octopetala rosea*, 49; *ornata*, 185; *President Burrello*, and others, 607
- Begonias* as basket plants, 274; tuber-ous-rooted, 208, 251; winter-flowering, 117; various seedling varieties at *Forest Hill*, 699
- Belle rotundifolia caeruleoens*, 690
- Berberis Aquifolium* for spring bed, 272; *Darwin* a good hedge plant, 2; ditto, large, 407
- Berries and bits*, 67
- Berry-bearing plants*, 203
- Bertolonia Van Houttei*, 261
- Beschornia bracteata*, 15
- Bichlme*, some uses of, 2
- Bird Cherry* in hedges, 433
- Birds and berries*, 67
- Blandfordia Cunninghamii*, 309
- Blandfordia grandiflora*, 365, 661
- Blandfordia*, various, 638
- Bloomeria aurea*, 639
- Blood-tits and caterpillars*, 492
- Bolice cerasia*, 59; *Palini*, 272
- Boltonia latiguamma*, 94
- Bombare Carderi*, 108; *Caldasi*, 465
- Bones*, discharging, 555
- Bone dirt*, as manure, 652
- Boronia Drummondii*, 458; *serrulata*, 581
- Botanical and Horticultural Society of France*, 114
- Botanic garden*, Cambridge, *Massa*, 91
- Botanic Garden*, *Chicago*, 144
- Botanic instruction* in *Berlin*, 329
- Botany for young women*, 47; progress of, 347
- Bougainvilleas*, at *Nice*, 600; continuous flowering, 79, 146, 489, 549
- Bouvardias* as flower garden plants, 535
- Box edging*, 346
- Brambles and Briars*, 695
- Bread* a scientific diet, 232
- British fine-foliaged plants*, 84
- Briars and Brambles*, 695
- Broad-bills*, 478; *Carters' Summer*, 453; select kinds of, 311; sowing late, 493; *Veitch's autumn*, 92
- Brodiaea congesta*, 690
- Browallia*, 414
- Brownsea macrophylla*, 158
- Brownsea Sprouts*, early sown, 92, 176; large, 176
- Buck Beans*, white, at *Christmas*, 3
- Buildings and trees*, 23
- Bulbs*, wintering, 84; and *Rose beds*, 224
- Burlingtons*, culture of, 337
- Bush*, a *Blue*, in *May*, 459, 633, 669
- Bush*, *Burning*, 699
- Bush flowers*, manning, 68
- Buttercups and Daisies*, 133
- Butterworths*, the, 338
- C.**
- Cabbage*, *Barr's Criterion*, 196; *Couve Tronchuda*, 494; cross-fertilisation of, 371
- Caccinia glauca*, 274, 490
- Cacti*, free-flowering, 290, 363
- Cactus*, a *Turk's-cap*, 269
- Caladium*, *La Perle*, 459
- Caladiums and Gloxinias*, 669
- Caladiums*, propagating, 619
- Calanthes in masses*, 60; notes on, 188
- treatment of*, 447
- Calceolarias*, treatment of, 503; at *Reading*, 538; herbaceous, 285; in trenches, 336
- Calla aethiopica* planted out in summer, 439
- Callia palustris*, fl.-pl. minor, 377, 391
- California*, notes from, 328
- Camassia Brown*, 456; *Fraseri*, 229
- Camellia Angusta superba*, 339; blooms, 112; buds dropping, 113; from seed, 539; grafting, 447; in *Japan*, 369; in the open air, 197, 239, 274, 412; in winter, 570; leaves dropping, 24; propagating, 385; treatment of, 382
- Camellias and their culture*, 181; at *Chelsea*, 226; at *Exeter*, 94; at *Flor-ence*, 647; *Walham*, 269
- Campanula macrostylis*, 117; *Medium*, 278; *speculum*, double, 367
- Campanulas*, 414; for baskets, 621
- Camphor water and soods*, 244
- Candytufts*, new dwarf, 433
- Canker in Parsley*, 453
- Canistrum saratanicum*, 69
- Carbolic soap* in roses, 265
- Carnation*, a good, 135
- Carnations*, *Trees*, *La Belle*, 433; various, 378, 490; in open borders, 197
- Carratons and Picotees*, treatment of, 123, 197, 234, 241, 294, 499
- Carob Bean Tree*, 624
- Carrots and their culture*, 310
- Castanea pumila*, 378
- Catalpa* at home, 310; speciosa, 697
- wood*, 672
- Caterpillars*, cure for *Gooseberry*, 498
- Cats*, garden, 595, 499, 592
- Cauliflowers*, Autumn *Giant*, 208; and *Levences*, 294; blanching, 311, 430, 497
- Cava Muscato*, 16
- Ceanothus rigidus*, scale on, 348; divaricatus, 589
- Cedar*, *Silvery*, of *Lebanon*, 318
- Celastrus nemosa*, 205
- Celeriac*, three varieties of, 311
- Celery*, blanching, 174; crisp, 349; *Charles Waterer*, 407; *Cherry*, 419; *huttonii*, 301; late, 372; notes on, 242; worms in, 121, 154
- Celosias*, 414; created, 251
- Chemist*, 199
- Chemistry*, a garden, 60
- Cherries*, *London*, 148
- Cherries*, *Centauria*, 142
- Cherries*, *Waterer*, 407, 433
- Chersonia gilvica*, 424
- Garcia Siliquastrum*, 155
- Cereuses*, *MacDonaldias*, 292; free-flowering, 337
- Chamaerops*, hardy, 7; *Fortunei* in *Lind-colnshire*, 84
- Chelidanthus elegans*, 329
- Chelidanthus*, 199
- Chelids*, *Orchids*, at, 74
- Cherry Plum*, the, 109, 269
- Cherry*, *J. Waterer's* *Bagehot*, 407
- Chrysanthemums*, large wild, 205
- Cherries*, wild black, 360; imported, 170; Morello, shedding fruit, 593
- Chestnut*, *Horse*, erratic habit of, 504; the largest, 392
- Chilias*, 414
- Chinese teapot*, 416

## T.

*Tahermontana canasana*, 429  
*Tamaris* in French Gardens, 629  
 Tax-paving c. weeds, 219  
 Tasmanian vegetation, 270  
 Tea plant, yield of, a, 23  
 Temple, rule of the, 280  
*Terminalia elegans*, 37  
*Taustocella halitoides*, 673; Mangel, 673  
 Testimonial, Professor Balfour's, 430  
*Thalia dealbata*, 594  
*Thalictrum* for wild garden, 622  
 Thermometer, a new, 53  
 Thickets, tangled, 484  
 Thorn, the Glastonbury, 609  
 Thrifts as an edging, 694  
 Thrifts, large, 539  
*Thuja gigantea*, 454, 559  
*Tillandsia zebrina*, 114  
 Tillandsias on Fern stumps, 182  
 Timber, Holly, 429  
 Todea superba, 446, 814; seedling of, 282  
 Tomato Concoction, 176  
 Tonatoes, early planted, 453; at Chiswick, 813  
 Tools, garden, 173  
 Top-dressing Arniculas, 123  
 Torenia, a yellow, 485, 589  
 Torquay, plants at, 33  
 Tovaria oleracea, 612  
 Town garden, my, 33  
 Town trees and shrubs, 40

## DAVID MOORE, PH.D., F.L.S.

To those who have the pleasure of a personal acquaintance with the excellent Director of the Royal Gardens at Glasnevin, near Dublin, it needeth not to be said that he is of Scotch descent; indeed, we believe that his native home is in Forfarshire, and that his young days were spent not far from the Brees of Angus. Early showing a remarkable taste for floriculture, he was sent very early in his life to Dublin, to be a pupil of Dr. Mackay, then Director of the Botanical Gardens belonging to the University of Dublin. As we write the name of Mackay we are tempted to a digression to tell of the genial, pleasant Scotchman who was the very founder of these gardens, and whose "Flora Hibernica" was a work well up to the standard of its day. Under such a master all young Moore's tastes for Natural History were cultivated, and he rapidly became an authority on the Irish plants. About 1834 the Ordnance Survey of Ireland was commenced, and David Moore was appointed on it. In 1837 the first volume of its memoirs was published, under the title of the "Ordnance Survey of Londonderry," and contained a memoir on the geology of this district by Capt. Portlock, on its political and antiquarian history by Geo. Petrie and J. O'Donovan, and on its botany by D. Moore. This was Moore's first contribution to science, if we except the assistance he gave to his old master, Dr. Mackay, in the production of the "Flora Hibernica," an assistance gratefully acknowledged in the introduction to that work. The projected survey of Ireland was, however, commenced on far too elaborate a scale to be in like manner continued; and although a vast amount of material was collected towards elucidating the history of others of the Irish counties, yet these were never published, and the botanist of the survey soon after this date resigned his post, and was elected Director of the Gardens at Glasnevin, then belonging to the Royal Dublin Society, with the improvements of which the name of Dr. Moore will ever be connected. Often sorely hindered for want of funds, with but few sympathetic spirits to cheer him on, the Doctor laboured long and hard, until he has, as now, made these gardens to hold their own amid the gardens of Europe. Pleasantly situated by the bank of the little Tolka, associated with the memories of Tickell, Swift, and similar men, Nature had done much for them—the gardener's art but little. It is now a story too well known to need repeating—how Moore, working in unison with Nature, made these gardens useful to the practical gardener, useful to the scientific botanist, ah! and useful, too, to the hard-worked citizen who, amid their gay parterres, shady walks, or by their river's side, shakes off some of that sad accumulation of week-day dust, and feels himself the better thereby. Moore, despite his Scotch descent, had learned in his adopted country that the Sabbath was made for man, and he welcomed the thousands who wandered over these grounds on a fine summer's Sunday. Time would fail us to tell of all the experimental work either carried out or superintended in these gardens by Moore. Many of our readers will recollect the numbers of new plants first introduced to our gardens from Glasnevin, the numbers of interesting plants first flowered or fruited here, and the numbers of new hybrid forms first raised there, all of which well merited the honourable mention of his name by the now President of the Royal Society and Director of Kew in the dedication to Dr. Moore of the 29th Volume of the Third Series of the Kew Journal of Botany, "to one who, maintaining a very rich and beautiful Botanic Garden at a high standard of excellence, has advanced Botanical Science by many original observations and experiments." Of Dr. Moore's more original botanical work we can here only mention the "Cybele Hibernica," undertaken conjointly with A. G. More, F.L.S.; his works on the Irish Mosses; on the Irish Liverworts; and on the Irish Grasses. For a record of his practical researches, of his many tours to Russia, Italy, Spain, France, Germany, and Norway in quest of botanical information, we have left ourselves no space. Still in the prime of life, now surrounded by many grateful and attached friends, we trust he may long be spared to preside over the beautiful gardens which owe so much to his labours.

CHARLES LAWSON.

## CHARLES LAWSON, OF EDINBURGH.

CHARLES LAWSON, whose portrait forms a frontispiece to the present volume, was born in 1794, and had, therefore, at the time of his death, which took place on the 21st of December, 1873, attained the age of seventy-nine. He was the son of Mr. PETER LAWSON, the founder of the nursery in connection with which the name was destined to become so well known, not merely in Scotland, but throughout the world. Established in 1770, the firm of PETER LAWSON & SONS had acquired a stable footing before the removal of its original partner. In 1821, CHARLES LAWSON, who had for some years been associated with his father in the business, succeeded, on the death of the latter, to its sole management. The energy and intelligence which he brought to bear on its affairs soon placed the firm in a most prominent position, rendered it, in fact, a power in matters agricultural as well as horticultural in this country, and extended its ramifications into all parts of the civilized globe. It was Mr. LAWSON who in 1833 introduced the Italian Ryegrass. To his enterprise, also, we owe, among other obligations, the introduction of the Austrian Pine and the Lawson Cypress, a species named after him, a compliment well bestowed. Besides his services in the way of introducing useful plants, he was a valued contributor to the literature of gardening, agriculture, and arboriculture. The horticulturist and the agriculturist are indebted to him for the "Agrostographia, or Book of Grasses," which has gone through many editions, and is still regarded as the standard British book on the subject, not only for the guidance of the seed trade, but for other purposes. The "Agriculturist's Manual," published in 1836, was a familiar description of the agricultural plants cultivated in Europe, with practical observations respecting those suited to the climate of Britain. This work has also proved its usefulness by running through several editions. The "Pinetum Britannicum" was a description of the hardy trees of the Pine tribe cultivated in our gardens, beautifully illustrated, and dedicated to H.R.H. the late Prince Consort, who was one of the original subscribers to the undertaking. Of this splendid book, which contained coloured plates of the various trees described, with enlarged drawings of their flowers and fruit, only one hundred copies were printed. In addition to the above, several other publications of a practical nature bespoke the unwearied attention that Mr. LAWSON bestowed on all departments of the business in which he was engaged. As a young man he joined with a few others of kindred views and interests in an endeavour to break down what was then known as the "Mark Lane monopoly," by which the seed trade was seriously hampered. This movement was successful, and Mr. LAWSON also did good service in securing the abolition of the duty on seeds imported into this country. His well-earned eminence in his business secured for him the appointment of seedsman to the Highland and Agricultural Society of Scotland—an office which he held for many years. He was likewise entrusted with the curatorship of the Agricultural Museum, formed under the auspices of the Highland Society, which at one time occupied a portion of the premises on George IV. Bridge, but for which some years ago more suitable accommodation was found in the Museum of Science and Art. In this connection, it may be mentioned that for the Great Exhibition of 1851 the LAWSON firm made a complete collection of all the Grasses and other vegetable products of Scotland, accompanied with a synoptical statement of much interest and value. This contribution to the Exhibition attracted great attention, and was deemed worthy of a Council Medal. The collection was ultimately divided between Kew Gardens and the Highland Society's Museum above referred

to. Mr. LAWSON's knowledge of seeds and plants was further turned to account in connection with the first Great Exhibition, in his appointment to the Chairmanship of the Committee charged with the duty of examining and reporting on that class of contributions. The Exhibition of 1862 was enriched by the LAWSON firm with a great collection of British vegetable products, which was subsequently acquired by the Russian Government. Mr. LAWSON's active participation in the business of his firm may, we believe, be said to have ceased about 1850. He never withdrew from partnership, but handed over the reins to his sons, by whom the business was carried on until, they being engaged in other pursuits, it was in January 1873 handed over to a limited liability company. It must have been about the time of his withdrawal from business that Mr. LAWSON began to take a leading share in the public affairs of his native city. As was to have been expected of one who had been so extensively engaged in trade, he became a prominent member of the Chamber of Commerce, of which body he became Chairman in 1859. The business of the Merchant Company also engaged a considerable share of his attention, and after the usual term of service in the lower grades of office, he was elected to the Master's chair in November, 1861. In connection with the proceedings of both these important corporations, he showed himself a clear-headed, sagacious man, resolute to concentrate attention upon matters of real public importance, and laying hold of these with a firm and comprehensive grasp. As Chairman in the one case and Master in the other, he further distinguished himself by his liberal conduct both in his town mansion and at his country residence at Borthwick Hall, a place which he had at considerable expense converted into a beautiful property. By a unanimous vote of the Town Council he was elected Lord Provost of Edinburgh in 1862 a position which he filled with credit to himself and to his fellow-citizens. In Edinburgh, whose Council Chamber is adorned with his portrait, Mr. LAWSON will long be remembered, and it is pleasing to think that when misfortune had overclouded his brilliant career, there were found a goodly number of eminent citizens to band themselves together to secure peace and comfort for his declining days.

## THE GARDEN.

VOL. XIII.

### A WEST OF IRELAND GARDEN.

BEAUTIFUL is this Christmas-day morning! The sun is fast transmuting the crystals of silver, formed by last night's feeble frost, into glittering iridescent pearls, and hanging them in myriads on countless blades of Grass—at the same time brightening with his rays the many flowers and leaves that adorn the small garden which I am about to describe. Situated immediately in front of the cottage occupied by the writer, this favourite resort of his and his belongings is enclosed for the most part by two crescent-shaped Boulderies that form a broken semicircle 208 ft. in length, and from 3 ft. to 8 ft. in height, made up of the remains, intermixed with earth, of old walls, which formerly partitioned the adjacent field into Potato plots; such old walls have made the suburbs of Galway famous in song and prose; but they are rapidly disappearing under the hand of ruthless culture. Little more than ten years ago, before this place was taken by its present occupant, there was no enclosure; four-footed domestics—the ordinary adjuncts of a country house in the west of Ireland—had free access to the "hall door."

The boulderies have the side which the cottage faces irregularly sloping; but the outer side is perpendicular, or wall-built. Fixed in the stones and earth of the sloping sides are large, much-weathered, erratic boulders of granite, many of them weighing several hundredweights each, irregularly piled one on the top of another, as if they had been shot off from a small glacier, and formed its terminal moraine; but the erratics, instead of being imbedded in an iceberg, or a glacier, as doubtless was once the case, are now embosomed amongst shrubs—mostly evergreens. These consist of *Escallonia macrantha*, partly in flower; *Cotoneasters*, loaded with coral berries, affording food for thrushes and other birds; *Berberis Darwini*; *Veronica Andersoni*, highly floriferous, and other species; *Myrtles* major, Japanese Honeysuckle, Sweet Brier, its branches suspending clusters of scarlet tips; *Yucca filamentosa*, and others; large-leaved *Myrtle*, in flower; *Phygelus capensis*; variegated form of *Euonymus japonicus*, Himalayan Cedar, too much exposed to become a tree; *Rhododendron hirsutum*, and other varieties of that genus; variegated *Osmanthus ilicifolius*, *Fuchsia gracilis*, and other varie-

ties, in their last stage of flowering and leafage; while interspersed here and there are perennial Candytufts, various Saxifrages, *Helianthemums*, *Lithospermum*, *Heaths*, *Aubrietias*, variegated Lemon Thyme, a spreading *Campanula*, still in flower, Ferns of hardy sorts, and a profusion of other plants. A projecting portion of the ridge has been made into a rockery, formed of time-worn blocks of limestone, between which are growing the Maiden-hair Fern, retaining its green fronds, and other tiny evergreen Ferns, and perennial *Mesembryanthemums*, the pretty *Lycopodium helveticum*, vying with the surrounding Moss in colouring with bright green the stony recesslets.

The enclosed parterre contains fourteen beds of various shapes and sizes, separated by broadish Grass verges, and set off with herbaceous plants and evergreens. Standing conspicuously are *Yucca gloriosa*, nearly 7 ft. high; a good-sized variegated *Y. aloifolia*, a large *Chamærops Fortunei*, *Retinosporas* of different kinds, and a noble *Cordyline australis* nearly 18 ft. in height (planted in too exposed a place, when quite young, eight years ago). This gem, which has not flowered yet, has braved many a bitter blast from the Atlantic. All who see it give expressions of surprise, and ask, how high will it grow? Associated with these, arranged somewhat in the "wild garden" style, are the herbaceous plants, generally in full foliage, and a good number of them bright with flowers. Here may be found *Pompeone Chrysanthemums* of various colours; *Schizostylis coccinea*—a glowing clump of which is growing in almost every bed; *Erodium Manescavi*—as bright and purely coloured as it has all along been since early spring; *Anemone Hortensis* and *Primulas*, too premature in their blooming; double and single *Stocks*—gaily dressed as in spring; and an *Iris reticulata*, nearly ready to unfold its purple and golden flowers!

On some trellis work, passing an uncovered or *al fresco* portico, *Rhodochiton volubile*, in its second winter, is hanging in festoons, which are strung with rosy-purple bells—rather uncommon for outside decoration at the present time of the year. *Rose Victor Verdier* is below with some imperfectly-developed buds (a full-blown one was taken from it the other day); in close companionship is a *Tropæolum*, bearing green

leaves, and a few flowers, wonderfully fresh. Adjacent, with its large leaves standing boldly erect, is a largish specimen of the so-called "Lily of the Nile," that gave birth during the past summer to nearly a dozen and a-half of its glorious flowers.

In the little arboretum, into which the garden gradually merges, there are growing *Coniferae*, *Arbutus*, *Evergreen Oaks*, *New Zealand Flax* in noble masses, *Benthamia fragifera*, and several more trees and shrubs—all green and fresh as though it were a summer day. Other plants I have tried, but they failed to grow. Doubtless, success would attend the trial of many that I have not been able to procure. I see no reason why some hardy kind of Tree Fern (perhaps *Alsophila australis*), with a little attention to it for a few years, could not be made to ornament a sheltered nook close by. My kind friend, Dr. Moore, of Glasnevin Gardens, has succeeded in growing in the open air, for some years past, a specimen of an *Andesia Palm*, *Jubaea spectabilis*, which promises much for this mild-wintered spot. I shall never be content until the *Lagerflora*-flowering-like *Phlœsia buxifolia*, and some other recent introductions, are flourishing on the boulderies. What a different aspect is presented by the place under description to that which the gardens of my early days, in the north of England, exhibited at this season! In summer, however, the gardens there make ample amends for their wintry dreariness.

I am now reminded of certain drawbacks, of which an amateur florist in this part of Ireland has some ground to complain. The Atlantic warms his winters and cools his summers, and the great amount of rain he experiences spoils many of his favourites. In all probability, insufficient heat in summer, and the large rainfall, combined with a not over grateful soil, prevents his garden being enriched during the full flowering season with that wealth of floral beauty, which, developing itself spontaneously as it were, adorns even the humblest cottages in England—especially in Devonshire, Dorsetshire, and Cornwall. Nevertheless, how lovely may a neglected spot in those favoured counties could be made if the aesthetics of natural scenery and a scientific knowledge of plants were more generally cultivated than is the case by those of whom, from their position in life, such is to be expected.

Returning to a regrettable theme, often do I complain of my inability to grow Roses. *Maréchal Niel* and others have gone; *Gloire de Dijon*, which I have endeavoured to train over the portico, will, to all appearance, soon follow; only one exception to these misfortunes can be recorded, which is afforded in the prolific and rampant *Félicité Perpetuelle*—justly so named. *Pampas Grass* seems to be a failure. Several of my *Fuchsias*, *Pelargoniums*, including a *Clematis*, are often attacked by that vile pest, the *Peronospora*, which shrivels up and blackens their flower-buds and young leaves, leaving them converted to tinder. As to *Pentstemons*, and most of the sub-tropical plants, such as I saw growing luxuriantly in *Battersea Park* in September last, they would only succeed here in a greenhouse, under which *Flora* is wont to smile freely and joyously.

It need, therefore, be no surprise that, influenced also by other and higher considerations, I am longing to meet with an inexpensive place on the south-west coast of England, drier and sunnier than it is in this district, and where dull, leaden-grey, impenetrable clouds more frequently give place to bright blue skies. Still, dear old Galway has charms, of which many other towns with higher pretensions may reasonably be envious.

WILLIAM KING.

*Glenoir, near Galway.*

### HERBACEOUS PHLOXES IN POTS.

GROWERS of herbaceous *Phloxes*, who wish to make a fine display during the coming summer, are reminded that now is the best time for setting about the necessary arrangements for effecting that end. As a rule, *Phloxes* are planted out in borders, where they are allowed to grow on year after year (often without even dividing them), the natural consequence being that the flowers grow small by degrees, and beautifully less as regards size, and the markings, as a matter of course, are not so well defined as when grown in a proper manner. *Phloxes* when grown in pots are impatient of shifts, and great care

should be exercised in such operations. Presuming the grower to have some good two-year-old plants, a careful shift should be given to pots one or two sizes larger than those which they are now in. This should be performed at once, and when they commence to push up their growths a judicious use of the knife, in removing all with the exception of the three or four strongest shoots, is necessary. Care should be taken in potting to leave sufficient room for a top-dressing of rotten manure later in the season; as, unless this be given them (from the fact of the roots rising to the surface) incalculable mischief will be done, both as respects flower and foliage. If the pots be plunged, well supplied with water, and frequent doses of very mild liquid manure be given (the latter simultaneous with the forming of the flower-buds), a grand display cannot fail to be the result. Those who intend growing these *Phloxes* for the first time are reminded that to expect a large head of bloom from plants as usually sold, would be fallacious; but if application be made to a nurseryman for two-year-old plants (costing but a trifle more than plants just rooted), a very satisfactory display will be the result—one well worth the time devoted to them. One drawback belonging to these plants for purposes of exhibition is the occasional opening of the individual blooms; but even this can be obviated by giving the plant a thoroughly good soaking of water and shutting it up in a close greenhouse; in this a few days will cause all the flowers to expand at once. To give a selection is unnecessary, as most nurserymen can supply good kinds at a reasonable rate, and many of the Continental and home-raised varieties differ only in name.

*Plumstead.*

F. T. DAVIS.

**Premature Spring Flowers.**—There is something singularly pleasing in having a fine, sunny day for the last of the year, and in being enabled to walk about one's garden in comfort to see the charming *Primroses*, *Polyanthuses*, *Aubrietias*, *Pansies*, and other plants coming freely into flower, and reminding one of the beauties to be looked for in April. The *Primrose* and *Polyanthus* varieties of the *Primula* family are the earliest and most beautiful of all the race, rich and varied in colours, and coming into bloom when the majority of hardy plants are at rest. A few dozens of these, lifted from their beds into pots and put into a cool house, will be found to rival the Chinese *Primrose* in floriferousness, and to excel it in colours and variety.—D.

**Berberis Darwini a good Hedge Plant.**—We have here a hedge of this *Berberis* 250 yards long,  $\frac{1}{2}$  ft. high, and  $1\frac{1}{2}$  ft. through, and well furnished from bottom to top. In fact, one can scarcely see through it, even at this time of year; but in spring, when studded with thousands of bright racemes of flowers, it is an object of special beauty, only requiring to be seen to be appreciated. In autumn, too, it has a fine effect when covered with myriads of purple berries, of which the birds are very fond. In short, a hedge of this *Berberis* will hold its own against all comers, and will be equally pleasing either in a large or small garden. There is no need for making the soil in which it is to grow rich, for here it is quite robust in common loam. After planting, all that is required is to clip it once a year, which it withstands quite as well as the common Thorn. In some places, *Privet* is planted along with *White Thorn*, so as to make an evergreen hedge; but *Berberis Darwini* would, in many respects, make the best hedge. There would be no difficulty in getting it 6 ft. or 7 ft. high, and well furnished from bottom to top, capable of resisting cattle and sheep. *B. Darwini* is, therefore, really one of the very best plants for making garden hedges.—C. PENFORD, *Powerscourt*.

**Some Uses of Birdlime.**—The Holly has its economical uses. The middle bark, under proper manipulation, yields birdlime, which, however, may also be obtained from the *Mistletoe*. The Japanese find some curious uses for this substance. Traps for rats are made in the simplest possible manner, by placing pieces of board or card smeared with it near their holes. Spread upon Bamboo leaves it is used for catching flies and other insects. Even fleas are no match for Japanese ingenuity, for they are trapped in bed by birdlime spread on pieces of board, the board being arched over with bent Bamboo to prevent the birdlime from adhering to the bedding. Possible uses of this viscid article, such as a snare for cockroaches, mice, &c., will at once suggest themselves to our readers. Even animals as large as monkeys are caught by its means in Japan. Ornithologists may take a hint as to bird catching from the Japanese method. Long stems of *Wistaria* are smeared with birdlime and floated out in estuaries, and even on the sea, in parts frequented by birds, and wild fowls are in this way bagged in considerable quantities. Many other uses are given in an interesting report on this subject from Mr. Consul Annesley.

## NOTES OF THE WEEK.

**Kew.**—This week there are several very beautiful *Oreobida* in flower, in addition to many which have been previously noticed. One of the handsomest is a very fine variety of *Dendrobium primuminum*, the pendulous, deciduous stems being clothed all their length with two rows of lovely flowers, so delicate as to appear semi-transparent. The ground colour is a very pale primrose, suffused with a pleasing rosy-purple. *Dendrobium nobile* var. *pendulum*, has larger and more richly-coloured flowers than the type; it comes from India, although China is given as the head-quarters of *D. nobile* itself. *D. Pierardi* has a drooping, deciduous habit, and white and lilac flowers; its strong constitution and free-flowering properties render it a favourite with *Orchid* growers. Given a sufficient number of plants, this species could be had in flower all the year round without any great trouble. *D. Wardianum* is a magnificent species from Assam; it has knotted stems somewhat similar to those of the next species. The sepals and petals are white, tipped with magenta; the lower part of the lip is rich orange, with crimson spots. *D. crassinode* is a very handsome species from Moulmein; the waxy-white sepals and petals are tipped with rich purple, and the lip is white, with a blotch of orange at the base. *Barkeria Skinneri* is a very useful winter-flowering *Orchid* from Guatemala; its compact habit, and deep rose-coloured flowers make it particularly valuable. Perhaps the most showy species of the genus *Polystachya* is *P. grandiflora*, from Sierra Leone; it has large flowers of a pale greenish colour, relieved by two purplish blotches. The habit of the plant and the general structure of the flower of *Angrecum pertusum* are identical with those of *A. aburneum*, notwithstanding the vast difference in the size of the flowers of the two species. In spite of the lack of colour, there is much grace and elegance in the drooping spikes of compact, greenish-white flowers. *Epidendrum xanthinum* has tall leafy stems (in the *Fl.* specimen from 3 ft. to 4 ft. in height) resembling those of *E. ellipticum*, and terminal racemes of small orange-yellow flowers. This species has been found wild in various parts of Brazil.

In the *Cactus*-house there is a good specimen of *Kalanchoe laciniata*, a beautiful succulent from Tropical Africa and the East Indies; it belongs to the *Crassula* family, and is a near relation of the genus *Bryophyllum*. The flowers are a fine citron-yellow, and are freely produced, a single plant affording a succession for a considerable time. The thick, fleshy, lacinated leaves are, in themselves, pretty. As a winter-flowering plant this is certainly worth a place in any greenhouse. *Iris fimbriata*, from China—one of the most striking species of that very beautiful genus—is also in flower; the broad, glossy, arching leaves, contrast finely with the flowers, which are blue, with the exception of a variegation of deep purple and yellow on the waved outer segments; the petaloid and fringed stigmas are erect. This is almost too tender for the open air, unless a good, dry, sheltered spot can be commanded. As a pot plant, either in a warm or cold house, or in the window of a dwelling room, this is most desirable.

*Amphicome Emodi*, a remarkably handsome *Bignoniaceous* plant, may be seen in the coolest compartment of the New Range. It is a dwarf, herbaceous perennial, with unequally pinnate leaves, the radical ones being composed of from five to eight stalked, toothed leaflets; the peduncles are terminal, and the large, trumpet-shaped flowers have a bright orange tube and a spreading limb of five rounded, rose-coloured lobes. Under cold frames treatment this plant, which comes from the Emodi Mountains of Northern India, makes a very pretty object.

*Abutilon vexillarium* is certainly most attractive as a rafter plant; in that position the drooping flowers show to more advantage, and the vivid contrast between the red calyx and the sulphur-coloured corolla is more easily seen. South America is said to be the native country of this species, although nothing definite is known as to its origin. A fine specimen has been very conspicuous on one of the rafters of house No. 4 for a long time past.

In the Winter Garden there is a very handsome *Taconia* in flower; it belongs to the same section as *T. mollissima* and *T. ariantia*, but is much finer than either of those species. Hartweg first discovered it in ravines near the city of Quito, whence its name, *T. quitenis*. The tube is very long—much longer than in *T. mollissima*, and the limb is of a very beautiful rose-crimson colour.—†

**Mr. Noel Humphreys** is now engaged in drawing the new hardy winter-flowering *Iris*s, and will be very much obliged to any one who will send him specimens to 7, Westbourns Square, Hyde Park.

**Enkyanthus japonicus.**—The *Enkyanthus japonicus* is a native of Japan. It is very hardy, and probably flowered for the first time in Europe, in 1877, at the nurseries of M.M. Thibaut & Ketseler, the well-known horticulturists, at Seaux. It flowers in the spring,

about the beginning of April, in fact, just as the leaves begin to appear. The plant is grown in coarsely-broken, turfy, heath mould, and, if possible, facing the north. In other respects its cultivation closely resembles that of the *Rhododendron*. It may be propagated by cuttings and half-mature buds, which are placed under a bell-glass in a propagating-house.

**All the Year Round Roses.**—On Christmas morning I gathered from the open air several excellent flowers of *Souvenir de la Malmaison* and *Clou de Dijon* Roses; and at this moment there are scores of buds on the plants as vigorous as they are in May and June. Our plants are on their own roots, and receive very little pruning, with the exception of what they get by constantly cutting the flowers for bouquets.—W. W. H.

**Monochætum eusiflorum in Winter.**—For conservatory decoration this plant deserves extensive culture. It is easy to grow, and its lively purple flowers, which are produced freely in winter, have a fine appearance. For furnishing the front rows of stages, plants grown in 5 or 6 in. pots are very useful, and it might also be grown in baskets with advantage. It is now flowering freely in several places.

**Aphelandra Roezli.**—This is one of the most attractive plants now in flower in the London nurseries; its bright scarlet blossoms are produced for many weeks in succession, and when plants of it are well grown in small pots, they have a fine appearance, associated with Ferns and similar plants. It requires stove temperature in order to grow it successfully, but, when in flower, the plants may be removed to a cooler situation, in which they will last in good condition for a longer period than if left in heat.

**Masdevallia tovarensis.**—The beautiful white flowers produced by several good specimens of this *Masdevallia* are now very attractive in Messrs. Veitch's nursery at Chelsea, and they are this year much larger, whiter, and of better substance than hitherto, a fact doubtless due to the increased strength of the plants.

**Ruellia rosea.**—This is a pretty winter-flowering plant lately introduced by Mr. Bull, of Chelsea. It grows freely and flowers abundantly, even during the dulllest months of the year. In the same house are also examples of *Tillandsia Lindenii*, bearing numerous spikes of rich blue blossoms.

**National Auricula Society.**—This Society's exhibition of Auriculas will be held in the Crystal Palace this year on Thursday, April 25; and, in order to enable the Committee to frame the schedule, an early return of the form sent to each subscriber will be gratefully esteemed by the hon. secretary, Mr. E. S. Dodwell, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W.

**Dahlia Maximilliana.**—The first flower of this *Dahlia* opened this morning, the only one, I believe, which has as yet expanded in this country; but, owing to the dull weather and the bad condition the plant is in, no proper estimate of its beauty can be formed. *D. Maximilliana* is quite a tender species, requiring similar treatment to *D. arborea*, imperialis, and others of that class. I may add that *Pansies* and *Primroses* are flowering freely out-of-doors. *Narcissus Clusii* and *Iris alata* in frames are also at their best.—A. PERRY, *Hale Farm Nurseries, Tottenham.*

**Rhinopetalum Karelini.**—This miniature gem, a *Liliaeaceus* plant from the Ural Mountains, is now in flower in the New Plant and Bulb Company's nursery at Colchester. The flowers, which are pinkish-lilac, are borne on stems that scarcely rise 2 in. above the ground. *Narcissus Clusii* and *Iris Histrio* have also been in flower in the same nursery for some weeks.

**The White Buck Bean at Christmas.**—The flowers of this are very useful at this season, when every white flower is an acquisition. They may easily be obtained by lifting plants from the open pond, potting them, and placing them in a warm temperature. The pots should be set in pans of water, or immersed to their rims in a tank. Instead of the plants going to rest, as is natural in winter, they start into growth and flower profusely. Treated in the way alluded to, numbers of plants in one of the houses in Messrs. Rollison's nursery at Tooting, are now throwing up flowers in abundance.

**Oncidium leucochilum at Ferrières.**—A plant of this variety was in bloom last month in the *Orchid*-house of Baron Rothschild, at Ferrières. It had two spikes each 15 ft. long, with twenty laterals, each spike having from 100 to 110 flowers on it in excellent condition.—B.

**Japanese Plants in Paris.**—A few days ago I had an opportunity of inspecting the collection of Japanese plants, to which allusion was made last week (see p. 607). The packing of the plants was no doubt faultless, but the long journey of at least two months had very

materially damaged the collection. Although there may be (to those who are acquainted with the plants of that country) nothing new from a scientific point of view, yet the interest attached to their manner of cultivation will be appreciated at its proper value. The Japanese have not as yet put into practice the botanical nomenclature to which we are accustomed. The tallies are at present illegible, except to the Japanese scholar. The plants being generally without foliage, it was with difficulty that one could distinguish the various Maples, Magnolias, Pæonias, &c. It is to be hoped that, before the opening of the Exhibition in May, the skill and industry of the two Japanese gardeners will have effected much to restore them to their native luxuriance.—W. MELLES.

**St. Pancras Gardens.**—The Baroness Barette-Conte is about to erect, in the St. Pancras Gardens, a sun dial as a memorial to illustrious dead lying in the grounds, which used to be the old St. Pancras and St. Giles graveyard. The memorial will probably cost £3000. The Baroness has also erected a monument to the memory of John Walker, the author of the "Pronouncing Dictionary," and has given £100 to erect a greenhouse in the same grounds.

**Cuphea Roezlii.**—This new and beautiful species, which has been introduced into the market by M. Charles Huber, nurseryman at Nice (Maritime Alps), was discovered in the district of Tepic, in Mexico, by M. Roezli, who sent the seeds to M. Ortgies. The first sowing was made by M. Charles Huber in August, 1875. The plant forms a soft-wooded very vigorous shrub, often growing to the height of 3 ft., or even more. The flowers are extremely abundant; they are covered all over with light down, and are slightly gibbous, or slipper-shaped. From its vigour, the abundance of its bloom, and the length of time it keeps in flower, the *Cuphea Roezlii* will be much sought after for the ornamentation of cold greenhouses in the climate of Paris, and for gardens in the open air in the south of France. If grown properly, there is no doubt that this plant will soon be common in our markets. Planted in good time in the open air, in a well-sheltered and sunny position, the *Cuphea Roezlii*, which is a very free flowering plant, will begin to bloom in the course of the summer, and continue to do so without interruption right into the winter. The plants, however, must be well protected from frost. This species of *Cuphea* may, according to circumstances, be cultivated as a biennial by leaving the plants in the open air, as is already done in the case of several greenhouse plants, such as Pelargoniums, or it may be looked on as a greenhouse plant proper, and re-potted and pruned in the spring according to the purposes for which we intend it.

**Exochorda grandiflora Root-grafted.**—It is not often that Americans claim to vie with the skill of French horticulturists, but Mr. Trumpy, of Messrs. Parsons & Sons, Flushing, Long Island, has long successfully root-grafted *Exochorda grandiflora*, which we now hear from English and French authorities, through the "Gardener's Monthly" of August, has been first employed by Monsieur J. Goujon. That others in various parts may have done the same, I do not question, only when our French brethren undertake to sound their trumpets over some feat at last accomplished, it may be gratifying to learn that America has long been doing the same thing quite successfully. We do not wish to depreciate the value of the achievement, for it is undoubtedly the best method of propagating *Exochorda grandiflora*. All difficulties will not, however, vanish on this discovery, for much skill and judgment are required to select the proper roots and grafts to ensure success. In fact, it will probably long remain a plant somewhat difficult to propagate. This beautiful hardy shrub should receive more attention, and perhaps, with increased demand, improved methods of propagation may be devised.—S. P.

—Mr. E. F. Luckhurst, foreman to Messrs. Hance & Son, Red Bank, New Jersey, writes as follows:—"I noticed in the 'Gardener's Monthly' of August last, an account of propagation of *Exochorda grandiflora* by a French horticulturist. He says the end of winter or commencement of spring is the most suitable time for putting in the grafts. All I have to say is, I grafted, two years ago last January, several hundreds, and raised about 80 per cent. of them."—"Gardener's Monthly."

**Dean Stanley on Industrial Work.**—At the opening of the Westminster and Pimlico Working Classes Industrial Exhibition, which took place the other day, Dean Stanley said, among other things, that he had been reading the life of the late Prince Albert, and remarked that it is impossible to read that life without seeing that the Prince was one of the most indefatigable and industrious of workmen. He was extremely fond of gardening when he had any leisure, which was rarely; and there is a very beautiful letter of his addressed to one of his daughters, the Crown Princess of Prussia, in which he commends her very much for the time she bestows on sculpture and making models. Gardening also appears to me, he

said, to have great advantages, because you can see how the things which you arrange and put in order really grow under your hands; you can look after them and begin to have a love for them, and in that way you will have the very best result out of the work you are doing.

#### HOME-GROWN ORANGES FOR DESSERT.

We have grown Oranges in pots, and have fruited them successfully, for at least a dozen years. No fruit is more valued, not alone for its flavour, which has always been superior to that of any imported Oranges that could be obtained at the same time, but because of the interest that is attached to the trees themselves, loaded as they are with large fruit almost bursting with juice—indeed, we have had specimens of St. Michael's that did actually burst. At the present time, we have a tree of St. Michael's in a 13-in. pot, which ripened its fruit—about four dozen in number—in December; they varied but little in size; the largest were  $8\frac{1}{2}$  in. in circumference, and weighed over 9 oz. each. This crop of fruit was set before the whole of the previous one was gathered in March last. We grow three varieties only, the Tangierine, the St. Michael's, and the Maltese Blood. The culture of these fruits is very simple. From the time the trees are started in February until the fruit ripens, as long a period elapses as is required for a house of Pine-apples or Muscat Grapes. The temperature and atmospheric conditions of the Pine-house suit Orange-trees admirably. Ours are grown on the back stages in the Pine-house, the plants being in pots of various sizes. The *modus operandi* of their culture may be summed up in a few words. A good foundation must be laid, by placing the tree in the right kind of compost. They are not over-particular as to this, but to do them well, tough, fibry, yellow loam must be procured from an upland pasture. It is best to use this before the fibre is too much decayed; pull it to pieces by the hand, and to five parts of loam add one part of rotted stable manure, and to each barrow-load an 8-in. pot full of crushed bones. If the trees are large, 1-in. bones are the best, but for small trees we prefer the bone meal or dust that is sifted through a  $\frac{1}{2}$ -in. sieve. It is also desirable, though not absolutely necessary to ensure success, to add a portion of broken charcoal to the compost. Drain the pots well by placing clean potsherds at the bottom, and over them a layer of fibre from which the finer particles of soil have been sifted; this is to keep the drainage perfect, by preventing the finer particles of the compost from working down into it. After the tree has been turned out of the pot in which it had been growing previously, with a pointed stick pick out the old material that had been used for drainage, and most of the old effete soil. The tree should not be potted deeper than it had been previously, and the compost must be pressed firmly round the ball with a wooden rammer. After potting the plants must be placed in a warm house, but it is not well to water the soil for a day or two, especially if the roots were not in a very healthy condition at the time of potting. The house may be kept rather close, and the trees be syringed until the roots begin to work into the new compost: this care is applicable to summer potting; in winter it is unnecessary. When the roots are active and have taken firm hold of the sides of the pots, plentiful supplies of water are necessary, and the trees ought to be syringed well twice daily.

The insect pests that attack Orange trees are scale and mealy bug, both of which will thrive on them. A clammy formation also gathers on the upper surface of the leaves in consequence of the presence of scale. To remove them we do not find any better plan than to wash the leaves and wood with tepid water, in which soft soap has been dissolved. The constant syringing keeps the trees healthy, but this must be discontinued when the fruit begins to change for ripening. A rather dry atmosphere is desirable when the trees are in flower, as the fruit does not set well in a moist close atmosphere early in the year.

There is another variety of dessert Orange besides those already named that ought to be in every collection. It has been grown by some persons for many years, and when cultivated under the best conditions it is superior in flavour to any other. This is named the Prata or Silver Orange. By following the above cultural directions success will be ensured, and the pleasure to be derived from successfully cultivating these fruits is very great.—"Florist."

**New Chrysanthemum.**—I have a fawn-colored sport from that justly-admired Chrysanthemum Lady Hardings, and, as it partakes in every particular of the good qualities of its parent, it will doubtless prove to be a valuable addition to our list of exhibition Chrysanthemums. It is characterised by breadth, depth, and smoothness of petal, very large size, and perfectly incurved—in fact, in the latter respect it stands unrivalled. It has been exhibited at the South Essex Chrysanthemum Show, and was highly commended. F. T. DAVIS, *Zark Nursery, Plumstead Common*.

## THE FLOWER GARDEN.

### HYBRIDIZATION OF LILIES.

TEN or twelve years ago, I began a series of experiments in hybridizing Lilies, and have continued them at intervals up to the present time, with results some of which are worth recording. My first attempt was to combine the two superb Japanese Lilies, *L. speciosum* (lancifolium) and *L. auratum*. The former was used as the female parent. Four or five varieties of it, varying from pure whites to deep red, were brought forward in pots under glass. This was necessary, because *L. speciosum* does not ripen its seed in the open air in the climate of New England. When the flowers were on the point of opening, the anthers were carefully removed from the expanding buds by means of forceps. As the pollen was entirely unripe, and as pains were taken to leave not a single anther in any of the flowers, self-impregnation was impossible. The pollen of *L. auratum* was then applied to the pistils, as soon as they were in condition to receive it. Impregnation took place in most cases. The seed-

until some time after; and when the buds at length appeared, they were precisely like those of the female parent, *L. speciosum*. The first bud opened on the 7th of August, and proved a magnificent flower, 9½ in. in diameter, resembling *L. auratum* in fragrance and form, and the most brilliant varieties of *L. speciosum* in colour. In the following year, it measured nearly 12 in. from tip to tip of the extended petals, and in England it has since reached 14 in. The stock of it has been placed in the hands of Mr. Anthony Waterer, of Knaphill, Woking, who has given it the name of *L. Parkmanni*. In this one instance, the experiment had been a great success; but of the remaining fifty hybrids, not one produced a flower in the least distinguishable form that of the pure *L. speciosum*. The influence of the alien pollen was shown, as before noticed, in the markings of the stem, and also in a diminished power of seed-bearing; but this was all. Next year, wishing to see if the male parent would not make his influence appear more distinctly in the second generation, I fertilized several of these fifty hybrids, with the pollen of *L. auratum*, precisely as their female parent had been fertilized. The crop of seed was extremely scanty, but there was enough to produce eight or

Landscapes of the Great Painters: River scene at sunrise, by Theodore Rousseau.

pods swelled, and promised an ample crop of seed; but the experiment was spoiled by the bad management of the man in charge of the greenhouse, in consequence of which the pods were attacked by mildew. In the next year, I repeated the attempt, with the same precautions. This time the seed was successfully ripened. Being sown immediately, a portion of it germinated in the following spring, and the rest, a year later. In regard to this seed, two points were noticeable; first, it was scanty, the pods, though looking well, being in great part filled with abortive seed or mere chaff; and, next, each good seed as there was differed in appearance from the seed of the same Lily fertilized by the pollen of its own species. The latter is smooth, whereas the hybrid seed was rough and wrinkled. About 50 young seedlings resulted from it, and their appearance was very encouraging, because the stems of nearly all were mottled in a manner characteristic of *L. auratum, speciosum*. Here, then, was a plain indication of the influence of the male parent. The infant bulbs were pricked out into a cold frame and left there three or four years, when, having reached the size of a pigeon's egg, they were planted in a bed for blooming. This was in 1869. Towards midsummer, one of the young hybrids showed a large flower-bunch, much like that of its male parent, *L. auratum*. The rest, about 50 in all, showed no buds

ten young bulbs. Of these, when they bloomed, one bore a flower combining the features of both parents; but, though large, it was far inferior to *L. Parkmanni* in form and colour. The remaining flowers were not distinguishable from those of the pure *L. speciosum*. While making these experiments with *L. speciosum* and *L. auratum*, I made similar attempts to produce hybrids of other Lilies. In the spring of 1867, I planted twenty or more strong bulbs of *L. superbum* in a favourable spot, and, when they began to bloom, fertilized them with the pollen of *L. speciosum, L. auratum, L. tigrinum, L. chalesoncum, L. umbellatum, L. Thunbergianum, L. longiflorum, and L. tenuifolium*. All the anthers were previously removed before ripening, by slitting the sides of the still unopened bud and extracting them with forceps. There were no other plants of *L. superbum* in the garden, or in its neighborhood; so that in this case, as in the former, fertilization by the pollen of their own species could not take place. Seed-pods, large and well shaped, were formed in abundance; but when they ripened in October some of them contained nothing but chaff. Others had a few imperfect seed, while others gave a fair supply of seed as good as could be desired. It was sown in pans, germinated in due time, and produced several hundred young bulbs; but when these came into bloom, not a single flower of them

all was in the least distinguishable from the pure *L. superbum*. Of eight different male parents, not one had impressed his features on his hybrid offspring. Not only in their flowers, but in their leaves, stems, and bulbs, the young plants showed no variation from their maternal parent. In the following year, I set some of them apart from the rest, and applied to them, as to their mother before them, the pollen of several species of Lilies. This time, the seeds were extremely scanty. A few, however, were produced; but the plants and flowers that resulted from them, were to all appearance, *L. superbum* pure and simple.

Another subject of experiment was *L. umbellatum*, which I fertilised with the pollen of *L. auratum*. Seed was produced in abundance, and the young plants began to bloom in the second year. Many of them were not to be distinguished from the pure *L. umbellatum*. Others showed unmistakable marks of their hybrid origin in the defective condition of the organs of reproduction, the anthers being abortive or wholly wanting, as were also, in a few cases, even the pistils. In some instances the corolla was deformed, some of the petals being absent, and others small and ill-shaped. But while the influence of the alien pollen was shown in these defects, no features of the male parent appeared either in form, colour, scent, or manner of growth.

No Lily seems to offer better prospects to the hybridiser than *L. longiflorum*. The species itself is not a good seed-bearer in our climate; but one of its varieties, known as *L. longiflorum Takesima*, bears seed very freely. This variety is also distinguished by superior vigour of growth, and by the dark markings of its stem; the pure white of the large trumpet-shaped flowers seemed peculiarly fitted to receive impressions of colour from an alien parent. I therefore fertilised them with the pollen of a deep red variety of *L. speciosum*. The operation was performed under glass and with the greatest care. The seed was abundant, and, being sown immediately, it all germinated in the following spring. When the flowers opened, two years after, they showed no sign whatever of the male parent; the pure white was without tint or spot, neither did the foliage and stem show the slightest trace of foreign influence; the plants were in pots. I removed a number of them to the greenhouse, and, having no pollen of *L. speciosum* at hand, fertilised them with that of *L. auratum*; several refused to bear seed, while others produced it freely. The young plants resulting from this last experiment bloomed in the greenhouses of the Bussey Institution in the spring of 1874. Neither *L. speciosum*, their grandfather, nor *L. auratum*, their father, had produced any effect whatever on the pure white of their petals; they showed differences of habit among themselves, some being very tall and vigorous, and others compact and bushy, with a tendency to bloom in clusters, but these may have been mere seedling variations, with which the hybridisation had nothing to do. Yet distinct evidence could be seen of the action of the alien pollen. Some of the anthers were small and abortive, and some of the pistils were imperfect; but what was more to the purpose was the changed colour of many of the former; the white petals had completely resisted the foreign influence, but the yellow anthers had undergone a marked change; about half of them were turned to a chocolate colour, approaching that of the anthers of the male parent, though not so deep.

I determined to try the effect of fertilisation in the third generation, and applied the pollen of both *L. auratum* and *L. speciosum* to ten or twelve of the young hybrids whose organs of reproduction appeared to remain perfect; not one of them would bear seed. In the present summer (1877) I repeated the experiment on a larger scale, and fertilised about fifty flowers after removing the anthers before they had ripened. Nine of these produced seed-pods, all of which were small and deformed, except two; these two contained, along with chaff, a few seeds of promising appearance; the remaining seven were full of chaff alone. The reproductive power had been nearly destroyed by hybridisation repeated through three generations. What will result from the few seeds obtained remains to be seen. Some Lilies refuse to be fertilised by the pollen of certain other Lilies. Thus I have found that *L. speciosum*, so readily fertilised by *L. auratum*, will give no seed to the pollen of either *L. Browni*, *L. longiflorum*, *L. canadense*, *L. tenuifolium*, or *L. umbellatum*. Yet the converse does not always hold true, for several of these last-named species will bear seed when fertilised with the pollen of *L. speciosum*.

A great number of subtle influences may modify the results of experiments in hybridization; yet those described above were so various, and extended over so many years, that the general facts to which they point may, I think, be regarded as assured. An eminent botanist has suggested to me that the tenacity with which Lilies fertilised by Lilies of other species retain their characteristics unchanged, may be explained by supposing that the offspring are really no hybrids at all, but results of parthenogenesis, that curious pheno-

menon which sometimes occurs in the lower orders of animals, and by which a single impregnation continues to take effect in several successive generations; in other words, that a Lily of which the flower was fertilised in any one year by its own pollen may bear seed in the next year without being fertilised again. There are two good reasons for believing that parthenogenesis had nothing to do with the cases in question. In the first place, some of the Lilies subjected to experiment were young plants that had never bloomed before, and consequently could not have been fertilised before. In the next place, every species fertilised by me with the pollen of another species showed, with the single exception of *L. superbum*, evidence of hybridity, which, though slight, was convincing. This evidence consisted in markings of the stem resembling those of the male parent, in a changed colour of anthers, also resembling that of the male, and in the frequent occurrence of abortion in both anthers and pistils, with consequent sterility. That the seedlings were really hybrids, there can be no reasonable doubt, though nobody would have suspected it from casual observation. The conclusion is that Lilies, or at least the principal species of the genus, when hybridised, produce offspring which show the features of the male parent very slightly, or only in exceptional cases. These exceptional cases are, nevertheless, so remarkable at times, that the rarity of their occurrence ought not to discourage the hybridist. FRANCIS PARKMAN.

#### MY TOWN GARDEN.

In addition to the hardy border plants which I have before named (see p. 491 Vol. XII) as being desirable for a town garden, I may now mention:—

**BUPHTHALMUM SALICIFOLIUM.**—This is a very showy plant. Its stems are erect and clothed with leaves, and they bear large bright yellow flowers, with broad spreading rays, height  $1\frac{1}{2}$  ft. It flowers in July, August, and September, and succeeds in ordinary garden soil. It is propagated by division of the roots.

**HARPALIUM RIGIDUM.**—This has bright orange yellow blossoms with large conspicuous brown and orange centre. The flowers are from 4 in. to 5 in. in diameter, and are borne in great profusion from early in July to October, height 4 ft., and habit neat, very effective in the mixed border, and will grow in any good soil. It is increased by divisions of the roots in autumn or spring.

**DICTANUS ALBUS** (known as *Fraxinella*).—The stems of this rise stout and erect to a height of about 2 ft., and bear a spike of pretty creamy-white flowers (there is a variety with dark coral red flowers). It succeeds best in rich, deep, but dry loam; it is a handsome border plant which flowers in spring, and which may be propagated by division.

**GAURA LINDHEIMERI.**—An elegant plant, producing beautiful masses of light flexible stems about 18 in. or 2 ft. high. The stems terminate in long open spikes of pink or red and white flowers, produced in July and August and onwards, in mild seasons and places, till October. It does best in sandy loam, and is propagated by division.

**ZAUSONHERIA CALIFORNICA.**—Grows about 1 ft. or  $1\frac{1}{2}$  ft. high, in an erect graceful style. Its flowers are produced in the axils of the leaves on short stalks. They are bright red or crimson, and appear in summer and autumn. It requires a warm situation, and rich, light well-drained soil. It is increased by division in early spring.

**ENOTHERAS.**—*Æ. Youngii* is without doubt one of the showiest perennials in cultivation, and one which can be highly recommended. It forms a pyramid of blossom about  $2\frac{1}{2}$  ft. in height, continuing in beauty for a long time; the flowers, which are large, are of a deep golden yellow colour; a grand plant for a light sandy loam, and one which may readily be propagated by division in early spring. *Æ. extima* is a pretty dwarf growing plant with large Magnolia-like blossoms of the purest white, and deliciously fragrant. *Æ. speciosa* is a very showy and effective species, and one which should be in every garden. It is a free-growing, hardy perennial, usually attaining from  $1\frac{1}{2}$  ft. to 2 ft. in height, and forming neat tufts composed of many erect stems, which are covered from June to October with numerous large white fragrant flowers. As a border plant few can be found to equal it. Propagation and soil same as above. *Æ. riparia* is another showy species, and one of the best; it grows about 2 ft. in height, and consists of a number of slender branching stems that produce abundance of showy yellow flowers.

**POTENTILLA**.—*P. formosa* is a beautiful plant which should be found in every garden. It is of neat, erect habit, about 2 ft. in height, and bears an abundance of Cherry-red flowers. It will thrive in ordinary loamy soil, and may be propagated by division in autumn or spring. *P. calabra* is a neat and pretty species with elegant silvery foliage, and large lemon-coloured flowers. *P. nivalis* is a very pretty white blossomed dwarf plant, the foliage of which is covered with long satiny hairs.

**POLEMONIUM CERULEUM** (JACOB'S LADDER).—A well-known plant, which has long been cultivated in gardens of all classes, but now rarely seen except in those of the cottager or amateur. It grows about 2 ft. high, and bears pretty soft blue flowers, which appear in June and July. It succeeds best in moist deep loam, and is benefited by being annually transplanted into new or fresh soil, and by being divided. A variegated variety of this plant is one of the most elegant hardy plants in cultivation. It has all the grace of fern that belongs to a delicate Fern, along with a distinct and beautiful variegation.

**STOKESIA CYANEA**.—A showy autumn-flowering perennial, about 2 ft. in height, with large blue flowers, from 3 in. to 4 in. across, something like those of an Aster. It succeeds perfectly in any ordinary garden soil, if well drained, and may be propagated freely by division of the roots.

**ERODIUM**.—*E. Manescavi* is a handsome plant, indeed one of the best of its family. It forms a tuft of graceful, much-divided foliage, about 1 foot in height, from which issue numerous stems, bearing umbels of large purplish red flowers, each 1 in. across. It keeps in flower from early summer until late in autumn, and grows freely in any tolerably good soil. *E. macrademum* is a graceful little plant, which produces tufts of Fern-like foliage, with numerous flowers, on stems about 6 in. in height. The two upper petals are of a pale rose colour, with a blackish blotch at the base, while the lower ones are of a flesh colour veined with purple. Ordinary garden soil will answer for both; they may be divided in the autumn.

**CEDRONELLA CANA**.—This grows about 2 ft. high, erect and graceful. The flowers, which are of a lively red, in compact whorls are arranged closely on the upper half of the stems, and appear in July and August. Light rich sandy loam suits it perfectly. *C. mexicana* is taller than the last, and more luxuriant in every way. The flower spikes consist of interrupted whorls of red flowers which open in September and October. These two Cedronellas are both choice border plants.

**ERYNGIUM AMETHYSTINUM**.—A very striking plant. It grows about 3 ft. high, and has stout woody stems clothed with deeply-out and jagged hard leathery leaves, grey, green, or glaucous below, but growing gradually blue, as do also the stems and every part of the plant, a colour which increases in depth as the flowers are reached. The latter are light blue; they appear in July, and last for a month or two. *E. bromeliifolium* is also a distinct and striking plant, which has long Yucca-like leaves, very spiny at the margins. It grows 3 ft. high, and produces numerous white flowers. *E. maritimum* is one of the most attractive plants in cultivation; it has glaucous rigid foliage of great substance, and very spiny along the margins. It grows about 1 ft. high, and bears numerous small blue flowers, which appear in July and August. It succeeds well in light sandy soil, and is readily propagated by division. L. E. X.

#### CLEMATISES FOR LOW WALLS.

It has been said that Clematisses are unsuited for planting against low fences, but that is a mistake. I have a low west wall not more than 4½ ft. in height, against which I have planted several kinds of Clematisses, and by means of a little careful training they are made to cover the wall with blooming wood, and they present a charming sight from July on to quite late in the summer. In the first place, the wall is covered with a galvanized wire-netting of a two-inch mesh. Being securely fastened at top and bottom, it greatly aids the proper training of the branches, and saves an immense deal of labour in the way of nailing, &c. It is not necessary that the plants be young, for those to which I am referring were planted three years ago; they are cut down quite close to the surface of the

ground in spring, after being well mulched with manure during the winter.

The plants generally make an early growth, and throw up seven or eight strong main shoots. These are stopped just beyond the first joint, and are tied out in a horizontal position as close to the ground as possible. Then from each of the two eyes another shoot pushes, and these are again stopped and similarly tied out. This is done again and again, until the surface of the wire-work is covered with young flowering wood from the bottom to the top, and when in bloom the plants present the appearance of a perfect surface of flower.

Two things result from this mode of treatment: the individual flowers are not so fine, but they are much more numerous, and this makes up for lack of individual size; secondly, the time of blooming is somewhat retarded; but it is in its turn compensated for by the fact that it is much more prolonged. This past season I had Clematiss flowers right up to the beginning of November, and, it is not too much to state, in perfect sheets. The lateness of blooming is not of much moment, because the wall is also partly covered with other things that bloom earlier in the summer, such as *Fuchsia Riccartoni*, *Gum Cistus*, and climbing *Tropæolums*. The *Jasminum nudiflorum*, too, flashes out in golden-yellow at mid-winter, in company with the Orange berries of *Cratægus Pyracantha*, and *Pyrus japonica* in early spring. Some of the spring-flowering section of Clematisses might be employed with advantage where the aspect is warm and sunny, but my wall, not being this, I have refrained from planting them.

What are the best varieties? it may be asked. I recommend *Alexandra*, pale reddish-violet; *Jackmani*, deep violet-purple; *Lady Bovill*, greyish-blue; *Magnifica*, purple, shaded with crimson; *Rubella*, rich claret; *Rubro violacea*, maroon, shaded with reddish-violet; *Star of India*, reddish-purple, with purple bands; *Tunbridgensis*, dark blue, shaded with purple; *Velutina purpurea*, rich blackish-mulberry; and *Viticella rubra grandiflora*, a very near approach to a red Clematis, the flowers not large, but freely produced, and of a fine, bright puce-crimson colour. All the foregoing are vigorous-growing varieties, and I have not included any of the more delicate of the lanuginosa type, and those that are intermediate between the spring and the summer-flowering type. These can be introduced at any time by any one adopting this method of growing these fine climbers. New ones are constantly appearing, and a little change is advisable at times.

Now is the time to plant Clematisses. Every nurseryman grows them because they are so much in demand. They should be had in pots, but the ground in which they are to be planted should be deeply dug and well manured before planting is carried out. Clematisses are gross feeders; they throw out a large number of stout, wiry roots, and these roots need abundant nutriment. During the summer months all Clematisses, and especially those planted against walls, need abundance of water when the season is at all dry, and a good surface-mulching with fresh cow manure materially assists them; soap suds are also of advantage, and a little guano-water at the flowering time. D.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN:

**Hardy Chamerops**.—I shall be glad if any reader of THE GARDEN will inform me whether *Chamerops excoela* and *C. Fortunii* are one and the same Palm, and if not, whether they are equally hardy. Under the impression that they are, I have recently imported some large specimens of *C. excoela* from Algeria, with the view of planting them out permanently in a wild garden in the north of England, but some dealers here, I perceive, quote them in their catalogues as distinct Palms, whilst Messrs. Backhouse & Sons and the Societè Algerienne class them as *synonymous*.—T. B.

**Plants in Bloom in Sussex**.—The following plants are now in flower in this and neighbouring gardens, viz., *Scabiosa*, *Paeonias*, *White Rocket*, *Wall-flower*, *Erythronium*, *Marginal*, *Purple Verbena*, *Mignonette*, *Silene*, *Carration*, *Gladiolus*, *Aranthus*, *Myrtle*, *White Heath*, *Erica carnea*, *Berberis*, *Yellow Alyssum*, *Lanterninus*, *Andromeda*, *Christmas Roses*, *Violets*, *Garden Anemones*, double and common *Primroses*, *Polyanthuses*, *Tritoma Uvaria*, *Sweet William*, *Rose-buds*, *Candytuft*, *Ceanothus*, *Fuchsia*, and *Forget-me-nots*; Ferns are untraced in some gardens, and *Gloire de Dijon* roses are well in flower.—S., *Waverleyfold*.

## GARDENING FOR THE WEEK.

## Orchids.

NEXT in importance to the treatment requisite to promote good growth amongst Orchids during the active season, are the conditions under which they are kept through this, their period of rest. It often happens that comparatively little thought is bestowed upon the important, yet necessarily somewhat varied treatment to which the different groups and individual species should be subjected during the winter season, the prevailing impression amongst inexperienced growers being, that if the plants be submitted to a certain period of dry treatment, frequently carried out, without sufficient discrimination being exercised as to the requirements of the various families and kinds, by which the system pursued is anything but in accordance with the well-being of a great portion, all is well. There can be no doubt that the treatment which Orchids receive through their time of rest, both as to temperature, and the more or less dry condition of the roots, as well as the atmosphere, requires to be regulated to a very considerable extent by the conditions under which they have existed during the growing season; for instance, where plants are subjected to a high temperature, far away from the glass, and closely shaded, with comparatively little air—such conditions, in fact, as are calculated to produce a collective maximum growth, with large leaves of that deep green colour so much prized by many, they are anything but calculated to bear the severe drying ordeal to which they are often submitted; nor will they, under such conditions of growth, bear without injury so low a temperature as might be hazarded in the case of plants, the growth of which had been produced under treatment of a nature such as to give a promise of better permanent results. From long practice and observation, I have, indeed, come to the conclusion that in the case of no other family of plants is the fatal mistake of too much heat, with a moist, coddling atmosphere, so much committed as in that of Orchids. Coming, as many of them do, from hot, excessively damp regions, where the atmosphere during a great portion of the year is charged with moisture almost up to the point of saturation, led many to suppose that under our necessarily highly-artificial conditions of cultivation it was requisite to imitate this, which, no doubt, to a certain extent is correct, but the extremes in these directions have been carried so far as to result in the ultimate death of hundreds of thousands of plants, worth in the aggregate immense sums of money. It should ever be borne in mind, that in the cultivation of plants under glass, and more especially such as in the continuous application of artificial heat, with the limited admission of air consequent upon the necessity of confining the moisture in the atmosphere requisite to maintain the required humidity, a given temperature resulting from fire-heat will have a much greater influence in promoting, or perhaps more correctly speaking, forcing growth, than a similar temperature would have in the open air, where the plants existed in a wild state. This, so far as I have been able to judge from the temperature during the growing season of the localities from which many species come, and the progress the same plants make under the lower artificial temperature of the Orchid-house, will make a difference of 7° or 8°; hence it follows that a summer temperature of 75° or 80°, resulting from fire-heat in the Orchid-house, will exert as great an influence upon a plant of *Saccolabium Blumei* or *gottatum* from Java or Ceylon, as the higher range of 84° or 88° would have on them in a wild state. This is a subject to which I have given particular attention, not only so far as it relates to Orchids, but other heat-requiring plants as well; and I have noticed that the difference in the effects resulting from an artificial temperature, and that produced by the sun in the open air, was correspondingly greater in proportion to the lessened admission of external air to the structures in which the plants were grown. Even in one's own case, the feeling produced in a glass-house with a high temperature and a moist atmosphere with comparatively little external air admitted, the oppression experienced is such as often to lead us to suppose that greater heat existed than was really the case when the thermometer was looked at, and I have not the slightest doubt that heat under such conditions has a like influence in forcing growth; and a few year's experience in the cultivation of these plants will not fail to show those who are at all observant, that in Orchid-houses in which a high temperature is maintained during the growing season, the plants assume a character in accordance with this view. Yet, however fresh and vigorous the plants so treated may appear at the end of the growing season, they are anything but calculated to bear an ordeal of several drying up through the winter. The large-leaved *Vandas* of the *suavis* and *tricolor* sections, too, often show the effects of coddling treatment through the growing season by losing a disproportionately large number of their lower leaves when the atmosphere, and particularly the material in which their

roots exist, are subjected to the severe drying process in the winter, by many deemed essential to their flowering sufficiently, a consumption which would be much better insured by a lower temperature whilst growth was being made, accompanied by more light, more air, and less moisture than they are frequently subjected to. *Saccolabium* and *Ardisias* are alike, though not quite to the same extent, influenced, and where plants have been grown in a way that renders the foliage unable to bear a considerable amount of drying up, it is better to be content with a less display of flower at the blooming season than to treat them in a manner that will cause a loss of too many leaves; the drying should not be carried so far as to make the foliage shrink, or destruction will be the result. *Phalaenopsis* have suffered to an incalculable extent through the maintenance of too high a temperature during the winter season. I have invariably observed that where these plants have continued for any number of years in a healthy, flourishing condition, it was where they were submitted for a considerable length of time during the winter months to a lower temperature than, judging from the countries from which they come, it might be supposed they could bear. This has sometimes happened in houses in which the heating was insufficient in cold weather to keep the temperature within a good many degrees so high as the grower would have liked; they do best with a night temperature of 60° during the winter, and a longer rest than many Orchids from countries where a high temperature exists require. At the same time, care must always be taken to prevent these plants from getting too dry at the roots, existing as they do without pseudo-bulbs or strong fleshy stem—little, in fact, excepting leaves and roots; therefore, if the latter be allowed to get over dry, the lower leaves are certain to decay sooner than they ought. T. BAINES.

## Stove and Greenhouse Plants.

Camellias cannot withstand dryness at the roots, and when this happens, particularly when they are making their growth, they become stunted, the roots are weakened, and the flower-buds fall without opening; this will also occur if the atmosphere be too dry when they ought to be expanding. They must not, however, be over-watered. Sow Palm seeds, as soon as imported in pans or boxes of loamy soil; the boxes may be kept in any odd corner until the seeds have germinated, when they must be placed in a more prominent position. Rooted cuttings of *Stephanotis*, *Gardenias*, *Bouvardias*, *Aralias*, *Ixoras*, *Dracaenas*, *Dieffenbachias*, *Pavettas*, &c., must be potted singly, plunged in bottom heat, and kept under hand-lights or bell-glasses. Sow some *Anthurium* and *Aglaonema* seeds in some damp, spongy material, in heat. Gather the seeds of *Aroids*, *Ardisias*, *Solanums*, &c., as soon as ripe. Sow some *Cyclamen* in an intermediate temperature, and keep the pans containing the seeds near the glass. Sow Fern spores in rough peat, either in pans or pots, under bell-glasses, &c. Pot off the seedlings as they become fit for that operation, and also give older seedlings a shift. Cuttings of soft-wooded Heaths may yet be struck, as may also the young points of *Boronias*, *Polygals*, and other hard-wooded greenhouse plants. Cut over a few *Euphorbias* and place them in a moderate heat, to yield young shoots for cuttings. Separate and pot singly autumn-struck cuttings of *Azaleas* and *Camellias*. Place last autumn's struck *Camellias*, or those now sixteen months old, on a shelf near the glass, for grafting on in February and March. Repot some of the Heaths, in order that too much work may not occur at a time when it cannot be overcome. Introduce *Pelargoniums*, *Verbenas*, *LOBELIAS*, *Tropaeolums*, *Lantanas*, *Coloneses*, *Iresines*, *Alternantheras*, *Mesembryanthemum cordifolium*, and similar plants into a brick moist temperature, to start them into growth for cuttings. Keep roots of *Cannas* in pots dry by building the pots one above another in some dry, cool place. Gradually dry off roots of *Dahlia imperialis*. If seeds of the silver-leaved *Centaureas* be now sown in heat they will make fine plants by bedding-out time; they should be sown in shallow pans in fine soil, containing a little sand and well-rotted leaf-mould; let the seeds be only just covered with soil, and keep it slightly damp. *Ageratum* which have to be raised from seeds may be treated in the same way. Golden *Pyrethrum* is best raised from seed, as propagated in this way, the plants have not such a disposition to flower, and are finer than those obtained from outtings or division; sown now in warmth they will soon be up, they can then be placed in boxes or pots. For carpet bedding such subjects as *Alternantheras* and the crimson *Iresine Lindeni* are almost indispensable; their propagation should be at once attended to. *Verbenas*, more particularly the white kinds, are very liable to the attacks of mildew; on its first appearance they must be dusted with sulphur. It will be well now to put the store plants of *Verbenas* in a little heat to cause them to push young growth for outtings; 50° by night will suit them well; let them be on a shelf or in some place where they will receive plenty of light, and keep them regularly supplied with water; an application of liquid manure once a week will be

beneficial to them, and will cause the production of more cuttings. Heliotropes, Lobelias of the speciosa section, and Ageratum should also be put in warmth, for if the cuttings be not soft and young they do not root so readily. *Humes elegans* sown last summer have plenty of roots, shift them now in pots big enough to serve till planting-out time arrives. Aphides must be guarded against, for if left for any length of time undisturbed they spoil the leaves.—T. B.

#### A Vase of Flowers.

It may have been noticed in the various engravings from flower pictures we have published in THE GARDEN, how free and open the compositions usually are. They are arranged, in fact, by no means in the close-headed bouquet plan as yet so common, notwithstanding considerable recent improvements in arranging flowers. In these Cauliflower-like nosegays, &c., we get too many flowers, so that one destroys the good effect of another, and the individual grace of any one plant is lost "in the mass." Boldness of form is rarely allowed in such compositions, whereas in the painter's productions we see it

A Vase of Flowers.

allowed full play. The ideas that guide the artist may well be followed by the gardener. A few flowers shown with all their beauty of form and foliage, in addition to the flower, will afford a better effect than many crowded together, and the crowd is much more difficult to arrange well than the few.

#### Flower Garden.

In order to have a garden enjoyable, the roller, broom, and rake must be frequently at work. Use the hoe amongst growing plants, for a loose and open surface is congenial to their health. Prune deciduous shrubs; but the pruning of evergreens should be deferred until spring. All kinds of trees may still be transplanted, especially such as are deciduous. Proceed with any alterations that may have been previously determined upon. Any ground yet unreturned should be dug over as soon as practicable; if for Dahlias, Foxgloves, Hollyhocks, or other strong growing grass-feeding plants use plenty of manure; but if for Pelargoniums, or other plants that are required to produce abundance of flowers and to keep dwarf in growth, a dressing of leaf-mould will be more beneficial. Lay up the ground quite roughly, in order that the frost, wind, and sun may ameliorate and sweeten it. Break up the surface of gravel walks, but not so deeply as to disturb the rubble in the bottom; and, if necessary, apply a coating of fresh gravel. Roll Grass verges, so that they may not appear too high above the gravel when cut. Protect all tender plants with

mulchings and temporary light coverings against frost. In the case of flower beds, the surface soil should be slightly loosened whenever the weather is dry, but not so deeply as to injure bulbs planted therein. Push forward, as much as possible, such operations as involve the removal of soil or the wheeling of gravel, compost, and manure; remove overgrown or superfluous trees from the lawns or elsewhere during dry weather. Shrubberies may also be thinned out by the removal of unnecessary plants. When the weather is such as to stop the progress of all operations in the open-air, attend to the preparation of stakes, labels, and birch besoms, &c., all of which will be found useful as the season advances. Many bulbs and hardy herbaceous plants cultivated in the open border disappear altogether during winter, and their crowns are not infrequently injured by being trampled upon, unless they are all distinctly labelled; but where this is not considered necessary, a stout oak peg should be fixed in the centre of each group or patch of bulbs or herbaceous plants of any kind which disappears, and this peg should stand some 4 in. or 5 in. above the surface of the soil, and will serve to indicate the whereabouts of the plants, and prevent them being injured when the borders are dug or pointed over early in spring. Hardy annuals in pots intended to be planted out early, with the view of producing an early display, should have, for the present, the protection of a pit or frame, and are not unlikely to be injured by slugs or snails, to prevent which they should be frequently examined and occasionally dusted with quick-lime, if found to be necessary. Protect also such winter-flowering plants as the *Chimonanthus fragrans*, and the Christmas Rose, which will now be in full bloom if protected by a frame or a hand-glass.

#### Hardy Fruit.

This is a very good time for the planting of all kinds of hardy fruits, and, if weather permits, the sooner it is done the better; but on no account attempt to plant when the ground is in a sodden condition. Do not plant too deeply; as a rule, trees should never be planted deeper than they originally were in the nursery. After planting, mulch with either rotten manure or litter. This mulching is of the greatest importance, for, in the first place, it protects the roots from drying winds and frosts; and, secondly, it matures the ground. The pruning of Apples, Pears, Plums, and Cherries should be done as opportunity offers; and, in the case of strong growers, it may be necessary to root prune to get them into a fruitful condition, which operation is best performed by entirely lifting and replanting trees of a manageable size, and, in the case of larger ones, digging out a trench a reasonable distance from their stems, and gradually working round them, taking care to cut the tap roots especially. The pruning of Gooseberries and Currants should yet be delayed, as frequently the birds make such havoc of them when the buds first begin to swell, and immediately after severe weather, that it is better to wait till food is more plentiful for the birds than lose the entire crop by early pruning. Strawberry beds that were trimmed and dug in the autumn ought now, if not previously done, to be well manured, leaving the material on the surface of the ground as a protection to the plants. Draining, levelling, soil carting, and otherwise preparing ground intended for fruit trees, may be done when the ground is not in a fit state for planting, and advantage should thus be taken to forward all operations of this nature in anticipation of the busy time approaching. Proceed with the pruning and nailing of wall trees, such as Plums, Pears, Cherries, and Apricots. Moss growing on the stems of old trees should be scrubbed off, and afterwards the large branches should be washed with a mixture of lime-water, soot, and brine. Cut off shoots to be used as scions in grafting, and insert their ends in soil in some well-sheltered situation, and head back stools.

#### Indoor Fruit Department.

In starting Vines, the chief point to be kept in view is a moderately strong bottom heat to stimulate the roots into action. To ensure this, therefore, form new beds of fermenting material, both inside and out on the top of the roots of Vines newly started; make these beds of sufficient thickness to raise and retain a heat of 90°. The inside bed will greatly assist in keeping up the temperature to 55°, which is quite high enough for the first week or two. When a portion of the fermenting material is turned over daily, it gives off a warm steam, which is very beneficial to the Vines during hard firing. Cover the outside bed with glass sashes or boards, to keep out wet and wind, thus economising the heat. Add fresh lings to outside beds made up a month or two ago, should they need such attention. The root temperature must, on no account, be allowed to decrease at this stage of growth, or a severe check will be the result. The fermenting material may now be removed from the inside of houses which were started in October or on the 1st of November. Tie in the young shoots as they require support; any which have

grown in an upright manner should only be brought at first half way into their proper positions, but at the second tying with strong matting, bring them into their right places. Those who propagate Vines in pots put in the eyes about this time. Select the eyes from the best ripened prunings preserved for that purpose; cut the wood straight through, directly above the eye, leaving about 1½ in. of it underneath the eye, out off slantingly, and make an incision opposite the eye, and the operation is complete. Three-inch pots should now be prepared for their reception; these should be dry and quite clean. A few small crocks should be put in for drainage, and the rest of the space should be filled up with good loam. A hole should then be made in the centre of the soil, and filled with silver sand, and the eye should be firmly pressed into position with the hand until the notch made opposite the eye is covered. This will leave the eye only above the soil, into which roots will be pushed from the notch. The whole should be gently watered, and then set in some cool spot, from which frost is excluded, for a month before being placed in heat. Look over all Grapes still hanging on the Vines or in bottles, and remove all decayed berries. Keep the air of the house dry and airy, and the water bottles regularly filled. Great care and attention will be required in every stage of Pine-apple culture for the next six weeks to be successful with the plants when in blossom, and with fruit that is up, to prevent any kind of abortion to a single pip, or the uneven swelling so easily produced at this season. There must be no check or hurry, either by attempting to drive or retard those fruits that are in any stage of swelling.

#### Kitchen Garden.

In ordering seeds for the coming year, reliance should principally be placed upon old well-tried varieties; at the same time, in order to keep pace with the times, a few of the novelties introduced may be tried. Take advantage of the present wintery weather to finish wheeling the manure to uncropped land; place it in large heaps in the centre of the plots, to avoid loss from the drying influence of the atmosphere, and do not level it down till just before the land is in a fit condition for digging. Prepare fresh stable manure and leaves for making hot-beds by thoroughly shaking and mixing the material together. Where leaves cannot be readily obtained, it will be a very great advantage in making hot-beds if cow or pig-manure can be had to mix with the stable-manure. Horse-manure is hot and fiery, and the addition to it of about one-third, or even a fourth, of its bulk from the cow-shed or pig-stye—which is of a cooler nature—will cause the heat to be more steady and permanent. Where hot-beds are depended on for the first early Cucumbers, a bed large enough for a one-light frame should be put up now for raising the young plants, should no other means exist for bringing them forward. In cold situations, where it was not thought desirable to sow Peas in autumn in the open-air, preparations should shortly be made for fetching up lost time, by sowing some under glass for planting out when the weather becomes more favourable. They may either be sown in 48-sized pots or in troughs, which any unskilled workman, who has a few rough boards, can put together, or they may be sown in fibry squares of turf, hollowed out in the centre. It is not advisable to start them in too high a temperature, as there is plenty of time without undue forcing. A frame placed on a bed of leaves, where they can be near the glass, will do well, or, if more convenient they may be placed in any house where forcing has just commenced. Loosen the soil amongst Cabbages, Coleworts, Lettuces, Parsley, transplanted Onions, and similar crops. Get August-sown Onion beds thoroughly cleaned. When finished, slightly dig or loosen the alleys, and transplant Lettuces or Cabbages therein. Get all empty quarters manured and trenched, throwing the soil into ridges 2 ft. apart. Vacant ground under fruit trees manure and dig for Radishes, and be sure to have the trees thinned or pruned before the ground is interfered with. Radish beds sown early in December should be uncovered every morning, replacing the litter at night. Warm borders which contained Tomatoes in summer are best adapted for winter-sown Radishes. Under fruit trees the beds receive a little shelter, whilst the shade caused by the naked branches does no harm. Remove hand-lights and sashes from Cauliflowers, Lettuces, and Onions during the daytime, but replace them at night. The smallest amount of rain must be excluded from the Lettuces, as they are so apt to damp off if they become wet; therefore rather tilt up the sashes than altogether remove them. Thin and weed the plants, and stir the soil a little amongst them. Scatter some lime over all kinds of crops, more especially over those transplanted permanently, such as Cauliflowers transplanted under hand-lights. If ground be required, lift the Jerusalem Artichokes and store them; if land is not wanted, merely cut over the stalks and spread a layer of litter along the top of each drill. Dig the ground between lines of Rhubarb, and place a forkful of litter over each crown. Any Eadie plants to spare plant in front of palings or walls. If the ground be required in which

the general crop is growing lift the plants, tie a piece of matting around each, and lay them in thickly in a bed for a time. Protect them from severe weather by shaking some rough litter over them.

#### Trees and Shrubs.

Prepare stakes for steady and supporting any plants that have been recently transplanted, or that may require such assistance. Trench and prepare large holes, if the ground has not become too frost-bound. Care should be taken to clear off all snow from the surface before opening the trench, for, if buried in the soil, it is a long time thawing, and considerably reduces its temperature. In severe weather, in the absence of snow as a protector, a load or two of straw rubbish should be kept at hand to throw over the surface of the ground to be trenched, as it will prevent frost penetrating, and the work of trenching can then be carried on without interruption. At this late season it is better to defer planting all kinds of evergreens till April, unless the plants to be removed are of small size, and are to be transferred to very sheltered situations. The last few mild winters have induced many to continue planting evergreens much too late, and many have been killed in consequence. All recently transplanted trees should receive a heavy mulching, so as to prevent the ground about the roots from becoming frozen. In planting very large deciduous trees, the stems and main branches should be bound up, either with bands of Hay or Moss, but the latter is preferable, as it is neater and more retentive of moisture. If the trees are to be planted in exposed situations, this protection will be found of the greatest assistance in keeping the bark plump till root action takes place. Plants of questionable hardiness should at once receive protection by shaking a quantity of dry leaves round their base. These should be afterwards covered with Laurel branches or Brakes, to prevent them being blown away. Numbers of shrubs and plants, that would otherwise be killed or greatly injured, will stand severe winters if protected in this way. Take advantage of favourable weather to push on the planting of all kinds of deciduous trees and shrubs, for if frost again sets in, it may throw this work too far into the new year. If any trees are received from the nurseries during frosty weather, they should be placed in a close damp shed till a thaw takes place. For ornamental planting, few deciduous trees excel the *Taxodium distichum*, as it is always beautiful, from the first opening of the bud to the fall of the leaf. Its light, elegant, pale green foliage equals in beauty many of the Fern fronds, and might be used to great advantage in lieu of them for dressing out flowers. In the autumn nothing can surpass the warmth of colour the foliage of this tree assumes, and even at this late season the trees are not yet bare. For rich autumnal leaf colouring, the Liquidambar is one of the most striking, and should have a place in every shrubbery, where, associated with variegated Hollies, &c., it will show off its lovely hues of rich colouring most effectually. The different varieties of Rhus are invaluable for the foreground, especially the lovely *R. Cotinus*, with its richly-coloured silky plumes, and lacinated, which makes an effective plant for the sub-tropical garden. *Ampelopsis japonica* is another desirable plant on account of its richly coloured leaves, and *A. Veitchii* is valuable for covering walls. If planted alternately with white variegated Ivy, the effect is most pleasing.

#### Cottage Gardening for January.

FLOWERS.—Plants in pots in rooms, the pit, or small greenhouse must be watered with a careful hand in the mornings of fine days, so that all damp may quickly dry up; all dead leaves must be removed, and everything pertaining to them should be kept scrupulously clean. During severe weather, sheets of paper laid over half-hardy plants in the turf pit will be a great protection, and if placed over plants on the shelves in the glasshouse will economise fuel. Hardy plants growing in boxes outside the windows, when the weather is very severe, may be sheltered by having a few evergreen branches laid over or amongst them, or by some other temporary expedient. Many plants that would be safe planted in the open ground may perish in an exposed window from having the whole mass of soil in a shallow box frozen through. Hyacinths in glasses that have been placed in a dark situation to start them should be examined occasionally, and, as soon as the roots nearly touch the bottom of the glasses, they should be gradually inured to the light. Keep the base of the bulbs, as well as the roots, free from all decaying matter, and have the glasses filled up with clean water till it nearly touches the bulb. If at any time the water smells offensively change it, but a bit or two of charcoal will help to keep it pure, and, at the same time, impart strength and colour to the blooms. Bulbs in pots that have been plunged in ashes should, as soon as the pots are full of roots, be moved where they can be protected from frost, and be brought on to flower in the room as required.

FRUIT.—All pruning and training should be pushed forward during mild weather, but do not prune during frosty weather. If any old

trees are much subject to the attacks of insects, well wash them with some insecticide, such as Gishurst Compound (8 oz. dissolved in 1 gallon of soft water); it should be well brushed in to all the cracks and crevices of the bark. A good sprinkling of quick lime will be beneficial in eradicating Moss or Lichens; it should be dusted on when the trees are damp. Vines and Peaches on walls should also be dressed with Gishurst before the buds get too prominent. Where there is a Vinery the Vines should be dressed, and the paint and glass cleaned in good time. The inside borders should be examined, and, if very dry, should be watered, unless the house is full of plants. In the latter case the watering had better be left till next month; then choose a bright day for doing it, and, when finished, scatter a little dry soil over the surface to prevent the damp rising too much. All plants in houses should have abundance of air given them on all favourable opportunities.

**VEGETABLES.**—Although this is generally looked upon as a leisure month, yet an industrious person can always find employment in a garden, no matter how small it may be. During frosty weather manure heaps may be turned over and prepared for the land. All the corners where rubbish of any kind has accumulated should be overhauled, and everything that is sufficiently decayed made ready to go on the land. All sticks, roots, or cuttings should be charred or smother-burned. All wheeling should be done in dry, frosty weather, when it can be done cleanly. Vacant plots should be ridged or trenched up deeply whenever time will permit. If during the long evenings a rough plan is made of the garden, and an estimate formed of the space that can be devoted to each crop, a better idea can be formed of the quantity of seeds that will be required of each kind. A well thought out plan is of great assistance during a busy season. Cauliflowers, Lettuces, and Cabbages on the early border should, in very severe weather, be sheltered in some way. If any place exists where a little artificial heat can be had, Rhubarb, Seakale, and Chicory can be brought forward without much trouble by lifting the roots and planting them in some light soil nearly close together. Broad Beans may be planted thickly in some warm sheltered corner, to be transplanted early in March, or sown thickly in boxes and placed under glass. Beans transplant with the greatest ease and certainty, and a week may be gained without much trouble. If not already done, place the early Potatoes in shallow boxes or trays in some light place, from which frost can be excluded, to sprout for planting.

E. H.

**Diary.**

**January 7.**—Getting into the Muscat-house a ridge of manure and leaves, in order to assist the Vines in breaking. Sowing a three-light frame with Woods' Early-frane Radishes. Getting into the Mushroom-house more Rhubarb; also a little Dandelion and Chicory. Turning over leaves and manure for making hotbeds. Pruning Lady Downe's Vines.

**Jan. 8.**—Sowing Cucumber and Melon seeds. Getting into the forcing pit more Lilies of the Valley, Delytras, Deutzias, Hyacinths, Tulips, and Narcissi. Early Peach-house in full bloom. Getting into a pit previously prepared for them another batch of Strawberries. Pushing on with the pruning and nailing of Pears and Plums; also with digging and trenching whenever the weather will permit.

**Jan. 9.**—Putting in Vine eyes, also cuttings of Chrysanthemums. Making up a hotbed for Carrots and Potatoes. Forking over the ground between Gooseberry and Currant bushes. Getting manure on to land where it will be required whilst it is dry. Looking over Grapes in bottles, and removing any berries that may be bad, and filling up the bottles where required.

**Jan. 10.**—Putting off Cucumbers and Melon plants. Getting Heliotropes, Petunias, and Fuchsias into gentle heat for cuttings. Looking over netting and getting it repaired, also Tiffany used for the walls. Washing over the paint in late Vinery with soft soap and warm water.

**Jan. 11.**—Sowing 100 pots with Osborn's Early Forcing French Beans, and earthing up a more forward lot. Covering up another bed of Seakale, and getting in another three light frame of Asparagus. Getting into the early Peach house a quantity of turfs, 12 in. by 7 in., in which to plant William the First, Little Gem, and Unique Peas.

**Jan. 12.**—Sowing a pan of each of Carter's Dwarf Crimson and Dwarf White Celery. Covering up Celery to protect it from frost. Clearing up pleasure grounds and rolling down all gravel walks. Clearing out all vegetable refuse, and cleaning up kitchen garden walks. Looking over fruit room and removing any that are decaying, also Onion stores, and watering Pines.

W. G. P.

**Poppies in India.**—It is stated that the Poppy monopolises 1,000,000 acres of the most fertile land in India. Thus, while the people die for want of food, they have the satisfaction of knowing they can produce the means of stupefying and poisoning about a tenth of the race, with the encouragement of a paternal Government.

**THE FRUIT GARDEN.**

**THE MOUNT ATLAS NUT.**

(*CORYLUS ALGERIENSIS*).

The very fine Nut, of which the annexed is an illustration, was imported some twenty years ago from a Continental nursery by my father. Its native country is the slopes of Mount Atlas, a district particularly rich as regards fine Nuts. The tree is vigorous and hardy when mature, but I have noticed that the young layers are liable to be slightly injured by frost. It is singularly fertile, and the fruit is borne in large clusters, covered by a hairy, spreading, and handsome husk longer than the Nut, and furnishing a very ornamental design for the electro-type

The Mount Atlas Nut.

makers of baskets and epergnes. The nut itself is large, full, and well flavoured.  
T. FRANCIS RIVERS.  
Sawbridgeworth.

**FRUIT TREES ON ARCHES OVER WALKS.**

I HAVE often thought that in many gardens where espalier-training is adopted—and a capital system it is—the trees are too much cramped by the espaliers being too low, especially in this the case, where both soil and climate are fairly suitable for fruit culture. In inferior soils it may be necessary to restrict growth, in order to retain sufficient control over the trees to secure fertility, but in favourable situations it would certainly pay better to allow a fuller and freer development. As a rule espaliers are pretty much the same height everywhere, and the soils that are capable of developing and sustaining large fertile trees are placed on the same level as those of an inferior character where the trees are shorter lived. It may be said, of course, that the trees should be planted wider apart, and so permitted to extend themselves laterally, and this is done, no doubt, to some extent; but espaliers might be raised much higher than they now are, with advantage to the fruit crops, without any corresponding disadvantage worth serious consideration, as the shade will be only nominal; and there are many light crops in summer that would be benefited by the partial shade of a line of espaliers. Were it not for the cost of erection, wire arches over the principal paths would be an interesting way of growing Pears and Apples, especially the former, and, if they were trained as five-branched vertical cordons, a good sized arch would soon be covered, and if the arches were substantial there would be but little cost afterwards, beyond an occasional coat or two of paint. Most of the work of training and attention to the trees could be carried out on the under side with a pair of steps on the path

cleanly, and without treading the borders into mortar. The trees, of course, would be planted close to the edge on each side of the walk, without any intermediary borders. I was in a kitchen garden, about a month ago, where the centre-path was covered with such an arch, on which was trained an interesting collection of some 50 kinds of Pear trees, in capital health and condition. Probably, a less number of kinds would be more profitable. Still the planter of a large number of different kinds of fruit trees in any district may be looked upon as a public benefactor, owing to his showing his neighbours which are the most profitable kinds to grow. Not only may Pears and Apples be treated in this way, but some of the hardest Plums and Cherries, as well as Gooseberries and Currants. This is an excellent plan for suburban gardens, where land is valuable, and the kitchen and fruit gardens must necessarily be small. If the fruits be trained over the walks, the open squares or quarters could be wholly devoted to vegetable culture, unshaded but not altogether unsheltered by the fruit trees. And in cold springs a shelter of a simple, efficient kind might easily be applied to protect the blossoms. At any rate, to say the least of it, there would be a good chance of securing a crop of fruit by this mode of training as by any other. No doubt the first cost will deter many from attempting it, but those who are fond of their garden, and who wish to make the most of a small space will find these fruit bowers or promenades exceedingly interesting and, in the end, profitable.

E. HOBDAY.

#### An Apple Tree Killed by Mistletoe.

In confirmation of the statements made as to the injury caused to fruit trees by this parasite, I may mention a case of death of a tree on which it grew here. Mistletoe being very rare in Cornwall, I accepted the offer of a young Apple tree from a friend some fifteen years ago, having a healthy plant of the parasite upon it, and young enough to bear transplanting. The tree was carefully planted in a walled garden, and grew vigorously after the first season, the parasite also growing steadily. In the course of a few years, the juices of the Apple tree had become so thoroughly impregnated by that of the Mistletoe, that young shoots of the latter continued to show themselves on different parts of the tree, and at distances from the original plant of the parasite, until at length the Apple tree ceased to bloom, and gradually died, for no apparent reason but that the parasite had entirely exhausted the vital power of the tree on which it grew. No fewer than 35 separate bunches of Mistletoe had taken possession of the Apple tree in question.—J. N. B., Penrose, Cornwall.

The Victoria Nectarine.—“When doctors differ who shall decide.” We have recently had too opinions as to this Nectarine (see p. 557 and 503, Vol. XII.), and now I as a third, and a grower for years, of the variety in question, wish to endorse all that the first writer advances in its favour, except that of planting it exclusively. Indoors or out a succession of fruit is desirable.—W.

#### PLATE CVIIT.

#### WARD'S ANTHURIUM.

(ANTHURIUM SCHERZERIANUM WARDI).

Drawn by MRS. DUFFIELD.

This is unquestionably the finest of all the varieties of *A. Scherzerianum* yet introduced to British gardens. A few years ago Mr. Ward, late gardener to F. G. Wilkins, Esq., of the Poplars, Leyton, selected a very small plant, showing distinct foliage, from among others just then imported. Under Mr. Ward's culture, this plant developed its brilliant spathes, which exceed 6 in. in length and 4 in. in breadth. It was exhibited at the Royal Horticultural and Botanic Societies' Shows, where its great merits, both as a decorative and an exhibition plant, were acknowledged. It has since passed into the hands of Messrs. Veitch & Sons, of the Royal Exotic Nursery, Chelsea, who possess the entire stock, and by whom it will be distributed this spring.

A Group of Rocks with Ivy and Briers.

#### Rotten Row.

—Michael Scott, we are told, hept his assistant demons in subjection under the condition of finding them never-ending work, the penalty for failing in doing so being his own destruction. He solved the difficulty by setting them to make ropes out of sea-sand. Surely the department having charge of Hyde Park must, according to "Land and Water," be under some similar obligation to the clamorous jobbers, their demons, and meet it by setting the endless and hopeless task of constructing a serviceable road out of broken bricks and rotten plaster. The attempt is now, as it has been for many years past, in progress,

and the result not only a failure but a disgrace and a scandal. The same system goes on year after year. In autumn the Row is closed from end to end; hundreds of laborers, with carts and horses, are employed; the filthy surface and decayed substance beneath are scraped off, picked up, and replaced with loads of similar rubbish, the refuse of condemned houses, a substance which builders in general pay heavily for permission to "shoot," but which in Hyde Park is purchased, doubtless at a high price. About November, the Knightsbridge ride having in the meantime become thoroughly broken up and dangerous, one-half of the Row is opened to the public, and long before the other is ready, as is the case at this moment, it is at least partially worn out. At this moment numerous gangs of men are employed in "darning" it, and so the work goes on, like Tennyson's brook, "for ever." We have heard that this work costs the public £8000 a year. Besides the enormous expense and inconvenience to which the riding public is subjected, another evil arises from the stupid system pursued, which is daily becoming more apparent, and which affects all frequenters of the park. The constant accession of rubbish and sand has so raised the ground that the stems of the Elms forming the avenues have been buried some feet below the surface, and in consequence their tops are fast dying. They are all young trees, but in nearly as

WARD'S VARIETY OF THE 'FLAMINGO PLANT' (*ANTHURIUM SCHERZERIANUM*-VAR.)

decayed a state as the old ones in Kensington-gardens. Elms are, perhaps, not the best trees for the purpose, but they will live and grow into fine timber, if only their roots, which run along near the surface, have room to spread. This the mass of concrete and rubble entirely forbids, and the trees, especially at the east end, are already half destroyed.

## TREES AND SHRUBS.

### A VICIOUS SYSTEM OF TREE PLANTING.

This little cut shows a system of tree planting too often resorted to in Paris, where so much money is spent on trees for city planting. Instead of clearing a portion of the ground, thoroughly preparing, and replanting it with, as a rule, a different species from what went before, young trees are planted in the shade of very old ones. They are planted in pits, into the fresh soil of which the old roots soon after rush, so that neither above nor below have the young trees a chance.

The result is that there is scarcely a fine tree in the place. Our sketch is from the Tuileries Garden.

### IVY ON TREES IN PLEASURE GROUNDS.

Ivy, like the Yew, and the Holly, would appear to thrive with peculiar vigour in this country. It is to be seen in every hedgerow, draping with its never changing deep-hued foliage any tree of sufficient dimensions to afford it support. The Ivy is, in fact, a characteristic feature of this country, and its exuberant development is often a subject of admiration with foreigners. Our shady lanes and moist climate have doubtless much influence upon its growth, and it is the peculiarity which it possesses of adapting itself to circumstances which renders it invaluable for many purposes. Appreciated as it is as an ornamental plant, I venture to affirm that it is not nearly so much employed as it should be. It is, indeed, but rarely seen in its highest development. Its chief employment is to drape old walls and fences, or cover unsightly buildings, and for that purpose it is eminently adapted. There are, however, several other methods of utilising it in pleasure grounds, to which attention may be usefully directed. When Ivy can climb no higher, it branches out and forms irregular masses—assumes, in fact, a shrubby character. In this state of development it is seen to great advantage, as it then flowers and becomes covered in winter with rich purple-black berries. It is comparatively seldom that one gets a near view of Ivy in this stage, as it is only at the tops of trees and on the gable ends of buildings, where it never gets clipped, that this development can take place. It flowers, too, in the month of October, and although not showy, its blossoms are fragrant and interesting, owing to the scarcity of blooming plants at that period of the year. A short time ago I noticed a very pretty effect thus produced by Ivy. On each side of a gateway was a large tree, the trunks of which were completely draped with Irish Ivy as far as the main branches, at which points the shoots had been kept stopped, thus inducing the bush formation. At that period they were loaded with berries, and an unusually bright and cheerful appearance was thereby given to the entrance. Those who may find it needful to thin out forest trees in their

pleasure grounds, should leave here and there a stem, merely lopping away the boughs, and plant Ivy against it. Beautiful green masses will be thus formed, the changing verdure of which will impart an air of warmth and freshness to plantations mainly composed of deciduous tree and shrubs. Occasionally such an effect is seen in a wood where a tree has died and the branches decayed and fallen. Woods, plantations, shrubberies, open spaces even, might be much brightened up in this manner, for Ivy thrives both in full sunlight and in perpetual semi-obscurity. Where rustic bridges are necessary, or considered as such, in the pleasure grounds, they may have Ivy trained about them, which by drooping in irregular festoons therefrom, soften down the formal architectural appearance which such structures more or less present. Ivy should be more employed in park scenery than it now appears to be. In those portions of the park seen from the windows of the house, there might always be arrangements made to admit of the employment of Ivy, either as trailing loosely and unrestrainedly over rock-work, mounds of earth, or used as in the manner above indicated. The English Ivy, too, may be advantageously employed in the place of Grass as an edging. I have seen it used in situations where it was a matter of difficulty to keep Grass alive. It has an extremely fresh and neat appearance when kept pegged down or clipped.

There is one way in which Ivy may be made to play an important part in flower-gardening, and which I would recommend as calculated to give real satisfaction. It is the custom in many places to grow flowering plants in large pots, tubs, or vases, and place them about the grounds. These are often set upon a pedestal, or elevated in such a manner as to enhance and display their beauty. Now pots and tubs, although indispensable, are far from being ornamental, and there is a general desire to so clothe the plant with foliage that such appliances are as much hidden as possible. For effecting this, the following will be found a good plan:—Let the trunk of a tree be cut into pieces—say about 4 ft. or 5 ft. long—one end of each piece to be sawn off quite level. Let these be inserted in the ground to the depth of 2 ft., the level end being uppermost. Then procure some strong Ivy plants, and place them round the stump, nailing them thereto in such a manner as to cover it all over. In the course of a season, if the Ivy be planted either in the autumn or early in spring, the stump will be completely covered. If on this stump the flowering-plant be placed, the question naturally arises, how to conceal the pot that will still be a prominent feature? This Ivy will do effectually; it will partially in the first, and completely in the second season, run up to the rim of the pot, and entirely cover it. When the pot is removed at the end of the summer it will be found that the Ivy will remain in its place and preserve its shape, forming, in fact, a kind of basket, in which the pot has merely to be placed the ensuing summer. As the Ivy increases in thickness it is found sufficient to hold the plant against rough winds, unless the specimens should be very large, in which case it is advisable to pass a string or piece of wire across the top of the pot, fastening it to a staple driven into the stump. This contrast of flower and foliage is very pretty. Large, well-grown Zonal Pelargoniums are very suitable for this purpose. A pretty combination is that of a scarlet Pelargonium with the variegated Ivy-leaved kind or Mangles' variegated planted round it. These latter droop down gracefully amongst the dark foliage, and have a very pleasing effect. A well-grown Hydrangea, with two or three dozen heads of bloom, and allowed to grow in a free, natural manner, is shown off to much advantage when thus placed. If the Ivy is allowed to spread at the base of the stump, some common hardy Ferns, and Fuchsias, and Snowdrops may be planted amongst it; they will spring up through it, and present a very graceful and natural appearance. The protection which they thus receive appears, moreover, to benefit them considerably. In small gardens, where there is not sufficient space for evergreens to develop themselves, or where the space is too limited to be occupied to any great extent by them, the Ivy thus employed is very suitable, inasmuch as it can be kept within bounds. When the clumps get too bulky they can be clipped, having it done early in the year, and cutting every leaf away; and very beautiful is that wealth of tender green foliage with which it is soon again covered. I

do not know of anything more delicately beautiful than the fresh, young growth of Ivy. The pleasure experienced when looking at it bursting into leaf again amply compensates for the short period of unsightliness which the cutting entails.

*Byfleet.*

J. CORNHILL.

#### HODGENS' HOLLY.

THE remarks lately made on Hollies have reminded me of a desire which I have often had of saying a few words about that fine shrub Hodgens' Holly, sometimes called *Ilex latifolia*. This is, perhaps, not only the most noble, but the most hardy of all Hollies, harder even than our indigenous species. Some years ago, our new burying ground, a bleak spot, right in the teeth of the west wind, was planted with various shrubs, four of the above-named Hollies being in the centre, one at each corner of a square Grass plot; every shrub died out, after a struggle, except the Holly, which are now fine, large, handsome bushes; and the almost black green of their ample foliage renders them peculiarly adapted for cemeteries. This Holly is of freer, quicker growth than most other kinds, and as a screen it has no equal. At West Derby, near Liverpool, in a villa garden, is a hedge of this Holly, worth going some distance to see. It stands at the bottom of a lawn, sloping down from the house, separating it from the kitchen garden. It is at least 20 ft. high, and about 10 ft. wide; passages are cut through it giving access to the kitchen garden ground; but, owing to the enormous mass of verdure, these, viewed from a little distance off, are scarcely visible. This Holly has a nobility of its own, and does not associate well in groups with other kinds, forming, as it does, a low, round, dense mass of foliage close on the ground, generally wider through than high; it has not the least tendency to grow spindling, or get naked below, and I should say a free use of this variety, either in parks, or in the vicinity of mansions, would produce an effect that no other shrub possibly could do. It should be planted by the thousand.

T. WILLIAMS.

*Ormskirk.*

#### PODOCARPUS TOTARA.

AMONG collections of Conifers, large or small, we do not remember, with one exception, meeting with this very striking New Zealand Podocarpus. It would seem, also, to be a stranger to nurserymen; for, on examining several of their lists, we looked in vain for this species. Even in Fraser's recently published "Handy Book of Ornamental Conifers" we find no mention of the Totara, though three other species of Podocarpus are enumerated. It appears to us, therefore, that the present planting season should not be allowed to go by without bringing under the notice of our readers who take an interest in Conifers, one of the tribe which appears to be as much a stranger to them as it is in its aspect unlike the forms with which they are familiar. In fact, as regards appearance, the Totara is so unlike the ordinary needle-leaved Conifer that at first sight one would scarcely think there was any relationship whatever. The close, shrub-like form, broadish lanceolate foliage, and pale-green tint of the latter, are altogether so different from the general run of Conifers that one does not wonder at the surprise we have seen manifested by parties when told that the handsome evergreen shrub which they were admiring was privileged to find a place in the Pinetum. That it is quite hardy in the south of Ireland we know; that it should be hardy anywhere may be inferred from its habitats in its own country, where it is found growing "from the borders of rivers to the summit of Tongariro amid eternal snows." It is described in Hooker's "Journal of Botany" as an evergreen tree attaining a height of 80 ft. or 90 ft., and a circumference of from 15 ft. to 20 ft., and as being considered next in diameter to the Kauri Pine (*Dammara australis*). The timber produced from it is of a reddish colour, becoming darker from age and exposure; the wood (of excellent quality, both in plank and in wear), is, we are told, held in high estimation by the natives, particularly for the construction of their canoes, its lightness and durability causing it to be preferred to any other. The value placed on it by the natives of New Zealand has been sometimes the occasion of quarrels, ending in bloodshed, if it is cut down by others than the party by whom it is claimed, for which reason, and as a token of ownership, we are told, a mark is placed on the tree, and it is then reserved until it has grown to a size sufficient to make it of use, so that in this way it is not unusual for these trees to descend from father to son. Even if the Totara never formed a tree, it would be worth growing.

#### OUR WASTE LANDS.

In such times as these it is desirable to consider, says the "Echo, not only whether we make the best use of our cultivated land, but whether we do not allow a great deal that is cultivable to lie waste. In both respects we are wanting. Much of our cultivated land is only half cultivated and a great deal is not at all. It is far too readily assumed that our uncultivated land is uncultivable, while much of it is only so as long as the cultivator is burdened by restrictions. Our American cousins are not only supplying us with corn and meat, but, to a large extent with fruit. The fruit crop of Michigan is worth four millions of dollars per annum. Last year the United States exported to Europe 14,000,000 lbs. of dried fruit and 726,000 dollars worth of canned fruits. In this age of tin there is hardly a grocer but has American fruits on sale. Our small cultivators can compete with them if they only had a fair chance. For example, in the parish of Cadham may be seen a number of large, well-built houses, surrounded by fruit grounds. The men who built them were mostly but ploughmen and shepherds thirty years ago. The late Lord Stanhope cleared some wood lands, and gave these men a chance. Acre by acre they stubbed the land and brought it into cultivation hiring it on a 20 years' lease at 10s. an acre, its average value as woodland. The land was poor, but they had something to work for, and when their leases ran out the rent was raised to 25s., which they gladly paid. To-day these men are cultivators of from 30 to 60 acres, and living in their own houses, built at a cost of from £300 to £400 each. Mr. Henley, the Member for Oxfordshire, has on his estate some large allotments for which men are paying more than double the amount which a large farmer declined to give because the land was naturally so poor. There are hundreds of parishes where men are paying for allotments at the rate of double and treble the rent of the contiguous land. But as a rule, we have shut out the industrious and enterprising man, who has little but his own perseverance and energy. In the towns he may hope to make his way; in the country, born a labourer he must die a labourer, and nothing more. Even the local charity lands are closed as far as possible against such men.

**Care of Newly-set Trees.**—There are various modes for preparing young trees for the winter. If they have been set in the present autumn, they must be well secured against wind, if in exposed places. The best security against displacement consists in long roots in trees which have been carefully taken up. If the trees are of moderate size, and the spade in digging was set 18 in. off from the stem on each side, the roots when spread out in transplanting will brace the tree perfectly. With larger trees staking may be required, but for trees intermediate between large and small, a solid mound of fresh earth around the trees will serve to brace against the wind; such a mound will afford some protection against hard freezing, or operate as a mulch; it will also exclude mice. It must be made of clean, mellow earth, beaten smooth with the spade. Throwing up blocks of turf makes a harbour for mice, and is worse than nothing. Protecting the roots with straw through winter is dangerous and invites mice, unless such mounds of good size (1 ft. or more high) are made. It is therefore better to mulch with coarse, wet manure.

**Value of Screens.**—G. F. B. Leighton, of Norfolk, Va., widely known for his great success in raising large Pears, has a screen some 60 ft. or 70 ft. high, running east and west. He has 1000 Bartlett Pear trees planted on the north side of this screen, and 700 on the south side. There is no perceptible difference in the blossoming of the trees on each side in spring, but the fruit ripens a week sooner on the south side. The principal advantage in the screen, however, is in preventing the blowing off of the Pears by winds. The fact of later ripening also presents a suggestion which might be used to advantage farther north, where the latest Bartlett Pears bring the best prices, after the more southern and earlier supply is exhausted.

**Clapp's Favourite at Norfolk.**—Mr. Leighton states, in a letter to the Massachusetts Horticultural Society, that Clapp's Favourite Pear proves very healthy in that region, but, what is remarkable, it does not grow so large as in Massachusetts, although Mr. Leighton's Norfolk Pears are, however, made up by its handsome appearance. Its ripeness is ten days before the Bartlett, which may be an important advantage at that place. In the north this early maturity would throw it into market at the same time as the Bartlett from a few degrees south. Mr. Leighton says it is a tardy bearer as a standard, but bears early as a dwarf. He has 200 dwarfs, from three to eight years old. They require frequent heading back to give the tops a good shape. He gathers the Pears ten days before maturity, and, thus treated, they never rot at the core.—"Albany Country Gentleman."

## THE INDOOR GARDEN.

### BESCHORNERIA BRACTEATA.

This is a Mexican plant nearly related to the Agaves, and stemless. Its foliage, which is glaucous green in colour, is graceful and spineless, and being flexible the plant is better fitted than some others for temporary indoor decoration. When set on a pedestal its leaves droop down in a very elegant manner. It flourishes under the treatment usually given to Agaves. Its flowers are not remarkable for beauty, but it is a plant well worth growing by even the inexperienced, for even if through bad treatment it loses its foliage, it soon

Beschorneria bracteata.

regains it if given anything like proper attention. It requires plenty of water when young, but it may be kept dry if not wanted for a time.—J. CROUCHER, *Sudbury House, Hammersmith.*

### ZONAL PELARGONIUMS AND THEIR SPORTS.

Amongst the large numbers of Zonal Pelargoniums that have made their appearance during recent years, a few possess new shades of colour, and there are many in which the size of the individual flowers is greatly increased; whether, however, this latter is an advantage or otherwise, when the plants are employed for greenhouse and conservatory decoration, is wholly a matter of taste, some preferring large flowers, others those of a medium size, but for use in a out state, especially in bouquets, for which they are largely used, there can be no question that those with medium-sized flowers, such, for instance, as those of the well-known scarlet variety, *Vesuvius*, are much the best. For the London flower trade there has, in all probability, up to the present time, been very much more of this variety grown than of all other scarlets put together; but if we may judge by the stock that the growers for market are getting together of Wonderful, the semi-double sport from *Vesuvius*—this is likely to supersede all as a scarlet. Red is, however, a colour that in all combinations of flowers should never be allowed to predominate, and the half-expanded buds

of this variety are peculiarly well adapted for supplying that colour for bouquets, being not too large, and their lasting properties unequalled. Some varieties of plants are much more prolific in flower-sports than others, as, in addition to Wonderful, Mr. Cannell has got a white sport from *Vesuvius*—White *Vesuvius*—exhibited at the last meeting of the Royal Horticultural Society, at which it received a first-class certificate. It appears to be an exact counterpart of *Vesuvius* in everything except colour, and as such, may be hailed as an acquisition by all who require cut flowers in winter, independently of what it is likely to be as a flower-garden plant. I have also seen another sport from the same source, which is bright pink in colour, and which, when sufficiently plentiful to be distributed, will give the three principal colours in this flower requisite for general use. Speaking of Pelargoniums, as an instance of how often it happens with the public generally in the case of these as of other flowers, that old varieties of sterling merit are cast into the shade for new comers, frequently inferior to them, I may mention that in one of the largest establishments for cut flowers in London, as a pink Pelargonium, nothing is used except the old *Christine*, which is found superior to all others; and yet we should suppose that there are few private places in which plants are largely grown where this most useful old variety could now be found cultivated in pots. So much for mere novelty! T. BAINES.

### AN AMATEUR'S GREENHOUSE IN MID-WINTER.

THERE is a general tendency on the part of the inexperienced to use artificial heat more than is really required, and also to keep their houses much closer than there is any necessity for; air should be freely given at all times when the weather is mild and open. If a continuance of damp, wet weather happens, a little fire-heat may be furnished in the daytime, at the same time giving air so that the air may dry. Care should always be taken not to allow chilling currents of air to play on the plants; therefore, keep the windows closed on the windward side, and open those on the leeward side. As it sometimes happens that the plants have to be kept close for a time, such as during sharp frost, dirt and other deposits will congregate on the leaves of *Camellias*, *Oranges*, *Myrtles*, *Ficus*, *Nerium Oleander*, and other smooth-leaved plants, which will be greatly benefited and improved in appearance by having their leaves washed with a sponge and warm water. *Calceolarias*, *Cinerarias*, *Pelargoniums*, and other hairy and woolly-leaved plants, can have the dust removed from their leaves by means of a soft brush, followed by a gentle syringing on the first mild, drying, sunny day. After the leaves are cleaned the plants may be further helped by washing the pots, if required, and adding a little fresh surface soil. Any *Calceolarias* or *Cinerarias* that are getting pot-bound should have a shift into larger pots to keep them growing gently; the plants should be near the glass, where they can have plenty of light and air on all favourable occasions. If kept close, the leaves become yellow, and get affected with green fly; then a fumigation with the smoke of Tobacco paper is absolutely necessary. *Camellias* must not be allowed to become dry at the roots, as if neglected the buds fall without opening; the pots should always be well drained, so that water might pass freely from the roots. Large-flowering *Pelargoniums* are a favourite amateur's plant, and, owing to the prevailing mild weather, they are growing freely. It is a good plan to pinch back the leading shoots, and tie out all towards the rims of the pots, so that the air can circulate among the branches. Any store plants of cuttings, such as *Pelargoniums*, *Gazanias*, *Lobelias*, *Tropaeolums*, *Calceolarias*, *Verbenas*, &c., should be looked over, and decaying leaves removed, and any dead shoots, keeping the soil a little dry during the dead season of the year; damp is more dangerous than drought just now. Every amateur's greenhouse should contain a few of the hardier *Solanums* for decoration at this season of the year; the bright coral-red berries supply any lack of flowers at midwinter. D.

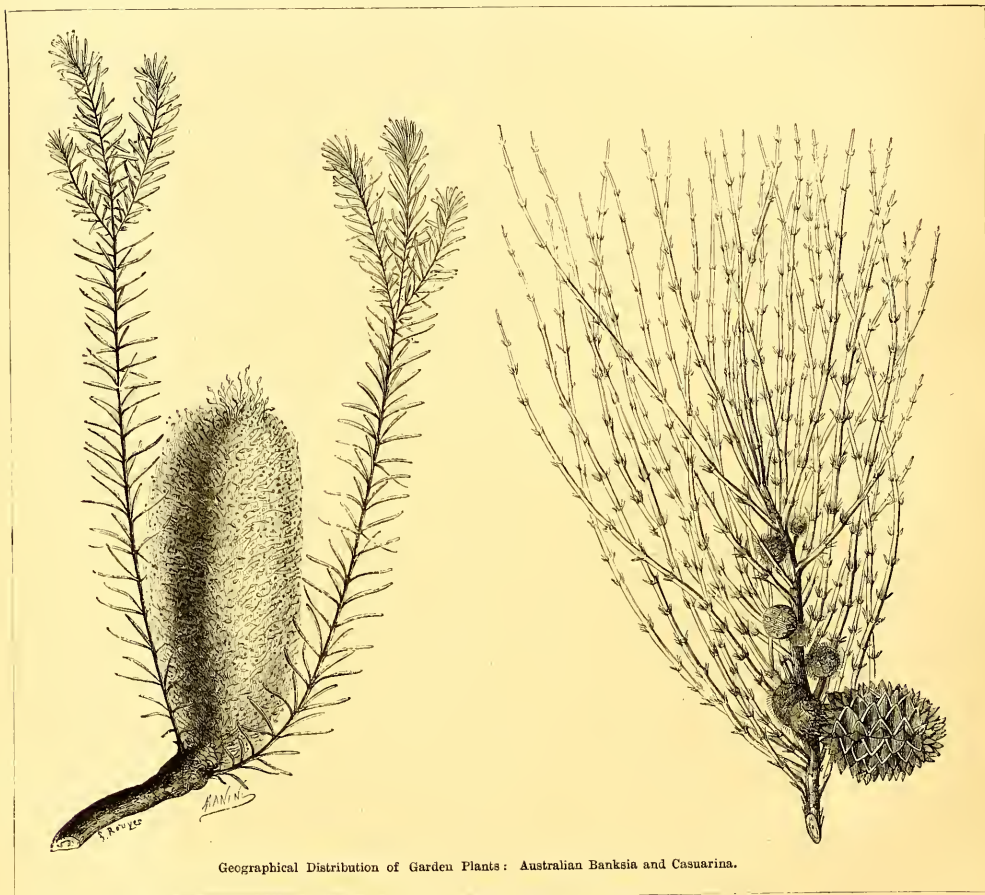

*Libonia floribunda* in Winter.—This is one of the best of plants for winter decoration. We have a dozen or more plants of it that came into flower in October, and they look as if they would flower all winter. Their orange and red blossoms have a pretty effect mixed with such plants as *Epicurises*, *Heaths*, and *Camellias*. As to culture, we grow it in a cold frame all the summer, and give it plenty of water. Liquid manure, too, it likes occasionally when in a growing state. It requires all the sunlight which it is possible to give it, to order to thoroughly ripen the wood, and after the growth is made, water should not be given so freely for two or three weeks as before. Afterwards encourage it in a close frame, and the result will be a mass of flowers all the winter.—W. CULVERWELL, *Thorpe Perrow.*

## THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

### *Australasian Region.*

DEFINITION.—As here limited, this includes Australia (with the exception of the extreme north), New Zealand, and adjacent islands, and has a flora closely approaching 10,000 species. A general analysis of the flora of New Zealand has already been given, and a selection of some of the most noteworthy greenhouse plants from thence is all that is necessary in this place.

ised as dry. Sometimes the drought is of long duration, followed by torrents of rain, causing destructive floods. Large expanses of the interior appear to be nearly, or quite, rainless, and they are almost devoid of vegetation. Succulent plants are almost entirely absent. Nearly all the woody plants are evergreen; but the peculiar bluish-green hue of the foliage of the greater part of the shrubs and trees gives the landscape anything but a refreshing aspect, and umbrageous trees are rare. In the Eucalypti or Gum Trees, which constitute the greater part of the aborescent vegetation in many districts, the

Geographical Distribution of Garden Plants: Australian Banksia and Casuarina.

PROGRESS OF DISCOVERY.—With regard to the botany of Australia, our knowledge of it has progressed almost as rapidly as the colonisation of the country. The first settlement (New South Wales) was made in 1788, and nothing was known of the vegetation of the country a few years previously, when Captain Cook visited it. Sir Joseph Banks with Cook, Robert Brown with Flinders, and Allan Cunningham were among the earliest botanists who collected in Australia.

CLIMATE AND CHARACTERISTICS OF THE VEGETATION.—The climate of Australia varies considerably, as might be expected, in widely distant localities, but in general it may be character-

blade of the leaf is spread vertically instead of horizontally, as in our forest trees, hence they afford only a partial shade. A very large proportion of the remaining shrubs and trees have very small or needle-shaped leaves, and those which are large are usually very dry and bare, and almost woody. There are, however, many exceptions, and some plants have a very elegant and beautiful foliage. The flowers, which are not often of a large size, are, as a rule, very brilliantly coloured, and produced in great profusion. The greatly preponderating element in the flora is, in fact, the almost endless variety of shrubs and trees with conspicuous flowers. The trees alone number nearly a

thousand species. Bulbous plants are not wanting, but they form by no means so large a proportion of the flora as in South Africa. Terrestrial Orchids are numerous, and nearly all endemic, and they exhibit a great variety of curious structure in the flowers.

CHARACTERISTIC NATURAL ORDERS.—Among characteristic families we may name the Dilleniaceæ (Hibbertia), Pittosporæ

CHARACTERISTIC GENERA AND SPECIES.—Briefly examining the numbers and composition of some of the foregoing families, we obtain some interesting particulars of the nature of the Australian flora. The Rutaceæ number about 160 species, belonging to 29 genera, including *Boronia*, of which nearly 50 distinct species have been described; *Correa*, *Crocea*, *Eriostemon*, *Phebalium*, *Zieria*, and several others are represented in

Australian Forest Scene.

(*Sollya*), Rutaceæ (*Boronia*), Stackhousiæ (*Stackhousia*), Leguminosæ (*Acacia*), Droseraceæ (*Drosera*), Myrtaceæ (*Eucalyptus*), Compositæ (*Helichrysum*), Stylidæ (*Stylidium*), Goodeniæ (*Goodenia*), Epacridæ (*Epacris*), Myoporinæ (*Myoporum*), Amarantaceæ (*Trichinium*), Proteaceæ (*Grevillea*), Thymelææ (*Pimelea*), Santalaceæ (*Exocarpus*), Casuarinæ (*Casuarina*), Orchidæ (*Dracæa*), and Restiaceæ.

our greenhouses. The Pittosporæ and neighbouring family, *Tremandrea*, comprise together about a dozen genera, nearly all of which are, or have been, in cultivation, and many of which are exceedingly beautiful. Examples are—*Sollya heterophylla*, *Pronaya elegans*, *Cheiranthra linearis*, *Platytheca galioides*, and *Hymenoporum flavum*. A very numerous, and especially characteristic family, is the Leguminosæ. Upwards

of 950 species are enumerated in the "Flora Australiensis," belonging to 92 genera. Among the genera are *Oxylobium*, *Gompholobium*, *Choriozama*, *Daviesia* (35 species), *Pultenaea* (75 species), *Hovea*, *Dillwynia*, *Goodia*, *Clianthus*, *Kennedyia*, and *Hardenbergia*.

**ACACIA.**—The most numerous genus of this family in Australia is *Acacia*, which is represented by about 300 well-marked species, many of which present a variety of forms. About 270 of the species belong to the phyllodeous section—that is, having no pinnate leaves—the leaves being really reduced to flattened or round, most variously-formed petioles. The arborescent species form entire forests, and those of shrubby growth constitute the principal vegetation of much of "scrub," as the expanses covered with dwarf, woody plants, is termed by the Australians. It is almost superfluous to add, that many of these are exceedingly ornamental, and during the flowering season they form a most striking feature in the scenery of many districts. A small family of herbaceous plants, the *Droseraceae*, deserves mention. The genus *Drosera* numbers 40 species in Australia, and many of them are very curious and beautiful. They are especially abundant in West Australia, where 30 out of the 40 species occur, and 27 of them are there endemic. A less numerous, though more important, family than the *Leguminosæ* is the *Myrtaceæ*. It comprises about 600 species belonging to 45 genera, nearly 30 of which, forming a distinct tribe, are peculiar to Australia and the adjacent islands.

**EUCALYPTUS.**—The largest and most important genus is *Eucalyptus*, the Gum, Mahogany, and Box trees, and Iron-barks, Stringy-barks, &c., of the Australians. The species, of which Mr. Bentham describes 134, are very difficult of discrimination. They are dispersed over the whole of the country where there is vegetation, and many of them are exceedingly valuable timber trees, to say nothing of their other products. Some of them occasionally attain gigantic dimensions, surpassing the famous Mammoth Tree of California. A tree of *E. amygdaliua*, growing in Dandinang, was ascertained to be 480 ft. high. Among ornamental plants belonging to this family are many species of the genera *Darwinia* (syn. *Hedromia* or *Genetyllis*), *Verticordia* (37 species), *Calythix* (34 species), *Bockea* (42 species), *Leptospermum* (20 species), *Callistemon* (the long, brilliant red or yellow stamens are the most conspicuous part of the flowers of these handsome shrubs), *Melaleuca* (100 species), *Beaufortia*, *Calothamnus*, and *Tristania*. The beauty and variety displayed by the species of several of the genera named is almost inconceivable.

**COMPOSITE.**—The next group of importance is the *Compositæ*, of which there are 95 genera and 500 species. A large proportion of the genera are endemic, and 40 of them are monotypic, or represented in Australia by a single species. Only eleven count more than 10 species each; and the only large characteristic genera are *Olearia* and *Brachycome*, having respectively 63 and 36 species. Of the widely-dispersed and large genus *Helichrysum*, there are 52 species. Shrubby species, and a rich variety of annuals of the *Helichrysum*, or *Everlasting Flower* tribe, constitute the bulk of this family. Many of the latter are elegant miniature plants only a few inches high, having relatively large glistening red or yellow flower-heads—*Myriocephalus*, *Angianthus*, and *Calocephalus*, for example. Some of the more familiar species, in cultivation are *Craspedia Richea*, *Ammobium alatum*, *Humea elegans*, *Podolepis gracilis*, *Schoenia cassiniiana*, *Helichrysum bracteatum* (the numerous varieties under diverse names), *H. apiculatum*, *Waltzia corymbosa*, *aurca* and *nivea*, *Helipterum Manglesii* (syn. *Rhodanthe*), and *H. roseum* (syn. *Acroclinium*). Besides those named, there are scores of elegant little species that have never been introduced. Of the shrubby species, few have been cultivated, and those chiefly belonging to the genus *Olearia* (including *Eurybia*), as, *O. argophylla*; and *Ozothamnus* (united with *Helichrysum*, by Mr. Bentham). *Brachycome iberidifolia* and *Vittadinia australis* (Syn. *V. triloba*) are also Australian. The genus *Stylidium*, which constitutes nearly the whole of the family *Stylidaceæ*, is entirely Australian, with the exception of one or two species which extend to tropical Asia. There are between 80 and 90 species, nearly all of which are herbaceous plants. They are interest-

ing botanically rather than as ornamental plants. The neighbouring family, *Goodeniaceæ* is also almost exclusively Australian. It comprises (in Australia) 12 genera, and 187 species, nearly all herbs or small undershrubs. *Leschenaultia*, 16 species, *Goodenia*, 69 species; *Scævola*, 50 species; and *Dampiera*, 33 species, all contain pretty and interesting species.

**EPACRIDÆ.**—Another order, almost confined to this country, is the *Epacridæ*, of which there are 24 genera and 272 species. It is sufficient to name the genera: *Styphelia* (11 species), *Lissanthe* (3 species), *Leucopogon* (118 species), *Epacris* (22 species) and *Drachophyllum* (9 species). The *Myoporinæ* is an order chiefly Australian, consisting of shrubs allied to the *Verbeuceæ*. There is a considerable number of *Amarantaceæ* including about 50 species of the ornamental genus *Trichinium*. The *Chenopodiaceæ* number about 100 species, chiefly salt-water plants; the largest genus, *Atriplex*, is represented by 30 species.

**PROTEACEÆ.**—Another characteristic family is the *Proteaceæ*. It consists of shrubs and trees presenting the greatest variety of foliage, brilliant flowers, and curiously-shaped woody fruits. The Wooden Pear of the early settlers is a member of this family, *Xylomelum pyriformis*. Thirty genera and 575 species are Australian. Of *Banksia*, *Dryandra* and *Persoonia* there are nearly 50 species each; *Hakea* numbers 95, and *Grevillea* 156 species. *Teleopa speciosissima*, *Grevillea robusta*, *Stenocarpus Cunninghami* and *Dryandra carpucea* are some of the numerous species that have been introduced into European gardens. The familiar genus *Pimelea*, belonging to the *Thymelacææ*, is represented by nearly 70 species; and the *Casuarinæ*, or the She Oaks, forming a natural order of themselves, find their head-quarters in Australia. They are leafless trees with slender, erect or pendulous branches, and whorled, jointed branchlets, clothed with minute scales, and inconspicuous flowers. There are about 20 species widely scattered, and giving the landscape a special character in some districts. The small order of *Santalacææ* should be mentioned for the sake of the singular genus *Exocarpos*, some species of which are the native Cherry trees of the colonists. These are what are enumerated in the list of anomalous Australian vegetable productions, as Cherries with the stone outside. The fact is that the true fruit, or seed-vessel, is a dry nut seated upon a fleshy edible stalk. Yet another family to name, the *Orchidææ*, comprising 18 genera and above 200 species, the majority of which are terrestrial and little known in cultivation.

**GRASS GUM-TREES.**—Among other peculiar plants are the Grass Gum-trees, or Black-boys, species of *Xanthorrhoea*, a genus of the *Liliacææ*. Some of them are stemless with a dense tuft of grass-like leaves from the centre of which springs the inflorescence, which reminds one of a giant Reed-mace; and others have a stout trunk, 10 feet, or more, high, and densely clothed with the bases of the old leaf stalks, and pendulous leaves. The flower-shaft of some of the larger species is 15 or 20 ft. long, and, when in flower, these Grass Gum-trees are very conspicuous objects in the landscape. Palms are rare, as are also *Cycadææ*, in Australia; but they are most numerous on the eastern side. For the convenience of being able to see them at a glance, this brief sketch of Australia may be brought to a close with a list of the principal characteristic Australian genera, in cultivation, in systematical sequence.

<i>Chorizema</i>	<i>Melaleuca</i>		<i>Gleichenia</i>
<i>Gompholobium</i>	<i>Callistemon</i>		<i>Dicksonia</i>

*South African or Cape Region.*

The South African flora in its general features closely resembles the Australian. Many of the same families are prominent factors in the vegetation of both regions: For instance, Leguminosæ, Compositæ, Proteaceæ, Rutaceæ, Restiaceæ, and terrestrial Orchids. Some large families in the one region, are represented by closely allied families in the other; thus the Epacrideæ of Australia are replaced by Ericaceæ at the Cape. Again, some families forming a conspicuous feature in the vegetation of one country are almost absent from the other, and not replaced by a kindred group. This is the case with the Myrtaceæ, which are 600 strong in Australia, whereas, only 12 species, belonging to 5 different genera, neither of which is

bare of vegetation, when after the rains it is suddenly covered with flowers. But it is in the southern and less elevated part that the richest and most luxuriant flora exists. The extent of extra-Tropical South Africa, which coincides with what we call the greenhouse region, is given as about three quarters of a million square miles, and the flora, from a rough calculation, comprises at least 9000 to 10,000 species, a very large proportion of which are endemic.

CHARACTERISTIC NATURAL ORDERS, &c.—Examining some of the more important orders in their natural sequence, the Cruciferae is the first having a considerable number of species. Of this order there are nearly 100 species, 60 of which belong to the solely South African genus *Heliophila*. The Polygalæ

peculiar, occur in South Africa. As with orders so with genera. There are two and three species respectively of *Pelargonium* and *Mesembryanthemum* in Australia, whilst the former numbers upwards of 160, and the latter about 300 species at the Cape. *Drosera* is a genus in which the contrary obtains; many other comparisons of this nature might be made, but the reader may be left to make them himself. Some other points in which the Cape flora differs from the Australian are the relatively smaller proportion of trees, the abundance of succulent plants belonging to different families, and the large number of petaloid *Monocotyledons*, chiefly bulbous-rooted plants. The country, advancing northwards, consists of a number of successively higher terraces, each one less fertile; The northernmost and highest is, at certain seasons, almost

number 40 species of *Polygala* and 50 of *Muraltia*. *Hermannia* and *Mahernia*, belonging to the *Sterculiaceæ*, contribute about 100 species; and of the *Geraniaceæ* there are about 300, whereof 160 of *Pelargonium*, and upwards of 100 of *Oxalis*; of *Rutaceæ* there are 14 genera, and about 190 species, 100 of which are referred to the genus *Agathosma*; *Leguminosæ*, 82 genera, and 735 species. A majority (60) of the genera belonging to the last named family have less than 10 species, and 32 of them only 1 each. Among the genera most numerous in species are, *Aspalathus*, 150; *Indigofera*, 120; and *Lotononis*, 56.

SUCCULENT PLANTS.—*Crassulaceæ* and *Ficoideæ*, orders consisting mainly of more or less succulent plants, are represented by about 450 species; 100 of *Crassula* and 400 of *Mesembryanthemum*. *Compositæ* number about 1,400 species, referred

to 150 genera. Of large genera we may mention, *Senecio* 180 species; *Helichysum*, 137; *Othonna*, 58; *Pteronia*, 51; *Aster*, 46; and *Sphenogyne*, 44. There are 56 genera of only 1 species each, and of 60 others there are none having more than 9 species.

**HEATHS.**—The *Ericaceæ* come next with 500 species, nearly 400 belonging to *Erica* itself. Most of the species are, however, local, and many of them very rare, in striking contrast to the wide range of nearly all the few species found in the northern hemisphere—in the Mediterranean region, Western Europe, and North Asia. The large tropical and sub-tropical order, *Asclepiadiæ*, contributes 45 genera, and 320 species, many being climbing shrubs, and upwards of 100 succulent plants belonging to the *Stapelia* tribe. *Scrophulariaceæ* adds 240 species; *Verbenacæ*, 130; and *Acanthacæ*, nearly 100. A small, but curious group is the *Pedalaria*, to which the "Grapple plant," *Uncara procumbens*, belongs. The seed vessel of this plant is of a most unusual form, being furnished with long ir-

W. B. HEMSLEY.

**Playing Corners in Squares.**—A commendable feature in the Paris squares—so freely open to the public at all hours of the day—are the small spaces provided for play and rest. These are usually formed by widening the out walk of the square at each corner,

Playing corner for children in the Square Montrouge.

regularly-branched, claw-like, barbed appendages. There are 125 species of *Thymelacææ*; the largest, genus *Guidia*, having 40. We now come to the characteristic *Proteaceæ* represented by 11 genera and 250 species; *Serruria* counts 43 species; *Protea*, 60; *Leucospermum*, 23, and *Leucodendron* 49. *Leucodendron argenteum* is the silver tree of the colonists, so called from its handsome foliage. It was formerly very abundant, and formed a very striking feature in the scenery, but it has been nearly extirpated for fire-wood.

**BULBOUS AND TUBEROUS-ROOTED PLANTS.**—Petaloid Monocotyledons form a total of about 850 species, of which about 170 are *Orchids*, nearly all terrestrial, and the majority tuberous-rooted, including the magnificent *Disa grandiflora*, or "Glor'y of the Table Mountain," as Harvey calls it. *Iridææ*, 160; *Amaryllidææ*, 110; and *Liliacææ*, 360 species, are the principal other families contributing to this total. Of grasses, sedges and allied families there are about 650 species. Finally, there are about 130 Ferns, of which only about a score are endemic. Appended is a list of characteristic South African genera, species of which are, or have been, in cultivation.

where trees are generally planted, so as to afford shade. Here the children play and their nurses work. It is one of the pleasantest sights in Paris, to see these playing places with crowds of happy children on fine days. A comparison of such squares with others at home—not the more cheerful or beautiful for being closed to the public, can hardly fail to occur to most persons who have seen our city squares.

**Vesuvius a Good Forcing Pelargonium.**—I find that *Pelargoniums* which flower most freely out of doors are, as a rule, the best forcers. This applies particularly to that now popular outdoor variety, *Vesuvius*. With it in plenty we need never be without an effective scarlet during the winter months. My old plants, which were lifted early in November, potted, and placed in a warmish dry pit, are now flowering in the greatest profusion from the new growth they have made since they were potted, and the flowers are exceedingly fine. They will go on flowering, as they did last year, all the winter. The best way with the plants is to keep them growing slowly, with plenty of air, and just sufficient water at the root, and a dry atmosphere overhead. The best may be placed in the conservatory or cool greenhouse, where they will last for a time; and when they have done flowering, all that is wanted is to move them

back to the same pit again, and fill their place by others. Where they are stored by the hundred or thousand, for bedding purposes, this is easily done. Autumn-struck plants bloom just as well as old plants; and if the cuttings be put into 5 in. or 6 in. pots, they make even a better show than single old plants placed thickly together in the pot. Mostly all Pelargoniums force more or less successfully; but a good deal depends upon management. I find that they do not flower well if forced in a moist Vinery or stove, for example, as they grow too much. On the other hand, the greenhouse is too cool for them; for, though they come on slowly, the flowers never expand perfectly. An intermediate dry and airy temperature is just what suits them; in fact, the air cannot be kept too dry, nor the plants too near the glass.—J. S.

**Domestic Wheat Mill.**—Messrs. Barnard, Bishop, & Barnards have introduced a very effective little Wheat mill, which cannot fail to interest those who seek for pure and wholesome bread. The common brown bread of towns, especially of London, is as unwholesome as it is disagreeable to the taste. It is, as one well-known London physician says, "made to send us patients," being composed of Bran and very ordinary flour, often adulterated. With this little mill one has only to procure some of the best Wheat, and grind it in such quantities as may be desired for baking. The flour, even, seems to be more finely ground than in an ordinary mill. This flour bread, which may easily be made, has only one fault—that of soon making, to those who give it a fair trial—common bakers' bread for ever distasteful.

**Propagating Vines in Gardens.**—Is "Cambrian" (see p. 608, Vol. XII) serious when he writes:—"It is surprising that the propagation of the Vine in gardens is not more generally practised than it is?" Why, I had always imagined that the exception was the rule in this matter. Surely "Cambrian" has never left his native mountains, or he would never have penned such a sentence. With his mode of propagation I have no fault to find; but I must protest against the assumption that Vine raising in private gardens is the exception. Referring to the last sentence of his note, I doubt as to whether there is any other mode of propagation more complicated than the one he gives. Why, everybody knows that no matter how a Vine cutting is put in, it is sure to grow.—W. W. H.

**Apricot Branches Dying** (see p. 564, Vol. XII).—A thorough ripening of the wood of Apricots has no doubt a great influence on them in more ways than one; but, as a rule, I have observed that their branches die when they are growing most luxuriantly, and when they appear to have entirely got over any deficiency in the way of ripening the wood. I am acquainted with a long wall of Apricot trees in one of the wettest parts of Scotland, where the trees never suffer through want of water at the root, and the wood is often fully matured in autumn, and yet I never remember seeing a branch die off one of the trees. I am of opinion that dryness at the root during any period of their growing season will cause Apricot branches to die suddenly, and I believe that more die from this cause than from any other. If we were as careful in watering our fruit trees in the open air as we are those under glass in hot weather, healthier trees and better crops of fruit would be the result.—CAMBRIAN.

**Bottom-heat for Pot Vines.**—For some years past I have grown from sixty to seventy pot Vines for an early crop, and the results have been fairly satisfactory. Until this season, I have always plunged them in leaves; but when they began to break, we have been terribly bothered with slugs and woodlice. This year I determined to use no leaves at all, or anything else in the way of bottom-heat, and I am pleased to say that the ones have broken in a most admirable manner, and in a few days they will be ready for stopping. In the case of early Grapes, I find that in the dark days of winter there is always a humid, close atmosphere wherever heating material is used inside the house. This season, on the contrary, when none is used, the air is always pure and wholesome, with little or no humidity, which, in dull weather, induces mildew, and air cannot at all times be admitted to sweeten the house. Moreover, I am no admirer of that white fungus which always makes its appearance in half-rotten leaves. Many of us are also too fond of saturating early houses with water, which causes warts to arise on the under sides of the leaves. I would recommend the air to be always kept buoyant and sweet. If air can be given but for an hour, the good which it does is incalculable.—R. GILBERT, *Burghley*.

**Fruit Culture in the Rhine Districts.**—Fruit culture is one of the most important industries in the Rhenish Palatinate, many of the municipalities and parishes finding therein their chief source of income. All its towns are surrounded with gardens of fruit trees, and the countrymen take care to plant them in every uncultivated corner in his fields. Chestnuts, Apples, and Pears are the chief crops in the north, Plums and Damsons in the west, and Cherries on

the Rhine border. These last are exported in enormous quantities to Hamburg, Amsterdam, and Liverpool. One small parish alone derived more than 70,000 marks (about £7000) from its Cherry-trees some three years ago; and another still smaller one has netted 12,000 marks (about £1200) from a similar source, in the very unavourable season of last year. No small part of this success is due to the care which is taken to grow superior kinds of fruit only, a policy which might well find imitators elsewhere, since a choice tree occupies no more space than a poor one, and yields an infinitely richer return.

## GARDEN WALKS.

THE comfort and convenience derived from good garden walks can scarcely be over-estimated, as they enable the pedestrian to enjoy a stroll under conditions of weather that would render it anything but a pleasure to make use of them were they not sound and well made. Not only is this the case, but operations are greatly facilitated, as they admit of barrows or other traffic going on at any time instead of having to wait—a very important matter, inasmuch as a few days' delay at a particular time often leads on to another of still greater duration, and throws work sadly behind. This, no doubt, has been the experience of many connected with gardening; and as nothing detracts so much from the general keep and finish of any place as bad walks, independent of the great inconvenience they cause, every effort should be made to improve them. Unless the foundations are firm and solid, slight dressings of gravel, however good and adhesive it may be, is of little avail, for, although it may bind hard and remain so during a dry time, a few days' rain converts it into a perfect quag, that is not at all improved by passing a roller over it. It is better, therefore, with any that have been improperly made to wholly re-form them, which can be most readily be done by beginning at one end and taking out sufficient of the under part to admit of hard broken bricks, slag from furnaces, coarse stones, or anything of that kind being placed on to the depth of from three to six inches, according to the amount of hard wear they are expected to have, or the weight that is likely to pass over them. The great mistake many make when using this rough material is in not filling up the interstices between, thinking that by leaving the bottom loose and hollow they thereby secure free drainage, and lay the walks dry. This is a most erroneous notion, and is a frequent cause of rottenness, as the gravel shifts with the traffic and thus becomes broken, whereas, had it a firm bed to rest on, traffic would improve and consolidate it rather than otherwise. Instead of water passing through, as is the case when the basis is formed in the way noticed above, the top should be made as impervious as possible, that what rain falls may be conducted quickly away and carried off through gratings and drains made for the purpose. Without these no walk, except on a hill side, can remain in good order for any length of time; and therefore in laying out any fresh ones or re-making such as are already in existence, attention should be given to this first; and to save labour and pipes or tiles, the best way is to lay a main drain down the centre, with branches from the sides at about 20 ft. apart leading to it. Each of these should be connected with a small brick cesspool, made somewhat deeper than the drain, so as to catch any sediment that may wash in through the gratings; the neatest and most suitable of which are those cast so as to fit in an iron frame, from which they can be lifted and replaced when necessary for the purpose of cleaning out the cesspool. If these gratings are got about 6 in. long by 4 in. wide, they are not at all conspicuous, and are far preferable to any other on that account as well as on the score of cost, as there is no expense in making frames for them. Where there is a difficulty in getting an outlet for drains, dead wells may be formed at intervals to send the water in; but in all cases where these are resorted to, care should be taken to render them safe by backing up the sides and covering the tops with rough stone slabs or darning them over. These, however, are of little use, unless the subsoil is of an open nature to let the water soak away quickly, and should only be used when there is no other easy means of getting rid of it.

As a material for binding the slag or whatever else is used for the foundation, there is nothing equal to fine chalk, as it not only sets hard and firm, but is likewise most objectionable and impenetrable to worms, which, unless this is used, are

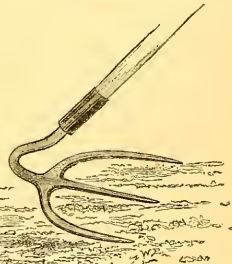

often very troublesome, as they not only disfigure the surface of the walks by the soil they exude, but they are the means of stocking the gravel with weeds, as the seeds of these can only germinate to any extent when so assisted. With a solid, compact mass for a bottom, such as the above-named mixture would form, and about three or four inches of gravel, consisting of two-thirds or so of fine stone, walks may be made that, with an occasional top-dressing, will last sound and enjoyable for any length of time, and such as will incur but slight labour in keeping them clean. In making choice of gravel, preference should be given to that which, when found in the pit, is in a hard compressed vein, as when in this state before being disturbed, it soon, with proper rolling and attention, gets into the same condition again. Any not so firmly imbedded, and therefore of a more sandy nature, may be greatly improved by mixing with it some finely-pulverised clay to give it adhesiveness, but this must not be overdone, or it will work out and be unpleasant to walk on. In sifting the gravel to separate the superabundance of fine material, two sorts should be made, the coarser of which to lay at the bottom and the small at the top, so as to finish off without any large stones cropping through in the way they otherwise would. A sieve of  $\frac{1}{2}$ -in. gauge is the proper thing to use in preparing the material for the surface, as any that will pass a mesh of that size will bind firmer and be more serviceable and agreeable to walk on than if it were coarser. Shingly gravel, or that which has at some time or other been subjected to the action of water, should always be avoided, as it is sure to be loose and constantly shifting under even slight traffic, on account of the smooth round nature of the pebbles it contains, besides which, they are always imbedded in sharp, sandy veins of earth that is totally unfitted for forming good sound walks. Stones that are more angular, and have sharp edges, get a firmer grip, and cannot well be displaced after having been once rolled in, as may readily be seen by any one at all acquainted with such matters.

Walks badly formed are a constant source of trouble and annoyance, ever requiring attention of some kind or other, particularly in the matter of weeding, as, from their loose surface, seeds effect a ready lodgment, and germinate and grow rapidly after every shower that falls. These weeds, in most cases, are difficult to deal with, and the more so where there are live edgings to the walks, as these prevent the use of salt, which is the best and most effectual means of ridding walks of their presence. Where there are Grass verges, it may be applied without doing the least harm, provided a favourable time be chosen for putting it on, which is after heavy rains with a rising barometer, as then there will be no risk of having it washed to the sides and damaging the Grass. The damp gravel and the night dews are sufficient to dissolve the salt slowly, in which way it is far more effectual than if done by a shower, or from watering, as then the strength is carried away from the crowns of the weeds, which are their most vital parts, and where they suffer immediately the sun shines hotly upon them. Not only is salt desirable for the purpose of cleansing walks from weeds, Moss, or other vegetable growth to which they are liable, but it has also a most beneficial effect in brightening and rendering them much more solid; and, if dressed annually about May, they will require nothing further, except the usual rolling and sweeping for the remainder of the season. For kitchen gardens, and places of that kind, where real utility ought to be considered before ornament, dead edgings should always be used, and something that is hard, neat, and durable is greatly needed for this purpose to replace Box, which, although it looks well, is always a harbour and breeding place for slugs and other insects that prey on young tender crops. Walks might then be kept in first-rate order with a tenth part of the labour they now entail, as hand weeding is slow work, and to break them up, as is frequently done, causes them to be rough and unsatisfactory for some time afterwards. Asphalt, when well done, is very durable and serviceable, and does away with the weed nuisance; but when made with tar, the cheapest and best material for the purpose, the colour is objectionable, unless white spar, or something of that kind can be used freely to take off its dead black, sombre appearance. In cases where good binding gravel cannot be obtained at reasonable cost, tar paths form

most excellent substitutes, but they should never be laid without a good solid foundation, or they will heave, from the action of frost, and break up into holes, which, if mended, always have a patchy, unsightly appearance. The bottom for these, as for gravel, may be made with fine chalk and stones, clinkers, or material of that kind most ready to hand, which, when put into its place, should be firmly rammed, to prevent any further subsidence. With such a foundation, walks may be made that will last a lifetime, if only subjected to fair ordinary wear; and, as they require no further expenditure of labour, or means to keep them clean when once formed, they are, in the end, the most economical, although they may cost a little more in the first place when laying them down. One important matter in connection with the formation of these asphalt walks is that they are well supported at the edges, otherwise they do not last sound long, as they break away at that particular part, and a kerb of some kind is therefore necessary, against which they may be finished. Strips of York stone, about 2 in. thick, and rounded off slightly, are the neatest and most lasting kerbs that can be used, and from their grey tint of colour they form a good contrast to that of the tar. S.

#### KITCHEN GARDENING MADE EASY.

I HAVE read with much interest the useful and practical remarks of Mr. Gilbert on this subject; but with reference to his observations (see p. 543, Vol. XII.), I do not think it can be easily understood whether he means that the Celery is planted between the Strawberry rows, or that the Strawberries have been taken up first; if he means that the Strawberries are left in the ground, I do not think it will be a very easy matter to make Celery trenches between Strawberry rows only  $2\frac{1}{2}$  ft. apart without damaging the plants. Mr. Gilbert says he uses a cultivator, or hoe, instead of a spade. I shall be much obliged if he will tell me what kind of hoe it is. I also think that what he says with reference to too much digging being injurious does not

apply to all soils; for instance, the soil of my kitchen garden is a very heavy one, and I am sure that if it were not dug and trenched well every year it would get as solid as a high road.

West Bank, near Macclesfield. C. LINDSAY HERFORD.  
[The annexed illustration is a representation of Mr. Gilbert's Cultivator.]

**Watercresses in Winter.**—From this time until the month of April or even May, Watercresses of really good quality will be scarce. Those gathered from the brook or bed now are good in their way; but a much finer sample may be secured by growing a few pans under glass, and in fact the table should be supplied all the winter through with frame or house-grown Cresses. Prepare the pans with a mixture of light rich loam and lumps of chalk or old mortar, and press the material firm, and heap it up as a pie. Into the pie crust insert the tops of fresh Watercresses one to two inches long, and press them firm, remembering that any sort will serve the purpose, and therefore you have but to buy a bunch to be fairly started. Put the pan into a water-pan, put a bell-glass over, and place the whole affair in a warm place, and the cuttings will be rooted in the course of a few days. A great many have blundered through putting in large cuttings, or through sticking them in sand and shifting them afterwards. The easiest way is the surest way. Put the cuttings into the soil they are to remain in, and when fairly rooted remove the bell-glass and let the plants have plenty of light. Cuttings started now in a warm greenhouse will supply good Cresses from about the end of January to the end of April, when they will be worn out.—S. H., in "Gardener's Magazine."

GARDENS AND WOODS IN BRITAIN.

BLUE BOOKS are not generally attractive reading. Among the most interesting matter in the recently-issued Parliamentary Returns is Table III (p. 467), giving the actual or computed acreage under orchards, market gardens, nursery grounds, and woods in each county in England, Wales, and Scotland in the year 1877. No doubt these figures are often estimates, while the designations to which they are applied, are, in the nature of the case, not easily or exactly defined. The acreage returned under orchards, &c., includes, besides orchards, arable or Grass lands which are planted with fruit trees. Market gardens includes land used by the gardeners for growth of vegetables and other garden produce, and as market gardeners are generally alive to the possibility of obtaining quick returns, and securing the most rapid succession of crops in, on, and above ground, the land so classed supports a considerable sprinkling of trees, and repays its cultivators by the variety of its fruit, root, and surface crops. The land classed as woods—including coppices and plantations—does not include gorse land and garden shrubberies. Taken in groups, the figures stand as under, representing the—

ACREAGE UNDER

	Orchards, &c.	Market Gardens.	Nursery Grounds.	Woods.
England .....	159,095	34,464	9,961	1,325,765
Wales .....	2,619	445	367	136,323
Scotland .....	1,579	2,939	1,624	734,490
Islands .....	1,713	303	73	
	165,003	38,162	12,025	2,187,078

Taken in detail, county by county, the figures in these returns show some curious results. Everywhere, except in the Islands of Man, Jersey, and Guernsey, which form our last division, the woods largely preponderate. These islands, however, return no woods whatever; but, notwithstanding their small extent, they return 1713 acres, or rather more than entire Scotland, under orchard culture, and 303 acres, or two-thirds of the amount returned from all Wales, as market gardens, with 73 acres used as nursery grounds. The islands appear to have turned their land to wise account, for while so large a part of their surface is under trees, these are, in most cases, fruit-bearing trees, furnishing at once a profitable industry for their own employment, and contributing substantially to the food supply of their neighbours. The Channel Islands have been well termed the Garden of England. The Isle of Wight escapes special mention from being included in the county of Hants, while the smaller islands either escape mention or are similarly included in county returns.

The whole acreage under nursery grounds, nearly 10,000 acres of which is in England, and about 367 acres in Wales, barely exceeds 12,000, or rather better than one-third the acreage under market gardens. Wales is far from being so rich in orchards or market gardens as might have been expected. It has little over 3000 acres in orchards and market gardens put together; or considerably less than may be found in the large county of York—which county, moreover, has over 118,000 acres of woodland, where all Wales has not quite 127,000 acres.

As would be expected, the greatest inequalities prevail between the different counties. The small county of Rutland has nearly as much woodland as Middlesex, though the latter has upwards of 5000 acres of market gardens, and 3000 of orchards—items, which in Rutland are barely represented by the figures 18 and 58. Durham, Northumberland, and Westmorland, stand in the tables for 197, 177, and 211 acres. On the other hand, we have Devon, with orchards covering 24,776 acres; Hereford, with 24,885; Somerset, with nearly 21,000; Worcester, with 14,600; Kent, with 13,000; and Gloucester, with nearly 12,000.

The proportion of orchard to the total of woodland varies considerably; fruit trees, of course, abounding most in the southern parts of the island. Thus, while Gloucester has nearly one-fourth of its total woodlands under orchards, Somerset has one-third, and Worcester nearly one-half. Essex follows Middlesex with upwards of 4000 acres of market gardens, with nearly 4000; Yorkshire with 2400; Surrey, with 1682; Worcester, with 1350; and Lancaster and Gloucester, with 1030 and 1002; Hereford returns only 13, and Westmorland 19. In nursery grounds, Surrey comes first, with 1519 acres; Sussex follows with 522; while Yorkshire has 886.

In woods, Yorkshire heads the list, followed by Sussex, with 101,000 acres; Hants, with 87,000; Kent, with 78,000; Surrey, with 68,000; Wilts and Salop, with about 40,000 acres each. Rutland, Middlesex, Huntingdon, and Cambridgeshire, come last, with 2500 to 5000 acres each. Wales shows great variations, from Anglesea, having only 7 acres under orchard, to Brecon 859. Anglesea returns no nurseries, and Radnor no market gardens.

Perhaps the Scottish returns are most curious. The counties of

Lanark and Perth return 493 and 378 acres respectively, under orchards, while Bute, Kincardine, Kinross, Peebles, and Shetland return none. Again, the counties of Edinburgh and Haddington have respectively 865 and 409 acres of market gardens. Nairn, Orkney, Shetland, and Sutherland have none. Then Edinburgh has 382 acres of nurseries, and Aberdeen 199; but again we have Clackmannan, Dumbarston, Orkney, Selkirk, and Sutherlandshire. Shetland, indeed, returns no woodland whatever, while Orkney shows a single acre of orchard land. In woods, the county of Inverness heads the list with 118,818 acres. Perth follows with 83,525, Aberdeen with 93,339, Argyle with 45,641. In Caithness we have 440 acres only.

These returns are in every way worthy of study. It is gratifying to hear that the planting of orchards is on the increase. There is great need that it should be so, and we should heartily rejoice if the thousands of acres of waste, moor, and mountain land now yielding no return, were to be planted with suitable trees—wherever possible with fruit or Nut-bearing trees—but planted certainly they ought to be by every intelligent proprietor, or leased by him, if indoped to discharge his own responsibilities, on such terms as to allow others to fulfil this imperative and patriotic duty. It is to be regretted that the returns from Ireland cannot be included for purposes of comparison with the larger island.

R. BAILEY WALKER, F.S.S.

**Paper from Asparagus.**—Those who are fond of making experiments, says the "Globe," may, if they wish to make a fortune in a novel way, start a company for utilizing the ends of Asparagus. The world has yet to learn that these despised bundles of white stalk, from which the tips have been bitten, are good for something else besides being thrown to cats and pigs, or cast into the dust heap. A man of science, writing to the "Patrie," explains what is the principal use to which they may be put. They may be made into paper, and that not ordinary brown paper, or even foolscap, but letter paper of the finest description. It appears that in a few favoured places there are manufactories where the Asparagus ends are used in this way, so that the only course which would seem likely to promise success would be that of starting some such thing as an Asparagus End Company (Limited).

**Propagating Crotons.**—Though Crotons are easily struck from small cuttings, where it is desirable to obtain good plants of them in a short time, the method usually adopted in the case of *Draecenas* and *Ficus elastica* may be practised with good results as regards Crotons. Any one having old straggling plants, should stop the leading shoots, and when they begin to break again surround the stems with a flower pot which has been split in two, securing the halves by means of wire or string. Fill the pot with sharp sandy soil, make a slight incision all round the stem under the pot, and in a few weeks roots will be emitted into the soil. Then gradually cut through the stem until the portion in the pot is finally severed from the plant, plunge the pot in a little bottom-heat, and when well rooted shift into a larger pot. In this way dwarf bushy plants for table decorations may be secured in three months, whereas from cuttings it would take at least two years to produce them. The old plant, which will break freely if placed in a moist heat, will make a lovely specimen, and may be used, if desired, for a further supply.—C. S.

**New Potato Granpian.**—This variety, just now being put into commerce here in the south, is of Scotch origin, and has for the past two years occupied a prominent position on exhibition tables. It has a pale red smooth skin, yellowish-white flesh of good quality, and boils mealy. Although not so handsome as Red Emperor, and wanting its rich deep red tint of skin, it nevertheless bids fair to displace that old kind as a show red round. In the north it is described as early, but here in the south it is quite late, indeed, one of the latest sorts to ripen which we have. The main stem attains a height of 2 ft. and is spreading.—A. D.

**Rhopala elegantissima.**—This is a useful plant for table decoration; it is dwarf in habit, and its elegantly cut leaves are produced on each side of long graceful stalks, close down to the pot. I saw neat plants of it the other day in Mr. Fraser's Nursery, at Lea Bridge.—S.

**Niagara.**—The Horseshoe at Niagara, the "New York Tribune" states, is now a right-angle rather than a curve. The rocks in the centre have been eaten away from year to year, and now the side walls are crumbling. On November 17th a large section of rock toward the Canada shore fell with a tremendous crash, and during the night a still larger area went down.

The average annual yield of a Tea plant is said to be about twenty ounces. The plants live from twenty to thirty years, and when old are frequently cut down and a young shrub grafted into the old stock.

## THE LIBRARY.

## THE ROSARIAN'S YEAR BOOK FOR 1877\*.

A small handbook of fifty-seven pages, edited by the Rev. H. Doubrain, secretary of the National Rose Society. It is a well got up little book, but, nevertheless, somewhat disappointing, no fewer than twenty-four of its pages being devoted to dry reports of Rose shows—merely long lists of names of Roses. Short reviews of recent Rose literature are, however, also given, and lists and descriptions of new Roses for 1877. Mr. George Paul contributes to its pages a useful article on Rose stocks, from which we extract the following:—

“The Dog Rose seems to have been naturally the first used, and we hear of the first imported standards coming for sale here from Paris at high prices. Since then we have learnt to work our own, but have made but slow progress in standard Rose culture. More careful knitting—the gradual adoption of shorter stems—are mere details. The old hedge-gathered standard Brier seems to remain the only stock here used successfully for standards. As far as the writer has seen, we gain nothing in allowing seedling Briers to stand long enough on quarters to throw up suckers fit to work upon. The four years they have to stand lead to coarse and more immovable rooted plants than Briers which have only stood two years after planting, and which consequently have, if properly grown, a good stock of young, freshly formed roots. The Dutch see some of the climbing Roses. The Garland, as tried here, is the best, but there is a zigzag form in the stem which does not compare favourably with a well-grown Brier stock. Taken altogether, while the supply lasts, the hedge Brier must be the stock for standard or half-standard Roses. One word more: Will not experience show that only vigorous sorts should be grown as standards? It wants good growth on any tree to bring the sap up through a long unfurnished stem. For dwarfs there is more variety. To return to our Manetti, we have learnt much since its introduction; but we owe it one debt—that it has let Roses be grown in gravelly, poor soils, where before they were unable to be cultivated. On such soils almost all the Hybrid Perpetuals do on it; on the richer good Rose soil, it will assert itself, and kill off the weaker kinds. Again, with the Tea Rose, it has no affinity, and makes but a bad stock. When in Victor Verdier, La-chaerme gave us a Tea-hybridized Hybrid Perpetual, a new race with Tea-blood began, and the series showed at once their origin by a gradually growing dislike to the thorny, thick-barked Manetti. Victor Verdier, the first, succeeds fairly; Captain Christy, the last and most Tea-like, refuses altogether to have to do with the stock. What conclusion should we draw from these observed facts? That the Rose growers should use this stock for the strong-growing, Jacqueminot-originated Rose, the hybrid Chinas, the free climbers, Moss, and hybrid Bourbon Roses. It must also always be valuable as a *porte-plante* for the newer Roses of all kinds, and for pot culture. We all know that, kept well beneath the surface, the variety it carries (so to speak) roots itself, and so the Manetti acts as giving a double tier of roots to the plants. For pot-culture, where too many roots cannot be had, the peculiar, much-fibred root of the Manetti is particularly valuable near the side of the pot. It will not cease to be used for pot-culture for even the smooth-wooded kinds, and (with its suitability for gravelly soils) so the lighter soils usually used in pot Rose-culture also meet with encouragement. This is a most important point; Roses on Manetti give us flowers at least a fortnight before those on seedling Brier, adding a month at the best time, too, to our Rose season. I have not much knowledge of the Celino, but know some growers, like Mr. Rivers and Mr. Curtis, use it for strong Teas, the Dijon race, and Bourbons. It is a hybrid China; but I hold the old Rose of the same class, De la Griferie, to be a better stock for the same kind. On this, which has been used at Cheshunt for ten years or so, the Maréchal Niel, Gloire de Dijon, kinds of Teas, and La France, seem to form a perfect union, and grow as if in full accord with their root-supply. It has one fault, a tendency to grow early, which it perhaps slightly imparts to the kind it carries. I am not quite sure, but fancy the Napoleon stock of the ‘*North Country*’ is this, or a nearly resembling variety. In the light, sandy, peaty soil of Surrey, the climbing Roses, the Garland more especially, and Félicité Perpetuelle, are used for Tea-scented and Noisette Roses. Here they grow so much in one season as to be too big, and have too thick rind to bud. The transplanted seedling Dog Rose or cultivated Brier is for Teas the stock. It should be also used for Captain Christy and the Victor Verdier race. Henri Ledescheaux, refusing to grow on the Manetti, is on the Dog a grand Rose. In an article, space could not be given for a detailed list, which is, moreover, a valuable acquired knowledge of the individual cultivator; but the broad rule is given as regards the Hybrid Perpetuals. Maréchal Niel

and the Dijons do thoroughly on this, and all the Teas, without exception, seem to thrive. Perhaps Niphetos and Madame Willermoz, and one or two of the feebler Teas, are hardly sucker-proof without extraordinary care. As Niphetos is, with shelter, so good a standard Rose, this does not much matter. For gravelly soils, as said in speaking of the Manetti, we doubt the adaptability of this stock; for rocky, brashy soils it seems suitable.”

The remainder of the book consists of a report of the weather during the past year, a chapter on Rose showing, and a well-deserved tribute to the memory of Thomas Rivers, by Canon Hole.

**How to make an Amateur's Rose Garden.**—Look out an open bit of land of whatever size is thought desirable. Beginning at one side, take out a trench 2 ft. deep if possible, and thoroughly trench the piece, mixing with the soil the best manure you can find available. When finished trenching, wait until the soil gets partially dry at the top, then give it a good treading all over, making it quite firm. Go to the best Rose-grower in your locality and beg the prunings of Roses, which any true amateur will give you ungrudgingly. Select of the shoots the strongest and best ripened wood, cut them into lengths 8 in. long, planting the pieces all over the ground at 8 in. apart and 6 in. deep, merely leaving above the surface two buds. This is as good a time as any to begin the work. Should the weather become very severe, protect the cuttings either with a few half-rotten leaves, fir branches, or, best of all, Bracken. When April arrives, take away the covering, but be careful not to hurt the young buds, which will now be showing. Keep the land open by hoeing—but not raking. If these remarks are attended to, you will have the first year a few late-blown Rose flowers, and the second year, by cutting all down in March, and mulching the bed with a little manure, you will possess a bed of Roses that would not disgrace the best garden in the land.—R. GILBERT, in “*Horticultural Record*.”

**Chrysanthemums.**—What is the difference between Mrs. Dickson and Golden George Glenn? Would they be disqualified if shown together in one class? Three years ago last autumn I had a yellow sport on George Glenn; but, seeing that Mr. Dickson had also one from the same, I gave mine away to my neighbours under the name of Golden George Glenn. This season I have a yellow sport on Barbara.—C. OGDY, Broughton, Manchester.

**Artificial Manures.**—What is the best kind of artificial manure for a fruit and vegetable garden where animal manure cannot be obtained?—X. Y. Z. (Guano, soot, salt, and bones are perhaps the best manures under such circumstances. Night soil (deodorized) might be used on poor land. Many other kinds of artificial manure are also advertised, but it is difficult to say which amongst them is the best.)

**Camellia Leaves Dropping.**—Can any one tell me the cause of my Camellias dropping their foliage, the buds on the ends of the shoots only being left? It is two years since they were potted, and the roots are all round the pot, and appear to be in good condition—quite white and clean.—H. S. (See if the roots are not too dry. If so, soak them and the ball of earth in which they are growing in a tub of water for an hour or two. You will be able to judge if the inner portion of the ball be dry by the air bubbles which will be produced on immersion.)

**Basket Plants.**—What are the most suitable plants for hanging baskets in a small Aquarium, where there is, of course, an abundance of moisture and also a little heat given off from a small steam boiler used in the building? (The best plants for such a purpose are Ferns and Lycopods, and amongst flowering plants Achimenes, Ivy-leaved Pelargoniums, and some of the half-hardy annuals. Much, however, depends on the heat which you have at command; if a temperature of 60° can be maintained, there are many Orchids which might be grown in such a place with advantage; also *Torenia asiatica*, *T. Fournieri*, and *Zeschmianthus grandiflorus*.)

**Cornelia glauca out-of-doors.**—Allow me to inform Mr. Osborn (see p. 562, Vol. XII.) that I have found this to be quite hardy in Queen's Co., Ireland. We have two plants of it about 6 ft. high and as many feet through, which always bloom freely; they are sheltered from the north by other shrubs. I have seen much larger plants of it in other places in this county outdoors, sheltered by walls.—W. H. H., Dublin.

**Begonia Frébelli from Seed.**—In raising this Begonia from seed, the temperature should have been 65° instead of 45°, as stated (see p. 604, Vol. XII.). I am now propagating it by means of cuttings, and I find it to strike freely.—J. Claws, *Headfort, Kells*.

**DURING THE YEAR 1877** Messrs. James Veitch & Sons, of the Royal Exotic Nursery, Chelsea, were awarded at the various meetings of the Royal Horticultural Society, 38 certificates, 34 being first-class, for new plants, 2 first-class for new vegetables, and 2 second-class for new plants. They also received from the same Society, in the same period, 2 botanical certificates, 1 cultural certificate, and 2 botanical commendations. This is the largest number of certificates, we believe, that has ever been awarded by the Society, in a single year, to one firm. Messrs. Veitch also received from the Royal Botanic Society, in the season of 1877, 33 certificates of merit for new plants, 27 of which were botanical, and 6 floricultural.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### ENGLISH GROWN ORANGES AS DESSERT FRUIT.

The culture of Oranges for some reason is not so popular as it deserves to be. The Orange-house here (established many years ago by my father) was a "picture of beauty" in October, when the fruit was fully coloured, if not ripe, and to all appearance it will remain equally attractive for the next three months; thus for six months during the dead time of the year it is a never-failing ornament. This mild winter the temperature in the house has averaged 55°, and consequently the cost for fuel has not been excessive. The trees are hardy, and require little attention or skill in pruning. My fruiting trees, which are from seven to ten years old, and from 4 ft. to 5 ft. high, are half-standards, a form which the Orange takes naturally. The soil in which they are grown is a strong loam (the ferruginous loams of Sussex are best). For supplementary food, oil yags or the wool-waste of Leeds or Bradford should be used in preference to stable manure; but if wool waste cannot be had, cow manure should be used. Such liberal fruit-yielding trees must be well nourished; and to give an additional help, plunge the pots in a border, and allow the roots to pass through into the soil. In November, when the fruit is perfected, prune all the roots outside the pots (for Orange culture perforated pots should be used); thus treated, the trees will be kept in a fruitful state, and excessive growth restricted. The St. Michaels, Blood, and Tangierine are three sorts which will satisfy all the requirements of an Orange cultivator. There are, however, many sub-varieties of the St. Michaels; of these the Prata, or Silver Orange, is noteworthy. It possesses a finely-grained thin rind, and when fully ripe is specially good. The Maltese Blood Orange should be in every Orange-house. Curiously enough, on the same tree some of the fruits are entirely free from blood stains. The Tangierine completes the group of dessert Oranges. It is a charming little fruit-bearing shrub, almost hardy, and an abundant bearer, forming a miniature tree of straggling, but graceful growth; it should be in every Orange-house, and, indeed, in every conservatory.

After Oranges the Lemons follow naturally. Of these the Imperial Lemon is the best. It is large, handsome, and of fine flavour. This and the Bijou are worth a place in every collection. The latter is a beautiful little plant, very dwarf, bearing Lemons, when full-sized, not larger than a Walnut, but of excellent scent and flavour. Unlike the Tangierine Orange, it makes a fruitful dwarf pyramid, and, when laden with fruit, it is surpassed by few plants for winter decoration. Limes, Shaddocks, and Citrons have all fruited here, and have been discarded as fruit-growing plants. Room and time given up to the growth of a worthless fruit is a mistake. The Myrtle-leaved Mandarin is a pretty bizarre shrub, but the fruit is worthless for the table.

Scale is a bitter enemy of the Orange tribe; but the use of paraffin will, in time, entirely destroy it. It must, however, be watched continually and vigilantly if the cultivator desires to keep his plants in health.

I have looked upon the Orange as a fruiting plant for so many years, that I have not alluded, (as an additional inducement to the cultivator) to the fact that it produces flowers in great profusion, and that these alone will repay any expenses which may attend its cultivation; but—they must not be in the market during Lent!

T. FRANCIS RIVERS.

*Sawbridgeworth.*

**Mammoth Bunch of Grapes.**—There was recently on exhibition in San Francisco, a mammoth bunch of Grapes from the great Grapes-vine of Santa Barbara. This cluster weighed 125 lb., and was 6 ft. in circumference and 3 ft. long. The Vine from which it was cut is sixteen years old, and produces annually from 10,000 lb. to 12,000 lb. of Grapes. This is probably the largest bunch of Grapes ever grown.—*American Paper.*

### FRUIT TREES ON NORTH WALLS.

WALLS with a north aspect may be made quite as useful as walls with a south aspect. The north walls here are just as well furnished with fruit trees as any others about the place, but of course with a different class of fruits. Cherry trees do better on a north wall than on any other aspect, and Gooseberries, and red and white Currants also do famously on a north wall, on which they have the advantage of being a month or six weeks later than in any other part of the garden, a circumstance worth attention, where a long succession of fruit is wanted. When Gooseberries are grown for preserving, the earlier they are ripened the better; consequently there is no need for them to be grown on a wall which should be devoted to the best dessert sorts. Ours consist of Garibaldi, Binger, Admiration, Brown Bob, Champagne Charley, Green Overall, Whitesmith, and Champion, and they answer so well that I have no hesitation in recommending them to others. Sometimes when there are no fruits or standard bushes the wall once covered, and they are easily protected from both cold in spring and birds in autumn. They are planted 2 ft. apart, and two shoots are allowed to grow from each root. These are trained straight up to the top of the wall at equal distances from each other. When pruned all the young shoots, which are growing straight out from the wall are cut in close. After pruning, a quantity of manure is annually forked about the roots. We had a fine crop of red and white Currants on a north wall this season. They are treated exactly like the Gooseberries, only they are planted further apart, and from six to eight branches are taken up from each root. Some old Cherry trees on east, west, and south walls, do not bear every season, but those on the north wall never miss a heavy crop, and were it not for the trees in this position we would frequently be in want of Cherries. These are planted from 12 ft. to 20 ft. apart and trained fan-fashion. The Morellos make most wood, and this is laid in closely as soon as the leaves fall. Archduke, Black Eagle, Black Tartarian, Late Duke, May Duke, and Transparent are a few good sorts which succeed well on a north wall. As this is the proper time for planting all these trees, wherever there is a vacant space on a north wall it should be at once filled up. Cherries grow best in a rich sandy loam, and Gooseberries and Currants will succeed in nearly any kind of soil. We have several Apple trees on a north wall, but they do not fruit with much certainty. As to the crops that do best on north borders I find Lettuce to do exceedingly well in summer, and salads generally seem to do better in such cool positions during hot weather than elsewhere.

CAMBRIAN.

**Victoria Nectarine.**—Notwithstanding "W's" remarks (see p. 12) in favour of this Nectarine, I repeat that such an unqualified recommendation as that given by the writer of the article to which I replied, is likely to mislead, as the Victoria Nectarine will only succeed out-of-doors in favoured localities. Trees of this fruit take some time to get established; they are expensive to purchase, and therefore anyone having only a limited amount of wall room must naturally be discouraged to find what they plant turn out a failure after being so lauded. On referring to several of the principal fruit catalogues, I find I am borne out in what I say respecting this Nectarine, as the remarks in each case are, "requires a warm situation." Surely your correspondents will not, after this, recommend it as the best of all Nectarines, and advise its being planted almost exclusively. The writer of the first eulogistic notice of it appears only to have it under glass, where it has done well, but its success under such conditions does not guarantee that it will do equally well on open walls. If your correspondents had stated the districts in which they reside, and the kind of soil in which they find this Nectarine to do so well, others could better judge of its merits and suitability for their own gardens. I should be the last to discourage the trial of any new or improved variety of fruit, and I only do so in this instance to save amateurs being disappointed after years of waiting and attention, knowing, as I do, that there are other harder varieties that will give more satisfaction.—S. D.

**Mildewed Grapes.**—I have found the following method efficacious in arresting mildew in the case of late Grapes:—On a still day, heat the hot water pipes as hot as the water will make them, and damp every part of the floor well with water, keeping all ventilation closed. Take a stone of fresh lime and slack it in a bucket, allowing it to boil well. Then reduce it with water to the consistency of thick paint, and into half a bucketful put three handfuls of flowers of sulphur. Mix all well together, and with an old whitewash brush put the mixture on the hot pipes. After the Grapes are all cut, it should be all washed off the pipes quite clean, or the result will be a crop of rusted Grapes the following season.—JAMES SMITH, *Waterdale.*

## NOTES OF THE WEEK.

**Kew.**—At the present time in the greenhouse (No. 4) there are several Australian plants in bloom which well deserve mention. *Correa speciosa* is there in three distinct and handsome varieties—*ventricosa*, with scarlet, green-tipped flowers; bicolor, with a pink tube and whitish limb; and *Bachnosiana*, with fine, bold, whitish flowers. All the *Correas* are very desirable greenhouse shrubs, and do not demand much skill on the part of the cultivator. A pretty twiner is *Hibbertia dentata*, with its purplish leaves, placed alternately, and its showy yellow flowers; other recommendations, besides its beauty, are, that it can always be easily kept within bounds, and does not suffer from insect attacks. *Stenantha pinifolia* is the only species of a genus of *Epacrids* which, we may remark, take the place of the Heath in Australia. (An interesting fact in plant geography is, that the Natural Order *Ericaceae* is not represented at all on the continent of Australia.) *S. pinifolia* is a very pretty bush; the branches are much crowded with needle-shaped leaves, and the flowers have a scarlet tube and white limb. *Styphelia tubiflora*, another *Epacrid*, has sharp-pointed leaves and scarlet tubular flowers, somewhat like those of some *Epacrises*.

In the Cactus-house may be seen two *Dianellas*—*D. tasmanica* and *D. corulea*. The pale blue, yellow-stamened flowers of both species are borne on large, lax-branched, many-flowered panicles; the ensiform leaves are from 3 ft. to 4 ft. long. *D. tasmanica* sets an abundance of bright blue berries, which hang for a long time on their hair-like pedicels; it is the finer of the two, and is certainly not one of the least beautiful members of the Lily family. The red, wax flowers of *Cotyledon* (*Echeveria*) *fulgens* and *C. retusa* are extremely showy. These *Meibomia* succulents should be specially grown for winter flowering.

*Stephanophysum Baikie*, now in flower in the stove, was discovered during Dr. Baikie's Niger Expedition. This *Acaethad*, when well grown, makes a pretty pot plant; and although the individual flowers do not last long, a succession is produced in tolerable abundance for some time. The inflorescence is terminal, and is composed of many-flowered opposite spikes of tubular, curved, scarlet flowers about 2 in. long. *Astrapea Walli* is a very striking *Bytneriacae* plant from Madagascar; it has large, cordate leaves and bright red flowers. Dr. Lindley and Sir Joseph Paxton say, "This may be considered one of the finest plants ever introduced; when loaded with its magnificent flowers, we think nothing can exceed its grandeur." The Rev. Mr. Ellis, to whose efforts our gardens are indebted for the glorious *Angreem* *sesquipedale* and that extremely strange vegetable production, the *Laticia*-leaf of Madagascar (*Ouvriandra fenestralis*), thus speaks of it: "But the most magnificent objects were the fine trees of *Astrapea Walli*. The name of this Malagasy plant is derived from the word for lightning, on account of the brilliancy of its flowers. I had seen a good-sized plant growing freely at Mauritius, but here it was in its native home, luxuriating on the banks of the stream, its trunk a foot in diameter, its broad-leaved branches stretching over the water, and its large, pink, globular flower-heads 3 in. or 4 in. in diameter, suspended at the end of a fine, down-covered stalk 9 in. to 1 ft. in length. These, hanging by hundreds along the course of the stream, surpassed anything of the kind I had seen or could possibly have imagined." Heat, moisture, and a fair amount of pot-room are essentials in the successful management of this plant. If these be given, it flowers pretty freely in a small state, say at from 4 ft. to 6 ft.

*Maettia cordifolia*, a handsome Brazilian *Cinchonaceae* shrub of climbing habit, is in flower in the old Lily-house. It has opposite leaves and a bright scarlet, tubular corolla about 2 in. in length. The root possesses emetic properties, and is used by the Brazilians in dropsy and dysentery.

In the Winter Garden, many of the Himalayan *Rhododendrons* will soon be making a fine show. At present, *R. arboreum* is covered with its refulgent crimson-scarlet flowers. Although, in its native haunt, this has to withstand a much colder climate than that of Britain, a glass structure is required for its successful cultivation in this country, except in the most favoured spots. Its flowers are boiled down in the Himalayas, and made into a sort of jelly.

In the Orchid collection, the following are the most noteworthy: *Dendrobium Devoniannum*, from the Khasia Hills in India, is one of the most delicate and lovely of all Orchids; it has jointed, nearly cylindrical, elongated, whitish-brown stems, and is of weak and slender habit. Its large, handsome flowers are borne at the ends of the leafless shoots; the entire ground colour is white, the sepals being faintly tinged with purple, and the beautifully ciliated petals bearing a purple spot at the apex; the very large cordate lip is elegantly fringed, is also tipped with purple, and bears two large orange spots on the pure white ground. *Oncidium ornithorhynchum*—in a genus

in which yellow so greatly predominates—is remarkable for having flowers of a pretty rose colour, with scarcely a tinge of yellow. It is a neat, pleasing little species, which, however, varies considerably in merit, both as regards size and tint of flowers. In its wild state it grows in damp, shady places in Mexico, Guatemala, and Peru, where the temperature varies between 68° and 75°. *O. aureum* is a Peruvian species, with an erect, loose panicle; the flowers have olive-coloured sepals and a golden-yellow lip. *O. sphegiforme*, from Brazil, has yellow-crimson spots on lip, and dull purple stains on the sepals and petals. *O. pubes*, also from Brazil, has a pyramidal panicle of small, brown, yellow-edged flowers. *O. serratum* is somewhat similar in appearance to *O. crispum*; the tall, oval pseudo-bulbs bear one or two long, erect, acute leaves; the panicle is lax, many-flowered (wild specimens have been gathered with panicles 9 ft. or 10 ft. in length); the sepals have crisp, serrated margins, and, as well as the petals, are of a brown chocolate colour, tipped and margined with yellow; the small, spear-shaped lip is yellow-crested. This species is a native of Peru. *Odontoglossum cordatum* is a Mexican species, with two-leaved pseudo-bulbs and broadly-oblong, smooth, acute leaves; the linear-lanceolate sepals are greenish, barred with brown; the petals are similar to the sepals in shape, and are light yellow, spotted with brown; the lip is cordate, acuminate, and of the same colour as the petals; the top of the column is white. *Mesospitium aurantiacum*—perhaps better known by the name under which Lindley first described it, viz. *Ada aurantiaca*—is a remarkable plant, with brilliant orange-yellow flowers collected in a close raceme. The pseudo-bulbs are about 4 in. long, and bear from one to three broad, linear leaves at the extremity; the drooping scapes are about 1 ft. in length. It inhabits the Pamplona, in New Granada, growing at a height of 8500 ft. above the level of the sea. *Maxillaria setigera*, also from New Granada, is one of the most attractive species of the genus. Its very pretty conspicuous flowers are freely produced, and are of a fine golden-yellow colour, with the exception of the base of the three sepals, the two linear petals, the column, and the edges of the small lip.

**A Clematis Christmas.**—My gardener has just presented me with a New Year's gift such as I do not remember to have seen at this date during my long experience as a Rosarian—namely, a well-formed bloom of *Paul Neron*, grown, without protection, in the open ground.—S. REYNOLDS HOPE, *Causton Manor*.

**Clematis Pitcher**.—This scarlet-flowering *Clematis*, recently figured in the "Revue Horticole," is a more striking plant than it is represented, as we can say from having seen it in flower. It will no doubt prove a hardy species, and be a charming plant for the rock-garden and for large walls. We first saw it in the Garden of Plants.

**Pleione humilis**.—This, one of the most singular as well as handsome of what are called Indian *Crocuses*, is now in full flower in Messrs. Veitch's nursery. It is grown in 4-in. pots, and on some plants it may be counted as many as twenty beautifully-fringed, violet-tinted blossoms and buds.

**Orchids at Holloway.**—An attractive display of Orchids may now be seen in the Victoria Nurseries. *Colax juncos* is flowering freely on suspended blocks, associated with the beautifully-marked *Odontoglossum Rossi majus*, fine spikes of *O. cirrhosum*, and the scarlet wax flowers of *Neottia maculata*. The graceful *Oncidium ornithorhynchum*, and a group of *Calanthes* and *Lady's-slippers*, intermixed with Palms and Ferns, are also at present striking features in this nursery.

**Primulas at St. John's Wood.**—A house filled with double and single-flowered Chinese *Primulas*, in the Wellington Road Nursery, is now well worth going a considerable distance to see. They consist chiefly of old plants, grown on purpose to supply early cut bloom. Amongst them the brightest red is *Magnifica*, a robust double-flowered kind; and we also noticed the Fern-leaved, lilac-rose flowered sort called *Emperor*; *Blushing Bride*, one of the largest-blossomed white kinds, delicately suffused with lilac; and the beautiful semi-double, flesh-coloured variety named *Maiden's Blush*, a kind which comes true from seed, and which furnishes blossoms unusually well adapted for use in a cut state.

**Angreem sesquipedale.**—A large plant of this *Angreem* in the Royal Exotic Nursery, Chelsea, is now bearing nearly a dozen blossoms, each of which measures about 6 in. across; they are of snowy whiteness, and last, in good condition, from fifteen to twenty days. A miniature form of this *Angreem* not yet named, also in bloom at Messrs. Veitch's, promises, for many purposes, to be equally valuable. Its flowers, as regards shape, are exactly like those of *A. sesquipedale*, but they are no larger than those of a *Stephanotis*.

**Dendrobium superbiens.**—This will probably prove to be one of the most valuable additions to this beautiful genus which has been introduced of late years. It is now flowering freely in Mr. Williams' Nursery at Holloway. Its blossoms, which are similar in shape, and nearly as large as those of the well-known *D. nobile*, are

of a most beautiful mauve colour, and are produced on long, gracefully drooping slender stems for a long time in succession. For cutting for small bouquets these blossoms will be very valuable. The plant itself is of freer growth than *D. bigibbum*, of which it is a variety, and its flowers are totally different from those of that species both in shape and colour.

**Azalea Rollissonii.**—This new double scarlet Balsam-flowered Japanese variety is now in flower in Messrs. Rollisson's nursery. It is very dwarf in habit, and it is expected that it will prove to be hardy; if so, it will be a valuable addition to plants suitable for the Alpine garden, as well as for planting in masses in the flower garden. As a market plant, too, when plentiful, it will doubtless be grown extensively.

**Dwarf Poinsettias.**—A fine display of remarkably dwarf Poinsettias has been made during the last month in one of the houses at Harrow Weald Park. They were struck from cuttings taken from old plants in August last, and were grown in 5-in. pots in good sandy loam, peat, and leaf-mould. The plants are now from 12 in. to 15 in. high, clothed with large, healthy foliage down to the pot; and the heads of bracts which they are bearing are the largest we have seen this season, some of them measuring 13 in. across, each bract being very broad and bright in colour. They have been fed with Standen's manure, have had abundance of water, and been kept near the glass in a light, airy house.

**The Douglas Fir at the Paris Exhibition.**—The Canadian steership Newfoundland is on its way to France, having on board two pieces of Douglas Fir (*Abies Douglasii*) for the Paris Exhibition. The pieces are a transverse and a longitudinal section, taken from a tree over 400 ft. in height and 8 ft. in diameter, found growing on the slopes in British Columbia.

**Cypripedium Boxalli.**—This recently-imported Lady's-slipper may now be seen flowering freely in the principal London nurseries. It is of robust habit, and, being already plentiful, it will no doubt be grown extensively in most gardens.

**Lomaria gibba var.**—In Mr. J. H. Ley's nursery at Croydon there is a new *Lomaria*, a variety of *L. gibba*, the peculiarity of which is a singular extension of the main rib at the end of each of the pinnae. It is a handsome Fern, apparently more robust in habit than *L. gibba*.—J. F.

**Early Outdoor Flowers.**—If the weather continue open, we will soon have a pretty display of spring flowers. *Botryanthus pallens*, *Abrotia superba*, *Gentiana acualis*, *Pansies*, and *Primroses* are already flowering freely, and the buds of *Saxifraga pyrenaica var. maxima* and *S. Borsariensis* are on the point of opening. Those, too, of *Galanthus Imperati* are through the soil, and will form striking and lovely objects when in full bloom, as there are thousands of bulbs of this, the finest of all Snowdrops, massed together in the nursery-beds in the Messrs. Backhouse's grounds. To all appearance it will be earlier in expanding its flowers than either *Galanthus nivalis* or *G. plicatus*.—R. P.

**Botanical Geography at Kew.**—"A selection of the larger tropical Ferns—Aroids, Marattaceae, &c.—has been planted in the beds under the Palmæ, which have hitherto been quite bare. They are now covered with an undergrowth of singular picturesque and luxuriance." So says the Kew report for the year 1876; and we can ourselves vouch for the beauty and luxuriance of some of the objects, which display a rude health and vigour somewhat surprising to those who have always been accustomed to see them confined in pots. The arrangement of some, however, strikes us as not being particularly happy. For instance, the trunk of a South African Palm, *Phoenix roscinata*, supports a fine fruiting specimen of the Mexican *Monstera deliciosa* and several Bromeliads, which, of course, are exclusively New World plants. Again, *Dendrobes* are associated with a Mexican Palm, *Trithrinax aculeata*, and we need hardly say that there are no *Dendrobes* at all in the Western Hemisphere. The *Dendrobes* would, to us, have seemed more appropriate on some Indian Palm, and the *Monstera*s and other American climbing Aroids on New World Palms. Kew, as a great educational establishment, does not fail to acknowledge the importance of geographical distribution, as is shown by the selections on the shelves round the Palm-house and Winter Garden, in both of which places a vast number of species, properly arranged, convey to the uninitiated in botanical geography a far more correct idea of the flora of any particular region than can possibly be obtained from whole chapters of the most graphic descriptions, unless these be very profusely illustrated. In connection with Mr. Hemsley's contributions to THE GARDEN on this subject, an intelligent glance at the collections just named cannot but be most interesting and instructive. In a place like Kew, when the same result, as far as regards appearance, may be obtained by associating subjects belonging to the same region, it is surely advisable to follow out, as far as practicable, the arrangement which obtains on the shelves.—S.

## FALLACIES OF LILY GROWERS.

THE readers of THE GARDEN who are interested in this subject, can hardly have overlooked the fact that Mr. Frank Miles' letter (see p. 546, Vol. XII.) is singularly consistent with my views. As regards his one doubtful point, namely, "whether the Lily is annual, biennial, or triennial," he will see from my last letter (see p. 557, Vol. XII.) that, before I could have seen his, I had stated my views on this point when illustrating the phenomenon, called "Three generations in one." I know of no other plants, though there may be some, which we can compare in their underground action with the Lily. With it there is undoubtedly an annual bloom, but not from the same bulb, though many who have not studied the matter sufficiently believe it is. From what I said in my last paper, it may be seen that, while one bulb is flourishing in its first and only bloom, another bulb within it—mark these words, "within it"—not outside, as offsets of any description whatever, another bulb, a new bulb within it, is progressing in its growth, so as to be enabled to bloom next year, in place of the one now blooming, which will then be dead; thus keeping up a yearly bloom from successional bulbs, *ad infinitum*, if properly cultivated. There is, therefore, no foundation whatever for saying that "the bulb goes on living and blooming for an indefinite period, and then dies of exhaustion or old age." A greater fallacy than this could not be uttered; for the term of a Lily's existence, from the period of germination till the final decay of the plant, is so designed by Nature as not to exceed two years. It is thus, that every year witnesses a birth and a death; that is, the birth of the seed-bud, and the death of the flowering bulb, being the youngest and the oldest of the "three generations in one," the new bulb being always an intermediate between these two. I think, when illustrating some of these points, I mentioned in a former paper that I have in my garden a bulb of *L. croceum*, the progenitor of which I planted 35 years ago. During all these years, I have watched this plant with more than an ordinary interest; and, as I lifted and replanted it every year, I found that the fading flower-stem was always attached to the fading parent bulb, and not to the new bulb, which appeared every succeeding year, fresh, clean, plump, and crisp, with the scales firmly and closely set upon one another, while the scales of the parent bulb were discoloured, loose, and flabby. How far back the pedigree of this bulb could be traced it is difficult to say, though I believe I could get evidence of ten years more to add to the thirty-five. But be this as it may, I think that, while considering the wonderful organization of the Lily, we might be pardoned for indulging in the reflection that some of the Lilies which we now see around us may have had progenitors among those Lilies which historians have mentioned as blooming in all their glory more than 3000 years ago. A distinguished writer, who spent twenty-five years in Syria and Palestine, in his description of the Hühle Lily, says:—"This Lily is very large, and the three inner petals meet above, and form a gorgeous canopy, such as art never approached, and which never sat under, even in its utmost glory. When I met with this incomparable flower, in all its loveliness, among the Oak woods around the northern base of Tabor and on the hills of Nazareth, where our Lord spent his youth, I felt assured that it was to this flower he referred, nearly 2000 years ago, when he said, 'Consider the Lilies how they grow.' This Lily is to be found on the mountains; but it delights most in the valleys, and appears to be the identical flower to which Solomon refers, when he wrote, 'I am the Rose of Sharon, and the Lily of the valleys; as the Lily among thorns.' The Hühle Lily grows luxuriantly among thorns, and I have had my hands sadly lacerated in extracting it from them. Nothing, indeed, can be in higher contrast than the luxuriant, velvety softness of this Lily, and the crabbed, tangled mass of thorns growing about it."

Returning from this digression, I may now mention that a writer in the "Journal of Horticulture," when describing *Lilium auratum*, as it is grown in the garden of Mr. McIntosh, at Duneevan, says:—"Last year a plant in that garden attained a height of 11 ft.; and this year, although the summer has been so dry, the same bulb has thrown up a spike 10 ft. 6 in. in height." The Lilies at Duneevan, from all that I have heard, are indeed splendid; but my object in quoting this

paragraph is simply to show that the writer says that the spike was thrown up by the same bulb that bloomed the previous year. This is a fallacy, which, from the position the writer holds, is calculated not only to confirm those who believe in such a theory, but to retard desirable investigation. Another writer, in June last, wrote, saying:—"Five years ago I purchased a bulb of *L. Szovitzianum*, carefully taken up with its roots. The first year it had three blooms; the second, five; the third, eight; the fourth, fifteen; and this year it has fifteen again, all on one stem, as it has never sent up a second one, a peculiarity said to belong to it." I trust this writer will soon be able to satisfy himself that it could not have been every year from the same bulb. There is another fallacy which, by long usage, has been so thoroughly ingrained in the minds of many Lily growers, that, I fear, it will meet with much opposition before it can be completely eradicated. I mean the objection against annual lifting and transplanting. In order to solve the difficulty, it should be asked in the first place—"Why annual transplanting is, at present, the exception rather than the rule?" Simply because there is a very general belief that the first year's growth and bloom, after transplanting, are inferior to the second; and that, consequently, annual transplanting would simply be encouraging a constant repetition of this inferiority. And so it would, if late transplanting is persisted in. I admit that it would be an act of great folly to transplant the general run of Lilies annually, with any prospect of success, if we left them in the ground until "the end of October or the early part of November," as a cultivator, in a book lately published, directs. But it would be the very reverse, if the transplanting took place soon after the flowers have faded. In dealing with Lilies in this country, we should never overlook the fact that they are here under artificial cultivation; whereas, in their native places, Nature has provided for them everything that is requisite for their luxuriant and annual successional bloom. To those who may think that annual transplanting is an unnecessary trouble, or who may not care for superior bloom, the present system may be all in all. But to those who would like to know that their favourites are doing well, and not left a prey to vermin, and, consequently, to retarded growth, the annual system is the best; for too well we know, that a clump of Lily bulbs, left two or three years in the ground—the dead and rotten mixed with the living and the growing—is, in this country, quite a paradise for grubs, slugs, and every other pest that is destruction to the growth and flowering of the plant. In order, then, to sweep all such enemies out of our way, let us, about eight or ten days after the flowers have faded, lift the plants, and, in doing so, take care of the new bulbs that are connected with the stems that have flowered, and are within the old bulbs, as that is the proof that these new bulbs are those which will flower the next year. Let all other bulbs, large or small, be picked off, and put aside for planting in a separate place until they also have flowered. Carefully examine the new bulbs, so as to make sure that they are cleared of vermin; and, when this is done, replant either, singly or in clumps, in congenial soil, and leave the rest to Nature. It is said by some writers that "Lilies are not ripe for lifting and replanting until the growth ceases, and the stems and leaves die down." But this is a fallacy which—whatever may be its value as regards Tulips, Hyacinths, and some other bulbous plants—is altogether inconsistent with the constitution of the Lily. I have cut down the stems when the plants were in full and fresh bloom, without in the slightest degree affecting the growth of the new bulbs, which, at this time, are themselves sending down roots, by which they can gain subsistence sufficient to make them independent of the parent bulbs. Those who have carefully studied the connection that exists between the old and the new bulbs will understand this. When lifting, I prefer leaving a portion of the stems in the old bulbs, as they make a convenient handle for moving the new bulbs about, without rubbing and breaking the scales with the hands. If this plan of lifting and replanting annually were adopted, I will venture to say that the result will be far better than by leaving the bulbs in the ground for some years undisturbed. It seems to me to require no science to tell us this. If we leave the bulbs in the ground for a few years, what can we expect? The offsets, instead of being removed, are growing

and drawing the essential principle of life out of the expectant-flowering bulbs; and these offsets, transformed into bulbules, will also generate offsets, so that all combined to the second and third generations, will be drawing vitality from the fully-developed or flowering-bulbs—the very reverse of what we have in view in giving periodical supplies of nourishment in the shape of mulchings, top-dressings, &c.

There are other fallacies to which I am desirous of drawing attention, but these must stand over for another occasion. With regard, however, to the remarks I made (see p. 557, Vol. XII.), on the subject of imported bulbs, Mr. Stewart Hardy informs us, in a note at the foot of p. 534, Vol. XII., "that last year he bought 100 bulbs of the importer at 1s. each, and that he planted them here and there in Rhododendron and other beds, and, so far as he knows, not one failed to flower, and some produced as many as seven blossoms." As Mr. Hardy has prefaced his communication by saying, "that my article on Lilies rather leads people to believe that they cannot reckon on imported Lilies flowering the first season," permit me to say that such was really my intention when I wrote, and having now frankly admitted this, may I ask Mr. Hardy, in all sincerity, if, by the information he has conveyed to us, he means that people should believe that the 100 bulbs he purchased was a fair sample of the whole of the importer's "shipments of that year?" As it is my desire to bring forward, not only my own experience, but the experience of others, in support of the correctness of what I have written on this subject, I shall take it kind if Mr. Hardy will, in the meantime, answer one or two questions. He writes his note in December last, and says it was last year he purchased the bulbs. Now I am somewhat at a loss to understand whether he means 1876, or last season 1877; he will therefore oblige me by saying when he really did purchase the bulbs; when he planted them; when they commenced to bloom; what height, at an average, they grew; if many produced only one blossom; if he tried any of the 6d. ones; and, supposing they bloomed in 1876, what was the result of the past season's bloom? I trust Mr. Hardy will believe me when I say that these are not merely idle questions, but are, as I know, of considerable importance to some of the readers of THE GARDEN. DUNEDIN.

**Trees and Buildings.**—The view on the opposite page shows the result that may be obtained by a little judicious planting near fine buildings. In this case, a small spot of ground is planted with trees and shrubs; there being a small circular lawn in the centre which allows of a view of the buildings and trees being well seen from various points. We have never seen a more instructive lesson in city planting. It is in the small gardens in the Place du Carrousel, with the stately buildings of the Louvre around.

**Arbutus Andraehna.**—In the grounds here we have a fine example of this Arbutus, which, I regret to say, got injured on Christmas Day by the sharp fall of snow which lasted over the 25th and 26th. The plant, which is an old one, occupies a prominent site on a sloping bank, which forms the western boundary of an undulating plot of pleasure-ground debouching from the house in a southerly direction towards the Mersey. It had been injured in a young state probably by "vibration," the consequence of neglect in not tying it firmly to a stake when it was planted. The wound had healed up, so as to be unobservable; but old age and premature infirmity, brought on from want of a proper supply of water at the root, had laid the germs of decay, the result being that the weight of snow resting on the branches brought matters to an unhappy culmination, by the tree being cleft in two at its base, where the old rent had apparently healed up. I should be glad to hear from anyone having experience in the propagation of hard-wooded evergreen shrubs, whether I stand any chance of securing a young stock from the branches by the ordinary means of propagation, and also whether it is correct (as many have told me) that this species is almost extinct (as far as large trees are concerned), with a few exceptions, in England.—W. HINDS, Otterspool.

**Christmas Decorations.**—While at the "Magpie" Hotel, Sunbury, a few days ago, my attention was directed to what I consider to be a charming novelty in Christmas decorations. At the end of the large dining-hall the greater part of the wall was covered with a fine bough of Cedar of Lebanon with about thirty cones scattered over it. The effect produced was far superior to the ordinary display of evergreens one usually sees.—R. O.

## TREES AND SHRUBS.

### TRANSPLANTING TREES.

TRANSPLANTING is an art which has long been in general practice, although not always carried out in a thoroughly scientific manner.

Much disappointment from failures often arises from the non-fulfilment of certain principles which are absolutely necessary, in order to obtain satisfactory results. Transplanting shrubs may be done, and is done, with adherent balls of earth varying from 8 lb. to 10 lb. in weight to as many tons, according to the lifting appliances at the command of the operator. The most simple of all methods is lifting a shrub or tree with an ordinary garden spade, and even by this simple process the greatest difference is observable in the execution of the work by different operators. This is easily seen by the way in which some parties go about such work. Some, from long practice, particularly in nurseries, will lift a small-sized shrub with a good adherent ball, while another, from want of the requisite skill in guiding his spade, will allow the ball to fall to pieces. Retentive soils and frequent transplanting have often much to do in the successful lifting of certain plants. With many deciduous trees and some shrubs it is not always necessary that they should be lifted with a ball of earth, even when of medium size, unless in the case of very rare or delicate specimens, when successful transplanting is absolutely desired. Deciduous trees, both forest and fruit, varying from 4 ft. to 6 ft., or even 10 ft. in height, where the roots have been prepared by previous cutting or frequent transplanting, can be moved with safety even without a ball, and at any time during the transplanting

season. If transplanted without any previous preparation, particularly if 10 ft. or 12 ft. in height, such trees are apt to lose many of their branches, frequently get into a sickly condition, and have ultimately to be uprooted. This state of matters frequently occurs in the case of forest trees which have been thinned out of young plantations where they have

been growing for many years in a crowded condition. The roots of such thinnings, if lifted by an inexperienced hand, and even sometimes by experienced ones, are sure to encounter a certain amount of damage. In the case of such root-mutilated trees, it is best at once to foreshorten all the points of the branches, in order to counterbalance the want of roots unavoidably injured, say in the proportion of eight to one as regards the roots, and even more as respects the branches. While lifting large deciduous and fruit trees without balls, or even with balls, it is absolutely necessary that all injured roots be cut off, particularly those partially broken through. These should afterwards be smoothed over with a sharp knife, as well as all surface-skin damages, instead of having them planted with their roots hacked with the spade, a system which is not unfrequently pursued. It will be found that all clean knife-cut roots will put out young fibres much freer than those that are cut with a spade and planted without any smoothing. Root-lifting is now much practised, both in the case of wall and standard fruit trees, and it is well known that this

Trees and Architecture.

system has a very beneficial effect upon them as regards after-fruiting. The branch-cutting system, on an extensive scale, is frequently practised on forest trees from 20 ft. to 30 ft. in height. The roots, although not damaged, ought all to be cut, that is, in cases in which no adherent earth can be removed with them. Large trees so treated often succeed well, and

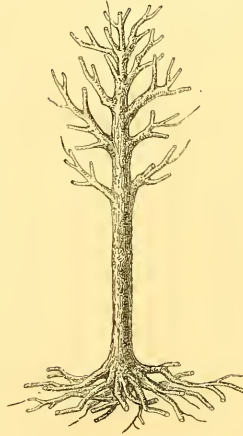

ultimately make as good a shaped top as unpruned specimens removed either with or without a ball of earth. The forest-shortening causes them to break more rapidly from the old wood than they otherwise would do; besides, forestshortened specimens do not require the assistance of ropes and props, which are generally necessary in the case of large deciduous trees where no branches are removed. The percentage of unsuccessful transplants is often very few in point of number compared with trees in which no branch or root-pruning had been carried out.

In order to transplant comparatively rare specimens, both large and small, it is in most cases desirable to resort to machinery or other appliances, however simple, such as surrounding the ball with canvas, staves, and ropes, particularly in cases in which balls of earth must accompany the plants. For this end I wish to offer a few remarks on the various systems adopted here for lifting and removing trees and shrubs of all sizes; and, in order to render this paper as complete as possible on the subject of transplanting, I shall also allude to systems carried on, although not practised here, from the want of the requisite machinery to do so.

The remarks which I intend to give will be chiefly confined to operations which have been carried on in Scotland, where much heavy work of this description has from time to time been done. In old gardening journals we find the names of many able transplanters, such as Mr. James Stewart, Pinkie House, Musselburgh, who was a very successful planter of large fruit and forest trees as far back as 1807. We have also other names more or less celebrated for heavy transplanting, such as Reid, Norval, Murray, McIntosh, Gorrie, Wilson, Lock, Hepburn, and Sorlie. The most celebrated, however, is the name of the late Sir Henry Stewart, of Allanton, Lanarkshire, who carried on for many years the transplanting of large forest and ornamental trees, all on the Janker system. As described in his "Planter's Guide," published in 1823, Sir Henry was very successful with all his transplants, as Allanton abundantly testifies. My late father, who was entrusted with the removal of the trees from the old Botanic Garden at Leith Walk to its present site, transplanted perhaps a greater number of weighty trees than most of the others put together, the largest proportion of them being done with large adherent balls of earth, mostly varying from 12 ft. to 18 ft. in circumference, and averaging about 2½ ft. in depth, one large specimen of *Arbutus Andrachne* having a circumference of branches of 56 ft. The root portion was surrounded with a box 10 ft. long, 5 ft. broad, and 3 ft. deep, requiring twelve horses for its removal. By far the greatest number of trees were raised on the tress and roller system, as afterwards described, and placed on a heavy carriage for removal, all being conveyed in an upright position, requiring six, and frequently eight horses to take them along. The Janker system was also extensively employed, but in all cases with trees whose roots had been previously prepared. All the trees transplanted from Leith Walk were moved during the years 1821, 1822, and 1823, and all are now in a very satisfactory condition.

As previously stated, small shrubs can be safely lifted with the spade, and after lifting, they can be tied or rolled up in a piece of mat or canvas, to keep their balls together for the purpose of transmission; but it sometimes happens that a plant requires to be taken from amongst others, and its removal is apt to injure a neighbouring specimen. A simple machine, invented by the late Mr. Stewart McGlashan, Canonmills, near Edinburgh, is admirably adapted for this particular purpose. It consists of two curved spades rounded at the bottom; these are forced into the ground in an upright position, one on each side of the plant. On the top of the spade first put in are two projecting eyes of iron, and on the other the hooks projecting downwards, which fit into the eyes of the spade first inserted. A tension-rod, deeply toothed backwards along the under surface, is fixed on the side of one of the spades by means of a permanent hasp, which causes the tension-rod to hang down when not in use. The other spade has a fixed projecting pin, square on the upper surface, and fixed on one side immediately below the handle. After the spades have been properly adjusted, the handles are drawn tightly apart, thus causing them to press in the bottom of the ball, which yields, in consequence of the curved nature of the

lower portion of the spades. When tightened, the teeth at the end of the tension-rod becomes fixed on the top of the iron pin on the opposite handle, and while in this position the plant can be easily lifted out of the ground. If the distance for removal be near, the plant can be easily carried in the spades direct to its new abode; but if distant, a slight tie of the tension-rod to the pin will secure it against movement. After being placed in position slacken the tension-rod and remove the spade last put in; scratch the surface of the ball exposed with a sharp instrument, as it sometimes becomes glazed, and also to set free any roots which may have been pressed down, soil being first put against the side exposed to keep it steady. The other spade is then taken out, the side scratched as before, soil being placed against it, and the surface afterwards is prepared for water. These rounded

Tree pruned top and bottom.

Rounded spade planter

spade planters are exceedingly useful, as plants can be lifted by them when in full flower, and placed in boxes or flower-pots without the roots sustaining any injury. The sizes generally in use for the pot planter are chiefly made for lifting balls 7 in. and 10 in. in diameter. The figure here given will illustrate this very simple and effective machine.

JAMES McNAB.

(To be continued.)

### STREET TREES.

It is probably well known that many of our streets are formed of refuse (I do not refer to the metalling) not at all adapted to the growth of trees. The materials used, indeed, are often positively injurious to all kinds of trees and shrubs. The refuse from gasworks, chemical and metal factories, stiff clay, &c., in fact, any rubbish that may come to hand, is used for filling up where necessary, often to a depth of several feet. Gas-pipes, sewers, and drains of various descriptions run in all directions, often emitting vapours destructive to vegetation. Therefore, when it is proposed to plant the margin of a street, it is necessary to consider what should be done, in order to ensure success. First, then, it is most important, at whatever cost, that the trees should be supplied with suitable soil, and in such quantity as to give them a reasonable chance of becoming thoroughly established. To do this, it is necessary to make holes or pits in proportion to the nature of the subsoil, whether very bad, bad, or indifferent, making the largest in the first case, and the smallest in the last. It is advisable to remove from 8 to 10 cubic yards at least where the subsoil is of a very bad description, coming down to 4 yards or 5 yards where it is indifferent. The depth of the holes should be from 3 ft. to

5 ft., according to the quantity to be removed. Where good soil is easily obtainable, and the cost no object, the amount of excavation can be increased even further. In cases of leakage from gas-pipes and sewers carrying away chemical liquors, planting is extremely difficult, and can only be carried on by forming receptacles of brick, concrete, or other suitable material sufficiently deep to be below the escape of noxious gases, thoroughly plastering both inside and out with cement, placing sufficient drainage in the bottom, and filling up with good soil. This is expensive work, but it should nevertheless be done where it is necessary to maintain a good line of trees. Trees planted in soil impregnated with coal have been known to die in two years, even after the leakage has been stopped. We may therefore infer that soil once tainted is a very long time in again becoming fit for the maintenance of vegetation. The distance at which trees should be planted from the edge of the kerb depends, in a great measure, upon the width of the roadway; they should, however, never be planted within the roadway, as a post and rail or post and chain fence (which would in that case be necessary, to protect them from damage, setting aside cost and unsightliness) prevents crossing the roadway freely. By far the better plan is to widen the footways sufficiently to allow the carrying out of the planting within their boundaries. Where the width of the roadway does not exceed 10 ft., the best position for the trees is from 2 ft. to 2½ ft. from the edge of the kerb. Upon wider footways the distance may be increased to 6 ft., giving sufficient room for large iron gratings and tree guards. The gratings should be movable, and, if possible, not less than 4 ft. square or 4½ ft. in diameter; if circular, paving carried close to trees is most injurious; moreover, the gratings admit of mulching, applying artificial manure, watering, &c., when necessary.

#### Distances at which to Plant.

With respect to the distances apart at which trees should be placed, much will depend upon the kind of tree planted. Two of the best smoke-resisting trees at present known are the Plane and the Poplar. The best distances for these trees are from 35 ft. to 40 ft. apart. No greater error can be committed than planting too thickly, and, unless we are prepared to cut down or transplant every alternate tree, it should never be done. It often, however, happens in carrying out the thinning that the best trees are removed; while if trees be planted at the distances just mentioned, should one or more fail, it is an easy matter to replace them at once with others that would match those already planted. In those districts where the atmosphere is purer than that in the more densely populated portions of London, Chestnuts, Limes, Sycamores, Acacias, and a few other varieties may be planted with advantage. These should be planted from 25 ft. to 30 ft. apart, and where variety is a consideration, the first three mentioned may be mixed with very good effect. I would, under no consideration, associate Planes and Black Italian Poplars with them, nor would I plant Planes and Poplars together, unless it was positively understood that the Poplars would be removed before the Planes were injured. Where rapid growth and dense foliage are required, nothing is more suitable than the Black Italian Poplar. The Plane, however, although slower in growth, is far more lasting as a tree, evidence of which may be seen in many parts of London. The foliage of both remains in excellent condition until very late in autumn; and this cannot be said of many trees, as, for instance, the Lime, Chestnut, and Sycamore. In street planting, it is important that really good, stout, and straight trees be procured. It is painful to see the miserable material under the name of trees that is sometimes planted; and when the cost of guards, stakes &c., is considered, it will be seen that a few shillings more than is usually paid per tree would really be a great gain. It is surely false economy to put a guard costing £1 to a tree costing but 2s. It cannot be too widely known that, to ensure success, the planting should be done by a thoroughly practical man, as it often happens that after every preparation has been made in the best possible manner, the work is a failure, through a want of knowledge of the simplest rules of planting. The hole should in all cases be sufficiently large to allow the roots to lie in it in a natural position. The bottom of the hole should be well loosened, and all broken or otherwise damaged roots

should be cut away. Some of the finest soil should then be introduced and the tree placed upon it in the centre, slightly below where it is intended to remain, in order that it may be raised to its place when some of the best soil has been placed upon its roots. This operation allows the soil to pass freely among the roots, and disposes of them in a natural manner. A tree should never be planted deeper than it has been when growing in the nursery, or wherever it may come from. Deep planting is the cause of many trees dying, whereas the loss does not exceed 1 per cent. when the planting is carried out as has just been stated. When the tree is in its proper place the soil should be made tolerably firm by treading, but great care must be taken not to tread too near the stem, as it often occurs that the stem and some of the best roots are injured thereby. It is much better to make the soil firm round the outer part of the hole than close to the tree.

#### Staking and Tree Guards.

Planting being finished, the next thing is to stake the tree securely. For this purpose strong Ash, Oak, or deal poles are suitable; they should be straight, and long enough to go well up amongst the branches of the tree, as it is the head which requires supporting. A very common method of tying, and one which may be recommended for its simplicity, is using old sacking about 6 in. in width. This is bound round the tree for protection, and tied tightly to the stake with tarred cord; the stake is then made fast to the guard by tying in such a manner that the wind does not cause the tree to chafe against the iron or woodwork of the guard, as is too often the case. During the growing season, especially with such rapid-growing trees as the Poplar, the ties should be frequently examined, to prevent damage being done by the strings. Where labour is not plentiful, and the trees are likely to be neglected in this respect, a good plan is to use jute, matting, or any durable material in the form of a band, which is put round the tree, crossing the two ends between the tree and the stake, and tying them at the back of the stake. Thus treated, the cord cannot injure the tree, the crossing between it and the stake forming a kind of cushion, which prevents chafing. Where guards are not used, the best plan is to place three stakes, in the form of a triangle, about 2 ft. from the stem of the tree; their tops are then brought together and tied, using old sacking to protect the tree, as before. Although this method has the advantage of firmness, I very much prefer the guards for roadways, affording, as they do, greater protection to the stems. Tree guards, whether made of wood or iron, should be close enough to prevent damage being done to the trees by mischievous persons. Circular guards are handsomer than angular ones; they should be ample, and not less than 7 ft. out of the ground. I may add that the expense of planting is, of course, materially diminished where the soil is sufficiently good not to necessitate further excavation than that which is needed for the trees. In such cases the soil should be removed to a fair depth, say at least 3 ft., and in every instance good drainage must be assured. The after-management appears to be a disputed matter, authorities disagreeing as to how far pruning and thinning should go, and in what manner it should be done. Trees, however, do not, as a rule, grow with any extraordinary vigour in London, and therefore it is, perhaps, best to leave them very much to themselves, unless someone thoroughly conversant with the matter is consulted.

*Southwark Park.*

CHARLES DENNIS.

**Rhododendron Early Gem.**—This comes into bloom quite a month earlier than any other kind of Rhododendron; it is, therefore, well adapted to forcing. Small bushy plants of it, loaded with delicate white-pink blossoms, may now be seen in several of the principal nurseries near London.—S.

**Large Cork Tree in Ireland.**—In the kitchen garden at Somerstown House, Cork, the residence of Mr. Alexander, there is what is, perhaps, the largest Cork tree that exists in Great Britain or Ireland. It is probably as large as the largest to be found in the Cork woods of Rhonda. The following are the measurements which I made of it last week:—Girth at 1 ft. above the ground, 13 ft. 5 in.; girth of trunk at 7 ft. above ground, 15 ft. It branches out at the last-named height. The arms are very large, the girth of one being 7 ft. 5 in.; the spread of the branches is over 60 ft., and both trunk and branches are covered to a great depth with Cork bark.—“Gardener’s Record.”

## THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

### The American Regions.

GENERAL REMARKS ON THE FLORA, &c.—It is still impossible to give approximate figures concerning the vegetation and climate of most parts of America, that is to say, anything so nearly approaching the truth as those quoted for South Africa and Australia. With unimportant exceptions, and excluding the temperate and frigid regions or the north, there are no works extant relating to America of the same comprehensive character as Bentham's "Flora Australiensis," &c. This refers more especially to Mexico, Central America, and the Mountains of the northern and western parts of South America, whence we derive a large and splendid array of greenhouse plants. But, although the American sub-tropical regions furnish us with many beautiful plants of different classes, these plants do not constitute so prominent a feature in the

Cantua.

greenhouse or cool conservatory as the Australian and Cape elements. There are interesting exceptions, one of the most important being the genus *Fuchsia*.

DIFFERENT CLASSES OF PLANTS.—There are three or more quite distinct classes of American greenhouse plants to be distinguished inhabiting wholly different regions, the climatal conditions of which are very diverse. To give an example or two: the Cactus tribe, denizens of a dry climate and barren soil; the epiphytcal Orchid and Bromelia tribes, found in the humid forest regions; and the annual and perennial herbaceous plants of the plains of Texas, New Mexico, California, Chili, &c. It is evident, therefore, that one reason why American plants requiring only a greenhouse temperature are not generally more conspicuous in ordinary greenhouse collections is, that they require somewhat exceptional atmospheric conditions.

EXTENT.—The sub-tropical regions of America embrace the Southern States and territories of the United States of North America; the whole of Mexico, with the exception of the less elevated coast region, which is tropical; the mountains of Central America and South America, particularly of the western side; and the plains of Chili, Uruguay, and South Brazil. A few words respecting the more important centres of American greenhouse or half-hardy plants will be more useful than a general sketch, and therefore we take them separately.

VENUS'S FLY-TRAP.—The Southern States of the North American Union do not contribute many noteworthy plants.

Immense tracts are swampy and covered with forests of ever-green trees, Oaks, Pines, &c.; where also the singular Venus's Fly-trap, *Dionæa muscipula*, is at home. Cotton, Tobacco, Rice, and Maize are extensively cultivated.

ANNUALS.—The sub-tropical plains of North America are remarkable only in plants of annual duration. They vary in their degree of hardness, though most of them require raising under glass to have them in perfection before the autumn sets. Others, under favourable conditions, are able to ripen seed and reproduce themselves without attention. In a word, they are on the borders of the superior limit of hardy, and the inferior limit of greenhouse plants. The country to the immediate north of Mexico is exceedingly rich in this class of plants. Familiar genera are:

Platystemon	Bartonia	Cosmos	Leptosiphon
Linnanthus	Ageratum	Sanvitalia	Nemophila
Zinnia	Zinnia	Tugetes	Gilia
Eriogonum	Coreopsis	Phlox	Collinsia
Gaura			

THE CACTACEÆ AND OTHER CHARACTERISTIC PLANTS.—In Mexico proper, from the upper limit of tropical vegetation almost to the upper limit of vegetation, the flora consists of plants requiring shelter in this country during the winter. It is true that some Mexican plants, as *Bouvardia triphylla*, are

Gonolox pulcher.

able to withstand our ordinary winters on the south coast; but none of the numerous Oaks and Pines, forming the highest belt of forest, are perfectly hardy in the climate of London, though some of them may be in the milder parts of the west. The Cactaceæ find their maximum development in Mexico, presenting an almost numberless variety of forms. They are particularly abundant in the almost rainless parts of northern Mexico and the contiguous countries, but they also abound in nearly all barren, rocky, or sandy places, from the sea level up to an altitude of 10,000 ft. Upwards of 700 Mexican forms have been described, but it is right to state that the difference

between some are extremely slight and trivial, and appear in some cases to be individual rather than specific. Proceeding northwards, they become gradually rarer, and find their boreal limit in about 50° N. latitude. In South America they are rare in the northern parts, but in the dry regions of Peru, and in the almost rainless tract across Chili and South Brazil, &c., they are characteristic of the flora. These Cacti vary in size from the smallest *Mammillaria*, 1 in. or 2 in. high, to the lofty columnar species of *Cereus*, one of which, *C. giganteus*, is said to attain an height of 50 ft. to 60 ft., with a proportionate thickness. Other characteristic genera of the dry regions of Mexico are *Yucca*, *Agave*, *Dasyliirion*, *Echeveria*, *Cycadææ*, &c. The forests of Mexico, the mountains of Central America, and the northern parts team with climbing plants and epiphytes of various families, many of the genera ranging from Mexico to Peru, and in some cases to Chili; *Fuchsia*, for example. The small Order *Columelliaceæ*, consisting of two species of *Columella*, is limited to the Andes of South America. Miniature Palms, *Araliaceæ* with highly-ornamental foliage, brilliantly-coloured *Vacciniææ*, numerous *Salvias*, and many other groups, comparatively unknown in our gardens, form a luxuriant vegetation unparalleled in the sub-tropical countries of the Old World.

**Climbing Plants.**

- Tropæolum majus*
- " *Lobbianum*
- " *aduncum* (canariense)
- Pæsiiflora Medusæ*
- " *ligularis*
- " *holocerica* and many other species
- Tacsonia mollissima*
- " *Van Volkemi*
- " *insignis*
- Cobæa scandens*
- Lophospermum scandens*
- Rhodochiton volubile*
- Maurandya Barclayana*
- Aristolochia foetida*
- &c.

**Orchids.**

- Acineta*      *Lycaste*
- Atrophyllum* *Macleayella*
- Barkeria*    *Odontoglossum*
- Brassia*    *Oncidium*
- Catasetum* *Sohraha*
- Cattleya*    *Sinhopea*
- Epidendrum* *Trichoptilia*
- Lælia*      &c.

Some of the foregoing genera have tropical species also; but some, like the large genus *Odontoglossum*, are confined to the cool regions.

**Miscellaneous Plants.**

- Fuchsia*
- Melocactus*
- Mammillaria*
- Cereus*
- Opuntia*
- Echeveria*
- Begonia*
- Didymopanax*
- Dahlia*
- Lobelia*
- Abelia*
- Bouvardia*
- Rondeletia*
- Habrochamnus*
- Nierembergia*
- Petunia*
- Brugmansia*
- Haltotropium*
- Calceolaria*
- Salvia*
- lantana*
- Chamæstoria*
- Tillandsia*
- Pitcairnia*
- Dasyliirion*
- Agave*
- Pourcroya*
- Yucca*
- Ceratozamia*
- Dion*

**CHILIAN PLANTS.**—The foregoing lists do not include Chilian plants, which usually belong to different genera. Some of

those which are hardy in the south-west of the kingdom are repeated here, because they require the protection of a greenhouse in the rest of the country.

Schizopetalon	Collomia	Eccremocarpus	Philesia
Portulaca	Salpiglossis	Lapageria	Jubæa
Eugenia	Schizanthus		

*The Indo-Chinese Region.*

So many of the genera, and even the species of the Himalayan Mountains and South China and Japan are identical, that, for our purpose, we may combine these countries, especially as the number of commonly cultivated plants from this part of the world is small. The most important are the Orange tribe (the precise home of which it is now impossible to determine), *Azalea indica*, &c., *Camellias*, the *China Aster*, and *Dendrobium Orchids*.

<i>Citrus</i>	<i>Rhynchospermum</i>
<i>Camellia</i>	<i>Amaranthus</i>
<i>Impatiens</i>	<i>Diaphne</i>
<i>Pæsis</i>	<i>Rhodoleia</i>
<i>Ficus</i>	<i>Rbapis</i>
<i>Callistephus</i>	<i>Dendrobium</i>
<i>Primula</i>	<i>Bambusa</i>
<i>Gardenia</i>	

**OTHER SOURCES OF GREENHOUSE PLANTS.**—

Besides the foregoing great sources of greenhouse plants, there are some few other less important ones deserving of mention. Thus, the Canary Islands furnish the curious fleshy, Cactus-like *Euphorbias*, as *E. canariensis*, and various species of *Cinearias*, from which the splendid florists' varieties have descended, and the beautiful Composite plant, *Argyranthemum frutescens*, so largely grown for the markets; and from some of the Pacific Islands many beautiful species and varieties of *Croton*, *Cordyline*, *Acalypha*, *Eranthemum*, &c. Two familiar winter-flowering plants from the Mediterranean region are *Coronilla glauca* and *Cytisus racemosus*.

*Distribution of Stove or Tropical Plants.*

**EXTENT AND CLIMATE.**

—A map of the world on a plane projection, in which the degrees of longitude are represented

of equal extent in all latitudes, gives a very imperfect and distorted idea of the actual proportions of land in the different zones, and it is difficult to realise the fact that upwards of two-fifths of the dry land is within the Tropics. Nearly half of the immense area, or about 10,000,000 square miles, is in Africa, and the other half nearly equally divided between the other tropical countries of the Old World and America. The climate of tropical countries is much more uniform than in other regions; the extreme fluctuations of diurnal and nocturnal temperature being limited to a few degrees. The mean annual temperature varies in different parts from 70° to 82.5°; so that

Cool American Region—*Odontoglossum*.

there is sufficient heat in any part to meet the wants of the most heat-loving plants. The greatest heat is in the centres of the large continents; but it is the distribution of moisture, as already pointed out, that determines the distribution of plants in hot regions. In the vast plains of Central Africa and Australia little or no rain falls, years sometimes passing without any. On a smaller scale this happens in America. In other parts the alternation of rainy and dry seasons, corresponding to the active and dormant states of plant life, occur with great regularity; though sometimes, as during the last and present years in India, this regularity is disturbed, and the rainfall for several successive seasons is insufficient to feed the growing crops; the consequence is a complete famine, during which thousands and thousands of beings perish from starvation. Something has already been said respecting the enormous rainfall of some parts of the Himalayan range, and it may be added that in most of the coast and mountainous parts within the Tropics the rainfall is large; but, contrary to what obtains in rainy districts of temperate climes, the number of rainy days is not in proportion to the quantity of water that falls. It is no uncommon occurrence in some parts of the Tropics for as much rain to fall in one day as we get in the neighbourhood of London, on an average, during a whole month. It is well to remember, also, that tropical vegetation is subject to alternate equal periods of light and darkness every day all the year round.

**NUMBER OF SPECIES.**—The total number of flowering plants and Ferns in the tropical regions is very large—perhaps as high as 40,000, or even 50,000, but possibly not more than 30,000. There is an immense amount of work to be done, both in exploring and comparing the vegetation of different districts, before we can arrive at a satisfactory conclusion. Beyond the coast regions almost nothing is known of the flora of tropical Africa, save the fact that large expanses in different parts of the interior are covered with a luxuriant vegetation. Recent explorations in Borneo have resulted in a rich booty of new species; and the number of forms in South America seems literally inexhaustible. Every successive traveller adds to the number previously collected, and years must elapse before the country can be thoroughly botanised.

**RANGE OF SPECIES, &c.**—With some notable exceptions, the plants of tropical regions do not seem to be so restricted in their area as those of the sub-tropical regions of South Africa and Australia, for example; but comparatively few, perhaps not more than one in a thousand, range all round the Tropics. It is not easy to choose examples from among our cultivated plants having this wide range; but several species of *Abutilon* and other Malvaceous plants are apparently indigenous in the most distant parts. A much larger proportion of genera are generally dispersed, and very few of the Natural Orders are restricted to one or the other of the great continents; but we shall return to this point when examining the vegetation of each of the principal continents. Many of the food and other economic plants are the same in the tropics of America and the Old World, and it is quite as impossible to say where they are indigenous as it is to indicate the native countries of many of the cultivated plants of temperate regions. The Banana and Plantain belong to this category. Rice is the staple grain used for food, but there are many kinds of Millet cultivated, as well as Maize. With respect to vegetable food, it may be asserted that where vegetation attains its greatest luxuriance there man, civilised man, at least, draws most largely upon it for his sustenance. Indeed, some races in the Tropics are almost absolute vegetarians in their diet; and in gradually colder countries the proportion of animal food, generally speaking, increases until we pass the boreal limits of cultivation, where the inhabitants are entirely carnivorous.

**NATURAL ORDERS CHARACTERISTIC OF TROPICAL CLIMATES.**—A few of the more prominent Natural Orders characteristic of tropical countries are: Anonaceæ (furnishing several delicious fruits, as the Cherimoyer (*Anona cherimolia*), Menispermaceæ (climbing plants, many of them having a very wide range of distribution; *Menispermum canadense* is a hardy out-lier; Cappariaceæ (Caper family); Guttiferæ (an arboreous family, of which the Mangosteen and Gamboe trees are

examples); Dipterocarpeæ (a small group of large and valuable timber trees); Malpighiaceæ (trees, or erect or twining shrubs, usually having showy flowers); Banisteria and Galphimia; *Sinarubææ* (trees and shrubs remarkable for the bitter principle which most of them secrete); *Quassia amara*, Meliaceæ, Sapindaceæ, several tribes and sub-orders of Leguminosæ; Melastomaceæ (*Medinilla*); Myrtaceæ (*Engenia*); Rhizophorææ (the "Mangroves" of the muddy sea-coasts); Cinchonææ (a sub-order of Rubiaceæ, including the quinine trees); Gesneraceæ, Acanthaceæ (*Apelaudra*), Lauraceæ (*Cinnamomum* trees), Myristicaceæ (*Nutmegs*), Moreæ (the large genus *Ficus*); Artocarpeæ (*Bread-fruit*); Palms, Screw Pines, epiphytic Orchids, Aroidæ (*Anthurium*), Marantaceæ (*Canna*, &c.), Zingiberaceæ (Ginger family), Bambusæ (*Tree Ferns*), &c. There are three distinct tropical regions, namely, the American, the African, and the Asiatic, including the Malaccas and tropical Australia. W. B. HEMSLEY.

## THE FLOWER GARDEN.

### ARUNDO CONSPICUA AND PAMPAS GRASS.

It is a very common, but erroneous, idea with most people that all those large luxuriant tufts of feathery plumes on lawns and borders are clumps of Pampas Grass, and but few, even garden-loving folks, are aware that many are plants of quite another genus—viz., *Arundo conspicua* (or *A. Veitchii*). This most remarkable plant possesses a great advantage over Pampas, as it throws up its bloom-spikes at least two months earlier than the latter—often in September. The glumes are very long and graceful, and the leaves are broader and less sharply serrated. During the late moist and shady autumn, when there was but little heat or sunshine, the Pampas has been so checked in its power of expansion, that in most cases the glumes of inflorescence have not been visible; being quite locked up by their closing bractæal leaves. I opened most of my specimens, beginning at the apex, and found that in all cases the lower part had quite rotted away; but when placed on a hot plate, the inflorescence expanded into beautiful silvery plumes, fit for the porch or hall as a winter ornament. The foliage of both plants has been more dense and luxuriant than usual, from the great amount of rainfall. I venture to suggest that both plants should be planted together, and then there would be a continuous show of bloom from September to January, by which time the flower-stems become decayed and beaten down by the gales and heavy rains. Another magnificent ornament to the lawn is *Bambusa Metake*, especially in a low or moist situation; the flower is inconspicuous, but the stems rise to a considerable height (8ft. to 10 ft.), and the numerous leaves are broadly lanceolate, and of a vivid green. On the margin of a river or lake, or on low swampy ground, it is invaluable, and forms a striking contrast to Pampas or Arundo. E. W. C.

*Glen Andred.*

### WINTER TREATMENT OF LILY-BULBS.

The writer, in a recent number of THE GARDEN, who seeks advice as to the proper treatment of Lily-bulbs, may not, perhaps, be aware that, if left in the ground during winter, they become much stronger and more luxuriant than when taken up; but how contrary to all the principles of Nature it is to remove them from their native home. In the Japanese woods they are never dug up, except as a final move to Europe for sale. Stevens, in the early months of the year, has consignments of 10,000 at a time for his sales in King Street. After flowering, the old stems of *L. auratum* remain a considerable time; and before they are removed, my plan is to mark with sticks, having a piece of red serge or cloth fixed to the top, all the places where the bulbs are; then I remove the old stalks, and cover with a small heap of Cocoa-nut refuse, ashes, or sawdust and leaves, by which means the severest frost is effectually kept from the bulbs. White sand will answer equally well; and if the spring shoots appear too early to escape late frosts, the heap of light material can be enlarged, and through which the tenderest growth can develop itself. Every year my plants of *L. auratum* show an increased number of blossoms. I had some last summer with from twenty to twenty-four fine flowers. I find that the Martagons and several other species do not

need the same protection, but I place most of my tender species in a sheltered spot, backed by tall Hollies, and there are always enough of drifted leaves formed about them to afford the necessary protection. The same plan holds good for Chinese Paeonias, *Dioslyra spectabilis*, &c., &c., which, by the way, always appear too soon, before protection has been previously applied.

E. W. C.

**East Lothian Stocks.**—Many sow these in August, and no doubt it is a good plan; but if they are sown early in the spring in

heat, pricked off when large enough to handle, and treated liberally until they are fit to plant out, say early in May, they will be in flower in July. In warm, porous soils early planting is desirable, as it enables them to get well established before hot weather sets in. When the seeds have been sown with care, these Stocks are well adapted for planting in masses in the flower garden, as a considerable proportion of the plants will produce double flowers; and what few single ones there are do not, as is the case with many other kinds of Stocks, run up with a loose, straggling habit, but retain the compact orderly style of growth peculiar to this variety; therefore the fact of these flowers being single is not noticed so much, as it does not bring them objectionably into prominence. They will flower beautifully all through the autumn; in fact, unless the winter be severe or very wet, there is no cessation in their flowering. Continual wet weather and a water-logged soil are more fatal to them than even frost. Last year the cold rains killed them completely.

This season the rainfall here has been less, and they are now beautiful; and the few days of rather cold, dry, frosty weather in the Christmas week seems to have added to their freshness rather than otherwise. At present this variety of Stock does not appear to have run into so many colours as other kinds, and there seems to be little difficulty in keeping the individual colours distinct. The white variety is especially pure and good.—E. HOBDAY.

**Begonia Fröbeli in New Jersey.**—This is one of the best winter-blooming Begonias ever introduced, and I think M. Fröbel must be mistaken in considering it a rival to scarlet *Pelargonium* in June. It might probably flower once at that season, from being at

rest during its season of growth; but I have found that the resting season is during summer—a fact confirmed by one of the correspondents of THE GARDEN. We obtained a quantity of larger bulbs of the first importation even before, I believe, it was sent to Europe, and it has maintained its winter blooming character each season. It commences to grow in August, and the first flower opens about the middle of September. We have a few dozen plants of it in full bloom now (Christmas Day), and another lot, not started until the end of October, are just commencing to show flower. I noticed the great variety, both as regards size and colour, of flowers mentioned in a

previous number of THE GARDEN, and there is also a great difference in the size and colour of the foliage, many of the young leaves being covered with bright crimson hairs. B. Fröbeli is one of the easiest of all the tuberous-rooted Begonias to cultivate, for I find many of them either die while at rest, or while apparently some refuse to start into growth, and the hybrid varieties are worse in this respect than the species. I have observed that a few extra strong flowers seem to be inclined to take the floral bract form mentioned by one of your correspondents in reference to some other variety. I may add that the B. Sandersi section grow beautifully all the summer planted in the open ground, and make fine plants for winter decoration if lifted before frost sets in; but of course they would not be likely to do so in the climate of England.—J. TAPLIN, *South Amboy, New Jersey, U.S.A.*

**Late Gladioli.**—It may not be generally known that Gladioli can be had in good condition much later in the season than is generally supposed. This

year I was desirous of extending their flowering period as far as possible into the autumn. Consequently, instead of finishing the planting at the usual time, viz., about the middle of April, I retained some three or four dozen bulbs, which were stored in a cool, dry place, until about the last week of May, when I had them planted in clumps in the herbaceous borders, three or four bulbs being set in each clump. I had holes made for them 1 ft. wide and about 8 in. deep, and these I filled with rich light compost from an old Cucumber bed. In this the bulbs were planted, and made luxuriant growth. They commenced to flower in the middle of October, and all through the month of November they made a brilliant display, which lasted

Geographical Distribution of Garden Plants; Mexican Cactaceae and Agave (see p. 32).

nearly up to Christmas. Such late planting might not succeed in every place, but there can be no doubt that Gladioli can be had in good condition a month or six weeks longer than they usually are, and that at a time when there is little else to brighten our flower borders.—THOS. SPELMAN, *Derry Castle*.

**Plants in Flower at Torquay.**—The following is a list of plants in flower in my garden this day (Jan. 6) in the open air, viz., Chrysanthemum (both small and large-flowered), Pinks, Virginian Stocks, Lobelia compacta, yellow Everlasting Flower, Pyrethrum, Violets, coloured and other Primroses, Gloire de Dijon Rose (buds), St. John's-wort, white Alyssum, Genista, Coronilla, Silene compacta, Cotoneaster, Berberis, Veronica, Polyanthus, Oxalis floribunda, Lantana, Hellebore, scarlet Pelargonium, Wallflowers, double Gorse, Escallonia, double Daicies, sweet-scented Narcissus, Anemone, Jasminum revolutum and nudiflorum, Clematis Jackmanni, Daphne indica, double Stocks (white and coloured). I may mention, also, that evergreen Honeysuckles have made young shoots quite 1 ft. in length, and that a climbing Devoniansis Rose on an arbour has made young wood fully 3 in. long.—LOUIS R. COOKE, *Lauriston Hall*.

## PLATE CIX.

## POLYGALA CHAMÆBUXUS PURPUREA.

Drawn by MRS. DUFFIELD.

This charming little Polygala, for the specimens from which our plate was prepared we are indebted to Messrs. Backhouse, was recently found in Alpine valleys in the South Tyrol, and, considering the numbers of English tourists who yearly visit that locality, it is surprising that it has not long ere this become common in our gardens. It is closely allied in all respects, except in colour, to Polygala chamæbuxus, a well-known and deservedly popular plant. The colour of the wings of the flowers in the variety under notice, as will be seen by the annexed figure, is a lovely bright magenta-purple, while the centre is clear yellow. It appears to have a greater tendency than P. chamæbuxus to expand a portion of its blossoms during the autumnal months; but whether or not

Geographical Distribution of Garden Plants: Tropical Region—a Mangrove Swamp (see p. 31).

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Dividing Anemone fulgens.**—Now when this beautiful plant has thrown up foliage is a good time to lift the roots and divide the crowns, in order to increase the stock. Some of the strongest crowns might be placed in pots to flower early, and the rest might be left to bloom in the open border. A sharp knife will sever the crowns without injuring the crowns or affecting the roots. I have recently treated a large quantity in this way, and they are now showing blooms, and those under glass will be in flower by the end of the month, or perhaps earlier. In this way a succession of rich scarlet flowers may be had for three months. This new flower will make one of the grandest of spring flowering plants when it becomes plentiful.—A. D.

**Mignonette and Bees.**—This is an universal favourite with all lovers of flowers, including our honey-bees. Linnaeus compared its perfume to Ambrosia. A native of Egypt and Northern Africa, it has long been cultivated in France and England. In France it is called by its Latin name *Reseda*, which seems singular, while with us its French name is the popular one. A bee-keeper estimates that one acre of common Mignonette will supply with nectar the bees of a hundred hives.

this will prove constant remains to be seen. It is a plant of easy culture, succeeding in any sandy, well-drained soil, and in almost any situation. It may be as well, however, to remark that it seems to do best in sandy peat, and slightly shaded from the mid-day sun. It is a most desirable addition to hardy spring flowering plants, and one which will prove alike useful in the rock-garden and ordinary flower border; and even when out of flower it is interesting, owing to its dwarf, compact habit, bright shining evergreen leaves, and olive-purplish stems. R. P.

**The Wellingtonia as an Avenue Tree.**—Many specimens of this tree, here and there, have already attained considerable size. It is perfectly hardy, but very liable to suffer from storms, and should always be planted in sheltered situations; yet it is impatient of being overhung or darkened by taller trees. A moist climate and a dry deep soil appear to

THE PURPLE ALPINE MILKWORT. (FOQUIERIA SPLENDENS.)

suit it best. Few trees are likely to attain great size or age, or develop their true character when grown from cuttings; nevertheless, it must be confessed that Wellingtonias grown from cuttings do not appear to differ greatly from seedling plants either in rapidity or symmetry of growth, at least up to the age at which we alone have opportunity of judging them. The timber being of little repute, it is only as a stately ornamental tree that it should be planted. It is well adapted for avenues.—S.

UGLY STRUCTURES IN GARDENS.

THE annexed are specimens of the hideous and trivial buildings with which depraved architects do their best to spoil otherwise

pretty gardens when they are allowed to work out their own wicked designs. Such abortions are, we are happy to say, much less frequent in private than in public gardens, though so few private

gardens can claim to be laid out in perfect taste. These sad examples are from the Parc Monceau.

*Terminalia elegans*.—This pretty Croton-like plant has long narrow gracefully drooping leaves of a dark bronzy-green colour, and a bright red mid rib. This plant is admirably adapted for table decoration on account of its graceful habit, and its effective appearance under gaslight.—S.

**White Hardy Flowers.**—It cannot be too widely known that white flowers can be had in every garden all the year through from hardy plants alone, but specially it is possible to have a supply of these during all the winter months, when, as a rule, tender flowers of all kinds are available only to those whose circumstances enable them to have glasshouses. During the summer months flowers of all hues are so abundant, that the special need for white ones is scarcely felt; nevertheless, both tender and hardy ones can be had in plenty. In the winter it is different. Plants that flower during its prevalence are few; but, fortunately, there are some that will flower in every garden. In the white *Anemone japonica* we have a hardy border plant that should find a place in every border. This blooms from the beginning of September until the end of November, the flowers being produced in great abundance, and most valuable are they for house decoration or for bouquets. Before these have ceased to bloom the white *Chrysanthemums* are gay with flowers; and although, as a rule, short-lived in the open air, they tide over one of the duller months of early winter. Then the Christmas *Rose* flowers, and established plants of these will carry large quantities of fine pure white blooms until the end of February. A hand-lily placed over each plant will keep the flowers clean and fresh. Then comes the *Snowdrop*, the white *Primroses*, the white *Arabis*, the double *Saxifraga*, the *Stock*, *Pink*, *Lily*, &c., until the season for tender flowers is again at hand. Those named are only a few of many, but these few will give a regular supply of white blooms with a very minimum of trouble. Of the thousands who have gardens, how few can boast that they have ever such useful hardy plants as these.—"Gardener's Chronicle."

GARDENING FOR THE WEEK.

Orchids.

*Cattleyas* and *Laelias* are often met with more indifferently grown than other Orchids, the prevailing error in their cultivation being that of giving too much water at the roots; this, even through the growing season, they cannot bear unless when, grown on blocks with little material that will absorb moisture in contact with their roots. When in good health, many of the species root freely during the winter when the top portion of the plant is at rest; but even when growth is thus observed actively at work, they should have no more moisture than will keep the bulbs and leaves from more than slightly shrivelling. For most of the species, with the exception of such kinds as *C. nuperiensis*, that requires more warmth than the generality of *Cattleyas*, a night temperature of 50° is sufficient. All the *Dendrobies* indigenous to the hill regions absolutely require through the winter a lower temperature than such as are found in lower districts; from 48° to 50° will be enough for them. Such as grow naturally near the sea level should have 5° or 6° more. The whole genus, with few exceptions, require to be kept during the winter much drier than most Orchids. In keeping with what I have already stated in reference to the influence that fire-heat exerts on the energies of plants, I look upon it that there should be no hard and fast line kept to, as regards exact temperature, either day or night during the winter season with either the East Indian or plants requiring an intermediate temperature. In place of this, when the weather is severe and it becomes necessary to keep the water in the pipes hot, a temperature lower by a few degrees will be found best. With what are usually termed cool, Orchids, the opposite excess is, however, often fallen into by keeping them too cold. Owing to what has been said about their ability to bear a low temperature, many have been induced to keep them, not only in the winter, but also during the growing season, so cool that they have gradually fallen into ill health or died right out, especially when under the low temperature they were kept too wet at the root; during the season of rest a night temperature of 45° will be low enough. T. B.

Roses.

Amongst the ever-increasing demand for cut flowers that appears to have scarcely any limit, *Roses*, as they have always, and doubtless ever will, hold the first position; neither is this to be wondered at, comprising, as they do, sufficient diversity in form, shades of colour, innumerable texture, &c., unequalled in delicacy of fragrance, combined with their handsome foliage, which collectively are not approached by any other flower. In any sort of floral arrangement it would be difficult to find a place in which some or other of the family in the varied stages of development were not suitable; *Roses* are amongst the few flowers that even in large quantities can with good effect be used alone. A vase or an ornamental basket filled exclusively with *Pelargoniums*, *Fuchsias*, *Camellias*, *Azaleas*, or even *Lilies*, always appears to want something to give diversity. Not so with *Roses*. When judiciously arranged with correct appreciation of form and colour, combined with their own foliage so far complete in themselves, that the addition of anything else becomes questionable as to being an improvement. To meet the continuous demand, it is necessary to take means somewhat different in different parts of the country; for instance, in the more favoured southern division and on the western coast, where the air is tempered by the sea, a fair selection of sorts, including a sufficient number of the Chinese varieties and their hybrids planted in open quarters, sheltered borders, and against walls, will generally afford a succession from the time they first come in in spring up to late in the year; in less favourable localities and in the northern portion of the kingdom they are nearly always cut off sooner than this. To keep up a supply through the winter and spring, at which time their flowers are the most acceptable, there is no resource but plants under glass. As is well known to every one at all acquainted with gardening matters, *Roses* have long been grown in pots; yet, excepting by those that have given more than usual attention to this method of growing them, their cultivation has often not resulted in the success attending the majority of other plants; for this reason, many are deterred from going largely into them, dependence being placed for winter flowers upon things generally looked upon as more easy to manage. Thus it often happens that a group of flowers, taking in appearance, or a bouquet artistically arranged, are met with without a single flower in them possessing any perfume, an absence that makes a nosegay a misnomer, and deprives any combination of cut flowers of its first and not least important essential. No doubt difficulties are experienced in growing *Roses* under glass, as they ought to be when associated with other plants, for the simple

reason that, to do them well, they require different treatment from anything else. Consequently, when grown with other things, either one or the other must suffer, or it entails a compromise in which neither the Roses nor the plants grown along with them can be treated in a way to give satisfactory results. At a time like the present, when probably more glass houses spring up in any given year than previous to the advent of the last quarter of a century were built in ten, we find houses almost exclusively devoted to individual families of plants. Nothing is more common now than to see a house entirely filled with Zonal Pelargoniums, wherein the glare of the various shades of red and pink—the former much predominating—is almost unbearable to look upon. Yet how much more interesting would such houses be filled with Roses through the autumn, winter, and spring, during which time, by the necessary application of fire-heat, a continuous supply of flowers could be kept up. There are two methods of growing them—one, by planting out all or the greater portion; the other, by confining all or nearly all to pots. Some difference of opinion is frequently expressed as to which method is to be preferred. Those who advocate planting out point to the stronger growth and more profuse flowering capabilities of plants treated in this way, which is no doubt correct; but, like the adoption of this system of cultivation exclusively with any plants under glass, it possesses its disadvantages, that far outweigh all that is gained by the greater profusion of flowers which the plants produce for a time, the worst of which is that, being immovable, there is no means of controlling individually their time of blooming; consequently, there is sometimes a glut, and at others a scarcity, with the ever-present difficulty with plants of any description when planted out, that those of a vigorous habit overgrow the weaker ones. Another disadvantage is, that when the roots have full play in soil of a rich border, the heads of the plants increase in size correspondingly to an extent that cannot be corrected without a too free use of the knife, the effect of which is that few can be grown in the given space, resulting in much less variety than is obtainable by pot-culture. One advantage gained by pot culture is that, with the addition of a cold pit from which to introduce fresh plants, and to remove others to, that have done blooming, a considerably greater number can be grown. Another and highly-important advantage is that, during the summer season, when the supply of Roses is not dependent upon those grown under glass, the house may be used for any other purpose; consequently, I should advise all who contemplate Rose-growing to any extent under glass to keep to pot-culture exclusively, or nearly so. Of course, there can be no objection, but rather the reverse, in a house wherein the growth of Roses is the principal object, to training a few on the roof, as, if these are judiciously managed, they can be made to drape the rafters, and take off much of the objectionable appearance arising from bare timber; but when introduced in this way, care must be taken to keep them sufficiently thin, or they will completely defeat the object in view, by excluding too much light from the plants below. As a matter of course, these roof-climbers will be best planted out. The Rose is essentially a light-loving plant; all that can be given it is not too much; therefore, the house in which Roses are grown should be so constructed as to admit every ray possible. The best Rose-houses I have seen consist of glass down to within 1 ft. of the floor-level, not too high, and without stages, the surface covered with finely-sifted ashes or some similar material, raised about 1 ft. above the paths; on this the plants are placed, or on inverted pots, according to their size.

T. BAINES.

### Stove and Greenhouse Plants.

In stoves maintain a temperature of 55° at night, and permit it to rise to 65° or 70° during the day with sun-heat. Plants of *Poinsettia pulcherrima*, the floral beauty of which is past, should be removed to a corner and kept dry. Plants of *Hexacentris* which have done flowering may be cut well back, and allowed to go to rest. Give weak manure-water to *Erantemum pulchellum*, and other soft-wooded plants coming into flower. Lay plants of *Lacstromia indica* on their sides in a cool house. Plants of *Stephanotis*, *Allamanda*, *Passiflora*, *Clerodendrons*, *Cissas*, *Echites*, and other climbers, if required to bloom early, should be pruned, and syringed daily to encourage growth. Start a few roots of *Achimenes*, *Gloxinias*, *Caladiums*, and herbaceous Gesneras for early flowering; cut down all long naked-stemmed *Dracenas*; use the tops as cuttings, and place the pots containing the stamps in moist heat, in order to promote the production of fresh shoots, which can be taken off as they attain the length of an inch or two and used as cuttings. Place in heat *Hycinths*, *Narcissus*, and *Crocuses*, so as to bring them into flower, but see that they are well supplied with roots before being excited. Keep them close to the glass, and water freely bedding plants or general greenhouse stock in pits or frames; but should anything happen to get frozen, get up the heat a few degrees above the freezing point, closely shade the plants, and then syringe them freely

with cold water overhead, keeping them as dark as possible for a few days. *Rhododendrons*, dwarf *Prunus*, *Ghent Azaleas*, &c., should, at regular intervals, be placed in heat to bring them into bloom. *Pelargoniums* must be kept rather dry, with the exception of a few plants, which should be placed in a warm house and moderately watered, in order to induce them to make young wood for propagating purposes. Keep all the finest-leaved kinds, such as tricolors and bicolors, near the glass, in light airy pits or greenhouses, and give them sufficient water to prevent them from flagging. *Verbenas*, *Ageratums*, *Salvias*, *Tropaeolums*, and similar plants should be cleared of all decaying leaves, and dry wood-ashes or sand should be scattered over the surface of the soil in the pots or boxes that contain them. If the stock is short, introduce a few plants to a warm house, and they will soon produce young wood, which may be made into cuttings. *Ageratums*, &c., may be forced and propagated in large quantities, for the cuttings root readily, and soon furnish tops and side-shoots, which may be used for a similar purpose. Sow *Lobelia* seeds in heat, and prick off the young seedlings as soon as they are fit to handle into pots, pans, or boxes containing light sandy soil. Cuttings of *Lobelias* may also be inserted as soon as convenient. Leave *Gazennias* undisturbed till March, for early-struck plants become long and weakly before they are planted out. *Calceolarias* in frames and boxes should be well ventilated in fine weather, and all decaying matter removed from amongst them. Remove the points of any shoots that are growing too rankly, and prepare cold frames for purposes of propagation next month. *Calceolarias* strike as well in cold frames if inserted in early February as they do if inserted in October; but, if the operation is delayed till March, they require a little heat to induce them to root readily. Any kinds of *Dahlias* that are scarce may be started in heat at once, and cuttings of them may be taken off and rooted as soon as they can be obtained. If a good stock of *Caladium esculentum* be required, start some of the rested plants in a brisk bottom-heat, and, when they have begun to grow, remove the top and insert it as a cutting, still retaining the old root-stocks in the plunging material. Before long the latter will push forth a number of young shoots, which may be separated and used as separate plants. Seeds of sub-tropical plants, such as *Solanums*, *Wiganacias*, *Perdianas*, *Udeas*, &c., should be sown in heat as soon as possible, in order to have good strong plants before bedding-out time; and all old plants of them wintered in pots should be plunged in bottom-heat, in order to produce young shoots to be used as cuttings. Prune back *Hibiscuses*, *Cassias*, *Fuchsias*, *Abutilons*, and similar plants, so that they may begin to grow slowly and hardly. *Acacia lophantha*, raised from seeds sown now, makes good plants before May for mixing with other plants in small beds. In conservatories use only fire-heat enough to expel damp and frost, and no more; and, when for the former, ventilate the house at the same time. Maintain a temperature of 40° at night, with the usual daily rise.

### Flower Garden.

If not already done, let all plants occupying prominent positions, or specimens which can ill be spared, or such plants as the *Arbutus* or *Strawberry tree*, *Ancubas* of various sorts, and *Daphnes*, *Desfontainia spinosa*, *Escalonia*, the *Laurus nobilis* or the *Sweet Bay*, and various kinds of *Yuccas*, and Asiatic species and varieties of the *Rhododendron*, new *Coniferous trees*, &c., be protected, should severe frost set in. The time is now nearly at hand when the propagation of bedding plants should be commenced; the preparation of materials for the formation of hotbeds, &c., should therefore be at once attended to, incorporating tree leaves with stable-yard manure by frequently turning the same. If bulbous plants are so forward as to be likely to be injured by frost, top-dress the beds with leaves, ashes, or similar materials, among which *Cocca-nut fibre* is the neatest and best. Transplant trees and shrubs, repair and make walks, construct, reduce, or otherwise renovate rockeries, relay turf, and energetically proceed with all similar alterations. Sow *Sweet Peas*. Remove dead wood from climbers on walls and on pillars, and tie up healthy shoots. In wet weather prepare stakes for *Sweet Peas*, *Dahlias*, standard *Roses*, and similar plants. Examine *Dahlia*, *Canna*, and other roots, removing from them all decaying portions, and keeping the sound roots dry and cool.

### Indoor Fruit Department.

Young Vines, kept in small pots, last summer for cutting back and growing into strong fruiting canes this season, should now receive attention. Cut them over at two eyes from the base, and apply some styptic to the wound, to prevent bleeding when growth begins. When cut and dressed, turn them out of their pots and shake most of the old soil from their roots. Have a corresponding number of 6-in. pots cleaned and drained, and into these pot the roots singly, using a free, open, pure loam, mixed

with a little horse-droppings. Give sufficient watering to damp the whole of the soil, and plunge the pots to the rim in a hotbed where a bottom-heat of 85° exists. They may be plunged as closely together as the pots will stand, and, where a suitable place cannot be obtained for their accommodation in a house, a hotbed, covered with a frame, will form a suitable place in which to keep them during the first stages of their growth. Another equally successful mode is to cut and dress the Vines, and plunge them, without disturbing the roots, in the soil in which they grew last year, retaining them in this way until they have made a young growth of 2½ ft. or 3 ft. in length, when they may be shifted into larger pots without breaking the ball. In this way they grow more freely when young, but they do not root so readily into fresh soil as those which had their roots disintegrated. Such Vines are generally grown for starting into growth, with the view of fruiting in October or November, and the earlier they are started the earlier will the fruit be ripened, and thereby have the advantage of a longer rest before the operation is again repeated. Where it is desirable to start pot Vines about the time stated, it is impossible to get them of a satisfactory kind, unless they have been cut back. Such Vines start into growth more quickly, grow faster, and ripen their wood sooner than one-year-old canes do. Where, however, it is not necessary to start them into growth before January and afterwards, one-year-old canes are as suitable as such as have been cut back, as it does not take so much trouble to attend to the growth of the former as the latter. If plunged in a dry place, a damping overhead with the syringe every afternoon softens the buds and assists them in breaking. Do not water abundantly until they are growing freely, and avoid by all means letting any cold draught pass into the early Vineries by having the door open for any length of time. During severe weather, access to such structures should be obtained through an inner door, or, where such convenience exists, from a corridor behind them. Begin forcing Figs with a night temperature of 50°, and thoroughly moisten the soil, for, if too dry, the young fruit is sure to drop. Peaches and Nectarines set their fruit much better if fire-heat and ventilation are given night and day during the time in which they are in flower, than they otherwise would do. Syringe the trees after the fruit has fairly set, and before the bloom has expanded, but not whilst they are in flower. Begin the forcing of Cherries with a night temperature of 45°, and give fresh air freely.

#### Kitchen Garden.

Look over Mushroom beds twice a week if bearing well; if not, once will suffice. Examine Seakale beds producing Kale, and, by means of the litter in the alleys and that covering the beds, maintain an equable temperature. If necessary, start two other beds by filling the alleys with fermenting manure, placing a covering of the same on the surface; or that pit hoops and mats, to be covered with litter if wanted. Succession beds leave exposed. Treat Rhubarb in a similar way, but give the roots more room. Take the litter of sashes put over Mint frames, but replace it at night. Make another hotbed, lift another lot of roots, and start them to succeed those already in bearing. For the first sowing of Peas, the driest portion of ground at command should be selected; the soil may be drawn in ridges about 8 in. high, flat at the top, and 12 in. broad; they should be made by drawing as much of the soil from the whole surface of the bed as will form these ridges at a distance of 3½ ft. apart for such varieties as William the First or Sangster's Number One. Sow on the top of the ridges, covering with about 3 in. of any sandy, open material, such as old potting soil covered with 1 in. of ashes; or if this be not at hand, the ordinary garden soil, mixed with one-third of its bulk of sifted coal-ashes, is a good substitute. As a precaution against mice, coat the Peas with red lead, or to lay under the covering of soil 1 in. of Gorse chopped fine on the top of them. It is advisable to sow thickly at this early season; a quart of early kinds will be found sufficient for a row about 18 yards in length. If the situation be at all exposed, as soon as the Peas appear above ground, take as much more soil from between the rows as will form a ridge on each side of the Peas high enough to break the force of the wind. Do not tread on the land more than can be avoided. Should the ground have been dug early in the autumn, such crops as the above may be put in without trampling upon the soil at all by simply using a few boards about 10 in. or 12 in. wide that will reach across the bed; the little extra labour involved in their use will be amply repaid in the produce. Broad Beans, where required early, should also now be sown. If the land be at all inclined to be wet, sow on the surface and cover as recommended for Peas, in which way it is evident the seed will be much better able to resist the effects of the excessive moist condition of the soil. In heavy, retentive ground, and in localities where the spring is backward, it is far preferable to defer sowing for at least a month. The earliest sorts of Potatoes should now be placed in single layers in shallow boxes, in a place where they will receive sufficient light to

cause the sprouts to grow stout and strong. The best varieties for general cultivation are the Ashleaf Kidneys. Of Round Early Frame kinds, Handsworth and Early Oxford are among the best. The boxes in which the tubers are placed should be protected from frost. A box of Mustard and Cress may be sown every week or so in the stove or forcing pit. Plant Cabbage out according to demand from the store beds of the autumn sowings, and sow a sprinkling of some small early sort in a frame or in a warm border. Rather than encumber the ground any longer with Cardoons, lift and store them in clean sand in a shed, where they will become blanched, and be always ready for use. Examine the stored roots of Carrots, and remove all decaying ones, from which cut away the decaying portion, and use the wholesome part at once. Sow a few Early Horn Carrot seeds on a slight bottom-heat. Sow Cauliflower seeds in frames in a very gentle heat. Freely expose on every favourable opportunity those wintered in frames, and tilt up the sashes at back and front during rainy weather. Sow Celery seeds in pans of light rich soil in gentle heat. In case of hard frost, protect the Celery in ridges with litter or Fern. Lift the old plantations of Horse Radish, and store the roots in sand in a pit or cellar, but every particle of the roots, small and large, should be removed from the soil. Make fresh plantations in deeply trenched ground. Sow some seeds of the white and green Paris Cos Lettuces in frames, and the Bath Cos in rows where they are to remain. Draw the lights off the frames containing late autumn sowings in favourable weather. If a frame can be spared for the purpose, sow some Tripoli or white silver-skinned Onions for salading, as they will come in six weeks sooner than the main outdoor sowings; and what are not required for this purpose can be used for transplanting purposes.

#### Diary.

**January 14.**—Putting in cuttings of Heliotropes, Lobelias, and Alternanthera. Removing Hyacinths and Tulips coming into bloom to cooler quarters. Looking over Pelargoniums, removing all dead leaves, and stopping them where required. Levelling ground, and relaying turf in pleasure grounds. Putting a little more long litter round Artichokes.

**Jan. 15.**—Sowing White Spanish, Giant Roca, and Giant White Tripoli Onions in 8-in. pots for transplanting. Emptying a four-light pit and refilling it with manure and leaves for Cucumbers. Pushing forward digging and trenching as fast as the weather will permit. Looking over the Grapes in bottles, removing any bad berries, and filling up the bottles where required. Turning over manure and leaves in Muscat-house, and adding a little fresh manure to it daily. Getting on with the pruning of pyramid Apples and Pears.

**Jan. 16.**—Planting four long rows of Early Long-pod Beans. Potting a few small Primulas. Making a hotbed for two one-light frames for cuttings. Getting in a quantity of Ash-leaf Potatoes in boxes, and covering them over with a little leaf-mould, in order to bring them forward for frames. Making a new plantation of Gooseberries and Currants, the ground being previously well manured and trenched.

**Jan. 17.**—Sowing a boxful of All the Year Round Lettuces. Putting Dahlia into gentle heat for cuttings. Covering up more Endive to blanch. Taking up all Snow's White Winter Broccoli that are fit for use, and putting them into large spare frames. Euster Benréd and Ne Plus Meuri's Pears now in fine condition. Knight's Monarch just coming in.

**Jan. 18.**—Sowing Marrow Peas in boxes for making Green Pea soup. Getting a little more Mint and Tarragon into gentle heat. Turning over gravel walks that had got very green. Carting home Pea-sticks from the grounds. Cleaning up the pleasure grounds and walks, and getting them all rolled down firmly.

**Jan. 19.**—Putting in 100 pots of Osborn's Early Forcing French Beans. Skaking and tying up Mignonette. Getting on with the pruning and nailing of Plums and Pears. Clearing off all garden refuse, and cleaning up the kitchen garden walks. Looking over Calceolarias, picking out rotten leaves, and stopping them when required. Turning over Mushroom-manure to sweeten. Looking over the fruit room, and removing all fruits that are bad. Looking over the Pines, and watering any that require it. Fruit in use for dessert—Pines, Grapes, Pears, Apples, and Nuts.

**Anoplophyton Rollisoni.**—This is a pretty little plant with bright silvery foliage, resembling that of *Tillandsia argentea*, but broader and more robust looking. The flowers are pink, and when the plant is growing on suspended blocks of wood, it has a pretty appearance, and well deserves a place in every good collection of stove plants.—S.

**Allamanda Schottii with double flowers.**—We have now in flower a fine plant of this growing in the border of a stove. The first bloom which it produced was very fine and perfectly double. Another has since made its appearance, but it does not differ from the original form. Have any of the subscribers to THE GARDEN ever seen a double Allamanda? If the shoot on which the double bloom appeared be eliminated and successfully struck, it is there any chance of the flowers produced by it retaining their double form?—E. H.

## THE CAVE MUSHROOM.\*

THE most complete account of the cave culture of Mushrooms which has been published by any cultivator on the spot well acquainted with the subject is that recently published by M. Lachambe, which we have translated for THE GARDEN, and herewith place before our readers.

The specific characteristics of the Common edible Mushroom, as cultivated in the subterranean quarries, underneath Paris, consist in its cylindrical stem or support, formed of a spongy tissue, covered with a thin skin and provided with a ring of fine filaments, which is nothing more than an expansion of the skin. The cup, supported by the stem, is in the form of a spherical cap symmetrically placed upon its support; its colour is dead white when it has been grown in the dark, but greyish-brown when it has been exposed to the light. The skin of the cap is very thin and tears off easily in strips. This is an essential character of the edible Mushroom, for in most poisonous varieties it is always strongly adherent. The inside of the cap is hollow, and furnished with a number of plates or "gills" which radiate from the centre to the circumference; these "gills" are of a light pinkish hue, which changes to light brown some time after the Mushroom has been gathered. The peculiar odour of the Mushroom is very characteristic, but does not, however, belong only to the edible Mushroom; while the pinkish colour of the gills forms one of its distinctive marks to such an extent that when this colour has once disappeared the Mushroom, although it does not become poisonous, is digested with such difficulty as to produce symptoms closely resembling those of poisoning.

The skin of the cap may vary in colour, according to the particular variety; it changes from white to yellowish grey, light brown or cream colour. These, however, are only accessory characters. It is more important, after having well determined the typical characteristics described above, to consider the relations which the size of the Mushroom bears to its culinary qualities. A good Mushroom ought to have a stem of not more than 1½ in. in length, the diameter of the stem should be half that of the cap, the circular edge of which should curve inwards in such a way as to conceal the "gills."

There are frequent anomalies in the growth of the Mushroom; for instance, we often find them with two heads growing on one stem, the second head being placed somewhat sideways. The Mushroom which is reared in the Paris quarries is always much smaller than that which grows naturally in old Melon beds, in meadows, or similar places. The earth for "soiling" is very poor, and contains but little humus; but this comparatively slow growth is advantageous from a commercial point of view, medium-sized Mushrooms selling better than very large ones in the Paris market. At Vitry, however, a specimen was grown which weighed no less than 6 lb. 2 oz.; the cap was 13 in. in diameter in its widest part, and 6 in. where it joined the stem. It was presented, in 1846, by M.M. David and Auguste Amiable to Louis Philippe, who presented them with a reward of 100 francs. It is somewhat singular that the bed which produced this wonder was otherwise most unproductive, the subsequent growings yielded nothing, its whole power having been apparently concentrated upon this single Mushroom. M. Carrière also mentions an enormous Mushroom which appeared suddenly, in October, 1872, in one of the nursery beds at the Jardiu des Plantes after a violent rain storm; the cap measured 8 in. in diameter at the widest part and 6 in. at the stem, which at 1½ in. from the soil measured 2½ in. in diameter. The weight was nearly 3½ lbs. It was of a dark grey colour, and when cooked was of excellent flavour.

To sum up, the Mushroom, as grown in the Paris quarries, is, so to speak, an artificial production. It is whiter and smaller than those grown in the open air, which is the result of the poorness of the soil and of the deficiency of light. Be this as it may, it has won its position in the market; it is liked and, so to speak, trusted, and the Mushroom grower would gain nothing if he tried to increase its size.

*Varieties.*

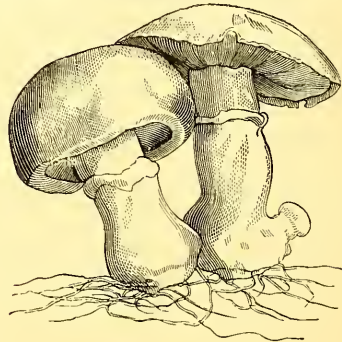

We shall only describe here those varieties which are grown for market, and which have found a place in ordinary cookery.

1st. The Small White Mushroom, whose cap is from 2 in. to 1½ in. in diameter, the cylindrical stem is 2 inches in length, and its flesh is more spongy than that of the cap. This Mushroom is greatly esteemed, as it is always eaten whole.

2nd. The Large White Mushroom.—The cap sometimes measures as much as 3½ in. in diameter without the edges of the cap ceasing to turn inwards, the stem is relatively short, measuring about an inch in diameter, and is milk-white; the skin of the cap, which is firm and fleshy, is slightly torn, and the "gills" are light pink.

3rd. The Cream-coloured Mushroom.—The stem is 2 in. in length, and ½ in. in diameter, and milky white. The cap is from 2½ in. to 2¾ in. in diameter. The skin is torn and clouded with cream-coloured spots on a white ground, and the "gills" are of a beautiful light pink.

4th. The Grey Mushroom.—This variety attains the largest proportions of any. Its cup sometimes measures 13 in. in diameter, the open portion near the stem being as much as 4½ in. across. The skin of the cup is greyish buff, and is generally torn into silky filaments. The stem is about 2 in. high, and 1½ in. in diameter; the ring is highly developed, and conceals the "gills" when the edges of the cap are open. The flesh is very firm, remarkably white, and emits a rich odour. In spite of these good qualities, this variety is less sought after than the others.

These varieties are pretty constant when grown under the same conditions, but I have seen spawn of the cream-coloured variety, when sown in a quarry, yield Mushrooms of the pure white variety, which would seem to indicate that the conditions under which they grow have a great influence on their colour. To be certain of the variety we are cultivating, we must grow successively two crops from virgin spawn, so as to leave the soil and the nature of the manure sufficient time to exercise their influence. For instance, virgin spawn grown on pigeon's guano, may, when a bed is first sown with this spawn, give a white or cream-coloured Mushroom, but the virgin spawn, grown on the same bed, having been influenced by the horse-manure, may produce a variety at the second crop.

*Mushroom Growing in the Quarries and Caves under Paris.*

THE MUSHROOM CAVES.—In the Department of the Seine there are 3,000 quarries; those which have been abandoned and which are situated close to Paris at Montrouge, Bagneux, Vaugirard, Méry, Châtillon, Vitry, Honilles, and St. Denis are used by the 250 Mushroom growers of the Department. There are several of these quarries with horizontal galleries driven into the calcareous rock from the level of the road which are mostly large enough to accommodate a good sized cart, but the majority can only be entered, like a coal-mine, by vertical shafts 100 to 125 ft. deep, down which everything has to pass. The labourers climb up and down a ladder, and the fresh manure is shovelled down the shaft from above, the waste stuff and the Mushrooms being hauled up in baskets from be-

\* Published at the Librairie Agricole, Paris.

low by means of a windlass. The inside of these quarries consists of a number of irregular corridors, varying in height from 2 ft. 6 in. to 7 ft. The manure for making the beds has often to be wheeled to a distance of nearly 350 yards from the mouth of the shaft. When there is plenty of headway, the work is comparatively easy, and the labourer rolls his load merrily along, lighted by the lamp which hangs at the head of his wheelbarrow; but, when the roof is less than a yard from the floor of the gallery, he must walk in a stooping or even in a sitting posture, pushing his heavy wheelbarrow painfully along. This part of the work is somewhat lightened by establishing relays at more or less frequent intervals. These galleries are all thoroughly ventilated, not only for the sake of the labourers, but for that of the Mushrooms, which would not thrive in confined air. If the air were not frequently changed, the breath of the labourers, the products of combustion of the lamps, and the gases given off by the slow fermentation of the manure would soon render these quarries uninhabitable. The ventilation is accomplished by means of small shafts sunk in different parts, and surmounted by a tall wooden chimney, the upper end of which is cut at an angle. The top of the chimneys should be above the level of the mouth of the principal shaft, and the bevelled edge should be turned towards the north. The number of ventilating shafts and their distance apart must be regulated by the special wants of each mine. Frequently the Mushroom-growers content themselves with using the ventilating shafts constructed by the former owners of the quarry, seeing that the construction of each shaft costs from £8 to £40, according to its depth. It sometimes happens that two quarries communicate with each other, in which case the ventilation is an easy matter; it is, however, necessary to guard against strong draughts and sudden changes of temperature, which would interfere with the well-being both of the men and the Mushrooms. For this purpose, the usual means employed for the ventilation of coal mines, such as fires and trap doors, is adopted. When the entrance to the quarry is

by a horizontal gallery, level with the road, the ventilation is comparatively simple and the work of cultivation much easier. The quarries are let at from £6 to £16 per month, according to the extent and height of their galleries, and the facilities for ventilating them. Not only should the ventilating currents be regular in their strength and motion, but it is advisable that they should always circulate in one direction. In fact, whenever the direction of a current changes, it is a sure sign that there has been a sudden change of temperature, either in some parts of the quarry, or on the surface outside, which is always dangerous to the Mushroom crop growing at the time. Atmospheric variations, both inside and out, must, therefore be narrowly watched, so that the temperature of the quarry may not rise or fall too far above or below the average, and that the ventilating currents should always be kept in the same direction and of the same strength. If the beds are in a cavern, the draughts should be in the direction of from north to south, and the ventilating shafts, and their dampers, should be so constructed that the quantity of air necessary for the proper growth of the Mushrooms may be obtained at will. Proper watering plays a great part in Mushroom culture; means must, therefore, be taken for obtaining a sufficient supply of water in the quarry itself. It often happens, however, that the opening of the quarry and the locality of the beds are far away from any dwelling, or well, in which the case water is conveyed

to the mouth of the shaft in large barrels, holding about 130 gallons, and mounted on wheels. By means of a sail-cloth hose, which is attached to the tap of the barrel, the water is led to the bottom of the shaft, where it is stored in large tubs or tanks. In some quarries sufficient water filters through the rock for the supply of the beds. This, of course, is a piece of good luck for the Mushroom-grower. In either case, the water is distributed by hand-watering-cans—a long and laborious process; but M. Renaudot hit on the happy notion of using a machine, consisting of a large tin or zinc barrel capable of holding 5 or 6 gallons of water, and carried on a man's shoulders like a knapsack. To the lower part is attached a tube, ending with a Rose, and provided with a tap for turning the supply on and off at will, so that the labourer can water the beds as he walks along, copiously or slightly, according to the amount of watering they require in different spots. It is true that this method is not applicable in caves where the height of the roof of the galleries is less than that of a man; but in other caves, such as those of M. Renaudot, at Méry, it is of great service, both to master and man. It may be mentioned incidentally that the galleries of M. Renaudot's magnificent quarries are no less than  $1\frac{1}{2}$  miles long, and 13 ft. high from floor to roof. The principal entrance of the quarries is in Méry itself, close to the station of the railway which conveys the manure from Paris.

When visiting M. Renaudot's quarries, in May, 1873, we had the opportunity of witnessing the influence of keeping the air at a proper temperature. The outside temperature was  $53\frac{1}{2}$ ° F. the inside nearly 5° lower. The beds, which were protected from the draught by the windings of the galleries, were covered with Mushrooms ready for gathering; whilst on those which were in the full current, the Mushrooms had hardly begun to make their appearance, even on those beds which had been made a day earlier.

THE QUALITY OF THE MANURE.—Success in Mushroom-growing depends very much on the quality of the manure employed; the choice, therefore, of the sources from

which the supply is obtained is an important point for the Mushroom-grower. Observation and experience have shown that the best manure for this purpose is that from entire horses abundantly fed, on dry, good, heating food, such as those of the Paris Omnibus Company, and the principal carters and carriers who always use horses of this description. The droppings from such horses are always dry and rich in nitrogenous matter, ammonia, and the phosphates, and ferment easily. After this kind of manure we may rank those of the mule, the ass, the sheep, and the rabbit; but the same rule applies in these instances as in the other—the harder the animals work and the more heating is their diet, the more valuable is their manure. The manure of milch cows and animals fed on green food is worthless, from being too watery. That from riding or carriage horses, which are only worked now and then, is but poor in quality, in spite of their good feeding, in consequence of its being mixed with too much straw, besides which it is not sufficiently impregnated with urine, owing to the necessity for keeping luxurious stables in a constant state of cleanliness. The price of manure, inside Paris, is as follows: Omnibus horses, 18 centimes, about  $1\frac{1}{4}$ d. per head per day; cab and fly horses, 14 centimes, about  $1\frac{1}{4}$ d. per day; tradesmen's cart-horses, 12 to 14 centimes, from  $1\frac{1}{4}$ d. to  $1\frac{3}{4}$ d. It is not only necessary that the Mushroom-grower should have the best quality of manure, but he must lay his plans so well that he

Mushroom Beds in Caves.

can always have sufficient material at his command to make a new bed within two or three days. In order to do this, he must apply to M. Chedeville, the contractor for nearly all the manure in Paris, who will speedily enable him to procure the proper quality and quantity within the time specified. Too much care cannot be expended in procuring the right kind of manure, as negligence and false economy are simply productive of loss by leading to poor crops, and a deficient supply of spawn. Good manure is, undoubtedly, the dearest material which the Mushroom-grower has to purchase, but the whole of it is not lost. As soon as a bed will yield no more Mushrooms, it is, so to speak, dismantled, and the exhausted manure is sent up the shaft to the top, where it is easily sold at from 4s. 2d. to 5s. 10d. per cubic meter, about 33 cubic feet. It must, however, be remembered, that not more than a cubic meter, or foot, of spent manure is produced from 2 to 2½ cubic meters or feet of the fresh material. In any case, it is much sought after by farmers and gardeners. The latter use it in large quantities for flower beds and pricked out vegetables. In the quarries, where carts can enter, the spent manure can easily be sold at from 5d. to 6d. per meter run, as it lies on the beds. It has been supposed that this spent material could be used for Mushroom-growing, but it is an error. Here and there, possibly, a few white filaments may be seen, which are easily mistaken for Mushroom-spawn, but they are nothing but inert, sterile particles of spent mycelium which are generally mouldy. It would simply be to court a failure to attempt to grow Mushrooms with exhausted material.

**THE FORMATION OF THE MANURE HEAP.**—Making up the manure heap which is to supply the beds with material at the proper stage of fermentation, is an important operation, which requires great care and experience. In fact, it is only by long habit and acute observation that the Mushroom-grower can recognise the exact point of fermentation which the manure must reach before it is in the right condition for making up into beds. To make a manure heap, a spot near the mouth of the shaft must be chosen. It should be dry, flat, and clean, and as near the water supply as possible. The necessary quantity of manure is first heaped up roughly on the particular spot chosen, and allowed to remain untouched for several days, after which the heap must be properly formed. The heap is a mass of manure to which a more or less elongated cubical form has been given, according to the quantity of manure at the Mushroom-grower's disposal, or the length of the beds to be formed. A cubic metre of heaped manure, properly prepared, gives a length of ten metres run, when placed on the beds, and a wheelbarrow load will give one metre. The heap is begun nearest the spot where the last load of manure has been shot, and is confined within the proper bounds by a border of boards, the length of which depend on the size of the beds for which the manure is intended. The smallest heaps in the Paris quarries are ½ yards long by ¼ yards across and ¾ yard high. The position of the border being marked, the manure is heaped up, shaking each fork full of stuff so as to mix the droppings and the straw as thoroughly as possible, taking care that the damp and dry portions should be well amalgamated. All foreign bodies, too, such as wood, iron, &c., should be scrupulously picked out and rejected. When the heap is begun, it ought to be made a meter high, at first, with an incline of about 30 to 35 in 100. It must then be frequently forked, mixing the parts together, and watering the heap whenever it becomes too dry. The heap, once formed, the incline is kept on the side which has last been finished, the sides being properly dressed with the fork, all the scraps being gathered up and added to the heap. The last operation is to tread down the heap until it is reduced to the height of ¾ yard. The heap should now remain undisturbed for six or seven days.

**FIRST TURNING OVER.**—At the end of six or seven days, the heap must be turned over, beginning at the side where the gauge has been left open. The border is re-marked, and the manure is well turned over and shaken with care, for the space of a meter, the whole being equally watered, so that every portion should be evenly damp. The outer and drier parts of the heap should be carefully turned into the middle. The operation is continued till the whole of the bed has been turned over. It is then trimmed up and made into the proper shape,

beaten down, and allowed to remain undisturbed for another six or seven days. The amount of water necessary is indicated by the comparative dryness or dampness which the bed exhibits during the first turning over.

**SECOND TURNING OVER.**—Six or seven days after the first turning over, that is to say the twelfth or fourteenth day after beginning the work, the bed will be found to be lower by some 4 inches than it was at first. The outer surface is brown, and a strong fermentation is still going on. The manure has, however lost its primitive odour. The interior of the heap, too, has changed; it is of a dark brown colour, and a number of whitish particles distributed through it, showing where the fermentation has been strongest. The second turning over is performed in the same way as the first, taking care to water each layer when it reaches a thickness of a foot. It is then beaten down to about a yard in height, trimmed and watered. In about three days it will have fallen to a height of about ¾ of a yard. The fifteenth day after the heap has been commenced, it is broken up and the contents carried away to the spot where the Mushroom beds are made. Such are the general rules for the formation and turning over of the manure heap, but it is often necessary to introduce modifications into them. For instance, it often happens that, during a rainy winter, or a thaw, fermentation goes on with great irregularity, so that it is necessary to remove the manure to the bottom of the shaft and finish the work at the foot of the ladder. By adopting this precaution, the losses sustained during the very rainy winter of 1872-73 might have been avoided. In that year most of the manure heaps were obliged to be sold for spent manure, the fermentation having proceeded with great irregularity. We must also take into consideration the quality of the manure we are using; for instance, that which contains a large proportion of urine mixed with much rotted matter, ferments most rapidly, consequently the operation of turning over must be regulated accordingly. The turning over, to be effective, must be performed at the proper time and not too often. For instance, the manure supplied to the Mushroom-growers of Méry is loaded into a cart at the stables, carted to the railway station, where it is transferred to a truck. When it reaches Méry, it is once more unloaded into a cart, which conveys it to the spot where the first heap is made. It is, therefore, turned over twice more in transit than the manure which is carted direct to the quarries near Paris. These extra turnings over do not increase the value of the manure, inasmuch as it becomes more broken up and preserves its heat during a much shorter space of time. The prepared manure, when made into a bed, ought to be unctuous to the touch, without leaving any trace of dampness on the fingers, it ought, in fact to show a certain amount of elasticity, without being too moist. Its odour should differ from that of fresh manure, its colour should be brownish yellow, with a certain mixture of whitish particles. The temperature should be about ⅓ of that of the first fermentation. French Mushroom growers use a term signifying "knocking down the manure heap," "*abatire le plancher*" for building it up. The expression is, of course, incorrect, and would tend to mislead any one not acquainted with its real meaning. When the contents of the manure heap is to be carried to the spot where the bed is to be made, in wheelbarrows, if the heap is near the shaft, but by carts if it is far away. The manure deposited either at the bottom of the shaft or at the entrance of the galleries, may remain there for three or four days and beaten down if it becomes too dry. It is then carried for a distance, which sometimes reaches nearly 700 yards, and is thrown out in small heaps, at regular intervals, forming what are called "chains." These "chains" once formed, the formation of the bed is proceeded with.

#### *Formation of the Mushroom-beds in the Quarries.*

We left the prepared manure deposited in the galleries in the form of chains. These chains are parallel with the walls of the galleries, and form as many longitudinal rows as there are beds to be formed. The number of beds in each gallery is variable, depending, first of all, on the width of the cavern, and, secondly, on the judgment of the labourers. Generally the beds measure from 17 in. to 20 in. wide at their base, and are separated from each other by a path of about 1 ft. wide, or even less. These data are sufficient to enable one to calculate the

number of beds that can be made in a gallery of a given width. The beds are built up by the hand, and not with the fork; first, because working with the fork would be impossible in low galleries, and secondly, because the labourer has better control over his work when using his hands and fingers. He begins with one of the beds which are against the sides of the gallery, the surface of which slopes gently downwards from the wall. The labourer takes the manure up by double handfuls, shakes it up well, and sprinkles it over the base of the bed for a width of from 18 in. to 20 in. He makes the portion next the wall 4 in. higher than the outer edge, and, still adding fresh manure, he presses it with his hands and knees, so as to make it into an even mass. He continues thus until the bed is sufficiently high, always taking care that it shall incline downwards from the wall, and finishing off by rounding the surface gently. The inclination of the bed should be such, that the earth to be afterwards added for "soiling" shall not slide off. He next forms the beds in the centre, but with a rounded double incline like the top of a trunk, taking care to leave sufficient space between each, and finishing up with a bed with a single incline against the opposite wall. The centre beds are made in the same way as the other, with the exception that they are rounded off, as described above, in such a way that they are nearly flat on the top for a width of about 6 in. or 7 in. The height of the beds from the ground is from 18 in. to 20 in., and is generally equal to their base. As the bed approaches completion it is divested of all loose straws and pieces with the hand, using the fingers like the teeth of a rake. The sides being made trim and ship-shape, the dressings are gathered up from the floor and sprinkled on the bed, so that there is no litter or waste. As each layer is placed on the bed it is beaten down firmly with the palm of the hand, so as to obtain an even, gently sloping surface throughout. Some labourers trim the beds as they make them, layer by layer, but it matters little which plan is adopted as regards the final result, as it is never necessary to retrace one's steps—no small advantage where the paths are very narrow. The beds are made by piece-work, the men being paid at the rate of 15 centimes (1½d.) per fathom of 6 ft. A good workman can make forty fathoms a day, making his wages 6 francs (4s. 1½d.) per day. The cost of the beds per fathom in the Paris quarries for labour and material is 2 francs (1s. 8d.). At Méry, owing to the greater cost of the material and to its having to be brought a long distance, the cost per fathom is increased to 5 francs (4s.).

M. Renaudot, of Méry, invented a method of moulding the beds in the form of gigantic bricks. The manure for this purpose was shovelled into moulds of sheet iron of the proper shape, open at the top like square cake tins, and well pressed down. The mould with the "brick" of compressed manure was then carried to the spot by two men and turned over, the operation being repeated until the necessary length of bricks, laid end to end, was obtained. The great difficulty which M. Renaudot encountered was that, no matter how carefully the operation was executed, there were always gaps between each "brick," so that the bed was divided into a number of sections instead of being continuous. It may be asked why the "bricks" could not have been made longer, but this would have caused too great an increase of labour; besides which it was discovered in practice that when the bricks exceeded a certain size, fermentation set in with such vigour, that the manure heated, giving off gaseous vapours, which, condensing on the roof of the gallery, fell on the growing Mushrooms, and spoiled them. The bed, too, could not be sown while it was hot; the labourer, therefore, had to wait until it became cool again before completing his work. This method had, therefore, to be abandoned also.

#### *Mushroom Bed-making in ordinary Cellars.*

When Mushrooms are grown in cellars, the same course of proceeding is adopted as when they are grown in quarries. Certain modifications, however, are necessary, according to the locality and the scale on which they are grown. As the scale on which they can be grown in cellars is necessarily a small one, it will be as well to calculate the length of beds we must have in order to provide for a continuous supply, basing our figures on those arrived at by wholesale growers. Taking

one-twelfth of this length for each month's work, we are almost certain to be able to keep up a continuous supply. The arrangement of the beds in the cellar will naturally depend on the space at our command. Whether large or small, however, we must adopt exactly the same method of culture as if the beds were a quarter of a mile long. We must also economise space as much as possible. Given the cellar, one may make Mushroom beds in it almost anywhere—on shelves against the wall, under the staircase, or even on the staircase, if the width of the steps will admit of it. The beds may also be higher and wider than those in the quarries; but in this case they require a larger amount of watching, as the fermentation is apt to become uncontrollable. All abnormal heating must be avoided now, especially when the manure has not been sufficiently worked. This elevation of temperature, owing to the fermentation becoming too strong, renders it necessary to delay sowing the spawn. The best remedy for such conduct is to allow the bed time to regain its proper temperature; but where this is not practicable, we may bring down the heat by making a number of holes in the bed. Every yard or so a stick as thick as a broom-handle is plunged into the heated mass, and worked round so as to produce a funnel-shaped hole. The vapours and gases generated in the interior escape by these outlets, which may be filled up when the manure has become cool. The manure may also be turned over with a fork in such a way as to form gaps between the layers, which should be filled up before spawn sowing is begun. For cellar work we must highly recommend the beds to be made in the form of conical mounds. The great advantages of this mode of forming the beds is, that they take up a comparatively small amount of space; they can be dismantled and renewed with greater facility than the beds already described; and as only small quantities of manure are used, the danger of heating is almost entirely avoided. Conical mounds of properly prepared manure may be formed almost in any cellar. Each conical ridge measures about 2 ft. high and 2 ft. in thickness. We commence by carefully laying down a compact mass of manure which is to form the base of the bed. It is next heightened gradually with more manure, taking care to press it down firmly, so that the sides may keep solid when they are transformed into a rounded angle of 90°. The conical ridge being well trimmed and dressed, it is beaten down with a narrow wooden shovel and left for about eight days, so that it may have time to get rid of its heat. After having tested in the way already indicated the fitness of the bed to receive the spawn, the sowing is commenced in three rows. The first row should be about 6 in. above the ground, each row being the same distance from the other. The bits of spawn should be placed at a distance of about 8 in. from each other in quincunx. If the temperature of the conical ridge is at the proper point, the operation of beating down may be proceeded with at once. A fortnight after the beds may be "soiled." Their fitness for this operation may be seen by their outside surface being covered with white filaments radiating in all directions, which give the beds a bluish appearance. The "soiling" may be done either with the hand or the shovel, and nothing more remains to be done but to water the soil with a fine-roset can wherever it shows signs of becoming too dry. The slope of the ridges being rather steep, care must be taken not to wash away the soil when watering the beds. At the end of about forty days the Mushrooms will begin to appear, and the beds ought to afford a daily supply for three months, if care be taken to fill up each hole with soil immediately after the Mushrooms are gathered. Here I must make a practical observation. Various writers on Mushroom culture have said that success can only be obtained by operating on large quantities of material, extending over a length of 12 or 14 yards; but I must protest against this assertion, for my experience has proved to me that with about a cubic metre of manure, or less, we may arrive at an excellent result, success depending much more on the quality of the manure we use rather than on the quantity, to say nothing of the care which we have bestowed on its preparation. The best cellars for Mushroom culture are those which have a great depth, a high roof, and are ventilated in such a manner that a draught of air can easily be set up. If the cellar is shallow and very dry, the floor must be watered for several days before the beds are begun. The air-holes should be shut during the day

and opened at night. There is a separate system to be pursued with each variety of cellar, which can be learned by experience by the aid of the principles laid down above. Beyond these little details, all the operations are the same as in carrying out Mushroom culture on a large scale.

#### *Preparation of Mushroom Spawn.*

The spawn is the seed of the Mushroom, and is called by botanists the mycelium. It shows itself in the form of a number of white threads, crossing and recrossing each other in all directions, and adhering to the scraps of straw contained in the manure, with which they form a kind of felted mass, which, when dry, forms the friable masses known to French Mushroom-growers as gallettes, or cakes. These cakes of spawn have the property of remaining fertile for many years, if they are kept in a dry, airy, well-ventilated place. Mushroom spawn is found naturally on the under sides of old water beds and manure heaps which have remained undisturbed for a lengthened period. This kind of natural spawn is not, however, always the best for sowing Mushroom beds. Sowings are often made with spawn taken from old beds, or from a bed which has ceased to yield Mushrooms, but by so doing we enlist ill-luck on our side. The best spawn to use is what is called "virgin spawn," that is to say, which has not yet produced Mushroom s. In this country this kind of spawn may be procured of any respectable nurseryman under the name of "French spawn." It differs from English spawn by being in the form of small tufty cakes, instead of in compact blocks. Large Mushroom growers, however, always provide themselves with their own spawn by taking it from a bed which is just about to produce its crop, or which has already produced a few small Mushrooms. By adopting this plan they avoid all expense of transport, besides the still heavier expense of paying for what they can produce themselves. By sacrificing an insignificant portion of the last crop, they obtain sufficient material for beginning again at almost no expense. It is true that by thus "breeding in and in," as it were, the Mushrooms show a tendency to deteriorate in quality after a time; new spawn must therefore be obtained as soon as any signs of deterioration begin to manifest themselves. It is by attentively watching natural facts that we gain our knowledge of natural processes, and apply them to our own use and profit. If we examine this peculiar method of Mushroom growth, whether on the surface of the soil or under the ground, we shall see that it is entirely due to the decomposition of organic matters placed under certain conditions of temperature, humidity, and light. By complying as much as possible with the same conditions, we shall succeed in producing as we like, when we like, and as long as we like, a regular supply of this mycelium, which, in its natural state, seems to be produced by accident and caprice.

(To be continued.)

Mr. RICHARD DEAN'S Catalogue of Potatoes will be found of service to those who take an interest in this esculent. It contains minute descriptions of sixty-six of the best varieties.

## PLATE CX.

### NEW SWEET PEA—BUTTERFLY.

Drawn by H. NOEL HUMPHREYS.

THIS beautiful variety was raised in Messrs. Sutton & Son's seed grounds at Reading. Its flowers, as will be seen, have a pure white ground, delicately laced with lavender-blue, tints which contrast admirably with the scarlet, black, rose, white, and other colours to be found in Sweet Peas already in cultivation. It therefore supplies a want hitherto existing in this favourite class of hardy, sweet-scented, climbing annuals. It possesses the same robust habit as the older varieties, and has proved itself to be perfectly true to colour and character. The annexed plate scarcely does justice to this Pea, owing to the difficulty experienced in giving to the flowers that softness and delicacy which they naturally possess. Vigorous plants of it sent us by Messrs. Sutton were covered with flowers, of which the plate gives only a faint idea, the flower being one consisting of neutral tints very difficult to render in colour printing. From having seen the plant, however, on several occasions, we may say that it is an annual of exceptional merit, and worthy of a place in every garden. It would deserve also what Sweet Peas

so often do not get—a good culture and a good position.

A Rock of Mushrooms.

**Pelargoniums.**—At whatever season of the year we visit Covent Garden we never fail to find the flowers of Zonal Pelargoniums playing an important part in bouquets and other floral devices, but especially during the dull months of winter are they to be found, and at this time of year their bright, lively colours are much more appreciated than when they are so plentiful in every garden and park in summer. Now that we have such a rich store of beautiful varieties of Pelargoniums in our gardens, much more might be done by private growers in the way of obtaining a good display in winter, as well as in providing a good supply of cut flowers. Growers for market manage their plants in this way:—In June cuttings are struck in the open air, and, when well rooted, they are potted in 5-in. or 6-in. pots, and fully exposed to the sun and air. A sandy loam, without any addition of manure of any kind, is used in potting, in order to induce the plants to make short-jointed wood, which will ripen thoroughly. For the promotion of the same object, no more water is given them at the roots than is absolutely necessary to keep them in health. The shoots are stopped twice before the middle of August. In September, or when the weather becomes unfavourable, the plants are placed on inverted flower-pots in light, dry, airy houses. As the blooms begin to push, a little guano-water is given once a week, and a little heat is applied, in order to keep the air of the house dry. The flowers are gathered as they expand until spring, when the plants are cut down, pushed again into growth, and when in flower are sold for window decoration. Where in private establishments large beds of Pelargoniums are required during the summer, plants to furnish them might be grown in this way; and instead of the houses being filled with store-pots containing small plants, a good display of bloom and an abundance of cut flowers might be secured; and in summer, when bedded out, each plant thus grown would be quite equal to three or four of the ordinary bedding plants, and if planted rather thickly an immediate effect would be the result; and, moreover, these plants would flower much more profusely than young ones.—C. S.

## AURICULAS—OLD AND NEW.

It must not be supposed that the estimate of a good Auricula held by modern florists is one belonging to the times in which we live. As far back as 1733, there was published the second edition of a floricultural work bearing on the cultivation of the Auricula, from which circumstance we may fairly conclude that the beauties of Auriculas were appreciated, and their culture carried on, to a considerable extent, at a much earlier period even than that just named. Be this as it may, it is evident that the taste for a symmetrical flower existed at that time, and that the florists of that day equally and as spiritedly took advantage of every improvement as we do now. This the following character of a good Auricula required at that time clearly shows:—"1. The stem of the flower should clear the foliage, and be sufficiently strong to support the bloom." It may be remarked that at the National Auricula Show, held in Manchester in the spring, supports are not allowed to the stems of flowers. It is held that it is a sign of good cultivation when the flower-stem can support the truss of bloom in an erect state, while weakly and ill-grown plants with high stems have a fictitious value given to them when supported by a stick. In the south, i.e., about London, Auriculas are shown so supported, and it is held that the plants have a neater and more attractive appearance in consequence.

The second article of the code of properties of the old florists was as follows:—"2. The foot-stalk of the flowers should be short, that the truss may be regular and dense. 3. The pipe or neck of each flower should be short and the flower large and flat, being no wise inclinable to cup. 4. That the flowers are very bright and well proportioned. 5. That the eye of the flower be round, and the paste of a good white, and that the tube or neck be not too wide." And as a kind of foot note to this table of properties, there is appended this remark:—"All flowers of this kind that want any of the above-mentioned properties are now rejected by all good florists, for as the varieties every year increase from seeds, so the bad ones are turned out to make room for their betters." It thus appears that the florists of 1733 were familiar with the properties of a good Auricula, and that they have handed down to us rules to which we cannot object at the present day, so far as they go. There are, however, little omissions; the necessary properties of the tube are not mentioned; it is important to the finish of a first-rate flower that the tube be circular and of a clear yellow colour; that the thrum or male parts be prominent and sufficiently bold; that the tube does not appear naked. And for an Auricula pip to be correct, the size of the tube should regulate the three other portions of the flower, viz., the paste, ground colour, and edging, for whatever the diameter of the tube, half that should be the diameter of the paste surrounding it; also of that of the ground or body colour; and also of the green, grey, or white that may form the outer edging. Let anyone apply this rule to a finely-finished pip of a first-class Auricula, and, apart from all geometrical rules or other considerations, he will find that where these parts are most evenly balanced there will be the greatest attractiveness from a floral point of view.

A caution is necessary to raisers of seedling Auriculas. Do not be in too great a hurry to decide on the merits of a seedling flower. At least three years' probation should be allowed before a flower is condemned as worthless. The age and strength of a plant has much to do with its floral qualities. In 1875 I flowered a number of seedling Auriculas obtained from an excellent parentage. They were generally of an indifferent character; but a certain number were retained for a second year's trial, while all the pin-eyed and irregularly-marked flowers were thrown aside. In 1876 the improvement in some of the flowers was remarkable, and especially in the case of the selfs; two in particular were highly promising, one a dark, the other a violet self coming near to Charles Perry. I have about 100 strong plants to bloom for the third year, and I am hopeful that others will prove to be of a high order of merit. D.

## OBITUARY.

We have to record the death of Mr. Thomas Moffatt, an event which took place on the 4th inst., in his 91st year. He was gardener to the late Viscount Sydney, at Fognall, for a period of twenty years, up to the time of his lordship's death. He then went to Clumber, where he served three Dukes of Newcastle in succession—the father, the son, and the grandson—and he was much esteemed by all the members of that family, being a man of large and varied information, and eminent as a thoroughly practical gardener. He was the oldest Fellow of the Royal Horticultural Society, and was appointed by that Society to form one of a committee of three to select a site for the new garden then about to be formed, when Chiswick was selected as the most eligible out of several sites inspected, and the recommendation of the committee was adopted. He was a man of high principles, strict integrity, and faithful in his friendships.

## THE KITCHEN GARDEN.

## FORCING ASPARAGUS.

In the case of Asparagus, as in that of other vegetables that are forced, the season at which supplies are most urgently needed regulates the time at which forcing should be commenced; and in all cases the best plan is to defer supplying any kind of forced produce until the resources of the place will warrant the supply being kept up continuously, for blanks, as regards supply, are worse than late commencements. For crops to be fit for cutting in November, we usually cut the decaying tops off the plants earlier in the season than from those roots intended to furnish later Asparagus, as I find that if cut down before the growth is quite completed, the crowns at the base start at once, and, when lifted for forcing, have made some progress, and only need a slightly elevated temperature to produce satisfactory growth. But, unless in exceptional cases, Christmas is a good date for commencing the regular Asparagus season; and here let me remark that I find young plants three or four years old, that have been grown specially for the purpose and never cut from, much superior, as regards both quality and quantity of produce, to old plants that have been cut from for years. Our supply is kept up in the ordinary way, by sowing a good-sized bed every year. The following spring, as soon as growth commences, the plants are carefully lifted and replanted on rich, deeply-cultivated land, covering the crowns with sharp sand or gritty soil. Under careful culture, they make fine crowns the third season; and by planting annually a piece of land equal to the quantity forced, a regular supply is maintained, and the permanent beds are left undisturbed; and, if not immediately cut from during the ordinary growing season, well-prepared beds should continue prolific at least fifteen or twenty years. For early crops under glass we lift sufficient roots to fill an ordinary two-light Cucumber-frame, which is set on a hollow bottom of stout planks resting on temporary piers of bricks. Under this some fermenting stable manure is placed and enclosed with litter, whereby a very gentle heat is raised. The frame is kept close, and the glass covered during severe weather; a temperature of from 60° to 65° is amply sufficient at any time both for roots and top growth. On fine days a little air is admitted as the produce appears above ground. One good soaking of tepid water, as soon as the roots are put in to settle the soil firmly amongst them, will generally be found to keep the soil moist enough until the crop is gathered. As soon as the produce of one frame appears above ground, a successional one should be prepared. For later supplies, that is, from the end of February until the open-air produce is fit for cutting, we get fine heads from beds in brick pigeon-hole compartments, to which movable span roofs are fitted with 4-ft. lights. The side trenches, which are 2 ft. wide and 3 ft. deep, are filled with leaves and stable manure a month before the produce is required. In other respects the treatment is the same as that for lifted roots, and the result is, produce finer and better in quality than the earliest growth in the open air, that usually has to contend with sudden fluctuations of temperature, frosty nights following bright days, rendering Asparagus hard and stringy; whereas growth made under glass is equal to that produced under the most favourable climate. The latest crop under glass needs scarcely any assistance in the way of bottom-heat, as the accumulated sun-heat under the glass roof warms the soil sufficiently to advance the growth at least a fortnight or three weeks before that in ordinary open-air beds. Of course, the cutting from such beds should be discontinued as soon as possible, in order to give a lengthened season of growth, so as to restore the energies of the plants. As soon as the cutting is discontinued, we remove the temporary roof, and use it as a shelter for late tender bedding plants, or for similar purposes, and give the beds a good soaking of liquid manure and salt, renewing the application during any periods of drought that may ensue during the growing season. It is also desirable in exposed situations to apply some supports to the tops, in order to prevent strong winds from breaking them off at the base. During the last few years we have used Conover's Colossal Asparagus, which certainly appears to possess finer heads in its earlier stages than the old variety; but whether it will ulti-

mately revert to the original form or not, it is, perhaps, premature to decide.

Henham.

JAMES GROOM.

#### WHERE TO PLANT THE POTATO CROP.

It becomes plainer year after year that if we are to contend, with any degree of success, against the Potato disease, it must be by altering our system of culture. When the Royal Agricultural Society tabulated the results of their experiments, about a couple of years back, they had little or nothing new to record. All varieties of the Potato were found to be liable to the disease, as had been proved before, though some sorts escaped more than others; as, for example, Paterson's Victoria and a few others. But the one thing which the various experiments tended to confirm, as was anticipated, was, that the disease was worst where the soil was wet or retentive, or where the rainfall was heaviest. Possibly, also, it was found to be bad in the richest soils. One of the most affected districts in England during the past season was that around Goole, in south Yorkshire, a district celebrated for its rich and deep "waup" land, and for its vegetable productions generally, and Potatoes in particular. It is a great Potato-growing district, and in good seasons the crops produced are enormous, and pay well, £30, or more, an acre being a common price for crops as they stand in the field; but last year £5 an acre was about the highest price that could be realised after the disease had set in in September. Later we were informed that even that amount would not have been risked upon crops in some places, so utter was the destruction by the disease. It was stated in the "Agricultural Gazette" at the time that probably something like "a million of money had disappeared" in about ten days in the district around Goole alone. Now this is a very important fact as affecting the culture of the Potato. A district, noted for its rich, deep, level land, produces the very finest and heaviest crops in dry seasons, but has them completely destroyed in those years that the disease is bad. And quite as remarkable as the extent and severity of the disease was the speed with which it did its work. In this district, some thirty miles from Goole, the crops were bad enough, but in plenty of instances half a crop or thereabouts was saved; yet the climatal conditions and the rainfall were much the same, the only difference being that the soil is thinner and poorer and better drained, the district being hilly or undulating, and not so well cultivated. The crops were neither so bad, nor so speedily affected; but of course they varied, being worst in the valleys and the heavy soils. But none of the soil hereabout is the best for Potatoes, being, on the whole, clayey, and nowhere light and sandy. About Goole, however, the chief characteristic of the soil is its depth and richness; the pastures are exceedingly luxuriant, and all crops are heavy and good; and, of course, the cultivation is usually of a high order. The same results, however, as regards the Potato crop are observable within much narrower limits, for on one part of a field, where the soil is thinner and poorer and better drained, the crop, as a rule, turns out sounder than it does perhaps a stone's-throw away, where the soil is deeper or heavier, and more retentive. These are all facts with which the gardener and farmer are perfectly familiar; and they know well enough that when they plant their Potatoes in their strongest and deepest land, they are trusting almost wholly to the chances of a favourable season for a good crop. The prospect of a heavy crop is no doubt a strong temptation; but would it not be worth while, at the same time, to try a portion of the crop at least on the poorer ground, and especially on sunny slopes, where the soil is shallow and not highly manured? The crop would not be so heavy, perhaps, but we are not sure if there would be so much difference in that respect when it is considered that one may plant somewhat thicker on poor soils, and that the crop is sure to be freer from diseases, and the tubers of better quality. One certain effect of free exposure and a poor soil is shorter and much woodier stems; greater maturity, in short, which is itself some protection against disease.

I noticed here that our garden crops, produced on a deeply tilled and well-enriched soil, within the shelter of the garden walls, invariably make a much more luxuriant growth than the

field crops; but they are always much more diseased when there is disease. This was very noticeable a year or two back, when the garden and farm crops were only separated by the walls. Those Potatoes in the field were growing on a sloping bank, where the soil was not more than an ordinary plough's depth—perhaps 8 in. The late sorts were the same in garden and field, but the percentage of sound tubers was greatly in favour of the field crop. The difference in the character of the haulm was equally noticeable, for on a high-lying and exposed field the wind had blown the stems about till they had worn quite a socket in the soil at their base, and in many places rubbed the soil away till the tubers were quite exposed. The consequence was, that the tops were much harder and woodier than those in the more sheltered garden quarters. So far as I have seen, the soundest crops have always been produced on stony or gravelly soils, in which the water passes away quickly, and such soils are less affected by heavy manures than those that are of a close and adhesive texture; but all manure of farmyard character, particularly if there is much cow-dung amongst it, is retentive of moisture. The kind of manure applied frequently depends upon the character of the soil; but wood, ashes, and especially charcoal, bone-dust, nitrate of soda, common salt, guano, &c., are preferable to those of a heavier description. In gardens, however, it would probably be found better not to apply fresh manure to the Potato at all, but follow some other crop for which the ground had been manured. But, at all events, I strongly recommend farmers and gardeners both to experiment in the direction suggested, viz., to plant in poor and dry soils, and compare the results. My advice to cottagers, is to drain and dung their plots well when needful; to plant in rows running north and south, in order that the sun may shine on both sides of the ridges, and thereby dry them sooner after rain has fallen. Cottagers cannot change their ground like the farmer; but I have often thought they might plant shallow and earth up well, so as to have the seat of the roots or tubers slightly above the bottoms of the furrows, in order to secure more complete drainage; and just before the crop began to ripen, if the ridges were patted smoothly with the back of a spade, it would help much to throw off the water at the critical period. The great point is either to prevent the rains from reaching the roots, or to provide means to let the water run away speedily when it does reach them. I once (in 1872) saved a batch of Potatoes, in the very centre of a badly-diseased quarter, by simply keeping them dry by means of glass lights placed over them, leaving the sides open and unprotected. It was simply an experiment, intended to demonstrate that I could keep off the disease by keeping off the wet. The lights were put on in July, before growth had ceased, and when the Potatoes were taken up the soil was quite dry, and the Potatoes perfectly free from disease, while all around, in the same quarter, up to the edges of the glass shutter, the crop was an almost total failure; and I have seen the very same results produced by planting the Potatoes alongside a row of Peas, which, as any gardener knows, draw the moisture out of the ground faster than any other crop; if there is a dry spot in a garden, it is where a row of Peas are growing. When I saw the row of sound Potatoes turned out, I thought of a preventive for the Potato disease which I read of some twenty years ago, and which appeared a very absurd one at the time—it was to plant a Pea either inside or beside (I forget which) each Potato set at planting time.—"Field."

#### KITCHEN GARDENING MADE EASY.

LET me say a few words this week respecting out-door Cucumbers. These require good land, enriched with leaf-soil instead of manure. The seeds should be sown in the middle of May in shallow drills, and covered slightly without any protection. The gathering season is in July and August, and the quantity of Cucumbers harvested from 12 in. to 15 in. long, of the right sort, viz., Walker's Champion Ridge is quite astounding, besides additional quantities for pickling. We plant amongst the Cucumbers *Rose Coleworts* in the first week in September; and when that month is fine, scores of Cucumbers are gathered while the Coleworts are small. In October all the Cucumber stems are cleared away, and here again comes into use the cultivator for breaking up the surface of the soil and destroying weeds. In November we plant Broad Beans between the Coleworts with a dibber

the Greens giving the Beans protection when young, but they must not be allowed to get drawn. As soon as they are well up, the whole crop of Coleworts is cut in the space of ten days. The Beans are slightly sarked up, and the crop stops long on the ground. I may add here, that when I dig, I do it effectually, taking out a trench at one end one spit deep only, and the crum, putting in each trench a good layer of farmyard manure fresh from the stable. I never have any old manure-heaps, from which the rain washes all the richness; on the contrary, I bury the manure in a fresh state, thus warming the land, and charging every particle of the soil with ammonia.

Durgley.

R. GILBERT.

I am truly grateful to Mr. Hereford (see p. 22) for the kind manner in which he speaks of my practice, and I have much pleasure in informing him that the Strawberries are all cleared off the ground before the Celery trenches are taken out. As Mr. Hereford's kitchen garden consists of a claysy soil, I would recommend him to burn a portion of it yearly, mixing the burnt earth with the clay. In this way he would soon alter the character of his soil to that of a mealy loam. The cultivator could then be worked with both pleasure and profit. I cannot expect my mode of culture to be applicable to all soils, but I believe it could be carried out in every sixty gardens out of the hundred.

R. GILBERT.

Durgley.

### THE VITELLOTTE POTATO.

This is the curious-looking, sausage-shaped, little reddish Potato which comes to Covent Garden from France. It is, we believe, used

in preference to all others for Potato salads. It may often be seen exposed in Mr. Gulliford's shop in the Central Row.

**Scottish Horticultural Association.**—The ordinary monthly meeting of this Association was held in S. St. Andrew Square, Edinburgh, on Tuesday evening last, Mr. Hugh Fraser, Vice-President, in the chair. Seventeen new members were elected, and thirteen names were proposed and seconded for admission at next meeting. Mr. Jas. Griev, of Pilrig Park Nursery, read a paper on the "Phlox and Pentstemon." At the outset he touched upon the neglect into which these good old plants have fallen, described the history of their introduction, and traced the progress of their cultivation to the present time. He gave his own experience as to the different modes of culture, and mentioned the various points requisite to make a good flower. As decorative plants, their various uses were also named. At the conclusion of the paper, several members expressed their opinions regarding the usefulness of these plants, referring to their suitability to the wants and demands of particular gardens. The thanks of the meeting were awarded to Mr. Griev for his highly practical and useful paper. It was then intimated that the subject for discussion at the next meeting would be the "Construction of Vine Borders," to be opened by Mr. William Priest, Newbattle.

**Examination for Prizes in Botany for Young Women.**—The Society of Apothecaries of London offer to young women students of Botany, for proficiency in that science, prizes to be competed for under the following conditions:—The competition will be open to all young women who shall produce from their teachers certificates that their age at the time of examination does not exceed twenty years. The examination will be in General, and not Medical Botany. The examination will consist of questions both written and oral, in—1st, Structural Botany; 2nd, Vegetable Physiology; 3rd, Description of Living Plants; 4th, Systematic Botany, so far as those subjects are contained in Sir Joseph Hooker's "Sciences Primer"—"Botany," and in Professor Oliver's "Lessons in Elementary Botany." The first examination will take place in London on the third Wednesday and the third Friday in June, 1878. A portion of the second day's examination will be devoted to microscopical demonstration. Certificates of merit will be awarded, in the first instance, to a certain number of candidates, to be determined by the examiner; and such selected candidates will be allowed to compete for the prizes, consisting of the Society's gold medal, to be awarded to the first in order of merit, or of a silver medal or of books to the second. Candidates will be required to send their names and residences, at least fourteen days before the examination, to the Beadle, Apothecaries' Hall, Blackfriars, E.C., when they will receive tickets of admission to the examination. Copies of regulations may also be obtained on application.

## THE INDOOR GARDEN.

### CINERARIAS AT BEDFORD.

The Cineraria is emphatically a plant which thrives best in a cool temperature. It simply needs to be just kept from frost. Its cultural requirements are of the simplest kind; as to soil, there could be no greater absurdity than to insist upon the stereotyped admixture of rich mellow loam, leaf-soil, rotten manure, and silver sand—a very fine compost, of course, but by no means necessary for the Cineraria, as I have often proved, and especially this year, as I have just now a fine lot of plants in 6-in. pots, having foliage of the most robust and healthy kind, growing in soil that is composed of portions of a decomposed couch-heap and leaf-soil. I have brought these plants to their present fine condition in this simple way:—The seed was sown in a pan in a greenhouse at the end of June, the young plants were pricked out singly into 3-in. pots about the middle of August, and finally shifted into the 6-in. pots, in which they will flower at the end of September. Nearly all have, even now, thrown up blossoms, and many will be in flower in the course of the next two months. I keep them in a span-roofed house where there is plenty of light and air, and where only the smallest possible amount of heat is given when frost prevails. So far, however, fire has not been needed for their protection more than half-a-dozen times this winter. Six-in. pots are too large for amateurs, unless they have plenty of room at their disposal, but the advantage is found in the after-culture, as the roots are less subject to drought, and therefore the plants less affected by the greatest enemy of the Cineraria—green-fly; and, also, the bloom is finer and longer continued. I should submit, as a simple course of culture for amateurs, that seed should be sown thinly in shallow pans or boxes, in fine sandy soil, about the middle of July, keeping the pans slightly shaded and the soil moist until the young plants are well in leaf. The advantage of thin sowing will be found in the fact that the seedlings can grow into strong plants before pricking off into 3-in. pots is necessary. When the plants have filled these latter with roots, they should be shifted either into 5-in. or 6-in. pots, as may be thought desirable, and in these the plants should flower. Soil should be the best to be got, but many amateurs are terribly troubled to get this good; they have to beg or buy where they can. Some good, well-rotted loam, and a plentiful mixture of leaf-soil, to keep it open and porous, will make a very fair compost, and the plants will thrive well in it. My own plants are growing in a similar mixture, and none could look better; the leaves are large and healthy, and the stems stout and vigorous. If green-fly should appear at any time, give the plants a moderate fumigating at once. It is really a case in which a stick in time saves nine. A little frost may not hurt once or twice if the foliage is dry, but it should be excluded if possible, and only just excluded, being careful not to rush into the other extreme of giving too much heat, and thus inducing a dry atmosphere, and the inevitable green-fly. When potting for the last time, use one large crock at the bottom of the pot and just a handful of rough pieces of turf or road manure for drainages, and thus the balls will not get over dry. Water most freely in mild weather, and especially after a thaw has occurred.

A. D.

### HARDY PALMS.

I HAVE *Chamaerops Fortunei* and also the so-called *C. excelsa* both in a large and small state, in neither of which can I detect the slightest difference between them. As to this Palm being hardy in the north of England, except in a very sheltered situation, I should be very doubtful, and should recommend your correspondent not to trust it in severe winters without some protection. It is surprising what even a very slight covering does for plants in carrying them safely through hard frost, as when this is kept out of the ground they appear able to endure almost any amount of cold. The way in which we manage it here is to scatter a few fresh fallen leaves around the stems, and on these put a handful or two of Brakes, to prevent their blowing away; this keeps all snug for the season. In ornamental grounds, where heaps of littery matter of this kind would be objectionable, all that is required to take off any unsightly appearance is a few Laursl or other evergreen branches stuck in, and if these get shabby, they can be quickly replaced. Protection of this kind is far better and neater than mats and similar coverings, and, what is of even more importance, it costs nothing, except the time and slight amount of labour involved in collecting and placing the branches in position. In protecting plants of this class the covering should in no case be heaped up very high, as keeping the air from their crowns engenders damp, and this is often as fatal as frost by causing decay, which soon takes place when growth is dormant, and when there is no drying influence in the atmosphere. Owing to its fan-like leaves, *Chamaerops Fortunei* gets much blown about and in-

jured by wind if planted in exposed positions, and this should be borne in mind when selecting sites for it. To be successful in establishing this Palm<sup>out</sup> of doors, it is necessary to plant in the spring, in order to afford time for it to become established and inured to the weather before winter sets in. Young leaves made under full exposure to the air and sun are altogether of stouter texture than any formed under glass, and consequently better able to bear the vicissitudes of winter. S. D.

—“T. B.” (see p. 7) may rest content, as *Chamærops excelsa* and *C. Fortunei* are synonyms. We have a fine pair here, which stand all weathers. I have, however, great doubts as to whether this Palm will prove sufficiently hardy to stand out in the north of England. W. WILDSMITH.

*Heckfeld, Hanus.*

**Forced Lilacs.**—Where cut flowers are in request, the Lilac is not only a great favourite, but also one of the most satisfactory plants that can be put into a forcing-pit. From this season, until blossom is obtainable out of doors, we lift a few strong plants of it at intervals of two or three weeks, and introduce them to the gently-progressive heat of a Peach-house or Vinery that has just been started. If too large for pots or tubs, they are set on the borders; we then cover their roots with soil, give plenty of root-moisture, and an occasional damping overhead on bright days, when they quickly unfold their bloom, which saves that of choicer plants from being out. The same treatment applies to *Deutzias*, *Wiegelas*, *Rhododendrons*, and *Guelder Roses*. When the blossom is nearly expanded, we usually remove the plants that are in pots to a cool conservatory or plant house, as, whether required for cut flowers or for plant decoration, they are much more lasting when hardened off a little. When deprived of their bloom, they are placed temporarily in cold houses until the season for planting them out in the reserve garden again arrives.—JAMES GROOM, *Henham*.

**Propagating Crotons in Bottles of Water.**—Not only may Crotons be propagated in the manner described by “C. S.” (see p. 23), but they will likewise strike freely in bottles of water; indeed, this is the easiest and most certain way of increasing them, and particularly when it is desirable to get large pieces of the tops rooted with the view of having well-furnished little plants with rich-coloured leaves for table decoration. It is well known by those who grow the Oleander how readily cuttings made from it root when treated as just described, and Crotons greatly resemble that old favourite plant in this respect, as it is very rare any of them fails. The plan of propagating Crotons and *Dracenas* by means of pots split in halves and attached to their stems is a good one, but in many cases it involves too much time and trouble; whereas suspending a few bottles in a warm position in the stove, and placing a branch in each, is only the work of a few minutes, and, what is of equal importance, they require no further attention till ready for potting. The only objection to striking cuttings in bottles of water is, that the roots formed are very tender, and become injured when placing the soil about them, unless great care is taken at the time to handle them gently. In potting, therefore, the soil should not be pressed down, but simply shaken in among the fibres, allowing it to subside of its own accord after a good sprinkling with warm water. Managed in this manner, there will be little danger of rupturing the rootlets, and at the next shift they can be potted more firmly, if at that time it is thought desirable to do so.—S. D.

**Miniature Cutting Frames.**—It frequently happens that a brisk bottom heat is required for striking a few cuttings of any special plant that may be received, or that cannot advantageously be propagated at the season when the bulk of such work is on hand; and even where a regular propagating pit exists it sometimes happens that, in conjunction with a brisk bottom-heat, a lower top temperature than that of such a structure is desirable for special subjects. We have for several years propagated thousands of soft-wooded plants during spring and autumn in ordinary Cucumber frames, set on a hollow floor of planks raised 2 ft. high with temporary piers of bricks laid on each other to the required height, without mortar, and heated with stable manure. But when the bulk of such work is over, and the frames are put to their ordinary use, we have adopted a modification of the same principle, on a very small scale, by substituting hand-light for the frames; and by using the short Grass from mowing machines in the place of manure, any amount of heat may be ensured. To retain the heat we build the little structure against a wall; and after the hollow portion is filled with Grass, the front is blocked up with any available litter, which, in the event of the heat becoming too violent, can be partially drawn away to allow any excess to escape; and by adding some fresh Grass at intervals of three or four days, quantities of cuttings may be rapidly struck. The floor or platform

should be furnished with a good depth of Cocoa-nut fibre or sawdust, in which to plunge the pots, and keep down the steam from the fermenting material. Hand-lights with moveable tops are best, as they can be wholly or partially removed when required.—JAMES GROOM, *Henham*.

#### RIVERS' ROSE AMATEUR'S GUIDE.\*

This work comes, as a *souvenir* from some beloved friend, bequeathed as he lay dying, and sent to us by his executors. We regard it with a tender, solemn sadness, as though it were the touch of a vanished hand, or the sound of a voice that is still. And yet, beyond the deep regret that horticulture has lost one of her most joyful sons, and we florists and fruitists one of our best-loved brothers, there is no cause for sadness. This roseate little volume reminds us that for forty years it has quickened men's appreciation of the beautiful, and guided young travellers who were searching for it; and, more than this, that, though the great Rosarian is gone from us, the love of Roses and of Rose growing which he evoked is spreading far and wide. The additions made to the present book are brief, but they are of special interest and importance. For example, it must have been a grand gratification to one who had worked so perseveringly to improve the culture of the Rose, to be informed by a Continental Rosarian who had seen our latest exhibitions that “no Roses were equal in brilliancy to those grown in England;” and, again (as he tells us in the same preface), to know that “our English seedlings are now fully as good as any raised in France.” These happy reflections must have come like sunshine to the old man's heart as he wrote these very touching and final words:—“I conclude in the hope that some day every man in England may have a garden, and that Rose-growing will be considered one of the Fine Arts, calculated to refine both mind and manners.” Once more, the last of his “general directions” well deserves the practical attention of those who love the Rose. 1, “Seedling Briars raised from the hips of the wild Rose form an excellent stock for all classes of Roses, and especially for the Tea-scented;” and, 2, “Roses on their own roots require patience, but undoubtedly they make the best plants, lasting for years when once well established, and entirely free from the nuisance of suckers.” May he rest in peace! S. REYNOLDS HOLE.

#### QUESTIONS AND ANSWERS.

**Plants from Mentone.**—As I have a friend at Mentone who is willing to send me some bulbs and plants for culture here, will you be good enough to inform me what are the best kinds of bulbs and perennials that will flourish, here if sent from Mentone?—J. P., *Adershot*. [All the bulbs from Mentone and the greater number of the perennials that grow there will be found to be perfectly hardy in England.—R.]

**Chrysanthemums.**—A question is asked (see p. 24) as to the difference between Mrs. Dixon and Golden Geo. Glenn, and whether, if shown together, the tray containing the two varieties would be disqualified. In the first place they are identical, both being sent out the same year, although by different firms, in addition to which another firm sent the same variety out under the name of Mrs. C. H. Glover. That such a fact is to be regretted, as it causes endless confusion. Sufficient care is seldom exercised by nurserymen and others as regards lists of Chrysanthemums whose synonyms are undoubted. In my own catalogue I have endeavoured to point out the synonyms as far as is possible and the usefulness of the practice is self-evident.—F. T. Davis, *Plumstead Common*.

**Chrysanthemums and their Culture.**—I am anxious to commence Chrysanthemum growing. 1. Will someone give me the names of twenty-four of the larger or show varieties combining shape with free-blooming properties and compact growth; also kindly name six of the best Anemone-flowered varieties and twelve Japanese. As I am quite a beginner, I do not care to commence with uncertain bloomers. I would like a few of each colour. 2. Cuttings of Chrysanthemums, after a few months' growth, often throw suckers. Ought they to be removed? If allowed to remain, do they bloom? 3. To what height should a Chrysanthemum cutting be allowed to grow before being topped? 4. How long should topping continue? 5. Do the Japanese kinds bear any topping? 6. What system of cultivation will keep the lower leaves on Chrysanthemums? 7. Would cuttings struck now make better plants, and bloom freer than those grown later?—Q. D.

**Flowering “Club Moss.”**—On page 61 of the last volume of *The Garden*, in a notice of the “Flora of Greenland,” by Clements Markham, mention is made of a very pretty Club Moss, with little bell-shaped flowers like miniature Lilies of the Valley. Will some reader of *The Garden* kindly inform me what this plant really is?—THOS. WILLIAMS.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### POLYGALA CHAMÆBUXUS PURPUREA.

I WAS much pleased to see in last week's number of THE GARDEN a coloured plate of the *Polygala chamæbuxus purpurea*, of which I had seen no previous mention. I had found the plant in 1870 at the Monte Generosi, in Tiëno; it was growing near the spot known as La Bella Vista, looking down upon the lake of Lugano. Near it was the familiar *Polygala Chamæbuxus*, of which I concluded it might be a variety, though I did not find it named in any of the books to which I had access. There was not much of the plant, but it may probably be found on other parts of the mountain. In ascending from Mendrisio, a small wood seemed to be filled with *Spiræa Arnica*; a little higher, in a vale by the way-side, *Ceterach officinarum* and *Aepidium Trichomanes* grew abundantly. I did not notice other Ferns, and it is, probably, too dry for them higher up; but under trees, chiefly ancient Chestnuts, the *Cyclamen* was conspicuous; also many large Campanulas, and other flowers, and the small *Saponaria ocyroides* a mass of bloom. Higher, and above the zigzags of the road, was a reach of Golden Broom, and above that, one of a dwarfed *Laburnum*, exceedingly beautiful; and on higher ground still, the spring seemed to return to us (in June); the Hawthorn was in full flower, and small singing birds and the cuckoo were heard. The flora is a very rich one. In some meadow land were found the *Ilac Thalictrum*, our own *Trollius europæus*, and the conspicuous *Agrostemma Flos Jovis*, with colour more brilliant than I have seen it in English gardens. On the mountain were many species of *Gentian*, *Pedicularis*, and *Achillea*; also the little *Astrantia minor*. I have omitted to say that the *Paeony* is also found there and two varieties of *Anthericum*, with many more familiar plants. M. BEEVOE.

*Coniston, Ambleside.*

I am glad to see a figure of the *Polygala Chamæbuxus purpurea* in THE GARDEN. All the plants I ever received turned out to be yellow. Perhaps we have not an enough to bring out the red or purple colour.—JAMES MCNAB, *Royal Botanic Garden, Edinburgh.*

**Hardy Palms.**—These impart quite a new feature to outside gardening, and, if capable of enduring severe weather, will be a great acquisition in this country. Your correspondents, "S. D." and Mr. Wildsmith, seem to have great doubts as to the hardiness of *Chamærops Fortunei* in the north of England, and it may be that they are right as regards many districts; but, at Messrs. Backhouse & Sons' Nurseries at York, two fine specimens, 5 ft. or 6 ft. high, have stood the exposure of several winters without protection, excepting, I believe, once; and they have not only thriven, but have produced healthy panicles of golden flowers. It would doubtless interest many of your readers if any of your correspondents, north of York, who have had experience in the culture of hardy Palms in the open ground, would state the result of their trials, and whether and what protection was given during frost. I do not fear wet, as I believe in their native habitats they luxuriate in damp places; nor do I expect that they will suffer from high winds after a few seasons, as the foliage will adapt itself to the altered circumstances and become more sturdy. The *Chamærops humilis*, a Palm very much like *Fortunei* in its growth, but not hardy in this country, abounds in the south of Europe and in Algeria on waste grounds, and there it may be seen, in the most exposed situations, without the damaged foliage suggested by "S. D." Of course plants grown under glass, or under shade, as they are in Algerian nurseries, by which the foliage is considerably drawn, should be acclimatized by gradual exposure for a couple of seasons, as otherwise the leaves will certainly become damaged by the winds.—T. B.

**Eucharis amazonica.**—I have a plant of this of which I had a photograph taken on the 12th December last, when it bore twenty-nine strong flower-spikes. It received similar treatment to that described by Mr. Groom in THE GARDEN of December 29, 1877. It was grown in an ordinary stove, as a stage plant, until July, 1877, when it was removed to a cool Vinery, and subjected to the process of drying off, *i. e.*, rested, as it is termed, for a period of about six or eight weeks; afterwards it was placed at the end of a Cucumber-house (not plunged, but set on an iron grating), and the result has been most satisfactory, even surpassing anticipation. I may just add, in corroboration of Mr. Groom's statement, that this plant was

in flower in November, and in full beauty on Christmas Day; even at the present date (January 15) it bears several very perfect flowers.—JOHN BROADHURST, *Trevallyn, Wrexham.*

**Winter Flowers at Bingham.**—A few days ago I brought in a handful of blossoms from the open borders. First and loveliest there was *Primula vulgaris grandiflora*, the great mauve *Primrose* wrongly known as *P. altaica*. This is blooming well now, but is still lovelier in a cold house under glass. *Primula vulgaris auriculata* is also in bloom, and many of Mr. Dean's fine seedlings, which ought to be everybody's plants. The double saffron, the double mauve, and the double white *Primroses* are also in full bloom. Another gem is *Veronica Blue Gem*, a dwarf, shrubby *Veronica* which seems to stand any amount of cold, and which is now smothered with buds and blooms. The spring *Cyclamens* are also showing their crimson buds. *Helleborus niger* is in first-rate condition; the giant variety has still a few blooms. At Worcester I saw beds of *Helleborus atrorubens* one solid mass of bloom, quite untouched by frost. The white *Helleborus aschasicus* was also in great beauty there. *Lonicera fragrantissima* is throwing out its exquisite sweet flowers; *Jasminum nudiflorum* becomes a bush of gold; *Chimonanthus fragrans*, on a wall, is sweeter than Orange blossoms; *Berberis Darwini* is still garlanded with Orange wreaths on a south wall. The last blooms of *Clematis Jackmanni* are not all gone.—FRANK MILES, *Bingham, Notts.*

**Propagating *Exochorda grandiflora*.**—The increase of this by means of root-grafting must, I think, be considered a slow and worn-out practice. The plant may be increased as easily as a *Fuchsia*. Introduce a good-sized bush of it into a little warmth in spring, and as soon as the shoots are 2 in. long, take them off, cutting through between the old and new wood. Insert the cuttings in the usual manner, placing them under a glass in a moderate amount of warmth; or let the shoots grow to their full length, and when they are just beginning to get firm, take them off and cut them up into lengths of one or two joints each, inserting them as just directed. The principal point is to keep them quite close and shaded; their foliage will be very tender, and, therefore, susceptible of injury. *Mm. Trumpy* & *Goujon* appear to have conjointly "caught a minnow."—T. SMITH, *Neury.*

**Lily Bulbs.**—I shall be most happy to answer "Dunedin's" questions (see p. 28) as accurately as I can. I bought the Lily bulbs in question in February or March, 1877—half for my father, Mr. Gathorne Hardy, and half for my father-in-law. I have no reason to doubt that they were a fair sample of the man's goods, as I am entirely unacquainted with him, and do not suppose he would treat me better than any other customer. As it was so late in the season when I got them, I had them all potted and started in heat, and they were planted out about the same time as the bedding plants. As I am in Parliament, I am, of course, away a great part of the summer. I cannot be very certain as to the minute details required, but some had begun to flower before I got home in August, and some had their flowers destroyed by the early frosts; very few seemed to have less than three flowers, and I should say, on an average, they were from 2 ft. 6 in. to 3 ft. high. I tried no sixpenny bulbs. Of course, I cannot tell how they will do this year, but if anyone takes an interest in their fate, I will endeavour to give a report of them in the autumn. My only reason for writing to you was that I thought "Dunedin's" article was likely to injure the business of a man who certainly had treated me very obligingly, and to prevent many, to whom the price of Lilies was an object, from trying to grow the *Lilium auratum*, which ought, in my opinion, to be planted out in every garden.—J. STEWART HARDY, *Camden Hill, Staplehurst.*

**Flowering of *Begonia octopetala rosea*.**—This distinct and ornamental species of *Begonia*, concerning which and its temporary name I made a brief communication a short time ago, on behalf of its introducer, Herr Otto Friesel, of Zurich, to THE GARDEN (see Vol. XII, p. 545), is now in bloom in my greenhouse, having opened its male bloom (borne on a hairy stem 9 in. high, from which the slender footstalk of the individual bloom rises another 2 in.) two or three days ago. The flower is about 2 in. square, and is composed of ten petals, the top and bottom ones being about double the size of the four smaller ones at each side; the colour of the under side of the petals is deep and rather dull red, that of the interior a very pleasing shade of bluish, and the bunch of pollen anthers in the centre of the flower is very conspicuous. The brace of female blooms, one on each side of the male, are not yet open, but promise to be poor and inconspicuous in size, as is sometimes the case in this family. The foliage has all disappeared more than a fortnight ago, going naturally to rest, and the bloom-stem comes up quite independently direct from the tube, and close to the side of the pot. As this species is a native of the north of Peru, would not *B. peruviana* be an appropriate name for it? or if a more descriptive name were preferred, it might be named *B. decempetala*.—W. E. GUMBLETON.

**Tussilago fragrans.**—This midwinter flower has been in full bloom since early in December. It is well named the Winter Heliotrope, for the scent is exactly like that of the better known "Cherry Pie, and recalls far-off summer days. It is of the easiest cultivation, and it spreads almost as freely as the irrepresible Coltsfoot, and is quite hardy. A waste corner cannot be better occupied than by this delicious flower.—SALMONFEES.

**Eulalia japonica.**—Mr. James Taplin sends us a plume of this lovely and most distinct ornamental Grass from South Amboy, New Jersey. We have not seen such a beautiful inflorescence on any Grass since the advent of the Pampas Grass and the New Zealand Arundo.

**Laelia anceps Lawsoni.**—This beautiful variety of one of our most useful winter-flowering Orchids is now in bloom in Messrs. Veitch's nursery at Chelsea. Its flowers are very large and of a pink-like substance, the petals being broad and of pearly whiteness, set off effectively by a rich, violet-purple-coloured throat.

**Early Outdoor Flowers.**—Until the sharp frosts of last week occurred a good display of Primroses was to be seen in Mr. Parker's nursery at Tooting. The beautiful *Anemone fulgens* and *A. blanda* were also opening their blossoms. In Mr. Cannell's nursery at Swanley, the flowers of *Violet Victoria Reginae* have been unusually abundant, but these, in common with others, were severely checked by the frost in question. A week's bright weather would, however, bring many of our beautiful hardy flowers into bloom, so forward are they this year.

**Calanthes in Masses.**—These attractive winter-flowering Orchids, though very effective when distributed amongst Palms and Ferns, are much more so when arranged in masses and surrounded by such plants. A group of some twenty or thirty plants of the rose-coloured *Calanthe*, now finely in bloom, makes an effective feature in Mr. Parker's nursery at Tooting.

**Persian Lilacs in Covent Garden.**—In addition to these Lilacs being grown in large quantities at this time of the year to furnish flowers in a cut state for the London florists, we now find neat little plants of them full of flower being offered for sale. They are furnished with a clean stem of some 6 in. or 8 in. high, surmounted by a compact head of green shoots, bearing from eight to twelve trusses of delicate blossoms. For indoor decoration such plants are highly useful, and few look better by gaslight.

**A Garden Cemetery.**—The fine engraving (see p. 60) showing a garden cemetery is from a photograph sent to us by Mr. Olmsted, of New York. It represents the cemetery at Spring Grove, Cincinnati, which is in many respects the most remarkable in the only country where cemeteries are designed in a masterly and tasteful way. Landscape effects—Grass, trees, and shrubs, native and introduced, and water—are seen in such cemeteries in all their beauty. The vast space prevents that overcrowding which is so horrible in many of our own cemeteries; and for the same reason the trees and shrubs escape destruction.

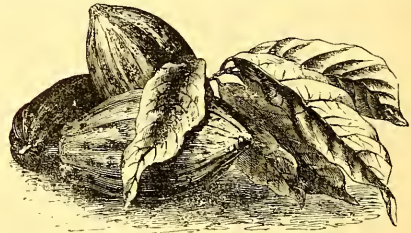

**An Apple Tree Killed by Mistletoe.**—The case mentioned by "J. N. R." (see p. 12) is an interesting one, but open, I think, to a few comments from one like myself, a devoted admirer and defender of this old Druidical symbol of the everlasting youth of Nature. The Apple tree in question was young, whilst its parasite was vigorous and "growing steadily." Mistletoe not being a rapid grower, this may mean a good deal. I presume, from "J. N. R.'s" account, that many years did not elapse before the Apple tree died with its thirty-five bunches of Mistletoe. If so, it never became an old, perhaps never a large, tree. Now the growth of Mistletoe, as of other branch parasites, is precisely analogous to that of an artificial graft on a stock. I doubt whether any horticulturist would assert the juice of a stock ever to become so thoroughly impregnated by that of the graft, that young shoots of the latter appeared on different parts of the tree. The thirty-four new shoots were, I believe, seedlings. The injury Mistletoe does to deciduous trees is that, being itself evergreen, it continues to draw upon the juices of the host during what should be the period of rest—that of defoliation. In other respects a bunch of Mistletoe is simply a vigorous, woody, un-Appleiferous, extra branch. It, therefore, is probably insupportably harmful on large trees in a small quantity; but thirty-five evergreen branches on a small tree, by Nature deciduous, is a very different matter. This is life at a very high pressure.—G. S. BOULGER, *Scientific Club, Saville Row.*

**International Potato Show.**—At a preliminary meeting of the International Potato Show Society's Committee, held at South Kensington on Tuesday last, a most liberal offer, made by the Crystal Palace Company, to hold their next Potato show, in connection with their great autumn fair and flower exhibition, on Sept. 24 and 25, was accepted, and the committee are now engaged in arranging a schedule of prizes.

## THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

### *The American Tropical Region.*

**EXTENT AND CHARACTER OF FLORA.**—This region includes the West Indian Islands, and, as a whole, the vegetation is the richest of the three tropical regions, and contributes largely to our collections of stove plants. Many of the most brilliant and gorgeous inmates of our hothouses have their home in this region. Taking a rapid survey of the more striking features in the composition of the flora, and noting particularly those plants or groups of plants, which are characteristic, as distinguished from those which are common to the tropical of the Old World, we have first of all, following the natural arrangement of plants, the grand Water Lily (*Victoria regia*), of the Amazon and its tributaries and other rivers of the northern part of South America. Although this magnificent Water Lily was discovered by Hænke as long ago as 1801, and subsequently seen by various travellers, it was not till 1836 that it was introduced into this country through Sir Richard Schomburgk, who discovered it in one of the rivers of British Guiana. The *Vochysiaceae* is a small Order peculiar to South America. It consists mainly of trees of large size, some of them with very showy flowers, and climbing shrubs. In floral structure these trees are allied to the *Polygalaceae*, one of the sepals being usually produced below in the form of a hollow spur. Seven genera and about 100 species have been described. *Trigonia laevis* and *villosa*, members of this family, were formerly in cultivation, and may be now in some collections. Of the *Guttiferae*, a family of large trees (*Cordia*, &c.),

Cocoa.

one sub-Order is entirely American; and the singular *Marcgraviaceae*, sometimes regarded as a sub-Order of the *Ternstroemiaceae*, are also confined to America. The latter are remarkable for their bracts, which are hollowed or hood-shaped, and for their manner of growth. Some of them are epiphytes, and the barren and flowering branches bear very differently-shaped leaves. A species of *Marcgravia* itself was exhibited at one of the meetings of the Horticultural Society in the spring of 1877. The genus *Theobroma*, different species of which yield the Cocoa of commerce, belongs to the *Sterculiaceae*, and consists of about half-a-dozen species of small trees, all endemic in America. The *Coca* family (*Erythroxylaceae*), which also finds its head-quarters in America, must be distinguished from the *Coccoloba*. A large tropical family, the *Malpighiaceae*, is numerously represented, including many of the *Lianes* or woody climbing and twining plants, so characteristic of the Brazilian virgin forests. These *Lianes*—which belong to various families, as the *Leguminosae*, *Combrataceae*, *Bignoniaceae*, *Aroidae*, &c.—embrace the largest trees, eventually causing their destruction, and form such a network of branches and aerial roots from tree to tree as to render progress impossible without cutting a road through. Most of the *Malpighiaceae* have showy yellow or red flowers, with crumpled, slenderly-stalked petals. The next characteristic group, is the *Simarubae*, of which there are many species, including *Quassia amara*. Passing by a number of tropical families which are not specially characteristic of any particular region, and which do not furnish many cultivated species, we come to the *Leguminosae*. Although this Order cannot be said to be characteristic of any particular flora, as it forms a large per-

GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS: TROPICAL AMERICAN REGION—CINCHONAS.

centage of the vegetation of most regions, except the frigid and New Zealand, still certain of its sub-Orders and tribes are characteristic in this or that country.

**LARGE FOREST TREES.**—In Brazil, for instance, the tribe Dalbergiæ, and the sub-order Cæsalpiniæ find their greatest concentration, constituting an important part of the large timber trees. Some of these trees are of a prodigious size. Martius mentions some, the trunks of which were so large that fifteen men with outstretched arms could only just embrace them. The magnificent genus *Brownia* is American, and belongs to the Cæsalpiniæ. The *Chrysobalanæ*, a small Order, or a sub-Order of Rosaceæ, consisting of trees and shrubs, is principally American, numbering nearly 200 species in Brazil, Guiana, &c. Another group of some 80 or more species, the *Lecythideæ*, regarded by some botanists as an independent Order, and by others united with the *Myrtaceæ*, is peculiar. They are all trees, and many of them of gigantic dimensions, as the *Brazil Nut*, *Bertholletia excelsa*. Like the tree just named they have mostly large, woody fruits, opening in the form of a lid to allow the seeds to escape. The fruit of *Bertholletia* usually contains as many as twenty nuts (seeds), and is 5 in. or 6 in. in diameter, and so solid and heavy that if it fell a distance of a few feet only on a man's head, it would

Frangipani.

seriously hurt, if not injure, him. Some of the fruits, as that of the *Sapucaia Nut*, *Lecythis Zabucayo*, and that of the *Cannon-ball tree* (*Couroupita guianensis*) are even larger. They present a great variety of shapes, from spherical to cylindrical, and urn or pitcher-shaped. *Myrtaceæ* proper, both shrubby and arborescent, are exceedingly abundant in tropical and sub-tropical South and Central America, a few reaching the almost temperate regions. The genera *Eugenia* (300), *Calyptranthes* (70), *Marleria* (50), *Myrcia* (300), *Myrtus* (100), *Campomanasia* (100), and *Psidium* (100), making up a total of more than a thousand species. Indeed, one botanist describes 500 species of *Myrcia* alone.

**THE MELASTOMACEÆ.**—The next family, the *Melastomaceæ*, consists of above 130 genera, and hard upon 2000 species. It is by no means confined to America, having representatives in Africa, Asia, and Australia; but, excluding the Old World genus *Memeceylon*, of which there are nearly 100 species, differing structurally from the *Melastomads*, it is in America alone that the family forms a prominent feature of the flora. Almost all the members are easily recognised by their opposite, three-nerved leaves, devoid of stipules, and the curiously-formed stamens. Upwards of 90 of the genera, and an even larger proportion of the species, are endemic in America, and none of the genera of the family are represented in both America and the Old World. Though this family is so much more numerous in America than elsewhere, and is there repre-

sented by a great variety of beautiful herbaceous, shrubby, and arborescent species, yet it will be seen that the Asiatic genera are better represented in gardens. Among the more familiar genera we may name *Miconia*, of which there are about 300 species, and to which the splendid *Cyanophyllum magnificum* belongs; *Pleroma*, 125 species; *Clidemia*, 40 species; and the smaller genera *Bertolonia*, *Centradenia*, and

Cannon-ball tree.

Guava.

*Heeria*. *Turnera*, the type of a Natural Order, of which there are only half-a-dozen other species belonging to two genera, is represented by about 70 species.

**PASSION-FLOWERS.**—Passion-flowers abound as well as in the sub-tropical regions. It is a curious fact that of the large genera *Passiflora* and *Tacsonia* nearly 130 of the about 150 species are American, whilst the remaining 12 genera,

Sweet Potato.

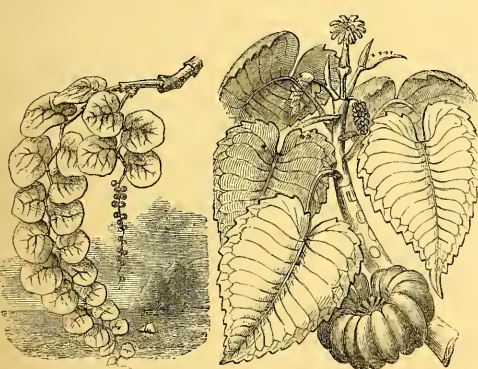

Avocado Pear.

comprising few species, are confined to the Old World; this is excluding the small groups *Malesherbiæ* and *Papayaceæ*, regarded by some botanists as tribes of the *Passifloræ*. Both of these groups are exclusively South American; to the latter belongs the genus *Carica*, the *Papaw*. *Passiflora quadrangularis*, *maliformis*, *macrocarpa*, *incarnata*, and other species yield the fruit called *Granadilla*. *Begonias* and *Cacti* also get into the tropical parts.

**SHRUBBY COMPOSITE.**—This family is numerous, Brazil being the centre of the shrubby element, altogether about 1000 species. There are 130 species of Vernonia, 100 of Eupatorium, and 100 of Baccharis. The Chilian, Andine, and Mexican regions have collectively nearly 3000 species of this family, but they are chiefly sub-tropical, temperate, and Alpine types. The ornamental genera Theophrasta, Clavija, and Jacquinia, forming a tribe of the Myrsineæ, are quite endemic.

**ALLAMANDA.**—Brazilian Apocynæ contribute the splendid Allamandas forming a part of almost every collection of stove plants; and the Asclepiadæ, the equally valuable Dipladenias and Echites; Gentianaceæ, Lisianthus; Convolvulacæ, Argyrea, Ipomæa, &c.; and Solanacæ, Browallia, Brunfelsia, and Solanum. Tropical America is the principal centre of the last genus, which numbers altogether upwards of 700 species, more than half of which are South American.

**GLOXINIA TRIBE.**—Gesneracæ, including the Cyrtandree, are generally dispersed, but most numerous in America, whence we obtain the genera Gloxinia, Achimenes, Nægelia, Gesnera, Alloplectus, Columnea, Hypocyrtæ, and Episcia. Brilliant-flowered climbing and erect Bignoniacæ abound, but they are mostly too big for ordinary glass houses. Spatheoda and Jacaranda are typical genera. Of Acanthaceæ, we may name Sanchezia, Apelandra, Geissomeria, Fittonia, and Thyrsacanthus; several of the other genera represented in our gardens

Seaside Grapes.

Sand-box tree.

by American species have a wide range in the Old World as well. All these families just enumerated, where not otherwise mentioned, are not specially American, but only the genera given as examples.

**FAMILIAR TYPES.**—Petrea volubilis (Verbenacæ), Bougainvillea (Nyctagineæ), Iresine (Amarantacæ), Poinsettia (Euphorbiacæ), Peperomia (Piperacæ), Rhopala (Proteacæ), Canna and Maranta (Marantacæ), Anthurium, Philodendron, Caladium, Dieffenbachia, and Phyllotæmium (Aroideæ), Eneharis (Amaryllidæ), Bromelia, Billbergia, Aechmea, Nidularium, &c. (Bromeliacæ), and numerous Palms, form the principal remaining types of tropical American vegetation commonly met with in cultivation. The families Piperacæ, Aroideæ, Marantacæ, and Bromeliacæ are numerously represented and characteristic in America. The Bromeliacæ, indeed, are confined to America, and chiefly tropical, and include the Pine Apple, Ananassa sativa.

**ORCHIDS.**—The typical genera of Orchids, as may be seen from the list given below, include some of the most gorgeous and some of the most curious of the family. The genus Catasetum is remarkable for occasionally producing flowers of three entirely different kinds of structure on the same spike. These three kinds of flowers were first observed separately on different plants, and were considered as the types of distinct genera Catasetum, Myanthus, and Monacanthus.

**ECONOMIC PRODUCTIONS.**—Among the important vegetable productions of this region, not yet mentioned, are the Custard Apple (Anona reticulata), Sweet Sop (A. squamosa), and Sour Sop (A. muricata), extensively cultivated and delicious fruits. Guarana Bread, made from the seed of Paullinia sorbilis; Mahogany, the wood of Swietenia Mahogany, in Central America; Rosewood, various species of Dalbergia, in Brazil; Balsam of Peru, from Myroxylum Pereiræ and Guava, the fruit of Psidium pomiferum and pyriferrum. Cinchona, obtained from the bark of various species of Cinchona, large trees, of which there were formerly extensive forests in Peru, but they are fast disappearing. Tomato, Lycopersicum esculentum; Greenheart the timber of Nectandra Rodriæ, a native of British Guiana. Cassava or Mandioca, obtained from the root of two species of Manihot—Aipi and utilisima (Euphorbiacæ), a staple article of food in some districts. Brazilian Caoutchouc, the inspissated juice of Hevea brasiliensis, also belonging to the Euphorbiacæ. Sarsaparilla, the roots of various species of Smilax; Vanilla, the fragrant fruit (seed vessel) of Vanilla planifolia, &c. Vegetable Ivory, the seed of a Palm, Phytelphas macrocarpa; and Palm Wax, an exudation from the trunk of Copernicia cerifera, Ceroylon andicola, and other Palms.

**General list of some of the tropical American Genera represented in European Gardens.**

Victoria	Vinca	Bougainvillea	Maranta
Theobroma	Dipladenia	Iresine	Batemania
Brownea	Lisianthus	Poinsettia	Betia
Mimosa	Argyrea	Peperomia	Burlingtonia
Pteroma	Ipomæa	Dieffenbachia	Castleya
Miconia	Gloxinia	Philodendron	Coryphanes
Clidemia	Achimenes	Caladium	Galeandra
Centradenia	Gesnera	Bucharia	Huntleya
Monochætum	Columnea	Bromeliacæ	Loelia
Heeria	Episcia	Phytelphas	Moradæes
Bertolonia	Sanchezia	Ceroylon	Ocoidium
Turnera	Apelandra	Attalea	Perieteria
Pasiflora	Fittonia	Geconoma	Pescatoria
Begonia	Thyrsacanthus	Sabal	Trichocentrum
Theophrasta	Jacaranda	Thrinax	Vanilla
Olavija	Spatheoda	Martinezia	Zygopetalon
Allamanda	Petrea	Canna	

W. B. HEMSLEY.

**Hardiness of Coronilla glauca.**—I observe that the hardiness of this little shrub is questioned; but here, on the east coast of Suffolk, it is not only hardy, but one of the most profuse midwinter flowering plants which we have. At the present time we have dwarf bushes of it in much healthier condition than I ever saw them indoors, and they are a perfect mass of yellow flowers. Under glass they usually become infested with white scale, but exposed, they do not appear to be affected by any insect plagues whatever. As regards soil, they will grow in anything; in fact, a poor soil suits them best, as moderate, sturdy growth is one of the first essentials towards ensuring hardiness. I have lately planted some against walls, and they promise excellent results mixed with Pyracantha and the early-flowering Pyrus (Cydonia) japonica. I have no doubt that the Coronilla will withstand any ordinary winter in any part of England, provided it is planted out early in the season, so that its growth may be completed and its roots well established before winter sets in, as no plant, however hardy, could be expected to withstand even slight frost if grown under glass and removed in its tender condition to a bleak situation.—JAMES GROOM, *Henham*.

**A New Thermometer.**—To be obliged to leave a warm, comfortable room in order to consult a thermometer outside, and that, too, when we see the snow falling through the window-panes, or when we hear the wind blowing before it the half-frozen rain, can hardly be called agreeable. It is, however, what every gardener is now and then obliged to do, not only by day, but also by night. This inconvenience has, we believe, been long surmounted in Germany by the invention of a thermometer with a transparent scale, which is fixed to the bars of a window and showing its face to the observer, who, by this means, can take his observations at his ease under shelter. The transparent scale in which the thermometer is fixed justifies the title of glass thermometer (*thermometre à glace*) which has been given to it. M. Eon, the well-known philosophical instrument maker, of 11, Rue des Boulangers, Paris, has improved the original instrument by making the divisions plainer, and by using the three scales, Centigrade, Réaumur, and Fahrenheit, which are the only ones now used in the sciences. By this valuable addition these thermometers can be used in any country.

## THE FLOWER GARDEN.

### THE PHLOX, PENTSTEMON, AND CHELONE.\*

#### Phlox.

AMONGST Phloxes, species may be found that grow from 2 in. to 4 ft. and 5 ft. in height, and they are nearly of every colour, except yellow and blue. Numbers of them are also striped, spotted, and oculated, as it is called. Some, too, have variegated foliage. The dwarf species, such as *P. frondosa*, *Nelsoni*, *verna*, *subulata*, *ovata*, and *divaricata* make excellent pot plants; they only require good loam, plenty of water, and to be plunged in the open air, where they are fully exposed to the sun, to succeed. They are also indispensable ornaments for the rock garden and herbaceous border.

THE EARLY PHLOX (*P. suffruticosa*), introduced from Carolina in 1818, is one of the best border and exhibition plants that can be had during July and August. It will grow satisfactorily in any good border or bed, but if the ground be not naturally suited for it, it can, with very little labour or expense, be made so. If the subsoil be too wet, it must be drained, and about 9 in. of good Hazel loam should be laid on the surface and enriched with good old manure and a small quantity of broken bones. In the herbaceous border a pit can be taken out—say 12 in. square and 9 in. deep—and filled with this compost. Phloxes of this class also make excellent pot plants; and if they be grown in 9-in. or 12-in. pots, and three or four shoots be left to each, according to the strength of the plant, they will be found very useful for greenhouse decoration in June and July. It is a good plan to grow a set of cuttings every year of the sorts best suited for this mode of cultivation, and to discard old plants, which will be found useful for propagating from, or for planting out in the borders or shrubberies. There is also a class of Phloxes especially adapted for pot culture that grow from 15 in. to 20 in. in height.

THE LATE PHLOX (*P. decussata*).—This was introduced from North America in 1812. It is stronger in habit than the Early Phlox, and has a far greater variety of colours. It also makes an excellent pot plant; and, being vigorous in habit, it requires a larger sized pot. Plants of this class are very attractive in conservatories in August and September, and they are also very fragrant. If grown like *Chrysanthemums*, they would create quite a new feature in greenhouses. When cultivated in beds or borders, the early and late sorts should be planted alternately, arranging them according to their heights and colours. They would thus produce a mass of bloom for at least three months, and the only labour required after they were planted would be to give each plant a good stake and tie them up when necessary, in spring reducing the number of shoots according to the strength of the plant and nature of the variety. They are also much improved by a liberal top-dressing every spring, of good, rich soil; and in very hot and dry seasons a good deluge of water will very much prolong the season of bloom.

Phloxes may be propagated by means of seeds, cuttings of the stems and roots, and also by division. The seed should be gathered from the best sorts only. It should be sown at once in boxes or pans in good free loam, and kept in a greenhouse or warm pit close to the glass. The young seedlings will make their appearance above ground in February and March; and as soon as they are fit to handle, let them be pricked into boxes of good soil, and kept close and warm for a short time, when they can be grown along with the other plants intended for the decoration of the flower garden. The strongest will be fit to plant out in April and May, and they will flower the first season; but not strongly and well before the second year. Then all the best sorts ought to be marked and grown a third year, in order to test them with the best-named kinds. Cuttings can be taken at all seasons of the year; and in the case of new or rare sorts, a few might be treated like *Dahlias* in a hot pit, the cuttings being taken off as soon as they are 3 in. in length, or they might be cut into single eyes, when they will

root in a short time in the bed of a propagating-house. They can also be propagated by means of the roots, the oldest of which should be cut into pieces about  $\frac{1}{2}$  in. in length, sown, so to speak, in boxes, and treated like seedlings. I have also struck the leaves, but they are long in making shoots, and altogether I consider this mode of propagating to be too slow to be recommended. The mode of propagating by division is simply taking the old plant and cutting it into small pieces.

As regards the properties of an exhibition Phlox, the form should be a perfect circle, quite smooth on the edge, and of good substance; the colours should be clear and well defined, the flowers arranged close on the spike and overlapping each other; their size should be about 1 in. in diameter. The spike of the Early Phlox ought to be quite conical, and that of the Late one a corymb. The habit of the plant should be strong and erect, with plenty of broad and healthy foliage, and it should not exceed 3 ft. or 4 ft. in height.

#### Pentstemon.

Of this useful genus I will just name a few species that are well worth growing, although the different hybrids now in cultivation are much finer. Nevertheless, for the herbaceous border and rock garden, *P. glaber*, *humilis*, *ovatus*, and *speciosus* are very unique, and no one can overlook the beauty of *P. Murrayanus*, *Cobaea*, *Kellermanianus*, *heterophyllus*, and *Palmeri*. As regards cultivation, Pentstemons will grow in any good garden soil; but when wanted for exhibition purposes, it is best to grow them in beds by themselves, well exposed to the sun and air, unshaded by trees or shrubs. Being cross-feeding plants, they require rich ground, and will stand a good watering with liquid manure or guano water during the growing season. When, in early summer, they commence to grow, put a stake to each plant, and if extra-fine spikes be wanted, all the side shoots ought to be pinched close to the stem. This will induce the growth of a number of short cuttings from the root, which will be useful for purposes of propagation. When they have to be cut for the flower show, it is of the greatest advantage to roll wet Moss round the cut part of the stem, and to immerse the spike in clean water; this will, in a great measure, exclude air, and prevent the flowers from flagging or falling. *Pentstemon Scouleri* is about the only species that has a shrubby habit, and it makes a fine plant to train on a low wall, where its blue flowers are very ornamental in August and September.

Pentstemons may be propagated by means of seeds, cuttings, and division. Seeds of the best sorts only should be saved, and they must be well ripened before they are gathered. They may be sown in heat in February and March, in boxes or pans, in good, free soil, and they should not be covered too deeply. As soon as the young plants are fit to handle they should be pricked out into boxes or in a frame, and planted out in April or May, when they will produce a dense mass of bloom in August, September, and October. Seeds may also be sown in the open air in June in a bed of finely-prepared ground, and the produce can be planted out in beds from 9 in. to 12 in. apart each way. These will flower in the following July, August, and September, and will ripen a great quantity of fine seed; the best sorts should be marked and propagated for further trial. When propagated by cuttings they should be selected, when about 2 in. or 3 in. length, from the sides of the strong shoots, and put into a cold frame close to the glass in good, rich, sandy soil, well watered and shaded from the sun. Division is chiefly employed in the propagation of the dwarf species.

As regards the properties of a show Pentstemon, the spike should be strong, stiff, and erect; the flowers should be in bunches of from five to seven, set on short foot-stalks, and arranged close to the spike; the blooms should be as near a circle as possible, and should stand nearly erect on the spike, and they should be of good substance; the colours should be rich and well defined, and if with a white throat, the lobes and the outside of the flower should be of one colour, and the circle of white well defined; if blotched, pencilled, or striped, they should be bold and effective—not running one into the other, nor flushing like ink on wet paper; the plant itself should not exceed 30 in. in height, and should be branching from the ground upwards.

\* Read at the Scottish Horticultural Association by Mr. James Grieve, Pirbright Park Nursery, Edinburgh, on Tuesday, January 8, 1878.

**Chelone.**

*Chelone barbata*, *mexicana*, *purpurea*, and *Torreyi* are generally grouped by themselves, being quite distinct from the *Pentstemon* proper. They constitute a class of dwarf, herbaceous plants which send up spikes of flowers from 2 ft. to 4 ft. high. They are quite hardy, and very ornamental in the herbaceous border. They differ from the *Pentstemon* in which the two upper petals are small, and the three under ones large, while in the *Chelone* the two upper petals are large, and the three under ones small, and the throat of the flower is full of strong hairs. The *Chelone* proper is a true herbaceous plant, dying down under the surface of the ground, and the shape of the flower, as I have just stated, is quite distinct from that of all the *Pentstemon* family. *Chelone Foxi*, *glabra*, *obliqua*,

quite a distinct variety, and well worth adding to any shrubbery or pleasure-ground where such plants are grown.—W. E. G., *Belgrove, Queenstown, Co. Cork.*

**Winter Crocuses.**—*Crocus Imperatorius* furnishes a kind of link that almost keeps up the continuity of flower between the autumn section and the favourite spring-flowering kinds. *Crocus speciosus*, and its autumn kindred allied to the giant section, as the *Colchicums* are termed, carry us through nearly two months of early winter. *Crocus Imperatorius*, a mid-winter kind, is also in habit allied to the first and last winter sections, as it has more leaves developed when in bloom than the autumn kinds, and less than the earliest of all the spring kinds, the old *Cloth of Gold*. Good clumps of the winter *Crocus* in sheltered places would be just now esteemed very charming, but perhaps it is best fitted for pot culture in a cool house.—A. D.

Lianes, or woody twining plants.

Palm (in flower and fruit).

Geographical Distribution of Garden Plants : Tropical American Region (see p. 52).

*Lyoni*, and *altissima* ought to be included in every select collection of border plants.

**Second Flowering of *Gynerium jubatum*.**—This new variety of the Pampas Grass, which I described in your columns in the autumn of last year as being by far the earliest to expand its graceful, feathery inflorescence of any variety with which I was acquainted, being, in fact, intermediate as regards the time of its flowering between the summer-blooming *Arundo conspicua* and the almost winter-blooming *Gynerium argenteum*, or ordinary Pampas Grass, is now blooming a second time in front of my house, planted out in the Grass in by no means a specially-sheltered or favoured situation, but fully exposed to the south-easterly gales, which are what we suffer most from here. It has sent up five good spikes, of which two are open, and if the present mild weather continue, I expect the others will also fully expand. I consider this *Gynerium* to be

**NOTES AND QUESTIONS ON THE FLOWER GARDEN:**

**Early Primroses.**—We have some plants of the common wild Primrose in full bloom on shrubbery banks in sheltered positions, and cultivated coloured varieties have been in bloom all the winter; I do not, however, attribute this altogether to the mildness of the season, as the real woodland Primrose beds have the ordinary wintry aspect. My impression is that high cultivation induces early growth, and consequently early flowering, which eventually becomes a fixed character in the Primrose.—J. Groom, *Heathon.*

**A Flower Garden on a Rubbish Heap.**—A few weeks ago we passed a railway station where a large bank of dug earth had been deposited in a conspicuous place, giving the spot an appearance exactly the reverse of ornamental. The occupant of the station, however, knew how to take advantage of things adverse. From pegs at the bottom of the bank to pegs at the top he had stretched a large number of cords at regular distances apart, and on these *Convolvulus* and other twiners had freely extended themselves, nearly clothing the whole surface with green foliage and purple bloom. In another place a compost heap was covered with *Petunias* and *Phloxes*.—"Cultivator."

## THE FRUIT GARDEN.

### SOWING AND TREATMENT OF EARLY MELONS.

From the beginning of January on to the middle of February is a good time to make two or three small sowings of Melon seeds for an early crop. The seed should be selected with care, and procured from trustworthy sources, always keeping in mind that certain varieties require more than a mere recommendation on paper for early work. By all means let us have new varieties, and if they turn out to be satisfactory, good and well; but I have found it best to keep to one variety for early or late work. I always observe that the longer I keep any single kind the more it improves in constitution, and the better it becomes adapted to our climate. The sort which we grow here for early fruiting is Malvern Hall, an old Melon possessing rare qualities as an early forcer. It ripens from ten days to a fortnight before any other kind which we have tried, but it does not present that imposing appearance on the dessert or exhibition table that many other varieties do, either in form or size. Neither is its habit of growth or vigour very striking; on the contrary, the stem is hard and wiry in appearance, and the leaves small and comparatively hard. To this fact we ascribe much of its merit for early or late growing in unfavourable localities, like that of the part of Lancashire from which I write. It is not so apt to damp off at the neck as more vigorous growers, nor are the leaves so suddenly affected by atmospheric changes. In their earlier stages of growth the young plants do not seem to thrive so luxuriantly as others do, but they make up for the deficiency afterwards. The early Melon crop is our most difficult one to manage. Early Grapes, Peaches, or Strawberries are comparatively easy to grow, simply because they have furnished themselves with all the essentials in the current year's growth, but with the Melon it is very different. The only advantage one can have is good seed and proper facilities for growing it, which is more the exception than the rule. Talk about growing early fruit, why a compact house, well treated and situated, is half the battle. Just compare our Lancashire climate with that of the Isle of Wight, and you have the difference at once. How rarely do we see a compact lean-to house, with abundance of top and bottom-heat, located in a sheltered corner which catches the first rays of light and the first and last gleams of solar heat? and yet these facilities would only be giving the gardener a fair chance of acquitting himself creditably in the matter of an early Melon crop. But it may be asked, How about the other side of the question? Well, I would just apply myself as best I could to improve on existing arrangements (if improvement were possible), and adapt myself to circumstances.

In sowing the seed for early crops, have the requisite number of small pots washed clean, and put a rough piece of soil in the bottom of each, filling the pot about half-full with any ordinary soil run through a  $\frac{1}{2}$ -in. riddle. Then drop two good seeds into each pot, and cover slightly through a fine sieve. The pots should then be plunged in a temperature of from 80° to 85°. If the bottom-heat be from fermenting material, there will be no need of watering before the plants have grown into "rough leaf." Meanwhile, they will be earthed up with soil that is warmed, either with hot bricks or some other appliance, to the same temperature as that of the soil in which the plants are growing. This is done by consulting the bottom-heat thermometer, and nothing is of more importance than avoiding checks in early growth.

While the young plants are progressing, the soil for the final planting out will be in process of preparation. Melons will grow in any soil, but they prefer a good fibry loam well incorporated with burnt clay and wood ashes; and preference should be given to limited room for early crops. Taking the "make-shift" principle for our guide, bottom-heat can always be supplied where there is a command of warm manure and leaves. A rude base of brickwork can be laid of sufficient height, on which to place either pots or square tubs with drainage holes in the bottom, to admit of a free passage for water, and the tubs might be made to come to pieces like a frame. By having a base of this sort, the bottom-heat could always be renewed and a steadier heat kept up than by planting out on a bed where the heat could not be renewed at intervals. When

about 1 ft. high, two or three of the strongest shoots should be stopped, in order to secure a few fruiting laterals; and in ten days or so two or three more might be pinched in the same way, and the remainder might be allowed to reach the top of the wires before they were stopped, and might be permitted to carry a full crop. Of course, pinching so early entails a little sacrifice, but the advantage of a few early fruits is no mean consideration with many people. Heat and moisture should be increased according to necessity as the days lengthen, and later conditions of cultural treatment ought to be governed by the exigencies of individual requirements. W. HINDS.

*Otterspool Park, near Liverpool.*

### FRUIT TREES ON ARCHES OVER WALKS.

THERE is certainly much to be said in favour of this plan of growing fruit trees, and most heartily do I second Mr. Hobday's remarks (see p. 11) by describing a plan which we adopted here some five or six years ago, and which has far exceeded our expectations. The kitchen garden is divided into four parts by two central walks running crosswise and lengthwise. Originally, as in many other kitchen gardens, ribbon borders lined each side of the walks; but, thinking that such a plan was a waste of space, I obtained permission to do away with the central cross borders and devote that space to fruit trees—Pears. The soil being light and very poor, I had the ground deeply trenched, and worked in a couple of layers of fresh stable manure. The borders, which are 6 ft. wide, were then marked out to receive two lines of trees, each of which was planted thus—

at 4 ft. apart in the rows. Two-years'-grafted trees were used, and trained the first year as upright cordons; the second year stakes were used for the two front rows, slanting towards the walk; and the following year an arch was formed over the walk with strong Hazel rods, to which each cordon in the front row was trained, till now the two lines of trees have met each other, and this season, by way of experiment, I grafted them together. The trees are so sturdy, that now they form an arch without any support whatever, and the grafting will add to its strength, though what effect the union may have on the fruit remains to be proved. The last two years they have fruited excellently, and doubtless they will continue to do so. It will thus be seen that this plan involves no expense of erecting supports or arches; and though I by no means wish to disparage these, I am of opinion that they are unnecessary. The two back lines of trees have been trained and trimmed into a pyramidal form, and, through having been allowed greater freedom of growth, they have had to be root-pruned twice to induce fruitfulness, which, I am happy to say, has proved to be the result. To make amends for the loss of bedding plants, now that the trees are established, I have planted the space underneath them with flowering herbaceous plants, so that in lieu of three months' gaiety we have something both of interest and profit all the year round.

*Hecksfield.*

W. WILDSMITH.

**Manuring Bush Fruits.**—I always like to give Gooseberries, Raspberries, and Currants a good dressing of manure at the season when the pruning is finished. There is not much fear of inducing too much grossness of habit in bushes or trees that bear a heavy load of fruit annually. The manure should only be lightly forked in, as this keeps a good many of the roots near the surface, and, consequently, the wood made is firm and short-jointed. If the land be well prepared before the bushes are planted by trenching and manuring, the fork and hoe will do all the cultivating that will be required amongst them afterwards, so long as they can profitably occupy the same plot, and when that period expires it is better to plant a fresh break and destroy them. On dry, porous soils, mulching early in summer is very beneficial, as it enables the trees to carry a much heavier crop with less signs of exhaustion than when mulching cannot be resorted to. The mulching need not necessarily consist of manure; the bushes will, of course, derive more support from manure, but in most cases it is simply moisture that is required, and anything that will check evaporation may be usefully employed.—E. HOBDAY.

## BIRDS AND BERRIES.\*

DURING the last few months certain trees have been observed covered with fruit, often in very large quantities. Many were early robbed of their produce, while others remain untouched even at the present time. The greedy way in which birds cleared off many varieties of the smaller native or hardy fruits and berries, to the total exclusion of others, although belonging to the same genus or species, is worthy of remark. This peculiarity was first observed during autumn in the case of the berries of most of the varieties of the Service or White Beam trees. During September and October trees of all sizes were covered with fruit, which was rapidly taken off by blackbirds and thrushes, often before it was thoroughly ripe. Of one variety, however, viz., the *Sorbus torminalis*, which has brilliant crimson fruit, not one berry was meddled with till the end of December, and then

upright branches. While the Yew berries last scarcely a Holly or Thorn seems to be meddled with.

Birds would appear to avoid certain fruits, the colours of which are different from those to which they have been accustomed. As I have stated, the rich crimson fruit of the *Sorbus torminalis* is avoided, although ripe at the same time as the other Service tree berries, which are of a yellowish tinge, spotted with red, and which are eaten. The two varieties may even be seen side by side, the yellow bared, and the crimson untouched; but whether this is on account of the colour alone or because of a difference in flavour I am unable to say. The berries of both, however, are pleasant enough to the taste. This selection of certain fruits is also applicable to the fruit of the yellow-berried Holly, which is found thick on the bushes during a severe winter when all the red berries are gone. Birds also seem to

Epiphytal Orchids, Bromelias, and Ferns.

Philodendrons.

Geographical Distribution of Garden Plants: Tropical American Region (see p. 53).

only a few, as clusters of them are still plentiful on many of the trees. The common red Rowan tree berries were likewise cleared off in a few days during the month of September. At the present season, as well as all through December, the Yew trees formed a great resort for birds, the red berries being greedily eaten by them, so much so, that besides passing a considerable quantity of pulp and seeds, which lay plentifully on the ground around, the branches were in many cases covered with ejected masses of crimson pulp. It seemed as if the berries were no sooner down the throats of the birds than they were immediately thrown up, always mixed with the small green nuts which are embedded at the end of the fruit. The Irish Yews (*Taxus hybernica*) were this autumn loaded with fruit, and it was remarkable to see the manner in which the birds cling to their

avoid the yellow-berried Yew, yellow-berried Mountain Ash, and the black-fruited Thorn, few of the fruits of these being touched till the common coloured kinds are gone. In this district of Scotland we have few ripe white berries on the Mistletoe this year, most being green, except in some very favourable situations. I find amongst the large bunches sent at this season from England, that although many berries are ripe and plump, numerous others are seen in the transition state from green to white. One can scarcely fancy that the Mistletoe berries are sought after by birds for the sake of food alone. It is evident that birds have an object to accomplish with regard to them. While eating the fruit, the extremely adhesive substance surrounding the seeds causes them to adhere firmly to the bills of the birds. In order to get rid of this foreign substance, recourse is had to rubbing their bills on the branches of neighbouring trees; and in this way the seeds are left sticking to the branches, where they afterwards take root and

\* Read the other evening by Mr. James McNab before the Botanical Society of Edinburgh.

grow. This method of distributing Mistletoe seeds seems to be assigned to them by Nature, as it is impossible for such seeds to grow in soil. We have just now several young Mistletoe plants growing on some out-of-the-way branches, evidently two or three years old, in positions in which birds have taken refuge to get their bills cleared of the glutinous substance, and seeds adhering to them. A similar practice is adopted by cultivators when propagating the Mistletoe, viz., by bruising the adhesive pulp surrounding the green central germ with the fingers, and fixing it on the bark of a tree to which it readily adheres. In order to prevent birds removing the green germ, which they frequently do, it is necessary at times to cover the germ with a piece of fine wire gauze netting or muslin, keeping the muslin tight over a piece of wire previously adjusted. The Sea Buckthorn (*Hippophae rhamnoides*) is another indigenous fruit-bearing plant which this year is fruiting in its native stations in the greatest abundance, the fruit clustering like that of the Holly, but of an orange colour, the leaves being narrow, and of a glaucous Ash colour. This Buckthorn is now very generally cultivated in many of the sandy districts of East Lothian. Perhaps the largest native tract of this plant is to be seen on the "Sandy Hint" at Tynningham Point, where

## PLATE CXI.

## A FEW GOOD ONCIDIUMS.

(WITH A COLOURED FIGURE OF *O. CONCOLOR*.)

Drawn by Mrs. DUFFIELD.

The genus *Oncidium* contains a very large number of species; the flowers of many of them are, however, small and insignificant, looked at from a gardening point of view, and, therefore, not worth the attention of those who have but limited accommodation; the few, however, here described, merit a place in every collection of Orchidaceous plants.

*Oncidium concolor*, the subject of the annexed illustration, is a native of Brazil, and has, until recently, been exceedingly rare; it is now, however, more plentiful, and well deserves the attention which it is receiving. Being close and compact in habit, it may be grown upon a block, or in a pot, whichever way may suit the taste or convenience of the cultivator. It should be placed at the warm end of the Cattleya-house, and be treated liberally as regards water,

A Garden Cemetery (see p. 50).

a great extent of the ground is covered by a dense thicket of this shrub, varying from 4 ft. to 10 ft. in height, and all in fruit-bearing condition, contrasting well with the Hollies and Thorns, which are also abundant in the district. I wrote to Mr. Lees, who was long gardener at Tynningham, to ascertain if the berries of the Buckthorn were eaten by birds like those of the other native fruit-bearing plants. In answer to my question, he stated that he never saw them much frequented by birds till all the fruits of Hollies and of Thorns were exhausted. During the severe winter of 1860-61, when birds were sorely pressed for food, blackbirds, thrushes, and bullfinches might have been seen in flocks upon them; but although they eat the berries, he did not think they were very fond of them. Mr. Lees adds that it is rare to see the Buckthorn fully covered with fruit two years in succession. Although the Buckthorn succeeds in cultivation, it is rare to see more than one or two dozen berries on cultivated bushes in any one place away from the sea. While on this subject I may state that the distribution of many fruit-bearing plants, particularly in some districts of Scotland, is chiefly through the agency of birds, many such plants as Yew, Holly, Thorn, Elder, and Mountain Ash being found in many inaccessible places on the hill-sides.

taking care, in the first instance, that the pots are well drained. Its rich, yellow flowers, which measure from 1 in. to 2 in. in diameter, are produced upon pendulous racemes during the months of April and May.

*O. macranthum*.—A noble species, producing large flask-shaped, much ribbed pseudo-bulbs, and long, narrow, bright green leaves; the flower-spike is much branched, and bears numerous blossoms, each measuring nearly 4 in. in diameter. The sepals and petals are thick and fleshy, and of a rich, deep yellow colour, tinged with purplish-brown; lip small and similar in colour. This species does best in a pot, and it should be placed in a cool house. It flowers during spring, and is a native of Peru and New Granada at considerable elevations.

*O. varicosum* Rogersi.—Until about a year ago this variety was extremely rare. Lately, however, large importations of the species have been received, and many plants of the variety (Rogersi) have appeared amongst them. It is a compact-growing plant, and has large, ovate, dark green pseudo-bulbs, more or less freckled with black; the flower-spike is large and much branched, and bears, in some instances, as many as 150 or more blossoms, each measuring

ONCIDIUM CONCOLOR.

nearly 3 in. in diameter. The sepals and petals are very small, the lip deeply bilobed, and of a rich golden yellow colour. It may be grown either in a pot or in a basket, and it thrives best in the temperature of the Cattleya-house. The blooms appear during autumn. It is a native of Brazil.

**O. Marshallianum.**—The pseudo-bulbs and leaves of this species somewhat resemble those of *O. crispum*, but it is, nevertheless, distinct. The flower-spike is much branched, and bears great quantities of large, handsome flowers during April and May; the sepals and petals are golden-yellow, spotted and barred with chocolate; the lip large and spreading, rich golden or orange-yellow. This fine species, which is a native of Brazil, thrives best in the Cattleya-house.

**O. Lanceanum.**—An old but extremely beautiful species, and an exception to the genus in being destitute of the colour which is so prevalent amongst its members. Its leaves are large, thick, and fleshy, carinate, and without pseudo-bulbs, bright green and profusely dotted with reddish-brown. The flower-spike, which is erect, is many-flowered; the sepals and petals are greenish-white, heavily blotched and barred with chocolate or deep red; lip rich violet and rose. It blooms during summer. The leaves of this species are very liable to spot. It is found to thrive best in the warmest end of the Cattleya-house, or even in the East India-house. It should be well drained, potted in peat and Sphagnum Moss, and carefully watered. If nothing is allowed to become stagnant about it, and sudden changes of temperature avoided, it will continue in good health and bloom profusely. It is a native of Demerara.

**O. sessile.**—A charming plant, of compact habit, producing oblong, slightly-compressed, pseudo-bulbs, and pale green, ligulate leaves. The flower-spike, which is erect, is much branched, and bears numerous large golden-yellow flowers, the sepals and petals of which are dotted with cinnamon. It should be grown in a pot and placed at the coolest end of the Cattleya-house. The flowers appear during spring and early summer. It is a native of Cerecass.

**O. saurodes.**—This distinct and handsome species is now tolerably plentiful. Its pseudo-bulbs, which are dark green, bear a pair of broad, obtuse leaves of the same colour. The flower-spike sometimes attains a great length, and is much branched, bearing numerous orange-yellow flowers, which are spotted and blotched with crimson. It blooms during spring and summer, and thrives best in the Cattleya-house. It is a native of Brazil.

**O. ampliatum majus.**—A fine, old, well-known plant, having sufficient merit to maintain its position even amongst the numerous novelties which have cropped up during the past few years. Its pseudo-bulbs, which are large and compressed, are pale green, freckled with reddish-brown, and bear a single, large, shining green leaf, which is paler on the under side than on the upper. The flower-spike, which rises from 2 ft. to 3 ft. in height, is much branched, and bears numerous large flowers, which are clear soft yellow on the upper side, and white beneath. It blooms during the summer months, and thrives best in the Cattleya-house. It is a native of Venezuela and Nicaragua.

**O. splendidum.**—This still continues to be one of the rarest of Oncids. It has small, somewhat compressed, dark green pseudo-bulbs, that support a single stout, leathery leaf of the same colour. The flower-spike, which is erect and branching and about 2 ft. in height, bears numerous very large flowers, the sepals and petals of which are greenish-yellow, transversely barred with cinnamon; lip large and flat, and of a rich deep yellow colour. It blooms during the spring and early summer months, and should be grown in the warm end of the Cattleya-house.

In the cultivation of the different species of *Oncidium* here enumerated, care as regards watering is one of the chief requirements, especially during the winter months. The drying-up system is now seldom practised, except in a few old-fashioned places. Experience goes to prove that during their resting season the plants must be carefully watched, and never allowed to show signs of suffering from drought before water is given them; the atmosphere should, however, as a matter of course, be kept dry, and any sudden change of temperature avoided at any season, but especially in winter. W. H. G.

[For the specimen from which the annexed plate was prepared we are indebted to Messrs. Veitch.]

**Abutilon vexillarium** as a Basket Plant.—This is at once one of the finest and most effective plants for hanging baskets, or as a pot plant for brackets that can be grown, and as there are not too many really good basket plants, those having each to furnish should obtain it forthwith.—W. W. H.

## TREES AND SHRUBS.

### TRANSPLANTING TREES.

(Continued from page 30.)

THE next form of transplanters which I find useful are flat transplanting spades, also invented by Mr. McGlashen. They are of various sizes, from the common garden form to spades 30 in. across. The sizes which I generally employ, and which I find by far the most useful, are those used for lifting a ball 13½ in. in diameter at top, requiring two men to lift; also a ball 17 in. across, requiring four men to lift; and one 24 in., requiring six men to move. As each set of spades requires its own apparatus, I shall simply detail the working of a 17-in. set, a size which I consider exceedingly useful, and therefore

Iron frame.

Hook for iron frame.

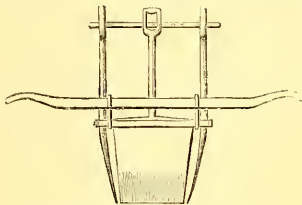

more employed here than any of the other kinds. It consists of four spades or lifters, having ordinary, but strong, garden-spade-handles, a strong iron frame 20 in. in diameter, having a curve in the centre of each side, and made in two pieces, with a curved hinge at one of the angles, which can be taken off by putting the two portions well back; this, however, is not necessary. A hooked nut is fixed to the opposite angle, which keeps the frame together when the pressure is put against it from within. The frame is first laid on the surface of the ground round the shrub or tree, keeping it equi-distant from the stem. A cut, 4 in. or 5 in. deep, according to the nature of the surface soil, is made round the outside of the frame. This enables any superfluous surface soil to be removed, and the top of the ball to be made to slope from the stem to the iron frame, which is placed at the bottom of the cut. By this

Method of using iron frame.

simple arrangement, I find that I can lift a much larger shrub with a smaller-sized machine than I could do by placing the frame wholly on the surface, which was Mr. McGlashen's original plan. By this partial sinking of the frame, it causes the widest portion of the ball, where most roots are generally to be found, to be at the widest part of the transplanting spades; besides, it is rendered much easier to lift, although the weight may be a trifle greater. After the frame has been placed in the cut intended for it, the four spades are inserted by merely pressing them down with the feet, beginning with the two opposite ones, and keeping them exactly in the middle of the side of the frame, the curve being intended for the back of the spade-handle. The opposite spades are next inserted. It is necessary that each spade should be put in at the same angle, which is easier done when the frame is inserted than when placed on the surface. Two tension-rods, of flattened upright iron, about 3 ft. 6 in. long, 1 in. deep, and ¼ in. broad, having a cross iron pin about 6 in. long, ¼ in. deep, are fixed across one end, but about 4 in. from the point, so as

to keep the tension-rod in an upright position. The other end, first inserted into the opposite handle, is graduated with elongated holes; another iron pin, 6 in. long, and for convenience, is generally fixed to a chain attached to the tension-rod. One tension-rod and chain is first put through the branches and between the opposite handles of the spades, the cross-pin preventing it going through. One man will pull the fixed cross end of the tension-rod, and another the opposite side. When sufficiently extended, the chain-pin is inserted in the most extreme elongated hole that can be reached, but inside of the spade-handle. The tension-rods should always be 10 in., or 12 in. longer than what may appear to be required, as it occasionally happens that if the spades are inserted with more slope than is necessary, the extra length will be found useful. Besides, the same rods can be used for different sized spades. For this end it is advisable that plenty of holes should be made in them. After the one tension-rod has been fixed, the other is placed through the handles of the opposite spades, immediately above the first, and tightened, as before stated. Four hooks, all of a uniform length, are then inserted under the iron frame, one at each corner, but on two sides only; or, as sometimes happens, particularly in the case of smaller-sized frames, oblong rings are permanently fixed on the corners, two on the opposite sides, large enough to allow of the insertion of a pair of lifting hand-spokes. If the tension-rods are sufficiently tight, four men will lift the plant out of the ground in a few seconds, and carry it to where it is to be planted; but with larger spades and heavy balls, it is advisable to use a long-handed truck or mason's "bogie." If the plant is to be conveyed in this manner, in order to keep

McGlashen's 17-in. Transplanting Spade.

the spades in position during the transit, it is necessary to take out the hand-spokes, and, with one long piece of soft rope, fix the iron handles to the tension-rods up and down all round. This simple precaution will prevent the frame from moving, which sometimes happens by the shaking of the spades or the bogie, or even when carrying, or while being rested on the ground, but which is seldom or never the case if the rope-fixing is attended to. When taken out of the pit, it is desirable to place a piece of canvas below the ball, tying it at the same time to the sides, to prevent any loose soil falling on the ground. As the hole for the reception of the plant is previously prepared, and is generally made about 1 ft., or 14 in. wider than the size of the spades employed, it is necessary to raise the soil in the centre of it, so as to fill up any vacancies arising from fallen earth; the plant is then lowered by means of the hand-spokes. At this stage it is necessary to see that the plant is standing perfectly upright; if so, the hand-spokes are withdrawn. The frame is then pushed down by pressing the feet on the corners; it is then unhooked and removed, the tension-rods are slackened and taken off, and the four spades fall back, leaving the plant standing in the centre of the hole. At this stage it is necessary to have the sides of the ball scratched round, as before recommended, in order to free the glazed surface acquired through the pressure; and if any roots have been cut by the insertion of the spades, their ends should be smoothed, and the hole filled in with prepared soil. When large spades are used, say 36-in., they are generally provided with solid iron handles, 1 ft. long, having a strong iron eye fixed near the top of each. These spades are generally driven into the ground (but within the frame) by means of a heavy mallet. The tension-rods in this case are provided with screws on each end, which are inserted

into the iron eyes placed on the side of the spade-handles, each being provided with moveable thumb-nuts at each end for tightening them to the spade-handles. Such transplanting spades require the assistance of six or eight men to lift them and the plants out of their holes, and a bogie to place them on. With larger balls than those now described, where one spade only on each side is insufficient, smaller spades are employed, two at each end and three on each side, suitable frames being used for them, 4 ft. 8 in. long, and 3 ft. 5 in. broad. In this case, like the 36-in. ball, all the spades are of solid iron, and each is provided with iron eyes and tension-rods. For such balls a moveable wheeled machine is employed. By the removal of the back frame and screw beam, the machine is placed on planks on each side of the spades, and the back frame and screw beam are replaced. By means of chains fixed at each end of the iron frame, the plant is raised by the screws out of the ground, and is thus left suspended in the machine for removal. As I have not witnessed any very satisfactory experiments conducted with the large solid-iron spades, I therefore leave this part of the McGlashen transplanting to parties who have the medium-sized horse machines in their possession. I have stated that the lifting of plants with the 13½-in. spades, and also with the 17-in. set, is an interesting process, being cheap, rapid, and safe. A few may come to grief at first from the want of experience, but after the principle is thoroughly understood by the operator, the number of plants that can be lifted in a given time is wonderful. I have seen two men preparing holes and planting as fast as any other two could lift and convey a 13½-in. ball.

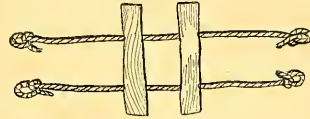

As I have now stated all that I intend to do about the ordinary McGlashen methods of transplanting, dwelling chiefly on the sizes of spades which I generally employ, I shall now give my experience as regards the removal of evergreen shrubs and trees of various sizes, lifted with adherent balls of earth, by what we call the rack system, and which has long been adopted here, and always with perfect success, occupying, however, much longer time than is taken up by McGlashen spades. Before doing so, however, I shall give a short notice of the machines or carriages which we employ for heavy transplanting purposes, in addition to those already noticed. One very strong carriage is 5 ft. 6 in. long, 3 ft. 3 in. broad, and 1 ft. 6 in. high. The upper surface of wood is 2 in. thick, supported above the axles, upon three longitudinal bars, each 5 ft. long, 8 in. deep, and 4½ in. broad, resting on and fixed to the heavy iron axles, supported by four solid wooden wheels, strongly iron bound. The wheels are each 15 in. in diameter and 7 in. broad. The back ones turn on a fixed axle, while the front one is moveable, and strongly pivoted in the middle, on the ends of which are fixed suitable appliances to be used for horses. This carriage is freely surrounded by hooks and rings. It is also provided with a double tram, to enable it to be drawn by horses, as it is only intended for trees to be moved in an upright position along a public road. When not employed for heavy work, two of the wheels are used for a strong bogie, 2 ft. 6 in. long, 2 ft. 5 in. broad, and 18 in. high, having a long handle attached to it. This carriage is also freely supplied with hooks and rings. The other two wheels belonging to the large carriage are likewise used for a medium transplanting machine. The top is 3 ft. 6 in. square, the two solid wheels being fixtures for a time, on a strong iron axle. It has also a smaller wheel in front, working on a moveable pivot attached to a long handle, and is drawn by ropes, the handle and small wheel guiding it. Besides those just mentioned, we have what we call frame-rollers, one 3 ft. 9 in. long, and 3 ft. 6 in. broad, resting on two strong iron-bound rollers, each 13½ in. in circumference, having a square iron axle passing right through them, the height above the ground being 6½ in. This machine is much used when the trees are moved in an upright position on planks. Another frame-roller carriage is 3 ft. 4 in. long, 2 ft. 6 in. wide, and stands 5 in. high, the rollers being 12 in. in circumference. These low frame-rollers are strongly bound with iron, and are made to carry very heavy weights.

We find them also exceedingly useful for removing large plants in tubs, both upright and on their sides. For the latter purpose these low-frame carriages have either three or four crossbars of wood, according to their size. When a tall Palm, or other exotic plant in a tub, is to be taken from one house to

another, it is first conveyed, so as to face the door, on common iron rollers. The sides of the tub are then supported on bricks, or blocks of wood made of planks 3 in. thick, plenty of them being always at hand. When the tub has been raised 6 in.—the height of two blocks—the smallest frame-roller is run below the tub till the back part of it is immediately over the two front cross-bars, fixing the front of the tub with blocks till such time as it is laid over. If the door be high enough, resting between the two front bars of the machine may be sufficient; but if not, it can be laid down by degrees, and supported on the back portion of the frame-roller with wooden blocks and wedges, and fastened with ropes to the hooks and rings; then it can be conveyed along on planks to the house intended for it. This is done with ropes drawn by men, strong iron crow-bars being employed to move it either to the one side or the other, so as to keep the machine on the middle of the planks; and when required to be turned, a sufficient number of the planks are laid side by side for the purpose. In a large plant establishment it is almost impossible to carry on heavy moving without some such appliances as those just described.

Let us now advert to the rack system of transplanting, which is suitable for balls of all sizes. Those which I shall describe are trees with balls varying from 1 ft. to 3½ ft. in diameter, the larger being the size we generally use here with the McGlashen spades. As an illustration of the rack system, I shall take a plant with a ball 6 ft. in circumference. After the ground has been opened up in the ordinary way all round, taking care to keep the sides quite upright and smooth by the use of a hand-fork, saving all the fibres that can possibly be got, cutting off or shortening any strong roots projecting beyond the ball, and saving all pliable ones to bend round the

the hole. The next operation is the undermining; this is done by means of a long narrow trowel, first on one side, and afterwards on the other. On the side to be first commenced, particularly when the balls are large, it is necessary to put a prop between the ball and the upright side of the hole, so as to prevent the ball leaning during the process of undermining. Two permanent lifting-boards, generally of Oak, slightly grooved on the under surface, to keep the lifting-ropes in their places

Lifting boards, flat.

are now provided. These are generally made in pairs, to suit the different sizes of trees to be transplanted. If the ball be small, two lifting-boards are sufficient; but if large, it is sometimes advisable to put in first a piece of thin deal, but of the same length as the lifting-boards, and the grooved Oak ones outside. It sometimes happens that the inner deal board cannot be taken out after planting without injury to the ball, being soft and thin, but that is of little importance, as it soon rots away. When

Lifting boards in use.

one side of the ball is completed, a prop is put to the opposite one; the undermining is again commenced, and the bottom boards inserted. The lifting-ropes, one for each side, are put below, beginning on the one side and then on the other. They are generally of a uniform length, and vary in thickness according to the weight of the ball. An eye is formed on each end of the rope, through which the hand-spokes to be used in the lifting-ropes are placed. The number of men to be employed for lifting the plant out of the hole depends upon the weight of the ball. In ordinary cases it can be done at once, but with larger balls we generally make a ledge in the upright bank, about half-way

Trowel for undermining.

Form of rope for fixing canvas.

sides of it, a piece of canvas, doubled longways, is then put round, keeping the doubled portion at the under side, and exactly level with what is to be the bottom of the solid part of the ball. The canvas is first fixed with a piece of soft rope, which is put round the lower portion of the ball double, and, after being drawn through the single loop and partially tightened, it is taken up the side immediately above the loop, and then taken round the upper portion, twisting the one end round the other in opposite directions, no knots being used. Numbers of thin barrel-staves, all naturally curved, and all of uniform lengths, are then adjusted round the ball, but within the soft rope, keeping them about 3 in. or 4 in. apart, according to the apparent firmness or softness of the mass. The soft rope being made at first sufficiently tight to keep the staves in their respective places, a strong doubled rack-rope, ½ in. or ¾ in. in diameter, according to the size of the ball, is then put round the staves, immediately above the soft rope, and treated in the same way, sufficiently slack, however, to allow of two rack-pins to be put in, one at top, and one at bottom, but on opposite sides of the ball. The rack-pins are then tightly twisted till the rope is hard and firm. The ends of the rack-pins should be fixed with a piece of tarred yarn, or small rope, put below the rack-rope before being tightened, so as to fix them securely. The ends of the rack-pins should be placed so that the top of the upper one should be tied to the under rope, and the under pin to the upper rope, the pins in no case to be longer than the depth of the ball. These minor details may not appear of much importance, but they will be found to be essential when much transplanting of this kind is carried on. We have now got the ball as firm as it is possible to make it, and standing securely on the bottom of

Hand transplanter.

between the bottom of the hole and the surface; on this ledge or shelf the plant is first lifted. It sometimes happens, in the case of large balls, that the hand-spokes require to be lowered, and if that is to be done it should be at this stage. It will always be found that the lowering of the hand-spokes generally facilitates the lifting of the ball to the surface. If the distance to which the plant is to be conveyed is not great, it can be carried at once to its destination, but if far, it may be placed on a strong transplanting bogie and conveyed there. Several kinds and sizes of these machines are used here. After the plant has been placed in the pit intended for its reception, the bottom boards are taken from below it. If the under part of

the ball be not quite firm, the inner deal one, if used, may be left; the lifting ropes are also taken out. If the plant be thoroughly upright, soil is packed securely under the ball and all round it. The rack ropes, staves, and canvas are then taken off, the bent roots adjusted, prepared soil is filled in, and water is freely applied. From the description given of preparing the balls, it will be seen that it takes a much longer time than is done by the McGlashen spades. With large balls, however, it is very much safer, and when performed by experienced hands it is really astonishing the rapidity with which such work can be carried on. The rack system, when properly done, enables the transplanters to withstand a good deal of

Transplating truck.

fatigue, and no injury is sustained in the event of a breakdown, provided a sufficient number of men be at hand for assisting in lifting.

JAMES MCNAB.

(To be continued.)

### GLYCINES GROWN AS BUSHY SHRUBS.

WE are so much accustomed never to see creepers in any other form than that of climbing plants, which enlase and hook on to the supports, by the aid of which they rise into the air and produce their flowers, that we should not be surprised if the title at the head of this article were read with some approach to doubt on the part of some of our readers, not so much perhaps with respect to the Glycine being able to grow in this form, but as to their flowering properly. Nevertheless, this is the case, and these two things are perfectly possible. Nothing is easier than to have even very small plants which every year will be covered with a considerable show of bloom. On the other hand, when the Glycines first begin to blossom, it is only necessary to examine them closely to perceive that these plants show a greater disposition than a large number of others to flower abundantly on the old wood. In fact, it is rare to see the Glycine flowering anywhere else but on the old wood, resembling most of the fruit trees in this respect. We must therefore allow certain parts of these plants to grow old, which is easily done by breaking off the buds a little above their insertion, so as to transform their base, as we do when we similarly break off the buds of Apple and Pear trees. If the shoots have not been broken off sufficiently short, we may, during the pruning season in spring, cut back almost to the old wood, so as to give them the proper dimensions. Even if, in the course of two or three years, these shoots become too long, we can, so to speak, regenerate the plants by cutting the old wood, so as to give them the form and size we desire.

These remarks are purely practical, for we know of Glycines which, by being submitted to the operations just described, have not yet exceeded the dimensions of 5 ft. in diameter by  $4\frac{1}{2}$  ft. in height, although they are now over twenty years old. Every year at flowering time, notwithstanding this change of form, they disappear for a fortnight under a mass of bloom, and form one of the most beautiful effects it is possible to imagine. By planting alternately the two China Glycines with blue and white flowers we increase their beauty by the pleasing contrast of colour. Those who are in a position to make a trial of this method of training Glycines will never have to repent it.

E. A. CARRIERE, in the "Revue Horticole."

## THE INDOOR GARDEN.

### LEVETZOW'S SELF-WATERING FLOWER-POT.

THE danger of under or overwatering plants cultivated in pots is by no means an imaginary one, as almost every cultivator knows to his cost, and any contrivance which will prevent the possibility of supplying them with either an excess or an insufficient quantity of moisture cannot fail to be duly appre-

Fig. 1.

ciated. This Mr. Levetzow's patent self-watering flower-pot, represented by the annexed illustrations (figs. 1 and 2) does, and, as we shall see, it is very simple in construction. It consists, in reality, of two pots, situated one within the other, but united so as to have only one bottom. Whilst the outer pot is intended to hold water, the inner one is filled with soil, and there is no communication between them except what is due to the porosity of the inner vessel and of the air-tubes attached to it. The upper ends of these tubes, as will be seen by the illustrations, reach to just above the level of the water, and their lower ones, passing through the side of the inner pot, open out near its base. The tubes being porous, not only damp air, but a little water escapes by the lower extremities on to the layer of charcoal in the bottom of the pot. Thanks to

Fig. 2.

the property which charcoal possesses of absorbing and retaining humidity, the layer of it just alluded to, whilst it serves as a protection against an undue quantity of moisture, is yet able to supply the plant with the needful amount, so long, of course, as there is water in the outer vessel. As one would naturally suppose, it is more particularly when the roots of the plant begin to approach the bottom of the pot that they have the full benefit of its peculiar construction. At the Seegerhall earthenware works, situated at Neuwedell, in the Neumark (Prussia), Levetzow's self-watering, or so-called "Culturtopf," is manufactured of different sizes, as well as of various degrees of porosity, so as to suit the requirements of different plants.

T. S.

**Canistrum aurantiacum.**—Thanks to the writings and figures published by the learned Liège botanist, Professor Morren, the Bromeliaceæ generally are now attracting the attention of a considerable number of horticulturists, particularly on the Continent. Some members of this family are exceedingly handsome plants, and by no means difficult to manage. Given porous loam and peat, heat and moisture, and success is certain. The smaller genera and species do admirably in the warm Orchid-house, and many of them seem to like being kept in a close, moist stove for many years. *Canistrum aurantiacum* is distinguished by its close head of numerous orange-yellow flowers, borne on a peduncle overtopping the leaves; the broad red bracts on the flowering stem also form a conspicuous feature. It is of medium size, measuring about 2 ft. in diameter and little more than 1 ft. in height, including the inflorescence. One of the greatest recommendations in its favour is the length of time it

*Canistrum aurantiacum.*

will remain in bloom; a healthy plant, under favourable conditions will continue for three months in full beauty. The genus was founded by Morren.

**Sowing Lobelia Seed.**—Some recommend this to be sown on a gentle bottom-heat in March. Anyone who has a cool house and does not wish to wait so long for a stock of seedling plants, will find that seed sown at once in pans or pots, and placed on a shelf near the glass, will soon germinate, and thus furnish strong plants ready for pricking out by the time for sowing in a gentle heat arrives, as mentioned above. I have now two pans of seed just germinating in this way, without the least assistance from artificial heat. I make it a rule to sow *Petunias* early in November, and *Lobelias* and *Mimulus* just before Christmas. In this way I have an abundance of plants early in the spring without any trouble. The *Lobelia* is a half-hardy annual, and does not require such forcing treatment as is too often applied to it. Good strains of the best bedding kinds also come very true from seed, and, as a rule, produce better and more robust plants than those obtained by means of cuttings. The old *L. speciosa* seedlings used to come with rank, straggling habits, but this kind has been almost superseded by such fine sorts as *Blue Beauty*, *pumila magnifica*, *Ebor*, *Emperor William*, *Blue Stone*, &c.; and all of these produce in, the form of seedlings, that same dense, compact habit that they show when propagated by cuttings. *Blue Lobelias* are indispensable to all summer bedding displays, and, therefore, it will be to many a boon to know that they are thus easily raised. Sow at once in shallow pans in fine sandy soil; do not cover the seed, but just press it in and gently water.—A. D.

**Phalænopsis at Clapton.**—The large house in the Clapton Nurseries devoted to these will soon be very attractive. Many of the plants have already opened their blossoms, and if fine weather prevail for the next few weeks a grand display will be the result.—S.

## GARDENING FOR THE WEEK.

### Roses.

In the selection of *Roses* for pot culture, especially such as are required to produce flowers in winter, it is necessary to exercise considerable judgment. It will not do to be ruled by mere fancy as to this or that variety; nor should we be guided in the selection by the colours and fine forms of outdoor *Roses*. Still less by the most conspicuous to be met with in the collections exhibited at the various *Rose* shows, a course too often followed without the least consideration as to the suitability of the kinds chosen for the purpose required; and which is a continual source of disappointment, as not one in fifty of the finest kinds which those who grow for exhibition cultivate are adapted for pot culture. In support of this I may mention that amongst those who grow *Roses* largely for the London flower market, it frequently happens that not more than half-a-dozen kinds are to be met with. House after house may be seen filled with even two or three varieties, and I am acquainted with one considerable grower who cultivates little but one kind, and that is *Devoniensis*; but it must be observed he has succeeded in managing this favourite sort in a way that few growers have been able to approach. No doubt it is necessary to keep in sight the desirability of having sufficient variety, yet private cultivators would do well to imitate the trade growers, who seldom make mistakes in either keeping kinds that do not grow and bloom freely, or in producing flowers that the public do not appreciate. There is no section of *Roses* held in such general estimation, no matter how arranged, whether it be in vases, bouquets, or as button-hole flowers, especially the two latter, as the *Tea* varieties. The long half-expanded flowers of these are unrivalled for general floral arrangements. To this must also be added their perfume, and the fact of their yielding a succession of flowers so long as they continue to make growth, and, above all, their ability to produce flowers in the winter under the influence of a considerable amount of heat. As a white variety nothing can compare with *Niphotos*, but it is a somewhat delicate grower. It is the favourite white *Rose* growing in the London market, and everyone who attempts pot *Rose* growing ought to have several plants of it. *Isabelle Sprunt*, a bright yellow, is probably the finest of all, and will produce the greatest number of flowers; *Madame Falco*, a dark apricot-coloured kind, is a good, vigorous grower; *Catherine Mermel*, a flesh-coloured sort, is very fine in the bud state; and a good grower; *Cheshant Hybrid*, pale carnine, is beautiful in all its stages, and a free grower; *Gloire de Dijon* is yellowish-white, the open flowers being tinged with pink—this, though not so beautiful in shape as the kinds already named, is such a free grower and bloomer, with the natural property in the flowers of lasting long when open, that it would not do to pass it over; *Devoniensis*, sulphur white, is one of the most charming of all in the bud state; *Duchess of Edinburgh*, bright crimson, is a good grower, and we must not overlook the apricot-coloured *Safrano*; the *Hybrid Perpetual General Jacquemont* is one of the very best dark *Roses* for forcing in existence, and deserves to have a first place; *La France*, light blush, from its fragrance and beautiful shape, and vigorous good habit, is worthy of a place in the most select company; the *Hybrid Bourbon Charles Lefran*, bright rose, is also another excellent kind, but I should not recommend its being forced so early as the others. As a climber on the roof there is none equal to the beautiful *Noisette Maréchal Niel*; it is one of the finest of growers, and it produces equally freely its rich yellow flowers. *Lamarque*, white, is also worthy of attention. The above, though, as will be seen, only a small selection, are thoroughly well-proved kinds; and where a continuous supply of *Roses* is required through the winter and spring, I would much rather place dependence upon them, grow'ng duplicates so far as necessary, than I would extend the number of kinds. To come in later on through the spring, the following two dozen *Hybrid Perpetuals* or any portion of them, will be found suitable, viz., *Anna Alexiff*, *Alfred Colomb*, *Duchess of Sutherland*, *Comtesse de Chabrilant*, *Charles Lefebvre*, *Fischer Holmes*, *Caroline de Sansal*, *Senateur Vaise*, *Marquise de Castellane*, *Maurice Bernardin*, *Duke of Edinburgh*, *Madame Lacharme*, *Mademoiselle Marie Rady*, *Madame Louis Léveque*, *Prince Camille de Rohan*, *Star of Waltham*, *Madame Victor Verdier*, *Pierre Notting*, *Paul Verdier*, *Victor Verdier*, *Emilie Hansburg*, *Elie Morel*, *Etienne Levet*, and *Marguerite de St. Amand*. These will be found to flower freely under the influence of a moderate amount of fire-heat, but are better not kept so warm as those given to come in earlier. The *Teas* through the winter in a thoroughly light house, after they have commenced growing freely, will bear to be kept during the night at a temperature of 55° or 60°, but if they are not put into heat until the present time, 7° or 8° lower will be better until they have begun to push freely; in each case the temperature may be allowed to rise 5° or 6° in the day, or even

more during sunny weather. But in Rose forcing there is one most important matter to guard against, that is, in giving air never to admit it at the sides of the house, as a cold current coming in direct contact with the foliage is certain to produce mildew. In a Rose house sufficient means should always be provided for giving all the air required in the roof. Another essential is to see that the plants, before being introduced into the house are of completely free from aphides, which will often be found on, or about the base of the buds, yet in so small a state as not to be noticed by the inexperienced. Previous to placing Roses in heat, by way of precaution I have always found it advisable to syringe them well overhead with a solution of Gishurst at the rate of 3 oz. to the gallon; this is equally destructive to aphides, the eggs of red spider, or the spores of mildew. With Lilies required for forcing it is very desirable that the plants should have acquired sufficient strength, and be large enough for the purpose, as the produce from small plants will be proportionately small. Those who are commencing to grow them will always be able to obtain a supply of plants from the principal Rose nurseries that have been grown on in pots, and that have attained a size to give the desired results at once without the delay and partial disappointment that are sure to follow from forcing plants that are too small to produce anything but puny flowers, and few of them. It will be well, at the same time, to procure a sufficient amount of smaller stock of the Tea varieties in pots to grow on, and of the Hybrid Perpetual sorts recommended for immediate potting, keeping them plunged in ashes in a cold frame. With the Teas this precaution in most parts of the country is an absolute necessity, and the others will be much better under cover, as, when so treated, their roots will not get saturated with rain, nor be liable to injury from frost, from which even the most hardy plant is sure to suffer when its roots are confined within a pot, and the ball of earth which contains them becomes congealed; the expansion of the soil, when thus frozen, crushes the fibres. As to soil, Roses, more than most plants, require it of a strong rich character; such as is light, containing too much sand, is quite unsuitable. I have never found that the addition of either peat or leaf-mould, even in small quantities, was any benefit, but the reverse. Good loam moderately enriched with rotten manure, and just enough sand to admit of the water passing through it, is what they require. In potting, drain sufficiently and ram the soil quite firm, so as to make the ball solid. I have said nothing about pruning. The Tea varieties under pot culture should, as out-of-doors, have the knife much less freely used than the others. When the plants have attained sufficient strength, the weakest shoots may be cut away, and the stronger ones slightly shortened back. T. BAINES.

#### Stove and Greenhouse Plants.

Pot on *Draecenas*, *Dieffenbachias*, &c. Divide and pot singly choice *Marantas*, and keep them for a time in a frame inside the propagating pit. Increase the stock of any plants that are scarce. Pot off singly seedling Palms from seed boxes. Have stocks of *Camellias*, Orange trees, *Azaleas*, *Gardenias*, and *Rhododendrons* in readiness for grafting on in February and March. Young plants of *Cyanophyllum magnificum*, *Ficus*, *Medinillas*, &c., must not be permitted to become pot-bound, otherwise they sustain a check; on the contrary, they must be potted when they require it, supplied liberally with water, and, if practicable, have the advantage of a good bottom-heat. Under this treatment good plants are soon made, and the growth formed before the end of the summer has time to become well ripened before next winter. Water all evergreen plants moderately, and keep deciduous ones nearly dry. Plants in borders require watering very seldom at this season; but plants in pots, especially such as are near hot-water pipes, require unremitting attention as regards water, for, although apparently moist on the top, the soil in the bottom of the pots may be dry. Rather than keep the conservatory too warm, in order to forward the plants therein, supply any deficiency there may be in the way of flowers by means of *Camellias*, *Azaleas*, *Jasminums*, *Weigelas*, *Kalmias*, *Prunuses*, *Acacias*, *Dioleytras*, *Lily of the Valley*, *Dutch and Roman Hyacinths*, *Tulips*, *Narissis*, *Crocuses*, and other plants from the forcing pits. Decaying leaves must be regularly removed, and a rather dry and healthy atmosphere is a good remedy for such an evil, and to effect this supply artificial heat and plenty of air. Keep *Heaths*, *Epacris*, *Chorozemas*, *Boronia*, *Tremadoras*, &c., in the coolest and freest ventilated portion, and forced shrubs and other flowers, *Orchids*, &c., in the warmest parts. Cut over *Chrysanthemums* that have done flowering, and keep a pot of each kind in a frame, if sufficient cuttings have not already been obtained. Plant the others in the open border, or, if not wanted out-of-doors, throw them away. Shift herbaceous *Calceolarias* and *Cinerarias* as they require it, and keep them cool and well watered. Fumigate to destroy aphids. Keep *Mignonette* near the glass, and stake and tie it as may be necessary. Have a good succession of it, *Violets*, and

other plants in pits. Regularly train *Tropaeolums*, and give them a little manure-water if they are making good progress. Continue to pot off singly good-rooted, early autumn-struck cuttings of *Azaleas*, *Camellias*, &c., but if neither time nor space can be spared for shifting them at present, leave them for a time in their cutting-pots set on a side shelf of a close pit or intermediate house. Any *Statice* becoming too long-stalked should have an incision made on each branch just at the base of the foliage crowns, after which some Moss should be tied round it. The Moss should always be kept damp, and if a little silver sand be mixed with it, so much the better, as it helps to encourage root production. Keep old and young *Statice* moderately moist and in a minimum temperature of 45°.

#### Trees and Shrubs.

This is a good time to re-plant and re-arrange masses of the better kinds of *Rhododendrons*. Sandy peat is the best soil for them when procurable; but, where it cannot be had, they will grow in sandy loam. In preparing positions for *Rhododendrons* resting upon calcareous matter, the whole of the soil in the beds should be above the ground level. In planting, hardy *Azaleas* must not be overlooked, their brilliancy of flower and delightful fragrance rendering them most desirable. They may be grown in masses by themselves, or interspersed with *Rhododendrons*, or used promiscuously in mixed shrubberies. The *Kalmia* grows freely in low situations; and, moreover, it is one of the few plants that game will not molest. Common *Laurels* should be cut down, but specimen *Portugal Laurels* should not be pruned yet. *Thorn* and other hedges should now receive their winter cutting. Evergreen hedges, such as those of *Holly*, *Yew*, or *Laurel*, should not be cut until the end of March, just before they begin to grow; *Privet* may be cut at any time during the winter, after all danger from severe frost is over.

#### Flower Garden.

One of the most important points in connection with flower garden operations at this season is preparation of the beds and the securing of proper composts. Where beds are not planted with spring-flowering plants, have them deeply worked up and prepared for planting. Flower-beds, to be perfectly successful, must be treated according to the crop which they are intended to carry. Some plants, as, for example, *Abutilions*, *Aralias*, *Cannas*, *Ferdinandas*, *Ricinus*, *Solanums*, *Wigandias*, &c., require a large amount of manure to give them nobility of aspect and perfect leaf development. In preparing beds for these, especially in cold wet localities, place the soil on brick rubble, which will secure good drainage, and raise the temperature of the soil used. Use the compost in a rough state. Hardy *Clematises* grown as bedding plants should now have attention; prune them at different periods, viz., in autumn, mid-winter, and early in spring. Cut them back now to the ground, and surface-dress with rich rotten manure. This is necessary to ensure continuity of bloom. Fill up all vacancies which occur among spring-blooming plants. The plan for the bedding out of the flower garden should now receive attention, in order that some idea may be formed as to what quantities of different subjects may be required.

#### Indoor Fruit.

All superfluous bunches should be removed from pot Vines on which the fruit is set, the quantity left on being regulated by the strength of the Vine. Five bunches will be sufficient for most Vines, but in some cases double that number may be left. In thinning the bunches from all sorts, the best proportioned should be allowed to remain, cutting away to the required number all loose long-stemmed scantly-set bunches. Thin the berries before they swell to the extent of being crowded together, but do not thin so much as in the case of permanent Vines, nor until it can be distinctly seen which berries are likely to swell best. These are always the largest, and soon outgrow such as are not fully fertilised. Permanent Vines started in December will now be breaking, and they should have air given them on all favourable opportunities; but during severe frosts and windy weather in January and February great care is necessary. A temperature of 60° during the night, and a rise to 75° in the day, when the Vines are in bloom, will keep all safe. Peel the rough bark off Vines lately pruned, and dress them with some strong composition, to keep mildew and insects in check. Maintain a temperature of 65° at night in mild weather in houses where the fruit is set, ventilate moderately and principally in the earlier part of the day, and do not fire strongly in cold weather. Ventilate freely, but avoid cold currents in houses where the Grapes are in bloom. Muscats require a higher temperature for setting them than *Hamburgs* do. Water the inside borders freely with tepid water, and mulch them with a thin layer of short manure. Stop the young shoots at two or more joints beyond the fruit, and rub off all superfluous growths. In late houses, where the Grapes are uncut, use a little fire-heat and

ventilation at the same time, to preserve a dry atmosphere at about 45°. Examine the hanging bunches weekly, and remove from them every mouldy berry. Strip off the loose bark from late Vine rods, and apply a coating of some insect-destroying paint. Keep the unstarted houses as cool and airy as possible, and prune any Vines not already operated on. Syringe daily until the flowers begin to open, but not after that, for plenty of atmospheric moisture may be maintained by damping the floors and walls. Nothing but time, patience, and persevering attention will succeed in kindly starting, blooming, and swelling Pine-apples to perfection while we have short and dark days. We must allow from fourteen to twenty-eight days longer for winter fruit, according to the variety, to swell than those that will start into fruit in February or March. If hurriedly forced, they will push up weak, long stalks productive of small fruit, weak and irregular blossom, causing some pips to swell imperfectly, also causing uneven and abortive fruits, light in weight and black inside, bearing overgrown crowns. From 65° to 70° should be maintained in the pits, with a kindly humidity during night, according to the light and sun by day, and the day interior atmosphere and humidity must be in proportion to the sun and light. For all growing succession plants, maintain a kindly bottom and inside atmospheric heat, advancing it as the days lengthen and light increases. Pot on plants in every stage that require it, never allowing their progress to be checked for want of pot room at any season of the year. A batch of Queens may be plunged and given increased heat. It will be some time before the bottom-heat gets fully up after plunging them, so that although the Pines first plunged are in a bottom-heat of 90°, those plunged now will be somewhat inured to the increased warmth before the heat has risen to that height about them. The plunging material should be made sufficiently firm to stand up to the rims of the pots until the fruit is ripe. If not previously done, every plant should be thoroughly watered with liquid manure immediately the fruit is visible. Smooth Cayenne, Black Jamaica, and Charlotte Rothschild are the best winter kinds; and, where winter fruit is desired, those kinds should be grown in quantities. Where too many are ripe at once, if the fruits are cut and laid in an air-tight box, they will keep perfectly well for six weeks. Boxes, lined with zinc, are made for this purpose, and should be about every place, as they are useful for preserving other kinds of fruit. When Pines are cut, the old stamps, to which suckers are attached, should be allowed, if possible, to remain where they are for a couple of months, as the present is a very unfavourable time for the propagation of such stock. Early Cucumbers are much the best sown singly in small pots, as by this method there is no mutilation of the roots by dividing the plants when re-potting. Put a small bit of flaky leaf-soil or fibrous loam in the bottom of each pot; this will be drainage enough for the short time during which the plants remain in pots before being removed. Ordinary loam, with one-fourth of sifted leaf-mould and a little sand, will be suitable material in which to sow the seed, which should not be covered more than half an inch. Fill the pots two-thirds full of soil at the time of sowing; this will leave room to add more when the plants have attained a few inches in height, and will induce them to throw out roots up the stem, which tend much to strengthen the plants. For ordinary purposes, few sorts equal the Telegraph. It is an abundant and continuous bearer, but so free is it, that if the fruits be not well thinned, the plants will soon exhaust themselves with overbearing.

**Hardy Fruit.**

If the weather continue favourable, planting may be proceeded with, unless the ground be very wet, in which case it had better be deferred for a time. In preparing borders for the reception of Apricots and Peaches, drainage is of the first importance, and nothing is better for this purpose than a good thickness of brick rubble, over which has been laid large turves, Grass side downwards. The soil (which should not be less than from 2½ ft. to 3 ft. in depth) best suited for Apricots and Peaches is a good holding loam, to which should be added a cart-load of chalk to every dozen loads of loam; or, of course, if the loam be naturally chalky, this addition is unnecessary. No manure should be mixed with the soil, as it is better to give it in a liquid state, or to mulch thickly with rotten manure, and allow the rain to do the rest. If any old trees of Apricots or Peaches be looking exhausted or starved, now is the time to renovate them. Remove the soil down to the roots, and, with small hand-forks, work out as much of the old material as possible; cut away all suckers and cankered roots, after which fill in with good loam, and mulch with manure. Other fruits, and especially Pears, may be treated in the same way. When the weather is favourable, prune, nail, and tie Pears, Ploms, and Cherries. If any are affected with scale, fly, larva, Moss, or Lichen, paint every particle of the tree with a composition of soft-soap, sulphur, and Tobacco-water, made to the consistency of thick paint by adding clay and cow-manure.

**Vegetable Forcing.**

Cut all shoots of Asparagus as they attain a length of 6 in. or 8 in., and, if the soil gets dry, gently sprinkle it with tepid water. Make up another bed for succession. These beds may be formed of manure, or leaves above the ground, or trenches may be cast out 2½ ft deep, and as wide as the frames, and filled with the fermenting materials, the frame being set on a level with the ground, and a lining of hot manure built all round it. A few inches of deep of light soil should then be placed inside to plant the roots in. Cover the roots sparingly with light mould, and keep all close until the Asparagus begins to grow. If blanched Asparagus be required, darken the frames by a covering of mats or litter, but be particular that neither the bottom nor top-heat rise above 70°, whilst 5° or 10° less will not hurt. Sow Early Horn Carrots on a slight hot-bed; also Lettuces, and keep those previously sown dry and clean. Introduce roots of Chicory and Dandelion into the Mushroom house, arched under Cucumber beds, under boxes in Vineries, Pine-stoves, or, in fact, any place where they may be kept dark, and in a temperature of about 60°. Lift some plants of Endive with good balls, and plant them in frames, where, as soon as they have grown enough, cover them with pots or boxes to blanch. A few seeds may be sown in the event of very early Endive being required. Make successional sowings of French Beans in pots half filled with rich loamy soil, and grow them on front shelves in the forcing houses. Earth them up before they begin to flower, and syringe them regularly, to keep red spider in check. Newington Wonder, Syon House, Palmer's Forcing, and Osborn's are good sorts for forcing. Young plants of Lettuces in frames should have the sashes tilted at back and front in mild weather if wet; but if dry, they should be removed entirely throughout the day, and replaced at night. Tie up a few old plants of the Brown Cos, as required. Place roots of Mint, Pennyroyal, and Tarragon in boxes or pots, using light soil, and introduce them into some heated house or pit. A portion of a hot-bed may be devoted to them. Maintain an atmospheric temperature of 55° or 60° in the Mushroom house, and gently charge it with humidity; the beds may rise 5° above the heat of the house. Prevent draughts in the house, as they are productive of severe checks to the crop. Obtain some fresh horse-droppings for succession beds. Turn and prepare this material in winter on the floor of the Mushroom house, a practice that produces, by gentle fermentation, just the natural, gentle ammonia-charged atmosphere, in which the Mushroom luxuriates. Sow some of the Tripoli Onion in a slightly-heated frame for drawing whilst young, for salading, or for transplanting. Plant some of the Early Ashleaf Potatoes in gently-heated frames, and sow some Radishes on the surface of the soil. Ventilate on favourable occasions, and do not over-water. Lift some roots of Rhubarb and Seakale, and introduce them into the Mushroom house, or other heated structure. Some crowns may also be covered, where they are growing, with pots, over which place some litter or leaves. In order to blanch Seakale it should always be kept dark. Sow a few seeds of Tomatoes, if early plants are required.

**Diary.**

**January 21.**—Sowing Marrow Peas in boxes for making Green Pea soup; also the following sorts of Peas in turf, viz., Carter's First Crop Blue, Extra Early Premium Gem, Maclean's Blue Petal, and Little Gem. Making up hotbeds for Carrots, Potatoes, and Radishes.

**Jan. 22.**—Sowing fifty pots of Mignonette; also Cucumber, Melon, and Sweet Basil seed. Putting in cuttings of Alternantheras, Celosia, Fuchsias, and Ageratum. Re-potting large tri-color Pelargoniums for exhibition. Getting into the potting shed a good store of peat, loam, and leaf-mould. Turning over Mushroom manure to sweeten.

**Jan. 23.**—Sowing a three-light frame with Wood's Early Frame Radish, and another with Early Horn Carrot. Cutting turf for laying down. Thinning out shrubs where overgrowing each other. Cleaning up pleasure-grounds and getting all newly-laid turf well rolled.

**Jan. 24.**—Sowing an early border with Snowball Turnips. Putting in cuttings of Hathaway's Excelsior Tomato; also of Heliotropes, Chrysanthemums, Gnaphalium lanatum, and Lobelia. Digging up Horse Radish beds and preparing the ground for planting again. Pruning Roses and digging up borders. Getting on with digging, and trenching as fast as the weather will permit.

**Jan. 25.**—Planting Hardy's Pedigree Windsor and Carter's Long Pod Beans. Planting also a three-light frame with Ashleaf Kidney Potatoes. Turning over leaves and manure for hotbeds. Disbudding early Black Hamburg Vines; Peaches, and Nectarines well set; beginning, therefore, to use the syringe freely. Looking over Pines and giving water where required. Removing all straw from Celery, very mild weather having set in.

**Jan. 26.**—Potting off Cucumber and Melon plants. Getting into the Peach-house a quantity of turves, and planting them with William I. Peas. Looking over Grapes in bottles, removing any berries that are decaying, and filling up the bottles where required. Looking over the fruit room and removing any that are bad. Clearing out all vegetable refuse, and cleaning up kitchen garden walks.

W. G. P., Dorset.

## THE CAVE MUSHROOM.

*(Continued from p. 44.)**Preparation of Mushroom Spawn.*

FIRST PROCESS.—Any time between April and September open at the foot of a wall, which is exposed to the east, a trench 2 ft. wide and 1 ft. 8 in. deep, the length, of course, being governed by the amount of spawn to be produced. Before digging the trench we must provide five or six wheelbarrow-loads of horse-droppings which have lain in a heap for some time, and have lost their heat. The horse-droppings should be mixed with a quarter of short stable litter, the effect of which is to give the resulting bricks or cakes of spawn a greater amount of solidity when they afterwards come to be hauled. The bed is formed in the trench by strewing the bottom with a layer of chopped straw, 3 in. or 4 in. thick, and then with a layer of the prepared horse-droppings of equal thickness, the whole being made smooth and symmetrical, walking regularly over each layer, and pressing it down firmly with the feet. The two layers must now be gently watered,

and then another double layer of chopped straw and droppings must be laid, trodden down, and watered, and so on until the top of the trench is reached. In treading down the layers great care must be taken to press evenly, so that the whole may be an evenly compact mass, not harder in one place than another. The bed ought to rise somewhat above the level of the ground, and the upper surface rounded off like the top of a trunk. To prevent excessive damp from heavy rain, which would bring about premature decomposition of the materials in the trench, the mound must be covered over with a thick layer of stable

litter. A trench which has been filled up at the beginning of September should be opened in December at the side or at one end. If the pieces of manure are well covered with masses of bluish-white filaments, giving off the characteristic odour of Mushrooms, the operation has succeeded, and the spawn is fit for use; but if the threads are only sparingly scattered through the mass, the trench must be covered up again and left for another month. This delay is no real inconvenience, for beds rarely begin to produce abundant crops of Mushrooms at this season. The trench should be emptied in January, or February at the latest, if the weather will allow of it, and those flakes of manure picked out which contain the largest amount of spawn filaments, all pieces showing a brown appearance being carefully rejected; the brown filaments being the spawn in a state of decomposition, the spores of which are unproductive. In order to quicken the drying of the cakes, they are divided as soon as they are taken out of the trench, and broken up into pieces, weighing from 1 lb. to 2 lb.; they are then placed in a well-ventilated shed or outhouse, but they must not be piled upon each other. When prepared thus, and dried by the air and in the shade, virgin spawn will keep good for ten years. We

have taken the spawn bed made in September as our typical specimen, because at that time of the year Wheat chaff is most easily procurable. The preference must always be given to Wheat chaff or chopped straw coming from the winnowing machines, as they are less mixed with grains of corn than other kinds. If we have all the materials at our disposal, we can, as has been said before, make our Mushroom-beds in the open air from the commencement of April to the beginning of winter, and at other seasons of the year, indeed, at all times in a cellar or quarry.

SECOND METHOD.—We have seen in the first method of procuring spawn that it forms naturally in the manure; in the second process, which is that generally adopted by Mushroom growers, the formation of the spawn is accelerated by adding pieces of old spawn here and there. Experience has shown that the two most favourable seasons of the year for this work are spring and autumn. At the beginning of April we must choose a piece of ground situated at the foot of a wall which faces the north. On the other hand, in the month of September we must have a wall with an eastern aspect. The soil

ought to be very open and light rather than heavy, so as to avoid dampness. Taking advantage of a fine day, we open a trench at about 8 in. from the foot of the wall, measuring 16 in. in width, and of a length adapted to the quantity of spawn we desire to produce. The earth is thrown out on the side opposite the wall. Manure which has been prepared for a Mushroom bed, as directed at p. 42, and has just come into condition, is then filled into the trench, leaving, however, a space at one end of it, about 2 ft. 6 in. in length, for the formation of a Mushroom bed, which is made by tossing the manure about, and shaking it up with the hands,

after which it is pressed down with the hands and knees. As soon as the layer of manure reaches about 6 in. in thickness, we place along the edge a number of lumps of spawn at about 1 ft. apart. These lumps are placed level with the manure on the edge facing the wall. This portion of the surface of the manure ought to be raised vertically, and should lean against the earthen wall of the trench. The other half of the surface ought to slope gently towards the wall, leaving a space of 3 in. or 4 in. between it and the side of the trench, so that it may be trimmed. The lumps of spawn on this surface should be placed a little backward, so that they may not be broken when the bed is trimmed. The bed is then covered with more manure until the first lumps of spawn are buried 3 in. or 4 in. deep. A second row of lumps of spawn is then inserted as described in the directions for making the first row, and the bed is filled up level with the surface of the soil. It is finished by covering it up with a layer of fine dry soil 3 in. or 4 in. thick. The spawn ought to be very dry, otherwise we shall get a premature crop of Mushrooms instead of fresh spawn. At the end of six weeks or a couple of months the new spawn ought to make its appearance, a fact which we may learn by opening the bed. One sign, which will save us the trouble of opening up the beds,

A Garden Cascade.

is the appearance of young Mushrooms on the surface. The layer of earth is first removed, and then the cakes of spawn are treated as described in the directions given for the first method of making spawn. As a matter of detail it may be mentioned that if the wall is not long enough for our wants we may dig several trenches, one before the other like Melon beds, taking care to leave a space of 8 in. or 9 in. between each. The spawn made by either of the methods described above is equally good, and success is as certain in one case as in the other. The second method is more expeditious than the first, but it necessitates the purchase of fresh spawn, which of course adds to the expense. It is naturally for the grower himself to consider the circumstances under which he is working, and to choose the method which will yield him the greatest profit.

**THIRD METHOD.**—By filling in a trench like that described in the first method by a series of layers of one-third of pigeon or fowl guano, and two-thirds of short manure, containing a large proportion of spent horse, droppings, treading it down, firmly watering it if it is too dry, and finishing up with a layer of soil as described already, we may at the end of a couple of months, or even a little longer, procure a supply of well-formed cakes of spawn of excellent quality, which may be used in the ordinary manner.

#### *Spawning the Mushroom Beds.*

A Mushroom-bed is prepared by planting in it lumps of spawn  $2\frac{1}{2}$  in. long, 2 in. wide, and  $1\frac{1}{2}$  in. thick. These lumps are planted on each slope in two rows, the first being 8 in. above the ground, and the second 8 in. from the first. The lumps in each row ought to be from 8 in. to 10 in. distance from each other, and arranged in such a manner that the lumps in the second row will be opposite the spaces of the first row, and *vice versa*. In spawning, remove the manure from the spot where it is intended to insert the spawn for a width of four fingers and for a depth of  $\frac{1}{2}$  in.; the lump of spawn is introduced into the hole with the right hand, pushed well into the bed, and covered up with the manure taken out of the hole, pressing it down firmly with the left hand. The work is continued in the same way, the two rows being sown at the same time, which is more expeditious than spawning one after the other. In practice we must know how to determine at what precise period a Mushroom-bed ought to be spawned. The manure ought to be neither too hot, nor too cold, and the most favourable moment may present itself any time between the seventh and the fourteenth day after the bed has been commenced. Experience alone can teach the grower the proper moment; and the clever labourer, when preparing the manure for making up the bed, will know by its condition whether the bed will come to perfection late or early, that is to say, whether it has got rid of the greater part of its heat or not. It is by estimating the amount of unctuousness left on his hands that the labourer is able to judge of the future temperature of the bed, but he can in any case only have a general idea of it. He may, however, be able to predict whether there is any danger or not from after-heating. It is only by direct trials all along the bed that its temperature can be tested. The best way is to plunge the hand into the manure, when habit will soon enable us to estimate exactly the temperature of the whole mass. Another way is to plunge pieces of wood into the manure at various distances, allowing them to penetrate to half their length. After remaining in a sufficient length of time, they are withdrawn and tested by the hand. When the piece of wood feels pretty warm, the spawning may be proceeded with without fear of failure. In the Paris quarries the beds are always spawned in two rows, but when it is possible to make the beds more than  $1\frac{1}{2}$  ft. wide, whether in a cellar or in the open air, it is best to spawn in three rows, the ultimate yield being much greater. If in a bed which we judge to be of the proper temperature we find that certain spots are hotter than others, rendering it possible that the bed will heat, we prevent all delay in spawning by simply thrusting the lumps of spawn into the hot parts without pressing the manure firmly down upon them. This should be left simply covered over with manure for several days, and then firmly pressed down with the hand. All these minute details may seem unnecessary to those who are already practically acquainted with Mushroom growing,

but for the sake of those who are not we have thought proper to be as detailed as possible; as it is, success is entirely dependent on the careful carrying out of the minutest particulars. We have endeavoured to make those who read this article as dexterous as if they had descended into the Mushroom quarries and seen the growers at work.

#### *Stratification of Spawn before Spawning.*

A bed in the open air, which is exposed to all the accidents of the weather, may be spawned with dry spawn, such as may be taken from the stock kept under the shed or outhouse, as we have described elsewhere. Experience, however, has shown that, for Mushroom-beds in cellars or quarries, it is better to allow the spawn to become damp, and undergo a kind of stratification. For this purpose, the cakes are taken out of the shed or outhouse, and placed in rows on the floor of the cellar or quarry, and allowed to remain for about eight or ten days, until the dampness of the atmosphere has caused the filaments of spawn to swell up and return to their normal cylindrical form, whitish colour, and felted appearance. It is of importance only to expose a sufficient quantity of spawn to the damp for immediate use, for it will not bear being dried and damped again. It must also be remembered that the spawn must be exposed at such a time that it will be ready for use simultaneously with the Mushroom-bed. Neither operation should wait for the other. If the spawn remains too long in stratification, its sporules become swollen with the damp, and, not finding a suitable temperature for their development, they wither away. On the other hand, if the Mushroom-bed has to wait until the spawn is ready, it will become cold, and fail to develop the spawn when it is put in it. Here, again, practical experience and intelligence must be the only guides of the Mushroom-grower. It is evident that the best way of ascertaining the heat of a bed would be by using a thermometer, but we are describing the method pursued in the quarries. The stratification of the spawn advances the gathering of the first crop of Mushrooms by eight or ten days. It is for this reason, amongst others, that the Mushroom growers in the Paris quarries take their fresh spawn from beds already in work, except when they desire to obtain an entirely new stock. When the bed has reached the proper temperature, the Mushroom grower chooses from among the beds already in bearing the one which appears in the healthiest condition, that, in fact, in which the spawn filaments are most numerous, thickest, and cling most closely to the particles of the manure. The best time for choosing the spawn is just when the young Mushrooms are first appearing. The bed we have chosen is broken up, and the cakes of spawn removed, and broken into lumps of the size already described higher up. This kind of fresh virgin spawn is in the best condition for yielding an early and abundant crop of Mushrooms, which may be gathered at least twenty days sooner than if dry spawn had been used. At the risk of repetition, and for the sake of calling my readers' attention to details which, although they appear to be insignificant in themselves, are of great importance when the success of Mushroom growing is considered, we return once more to the subject of the choice of spawn. No matter what care has been exercised in selecting the dry cakes of spawn from our stock, they must be carefully examined before they are used for spawning the beds, those only being chosen which show an abundance of bluish-white filaments, well fitted together, and giving off a strongly-marked odour of Mushrooms. All those portions which show traces of white or yellow mould, or have a floury appearance, must be rejected and destroyed. The floury patches are a kind of mould, which attacks the filaments of spawn and destroys them. Like all fungoid growths, it spreads very fast, and an almost imperceptible patch will quickly infect and kill a large quantity of healthy spawn. Where a bed is broken up for the purpose of procuring a supply of spawn, the cakes must be most scrupulously examined, and every particle which does not bear the characteristic marks of good healthy spawn must be rejected. Another disease which attacks the spawn is what is known to the Paris Mushroom grower as "verdigris." It makes its appearance in the form of very small agglomerated granules, of the colour of verdigris, and having a peculiar smell resembling that of chloride of lime.

All the portions attacked by this fungoid growth must be scrupulously rejected; in fact, if it is at all abundant, it is better to destroy the whole batch of spawn. This disease seems to be the result of the decomposition of foreign substances which have been mixed with the manure by accident, and its presence would only promote the growth of false Mushrooms, having possibly poisonous properties, or a sickly crop of the true kind. We must also be careful never to use old pieces of spawn in which Mushrooms in the rudimentary state have begun to be formed; in a word, every particle of spawn which has a doubtful appearance must be rigorously rejected. While making this examination, the cakes of spawn must be reduced to the proper size, in order to obtain uniform crops. If the cakes are too thick, they will produce clumps or "rocks" of Mushrooms of such compactness, that they will interfere with each other's growth, besides entailing an unprofitable expenditure of spawn. Some Mushroom growers remove all pieces of spawn which show signs of producing closely-serried clumps or rocks. A few days after the spawn has been put in, the filaments grow out of the manure and spread over the surface of the bed, the whole of which turns of a bluish-white colour. The French Mushroom-grower calls this *fleurir sur la panne*, an expression which is quite untranslatable, and takes it as a sign that the bed is ready for soiling.

(To be continued.)

#### NOTES FROM KEW.

ONE of the prettiest amongst plants not previously noted is a species of Bearberry, from California and the Rocky Mountains (*Arctostaphylos tomentosa*). This handsome Heathwort—in comparison with the Black Bearberry (*A. alpina*), of the Scotch mountains, and the Common Bearberry (*A. Uva-Ursi*), which is not exclusively Scotch, being found in the rocky uplands of the north of England—is a real giant; it sometimes attains, in its native haunts, a height of more than 20 ft. The snow-white, *Arbutus*-like flowers are crowded into dense, terminal racemes. *A. glauca* has pleasant-tasted fruits, which are much used as food by the Indians of Oregon and California. *Acacia lineata* and *A. stricta* are two very desirable species; the former is a neat-habited bush, which will flower well and make a compact plant in a small pot; the latter is more suitable for a large pot, and should be allowed to attain its full dimensions of about 6 ft. Neither of them bears true leaves, the flattened leaf-stalks or phyllodia taking their places. In *A. lineata* these are very small, almost needle-shaped, about  $\frac{1}{2}$  in. long, and bear singly in their axils small globose heads of deep yellow, fragrant flowers. *A. stricta* has long, narrow phyllodia, from the bases of which spring, in pairs or clusters, shortly-stalked heads of pleasing lemon-coloured flowers. This is an elegant plant, and is one of the most charming of the Australian *Acacias*.

In the Palm-house there is a dearth in the way of novelties. An Abyssinian half-climbing Composite, *Senecio abscondens*, is striking as a curiosity, although worthless from a gardening point of view. Fancy long, weak stems, clothed for about a length of 20 ft. with leaves much resembling in size and form those of the Common Sow Thistle, terminated by leafless, branched panicles of small flower-heads, the exact counterpart of those of the Common Groundsel, and a tolerably correct idea of this peculiar plant may be obtained. *Senecio* is, perhaps, the largest in number of species of any genus in the vegetable kingdom, and many very interesting chapters on plant mimicry could be written on examples furnished by it alone. *Barleria flava* is a very useful winter-flowering Acanthad; it is an erect shrub, with dark green, opposite leaves, and terminal spikes of funnel-shaped, bright yellow flowers.

Among the Orchids, there are several beautiful kinds in bloom. *Lycaste gigantea*, from New Granada, is remarkable for its long leaves and large flowers, borne on long scapes; the sepals and petals are yellowish-green; the lip a deep orange. The flowers of *Maxillaria punctata* are produced in clusters from the base of the pseudobulbs; the ground-colour is white, with a faint tinge of primrose, and is spotted freely with purplish-crimson dots. *Maxillaria variabilis*, var. *lutea* and *media*, from Mexico, have Grassy leaves and yellow and purple flowers much inferior in size and beauty to those of the last named. This species and its varieties are of very easy cultivation. *Orchidium Sophronitis*, from Colombia, is a perfect little gem; its creeping stems bear numerous, nearly spherical pseudobulbs, and small leathery leaves; the beautiful scarlet flowers are borne singly on scapes about as long as the leaves. *Dendrobium gratioissimum* is a very handsome species from Montsein; it has

weak, knotted, leafless stems and extremely beautiful flowers, the entire ground colour of which is white; the sepals, petals, and lip are tipped with rose, and the greater portion of the lip is of a fine orange colour. *Odontoglossum Ehrenbergi* is a pretty Mexican species; all the parts of the flower are similar in form, being somewhat lance-shaped; the sepals and petals are yellowish-green, blotched with chocolate-brown; the column and crested lip white. *O. Bictioniense* is a very vigorous and striking species from Guatemala; the erect, many-flowered spikes are freely produced, and often attain a height of 3 ft. or more; the sepals and petals are dark chocolate-brown, and the large triangular lip is of a purplish-rose colour. The Brazilian *Oncidium flexuosum*, with its large, branching panicles of clear yellow, brown-spotted flowers, is a general favourite, and is as accommodating as it is pretty. Few Orchids will stand more ill usage than this, or flourish under more diverse conditions. *Stenoryllis speciosa* and *S. maculata*, two very pretty terrestrial Orchids from the West Indies, are closely allied to the *Spicanthes* (*Lady's Tresses*) of our English pastures. They are herbaceous plants, with broad root leaves and stout spikes of reddish flowers, the large coloured bracts contributing not a little to the general effect.—†

#### ROYAL HORTICULTURAL SOCIETY.

JAN. 15.

At this meeting the most striking features were groups of Orchids, Cyclamens, and Cycads, and a few good stands of Grapes.

First-class Certificates were awarded to the following new and rare plants, viz. :—

*Zamia corrugata* (Ball).—A noble-looking Cycad, with broad oblong leaves, of a glossy green colour.

*Zamia lucida* (Bull).—A somewhat close-growing kind, having smooth leaves, with serrated edges.

*Microlepia hirta cristata* (Williams).—A graceful Fern, of dwarf habit, and beautifully-crested pinnae. An excellent plant for placing in vases, or in similar positions.

*Dendrobium superbiens* (Williams).—A beautiful Dendrobium from Torres Straits, bearing rich mauve-coloured blossoms on gracefully drooping, slender stems.

*Long Orange* (Rivers).—A new variety, well adapted for home growth.

**Miscellaneous Subjects.**—Messrs. Veitch & Sons sent a collection of Orchids, amongst which were good examples of *Angreum sesquipedale*, *Cypripedium calceolom*, *C. Bealii*, and *Leelia alba*. With these were also sent a beautiful variety of the rare *Odontoglossum Andersonianum*, the brilliant *Sophranitis grandiflora*, and *Pleione humilis*, together with well-flowered plants of *Saccolabium giganteum* and *Odontoglossum cirrhosum*. The same firm also contributed a basketful of plants of the dwarf *Rhododendron Early Gem*, a kind which should be largely grown for winter flowering on account of its early-blooming qualities. From the same nursery likewise came a remarkably fine collection of *Cyclamen persicum*, the flowers of which were large and finely coloured. Mr. Bull furnished an effective group of Cycads, which attracted considerable attention. Among them were good specimens of *Encephalartos villosus ampliatas*, *Cycas Armstrongi*, *Ceratocarpus nobilis*, *Catakiadomania Hopei*, *Zamia Lindenii*, and others. Mr. B. S. Williams, of Holloway, showed an unique group of *Cyclamens*, *Sarracenias*, and *Orchids*, amongst which may be mentioned *Odontoglossum Rossi majus*, *Cypripedium venustum*, and a fine variety of *Cattleya Trianae*. The beautiful purple-violet *Dendrobium moniliforme* was also shown in good condition, as was likewise a large specimen of *Sarracenia Drummondii alba*, bearing upwards of a dozen trumpet-shaped pitchers. From Mr. John Wile came an effective group of plants, consisting of *Palms*, *Ferns*, and *Orchids*. Amongst the latter were well-flowered plants of some of the best varieties of *Odontoglossum Alexandræ*, also *Leelia anceps*, and several *Phalaenopsis*. Mr. Cannell, of Swanley, showed cut blooms of *Zonal Pelargoniums*, amongst which we noticed E. Davis, a kind with large flowers nearly purple in colour; *Louis*, a beautiful pink; and the best of whites, *Jean d'Are*; the flowers of *Lizzie Brooks* were of a brilliant scarlet, large, and well-formed. Mr. Ollerhead, gardener to Sir H. Peck, Wimbledon, was awarded a vote of thanks for a remarkably fine variety of *Odontoglossum cirrhosum*. Mr. Richard Dean showed a potful of *Crocus Imperatorius*. Mr. E. Spary, The Queen's Graperies, Brighton, furnished specimens of a beautiful fern-leaved Chinese *Primula* named P. *Brightoniensis*, a variety which bears whorls of bright rose-pink blossoms. A group of *Senecio Giesbreghtii* was sent from the Society's gardens at Chiswick, consisting of plants well furnished with massive green leaves surmounted by large heads of golden flowers. Mr. Wildsmith, gardener to Lord Eversley, at Heckfield, contributed a most remarkable *Fuchsia*, the floral bracts of which were very large and brilliantly coloured.

**Fruit.**—Very fine examples of *Muscad* of *Alexandria* and of *Black Alicante* Grapes came from Mr. Atkins, gardener to Colonel Loyd-Lindsay, Wantage; and six very large bunches of *Gros Guillaume* came from Mr. Miller, Combe Abbey. A fine collection of Apples was shown by Mr. Louis Kilkie, Langley, Maidstone; amongst them were bright, plump fruits of *Warwickshire Pippin*, *Blenheim Orange*, *King of the Pippins* and *Cox's Orange Pippin*.

## THE LATE ANDREW MURRAY, F.L.S.

Most of our readers probably will have learnt through the daily press of the death of Mr. Andrew Murray on Wednesday, the 10th. We cannot allow the occurrence to pass without paying our tributes of respect to the memory of so conscientious and hard-working a student. Whilst different aspects of his nature and of his labours would strike different minds in different ways, there were two qualities he possessed for which we entertained special regard—the one was his desire for accuracy, at whatever cost of personal inconvenience it was to be obtained, and the other was the interest he took in making available for others the knowledge he acquired.

No better illustration of his patient and conscientious work can, perhaps, be given than by referring to his monograph of the Nitidulario, communicated to the Linnean Society in April, 1863. When he undertook it, he knew, he says, that it would be no easy task. "It implied the microscopic dissection of the parts of many hundred specimens, and the making of careful drawings of these dissections, a work rendered doubly difficult and laborious by the minute size of the insects to be examined. I knew, too, that its results would bear no proportion to the labour bestowed upon it; and that was perhaps more discouraging, I felt, that after it was done there were few from whom I could expect an intelligent appreciation of my work." The data for his monograph had to be seen in many different collections, public and private, throughout Europe, including St. Petersburg, Copenhagen, and Stockholm; at Philadelphia; and special collections were sent for the work from Ceylon, Siam, Singapore, China, California, Chili, Quito, Hudson's Bay, &c. The study was carried on during several years, and only those who have done similar work can appreciate the labour involved.

The interest which he took in making knowledge readily accessible to others was well illustrated by the way in which he planned and carried out the collection of economic entomology for the Science and Art Department at Bethnal Green. Its formation has been the work of years, and he was engaged on the last few cases of it just before the commencement of the few days of his illness. It was his hope that the collection will be used by teachers in preparing instruction in entomology connected with damage to gardens and crops; and with this in view he strove to make his points clear. Direct instruction in harmful and useful insects is given in elementary schools in France, and Mr. Murray repeatedly urged that similar instruction should be given in England. He not only urged it, but, with the authority of the Privy Council, made this collection as a type for teaching purposes. This is, without doubt, the most important practical work he did, appealing, as it does, to the material interests of so many classes. Some day the national value of his work may be duly recognised.

Mr. Murray's scientific knowledge was of a wide range, and he wrote on several subjects besides entomology and botany. Of these other works we have but space to mention his "Geographical Distribution of Mammals," for which he prepared more than 100 maps coloured to show the distribution of the different groups. The first of his entomological papers having a bearing on horticulture was published in the Ed. Bot. Soc. Trans., 1858—"Account of the Insect which infests the seeds of *Picea nobilis*," and as time passed on, practical subjects like this received more of his attention than descriptions and grouping. He wrote considerably on Conifers, and was one of the first to describe the Californian Conifers, and a series of papers on the synonymy of various Conifers, communicated to the Royal Horticultural Society, was reprinted in 1863 under the title "Pines and Firs of Japan." Mr. Andrew Murray, who was the son of Mr. William Murray, of Conland, was born at Edinburgh in 1812. He was trained as a writer to the Signet, and for some time practised. But the natural history classes had for him a greater charm than law had, and he soon became well known in scientific circles. The first paper he ever published was in 1851 in the Transactions of the Société Entomologique de France on some new Buprestides. When Prof. Fleming died he for one year gave the course of natural history lectures at the new college, Edinburgh. He also filled the office of President of the Royal Physical Society, and President of the Royal Botanical Society, and was a centre around which many students of science gathered, and the friend of many distinguished men. In 1860 he came to London, to hold an office under the Royal Horticultural Society, and since then his residence here has been broken only by occasional tours in America and different parts of Europe. He contributed notes and articles on insects to THE GARDEN from its commencement up to our recent issues.

**Paraffin and Scale.**—My Camellias are infested with scale, though they have been several times washed—both sides of the leaves—with soft soap and water. Is not paraffin a cure? How should it be applied? Is there a risk in using it of damaging the plants?—A. Z.

## CHRYSANTHEMUM QUESTIONS.

I AM anxious to commence Chrysanthemum growing. (1) Will some one give me the names of twenty-four of the larger or show varieties, combining shape with free-blooming properties and compact growth; also kindly name six of the best Anemone-flowered varieties and twelve Japanese. As I am quite a beginner, I do not care to commence with uncertain bloomers. I would like a few of each colour. (2) Cuttings of Chrysanthemums, after a few months' growth, often throw up suckers. Ought they to be removed? If allowed to remain, do they bloom? (3) To what height should a Chrysanthemum cutting be allowed to grow before being topped? (4) How long should topping continue? (5) Do the Japanese kinds bear any topping? (6) What system of cultivation will keep the lower leaves on Chrysanthemums? (7) Would cuttings struck now make better plants, and bloom freer than those struck later?—Q. D.

By way of answer to "Q. D." the following remarks may be of service.—Twenty-four really first-class Chrysanthemums for cut bloom may consist of Novelty, White Globe, Eve, Prince Alfred, Lady Slade, Prince of Wales, Mrs. Halliburton, Nil Desperandum, Princess of Wales, Golden George Glenny, Mrs. G. Rundle, Mr. George Glenny, Lady Hardinge, Empress of India, and its sport Golden Empress of India, Queen of England, Venus, General Slade, Empress Eugenie, Princess Teak, Cherub, Beverley, Jardin des Plantes, Mr. Brunlees, and Barbara. These flowers possess all the best qualities for exhibition purposes. The following are six of the best large-flowered Anemone varieties, viz., Gluck, Mrs. Pethers, Lady Margaret, Sundlow, Bifou, and Prince of Anemones, all very distinct. Twelve remarkably fine Japanese varieties may be represented by James Salter, Elaine, Fair Maid of Guernsey, Meteor, Bronze Dragon, Fulton, Baronne de Prally, Countess de Beauregarde, Dr. Masters, Gloire d'Or, Garnet, Glitter, and Hero of Magdala. The reflexed varieties appear to have been overlooked by "Q. D.," and as this is one of the finest sections (in fact, some of the finest colours are in this class), I have selected a few which are as follows, viz., Dr. Sharpe, Chevalier Damage, Julie Lagravere, Progne, Poach Christine, Golden Christine, Felicity, Beauté du Nord, and M. Lucien Barthere, the last being one of the most chaste and beautiful Chrysanthemums in existence, colour dark chocolate, edged with a gold stripe. The suckers arising from the base of the plants should certainly be removed, for if allowed to remain, they do not, as a rule, bloom. Stopping Chrysanthemums depends, in a great measure, upon the purpose for which they are intended; if for large cut blooms for exhibition, then they should be allowed to grow on from the cutting state without stopping till they bloom; but if for bushy plants, then they should be stopped when about 6 in. high, and again when the new growth has attained about four joints. The last stopping for large-flowering varieties should be performed about the second week in July; if stopped after that date the operation seriously jeopardises their successful blooming. The question of stopping, however, requires considerable explanation, and so much depends upon it that I would recommend "Q. D." to consult a good treatise on the subject; and, further, I would strongly impress upon him the necessity of not topping the Japanese varieties; on the contrary, he should grow them as strongly as possible. In order to ensure the retention of the lower leaves fresh and green, the plants must never be allowed to get dry at the roots. In reply to the question as to whether outtings struck now will make better plants than those struck later in the season, I would answer that the sooner they are struck the greater number of topplings can be given them, and that for whatever purpose they may be intended, I would recommend "Q. D." to get them in without delay. F. T. Davis.

*Plumstead Common.*

—In answering "Q. D.'s" questions, I will begin with outtings, which I would recommend not to be put in till next month; which, however, depends on circumstances. If the plants be intended to cover a trellis of any shape, or to form a "bush," the sooner the outtings are taken in November the better, and they should be grown on rapidly without check, and kept under glass till June. If "Q. D." resides in the sunny south this practise will be advantageous; but I am writing from a different climate. On the other hand, if the plants be intended to produce large shoots, the old stools or stock plants had better be kept back till next month in some airy position near the glass, and the young shoots should be thinned out to three or four, as circumstances will admit. Then, again, time and facilities will have to be studied. No one will throw away a good cutting because it is a fortnight earlier than he would like to propagate. The best plan would be to determine what mode of propagation would be best suited to the means at command; it is simple enough to accelerate the formation of roots by means of a little warmth, only it requires considerable space afterwards, as the plants are potted in find suitable quarters in which they will receive no check till the weather becomes warm enough to turn them out-of-

doors. And, again, if cuttings are put in a prepared bed out-of-doors, and severe weather sets in, they are apt to "draw" or damp through the exclusion of light caused by protection. On the whole, I would recommend a temporary frame being introduced to a coolinery or greenhouse, and filled with leaves about half-way up. Always leave a chink of air on, to allow excessive moisture to escape, and then there is no need of covering in severe weather; besides, you can take either one cutting or twenty, whenever they are ready, irrespective of weather, and put them in at your own convenience. By a system of coal propagation, you avoid much risk of checks, and the cuttings inserted singly into small pots prevent unnecessary shifting, and conduce to a stubby, short-jointed growth. By this system a beginner is most likely to succeed, and it is the best remedy to adopt in order to keep the stems clothed with leaves. The *Chrysanthemum* roots freely at all times, and the roots soon find their way to the sides of the pot; they are therefore often shifted too early, i.e., before the centre of each ball of earth is occupied by roots, as it should be. Before shifting make certain that every particle of soil in the pot is completely filled with roots, and follow the principle up to the last shift, which should be a liberal one, consisting of prepared compost. The summer situation, too, has something to do with leaves dropping. The site selected for summer culture should be open, and every shoot should be fully exposed to sun and light. If such a situation as this be at command, and protected from winds, and if the strength of the sun's rays be broken when they are most powerful (by intervening objects at a distance) from off the pots, little difficulty will be found in having fine, green leaves down to the rim of the pot. There is no insuperable barrier against anyone growing fine flowers, and fine leaves also (for the former is the natural product of the latter), if the last potting be deferred as long as practicable, and a proper summer situation be found, as recommended. They must never be allowed to get even once dry at the root, and they should also be syringed twice a day, once at least in the afternoon, when the work of evaporation is at a minimum. The surface-roots should be protected by a mulching of horse-droppings, amongst which *Chrysanthemum* roots increase and flourish amazingly. Liquid manure may be given in increased quantities as the plants develop in strength and quantity of foliage. Guano, if good, and cow or sheep manure mixed with soot make a first-rate stimulant, and so does farmyard sewage, diluted to safe proportions, with water.

As to stopping the plants, if I understand "Q. D." aright, he has a notion of becoming an exhibitor, in which case, if, as he states, he is quite a beginner, he had better not stop his plants at all that are intended for large flowers, but let them grow on till August, when each shoot will branch into three. These shoots may be allowed to carry one flower each, or the shoots may be reduced to one when it is seen which has the best-formed bud. This is one way, and the surest for beginners. Another plan is to stop the young plants early—say in April—merely nipping off the point of the shoot, and taking away three stems instead of one. This plan has the advantage of concentrating the whole energies of the plant at an early stage into a good base to work on afterwards, and it very materially decreases the unsightly length of the stems. At the usual time these stems will each branch into three shoots, two of which should be gently removed, leaving the best one, which will in the end produce exactly the same number of flowers as those treated according to the first-mentioned plan; but the system is more confusing to beginners. Of course, anyone wanting a mere display would simply encourage three flowers to each stem, which would give nine flowers instead of three. As to the height a plant should be when it is stopped, all depends for what purpose the plant is intended; if it be grown as an umbrella standard, it must first reach the top of the trellis; if it be meant to form a low bush, it can be pinched at every third joint or so up to June. The Japanese varieties will bear the same treatment, and, with few exceptions, are best grown as bushes. Formality ought to be entirely out of the question with flowers bearing such remarkable characteristics. Your correspondent seems to ignore disbudbing in his somewhat lengthy inquiry, which is the most important matter in the modern culture of the *Chrysanthemum*. No golden rule can be laid down to guide the beginner in the execution of this operation; practice alone will make perfect, and nearly every variety has some characteristic peculiar to itself.

In enumerating what I consider to be the best twenty-four incurved, large-flowering varieties, I have chosen only those with which a beginner would be most likely to succeed. I may also mention that the customs of different localities differ very much in this respect, as, for instance, Mrs. George Rundle and George Glennie take a leading place at some of the London shows, while in Liverpool it would simply prove amusement if an exhibitor was to set up a stand of flowers that included only medium-sized varieties. My selection of twenty-four large, incurved-flowered kinds is as follows:—Prince

Alfred, Mrs. Neale, Princess Beatrice, Golden Empress, Empress of India, Bronze Jardin des Plantes, Jardin des Plantes, Isabella Bott, Beethoven, Nil Desperandum, Prince of Wales, Princess of Wales, White Venus, Dingsal, John Salter, White Globe, Sir Stafford Cairre, Queen of England, Cherub, Pink Pearl, Baron Beuet, Beauty of Stoke, Lady Hardinge, and Mr. Gladstone, though not so large, yet invaluable for sake of colour. Novelsy and Eve are selling kinds if well grown, and go a long way in favour of an exhibitor with people who understand the merit of surmounting difficulties in the culture of peculiar varieties. Twelve Japanese sorts may consist of Elaine, Aurora, Colonel Hemery, Meg Merrilies, The Sultan, Grandiflorum, Madame Godillot, Wizard, Dea Masters, Fair Maid of Guernsey, Hero of Magdala, and Cromwell. The following are six Anemone-flowered kinds, viz., Fleur de Marie, Prince of Anemones, George Sands, Gluck, Acquisition, Louis Bonamy, and Princess Louise, a most invaluable sort for very late flowering. W. HINDS.

Otterspool.

## NOTES AND QUESTIONS—VARIOUS.

**Chrysanthemum at North Berwick**—One of the brightest borders which the writer observed during the past gloomy autumn was that surrounding the little Episcopalian Chapel at North Berwick. Throughout October it was glowing with richly-hued *Chrysanthemum*, planted close against the chapel wall, and surrounding the semicircular apse with a band of many colours. Interior decoration of churches is often carried to an absurd extent in these days, but we do not too often see successful attempts at the decoration of the external architecture of churches.—SALMONTERS.

**Victoria Nectarine**.—I quite agree with "S. D.'s" remarks (see p. 25), as to the questionable hardness of this Nectarine. It is, however, doubtless a valuable acquisition under glass, but, except in very favourable localities, I am persuaded that it requires a warmer and more certain climate than is experienced out-of-doors in most parts of the country. I would therefore by no means advocate planting it against open walls. I had here two fine trees grown upon walls and discarded both, as the fruit was so very uncertain in ripening as to be useless, although the locality is favourable for the growth of Peaches in general.—G. WESTLAND.

**The Big Cluster of Grapes** (see p. 25).—The "California Farmer" denies that California raised a bunch of Grapes weighing 125 lbs. It says it weighed only 12½ lbs., so it was really not much of a bunch after all; our English friends may therefore still claim the honour of having produced the largest bunch.

**Variegated Rock Rose**.—I have a golden-variegated sport from a robust form of *Heliathemum vulgare*. It originated in Bittersea Park during the late Mr. Gibbon's superintendence, and he gave it to me in the form of a single shoot from H. vulgare. It readily makes an edging about 1 ft. in diameter, and continues much longer in flower than any other *Heliathemum* of this class with which I am acquainted. The flowers are bright yellow, and this plant must not be confounded with the poor straggling white-flowered kind. During the spring months it is very bright and beautiful either on rockwork or elsewhere.—W. ELLIOTT.

**Striking Crotons in Bottles of Water**.—I, like "S. D." (see p. 45), think that Crotons are much easier struck in bottles of water than by the old plan. I have struck them in bottles for those last eight years; but, instead of suspending the bottles in the stove or propagating house, I put them on the pipes, a plan by which they strike much sooner. I have known *Dracenas* to make good roots in five days treated in this manner. I always put a little charcoal in the bottles, as it keeps the water fresh.—W. J. LANDERS, *Blankney Hall, near Slough*.

**Orchids now in Bloom in Mr. Philbrick's collection at Avenue Road, St. John's Wood**—

<i>Calanthe vestita oculata</i>	<i>Zygopetalum Mackayi</i>	<i>Oncidium sneebs</i> Barker
<i>lutea</i>	<i>Odoglossum</i> U.F.O.	<i>autumnalis</i>
<i>Turcici</i>	<i>Skinneri</i>	<i>orthochyrcum</i>
<i>Veitchi</i>	<i>nehlossum pardunum</i>	<i>Laelia alida</i>
<i>veratrifolia</i>	<i>roseum</i>	<i>Barkeria elegans</i>
<i>Angrecum sesquipedale</i>	<i>Roezli</i>	<i>Dendrobium heterocar-</i>
<i>phalaenopsis leucorhoda</i>	<i>circenseum</i>	<i>pum</i>
<i>Casta</i>	<i>Rosei majue</i>	<i>primitivum</i>
<i>Schilleriana</i>	<i>Alexandrae</i>	<i>Saccolabium giganteum</i>
<i>ambilis</i>	<i>Bictonense</i>	<i>violaceum</i>
<i>grandiflora</i>	<i>madroese</i>	<i>Cyrtopodium venustum</i>
<i>Rostropia antennifera</i>	<i>Cordatum</i>	<i>Roezli</i>
<i>Lycaste Skinneri</i>	<i>Sophrontis grandiflora</i>	<i>Boxalli</i>
<i>Masdevallia tovarensis</i>	<i>Vanda susvis</i>	<i>Harrisonium</i>
<i>polystachia</i>	<i>Oncidium nubiense</i>	<i>nivium</i>
<i>ignea</i>	<i>cuscutatum</i>	

On the *Sophrontis* there are no fewer than thirty-three fine blooms.—J. F.

**Flowering "Club Moss"** (see p. 48).—The plant referred to by Mr. Markham as a Club Moss (with flowers resembling miniature Lilies of the Valley), in his notice of the Greenland Flora, is probably the *Andromeda hypnoides*, which certainly occurs in Labrador, and is likely enough to be found somewhat farther north.—W. THOMSON, *Ipswich*.

—*Andromeda tetragona* covers the slopes of hills in Spitzbergen. It is slightly larger in the Himalayas.—THOMAS ACOTON.

No. 323.] SATURDAY, JANUARY 26, 1879. [Vol. XIII

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### A FEW GOOD GARDEN ROSES.

THERE are often so many disappointments arising from an improper selection of Roses for the garden, that while it is not yet too late to plant for the coming season, I venture to give the results of some dearly-bought experience in the matter, though, knowing that each must, in earnest, learn for himself, I can hardly expect it to go for much. The glamour of some glorious show Rose, grown and shown in perfection, chosen, it may be, out of many hundreds, will seduce each and all of us from our sternest determinations to try "at least this one" without inquiry as to its habit or wants; and, consequently, nine times out of ten we shall repent at leisure when, year after year, we find few flowers or, perhaps, fewer leaves on the plants we had fondly hoped would be the pride of the garden.

First, however, what is a good garden Rose? Its qualifications differ very considerably from those of an exhibition Rose, for in a garden brightness of colour and freedom of flower must dispute the palm with size and form, and a very double Rose is to be looked on doubtfully, as refusing to open in a wet, sunless summer like the one we passed through last year; above all, it should bloom freely in autumn, be sweet scented, and for small gardens be not too gross a grower. Capability as to standing hot sunshine as well as rain is also very desirable, but this last qualification is rarely found in any but light-coloured Roses.

Among old Roses none is more resplendent in a garden than Eugene Appert; its glowing colour, endurance, beautiful foliage, and freedom of flower still place it in the front rank. *Séateur Vaisse* is too well known to need further notice. Dr. Andry is a Rose that no garden should be without, a sure physician to heal all disappointment; his complexion is an index of his vigour, which defies all ordinary trials. Madame Victor Verdier is also a model Rose in every respect, brilliant in colour, deliciously sweet and free-flowering, handsome in growth and leaf. This Rose, I fancy, is not yet appreciated fully; perhaps from its resemblance to *Séateur Vaisse*, which, to my thinking, it surpasses. Duke of Edinburgh would be second to none if it were not scentless; and Paul Neron, were it not for the same grave defect, would be as necessary to a garden as La France is, for its huge size and coarse appearance vanish when treated with judicious neglect, and its autumn-flowering powers are indeed great when fully established and clothing some pillar. Baroness Rothschild and Countess of Oxford are, alas! also scentless, but who could leave such beauty in the lurch? Of less strongly growing Roses, Maurice Bernardin, Louis Van Houtte, and Xavier Olibo are remarkable for their excellence in every way, and the twin Roses Alfred Colomb and Marie Baumann make it an impossibility for anyone to choose between them. Charles Lefebvre and Jules Margottin must not be left out of our "garden party," though it is hardly necessary to mention them and other favourites whose fame is as great as their deserts. I go on, therefore, to the more neglected members of Rosedom, of whom none are more unjustly forgotten than the Bourbon Roses. Sir Joseph Paxton is peculiarly brilliant in colour, and will thrive almost anywhere, flowering abundantly; and another Bourbon Rose, Baron Genella, will in autumn yield blooms as beautiful as those of Eugénie Verdier, and with a sweet scent which that variety lacks. Count Bobrinski (red) is a wonderful late autumn bloomer on a south wall, but is rather tender, while Boule de Neige ranks with the hardest, and is very generous as regards its compact, white flowers at all times. Where abundance of cut Roses in autumn is required, the Tea Roses are indispensable, and nobody who can bestow a sunny bed on them with light, rich soil, and a little shelter from the north, need fear to grow them. In this selection great advances have been made lately in hardiness, so that when on their own roots, or, better

still, on the dwarf seedling Brier, or some equally congenial stock, obtainable at any good nursery garden, success is as sure as in any other kind. It is not necessary to grow many sorts where all cannot be equally good, but I mention a few which I have found to be of great use. Caroline Kuster is said to be a Noisette, but is not of a rambling disposition; Isabella Sprunt, Madame Falcot, Marie Van Houtte (best of all), Perfection de Montplaisir, and Perle des Jardins are all very good and trustworthy in their different ways, and embody various shades of yellow; Catherine Mermet, Goubault, Joséphine Malton, Regulus, Souvenirs d'un Ami and Paul Neron are also to be depended on as regards shades of pink and white, and, with those mentioned above, will afford cut blooms as long as any hardy flower can withstand autumn cold and rain. Among other and newer varieties Anna Ollivier, Jean Pernet, and Perle de Lyon (the last not so new), deserve trial, though not quite so certain to succeed, and for those whose gardens are in the "sunny south," Lamarque will prove a never-failing source of pleasure under a glass verandah with an east aspect, but a south wall forces him into growth too soon; his sweet, lemon-white flowers are by many preferred to those of any other Rose, and they are produced both early and late. Where there is plenty of space, and an evergreen is required, Fortune's White Banksian should share a place with Lamarque, for its flowers, too, are sweet, white, and of good size, and its period of bloom extends over several months in spring; appearing, also, in a mild winter, before March 21, as I have seen myself on the south coast of England, while on the shores of the Mediterranean its first blooms open in December, and a succession is kept up till the end of May, its earlier blooms combining peculiarly well with the Neapolitan Violet, so common in Paris flower-shops. In this incomplete list many well-known sorts are omitted because their fame needs no trumpeter. These will, of course, be added, or rather already be growing in every collection; but I trust that some of those just mentioned will be welcomed when once known, and as I write from the "North Country," where, as last year, summer forgets sometimes to pay us a visit, few exceptions need be made on the score of hardiness, except in some very low and damp situation. E. H. W.

### NOTES FROM KEW.

AMONG greenhouse plants in flower this week the following are most worthy of notice:—*Bonia tetrandra* is a neat-habited shrub, with pinnate leaves and pretty whitish-pink flowers. *B. megastigma*, of which there are several plants, produces an abundance of shortly-stalked, drooping, bell-shaped flowers, maroon-purple outside and greenish-yellow within; it is remarkable for its slender habit, sparse foliage, and the singular colour and delicious fragrance of its flowers. Sir Joseph Hooker thus speaks of it:—"Its somewhat aromatic fragrance resembles nothing known to me. It is most delicious, and, though not overpowering, scents fills a large room; and should it be capable of being obtained as a perfume, I may safely predict its being in great request. In these respects of delicacy of odour, accompanying a singular brown-purple colour, it resembles the *Tinnea* æthiopia of tropical Africa;" (noted in *THE GARDEN* of July 28, 1877) "and, like the *Tinnea*, the *Bonia* is very easy of cultivation, if treated like a Heath in an ordinary greenhouse." The two *Bonias* just mentioned are from West Australia. The Early-flowering Bitter Vetch (*Orobus vernus*), a native of Switzerland and Germany, lends itself readily to forcing purposes if taken from the open border in autumn, potted and placed in gentle heat; the pleasing, light green foliage, the bright purple of the flowers when first expanded, and the peculiar metallic-blue assumed as they get older, make a striking and pretty combination. A very graceful shrub, and one, moreover, readily forced, is the *Cytisus filipes*, of the Canary Islands; its long, string-like, drooping branches are sparingly furnished with leaves, from the axil of each of which are produced several sweet-smelling flowers. These, when held in the hand, appear to be pure white, without any tinge of colour; a closer examination, however, reveals the presence of several fine parallel lines of a rosy-red at the base of the standard, as the upper petal in the flowers of the Pea family is technically called. *Podalyria calyptrata*, from South Africa, is an elegant shrub, with alternate, entire, silky leaves, and purplish-pink, Pea-shaped flowers. In some parts of Ireland, and in sheltered positions in the south-west of England, there is a probability of this succeeding in the open air. More than a dozen fine species of this beautiful genus remain yet to be intro-

duced to our gardens. *Epaoris purpurascens*, with its upright, rigid branches, thickly beset with hard-pointed leaves, at the base of each of which, for a considerable length, are borne the short, tubular, pure white flowers, compares very favourably even with the beautiful cross-breds we owe to the art of the hybridist. It is not very frequent that the purely wild type can vie in beauty with the varieties formed after long cultivation.

In the Palm-house may be seen a very pretty little Bromeliad, *Bilbergia nutans*, from tropical America. From its tufts of narrow leaves spring the scapes, with their large, bright red, sheathing bracts; the flowers are about  $1\frac{1}{4}$  in. long, the three short outer segments being pink, slightly edged with blue, and the much longer inner ones yellow-green, margined deeply with dark blue. The contrasts afforded by the bright yellow anthers, the blue-edged yellow green petals, and the red bracts are very novel. In this house may also be seen *Rondeletia Bakhouseana*, which is classed by Mr. T. Moore, in the "Gardeners' Chronicle," among the new plants of 1877. Although we believe the species was first figured last year, it is anything but a new one, having been in cultivation for about twenty years. It is a rank, coarse, large-leaved plant, which, in spite of its large panicles of flesh-coloured or whitish flowers, will never be a favourite in general collections.

In the stove is a variety of Plumbago rosea, remarkable for its neat habit and the large size and brilliant colour of its flowers, which are some shades deeper than those of the type; *superba* is the varietal name, and one which is well merited by the plant in question. *Meziera erecta alba* is, in our opinion, not nearly so handsome as the splendid purple, yellow-throated *M. erecta* itself; like the last-named, it is a native of Sierra Leone. *Begonia prismatocarpa* is a charming little species, first discovered by Gustav Mann at an elevation of 3000 feet above sea-level, growing on rocks and trees near Fernando Po; it has creeping, herbaceous stems and small leaves, just above the level of which are borne umbels of from two to four two-petalled flowers, one of which is always a female. The petals are yellow, with a tinge of orange towards the base. To any collection of miniature plants this will prove a very welcome and elegant addition. A very noble and graceful Palm from Ceylon (*Ptychosperma rapicola*) is also in flower, perhaps for the first time in this country; the beautiful arching leaves are pinnate, and from the smooth trunk, well below the crown of the leaves, is given off the short, starchy, much-branched inflorescence, every part of which is of a deep red colour.

There are several fresh Orchids in bloom, the most interesting, from a gardening point of view, being the following:—*Odontoglossum pulchellum* var. *tenus*, from Guatemala, has long, narrow leaves and short, erect scapes bearing a few small flowers pure white, with the exception of the yellow crest on lip. The Indian *Eria obesa* has thick, leafless pseudo-bulbs about 2 in. or 3 in. long, and numerous racemes of white flowers scarcely tinged with pale pink; this is a very neat and pretty little Orchid, and does not possess the disagreeable scent emitted by some of the species in this genus. *Cattleya Warszewiczii* has white sepals and petals, the base of the lip exhibiting a faint but decided tinge of yellow, and the upper portions slight blotches of rose colour. *Dendrobium nobile* var. *elegans* is a very charming variety of an extremely useful and beautiful species; the flowers are larger and more deeply coloured than those of the type.—†

**Effect of the Weather on Vegetation.**—The damp mild autumn and winter which we have so far had are influencing everything out-of-doors. Previous to the 10th and 11th of this month, when the thermometer marked 12° of frost each night, we had not had more than 8° of frost, and many plants have flowered in a way not ordinarily seen. Of these the most unusual early in January were *Calceolaria aurea floribunda* and scarlet *Pelargonium*, which, although their bloom is now destroyed, are yet alive, and in many places have sustained little or no injury. This season the autumn and spring flowers may be said to have met each other. The following are finely in flower: Christmas Rose, Primroses (common, double white, and lilac), Violets, Polyanthus, Wallflowers (double and single), white Arabis, *Jasminum nudiflorum*, Veronica Anderssoni, Pyrus (*Cydonia*) japonica, and Hæpaticas; many Roses, both Hybrid Perpetual and Tea-scented, are still studded with numbers of opening buds, but amongst them the old Chinese blush and crimson have stood the cold the best; indeed, the unscathed buds of these in many places are still opening quite perfect. Laurustinus are more than usually full of flower. Fruit trees of all descriptions are thickly studded with bloom-buds. Peaches, Nectarines, Apricots, Pears (both standards and on walls), Cherries, Plums, and bush fruits of all kinds are alike promising, the buds being not so forward as they generally are at this time. Should the weather henceforward be sufficiently cold to keep them back until the spring frosts are over, there is every prospect of our having a good fruit crop during the coming season; but,

should it continue mild, its adverse influences will soon manifest themselves. Within the last few days many things show signs of moving. Honeysuckles, always amongst the first to push, are making considerable progress; the buds of Roses are also beginning to move.—T. BAINES.

**Halleborus orientalis.**—This is now finely in flower in the Fulham Nurseries. It is a handsome species, which should find a place in every garden.—P.

**The Sketch for our Plate,** issued this week, of Iris Victorine was drawn from a plant in Mr. Peter Barr's trial grounds at Tooting, where there is a very large collection of hardy Iriess.

**Dried Wild Flowers.**—Mr. Horsman has called our attention to some very graceful ornaments made from dried plants for Christmas and Easter cards by Mrs. Greston, of Colchester. They consist, to some extent, of annual everlasting, such as *Rhodanthe maculata*, ornamental Grasses, and some of our native plants, dried between ordinary newspapers, and they perfectly retain their colours. They are the prettiest things we have seen in dried flowers. Messrs. Hooper & Co., of Covent Garden Market, have a large collection of them.

**A Finely-flowered Cœlogyne.**—A specimen of *Cœlogyne* in Messrs. Veitch's Nursery, at Chelsea, is now furnished with forty-eight gracefully drooping flower-spikes, each of which bears from four to five flowers of snowy whiteness. A bank of this *Cœlogyne*, grown in 6-in. pots, also makes an effective feature, single plants in some instances bearing no fewer than six or eight flower-spikes. They are grown in peat and Moss, and in a temperature of from 50° to 60°, and are given abundance of water, especially when in active growth.

**A Winter-flowering Fuchsia.**—Mr. Cannell, of the Nurseries, Swanley, has sent us shoots of *Fuchsia splendens*, bearing numerous bright red flowers with green tips, a most brilliant and novel flower, resembling a very good and bright *Correa*. It requires an intermediate house, and if cuttings of it be struck about midsummer and grown on to healthy plants, they continue to produce an abundance of scarlet flowers throughout the winter. It is quite distinct from any other *Fuchsia* in cultivation.

**Dendrobium barbatulum Fitchianum.**—This *Dendrobium*, though comparatively little grown, is well worth attention on account of the tresses of soft, white, violet-centred blossoms which it produces freely during the dullest months of the year. It is now in flower in Messrs. Veitch's nursery at Chelsea, where the plants are growing on small strips of wood.

**Galanthus Imperati.**—This is, and has been for more than a fortnight, finely in flower with us at Colchester, while *G. plicatus* and the common Snowdrop are hardly above ground. *G. Imperati* seems to be not only the earliest, but also one of the finest of all Snowdrops. I may add that *Crocus alaticus* is likewise in flower with us.—F. HORSMAN.

**Begonia insignis in Winter.**—This is one of the best *Begonias* which can be grown for blooming in winter in the form of small plants. From cuttings of it struck in spring, and grown on liberally through the summer, good bushy plants, in 6-in. pots, loaded with delicate, rose-pink blossoms, may be obtained by Christmas. This plant grows freely in a cool house, and continues in bloom for several months, if occasionally watered with weak guano-water during its flowering period.—S. C.

**Cœlogynes in Small Pots.**—These beautiful winter-flowering Orchids, grown under any conditions, are both valuable and ornamental at this season of the year, but, when well cultivated in 6-in. pots, they are doubly useful, as such plants, when laden with four or five pendulous sprays of blossoms, as they may now be found in Messrs. Low's nursery at Clapton, may be used for vases and similar purposes in rooms, where they have an excellent effect, and last in good condition for a long time.

**Platycerium grande.**—Under no circumstances is this Stag-horn Fern more attractive than when grown on large blocks of virgin cork. A pair of plants of it grown in this way in Messrs. Jackson & Sons' nursery at Kingston are just now very ornamental. Strips of cork are set in an upright position in large pots, and bound together with wire to a height of 2 ft. or 3 ft. above the rim of the pots. On the sides of these are fastened the plants, which in a short time develop themselves into large specimens, some of the fronds of which measure from 3 ft. to 4 ft. across.—S.

**Gardeners' Royal Benevolent Institution.**—We are informed that Mr. Robert Marnock has consented to preside at the thirty-fifth anniversary festival of this charity, to be held during the ensuing summer.

KENTCHURCH COURT, HEREFORDSHIRE.

THIS ancient seat of the elder and unenobled branch of the Scudamore family lies to the right of the Pontrilas Station of the Hereford and Abergavenny Railway, at a distance of from 1½ miles to 2 miles. It is approached by a very old Elm avenue of considerable length, but somewhat detracted from in point of beauty by the coincidence of lines of hedgerow with some parts of it. Though the Scudamores of Hom Lacy—of which race was the first Viscount Scudamore, the friend of Buckingham and Archbishop Laud, the princely second founder of several Herefordshire churches, and (which is, perhaps, more germane to the columns of a horticultural journal) the first improver of Herefordshire orchards—are a more distinguished family in the annals of the county, the Kentchurch branch can boast an almost unique property of the same soil as their ancestors held five centuries ago, and of having in the course of that period not unfrequently represented the county

author of the English Georgic, "Cider," John Philips, assumed a poetic licence when he singled out the soil of Kentchurch, with some half-a-dozen other parishes, as noted for the growth of cider Apples.

Such is the Kentchurch, such Dantzeyan ground,  
Such thine, O learned Brome, and Capel, such, &c.

Book I., v. 66.

As his commentator, Dunster, explains, the parish of Kentchurch is not particularly noted for its cider. Possibly the poet assumed that it would be so, on account of the association of the owners of the soil with the lord of Hom Lacy above referred to; of whom Philips could with truth say, *apropos* of the Red-streak Apple, that

Scudamore's skilful hand  
Improved her, and by courtly discipline  
Taught her the savage nature to forget;  
Hence styled the Scudamorean plant; whose wine

Kentchurch Court. Drawn by C. O. Murray, after a photograph by Vernon Heath, and engraved by A. Sargent.

in Parliament. The last direct representative of the family, John Lucy Scudamore, Esq., of Kentchurch, was born in 1798, and died in 1875, being succeeded by his maternal grandson, Edward Scudamore Lucas, of Castle Shane, Monaghan, and Kentchurch Court, Hereford, a magistrate for that county, and a lieutenant in the Herefordshire Militia.

The present residence at Kentchurch is a castellated mansion, from designs by Nash, erected in 1824 to replace a quaintly irregular house, of which one old tower remains, as seen in our engraving. In this tower tradition holds that the mysterious John-a-Kent or Gwent, who is supposed to have been identical with Owain Glyndwr, and who is buried in the neighbouring church of Grosmont, was wont to hide himself, his daughters having married the representatives of the families of Scudamore and Monnington. The situation of Kentchurch, although the steep slopes of Garway Hill rise almost too abruptly in its front from the very edge of the drive, is eminently picturesque, and embraces some fine, park-like scenery, of a wild and secluded character. The oft-quoted

Whoever tastes, let him with grateful heart  
Respect that ancient loyal house.

Book I., 504, &c.

In Mr. Evelyn Shirley's work on "Deer and Deer Parks," we find that Kentchurch Park contains between 300 and 400 acres, and a herd of about 130 fallow deer. It was enclosed before the reign of Henry VIII.

*Colletias in Ireland.*—Perhaps there could not be found in the three kingdoms such examples of that curious shrub, *Colletias cruciata*, as are to be seen growing in the grounds of Mr. Smith-Barry, at Fota, near Queenstown. It should be remembered that the *Colletias* were at one time classed as stove plants, and, indeed, we believe they are still to be found so placed in some horticultural publications of rather recent date. The species referred to above we know—and, doubtless, all the other species are equally so—to be perfectly hardy in Ireland, and we strongly recommend it to the notice of all who are interested in rare and beautiful shrubs, as being well deserving of a place in their gardens; its pretty little creamy-white flowers, which are produced in great profusion during the autumn months, and its striking appearance always render it an object of interest.—"Gardeners' Record."

## ORCHIDS.

## ORCHID FLOWERS AT WHITECHURCH RECTORY.

The form, texture, colour, and fragrance of many Orchid flowers peculiarly adapted them for effective arrangement in a cut state. When judiciously mixed with other flowers, they add a charm to the combination which in their absence could be supplied by few other flowers. Where they are grown in sufficient quantities with the requisite variety, there can be little doubt that, independent of the estimation in which rare flowers are common with all rarities are held, they produce the best effect when grouped by themselves. This opinion, which I have always entertained, received additional confirmation the other day by a charming arrangement which I saw at the Rev. J. B. Norman's, Edgware, and which I will attempt to describe. The stand consisted of a massive glass plate 18 in. in diameter, covered with green velvet; on this stood some dozen and a half small specimen glasses, similar in shape to such as are used for button-holes flowers in the shops. The centre one was about 10 in. high, those surrounding it gradually decreasing to the outer ones, which were not more than 3 in. high. In the centre glass was a single flower of *Laelia purpurata*, associated with *Madevalla Lindeni*, *Harryana*, and *Veitchi*, also single flowers cut with good long stems, so as to avoid a dumpy appearance when set too closely together. The surrounding row of glasses contained varieties of *Cattleya Mossie*, *C. lobata*, and *C. Mendali*, a raceme of *Phalænopsis grandiflora*, and one of *P. Luddemanniana*, and several spikes of *Odontoglossum Alexandræ* and *O. Pescatorei*; the outer glasses were filled with *Dendrobium Ainsworthi*, *D. Dalhousianum*, *D. crystallinum*, *Odontoglossum Uro-Skinneri*, several flowers of *O. Rosali*, and *O. triumphans*, *Vanda Malesagris* (very fine), *V. suavis*, *Epidendrum vitellinum majus*, a single spike each of *Oncidium barbatum* and *O. pulvinatum*, the drooping feathery sprays of these lightening up the whole. To give colour there was a flower or two of *Anthurium Schoberzianum*, and also several of *Streptocarpus biflorus*, to afford the essential shade of blue. A few fronds of *Adiantum Farleyense*, *conneatum* and *gracillimum* completed an arrangement the beauty and elegance of which it would be difficult to over-estimate. There was a total absence of that crowding together which is so objectionable, yet so often met with in groups of cut flowers. The whole was covered with a high glass shade; the latter not with a view to improve the appearance of the flowers, but to prolong their duration, to which it very much contributes. It may with truth be said that few have such *recherché* material as this at command, but that does not in the slightest degree affect the principle on which such combinations should be made, for even flowers of a much commoner character would look much better than they do if not banded together in vases and baskets, as if the object were to pack the greatest possible number into a limited space, a condition which simply results in destroying the individuality of the flowers and all artistic effect. Mr. Norman is not only an enthusiastic cultivator of Orchids, possessing, as he does, one of the finest collections in existence, but he is equally successful as an amateur artist in the drawings which he makes of his choicest plants in flower. The productions of his pencil not only possess more than ordinary merit as pictures, but are true portraits of the flowers which he paints. Amongst large numbers of rare and beautiful kinds I noticed *Cattleya Bassetti*, *C. Dawsoni*, *C. Trianae magnifica*, *C. Mossie* (the Manley Hall variety), *Laelia purpurata*, *L. majalis*, *Aerides Fieldgieri*, *A. Veitchi*, *Dendrobium luteolum* and *D. crassinode*, *Vanda Bensoni*, and *Disa grandiflora*. In the colouring and in the delineation of the plants and flowers Mr. Norman is alike successful, rendering the delicate shades for which Orchids are so conspicuous in a manner that many artists of considerable repute would appear incapable of. Drawings, if striking in appearance, may pass muster with those who are not familiar with the flowers, but if not faithful representations of what they profess to be, they have little interest for those who are intimately acquainted with the originals.

T. BAINES.

## SEASONABLE NOTES ON ORCHIDS.

PLEIONES out of flower should now be re-potted, in order to have strong, well-developed pseudo-bulbs for blooming next autumn and winter. Pot them in a mixture of peat-loom, well decayed cow-manure, Sphagnum Moss, and a little sand; drain well, and treat them liberally as regards water when root action commences. There is one exception, however, respecting the flowering of these plants, for, although the instructions just given apply to *P. lagenaria*, *Walliichi*, and *maculata*, *P. humilis* is only now beginning to open its blooms, and must, therefore, be left until later in the month. *Laelia cinnabarina*, now sending up its flower-spikes, must also be carefully watered; plants of this species which are not showing flower should

be kept at rest as long as possible, because they will make stronger growth if started later.

*Cypripedium Boxalli*, be it species or variety, bids fair to become a favourite winter and spring-blooming plant. In habit of growth it resembles *C. villosum*; its flowers, however, differ from those of that kind considerably, and, indeed, in some respects they are more beautiful. The dorsal sepal is pale-green, beautifully blotched and spotted with dark purplish-black; the sepals have lost something of the pearly, varnished appearance of *C. villosum*, and are more or less blotched with brownish-black. With this plant the beautiful hybrid *C. Sedeni*, with its deep rose-coloured petals, forms a fine contrast. Amongst older kinds, *C. insigne* *Maslei* has few rivals, the large dorsal sepal being more than half pure white, blotched and spotted with brownish-purple and mauve, and, in addition to its beauty, it thrives by anyone having even an ordinary greenhouse. Plants of the variable *C. Trianae* are now unfolding their beautiful flowers, and amongst its many varieties few are more charming than the kind called *O. T. delicata*, a sort which should be sought after by all who do not possess it.

*Odontoglossum* now in flower, and, indeed, all other Orchids in the same condition, should be kept free from sprinklings from the syringe, or their beauty will soon be impaired, and their period of blooming greatly curtailed; care should also be taken that plants in flower removed to a low temperature should not be exposed to an atmosphere charged with much moisture, or loss will be the result. Plants in baskets or upon blocks should not be over-stimulated, or they may start into growth prematurely, and the display of flowers will be thereby much impaired. Plants with pseudo-bulbs may be kept in health and in a state of rest if they be taken down and dipped in water about once a week. At this season the syringe should be used with caution, especially after noon, as the sudden changes of temperature that take place may lead to much mischief in the case of plants hanging near the glass. Yellow fly now making its appearance should be diligently washed off; this little pest should be kept in check in this manner as much as possible, in order to avoid fumigation, which in many instances is injurious.

W. H. G.

Orchids in Flower at Chelsea.—*Cattleya bulbosa*, or *Walkeriana*, now in flower in Messrs. Veitch's nursery, though not new, is strikingly beautiful; it bears flowers as large as those of *Laelia marginata*, the petals are transparent in texture, and elegantly tipped with violet, the lip being rich purple. A rare variety of *Odontoglossum nabaloom* is also in bloom; its flowers, which measure quite 3 in. in diameter, are wax-like and beautifully spotted. An orange-scarlet *Chysis* is also very attractive, six large flowers being borne on one spike. It is a hybrid, raised by Mr. Sedeni, the result of a cross between *C. Limminghei* and *C. levis*. A very beautiful *Dendrobium* is also now in flower; it is named *D. Dominicanum*, and is the result of a cross between *D. noble* and *D. moniliforme*. Its flowers are nearly as large as those of *D. noble*, the petals being tipped with deep purple, and the throat rich dark crimson. Amongst hybrid *Dendrobies*, this is probably the best which has yet been raised.—S.

*Lycaste lanipes*.—This old yet valuable Orchid produces large, waxy, cream-coloured blossoms in abundance, and they are agreeably scented. The flowers issue from the bases of the bulbs, sometimes as many as from fifteen to twenty being produced round one bulb. We saw a good plant of it the other day in bloom in Messrs. Jackson & Son's nursery at Kingston.—S.

*Odontoglossum vexillarium* in Pans.—Young plants of this beautiful Orchid are found to succeed best in small shallow pans, filled half full of broken crocks, on which are heaped up lumpy peat and Sphagnum. The pans are suspended from the roof, so that the plants are placed close to the glass. Large plants are, of course, best grown in pots, but these should be filled at least half full of drainage, as if a large bulk of soil be used the roots do not increase nearly so fast, nor are they so healthy as when afforded plenty of drainage and loose material in which to ramble.—C.

Ferns and Ficus amongst Orchids.—Orchid houses might be greatly improved in appearance by introducing free-growing Ferns, Mosses, and *Ficus repens* amongst the pots in which the Orchids are growing. These are placed on stages covered with ashes or gravel, and the plants just named luxuriate under such conditions. The *Ficus* may be allowed to droop over the edges of the stage so as to form a curtain of green spray. Under the stages stones or cinders might also be placed, and in the cavities filled with soil might be planted *Selaginellas*, *Fittionias*, Ferns, and similar moisture-loving plants. In addition to the effect produced by such an arrangement a certain amount of humidity would always be maintained in the house, which would prove of benefit to the Orchids.—S.

THE GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS.

*The African Tropical Region.*

Including Madagascar, the Mauritius, and other small islands, the flora of this region has contributed comparatively little to our gardens. Though isolated from the other tropical regions, it contains no peculiar families, but a large proportion of the genera and species are endemic. The vegetation of the western side approaches, in some of its characters, that of the

Pacific Islands—The Bread-fruit.

opposite coast of America, and on the eastern side there is a greater resemblance to the Asiatic flora; but a very large number of the species of both sides of the continent are identical, and the general character is more Asiatic than American. So little has been published of what is known respecting the flora of this region, and so much remains to be explored, that a general comparative sketch is impossible. There is, how-

Tropics of the Old World—Tamarind.

ever, an absence of the wonderful profusion and brilliancy characteristic of the American region. Handsome plants are, however, not wanting, and further explorations will doubtless add many fine things to those we already possess. The most beautiful and the most singular of the plants from this region in cultivation are from the islands; for instance, the Lattice-leaf Plant (*Ouvirandra fenestralis*), the Traveller's Tree (*Ravenala madagascariensis*), and the indispensable *Stephanotis floribunda*, are all natives of Madagascar; and many of the fine Palms of recent introduction belonging to the genera

*Hyophorbe*, *Latania*, *Dictyosperma* (*Areca alba* and *rubra*), *Roscheria*, *Verschaffeltia*, and *Stevensonia*, are natives of the smaller islands of the Mauritius and Seychelles group. The Mauritius and Seychelles are also rich in Screw Pines (*Pandanus* genus). Sixteen species have been described as growing in these islands.

*The Asiatic Tropical Region.*

EXTENT OF CHARACTERISTIC VEGETATION.—The flora of this region, which is here understood to include the whole of tropical Asia and Anstralia, is probably not far short of 20,000 species. British India alone numbers at least 10,000, judging from the number of species of the first 44 natural orders, *Ranunculacæ* to *Sapindacæ*, which, in Hooker's "Flora of British India," amounts to exactly 2250. It is true that this total includes not only the species growing in the Tropics, but all those occurring in British India up to the highest limits of plant life on the Himalaya Mountains. But whilst some parts of this area have an exceedingly rich and luxuriant vegetation, other districts are comparatively poor. Thus it has been computed that the whole of the immense plain of Bengal supports only about 600 species of flowering plants. On the other hand, there is almost a complete absence of desert land. Comparatively little is yet known of the vegetation of some parts, as Burmah, New Guinea, and many of the islands of the Malay Archipelago. Of the 2250 species belonging to the orders named above, nearly 250 occur above an altitude of 10,000 feet. Already, under sub-tropical and temperate regions, something has been said of the contributions to our gardens from the Himalayan Mountains, particularly of the great variety of magnificent *Rhododendrons* from Sikkim. It remains now to point out some of the characteristics and peculiarities of the tropical flora. In doing this in a general way, it is not easy, in fact it is not possible, to draw any line of demarcation between the sub-tropical and tropical elements. Some species are common to both regions, and many genera characteristic of the country are represented by diverse species in the different regions. Disregarding some of the orders of general distribution in the Tropics, the following may be selected for remark:

CHARACTERISTIC FAMILIES. — *Anonacæ*, chiefly aromatic trees, 200 species in British India. To the *Nymphæacæ*, *Water Lily* family, belong *Euryale ferox*, a native of India and China, closely allied to the *Victoria* of American waters, having similar large leaves, but much smaller flowers, numerous varieties of *Nymphæa stellata*, in common with tropical Africa; *Nymphæa gigantea*, from Australia; and *Nelumbium speciosum*, *Sacred Lotus*, which is also widely dispersed in the Old World. Trees belonging to the *Guttiferæ* are numerous, and include those yielding gamboge. A characteristic Order of Indian timber trees is the *Dipterocarpeæ*, which, with the exception of three or four species occurring in tropical Africa, is confined to tropical Asia, and includes some of the most valuable of Indian timber trees, among them the *Sal*, *Shorea robusta*, and *Dipterocarpus laevis* yields a kind of varnish called wood-oil, used for painting ships, &c.; and *Dryobalanops camphora* furnishes a superior kind of camphor, called *Sumatra camphor*. A conspicuous character of the flowers of these trees is the growing out of one or more of the calyx-lobes into long wings as the seed-vessel advances towards maturity, giving the fruit somewhat the appearance of a shuttlecock. Belonging to the *Geraniacæ* is the genus *Impatiens*. A familiar species, *I. balsamina*, the *Balsam*, is a native of India, where also 120 out of about 150 known species of the genus are concentrated. They inhabit the tropical and sub-tropical regions, a few ascending into the temperate region. The remaining species are widely dispersed in temperate regions of Africa, North Asia, and North America. The Mal-

pihiaceæ, which we found so abundant in America, are rare in Asia, and represented in India by only about a dozen species. Anacardiaceæ (ex. *Mangifera indica*, the Mango) are abundant; and the next family of importance is the Leguminosæ, which is represented by no fewer than 132 genera—among them *Butea*, *Amherstia*, *Poinciana*, *Cassalpinia*, *Tamarindus*, and *Piptadenia*. In India the tribe *Dalbergiæ* is represented by a considerable number of species, but they are not so numerous as in South America. Some of them, as the *Sissoo* (*Dalbergia Sissoo*), are amongst the most valuable of timber trees. *Arborescent Myrtaceæ*, belonging to the genera *Eucalypta*, &c., are also very numerous, and include the Clove (*Caryophyllus aromaticus*) and Rose Apple (*Jambosa vulgaris*).

MELASTOMACEÆ.—The Asiatic Melastomaceæ, although they constitute no prominent feature of the flora, contribute a larger proportion of the commonly cultivated species than the American. The principal genera are: *Osebeckia*, 36 species; *Melastoma*, 40; *Allomorphia*, 3 or 4; *Sonerila*, 50; *Phyllagathis*, 2; and *Medinilla*, 50. The genus *Mecynoclon*, consisting of about 100 species of shrubs and trees, now generally referred to the Melastomaceæ, is almost exclusively Asiatic. The beautiful *Lagerstromia indica* belongs to the neighbouring family *Lythraceæ*. *Compositæ* are less numerous and less showy than the American. Mr. *Bentham* estimates the total number for tropical Asia at 326, and the tropical Australian species would not materially swell this number.

The *Rubiaceæ* (including the *Cinchonææ*), a family of upwards of 325 genera and 4000 species, chiefly tropical, are numerous in Asia, and include the finest species of *Ixora*, the fragrant *Luculia gratissima*, and the pretty *Mussaenda frondosa*. The species of *Coffea* (*Coffee*) are also Asiatic. *Hoya* and *Centrostemma* belong to the large tropical Order *Asclepiadææ*; *Torenia asiatica* to *Scrophularinææ*; *Coleus* to *Labiataæ*; *Chirita*, *Didymocarpus*, and the splendid *Æschynanthus* to *Gesneriææ*. *Verbenacææ* furnish many fine species of *Clerodendron*, including *C. coccineum* and the valuable *Tenk*, *Tectona grandis*; and the *Convolvulaceææ*, such ornamental plants as *Ipomœa Horsfallii* and *I. Leari*. *Laurinæææ*, *Myristicaceææ* (*Nutmegs*), and *Moracææ* (*Figs*) are characteristic families of large trees. The genus *Myristica* constitutes the Order *Myristicaceææ*, and has its head-quarters in the Malaccas or Spice Islands, and the species of *Ficus* are very numerous.

PITCHER PLANTS.—The *Nepenthæææ* (*Pitcher Plants*) are confined to the Asiatic region, and most abundant in Borneo and the neighbouring islands, only one species occurring in Australia, and that only in the extreme north. *Rafflesia Arnoldi*, a curious parasite on the roots of trees, has the largest flowers of any known plant, being 3 ft. or more across. It is a native of Sumatra, and there are some other smaller-flowered species in the same part of the world. *Screw Pines*, *Palms*, *Orchids*, *Zingiberacæææ* (*Ginger family*), and *Bamboos* are some of the principal remaining Orders, of which representatives are in cultivation in this country.

ECONOMIC PRODUCTIONS.—The economic plants of India and the Islands are numerous, but Australia has none of importance that do not occur elsewhere. *Papaver somniferum* (*Opium Poppy*) is extensively cultivated; *jute* is the fibre of *Corchorus capsularis*, now exported on a large scale; *gutta-percha* is the inspissated juice of *Isonandra gutta*, a native of the Malay Islands; *Cinnamon* is the bark of a *Lauraceous* tree of Ceylon (*Cinnamomum zeylanicum*); *castor-oil* is the product of *Ricinus communis*, believed to have been originally wild in India; *Piper nigrum* (*Pepper*), and *Ficus elastica* are also natives of India. The *Durian*, *Mangosteen*, and *Tamarind* are indigenous fruits.

General List of some of the Genera of Plants from the Asiatic Region.

Euryala	Ixora	Nepenthes	Anæctochilus

Phyllagathis	Clerodendron	Aerides	Vanda
Lagerstromia	Ipomœa		

PACIFIC ISLANDS.—A few words respecting the flora of *Polynesia* should be added, although we have very few plants in cultivation from this region. The vegetable food of the inhabitants forms the most interesting feature from our point of view. What may be termed the almost universally-cultivated bread-plants are the Bread-fruit tree, the *Cocca-nut Palm*, and *Taro* and *Cocca-meal*, the produce of the tobacco root-stocks of the gigantic *Aroids Colocasia antiquorum* and *C. esculenta*. It must not be supposed, however, that the vast number of islands widely scattered in the Pacific Ocean are uniform in their vegetation. Some of them are almost barren, whilst others have a luxuriant tropical flora, and the way in which the rising coral reefs gradually become covered with vegetation is one of the most interesting phenomena connected with the distribution of plants. Seeds of various littoral plants are conveyed by the sea from the neighbouring islands and spring up, forming the first vegetation of flowering plants. As the reef rises, and generation after generation of these plants live and die, and a soil is formed by their remains and the wearing away of the rock, other plants take possession. Among the first is the *Cocca-nut Palm*, which quickly establishes itself, and, in its turn, affords cover for other small-fruited plants, whose fruits or seeds are conveyed by birds, winds, and other agencies. Coral islands of different ages exhibit all the different stages imaginable, between a complete clothing of plants and a few seaside species springing up on the reef as it is just emerging from the sea.

#### Concluding Remarks.

By employing as much as possible familiar cultivated examples of different groups in illustration of the principal facts of the geographical distribution of plants, the foregoing mere outline of the subject should convey much interesting and instructive information to anyone tolerably well acquainted with the plants commonly met with in gardens of even moderate pretensions. But, of course, it can only be regarded as a foundation upon which to build up by degrees a complete superstructure, or a simple framework in which future knowledge shall enable the student to imagine perfect pictures. One of the most important lessons the practical cultivator learns from a study of the laws affecting the character of the vegetation of a given region, is the part played by climate (heat and moisture); thus, if a country in a temperate region has a large proportion of herbaceous perennial plants flowering during the warmer months, as in England, for example, we may take it for granted that the climate is always moderately humid. Where there is a large proportion of Ferns, as in New Zealand, an almost constantly humid atmosphere must prevail. In other temperate and sub-tropical regions, where rainfall is periodic, there is, according to the quantity and frequency of rainfall, and the duration of the rainy season, &c., a vegetation consisting mainly of bulbous-rooted plants and succulent plants, as in some districts in South Africa; or an almost exclusively woody vegetation, as in some parts of Australia; or a large number of annual plants, as in the Californian region. As soon as the rains begin, the seeds of annuals will germinate, and, with increasing heat, quickly grow, produce flowers, ripen seeds, and die. Succulent plants and bulbs as rapidly develop their flowers. In countries where the vegetation is of a mixed character the different classes of plants are subject to much the same conditions, as they vegetate at different seasons of the year. In unusually dry seasons many perennials become annuals, that is to say, they ripen seed and are scorched up; but the seed, being able to withstand the drought and heat, lies dormant until the rains come, to repeat the same process should the drought again kill the plants. In this way a perennial plant may gradually become of annual duration, or rather, to more exactly define its nature, flower only once. A change of climate, whether to a moister or dryer condition, heat remaining the same, would favour certain elements of the existing flora, and at the same time act unfavourably on the development of other elements, causing a corresponding change in the general character of the vegetation. This brings us to a clearer perception of the reason why many wild plants are often found in regions which are now not the most suitable to their perfect development, and why

GEOGRAPHICAL DISTRIBUTION OF GARDEN PLANTS: VEGETATION IN THE PHILIPPINES.

similar regions, differing only as to the amount of moisture, exhibit a totally different kind of vegetation. We see, too, that it is possible for a plant normally perennial to become monocarpic, or once-flowering, if the exigencies of climate require it. On the other hand, some plants that are monocarpic in their native countries become perennial, or polycarpic, under cultivation. In excessively dry climates the plants are either succulents, and do not readily part with their water by evaporation, or they are hard-leaved, like *Cycads*, *Dasylirops*, &c. Most Palms are hard-leaved plants, and, as a general rule, they may be said to be able to flourish in a dry atmosphere, but they must have plenty of water within reach of the roots. A forcible illustration of this constitutional peculiarity is offered by the Date Palm of the oases in North Africa, and the Dou Palm in Upper Egypt. How far plants may in time become modified by climate we can only conjecture, but the kind of change indicated is known to take place. On the other hand, if plants undergo any alteration in constitution in respect of their power to bear a greater degree of cold without injury, the process must be extremely slow, because, as has already been observed, the Potato, which has been in cultivation nearly three centuries, is not appreciably harder now than when first introduced, or than when it has been re-introduced. A modifying condition not to be lost sight of in countries subjected to intense cold during the winter is the presence of a more or less thick layer of snow, completely sheltering herbaceous and dwarf woody vegetation as well as the roots of trees, and the larger shrubs. This snow is a great protection to plants from the severe and prolonged frosts of continental places, even in a much lower latitude than London. Occasionally there is what is termed a black frost, that is frost without snow, which proves very disastrous to plant life. Dry litter is a very good substitute around the roots of choice shrubs, &c., and for covering dwarf plants during sharp frosts, but it should be removed when the frost breaks, where it is likely to cause damage in decomposition. Climate, being so potential in all that appertains to plant life, determines the nature of man's food to a great extent, in so far as it depends upon the plants that will succeed in any given country. It is true, one may live upon Rice in this country, and almost as cheaply as upon Wheat, though it is the product of a warmer climate. But, notwithstanding our being able to obtain the vegetable food of other climes, we subsist largely upon the produce of our native soil; and this, broadly speaking, obtains in all countries. With regard to beverages, however, we find a large foreign element, the English drinking Tea, the French Coffee, and so on; and these are brought from the most distant countries. Already under each region something has been said respecting the principal Bread plants; and it remains to point out the extraordinary extent to which the cultivation of these plants by man has modified the whole physiognomy of the vegetation of thickly-populated countries. Vast forests have disappeared, bogs have been drained, pasture land ploughed up, and many other things done to destroy the indigenous flora, and alter the climate. Some of these operations have proved of the highest benefit to mankind, whilst others have worked prejudicially, especially the indiscriminate destruction of the forests. If clearing the ground of trees over large expanses of country does not directly influence the rainfall, there is no doubt that, in the absence of trees, the rain quickly dries up, and immense tracts of fertile country have been transformed into barren deserts through the thoughtless acts of man. Now every wise government takes precautions for the preservation of forests; not alone to prevent land from becoming a waste, perhaps, because the supply of timber is another serious question. In countries enjoying a naturally humid climate all the year round, as the United Kingdom and New Zealand, no such danger exists; or if it exist, it is in a modified degree. It is in continental regions, where long periods of drought are not uninfrequent, and, where possibly trees exercise a direct influence on the rainfall, that deforesting has brought such direful consequences. In conclusion, a word to gardeners against attempting to imitate climate too closely; because, after all, it can only be imperfectly done under artificial conditions, and because the natural conditions under which plants are found growing are not always the most advantageous. Proof of this may be found in almost

any well cultivated garden, where we can see, both out-of-doors and under glass, such a luxuriant development and profusion of flowers as never or rarely occurs in Nature. Of course, we must not lose sight of the fact that plants under cultivation are altogether relieved from the struggle for existence to which they are subjected in their native habitats. Another reason why failure is almost certain to attend servile imitations of natural conditions is that light, one of the principal conditions, is wholly beyond our control—that is to say, we cannot provide the intense light many of our cultivated plants enjoy in their native countries, though heat and shade are within our reach. From what has preceded, it is clear that it does not necessarily follow that the gardener who knows most of the distribution of plants, and the conditions under which they grow in their native habitats, will be the best cultivator. Indeed this knowledge, employed without intelligence and reflection, may lead him astray. In spite of all the theoretical knowledge a man may possess, he cannot dispense with practical experience; and if he attempt it, he will probably undergo the mortification of seeing himself beaten as a cultivator by a rival who, mayhap, can neither read nor write, but who has observant eyes, and watches his plants so closely, that the slightest changes in their health for the better or the worse do not escape him; and thus he is able to modify his treatment according to circumstances.

W. B. HEMSLEY.

#### THE LINNEAN HERBARIAN AT BURLINGTON HOUSE.

THE one hundredth anniversary of the death of Linnæus was celebrated the other day at several places in Sweden. He died on the 10th of January, 1778. The occasion is an appropriate one to refer to the present condition of the relics of the great naturalist which Eogland guards. We have in London his herbarium, his collection of insects and shells, his library, and some few of his MSS. When Linnæus died his natural history collections and library passed to his son, who succeeded him as Professor of Botany of Upsala. The younger Linnæus died in 1783, and they then reverted to his widow. She wished to sell them, and referred the matter to Dr. Aroel, professor of medicine at Upsala, who wrote to Engelhart, who was then in London, and they were offered to Sir Joseph Banks for £1000. Sir Joseph was not disposed to purchase, but he named the offer to Dr. James E. Smith when at breakfast one morning, and recommended him to become the owner. Dr. Smith, who had recently completed his course at Edinburgh wrote to his father asking for the money to make the purchase. The letter is dated December 24, 1783, and the letter, interchanged, as printed by Lady Smith show that the request was not acceded to without some importunity. After some correspondence with Dr. Aroel, the sum agreed on for the whole collections and library, excepting a small collection for Baron Alstromer, was £300. Just as they were being despatched, the King, who had been away, heard of the arrangement, and endeavoured to have the collections retained in the kingdom, but he was too late. It is recorded that he gave instructions for stopping the ship that was conveying the collections to England, and there was even an engraving made showing the war ship chasing the other in mid-sea. This is supposed to be a myth, but, so far as we can find, no one seems to know what really took place. The important fact, however, was, that the collections did reach London, and up to the time of Dr. Smith's death, they remained his property. He died on March 17, 1823. During the time he had the collections he added to the insects and shells, but the plants, fortunately, were hardly touched. It was found by his will that the whole, with some of his own collections, were to be offered to the Linnæan Society of London for the sum of £3000. He had been for so many years President of the Society, that it was thought by many that he would have bequeathed them, but as he had not done so, and as the further conditions were that, if the Society did not purchase them, they were to be offered elsewhere, it was felt that an effort must be made to raise the money, or the collections might again pass out of the country. An appeal to the Government was made in vain. By May 24, however, £1593 8s. was raised by voluntary contribution among the Fellows of the Society, and the rest of the money was obtained on loan, and so the collections passed into the hands of the Society. The herbarium was some time ago catalogued by Mr. Kippist, according to the orders adopted by Linnæus. There are 1292 genera, illustrated by 13,737 sheets of mounted specimens. The paper is the same as that on which Linnæus mounted them, and the names are in his own handwriting. They are in the three tall wooden cases in which they were originally arranged, and

are all in good preservation. Together with the collection of shells and insects and the library, they are now in the meeting-room of the Society at Burlington House, and they are thus kept apart from the general collections of the Society. At the British Museum there are two collections which he used in working, but which, however, were not his own.

## THE INDOOR GARDEN.

### CONTINUOUS FLOWERING OF THE BOUGAINVILLEA.

THOUGH many now grow and flower this climber successfully, I am of opinion that the majority who attempt its culture fail. One reason for thinking so is, that, although one often sees the plant in gardens, it is an exceptional circumstance to see it in flower, and rarer still to see it flowering anything like so well as it ought, and can easily be made to do. Another reason is, that having had the plant flowering in unusual profusion from March till near the end of November during the last two years, I have had inquiries innumerable from proprietors of gardens who have not succeeded in flowering it as to the cause of my success. I take it, therefore, that an account of our mode of culture will probably meet the wants of some of your readers who have hitherto been unsuccessful. It is a plant that is worth all the pains that one can bestow upon it, for I do not think that for the warm conservatory or intermediate house a more useful subject can be grown. Although the Bougainvillea may be flowered by what may be termed the starvation process, which consists in withholding water from it some six months in the year, and giving it as little as possible during the other six, I have no hesitation in saying that such treatment is not only unnecessary but wrong; and so also is the practice of using the knife to the shoots, either with the object of shortening them or thinning them out. A little consideration as to the habits and wants of the plant might at once suggest the method of culture likely to succeed; but the three facts which it is of most importance to keep in view are, that it enjoys a tolerably high temperature during the season of growth, abundance of light, and, above all, that it flowers at the extremities of the shoots only—the shoots ceasing to produce leaves, and simply running out into long wreaths of flowers. A fourth point to be observed is that the plant should not have too much root room; but this is entirely a question having reference to the room allowed for the extension of the branches. If a large plant is wanted, a big pot or tub must be allowed for the roots, and *vice versa*. When we first set about flowering it methodically, these were the rules adhered to; but in other respects the plant was treated on anything but the starvation principle. We treated it, in fact, exactly as we do our Peaches—rushed it up into a tree as soon as possible, and into bloom by simply letting it expend its energies in growth. A beginning was made with a tolerably large plant in a 9-in. pot, and which had hardly ever produced a flower previously. This plant was shifted into a 20-in. pot in January, and potted in good strong loam, mixed with a little leaf-mould and peat, and a good sprinkling of Standen's manure. After potting, the plant was placed in an intermediate house, and the pot plunged in the bed where there was little or no bottom-heat; the branches, which had been pruned in as bare as a walking-stick, were simply laid on a few strands of wire under the apex of the roof and tied in one or two places to keep them from shifting; and this was all the tying and training the plant received during the next eight months. The roots were freely watered, like the rest of the plants in the house, and soon the bare stems burst into a very profuse growth, which was not allowed to be thinned or meddled with in any way. The result was that the large pot was filled with roots in a very short time, and by May every shoot was freely coming into flower, and very soon the whole plant was a sheet of mauve—the flowers appearing to be more numerous than the leaves. By September the shoots had nearly run themselves out of flower; but the copious supplies of water at the root were continued, with occasionally strong doses of liquid manure, and the shoots broke back behind the bracts, flowered again immediately, and continued to blossom till November, when the plant was again pruned close

in, and allowed to go nearly dry at the root. It, however, broke into growth again immediately; but, being kept dry and rather cool, the young shoots did not make above 6 in. or 7 in. of growth during the winter, and they were not disturbed. To have seen the plant so green at midwinter and unripe-like, many would have entertained little hopes of it flowering the next year, but we had no fear on that point. When February came round, about 4 in. of the top soil in the pot was removed, and a rich top-dressing given; and again copious waterings were begun, which were not discontinued till the middle of November last, when the branches were again shorn in close as before; in other respects it was treated in exactly the same way as last year, and it began to flower in March, and had still quantities of bloom upon it when cut back. During all that period it flowered most profusely, and produced three distinct sets of bloom; the third it was not allowed to finish. It may be stated that the variety is *B. glabra*, but *B. speciosa* yields to the same treatment, only, being a stronger grower, it needs more room. For most positions the former is to be recommended. In both the flowers are best coloured when they have plenty of air and light. Early in the spring they are rather pale, and they are the same in October and November. CHRS.

**Begonia manicata in Winter.**—How is it that this good old Begonia is not much more grown than it is? It cannot be said that it is useless for winter blooming; for what is there that looks better than a few dozens of this plant grouped together at this time of the year? Plants of it can be grown in 3-in. pots that will produce seven or eight spikes of flower, or they may be had in 6-in. pots with from twelve to eighteen spikes. I have some dozens of it, and I find it to be very useful. Its flowers are fit for bouquets, both button-hole and others. Gas does not seem to affect them; the foliage, too, is by no means unsightly; I would therefore recommend this Begonia to be grown more extensively than it is, particularly for winter decoration.—JOHN CLEWS, *Headfort Gardens, Co. Meath*.

**Forcing Lilacs in Darkness.**—During the autumn and winter months it not unfrequently happens that in plantations that are being remodelled and replanted, or even thinned out, there are scores of old Lilac trees consigned to the rubbish-heap as worthless and worn-out. This is to be regretted, because they may be used for forcing purposes. All that is wanted is four brick walls and a roof of thatched hurdles. Such a place, however, should be well heated, in order that there may be no difficulty in raising the temperature to 100°; if required. This is all the more necessary if vegetation be in an advanced state; the main object is to get the flowers before a single leaf appears. In renovating some shrubberies last autumn, we selected a few of the best old stools, and to-day (Jan. 16) one of these bushes is literally white with lovely sweet-smelling flowers. Springing ought to be discontinued as the flower-pips become prominent, but their expansion may be hastened by steaming the pipes occasionally. When the flower-buds are pushing forward next month, if good strong branches well set with them be cut and put into bottles of water and forced sharply, a moderate supply of flowers may be obtained, but of course not nearly so fine as they would be if they were not severed from the roots. I filled an ordinary-sized flower-basket last year from one bush, a great relief at times when there is an unusual demand for out flowers, and when it is remembered, also, that two or three sprays will scent a whole room for days. Old plants that occupy good situations, and that are fully exposed to sun and light, with all weakly shoots thinned out, thus concentrating the sap into fewer branches, will answer best, and produce the largest bunches of flowers.—W. HINDS, *Otterspool*.

### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Tree Carnations.**—A large collection of these is now finely in flower in the Royal Exotic Nursery, Chelsea. Among the best of them may be mentioned—Diana, rosy-pink; Vulcan, scarlet flaked; Mons. Baldwin, rich dark scarlet; La Belle, white; Garibaldi, rosy crimson; and the old but still valuable, Miss Jolliffe.

**Forcing the Lily of the Valley.**—This is forced in the Old Nurseries, Chesham, as follows:—A long trough of wood is fixed over the hot-water pipes in one of the houses. It is about 4 in. or 5 in. in depth, and is filled with Cocoa-nut fibre, in which the roots are placed, and covered with a board until they start into growth. When the boards are removed, the plants then quickly shoot up into bloom, and are pricked out into pots. In this manner a good supply for sale has been obtained ever since the first week in December.—J. F.

**Two New Clematises.**—Seeing the pitch of perfection which the genus *Clematis* has reached, it savours of boldness, if not of temerity, to introduce two new forms to the world, except on the ground of their great merit. Such, however, is the case; and we shall therefore proceed to describe them. The "battens" of the flowers are very large, villous, and pointed; the petals of the flowers, which are abundant, are very regular, curving back and forming a dorsal disc, which often reaches  $8\frac{1}{2}$  in. in diameter. The petals are thick, and are of a beautiful lilac-violet, with metallic reflections at the top, passing into a brighter lilac, but never becoming whitish. The name of Madame Emile Sorbet has been given to this variety, which, along with the one to be described presently, was obtained from the seeds of *Clematis lanuginosa*, by M. L. Paillet, who has just introduced these two new flowers into the market. The second, which has been called the Duchesse de Cambrères, has flowers nearly as large as the one already described, of which it possesses the vigour

## PLATE CXII.

## IRIS VICTORINE.

Drawn by A. McFARLANE.

OUR plate this week shows a variety of the common hardy Iris, a lovely and easily grown plant, just as precious for the garden as the most costly Orchid. It is as easily grown as the common German Iris, attaining, however, the greatest perfection in sandy, rich, moist soils; in such it grows from  $2\frac{1}{2}$  ft. to over 3 ft. high, and produces abundance of flowers, which are strikingly beautiful. Such plants need not necessarily be grown for the embellishment of the mixed border alone, inasmuch as they are easily grouped with other plants in such a manner that when not in flower no blank will be noticeable, as

Geographical Distribution of Garden Plants: Vegetation in the South Sea Islands (see p. 75).

and the general appearance. Its petals, however, are not so thick, and more elongated, so that the point in the centre of the disc is longer and thinner. The graceful arrangement of the points of the petals gives the flowers a peculiar appearance of lightness. The petals themselves are of a beautiful azure-blue, with rosy reflections, which produce a charming effect. Like the preceding, it is a plant of great value. It is hardly necessary to say that these two varieties are not injured by cold, and that they keep in bloom for a long time, as these are well-known characteristics for most of the members of the lanuginosa group, while they are pretty free-growing. These two Clematises may be obtained of M. Paillet, horticulturist, of Châtenay-lès-Sceaux (Seine).—"Revue Horticole."

**Rogiera cordata.**—This is one of the best of winter-flowering stove plants. Even in 4-in. pots it never fails to produce flowers, which are not only effective on the plant, but most useful in a cut state.

is the case in the mixed border. Such Irises, for instance, might be advantageously grouped with Lilies, or amongst low and choice shrubs, above which the flowers would show themselves, or they might be isolated in the shape of little tufts near water or rockwork. The variety now figured has been so much in demand, that it has never become very common in nurseries, but still it is not difficult to obtain. It was raised, we believe, or sent out by the late Mr. Salter, of Hammersmith, but it may now be found in all nurseries in which collections of hardy herbaceous plants are grown.

**Scilla sibirica.**—A great quantity of this spring-flowering Squill is now in Covent Garden, where it is sent by Mr. Herbert, of Richmond. Ten plants of it are grown in a 3-in. pot, a plan found to be very convenient for purposes of decoration.

THE IRISES

## TREES AND SHRUBS.

## TRANSPLANTING TREES.

(Continued from page 62.)

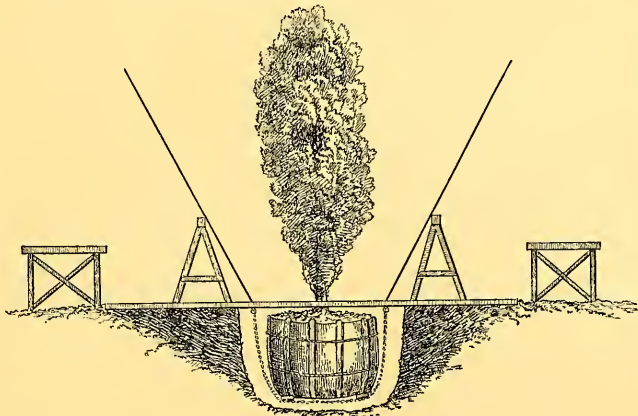

In order to facilitate lifting without the aid of hand-spokes, various systems and forms of machinery, as well as transplanting apparatus, are now employed. Amongst these, perhaps, the most simple form is the lever. After the ball has been prepared with canvas, staves, and rack-ropes, as formerly described, strong lifting-boards are placed below it; but instead of lifting-ropes, a doubled chain is put under them, keeping the entire portion at one side and fixing the two ends together on the opposite side. A rope is generally put round the ball, thus fixing the chains, and keeping them a little way apart. Two strong tressels, each a little higher than the depth of the pit, are placed on stout planks, one at each side of the ball, so that the feet of the tressels will rest upon them. Stools are also required, one at each side, for the operators to stand on. Two levers made of stout iron or wood, with iron placed along each side, are then brought into use, each being provided at one end with a strong hook, which is placed in the chain at each side. When the plant is raised to the proper level, which ought to be done at the first lift, provided the

fulcrum is of sufficient height, planks are put under the ball, with their ends resting on the cross planks first put down, and on these the ball may be rested. By lowering the chains and raising the planks a new lift can be taken, which will enable the ball to be raised sufficiently high to allow a low-wheeled machine to be run under it for transmission.

When the plant has been taken to the pit intended for it, the planks and tressels are arranged as before, the plant is lowered into the hole, and finally finished off. Where much transplanting

of this kind is carried on, it is necessary to have tressels of various heights always at hand. The transplanting machines which we employ for shrubs and trees, the balls of which are larger than those generally lifted with hand-spokes, are those known as the McNab transplanting machine. The first machine of this kind was originally invented by my late father, and although upwards of forty-five years old, it is still in active operation. These machines may be made of various sizes. No. 1, to lift balls 2 ft. 7 in. broad, 2 ft. 8 in. long, and 2 ft. 7 in. in depth; No. 2, to lift balls 3 ft. 5 in. broad, 3 ft. 7 in. long, and 2 ft. 9 in. in depth; No. 3, to lift balls 3½ ft. broad, 4 ft. long, and 3 ft. in depth. By these machines shrubs or trees weighing from 18 cwt. to 30 cwt., after being prepared, can be raised, conveyed, and planted without being subjected to any undue stress or even the possibility of injury. A small machine of this kind weighs about 8½ cwt., and is constructed of a strong frame of wood and iron, supported on wheels, with two windlass rollers in front and two at the back, the back rollers being so arranged that they may be taken off, to enable the machine completely to enclose the plant to be operated on. To show how this method of transplanting is performed, and to follow it through all the stages, we shall take, for example, a shrub 18 ft. in height, and the branches 16 ft. or 18 ft. in circumference. The first operation is to tie in all the lower branches together with a piece of soft rope or yarn, keeping them as close as

possible, and thus preventing them from interfering with the work while in progress. It is necessary, before tying up, to attach a mark on the best side of the shrub, or what is intended to be the front after planting; by so doing, it will save a good deal of trouble after the plant has been lowered into the pit prepared for its reception. The machine (No. 2) is capable of taking in a ball of earth with roots 3 ft. 7 in. long, 3 ft. 5 in. wide, and 2 ft. 9 in. deep. In every case it is necessary to be careful not to exceed this width, making allowance for the thickness of the canvas and staves to be employed round the roots. The preparation of the ball, viz., opening up, surrounding it with canvas, staves, and racking the whole together, is much the same, although on a larger scale as that described for the ordinary rack system for hand-spoke lifting; care, however, must be taken not to put any of the staves or rack-pins at the sides of the ball, as they are apt to prevent it from coming freely up between the wheels during the process of lifting, the frame being at this particular point ½ in. narrower than any other part of it. After the undermining has been carried through, the lifting-boards, four in number, the two outer ones being made of strong Oak, 1½ in. thick, curved in the middle, with a grooved recess on the under side at each end within 3 in. of the points for receiving and keeping the lifting-ropes in their proper places, are introduced. If the ball

Transplanting by means of Levers.

to be raised be compact and firm, the two Oak lifting-boards may be sufficient, but if the ball is inclined to be soft below, it is necessary first to introduce a piece of deal the same length as the lifting-boards in case it has to be left under the plant, as the removal of it in some instances is apt to injure the ball. The lifting-ropes, made expressly for each machine, are now put under the ends of the lifting-boards, one on each side, the centre or middle of each rope being placed in the centre of the ball, taking care that the rope is directly under the grooves of the lifting-boards. The ropes for the machine now under notice are 60 ft. long and 1½ in. in diameter. After being placed, fix in some soil to keep the bottom boards and the ropes securely in their places. The next operation is to lay two strong planks, one on each side of the plant. They must be laid perfectly level and parallel with each other, keeping them as low as the ground will admit of. The machine being at hand, remove the back binding-bar and the two rollers; then run the machine on the planks till the centre of the machine is exactly at the centre of the plant; replace the two back rollers and binding-bar, and secure the wheels with stones or wedges; likewise place a piece of board across the planks in front for the feet of the machine to rest on; next bring up the ends of the lifting-ropes over the rollers. This part of the work requires a little nicety, as the ends of each rope must be done exactly in the same way. The rope is first brought up and over the top of the inmost roller three times, winding it always towards the centre of the roller; then take it over the top of the outer roller, and work it also towards the centre, where hooks are placed for fixing the ends of the ropes on, each rope being previously supplied with suitable strings for the purpose. All the ropes being similarly adjusted, the plant is now ready for lifting and removal. The foregoing operation is easily accomplished with two men, but the lifting and removal require more; this,

however, depends on the size and weight of the plant to be raised; a moderate-sized ball, say 15 cwt., can be lifted by six men, but if larger, say 18 cwt., eight men will be required. If the tree or shrub is very tall, it will be desirable to have two guy ropes to steady the top and keep it perpendicular during the lifting and transmission. Each roller is provided with a cross-wheeled handle, and the outer rollers have a series of iron-bound holes pierced through them. By means of two round iron levers and the wheeled handles, the plant is easily wound up both back and front at the same time. The strong crank catches at each end of the inner rollers prevent the possibility of the plant running down, and secure it firmly at every turn when re-adjusting the levers. After the plant has been raised high enough to clear the bottom of the wheels, the levers can then be pushed through the holes so as to rest either on the inner roller or binding-bar; this will

before, and arrange the men as at the lifting, one always being employed to press down the machine handles. After taking off the strain sufficient to remove the four crank catches, lower gently into the pit by holding back the handles and levers. If the pit is found to be too deep, raise, and put in some soil, and then lower again. When properly placed, undo all the ropes, and take off the two back rollers and binding-bar, and remove the machine. Immediately the machine is withdrawn from the plant, but before it is finally taken off the planks, put on the two rollers and binding-bar, to prevent the possibility of twisting the machine by taking it upon uneven ground. The machine and planks being removed, withdraw the two lifting-ropes, which will be easily done, owing to the curve on the bottom of the lifting-boards. The bottom boards can also be taken out by a slight leaning either to the one side or the other, placing at the same time a little earth below to keep the plant in its upright position. If attention has been paid to mark the best side previous to the first tying up of the branches, the plant can be easily turned, so that the best part shall face any particular side; if this has not been done, it is necessary to loosen down the whole top, so as properly to adjust it—that, however, is very inconvenient till such time as the plant has been filled in and watered. After the plant has been properly secured in its upright position, take care to have the soil firmly fixed below the bottom of the ball all round, to prevent it sinking down on any one side after the water has been applied; next remove the rack pins and binding-ropes, staves, and canvas, loosen out all the roots, and fill in with prepared soil, taking care to adjust the roots in a horizontal manner while filling in; afterwards prepare a basin round it to retain water. In all cases apply water freely, but more particularly with summer transplants. After the branches have been loosened down, syringe freely if the weather be dry, and cover the surface of the ground under the branches with fresh-cut Grass to prevent the surface of the soil from drying up. In the case of summer-transplanted trees and evergreens, it is a good plan to roll some Hypnum or Sphagnum Moss round the stems and chief branches, as it assists in keeping the bark moist. I may state that these machines are in constant use here, and are employed with complete success, not only for tree-transplanting purposes, but for moving large and heavy plant tubs, such as Palms, Oranges, and Camellias, from one place to another, bottom boards and ropes being put first below, and afterwards worked as described for moving large trees. JAMES McNAB.

(To be continued.)

M'Nab's Transplanting Machine.

doubly secure the plant, and hold it tight in its position, till such time as it is conveyed to its destination. If the plant has to be taken over clean gravel walks, it is necessary to put a piece of canvas under the ball to prevent any loose earth from falling. If the distance for removal is not great, it can easily be taken along by the men employed in the lifting, but if the distance is considerable, the most convenient way will be to attach a horse and draw it backwards, taking with it, if necessary, the two planks, foot-board, and cog-wedges. If many removals are going on, it is desirable to keep a double set of planks and foot-boards. The hole for its reception being prepared, in all cases taking care that it is not less than 3 ft. beyond the diameter of the ball to be put in, place over it the two planks, adjusting them to the width of the wheels, then run the machine with the plant backwards upon it, till right over the centre of the hole, place the cog-wedges to the wheels, and adjust the foot-board as

#### NOTES AND QUESTIONS ON TREES AND SHRUBS

**A Large Ostrya.**—An unusually large specimen of *Ostrya virginica* is recorded in the "American Naturalist" for November. The girth of the stem at the ground was 9 ft. 11 in., at 4 ft. from the ground 7 ft. 2 in., height to first branches 6 ft. 4 in., spread of branches from east to west 47 ft., from north to south 45 ft., height of tree 43 ft. 7 in.

**Fructification of the Persian Lilac.**—Speaking some time ago, says the "Revue Horticole," on the subject of the *Yariv* Lilac, which has been stated to be sterile, we announced that, contrary to this opinion, we had gathered over 2000 fruits. We now have to inform our readers from another species which has hitherto been looked on as sterile, the Persian Lilac with lacinated leaves (*Syringa persica laciniata*), we have gathered 800 fruits, the seeds from which have been sown. It remains to be seen what they will produce.

**Influence of Trees on Moisture.**—M. Faurel has made observations in French forests, to determine the influence of trees on the distribution of rain and moisture. He finds that forests receive more rain than open plains, and Pines more than leafy trees. Pines retain more than half of the water that is precipitated upon them, while leafy trees allow 58 per cent. to reach the ground. Pines, therefore, furnish the best shield against sudden inundations, and the best means for giving freshness and humidity to a climate such as that of Algiers.

**Grafted Conifers.**—In the January number of the "Journal of Forestry" the practice of grafting Conifers is defended on the ground that there is no other way of getting up a stock of certain kinds except by grafting, and that the objections that formerly had force have been abolished by the adoption of better modes of procedure than prevailed in the early days of the practice. The avenues of the glaucous variety of *Picea nobilis* at Castle Kennedy are referred to as evidence in favour of grafting. "All these splendid trees, ranging up to 50 ft. in height, are grafted plants 'worked' by Mr. Fowler, who for many years has been gardener there to the Earls of Sutherland."

## THE FLOWER GARDEN.

### MY TOWN GARDEN.

IN addition to the hardy border plants mentioned in my last (see p. 6), I propose now to describe a few that would make a very ornamental round bed. The idea was borrowed by me a few years ago from a very useful work entitled "Hardy Flowers." At page 12 of that work the author says:—"First, then, for a noble circular bed in an isolated place, say on some little glade of Grass where there is a recess in a shrubbery, and where you perhaps never thought of putting anything. Have the bed thoroughly well prepared in the first instance, say 8 ft., 10 ft., or 12 ft. wide, according to the size of your place, or the nook in which you plant. What I mean by well prepared is, that the soil should be rich, free, well drained, and 3 ft. deep, if possible. Place a good plant of the very tall and late-flowering *Tritoma grandis* in the middle, and then around it a circle of the excellent and somewhat smaller *T. glaucescens*. Follow that with a ring of the beautiful white *Anemone Honorine Jobert* and the showy *Rudbeckia Newmanni*; mixed plant for plant; and outside of that again place a circle of the fine herbaceous *Sedum spectabile* (sold and known as *S. Fabaria*). This *Sedum* will form a grand edge to the bed, and flowers, like its companions, finely in the autumn. The above would form a grand autumnal bed, and a noble object from any point of view, its aspect all through the spring and early summer being fresh, healthy, and in every way unobjectionable."

The *Tritomas* mentioned above are valuable plants for various purposes. *T. grandis* is the finest variety, producing very strong flower-stems, which sometimes attain a height of 7 ft., and which are densely clothed for about two-thirds of their length with bright orange and red tubular-shaped flowers. The flowering season commences in September, and in mild winters continues until January. Its style of growth and gorgeous colouring are grand and unique. They require heavy drenchings of water during summer and autumn, and prefer light, rich, sandy loam, or peat and loam, well drained. *T. glaucescens*, sold as *T. Uvaria glaucescens*, is also a fine variety, in all respects similar to the preceding, except that it produces shorter flower-stems, and flowers in August, September, and October. The scape, when luxuriant, attains a height of 4 ft. or more. The colour of the leaves is glaucous, and the edges and keel are rough from short bristles.

*Anemone Honorine Jobert*, sold by some as *A. japonica alba*, and also as *A. vitifolia*, is a distinct and beautiful variety; its flowers, which measure  $2\frac{1}{2}$  in. in diameter, are pure white with golden centres, and they are borne in great profusion from August to December. The height of the plant is from 2 ft. to  $2\frac{1}{2}$  ft.; in habit it is neat and compact. I have had it in full flower at Christmas, and recommend it to be cultivated in quantity where large supplies of cut flowers are required late in autumn and early in winter. It is, indeed, one of the grandest ornaments which a garden can possess.

*Rudbeckia Newmanni* is a very desirable plant. Its flowers are rich orange-yellow, with conspicuous, velvety, maroon centres; the flowers, individually, are from 3 in. to 4 in. in diameter, and are borne in dense masses, in great profusion, from early in August to late in October. The height of the plant is from 2 ft. to  $2\frac{1}{2}$  ft., and its habit is neat and compact. It is easily cultivated, flourishing in any ordinary garden soil, but succeeding best in that which is moderately rich, light, and well drained.

*Sedum spectabile*, sold also as *S. Fabaria*, is an erect-growing plant, with stout stems, from 1 ft. to 18 in. high, furnished with broad oval leaves, glaucous and toothed, and standing horizontally on the stems. The flowers, which are rosy-purple, are produced in dense, broad corymbs in September and October. This is the handsomest of the tall-growing species, and is worthy of a place in the choicest collection of hardy plants, being very distinct and beautiful. In the flower garden it may be usefully employed in many ways, either for breaking the uniformity of large, flat surfaces, or for centres to small beds; and where the style is formal and severe, its rigid aspect will be found to harmonise well with the surroundings. For this purpose the plant is best divided annually into single crowns early in spring. Indeed, all the plants mentioned as

forming the round bed just alluded to increase so rapidly, that if all were taken up in two or three years, and divided into crowns, there would be enough to stock many such beds, or for general purposes. *Sedum spectabile* alone will increase in three years from a single crown to between 200 and 300 crowns. The plants, too, before they begin to bloom have all a refreshing green appearance, the leaves of the *Sedum* being large, fleshy, smooth, and very glaucous or greyish-green.

As an outside edging to the round bed in question, I have sometimes used, with good effect, the popular little *Pyrethrum* known as *Golden Feather*. A pennyworth of seeds sown in a shallow drill, formed round the outside of the *Sedums* with the point of a stick, would be sufficient for several beds. As the plants come up they could be thinned out to 2 in. or 3 in. apart, and the spare ones used for other purposes.

L. E. X.

### POTTING AND TRANSPLANTING LILIES.

I HAVE read "Dunedin's" remarks on Lilies with interest, and I quite agree with him as regards the importance of transplanting them annually. But although he positively asserts that Lily bulbs do not suffer from being cut down in full bloom, will he go so far as to recommend such a course as being likely to assist the perfect maturation of the succeeding year's flower-spikes? It would, in my opinion, be difficult to fix a date on which potting or transplanting Lilies could best be done, owing to the wide range that exists as regards the period at which they flower; for instance, *Lilium auratum* may frequently be had in bloom from early in summer till late in autumn. Is it not, therefore, safer to postpone the period for potting or transplanting until after blooming, as soon as the leaves are faded, when, in my opinion, the sooner these operations are done the better, as the bulbs soon commence to root afresh, and the fibres, being very brittle, are very easily injured. In the case of the finest collection of Lilies in pots with which I am acquainted, including all the lancifolium section, they were annually shaken out of their pots as soon as the tops decayed; the bulbs were then sorted into different sizes, to insure regularity as regards the size of the flower-spikes. The largest-sized bulbs were put, five together, in a 13-in. pot, well drained, and filled about half-full of fibry turf and dry cow, sheep, or deer manure, that had been baked in an oven to kill all insects. The second-sized bulbs were planted in 10-in. and 6-in. pots, and the small ones were planted out in well-prepared beds. The pots were then stacked in a cool shed until growth had commenced in spring, when they were transferred to cold pits, and, as the summer advanced, they were set on coal-ash beds in the open air. They received rich top-dressings to encourage surface-roots, and the watering was very carefully attended to; for, although moisture-loving plants, Lilies are easily injured by stagnant water at the root. As the flowers began to expand the plants were removed to light, span-roofed houses, in which they made a fine display. They were never cut down until the foliage had faded, and when shaken out of the pots the latter were positively full of bulbs. I am well aware that bulbs of all kinds, and Lilies in particular, are not generally managed so as to increase or even retain their bulbs at all, or why the great demand that exists for imported Lilies. "Dunedin" truly remarks that we must never forget that they are grown here under purely artificial conditions; let me therefore warn your readers that as their culture in pots is more artificial than that out-of-doors, a wide range must be allowed for the transplanting season; for, in the case above referred to, the potting could not have been done before November, as many of them were in bloom up to that period.

JAMES GROOM.

*Henham.*

**Iris (Xiphium) Kolpakowskiana.**—In the autumn, Dr. Regel kindly sent me two bulbs of this beautiful species. They were crushed nearly flat in the post, and I had little hope that they would live; some bulbs of *Crocus atlavicus*, which accompanied them, were utterly smashed. I planted the Iris bulbs in prepared charcoal, an excellent restorative for injured or mildewed bulbs, and one of them has recovered sufficiently to flower. It is, I believe, a native of Turkestan. It is a very distinct and lovely species, and a

meet companion for its beautiful and near relatives, *X. Histrionicum* and *reticulatum*. The leaves, as far as I can see, are two or three in number, short, obovate, lanceolates; stem, little or none; limb, pale lilac, shaded with white; falls obovate, tapering to a sharp point; at the base, fine white; tips, bright lilac; keel, bright yellow; feathered with lilac towards the base; standards and claws pale lilac, minutely flecked with white, giving the appearance of reticulation; bulb somewhat resembling that of *X. reticulatum*. It flowered in a pot in a cold frame.—H. HARPUR CREWE, *Drayton, Beauchamp Rectory, Tring.*

### BRITISH FINE-FOLIAGED PLANTS.

It is a point, perhaps, worthy of the attention of the sociologist that at about the same period at which our English ladies began to find sombre greens, browns, and blacks a dress in accordance with our dull northern skies, our landscape cultivators saw large masses of subdued colour to be preferable to a mosaic of gaudiness. These large masses of subdued colour are more easily attainable in foliage than in flowers, and hence has arisen the popularity of ornamental-leaved plants. The charms of graceful outline that many of them possess when not at a distance was, no doubt, a supplementary cause.

When we analyse the beauties of English scenery, we find them to consist, speaking broadly, of undulating surfaces and wide, open valleys, alike well wooded, of round swelling downs of perennial verdure, and of broad plateaux of Heath or Furze of an orange-dusted bluish-green, or a sheet of red-purple. The Heather in bloom and Elms and Maples in autumn are, perhaps, the gayest masses of colouring which we have. It is the prevalence of deciduous trees, with their melancholy winter associations, that has created our fondness for evergreen shrubs. In the British flora itself we have, it must be confessed, but few species that can be spoken of as fine-foliaged plants. It is hardly in accordance with horticultural usage to mention under this head the beauties of our Oaks and Beeches, the dark gloss of the Spanish and Horse Chestnut; nor do we generally speak of the small greens of the border or rock-garden as "fine-foliaged plants." The Fern-like delicacy of the lesser Meadow Rue, of *Corydalis*, of *Spirea Filipendula*, or the Milfoil (*Achillea Millefolium*), the mossy tufts of *Saxifragas*, *Herniaria*, or the Alpine *Cerastium*, and the characteristic foliage of the Sandwies, the Wood Sorrel, Herb Robert, the perfoliate Yellow Wort, or the Spotted Arum or Orchids are alike rather out of the category.

I cannot pass over the beautiful water plants which we possess—the leaves of the Water Lily and their miniature the Frog-bit, the grey swords of the Yellow Iris, and the grace of the Arrow-head; but what may fairly be classed as fine-foliaged plants are of a yet different type. The largest which I have classed among them ought, perhaps, to rank as trees. These are the Mountain Ash (*Pyrus Aucuparia*), the Holly (*Ilex Aquifolium*), and the Arbutus. Each pinna of the elegant leaf of the first of these is finely toothed; "the armed and varnished leaves" of the second, as Evelyn calls them, need no commendation of mine; and of the third, I need only say that it is naturalised on the carboniferous limestone of St. Vincent's Rocks, Clifton, and might well be in some few spots elsewhere. The Box and trim Privet, next in size, are wanting in character, and pale before the glory of the Dwarf Elder (*Sambucus Ebulus*), sometimes known as Danewort, a truly noble plant, of which an illustration is given (see p. 85) which can tell more than any words of mine. It is rare in a wild state; seldom exceeds 4 ft. in height; has smooth leaves and a pink tinge to its white cymes of blossom. May we soon see it in many a garden.

After it in order of size come the well-known Spurge Laurel (*Daphne Laureola*), the silvery cut-leaved Sea Wormwood (*Artemisia maritima*), the large, but perhaps not beautiful, leaves of the Deadly Nightshade (*Atropa Belladonna*), and the two *Spireas*, the Willow-leaved (*S. salicifolia*), a handsome shrub with pink flowers, suitable for moist plantations, and the well-known Queen of the Meadows (*S. Ulmaria*). Next I would mention our twining and climbing fine-foliaged plants; first among which must come the "Ivy never seen," with its varied forms and exquisite contrasts of greens in the stalks, leaves, leaf-veins and blossoms, with tints of red and purple

and the black of its berries. Alike beautiful in habit, shape of leaf, and surface-gloss is the Black Bryony (*Tamus communis*), whose bronzed heart-shaped leaves in autumn can only be compared in elegance to the young leaves of the same plant in spring. Even more beautiful in outline, though without the glossy surface, are the leaves of the Birthwort (*Aristolochia clematitis*), whilst the Wild Hop (*Humulus Lupulus*), and White Bryony (*Bryonia dioica*) may be mentioned together as having an elegant habit and outline and a lively colouring. Lastly, we have the shining tangle of the prostrate Periwinkle (*Vinca major*). A group of composite plants next claims attention—the grand Scotch or Cotton Thistle (*Opopordum Acanthium*), a glorious plant, with the curious and effective Milk Thistle (*Silybum marianum*), with its shining, white-veined leaves, and the monstrous foliage of the Great Bur-dock (*Arctium majus*), suitable for the banks of a wood-traversing stream. The cut leaves of the Crisped Tansy (*Tanacetum vulgare* var. *crispum*), and perhaps of the Ragwort (*Senecio Jacobæa*), a coarse-growing plant, with the rough, undivided leaves of the Great Torch Mullein (*Verbascum Thapsus*), the Foxglove (*Digitalis*), and the Comfrey (*Symphytum*), and the graceful Fennel (*Foeniculum*), and some of its allied Umbellifers, such as the Carrot, deserve notice. The leaves of the Carrot are often most exquisitely tinted, and are valuable for table decoration. To this order also belongs the Sea Holly (*Eryngium maritimum*), with its glaucous spiny leaves, very unique in appearance, and not difficult to cultivate in sandy soils.

Last, but by no means least, would I write the praise of the Great Water Dock (*Rumex Hydrolapathum*), the finest of our "near-shore" plants as far as foliage is concerned. Along the banks of the Colne, near West Drayton, it may be seen in all its grandeur.

Others might have been mentioned, especially among smaller plants, such as the Wood Spurge, the Helioberis, the Musk Mallow, the Columbine, the Cyclamen, the Lungwort, the Ivy-leaved Toadflax, Solomon's Seal, the Lily of the Valley, and the little Moneywort (*Lysimachia Nummularia*), which turns to a lovely pink in autumn; but the above are, I think, the best of what we may fairly term our native fine-foliaged plants.

G. S. BOULGER.

**Chamærops Fortunei in Lincolnshire.**—I have a beautiful specimen of this hardy Palm which has been planted out here in the north-east corner of Lincolnshire for these last two years, and has had no protection except a straw band round the stem every winter. Of this plant I am very proud, for all the plants that I have seen out-of-doors have been wretched objects to look upon. As regards treatment, in the first place, it must be in a sheltered spot, where no wind can reach it. Secondly, it must be protected from snow, which breaks all the leaves. In autumn, say the end of November, I begin in the centre and tie every two leaves face to face till the whole are collected like a fan when opened out. I then take eight partite laths, tie them across front and back, making a frame for the leaves; and thus they remain until spring, when each leaf will be found perfect. This plant had eighteen leaves when tied up perfect.—J. DEANE WAITE, *Manby Rectory, Louth.*

**Plants in Flower at Newry.**—In Messrs. Rodger, McClelland, & Co.'s nursery, at Newry, a great many plants are now very fully in flower, amongst which the most noteworthy are—*Hamelis arborea*, quite covered with blossoms; *Correa cardinalis* and speciosa; *Azara dentata*, going off; *Lonicera fragrantissima*, rather later than usual, and only partially flowering; *Berberis Beali*; *Arbutus Andrachne*, the latest to flower; *Filaria angustifolia*, flowers not very showy; *Schizostylis coccinea*, one of the very best late-flowering herbaceous plants in cultivation; its spikes were injured by frost about Christmas time, but they are now recovering, and in a few days, if mild weather continue, they will be in fine condition. *Azara Gilliesii* is excellent as far as foliage is concerned; it is as green and fresh at this season as that of Ivy, and is altogether one of the most effective of the genus to which it belongs.—T. S.

**Wintering Bulbous-rooted and other Hardy Plants.**—In wet districts many of the choicest of hardy border plants perish, or become weakened at the roots, through cold; it is, therefore, necessary to provide against this by protecting the roots in some way. At the Wellington Nursery, where the soil is cold, such plants as the rosy, crimson-flowered *Brava geminiflora*, *Schizostylis coccinea*,

A BRITISH PLANT WITH FINE FOLIAGE: THE DWARF ELDER (*SAMBUCUS EBULUS*).

*Tritonia aurea*, and *Commelina cælestis* are successfully preserved by being lifted in autumn, and having their roots laid in dry soil, in cold frames or sheds. The different kinds of *Oxalis*, too, are treated in a similar manner; their bulbs have now started into growth, and if planted in March or April they will flower all through the summer. The bulbs of *Arum cornutum* and *A. maculatum* are laid in sand in a cool shed, a way in which they keep much sounder, and are more likely to grow satisfactorily than those left in the open ground, even if protected. Many more plants of similar character would be benefited by being treated in this way, and an advantage would be gained by having the ground vacant, so that it could be thoroughly dug and manured as might be required.—S.

**Imported Bulbs of *Lilium auratum*.**—For the last three years I have purchased annually four or five dozen of imported bulbs, at a cost of about 1s. each, and I can confirm the statement of Mr. Hardy (see p. 49), the accuracy of which your correspondent "Dunedin" questions as to the satisfactory results to be obtained from them. The sizes ran from 2½ in. to 3½ in. in diameter, and all grew satisfactorily, and produced from five to nine flowers from each bulb, though two bore respectively twenty-seven and thirty-eight on one stem. I made the purchases in January, and had them potted three in 9-in. pots, and placed in a cold Vinery till they started, soon after which they were put into a frame under a north wall till the inclement weather was passed. When their growth was completed they were transferred to my conservatory. Those purchased last year began to bloom in August, and the last of them is only now fading. By slightly forcing those purchased in previous years I have had continuous bloom for nine months. In the north of England I have not had satisfactory results from those planted outside.—T. B.

**Is a Lily an Annual Bulb?**—The origin of a Lily is a germ or seed-bud, we are informed; but would it not be better to trace the Lily from the seed, and follow it through its various stages up to maturity (its flowering period)? If a Lily dies annually, how is it that the bulb grows larger year by year? I hold in my hand a Lily bulb grown from seed sown last year. If this Lily were an annual, this little bulb, which is about the size of a Pea, would surely flower. But no; it will continue to grow for a few years to come, and then flower. Common sense, therefore, tells me that the Lily is a perennial. That the germ or seed-bud constitutes one of the modes of reproduction I admit, but I cannot look upon it as the origin.—H.

—"Dunedin" (see p. 27) quotes a writer in the "Journal of Horticulture" as saying, "the same bulb has thrown up a spike," &c. I suspect the writer only meant the same plant, not to express an opinion what part of the bulb produces the new year's flower. The question raised by "Dunedin" is a most interesting one to Lily growers. It seems to me that *Lilium* like *Lilium giganteum*, where the old bulb clearly dies, and *L. superbum*, where only the new bulb flowers, give facts in his favour; but *L. tenuifolium* rather points the other way. I especially noticed one bulb of this Lily when reporting it. The flower of 1876 was figured in *Elwes' "Monograph of Lilies,"* Part II., and noticed in the letterpress for the unusual number of its flowers—eleven. Last year it had thirteen flowers, and last autumn I was glad to see that the bulb had still increased in size. I have not the pleasure to know "Dunedin," or even who he is, but if there be any *Lilies* in my collection which he has not had access to, I shall be most happy to see him here next potting season, and to take up any bulbs he would like to examine.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

**Early Flowers in the Isle of Wight.**—The following is a list of flowers now growing in the open garden here without any artificial heat or attention. The following are flowering freely, viz., purple *Veronica* (in the shape of large shrubs), *Arbutus*, Bay, white Broom, *Euroyonus*, Rosemary, *Lacustrinus*, *Berberis*, yellow *Jasmine*, yellow *Alyssum*, *Roses* (of several good kinds—dark crimson, pink, and yellow Tea-scented), *Fuchsias*, *Nasturtium* (in full flower, and with leaves unharmed by frost), *Mignonette* (luxuriant, one plant being 7 ft. in circumference), *Primroses* (various kinds besides the common yellow), *Violets*, *Periwinkle* (very large and bearing numerous blooms), *Wallflowers* (several kinds), *Lavender* (in flower), red *Valerian*, *Stocks* (the Ten-week, Glove-scented, and Brompton varieties), *Virginian Stock*, *Carnations*, *Candytuft*, *Campaula pyramidalis*, *Polyanthuses* (gold-laced and other kinds), *Saponaria calabrica*, white *Rocket*, *Margold*, *Christmas Roses*, &c. *Snowdrops* are in full flower thus early (January 21). Many kinds of English Ferns are in perfection, and show no signs of dying down. I may add that in the kitchen garden we have had Marrows in open quarters without any protection; a dish of new Potatoes to-day; Mint quite 12 in. high; Parsley as fine; and Fennel 16 in. high. Broad Beans are in flower, and are 18 in. high. Most of the fruit and ornamental trees are budding.—H. W. H., *Wolberton, St. Lawrence, Isle of Wight.*

## GARDENING FOR THE WEEK.

### Greenhouses and Pits.

Take plants of *Libonias*, and keep them for a short time in a warm pit, and when root action again begins transfer them to an intermediate house. Divide the rhizomes of the variegated-leaved *Acorus javanicus*, and keep the divided portions for a time in gentle heat. From male *Aconitas* in flower gather the pollen, and keep it dry between bits of glass for future use. Start into growth, in a warm pit, tropical *Orniums*. Re-pot and start some *Hæmatanthes*; they may be placed upon the floor in a warm house or pit, or on a back shelf. When there is any appearance of frost, it is a safe practice to put on a little fire sufficiently early in the evening to get some heat into the pipes in good time. This, amongst ordinary greenhouse plants, will be beneficial, provided the temperature does not rise above 40°. Should continued frost set in be careful that the plants are not placed too near the pipes, or they will get their roots dried by the heat. *Cinerarias* and *Calceolarias*, more than most plants, cannot bear being placed in such a situation; a low pit, if such exist, is the best for these plants, where they can stand on a bed of coals, with a hot-water pipe round it to exclude frost. If a place of this description be at hand, they will make satisfactory progress, and maintain their large bottom leaves in a healthy state. *Cinerarias* do not well bear heat to bring them on, but if the seeds be sown in good time, they will come in without using a high temperature. The deliciously-scented *Daphne indica* should find a place in every collection, keeping it during the winter at the warmest end of the house, but always being careful not to overwater it. If a few plants of *Deutzia gracilis* be placed in a warm house, they will come on gradually into flower. *Rhododendrons*, *Callas*, *Trees Carnations*, *Heliotropes*, *Mignonette*, *Lily of the Valley*, *Tulips*, *Hyacinths*, *Narcisus*, *Kalmias*, *Jasmines*, *Weigelas*, *Prunus sinensis*, *Lilacs*, *Ghent* and *Indian Azaleas*, *Camellias*, *Hippæastrums*, *Violets*, *Polargoniums* of different sorts, and several other plants might be brought to the flowering stage in early fruit-houses, and afterwards removed to the greenhouse. Such as are soft-wooded should be kept as near the glass as possible, and hard-wooded deciduous plants should be placed by themselves, so that they can be freely syringed. *Violets*, if planted out in frames on a bottom-heat, afford more flowers than under any other circumstances. Proceed with the staking and tying of specimen hard-wooded plants. Keep *Heaths* in the freest ventilated portion of conservatories, water them moderately, and neatly stake them. Remove plants of *Solanum Capsicastrum* when the berries begin to drop or shrivel, and save a few of the best berries for seed. The old plants, too, may be saved for next year's fruiting, by placing them under the stages or in frames, keeping them moderately dry for a time, then pruning them back closely, and planting them outside in a rich border in April. A few of the earliest-rusted plants of *Fuchsias* and Lemon-scented *Verbenas* may be pruned a little, and started in a genial warm temperature; just give the others enough water to keep the soil from being dust-dry. A few plants of *Lilium auratum* may now be brought into an intermediate house to start; great care being taken in watering, until the shoots have emerged some inches from the soil.—T. B.

### Orchids.

The material to be used in potting Orchids should be kept under cover, for if left in the open air it becomes saturated with water, and the most important part of it, the fibre, decays. Those who have their peat out-of-doors should place some under a shed, in order that it may get dry by the time it is wanted. If very wet, it may be built up one turf wide round a shed, a space of 3 in. or 4 in. being left between each turf to facilitate the drying process. Sphagnum Moss to be kept as sweet as possible and in a living state; it should be placed on a loft over some cold, airy shed, or on some boards over the rafters. Do not press too great a bulk of Sphagnum together, otherwise it will turn sour, and when used injure the plants. Living Sphagnum Moss is in many cases a test of good culture. It has been said that if cultivators can only succeed in growing the Sphagnum, the plants potted in it will take care of themselves. The demand for Orchid flowers for the decoration of vases, ladies' hair, &c., is unusually great, and such choice varieties as *Odontoglossum Blniti*, *O. pulchellum*, *Ceoloyne cristata*, *Lælia alba*, *L. anceps*, *Angræcum sesquipedale*, *Phalenopsis grandiflora*, *Schilleriana*, and *amabilis*, and *Cattleya Trianae* should be grown in dozens. *Dendrobium heterocarpum* is one that should have a place in every collection, not on account of the beauty of its flowers so much as for its perfume. *Cattleya maxima* should be more common than it is; and if grown in the Mexican house, it is almost certain to do well. It requires little shade during summer, and will produce blooms late in autumn. *Dendrobium chrysanthum* should now be put in baskets or top-dressed, as

the case may require. It should also be supplied once a week with weak manure-water, and the young growths should be sprinkled on bright days with pure water. This species should be suspended at the warm end of the Cattleya house until it has completed its growth, when it should be placed in a house to ripen free from shade. Keep plants of *Dia grandiflora* well supplied with water after they have begun to grow; also *Odontoglossum Bluntii*, *O. Pescatori*, *Oncidium macranthum*, and *Masdevallias*, all of which should be well supplied with water, in order to keep the *Sphagnum Moss* in a free-growing state. The latter should be encouraged to cover the surface of the pots. Now is a good time to look over plants and to make a list of such as require re-potting. Great care will now be required, in order to keep up a regular temperature, which should be allowed to fall a few degrees rather than rise; less moisture should also be used.

#### Hardy Flowers, Alpine Plants, and the Wild Garden.

An herbaceous border should be situated in the pleasure-grounds, with an aspect fairly open to the sun, and not overshadowed by trees. It should be about 8 ft. wide, and backed up by a bank of evergreen shrubs. This is an important point. Even the colours of our most brilliant flowering plants are more effective when seen against a background of those varying shades of neutral tints which are available in our mixed shrubbery. There are few places where a border of this sort cannot be formed. It is by no means necessary that it should be straight; a good bold sweeping curve is, in some respects, preferable, as it reduces stiffness and formality, which, if not entirely dispensed with in an herbaceous border, should be a matter of importance. Having selected a border, the next point will be the character of the soil. If it is necessary to invade the lawn, all the better, as the majority of these plants have a liking for fresh soil; therefore, after the removal of the turf, test the drainage, and be sure that there is no danger of any part of the border becoming waterlogged; rather put in an extra drain than run any risk, and let the drains be, if possible, 3 ft. below the surface, as the roots of the plants are partial to these aerial arteries. If the soil be a strong clay, instead of removing a portion of the clay and replacing it with loam, raise the border to a height of 12 in. or 15 in. There are exceptions; but, as a rule, herbaceous plants like a tolerably stiff and retentive soil. The front of the border, where the dwarfier and more delicate-rooting plants will be placed, may require some of the sub-soil taking out, so as to secure a depth of about 12 in. above the clay bottom. This done, give a good dressing of well-decomposed manure, such as an old Mushroom-bed will furnish; an equal proportion of leaf-soil, and about a barrowful to every 6 ft. of border of old mortar or plaster from any old buildings, or the same quantity of sand. Dig over the whole to the full depth of soil, so as to thoroughly mingle the materials together; it must then be left loose till early in March, when it will be in a condition for planting. If the soil be of a light sandy nature, and lying on a gravelly sub-soil, remove a portion of the gravel by trenching, and if it be at all possible, the use of an equal amount of strong soil, incorporating this with the natural soil—adding manure of a somewhat stronger character than recommended under the previous conditions, and omitting the leaf-mould and the mortar-rubbish as unnecessary in this case. Circumstances may occur in which it may be more convenient to remove some of the shrubs, so as to obtain the necessary width of border. In this case the treatment will be different. The remarks on drainage will hold good, but the ground must be trenched at least 2 ft. deep; in the bottom of each trench, as opened, 4 in. or 5 in. of any strong manure may be placed, and as the first spit of soil is turned over on the top of the manure, it should be trodden well down, so as to give it firmness. The trenching process completed, a surface-dressing of materials, the same as those previously described, should be lightly forked in. It will be well, even though a couple of months intervene between the formation and the final planting, to tread the border well over and thoroughly consolidate it, as herbaceous plants like a firm root-hold. Light surface soil tends to surface-rooting, and thus incapacitates plants from passing unscathed through even a moderate drought.—J. C. N.

#### Trees and Shrubs.

The planting of all kinds of deciduous trees and shrubs, the buds of which are fast swelling, should now be brought to a close as soon as possible. After planting, all should receive a good mulching of half-trotter litter; and if the appearance of this be objectionable, scatter a little fine soil over it. Trees should never be planted in a hollow, but on the summit or side of hills. In such positions they always look more natural, and show off to better advantage, and help to bring out any slight undulations in the ground in the most favourable manner. If the weather continue mild, *Anonas*, *Rhododendrons*, *Box*, and plants of this kind, that always lift with good balls of earth, may be moved with comparative safety. April is a good month for transplanting evergreens, and any choice specimens

should be left till that time. The ground between rows of *Conifers* not intended to be removed this spring should be dug over, but not so as to injure the roots. A rough weeding is necessary before digging, otherwise the overturning of the soil transplants the weeds. When the layers of deciduous plants, such as *Limes*, *Planos*, *Poplars*, *Cornuses*, &c., are sufficiently rooted, they should be removed and transplanted, so as to permit of the ground being dug. Insert cuttings of deciduous trees and shrubs in sheltered places, such as in narrow borders, at the base of walls or hedges, in rows 6 in. apart, and 1 in. or thereabout between the cuttings, which should consist of last year's wood cut into pieces from 6 in. to 9 in. long. *Limes*, *Poplars*, *Elders*, *Weigelas*, *Spiræas* (such as *prunifolia*), *Ribes*, *Dentzas*, *Cornuses*, *Buddelas*, *deciduous Magnolias*, *Viburnums*, *Jasminum nudiflorum*, *Willows*, and many other plants may be increased from cuttings inserted in this way between January and March. Retain the covering of Birch branches and other material laid over beds of seedling *Rhododendrons*, *Arbutuses*, *Cotoneasters*, &c.; and should hard frosts come, give some additional covering. Transplant *Conifers* of various ages, but not so thickly as to touch one another in the rows.

#### Indoor Fruit.

In the event of severe weather setting in, it will be wiser to economise the strength of Peach and Nectarine trees than to push them on with extra fire-heat, as a little loss of time can always be made up when the weather is favourable. Continue to maintain a sweet moist growing atmosphere by means of frequent syringings, and damping all wall and border surfaces. Endeavour to admit a little fresh air every day, more or less, according to the direction of the wind; easterly winds demand caution. If the houses be close-glazed, a very little top-air may be allowed to remain on all night during the blooming period. Maintain a temperature of from 50° to 55° at night, allowing a rise of from 15° to 20° with sun-heat. Now is a good time to get in the seeds of early Melons, which should be started in a steady bottom-heat of 80°. A bed of sweetened litter and leaves should be ready in a heated pit or house, in which to plunge the seed pots. Sow in dry loam; one seed should be inserted in the centre of each pot, and covered very lightly. Place the pots on the fermenting material in the pit, and fill in between them with sawdust, which is clean and keeps down rank steam. No water should be given until the seeds have germinated. Water at a temperature of 50° must be used. See that the borders in which Fig trees are growing are thoroughly moistened to the bottom, and begin forcing with temperature of 50° at night, syringing the trees freely with tepid water, and maintaining a moist atmosphere. As the trees begin to grow, gradually increase the temperature, and rigidly attend to stopping the shoots at the third or fourth joint by pinching the points. For starting pit Figs, no heat is so general as that contributed by fermenting manure, and for this purpose a bed of it inside the pits and in which the pots could be plunged so as to have a bottom-heat of 75° or 80°, is of material benefit to the plants. Attend to re-potting plants, and mulch over the surface of the soil in the pots with horse-droppings, or other rich manure. When Cherries are forced early, the temperature must be kept low, never allowing it to rise above 50° at night until the fruit is set. When they are in flower, the temperature may be raised a little, and a little fire-heat and ventilation given at the same time. For early forcing, Strawberry plants with good plump crowns should be selected; and those in rather small pots, with good matted roots, always set their fruit the best. Introduce them, according to demand, into a pit, Peach house, or Vinery, having at first a temperature of 45° to 50° at night, and keep them on shelves near the glass. When they are in bloom, and when the fruit is set, increase the temperature about 10°, and always keep them in airy positions, and well attended to as regards watering. Muscats require 5° more heat from the time they are coming into bloom until they are mature than any other sorts. In Vineries, where all the shoots have been once stopped, the temperature may be allowed to rise to 85° before giving a little air at the top; but no favourable opportunity should be neglected to admit fresh air, as growing Vines stand very much in need of it at this season. Attention must be given to the thinning of bunches and berries on permanent Vines. When all have been thinned, the inside border must be supplied with a copious watering. If this can be had of the temperature of the house, so much the better. A dusting of guano may with advantage be put all over the surface of the border before watering. When plants that are liable to be infested by red spider are placed in Vineries, a vigilant eye must be kept on them. If syringing be discontinued when the bunches are in bloom, it should be resumed immediately after the fruit has fairly set. No time should be lost in pruning late Vines, and cleaning the rods and house with as much care as has been exercised in former ones. After this has been accomplished, admit all the air possible, so that the Vines may have that rest before being started again which the

constant firing has hitherto prevented them from enjoying. Any odd bunches of fruit still hanging should not be allowed to interfere with these proceedings, but be cut and stored in the fruit-room.

#### Hardy Fruit.

In pruning orchard trees, have every branch clear of its neighbour, and so thinned that, when windy, they do not chafe together. The long and ugly spurs should be shortened back by cutting a few off each year, and in this manner gradually getting rid of all. Lichen and Moss must be cleared off, and, if necessary for its thorough destruction, the stems and branches painted with a mixture of quick-lime and soot. A good dressing of either fresh soil or manure should afterwards be given; and if digging amongst the trees be impracticable, leave it as a mulching over the roots. Raspberries should, at the earliest opportunity, be thinned out; all the old fruiting canes of last year should be cut away, and the new canes regulated, after which give the ground a good coat of rotten manure. Gooseberry and Currant bushes may be pruned, and the branches of each well thinned out. All kinds are best pruned on the spur principle, with the exception of Black Currants, and these bear the finest fruit on the wood of the previous year. Planting all kinds of hardy fruit, when the ground is in suitable condition, should be pushed forward, as it is desirable that such work should be completed early. The same remarks apply to trees growing too freely, which require root-pruning to induce greater fruitfulness.—W. W.

#### Kitchen Garden.

As soon as the surface of the soil is dry enough, go over such crops as Spinach, Onions, Lettuce, &c., with the Dutch hoe. The sooner all vacant plots of land are trenched or dug the better. Finish planting Box or other edgings; turn the gravel paths, and have them thoroughly trampled and rolled down. Sow early Peas in warm, sheltered positions; Ringleader and William the First are suitable; or, for small gardens, Tom Thimb or Beck's Gem may be substituted. The dwarf Fan or Cluster Bean is a good companion for the Gem Pea; it is very prolific, and occupies little space. A few early Potatoes may also be planted in a warm position, but unless the means are at hand for protecting them when they come up, the chances of success are remote. Early Horn Carrots may now be sown, but in cold positions Carrot seeds lie a long time in the ground, and under such circumstances it will, for very early crops, be better to cut a wide trench, and fill it with warm manure; cover it with 5 in. or 6 in. of light soil, and protect it with glass or other covering. Sow a few Wood's Fringe and French Breakfast Radishes and protect them as suggested. Where an autumn supply of Brussels Sprouts is required, a box or two should now be sown under glass. Plant out from the seed bed autumn-sown Cabbages to succeed those planted last September. Stir the soil with a fork between the rows of early Cabbages, selecting a drying day for the operation, and afterwards earth them up. Make a small sowing of Celery, in pans or boxes in heat, for favouring purposes. When the weather is suitable, and the ground in good working condition, a portion of the autumn-sown Onions should be transplanted. Select for them a piece of land that was manured and deeply dug in the autumn or early winter; wheel on a good dressing of charcoal dust or charred refuse, spread it evenly over the surface, and rake or fork it in. Soot also may, at all times, be beneficially applied. Make the ground tolerably firm, and put in the plants, not too deeply, 1 ft. row from row, and 4 in. apart in the rows. Make a sowing of Veitch's Autumn Cauliflower in pans in heat. Take up the remainder of the crop of Jerusalem Artichokes; select the best for use; place them in a cool cellar or shed, with a little dry sand strewed over them to keep them from shivering.

#### Vegetable Forcing.

In fine weather give as much air as can be done safely to Potatoes, Carrots, &c. Earth up early Potatoes that may require it with light rich soil that has lain in a warm shed a few days. Potatoes with their tops near the glass must be well covered up at night, to prevent the frost injuring them. When the early Radishes have all been drawn from amongst the first crop of early Horn Carrots, thin out the latter to about 1 in. apart, and, in order to fill up the holes and level displaced soil, sift a little fine rich soil all over the bed, and then moisten with tepid water.

#### Diary.

January 28.—Sowing Marrow Pea is boxes for making Green Pea soup. Putting in cuttings of Colous, Pelargoniums, Alternanthera, Fuchsias, and Ageratum. Getting more Strawberries into gentle heat, and removing more forward ones to the Peach-house. Getting on with pruning and nailing. Turning over Mushroom manure to sweeten.

Jan. 29.—Sowing Sweet Basil, and pot Marjoram; also nine rows of William I. Peas on a warm border. Planting an early border with Ashleaf Kidney Potatoes. Top-dressing a Vine border (Lady Downes)

with a mixture of new loam, old plaster mortar, charcoal and horse manure. Proceeding with the digging and trenching as far as the weather will permit.

Jan. 30.—Sowing another frame with Wood's Early Fringe Radish; also an early border. Planting a three-light frame with Ashleaf Kidney Potatoes that have been previously started. Looking over Pelargoniums, picking off dead leaves, and stopping them where required. Turning over leaves and manure in Muscat-houses, and adding a little more hot material, so as to keep up a moist temperature.

Jan. 31.—Sowing Cyclamen seeds in gentle heat. Putting in cuttings of Verbenas, Lobelias, Heliotropes, and Petunias. Giving late Peach-house a good watering. Getting peat and loam into Vinerias to warm, so as to be ready for potting Pines. Looking over Grapes in bottles, taking out any bad berries, and filling up the bottles where required. Making up hotbeds for Potatoes, Cucumbers, Melons, &c.

February 1.—Potting off Pelargoniums. Cutting back large Fuchsias, and putting them into gentle heat. Moving Cinerarias, Calceolarias, Verbenas, and other plants into a large pit for purposes of fumigation. Covering up another Seakale bed, and filling up another three-light frame with Asparagus for forcing. Getting more Rhubarb roots into Mushroom house to force; also a little more Dandelion and Chicory.

Feb. 2.—Putting in cuttings of Nasturtiums and Mesembryanthems. Looking over Parsley in frames, and picking out all decayed leaves. Cleaning up pleasure-grounds, and rolling down all gravel walks firmly. Looking over fruit-room and removing all fruit that are bad. Cleaning up kitchen garden walks. Looking over Pines, and watering them where required. Fruit in use for dessert—Pines, Grapes, Pears, Apples, and Nuts. G. W. P., Dorset.

#### CISTERNS FOR STORING RAIN-WATER.

THERE are a few things to be determined accurately before a cistern is made; these are the locality, the depth, the form, the capacity, the material, the cost, and the manner of constructing and preserving

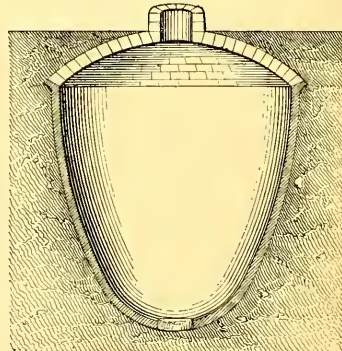

Fig. 1.—Cement Cistern (arched).

it. The locality in which a cistern is built should be such as will be convenient for receiving the supply of water, and also for drawing it for use, and it must, by all means, be either naturally so placed that surface water cannot enter it, or it must be made so artificially by raising a low mound around it. The depth should be such as to maintain a proper coolness in summer, and prevent freezing in winter. The top of the cistern should therefore be not less than 3 ft. beneath the surface of the ground. The shape should be that which will give the greatest strength with the largest capacity. Both of these are gained by using the circular form both for the sides and the bottom and top. Where the greatest strength is required, as in loose sandy soil, an egg form will give this, and with very little loss in capacity. The usual form is shown at Fig. 1, and there is no better shape than this where strength is the first consideration. Where economy of space and material is desired, the form shown at Fig. 2 may be adopted. This is circular, and a circle encloses more space than any other figure having the same length of line around it. The top, if of brick or stone, should be arched, or if covered with timber and earth, the most durable kind of wood should be procured. In the latter case the ends of the timbers should have a bearing of at least 2 ft. on the earth at each side of the cistern, and should be bedded in cement, as shown at Fig. 3. The capacity may easily be found by taking the diameter in feet and multiplying it by itself,

thus getting the square of the diameter. This is reduced to round measure by multiplying it by .7854, and ontong off the last four figures. A sufficiently near approach may be made by taking three-quarters of the square as the round measure. This gives the area in square feet, and for every foot in depth the number of cubic feet contained. As there are 7½ gallons in every cubic foot of water, and 30 gallons in a barrel, the number of barrels contained in any size may be soon ascertained. By doubling the diameter the contents are increased four times. Thus a round cistern 4 ft. in diameter will hold a little over 3 barrels for every foot in depth; if 8 ft. in diameter, it will hold 12½ barrels for every foot; but if 12 ft. in

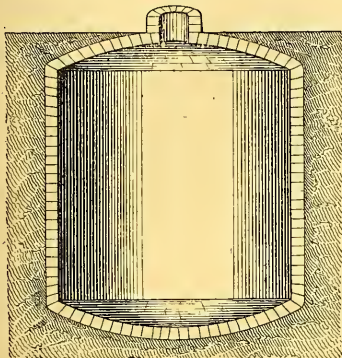

Fig. 2.—Cylindrical Brick Cistern.

diameter, it will hold nine times as much, for if the diameter is enlarged three times, the contents are increased nine times; and if enlarged four times, the cistern will hold sixteen times as much water for every foot in depth. Thus a great advantage is gained by making the cistern as wide as possible. Cisterns should be constructed of the most durable materials; and to preserve the purity of the water, these must be perfectly insoluble and unchangeable. Good hard-burnt brick, laid in hydraulic cement, or, as it is otherwise called, water-lime, because it will set hard under water, is the best material. The next best, or as good under some circumstances,

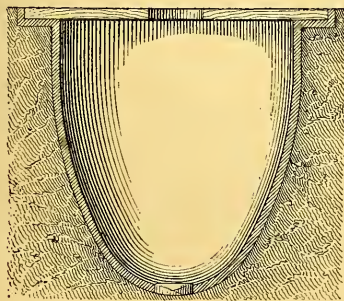

Fig. 3.—Cement Cistern, covered with plank.

is stone. Stone, however, being more bulky than brick, requires a larger excavation, and therefore costs more for labour. In the absence of brick, cement alone makes an excellent material both for durability and cleanliness. Wood of any kind should never be used, as it quickly decomposes, and charges the water with poisonous substances, which produce disease. The cost of constructing a cistern will depend upon its size and the material selected. The length of wall around it may be found by multiplying the diameter by three and one-fifth. Thus one 8 ft. in diameter will be over 25 ft. around it. Fourteen bricks will lay 1 square ft. of wall 8 in. or one brick thick; twenty-five will lay 1 square ft., 12 in. or one and a half brick thick. Thus for every foot in height an 8-ft. cistern will

require 350 bricks if the wall be one brick lengthwise thick, or 180 if it is a half-brick thick. For a small cistern the bricks may be laid in this manner, but those over 6 ft. or 8 ft. in diameter should have an 8-in. wall to resist the outside pressure, especially if the soil be of gravel or sand. To lay 1000 bricks, two barrels of cement will be required if used clear, but there may be one barrel of sand need to one of cement without any danger of weakening the wall. Where expense is no object as compared with durability, we would use clear cement. Where the wall is made of cement, it should be of such thickness as will perfectly sustain the sides of the excavation; but if the soil be solid clay or hard gravel, a 2-in. or 3-in. wall will be strong enough. If the sides be of sand or loose gravel, the wall should be 4 in. thick. The manner of constructing the cistern is as follows: The excavation having been made large enough to allow for the thickness of the wall, the bottom should be first covered with brick, or with a layer of cement; a flat stone should be placed in the centre to stand upon. If the cistern be of brick, nothing further need be done than to place a layer of cement smoothly and bed the bricks closely upon it, beginning in the centre and laying them in circles with the outer ends further apart than the inner ones, and keeping the spaces equal and even. When the bottom is covered, cement should be thoroughly worked into the spaces with the trowel. The cement should be mixed so thin as to spread very easily. The wall should be in the same manner until the top is reached. The last few rows should be laid so that the bricks incline, as shown in Fig. 2. If the wall be of cement, the bottom should be first laid, and then as much of the wall as will stand firmly until it is set. When this is done, a thin layer of cement should be laid upon the earth up to the top, just as a mason would plaster a wall. This will hold to the earth and soon set, and prevent loose sand from falling down. The portion of cement left to set should be made rough and uneven at the top, so that a good joint may be made when the next is laid on. As soon as the first part is set, more wall may be built up, and so on until the top is reached. As this is reached, the wall should be made thicker, and the top should be beveled off, as shown in Fig. 1, so as to give support for the arch. In case of loose earth, which renders the excavation difficult to be made, the plastering may be begun at the top, and as 1 ft. in depth is dug out, the side may be covered 1 in. thick with a coarse cement, made by mixing one part of hydraulic lime with four parts of coarse, sharp sand. This will confine the loose earth and prevent caving. A second coat of richer cement, and a finishing coat may be laid on, when the whole is dug and covered with mortar. After the rough wall is built a finishing coat of clear cement, made very thin, should be laid on, and when this is perfectly dry a final finish should be made by washing the surface over with a thin wash of cement and water laid on with a brush. This closes up all the cracks. If desired to have an insoluble surface, the wall may be, lastly, brushed over with a solution of water-glass (silicate of soda and potash); this combines with the lime of the cement, and makes a coating of silicate of lime, which does not favour the water. This will form naturally, in course of time, from the cement itself, but it may be made at once by using the water-glass. One barrel of cement, mixed with two barrels of sand, will make 9 cubic ft. of mortar, and this will make 1 ft. in height of wall 4 in. thick around an 8-ft. cistern. Thus 12 barrels of cement and 24 barrels of sand will be required to make the bottom and the wall of a cistern 8 ft. wide and 10 ft. deep, or holding 125 barrels of water. One extra barrel of cement will be needed for the finishing coat, and another with 5 barrels of sand, or half sand and half gravel, for the floor for the timber covering.—“American Agriculturist.” [Concerning these cisterns, Mr. Simpson, Wortley Hall, near Sheffield, writes to us as follows:—“We have a number of cisterns made here in the way just recommended both above and below ground, and nothing could be better or more enduring. If they do crack, a lick of cement puts all right in a few minutes. It is always worth while, however, to line the hole or excavation with a single brick first rather than lay the cement on the earth at once, unless the soil be hard and firm.”]

**Sewage and Market Gardening.**—Market gardeners admit that sewage farms have great advantage over their culture in being supported by the constant regulated supply of water to the city, and in being protected from droughts and the irregularities of rainfalls. It may be added that the sewer manure farms have a peculiar advantage over the market garden farms, as well as ordinary farms, in the ready and superior means of feeding the plants by liquified as compared with the common feeding by the solid manure. I have known a liquid-manure farmer who regulated his plant-feeding as he wanted woody fibre, the leaf, or the fruit developed, and who at will could change the colour of the leaves in twenty-four hours. This could not be accomplished with solid manures. By the liquified

manure culture the character of the produce is largely changed; there is a larger production of farinaceous and saccharine matter. The liquified manure culture converts some plants almost into new ones. The seaweed *Rhobarba* has been sought for their excellence to make champagne or a superior still hock. It may be hoped that this liquified manure culture will develop and accustom the people to new and superior edibles as common food, to give relief from the terrible consequences of main dependence on single crops—an evil against which the increasing insect visitations are giving additional national warnings.—EDWIN CHADWICK, *Park Cottage, East Sheen.*

## THE CAVE MUSHROOM.

(Continued from p. 68.)

### *Soiling the Beds.*

To soil a bed is to even the whole of its surface with a layer of soil specially prepared for the purpose, and about  $\frac{3}{4}$  in. in thickness. The Paris Mushroom growers use for this purpose the chips and powder of the stone which has been taken out of the quarry, and which may be procured in large quantities either on the floor of the quarry, or on the surface of the ground around the shaft. This rubbish is passed through a sieve, and the finer portions mixed with fine, light, dry earth, in the proportions of three of the former to one of the latter. The mixture is then watered so as to form a dry paste, in which the fingers will leave an impression. The addition of the earth to the powdered stone favours the development of the Mushroom. In the quarries the earth for soiling the beds is brought to the spot in baskets, carried on the back in knapsack fashion, and placed in heaps in the paths which separate the beds from each other. It is then uniformly spread over the beds by means of a wooden shovel, about 6 in. in width, with a short handle. The layer, which should be about  $\frac{3}{4}$  in. in thickness, is pressed lightly down by the shovel and smoothed, in order that it may adhere firmly to the bed. It is then watered by a very fine-rosed can, and it is allowed to dry until the next morning. The following day the surface of the beds is well beaten with the back of the wooden shovel just described. It must be beaten down so firmly, that it adheres thoroughly to the surface of the bed, so as not to be disturbed by the subsequent waterings. After soiling and beating, the beds need no other attention until the Mushrooms make their appearance, but they must be carefully watched and watered from a can with a very fine rose whenever the surface shows any signs of getting dry and white. About forty days after soiling, the first young Mushrooms begin to make their appearance, and form a fitting reward for the patience and perseverance which have been shown. On the other hand, it only too often happens that, through the neglect of certain precautions, a failure takes the place of success, and the grower loses his time, labour, and money. The action of the powdered stone is due to the nitrous salts with which it is always strongly impregnated, which furnish the Mushroom with an abundance of nitrogen, which is necessary to its existence. We may, in fact, as will be seen further on, replace the crushed stone by old lime rubbish, which has been pounded and sifted, and which, from containing large quantities of nitrous salts, greatly favours the development of the Mushroom. It is in consequence of the fertilising properties of the nitrates that Dr. Labourette has recommended them for artificial manures. The results obtained by him are very remarkable, but this system of cultivation has not yet passed beyond the experimental stage. We have already stated that a bed is ready for soiling from seven to eight days after the spawn has been inserted. The time may vary, according to the plan of the quarries and the height of the roofs of the galleries. Galleries with high roofs are always liable to be permeated by strong currents of air, their mean temperature being about 52° Fahr., and they are best for summer use; while those with low roofs, having a mean temperature of about 65° Fahr., are better for winter work. When it is necessary to soil a small bed in a cellar, it may be done by the hand, or with a kind of box made of Oak, 16 in. long and 10 in. wide. M. Renaudot, with his usual ingenuity, tried to perform the operation by machinery, but he was obliged to give it up, owing to the crookedness of the galleries, and consequently of the beds. I

also attempted to follow M. Renaudot's example by the use of a cylinder, working by means of cog-wheels mounted on a couple of ordinary wheels, but the difficulty of moving about in the narrow galleries of the quarries, and the impossibility of approaching the beds leaning against the walls, put an end to my experiments in this direction.

### *Mushroom-growing in the Open Air.*

Formerly the Paris market was supplied with Mushrooms by market gardeners, who grew them on beds in the open air, but they only began to make their appearance in the month of September; first of all, because the storms which usually occur before this date rendered useless all efforts to grow them without shelter; and, secondly, because the practice of forcing vegetables being much less common at this period than at the present time, Mushrooms were eagerly sought after during the earlier months of the year. Mushroom growing in the open air differs in no way from that which is carried on in the quarries, except in one or two minor details, which we shall proceed to point out. The choice and the preparation of the manure are the same in both cases. The manure heap is commenced, about the beginning of September, as near as possible to the spot where the bed is to be made. Where the soil is light and open, the heap may be made on the bare ground; if, however, the soil be heavy and damp, the drainage must be provided for by laying down a bed of broken lime rubbish, or by digging a trench about half a spit deep all round the heap, to keep it healthy and dry. After the heap has been well turned over for a fortnight, the manure may be taken to the place where the bed is to be made. The width of the bed should not be more than 2 ft. 3 in. at the base by 2 ft. high, the top being finished off in a double slope, as before described. The bed is built up by the fork, as, being in the open air, there is plenty of room to work. The material is then pressed down, trimmed neatly by means of a line, and allowed to rest for five or six days. The temperature of the interior of the bed is then tested, as before described, and the spawn is put in the usual way, taking care only to employ those pieces which are perfectly dry. This precaution is a very important one, for at this season of the year there is always an amount of rain, fog, and even snow, which is quite enough to damp the spawn without artificial aid. If fresh, moist spawn be used, there is great danger of its becoming rotten. If the weather be rainy, the bed, after spawning, ought to be covered over with straw mats, or clean stable litter, until the time comes for soiling. At the proper time the bed is soiled, with the precautions already prescribed, after which the whole is covered over with a layer of straw or clean litter. This covering must be removed from time to time, as it becomes soaked with the rain or melted snow. The first appearance of the crop ought to take place about the beginning of March, and the supply should last until April or May. When the first Mushrooms make their appearance, the manure generally becomes heated, and the soil dries up. In this case the straw covering must be taken off night and morning, and the surface of the bed well watered. The gatherings should be made in the morning, not in the evening. The covering is taken off and the gathering is then made, after which the holes are filled up in the usual way, and the covering restored to its place. The gatherings should be made every two days. An exceptional circumstance took place during the very mild winter of 1873-4. Several beds which were made in September began to yield as early as Nov. 11, and were productive until the May following.

### *Method of Growing Mushrooms without Manure.*

We have already seen in the first part of this treatise that the action of materials containing nitrous salts, such as saltpetre, had a great effect upon the development of the Mushroom. By fully carrying out this principle, I have succeeded in growing Mushrooms without the use of manure by the following process:—Take a cubic yard of old lime rubbish, and reduce it to fragments the size of a Hazel-nut. Moisten the mass, and transfer it to your cellar. Against one of the walls make a sloping bed of your lime rubbish, about 2 ft. 3 in. wide and 2 ft. high, the lower edge being kept in its proper place by means of thin boards. Smooth the surface with the hand. Prepare some lumps of spawn until they are fit for use, and

plant them in three rows, the first row being 8 in. from the wall, the second in the middle, and the third 8 in. from the lower edge. The lumps of spawn in each row should alternate with those of its neighbours. The spawning being finished, cover the whole over with river sand, or fine stone dust passed through a fine sieve, so as to form a layer about 1½ in. in thickness. The sand should be fresh, but not damp. As soon as the surface of the sand becomes dry, it must be watered lightly with a solution of 2 oz. of saltpetre dissolved in 10 gallons of water. It must be watered with great moderation, for any excess of moisture would rot the spawn. At the end of about six weeks the Mushrooms ought to begin to make their appearance. By following this inexpensive process, and by renewing the bed in a different part of the cellar from time to time, we may have a plentiful supply of Mushrooms all the year round. I give, to wind up with, an example which has been reported to me of the ease with which Mushrooms propagate themselves when they find a medium suitable to their wants. The perfection of the town of Clermont-Ferrand is installed in the buildings of an old convent built of granite. Saltpetre, or at any rate some nitrous salt, seems now to be contained in the stone, for near the horses' stables there is a kind of cellar underneath one of them, which is only used as a temporary receptacle for the litter. This cellar is much larger than is necessary, so that the litter is sometimes heaped at one part, and sometimes at another; but whenever the manure is removed, there always grows upon the spot it has occupied an abundant and regular crop of Mushrooms, without any pains having been taken with their culture.

#### Mushroom Destroyers.

Mushroom beds in cellars are frequently ravaged by rats, mice, snails, &c.

MICE.—Mice betray their presence by the prints of their front teeth, which they leave on the portion attacked. Rats make holes in the beds. Against these two kinds of pests we can only use the ordinary traps, or flower-pots turned upside down, one edge of which is supported with half a Walnut, with the kernel turned inwards.

SNAILS.—The grey snail often invades the beds, but as its passage over them is always recognised by the track it leaves after it, it may be easily caught by visiting the beds at night, and by placing here and there, within its reach, little heaps of damp bran or bits of Cabbage-leaf. It is very fond of these two baits, and is certain to be found feeding on them.

WOODLICE.—Woodlice, which are always to be found in damp places, also destroy the beds. They may be caught by placing in their haunts Potatoes, cut in halves and hollowed out. Every morning these traps should be examined, and the woodlice destroyed by boiling water.

BEETLES.—Two insect larvæ, which live on decomposing matter by reducing it to extremely fine particles, cause great damage by eating the spawn, thereby breaking up the reproductive filaments. One of these larvæ, which is commonly called the "Beadle" (*Suisse*) by the French growers, is the *Aphodius fimetarius*, one of the family of the Lamellicornes, of the genus Scarabæides. The larva of the "Beadle" is ¼ in. long and ½ in. broad. Its head is reddish-brown, and its horned mandibles very strong. The white transparent skin allows its internal organs to be seen, and its feet are white. The perfect insect is a small beetle ¼ in. long and ¼ in. across. The wing cases are yellow and streaked; the thorax, head, feet, and the under part of the body are black. The antennæ are yellow, with three joints. The other larva is that of the *Dermestes tessellatus*, a beetle of the family of the Clavicornes. The larva is like a little white worm. The head and mandibles are black, with two antennæ ending in clubs. The body is of a dirty white, and the skin is transparent, like that of the last-mentioned larva. It has six feet, and walks quickly. The wing cases, head, and breast of the perfect beetle are black, the feet brown, and the under part of the body white, marked with four black spots on each side of the wing cases. The body is oval, and the head small and bent downwards. The only means of fighting these grubs is by hunting for them with patience and perseverance. It is a difficult matter, too, for, when searching for them amongst the manure, we do more damage than we are seeking to prevent.

FLIES.—The manure attracts clouds of flies into the quarries. They deposit their eggs in the beds, and the larvæ, when hatched, destroy the soil by reducing it to fine powder. They are about 1-6th in. long and 1-25th in. in thickness. They spin a cocoon ¼ in. long, from which they soon emerge in their perfect state. These flies may be destroyed by placing about a number of pans filled with water, to which a few drops of oil of turpentine or soapy water have been added. The flies are attracted by the odour and drown themselves. They may also be caught with a floating light, in which they will burn their wings and fall into the water.

MITEs.—These are small insects, of a pale yellow colour, which, I think, belong to the parasite Acari. This little pest is wonderfully active; its body is ¼ in. long and transparent. The six legs, which are also transparent, project beyond the body, and the head is armed with a sucker. This insect is the parasite of the beetles mentioned above; also of the ordinary beetle, which is so very common in manure heaps. These parasites are found in crowds upon the scraps of straw in the manure heaps, the heat of which seems to favour their development. By watering the spot on which the heaps are made with water, containing in suspension fresh lime, I should think these insects might be easily destroyed, as their skin is very thin.

#### BOTANIC GARDEN, CAMBRIDGE, MASSACHUSETTS

Judging by the annual report of this garden, just received, its condition seems to be rapidly improving under Mr. Sargent's able directorship. The work of re-arranging the hardy plants, referred to in last report, has been continued, and it is expected that the re-arrangement of the garden will be completed during the present year, or at latest by the spring of 1879. During the past year 4018 square ft. of new rockeries have been built and nearly planted; and, as most of the ground used for this purpose has heretofore been considered unfit for plant growing, the capacity of the garden is considerably increased. The following plants of especial botanical interest, in addition to many others of less importance, have flowered in the garden during the year, viz.:—*Agave yuccifolia*, *Calypso borealis*, *Calycocarpum Lyoni*, *Clematis Davidiana*, *Cucurbita palmata*, *Erythronium purpurascens*, *Lewisia brachycarpa*, *Livistona chinensis*, *Momordella macrocarpa*, *Moricandia sonchifolia*, *Nymphaea flavia*, *Oncosmodium Thurberi*, *Orchis rotundifolia*, *Phalodendron Amurensis*, *Pinguicula lutea*, *Silene Baldwinii*, *Tillandsia usneoides*, *Tulipa Greigi*, and *Zephyranthes Treatii*, n. sp. The small arboretum, which was commenced during the past year on the grounds surrounding the observatory, has been considerably extended, and is now very nearly completed. The arboretum proper is reported to be doing good work. To its establishment, Mr. Sargent states, can be directly traced the planting during the past season of nearly half a million trees in the New England States alone, and amongst these may be mentioned the American White Ash, a tree of the first economic value, but one which has been rapidly disappearing from all but the more recently settled portions of the country.

Tree-felling by Machinery.—A public trial took place the other day on the Ronpell Park Estate, near Tulse Hill Station, of a tree-felling machine, the patented invention of Messrs. A. Bamsome & Co., of Stanley Works, King's Road, Chelsea. There were several timber merchants, engineers, and gentlemen connected with the colonies present. The first tree felled the other day was an Elm, 2 ft. 9 in. across the cut. The machine having been adjusted, the saw was set in motion, and the tree fell in less than four minutes. In a few minutes the machine was fixed to the second tree, an Elm 3 ft. across the cut, and the tree fell in a little less than eight minutes, there having been some interruption, owing to the saw now used being a new one, which had been too sharply ground. The third Elm, 2 ft. 6 in. in diameter, came down in seven minutes and a half. In seven minutes more the machine was at work on the fourth tree, which was about 2 ft. 6 in. in diameter, and which fell in less than ten minutes. When the work goes on uninterruptedly, the task is accomplished with great rapidity. Four or five other trees were felled, one of them, with a diameter of 22 in., being sawn through in a minute and a half, and, on account of the small size of the tree, without the use of the chain. In a private trial five trees were felled, inclusive of the time occupied in moving and adjusting the apparatus, in thirty-five minutes. In the heart of one of these trees, by the way, was found an entire brick. The saw was not made to cut bricks, but as it was driven by steam it had no time to debate the point, and so went

right through the impediment with the loss of a tooth. As the saw cuts well into the tree, wedges are driven in, as is usual in felling. It was the general opinion of those who were present at the trial that the machine was perfectly successful, and that where there was much wood to fell it would be of great service, particularly in American, Indian, and colonial forests, which it was desired to clear.

## THE KITCHEN GARDEN.

### VEITCH'S AUTUMN BROCCOLI.

FOR several years past I have had to rely on Snow's Winter White Broccoli to succeed the latest Cauliflowers, and, as a rule, by having several successive plantings, we have had few gaps in the supply; but it is a difficult matter to get Snow's in anything like a true form, as some years it has come in exactly at its proper season, and in succeeding seasons it has been fully a month too soon or too late. Last year, however, having found a small planting of Veitch's Self-protecting Autumn Broccoli to come into use just at the desired season, we have this year grown it largely and with most satisfactory results, as we have had an abundant supply daily that promises to last until the early spring varieties are fit for use. We sowed the seeds of it the first week in April, and as soon as the plants were large enough to handle, they were pricked out into nursery beds until the first crop of Peas was cleared off in the end of June, when drills were drawn, and the young Broccoli plants put out 2½ ft. apart, on Mr. Gilbert's system, with a crowbar, on solid land; one good soaking of water, and an occasional surface-hoeing, were all the attention which they received until November, when they presented as dwarf and even a surface as I ever saw in a plantation of Broccoli, every plant being short and sturdy in the stem, with a fine head of leaves that curled over and enveloped the heads so completely as to defy any moderate frost. As a precaution, however, against any sudden visitation of severe weather, we have laid them slightly sloping to the north, and packed dry Fern and litter securely among them, reserving a supply for effectually protecting overhead should frost become intense, as I find Broccoli or Cauliflowers are much better in quality when protected in this way than when lifted and placed in close pits or collars. As we planted a large plot of this variety side by side with Snow's Broccoli under exactly similar circumstances, I have had a good opportunity of comparing results, and up to the present time all the produce has been from the new variety, which is still producing heads in various stages of development. It is greatly to be desired that this fine Broccoli may be preserved true, as, up to the present time, I may safely assert that growing varieties of Broccoli that have been warranted fit for winter use, and that have eventually come in with the ordinary spring crop, has been the most vexatious affair belonging to kitchen garden produce with which I have yet had to deal; for, no matter how large or well ordered a kitchen garden may be, it is impossible to regulate the supply if the varieties of vegetables planted cannot be depended upon to be fit for use within a reasonable limit, allowing for the variation that takes place in the seasons.

JAMES GROOM.

Henham.

**Early Sown Brussels Sprouts.**—I was looking the other day at two beds of Brussels Sprouts, both growing in the same garden. The plants on one were sown in a box under glass in February last, potted singly when large enough to handle, and brought forward in a light, cool frame till the weather had settled in April, and then planted in a well-manured, open site, 2½ ft. apart each way; the other plot was furnished with plants sown in the usual way in March in the open air. The difference in every way was so much in favour of the first-named, that any little extra labour will be well bestowed, especially where it is necessary to obtain the greatest bulk and quality of produce from limited areas. If a succession be required, the better plan will be to make two sowings—one early, under glass, and the other in the open ground in the end of March. Too often such crops are sown too thickly, thereby not only wasting good seed, but the young seedling plants lack that vigour of constitution which can only be obtained by giving them at all times sufficient breathing space. In very backward districts, where the aid of glass cannot be

had in early spring, I should sow in autumn; but only a few seeds should be sown then, as, if sown too early, some of them may bolt in spring, and frequently a few days or a week will make all the difference, especially if the winter should turn out to be mild. When sowing in autumn I have always found October to be the most suitable month, varying the time from the beginning to the end of the month according to the season and situation. Autumn sowing, however, may be looked upon as a means to suit exceptional cases, and in no instance need it be adopted where the first sowing in spring can be made under glass.—E. HOBDAY.

**The Winter Heliotrope** (*Tussilago fragrans*).—"Salmon icps" (see p. 50) recommends the introduction of this plant into gardens and pleasure-grounds, but my advice is to keep it out of them, for when once it gets possession of a piece of ground there is no getting rid of it, as it spreads in all directions most rapidly. It has been a perfect nuisance here for many years, and though we have repeatedly forked over large plots of ground containing it, and seemingly picked out every particle of root, and afterwards covered the ground with fresh turf, it has forced its way through the Grass and grown stronger than ever. I quite agree with "Salmoniceps" as to its fragrance, its easy cultivation, and its hardiness, but, at the same time, I would be thankful if he can inform me how I am to get rid of it, as it is a most troublesome plant, and must be a source of discomfort wherever it grows in such masses as it does in this neighbourhood.—J. CLARKE, Cork.

## QUESTIONS AND ANSWERS.

**Apples.**—Could any of your readers inform me where the following Apple trees are to be got? The list is one which I copied from a correspondent's letter in *THE GARDEN* three or four months ago. I have tried several Apple growers, but have not succeeded in getting them. The sorts I want are—Slade's, the Hatchin Pippin, Blue Pippin, Aromatic Russet, Red Streak, Mashay Pippin, Royal Monard, and Box.—G. W.

**The Myrobalan Plum as a Fence Plant.**—Have any of the readers of *THE GARDEN* tried this Plum as a substitute for Quicks? If so, will they kindly give me their experience as to its value? also any hints as to planting, &c.? I have a great deal of hedging to do, and Quicks are very slow growers when properly attended to.—OXON.

**The Best Acacias.**—There are several varieties of small Acacias now in the market at Cannes. Which are the best kinds for a greenhouse or out of doors in England?—L. [The following will be found to be a good selection, viz.—*A. armata*, *Hicorea*, *ovata*, *pulchella*, *vestita*, *Drummondii*, *ericarpa*, *juniperina*, *retundifolia*, and *grandis*. *A. dealbata* has been found to do well even against walls in favourable localities in the southern counties.]

**Indoor Climbers.**—We have a corridor here between the dining-room and conservatory; it is 5 ft. long, 1½ ft. wide, front and back 11 ft. high, and span-roofed, the front and roof being glass, and the back a wall, which we want to cover with climbers that would also run over the roof. Will some reader of *THE GARDEN* kindly name what kinds would suit us best. I may add that three years ago I planted it with *Taeniocissis*, *Passifloras*, and some other plants, which did well for two years, then got sickly, and at last died. The hot-water pipes for heating the hall in winter run along the front of the corridor, and maintain an amount of heat which is useful for plants in pots that have been brought in from other houses where they had been forced; but I think the warmth thus obtained kept the climbers growing until they were exhausted, and then died. The corridor is only heated for about four months in winter; during the rest of the time it is used as a conservatory. There is a narrow border in which the climbers can be planted.—W. W. KAYSON.

**Propagating Variegated Hollies.**—I have a large variegated Holly, which has been in my shrubbery more than forty years, and which is now—as it has often been before—covered with berries. Can I reproduce the variety by sowing the berries as seed, and, if so, when, and in what soil or situation should they be sown? I presume grafting would be best, but what age should the wood of the graft be? as Hollies grow so slowly as to make very little new wood. Any information on this subject would be thankfully received.—H. R.

**Paris Exhibition.**—Mr. John Wills, of Onslow Crescent, South Kensington, is, we are informed, about to erect at the Paris Exhibition an ornamental glass structure, 80 ft. by 20 ft., in which it is intended to maintain a collection of choice plants and flowers, arranged from an artistic point of view, for six months.

**Wistaria on Trees.**—We shall be very much obliged to any reader for information as to where a good specimen of *Wistaria* running over a tree or trees in this country or any other may be seen.

**Large Specimens of *Araucaria imbricata*.**—Mr. Ernest Bergman will be much obliged to any of our correspondents who will give him some details concerning the height and size, position, and age of the largest *Araucarias* now growing in the United Kingdom.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### LOCKED GATES AT KEW.

A DEPUTATION of gentlemen, including the clergy, coming mostly from Richmond and Kew, waited upon Mr. Noel, Whitehall Gardens, on Wednesday, to again urge that Kew Gardens ought to be open to the public at more reasonable hours than at present. Nothing could be more temperate in tone than the reasons which were urged in order to effect this by Messrs. Nott, Drabble, White, Maxwell, Coleman, Selle, and other gentlemen, but, notwithstanding this, no satisfactory answer could be obtained, though the deputation was received with courtesy by the First Commissioner. To ourselves, every one of the speakers seemed to err on the side of moderation in not asking for the unreserved opening of the gardens, the houses excepted. Somebody has impressed the people about Kew that "science" requires the gardens to be closed for half the day, and even the most outspoken of the speakers accepted this nonsense in its entirety, and said they did not want the Botanic Gardens to be open at all, except at the absurd hours at which they are now open; but we tell them, and all whom it may concern, that this is not fighting half the battle. We do not speak from the point of view of the Kew or Richmond people at all, but from the point of view of horticulturists and botanists of England and throughout the world; and we say that it is an injustice to keep these noble gardens shut up during the best hours of the day. Even in the case of people who live on the spot at this time of year, if they are there at the moment the gardens are opened, there is very little time in these short days to see them at that end of the day when people are the least disposed to visit them. Throughout the whole of the winter and spring the most agreeable time to visit Kew is the bright morning and noon; in summer, too, it would be more agreeable to persons visiting London to go out to Kew in the early morning or even before breakfast, as many would do. Numbers of persons come from our colonies and America to London to whom a visit or several visits to Kew is important; and we speak from experience when we say that the time and convenience of these people are very often thwarted by the absurd rules that exist there. Then, taking the case of anybody in London wanting to see a certain plant in flower, or to look up any other question at any time of the year, is it not monstrous that this cannot be done as in any other national botanic garden? Mr. Gerard Noel said, in the course of his observations, that "there was no place where so much liberty was given as at Kew," and spoke of the Garden of Plants in Paris as a place more difficult of access than Kew, and for which payment had to be made at times! Now the Garden of Plants is the very opposite of a model of a national garden for us, but it is quite open to people throughout the day, with the exception of one or two small departments of very little interest to the public. There is, however, no reason to go so far for examples. Of late years the plants put out in the various parts of the London parks are even more choice and costly than those at Kew, as, for example, in various parts of Hyde, Battersea, and Victoria Parks. Yet there is no reason for keeping the public out at any time. People may be seen in Battersea, Hyde, and Victoria Parks enjoying the flowers in the morning sun. Surely if this be possible in London itself, with all its roughs and its millions, it is no less possible at Kew. To those who know anything of botanic gardens and their management, the "scientific purpose" objection to their being opened at reasonable hours would be amusing if it were not so very untrue and so very puerile, and one feels ashamed that anyone connected with the beautiful science of botany could urge it. How have "scientific purposes" suffered in Edinburgh, and Dublin, and Paris by the opening of scientific gardens at an earlier hour? However, a still weaker reason than this

was urged by the Chief Commissioner—"that a great many of the visitors did not arrive till long after one o'clock in the day." This opinion is evidently not an ill-considered one, as it has been uttered more than once in public and in the press. Considering how thoroughly well known it is in London and elsewhere that Kew Gardens are not open till the afternoon, we are not astonished that people do go after one o'clock. It is only the poor holiday-makers, who are not informed of the matter, who crowd outside the gates before they are open. Horticulturists may be a long-suffering race, but they are not so extremely foolish as to gather outside the gates of Kew before one o'clock with the hope of getting in. It is greatly to be regretted that Sir Joseph Hooker should not take a broad view of this matter. It is well known that he, and not the Chief Commissioner, is the real objector to the change desired. His conduct in this particular will tend to strengthen the charge of cliquism which is so often urged against the "Kew school," not by horticulturists, but by botanists. The matter cannot rest here. There never was a more reasonable demand, and it must be granted sooner or later. The question of expense is no excuse. Surely the first and most legitimate use for means in such a garden is that it may be seen by those who pay for it. We very much doubt, however, if early opening would increase the expense in any material way; but assuming for a moment that it would, the answer is—save it from things less needed than the opening of the Gardens. We could give, as no doubt many others could also give, various instances of very heavy expenditure at Kew for objects very much less important than that of opening the gardens at all reasonable hours of the day. The hours should be from six o'clock until dusk throughout the summer, and in winter from nine o'clock till dusk.

### CHRISTMAS ROSE BLOOMS MADE WHITE.

IN the majority of gardens there are no white flowers out-of-doors to speak of in winter, with the exception of that most useful of all flowers, the common Christmas Rose (*Helleborus niger*). The large-flowered variety of this is quite a mistake for decorative purposes. I fancy I have seen a small-blossomed sort, and that is really what is wanted—a Christmas Rose half the size of the ordinary kind, not one nearly as large again. But the Christmas Roses with which one meets in the majority of gardens are not white, but pink, or more or less suffused with pink or a dirty purple, and as this is the white flower within the reach of all which I venture to recommend, it is only reasonable that the way to make it white should be first pointed out. Well, there are two ways within reach of most people; some would add a third, and plant it in light soil, but that is not effectual, and is often impossible. Soil will be best only to advert to the two modes of making the Christmas Rose white. The first is to plant it in a warm, sheltered, partially-shaded situation; this seldom fails. It is the cold wind chiefly that makes this white flower pink or purple. I have patches of it in my mind's eye as white as driven snow behind walls, or fences, or snug on the sheltered sides of shrubberies; and others nearly all purple, set in the teeth of the wind, or rudely swept by the blast. My next mode of insuring white Christmas Roses is to cover them with glass; this does not mean a wooden box and glass light, far less the lifting of the plants and placing them in pits, frames, or houses. Such disturbances are ruinous to the perpetual supply of Christmas Roses; but the firmest means of protection with glass, such as the placing a few bricks on either side of a patch of Christmas Roses, and then laying a loose square or two of glass over from one to the other. Such cold and simple protection is sufficient to make Christmas Roses spotless as the driven snow. One of the finest exemplars of the success of such glass protection which I have ever seen was a border at the end of a greenhouse planted with Christmas Roses about 1 ft. apart. A few long squares of glass were laid across, and in the middle of January the ground was as white with Christmas Roses as an old orchard is with Snowdrops in February. Blooms had been cut from them since Christmas, and hundreds might have been cut when I saw them, and all without a spot. In fact, flowers of them in the drawing-room were so pure and spotless, that they were mis-

taken at a distance for the more rare but hardly more beautiful *Eucharis amazonica*. Christmas Roses also flower much more freely under slight protection than when exposed. This plantation of them had been treated in the way just named for years, care being taken neither to plant nor sow anything among them in summer, to allow no treading on their crowns, and to cover them with glass by November 1. Thus managed, they were always in flower before Christmas, and continued in flower till the first week in February, soon after which the glass was removed.

D. T. FISK.

**Boltonia latissquamma.**—This, though having a strong appearance of relationship to *B. glastifolia*, may nevertheless be distinguished from it very readily. Besides, its foliage being more glaucous, it does not grow quite so tall. Above all, it is distinguished by its flowers being larger and of a beautifully delicate rose colour, instead of being white, as in the first-named species. They are also much more abundant; and, owing to their ligules being much more numerous and placed in several rows, it is probable that before long this species will give varieties with double flowers. We may, however, mention that already *Boltonia latissquamma* is a very beautiful ornamental plant, which, by the abundance of its flowers (which last up to the first frosts), brightens up our gardens at a time when all other flowering plants have almost disappeared, which in itself is no small merit. Cut and placed in water, the flowers of this *Boltonia* will last for several days, and may be used to adorn our rooms, which is another good quality to be placed to its account. Up to the present time the propagation of this *Boltonia* has only been effected by division of the roots. Thanks, however, to the numerous experiments made by M. Henri Vilmorin, we can now raise it from seed, as we do *Asters*, *Golden Rods*, or *Solidagos*, with as great ease as if they were ordinary annuals. This discovery will allow us to obtain varieties, which it was nearly always impossible to do as long as we could only propagate the plant by root division. Like the other *Boltonias*, the *latissquamma* is a native of North America, and was first introduced to horticulturalists by Professor Asa Gray. To all its other merits *B. latissquamma* adds that of novelty, having been introduced into France in 1875.—E. A. CARRIÈRE, in the "Revue Horticole."

—Up to 1875 only three varieties of the genus *Boltonia*, which are all indigenous to North America, and consequently perfectly hardy in this country, had been introduced to European gardens, and these were known under the distinctive appellations of *B. asteroides*, *B. diffusa*, and *B. glastifolia*. Of these the first named is figured in the 52nd volume of the "Botanical Magazine" (t. 2554), and the last in the 50th volume of the same work (t. 2381). In appearance of flower they closely resemble some of the varieties of those well-known hardy border plants so seldom now seen, even in very old-fashioned gardens, known as *Michaelmas Daisies*. The fourth, or more recently introduced species, *B. latissquamma*, is said to be a great improvement on the others in size of flower and brilliancy of colour, producing blossoms of a beautifully delicate rose colour. It is more like the *B. glastifolia* in habit and form of flower than to either of the two other varieties named. It is also said to be exceedingly free-flowering, and the blooms, when cut, last well in water. These plants have hitherto been propagated only by division of the tufts at the root; but seed of this new and beautiful variety is now being distributed by Messrs. Vilmorin, the well-known seedsmen of 4, Quai de la Mégisserie, Paris, grown and saved by them at their own sea grounds in the neighbourhood of the French capital.—W. E. G.

**Gentians.**—Besides the happily common garden Gentian, and its exquisite companion *Gentiana verna*, a plant by no means easy to grow, I have two or three equally beautiful autumnal Gentians, some of which I have had better known. *Gentiana septemfida* is a large-growing Gentian, with clusters of blue blossoms which open in the sun; a good plant for any border. *Gentiana gelida* is somewhat similar, but rather smaller in its growth, and larger in its clusters; but *Gentiana gelida* Wallichi is the finest of all. This is, I understand, a seedling variety of *gelida* raised in the Edinburgh Botanic Garden. It is much larger and richer in all its parts, and altogether one of the grandest late summer border plants I have ever seen. *Gentiana ornata* is a most lovely carpet plant from the Himalayas, and may probably be as manageable as an *Aubrietia*. It blooms in the autumn.—FRANK MILES, *Bingham, Notts.*

**The Winter Heliotrope** (*Tussilago fragrans*).—I can fully endorse Mr. Clarke's opinion (see p. 92) with regard to this *Colt's* foot. I have in my garden a piece of ground 60 ft. square, on which I should like to build a rotery, and from which I should like (if anyone can tell me the way) to banish it, for in vain have I trenched the ground, forking out the roots, and in some places even covered it

with gravel. The only difference that I can perceive is that this year it is flowering more profusely than ever, which certainly is an advantage if you must have it. There are undoubtedly places in the wild garden where it is perfect, giving, as it does, a fragrant bloom in this the month most unproductive of outdoor flowers of any throughout the year, and at other seasons covering the ground with a carpet of handsome foliage; but I am sure that amongst other herbaceous plants it ought not to have a place, as when once it is thoroughly established, its removal becomes a matter of great difficulty.—E. F., *Petyards Hall, Swaffham.*

—Mr. Clarke (see p. 92) will experience some trouble in getting this plant extirpated from his garden where its roots have got a firm hold. I had once a patch of it in a corner in the kitchen, and, although bounded by a hard gravel walk, it spread about in all directions, and I only got rid of it by digging a strong dose of salt amongst the roots, and keeping the ground salted till all disappeared. Before doing this I made a plantation of it in a wood, where it might spread as rapidly as it liked, and covered the foliage slightly with Oak leaves. In severe winters, when in flower, I have some straw hurdles made to protect it, and I know no winter-flowering plant so grateful in perfume in the open air as a bunch of winter *Heliotrope*. The flowers are produced in great abundance, and they last in perfection a long time in water.—WILLIAM TILLEY, *Welbeck.*

**The Double Agapanthus.**—This is being largely imported by Messrs. Henderson, Pine-apple Place. Its easy culture, and the attractive character of its flowers, as well as their usefulness for bouquet-making, will doubtless soon gain for it extensive culture.

**Dendrobium Wardianum.**—A good display of this attractive *Orchid* may now be seen in the Pine-apple Nursery. The pseudo-bulbs, in some instances, are from 2½ ft. to 3 ft. in length, and studded with blossoms, a result brought about by thoroughly ripening the growth in autumn, and by subjecting the plants to all the light possible, and abundance of air when the flower-buds show themselves.

**Azalea mollis.**—A number of plants of this are now in flower in Messrs. Veitch's nursery, where they are making a fine display. Their colours are most brilliant, and, considering how easy the plant may be forced into bloom, this variety must soon become popular in every garden in which winter flowers are valued.

**Daphne elegantsissima.**—This is a pretty, variegated form of the well-known *D. indica rubra*, its flowers being similar in every respect to those of that kind. Its leaves are edged with a band of bright yellow, and plants of it treated liberally in a warm greenhouse are highly ornamental. It thrives best in a partially-shaded place, planted out at the end of a greenhouse, in which the shoots are allowed to cover the wall.

**Azalea narcissiflora.**—When grown in the form of a standard this *Azalea* has a fine appearance in the greenhouse early in the year. Its white, semi-double flowers develop themselves with very little forcing, and they last in good condition both on the plants and in a cut state for a much longer period than those of most of the other kinds usually found in flower at this season.—C. S.

**Camellias in the Lucombe Nursery, Exeter.**—Just at this season the chief attraction in this nursery is the *Camellia* house, the trees in which are loaded with blooms of the most delicate colours, and the thousands of buds that are just bursting indicate that for some time to come they will continue to be furnished with flowers. Judging from their size, some of the trees must be very old, but increasing age seems only to make them more prolific in the production of handsome flowers of almost every colour.

**Wreaths on Trees.**—The engraving on the opposite page shows some graceful wreaths of the common Irish Ivy, trained from hole to hole of a short grove of fine *Clauze* trees, on each side of a fountain basin. The Ivy is planted between the trees, where it grows vigorously; and it is so trained that the wreaths seem to fall to the ground from the trees. Above the wreath of Ivy there is a smaller, lighter wreath of the *Virginian Creeper*. The effect of the two is very charming, that of the Ivy being good throughout the year. Very often good gardens, and important spots in gardens, suffer from not paying attention to simple ornament of this kind. In the case in question the trees were very well of themselves, but these elegant wreaths give a fresh charm to the spot, and gracefully adorn both the ground and the stems of the trees.

**Orchids at Kingston.**—A good variety of *Odontoglossum Rozellii* is now in bloom in Messrs. Jackson & Sons' nursery at Kingston. Associated with it are also the beautifully-scented *Scaccolabium violaceum* and the white-flowered *S. Harrisonianum*, together with well-bloomed plants of *Phalæopsis*, all of which combine to make an effective display.—S.

## HARDY CLIMBERS FOR WINTER ADORNMENT.

IN most gardens there are positions where it is desirable to produce as cheerful an appearance as possible during winter, and where climbers, either on walls, arches, or trellis-work, may be made a conspicuous feature. Some dislike Ivy on buildings; but, even where such a prejudice exists, there can be no objection to its employment for covering arches or rustic work of any kind; and as there are now so many beautiful varieties of Ivy, a more extended use of it would add to the appearance of many gardens. Among fruit or berry-bearing wall plants scarcely anything has a brighter or better effect than the scarlet-fruited evergreen Thorn (*Crataegus Pyracantha*). Though not so fast-growing as some plants, when once a wall is covered with it, if the pruning and training be judiciously managed, it has a rich and striking effect in winter. I saw the other day, in a neighbouring village, a good-sized house, the front of which was completely covered with it, and the bright berries were set so thickly amongst the dark foliage as to arrest attention. *Cotoneaster microphylla* may be used as a wall plant under similar conditions, and it is very effective, both

when in flower and afterwards, when the numerous small scarlet berries are ripe. It grows freely in good soil. It is with regret, however, that I plant it where I know rigidity of training is required, as its habit of growth, when left to itself, is so elegant and graceful, as to clearly indicate that it is a plant better suited for the rockery or semi-wild scenery than for a position where every spray must be orderly and circumspect. There are several winter-flowering deciduous shrubs that are indispensable where bright, cheerful effects are desired, and foremost among these must be placed *Jasminum nudiflorum*, which at this season is loaded with bright golden blossoms. One almost wishes that it had the sweetness of the common Jasmine, but it is quite scentless. For covering any wall up to 12 ft. or 14 ft. it is most suitable, but I have never seen it growing above that height. I have it against a wall 30 ft. high, but it seems to stop when about half-way up, and makes but little upward growth afterwards. A later-blooming yellow-flowered companion may be had in *Forsythia viridissima*. It is even more hardy, free-growing, and vigorous than the Jasmine just referred to; and both, if growing on a wall, should be pruned back moderately as soon as the blooming is over, as they flower principally on the young shoots made in summer, and by cutting pretty well back, a larger number of elegant graceful sprays, of moderate length, are always obtained. The Japan Allspice (*Chimonanthus fragrans*) is quite indispensable in a collection of winter decorative hardy wall plants. Its flowers, which are freely produced from the time the leaves fall till well on through the winter, are deliciously scented. A small handful of the leafless flowering sprays will give fragrance to a large room. It is a free-growing shrub, and should have the shelter of a wall to preserve and protect its blossoms. There is a large-flowered variety of it, too, which is even better

than the type. *Berberis Darwini* should be planted wherever a good winter flower shrub is desired, as both foliage, wood, and flowers are so glossy and bright. It submits readily to training, and grows freely enough in good soil. When well established, it flowers profusely and almost continuously in winter. *B. stenophylla* is a free-growing, beautiful hybrid, not quite so erect in growth as *Darwini*; in this respect it partakes rather more of the character of its other parent, *B. empetrifolia*. It is a very desirable and handsome variety, either for a wall or for any other position. I have occasionally used the common evergreen *Berberis*, *B. Aquifolium*, for covering low walls, and very effective it is for walls not more than 3 ft. or 4 ft. high. *Garrya elliptica* is a dark-foliaged, handsome evergreen, of free, quick growth after the first two years, or when well established. It should be planted in good well-prepared soil, and will then speedily cover an unsightly wall. Its long catkin-like inflorescence is at this season both singular and interesting. *Escallonia macrantha* is one of the best and handsomest late-flowering evergreen, of comparatively recent introduction; or rather, I should say, it is not new, it is far

from being as common as it deserves to be. It is well suited for a wall where only choice subjects are admitted. In sheltered positions it will flower during the greater part of the winter. *Kerria japonica* I saw years ago brightening up many a cottage porch and front in Worcestershire in early spring, and its yellow rosette-shaped flowers are pretty and cheerful on low walls. Its height does not, under ordinary circumstances, exceed 6 ft., or 7 ft. *Lardizabala biter-nata*, although reputedly tender, should be tried in all sheltered situations where variety is sought, as it is very distinct, both in foliage, flower,

Wreaths of Ivy and Virginian Creeper Garlanding Stems of Planes.

and habit of growth. It would in most cases be advisable to protect it a little in severe weather for the first year or two, till well established, as afterwards cold would have less effect upon it. Several of the *Louiceras*, or *Honeysuckles*, should be added to the list, including *L. fragrantissima* and *grata*; indeed, a wall wholly planted with different kinds of *Honeysuckle* would be highly interesting. There are many plants well adapted for low walls that would not be suitable for loftier positions, notably *Pyrus* (*Cydonia*) *japonica* and its white variety; and, in point of fact, almost all of our flowering shrubs, both evergreen and deciduous, may be so employed if desired. In sheltered positions, *Laurustinus* will flower nearly all winter, and there are few shrubs brighter or more effective for walls not exceeding 10 ft. in height. I have seen *Cornifolia glauca* growing freely on a low wall in Norfolk; and the early flowers of *Magnolia purpurea*, when trained against a wall, are very beautiful. Where an unsightly wall has to be hidden without breaking up the formal outline, a row of *Cupressus Lawsoniana* planted quite closely at the bottom of it, and about 18 in. apart, will soon produce an elegant wall of living green. All strong branches must be tied to the wall, and the small twigs cut back with a sharp knife.—E. HOBDAY.

## EVERGREEN WALL PLANTS.

WE now possess a varied and excellent assortment of plants, both deciduous and evergreen, suitable for all situations and for mostly all purposes — for covering walls, open fences, palings, roeteries, trees, and for forming screen for covering unsightly objects. Taking evergreen species first, let us begin with the Ivy, of which there are numerous varieties, some of them exceedingly neat and pretty, and particularly effective in winter and spring, when many other plants are leafless. For covering walls or other objects quickly, none of the varieties surpass the common Ivy. A few plants put in here and there will cover a large space in one or two years. Ivy delights in a good rich soil, and it is worth while to place some well-rotted manure about the roots at planting time, if quick and luxuriant growth be an object. When planting Ivy for covering walls, or for forming screens, we have usually taken up good patches of it where it grew on the ground, and planted them in the mass. This beats any other plan for quickness. Ivy does not grow readily unless it has good roots to begin with, and these it never wants when growing on the ground. In many places it is employed for covering bare surfaces under trees, where nothing else would succeed, and from such places large patches of it may be cut out with a spade; but they should always be taken from the outside, where the growing points are, cutting in with the spade in a parallel line with the growth as much as possible, till roots are found in quantity, which will be a few feet from the outer edge, and then cutting across so as to secure a large square piece with plenty of growing points. It should be removed with the sod and soil adhering to the roots, and planted against the object to be covered, taking care to bury the roots deep enough, and to support the top with strips of band till growth begins and the shoots take hold themselves. We have seen unsightly walls completely covered in this way in a single summer. There are a number of green varieties of the Ivy, with large heart-shaped and lobed leaves, which are ornamental in their way and rapid growers, but which can hardly be said to be superior to the common kind. The variegated kind, named *Hedera maculata major*, may be mentioned, however, as an excellent variety, and nearly as good a grower as the common Ivy; but it is apt to run back to the green state if grown in too rich a soil. There are several neat-habited green sorts that are highly ornamental and suitable for covering limited spaces on walls. Against dark-coloured stone they are not seen to advantage, but a light ground shows off their small, neatly-cut, and closely-placed green leaves effectively. Some of the weaker-growing kinds do not cling readily of their own accord, and must be nailed; but such sorts it is better not to plant. The variegated gold and silver kinds are amongst the best wall plants which we have. In most kinds the variegation is very distinct, and the habit neat, the leaves alternating on the shoots, lying close to the surface of the wall, and look-almost as if they are pasted on. They should be in every collection of wall plants, and deserve a good position. The best are *Hedera elegantissima*, *Cavendishi*, *nana variegata*, *Silver Queen*, *anrea variegata*, and *tricolor variegata*. Those who wish to make a selection should first see the different varieties together. The Bramble is not reckoned an evergreen, perhaps, but it retains its leaves so long in some situations as almost to come under that head. The very free-fruited, Parsley-leaved variety is a tremendous climber, and grows at a great pace, and when planted against palings or open fences, it soon forms a formidable barrier. It is worth while planting it in good soil at the beginning for the sake of its fruit, which is so excellent and useful; and if the long shoots be trained along the fence for the first year or two, they will take care of themselves afterwards, with a little trimming now and then. The Evergreen Rose (*R. sempervirens*) is a strong and rapid-growing variety, unsurpassed by any other for covering walls or roofs and fences, and it is very hardy. There are two or three varieties of it, some producing red and some white flowers. It may be planted in almost any situation, and is a sure grower. For covering arbours and covered ways, it is an excellent subject. *Jasminum revolutum* hardly needs description. It is a free grower, but needs training and nailing in order to cover the wall properly. It produces large yellow flowers, grows in any ordinary soil, and is a good seaside plant.

## Deciduous Wall Plants.

The deciduous section of hardy climbers furnishes us with a better and more varied list of suitable subjects than the evergreen section. The Clematis almost deserves to be named first. All the varieties mostly, and they are now numerous, thrive in almost any soil, and in the most exposed situations, both in England and Scotland. For covering high or low walls, or fences, or for draping trees and similar purposes, they are unequalled; they grow rapidly, and flower early and profusely. *C. Jackmanni*, one of the first raised of the new race of hybrids, is still one of the best, if not the very best, for general planting. It flowers most profusely, as most of the varieties do, good plants being generally covered with masses of rich purple flowers of large size. The size of the flowers is, however, much influenced by culture, frequently measuring 5 in. or 6 in. across when the plants are grown in a good soil. When the Clematis is grown against a wall it may soon be made to reach the top, and spread out laterally as well, so as to cover a large amount of space if the quick-growing and rambling shoots be carefully trained, for they soon run into an inextricable bundle if not watched and nailed as they grow. After the plants have covered the space allotted to them they need less training, but should be pruned in closely every winter. Young plants should also be cut well down for the first year or two, in order to induce strong growths and good flowers. An ordinarily good garden soil, well manured, suits admirably, but fresh manures must not be placed close to the roots. When planted to cover roeteries, trees, or fences, the great point is to give the plants a good start by planting them in rich soil; but after they get up they are almost better left to themselves to grow as they please. In such situations slugs are sometimes very troublesome, as they eat the young buds as fast as they grow, and we are not sure that field mice do not also eat them. The only preventive is watching and trapping till the young shoots get woody and strong, and they should not be cut down too near the ground when pruned. The list of varieties is a long one, and new ones are being added to it; but among the best may be named: *C. Jackmanni*, purple; *lauginosa*, light blue; *rubella*, claret; *Fortunei*, white; *Lawsoniana*, reddish-purple; *Mrs. James Bateman*, lavender; *rubro-violacea*, maroon; *Lord Loudesborough*, rich mauve with dark stripes; *Otto Frøbel*, blue and white; *Miss Bateman*, white; *Lady Caroline Nevill*, bluish-white; *Henry*, cream colour; *Star of India*, violet-purple; *Vesta*, an early-blooming white variety, with fine large flowers. *Ampelopsis Veitchii*, or *A. tricuspidata*, is an exceedingly beautiful wall-climber, which, though introduced a dozen years ago or more, is still but imperfectly known. It is one of the neatest and most attractive of wall plants, is perfectly hardy, and grows fast. A plant of it put out against a wall two or three years ago is now some 20 ft. high, and is the admiration of everyone who sees it. A few others, planted only two years ago out of 3-in. pots, are now near the top of a 12-ft. wall. It is the neat habit of the plant, and the fresh green foliage, which changes to dark chocolate in autumn, and later to bright crimson, that render it so attractive. In habit we can only compare it to the neatest-growing of the Ivies. The shoots adhere to the wall so closely, by means of their little tendrils with holdfast-like appendages, that a pin point can hardly be inserted between the wall and the leaves, which are placed alternately and so closely as almost to overlap each other. The warmer and sunnier the exposure, the better coloured will the foliage be; but the plant itself thrives famously in open situations against trees, and soon clothes their stems with a verdure of changing hue. It succeeds best in a good rich light soil, and after it has once laid hold of the wall it wants no further attention in the way of training or nailing. *Ampelopsis hederacea*, the common Virginian Creeper, is too well known to need description. It is one of our best climbers, and is particularly valuable for covering arbours and fences, owing to its rapid growth and abundance of fine foliage, which also changes to crimson in autumn, though it does not approach *A. Veitchii* in that respect. It is, however, so accommodating in its habit, that it can be trained in almost any fashion, the long supple shoots bending and twisting easily in any direction. It succeeds in any common soil. *Aristolochia sipho* is a quick-growing plant, and its ample leaves render it particularly useful for covering arbours,

summer-houses, and similar structures. It is a native of North America, and is very hardy, growing fast in exposed situations even in the north, where we have seen it employed for covering trellised work in the open grounds. It prefers a light, well-drained soil, and the shoots should be tied in as they grow, to prevent them getting into confusion. With the *Wistaria* we are all familiar, and as a handsome-flowering wall plant it is unequalled. There are two or three varieties of it, but the blue and white are the best; and of these two the blue is the most vigorous grower and freest flowerer. One plant, if placed in a tolerably warm situation against a wall, may be trained so as to cover an enormous amount of space in a short time. There is a plant at Archerfield, in East Lothian, which, if we remember rightly, runs nearly the length of the garden wall, some 150 ft. or 200 ft., if not more. It needs a well-drained site, a good soil, and plenty of root room, and it will grow freely on any aspect, except the north. It is not a confused grower, like the *Clematis*, but requires to be trained carefully as it grows, in order to cover the wall quickly and uniformly. The shoots may be bent in any direction, according to circumstances. There are about ten or a dozen varieties of *Honeysuckle* now in cultivation; but the best are what are called the common white and the red, viz., *Lonicera Shepherdii*, *fragrantissima*, *scarlet Trumpet*, and the now well-known *L. aureo-reticulata*, or variegated-leaved variety. For general planting, the common native *Honeysuckle* is the best. In the shade the flowers are more delicately coloured and pretty, but in exposed situations they are more fragrant. The *Honeysuckle* needs little attention; indeed, it flowers best when left quite undisturbed, and, as for training, the less it is meddled with the better, after it has covered the objects it was planted to hide. It is an excellent subject for archways and bowers, and it may be trained so as to drape the branches of trees in a very ornamental manner. Indeed, it usually makes itself at home amongst the branches without any assistance in the way of training, and it seems particularly partial to the *Hazel*, which it coils itself round in the most regular manner, embracing it so tightly that it checks the circulation of the sap, and the bark consequently swells out and over the stem of the *Honeysuckle*, as it does over a ligature, the result being a spirally-fluted rod, much sought after by the woodman for making walking-sticks. Among other miscellaneous subjects suitable for our purposes may be named different varieties of the *Rose*, notably *Gloire de Dijon*, the *Ayrshire*, *Banksian*, and *Boursault* *Roses*; the hardier *Grape Vines*; and *Bignonia radicans*. Among herbaceous and annual climbers the following will be found exceedingly ornamental and of easy culture:—*Calystegia pubescens*, *Convolvulus*, *Tropaeolum speciosum*, *canariense*, *Nasturtium* of the *Tom Thumb* and *Lobbianum* class, and the usual seedling varieties, *Scarlet Runners* and *Sweet Peas*, all of which may be employed with success and good effect to cover rustic fences or rooteries.—"Field."

**Abutilons.**—For indoor decoration none of the *Abutilons* excel *A. Darwinii tessellatum*. It is compact and dwarf; its leaves are conspicuously variegated with gold and green, and from every shoot are produced a profusion of bright red bell-shaped blossoms. Mr. Wills has a number of it for decorative purposes.

**The Flame *Nasturtium* (*Tropaeolum speciosum*).**—A light soil appears to be the chief requisite for the growth of this pretty climber. In my garden, the soil of which consists of a loamy sand, having a sharp slope to the south, it grows both in the full sun and in the shade in great luxuriance, even becoming difficult to eradicate, as every little bit of its roots grows. Others, however, do not appear to find it so easy to cultivate, as I have often given it more than once to the same person. It does not flower quite so freely in the shade as in an open situation.—*Chislehurst*.

**The *Clematis* of the Future.**—This, I am told, is *Madame Grange*. This new *Clematis* I have not seen in bloom, but I saw a large stock of it the other day at Mr. Smith's nursery, Worcester. It is said to be a deep violet with maroon mid-rib, redder than any other *Clematis*, and in every way equal to *Clematis Jackmanni* for hardness and bloom. *Madame Grange* is a cross raised by M. Lecoqne between *C. lanuginosa* and *Jackmanni*. I have a great liking for *C. Viticella grandiflora*, owing to its red colour, but this is said to be very much better.—*FRANK MILLS, Bingham, Notts.*

**Self-watering Flower Pot.**—In THE GARDEN of the 19th inst. (see p. 62), this flower-pot is described as a new invention. Allow me to direct attention to an extract from one of the gardening papers, dated May 23, 1874, from which it will be seen I had the very same kind of pot made and exhibited; indeed, I have made this pot for five years, but have had little or no sale for it.—*J. MATTHEWS, Weston-super-Mare.*

## TREES AND SHRUBS.

### TRANSPLANTING TREES.

(Continued from page 82.)

WHEN lifting large shrubs, such as common and Irish Yews, Hollies, Portugal Laurels, and Conifers, having spreading branches larger than the McNab transplanting machines are able to take in, they are moved in the following manner, which is somewhat on the same principle as the McNab transplanting machine. This mode of lifting is what we call the tressel and roller system. The balls are all prepared with canvas, staves, and ropes, as formerly described, and the bottom boards are the same as those used for the large McNab transplanting machine. Two strong lifting-ropes, each 26 ft. in length and 3 in. in circumference, are put below the ball, one at each side, so as

High tressels, furnished with movable cradles.

to lie beneath the ends and in the grooves at the bottom of the lifting-boards. Stout 10-in. broad planks are then put across the pit, one along the back and another in front, having an upright support in the middle of each, fixed into the soil, in order to enable them better to sustain the pressure caused by the lifting. Two 10-in. planks must also be placed along the hole, resting across those first placed in position, to support the feet of the tressels. These planks must also be provided with upright supports, one being placed under the centre of each plank. Two tressels, each 5 ft. high and 9 ft. long, made with wood 9 in. deep and 3 in. across, are placed one on each side of the plant, but along the ends of the lifting-boards, each tressel being provided with two movable cradles, one being fixed on the top of each

Cradle detached, showing the iron pins and groove to receive the windlass roller.

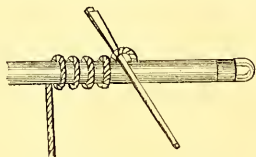

end of the tressels by means of two iron pins. Eight or ten holes are formed along the top ends of each tressel, at uniform distances apart, for the purpose of widening or contracting the spaces between the cradles according to the size of the ball to be lifted. Two strong iron windlass rollers are also necessary, each 8 ft. 2 in. long and 14 in. in circumference, provided

Iron windlass roller.

at each end with strong semi-circular pieces of iron securely bolted into them, but in opposite directions. These rollers are put across the tressels, the ends resting in the cradles just described, but always parallel with the bottom or lifting-boards, keeping the ends of them as far over the tressels as possible, as the winding up often causes them to work either to the one end or the other. The ends of the lifting-ropes are now brought up inside and over the iron rollers, working each toward the end, as seen in the annexed woodcut. This is done by doubling the rope with a slight twist, and giving the end of each three or four turns round the iron roller, keeping the

doubled portion for the insertion of a strong iron or wooden hand-spoke or winding-pin. Strong iron hand-spokes are also used for each end of the iron rollers. It sometimes happens that we prefer the lifting-ropes, put single four or five times round the iron roller, and made to hang down instead of being formed into a loop for a hand-spoke, a man being placed at each for the purpose of keeping the rope tight and holding fast the portion of rope wound off, leaving the winding up entirely to the men at the ends of the windlass-rollers, not less than two to each, according to the weight of the ball. If the top of the plant be high or heavy, it is necessary to have two or three guy ropes to keep the top steady during the lifting. When tressels 3 ft. high are used, the men can all stand on the planks which support the ends of the tressels, but when 5-ft. high tressels are employed, the men at the end of the windlass-rollers must stand on raised planks, while the men in charge of the loose ropes stand on the lower planks. But when hand-spokes are to be used for the side lifting-ropes, it is generally advisable to place a plank along each side, resting either on tubs or boxes, so that all the men may stand on it. After the plant has been raised above the level of the hole with the high tressels, two strong planks are put across, immediately below the ball and between the legs of the tressels, on which a strong, low, broad four-wheeled machine is run. While the plant is suspended a canvas is put over the machine and the plant is lowered on to it. Where the 3-ft. high tressels are employed (and they have long been used here), it is necessary to have four square blocks, one at each end, on which extra planks are placed, on which the tressels are to be raised. By this means the plant can be lifted sufficiently high to run the machine below it. After resting, all the apparatus may be

End of windlass-roller.

removed, fixing securely the ends of the lifting-ropes over the ball and the canvas to the rings and hooks placed round the sides of the machine. All the planks, tressels, and rollers can now be taken to the new pit; if not far distant, the machine can be taken along on planks, but if far and the ground hard, it may be conveyed along the walks either by means of horses or ropes. When the new pit is reached, the planks are put across, all being supported as before. The plant is then run on the centre planks immediately over the hole. The tressels and rollers are again applied, and the lifting-ropes adjusted to them. The plant is now raised a little, so as to allow the machine and centre planks to be withdrawn, and the plant is lowered cautiously to the bottom of the pit. This is generally done by having all hands at the ropes, and allowing the ball to go down gradually. When resting, remove the outer bottom boards and lifting-ropes, and see that the plant is standing perfectly upright; if not, it can easily at this stage be placed in that position. When upright, pack soil firmly in all round, then remove the rack-rope, staves, and canvas, adjust the roots, and fill in with prepared soil, and water freely. The tressel and roller system, as here described, is what we generally employ for the re-tubbing of Palms and other large, heavy exotics, for which purpose it is admirably suited.

It sometimes happens that a large tree or evergreen shrub has to be removed in consequence of its pressing on another equally good plant. In order to save the duplicate specimens, the subject to be moved can be prepared in every respect as described for the tressel and roller system. In doing this, an open trench is generally cut to the depth of the ball, and in the direction in which it is intended to move the plant, say 18 ft. or 20 ft. Planks, tressels, and rollers are now put round, the lifting-ropes adjusted, and the plant is raised about 5 in. or 6 in. While suspended, level the bottom, and place underneath it two planks or battens, then one of the low iron

rollers just described, or a few detached rollers, either of wood or iron—small hollow iron gas-pipes, cut of a uniform length, are what we frequently employ. When the small-framed rollers are not in use, it is necessary to place two short planks or battens immediately above the detached rollers; the plant is then lowered on them, and then drawn along with ropes on a series of planks or battens, all of a uniform height, to the point where it is intended to stand. After levelling the surface of the soil originally thrown out, the planks, tressels, and rollers are put round; the plant is again raised a few inches for the removal of all the planks and rollers, and then lowered. After taking out the bottom boards and lifting-ropes, and removing all the tressels and rollers, as well as the rack-ropes, staves, and canvas, the hole and trench are then filled in.

A similar operation as has just been described, but without the aid of machinery, can be and is not unfrequently performed in the following way:—The plant is prepared with canvas, staves, and rack-ropes, and care is taken that the lowest rack-rope is kept as low down on the ball as possible, twisting it extra tight with the rack-pin. Before undermining, the ball must be sufficiently ranced to the sides at four different points. This done, lower the soil at the bottom of the hole about 6 in. deep all round the ball, but without interfering with it. When done, excavate the one side nearly to the centre. If the lower rack-pin be tight, and the side rances sufficiently strong, the necessary excavating can be done without much difficulty. Care, however, must be taken both to have the surface-soil, as well as the bottom of the ball, as level as possible. First, place on the surface of the ground two planks or battens, above them three or four short wooden rollers, of a uniform diameter, and above them other two short planks or battens, fixing them tightly to the bottom of the ball. When the one side is completed, excavate the opposite one, and adjust planks and rollers in the same way as on the other side. If any centre soil should remain, it can now be removed, and the plant will rest entirely on the planks and short rollers. A few long rollers must now be at hand (wooden ones will best answer the purpose); one is put in as far through as possible in front. Under planks must now be laid at the bottom of the open trench to the extent to where the plant is to be taken, keeping the worst ones to the end, so as to be immediately under the plant when settled. By means of the larger rollers and a strong rope, the plant is drawn along, the short rollers coming out one by one, and the long ones taking their place. As it is often impossible without injury to withdraw the bottom boards, rollers, and planks, it is best to leave them in; and therefore the worst planks are kept to the end for this purpose. Soil is packed firmly in below all round; some bricks, of a uniform thickness, can also be inserted, and the soil filled in to the level of the bottom of the ball. Remove the rack-ropes, staves, and canvas then fill in with soil, and water freely. This method of transplanting is by no means uncommon in gardens where little transplanting is required. By this system I have seen many fine old evergreens removed because interfering with others, and all have succeeded well. Great care, however, is required in the different phases of the operation, particularly in keeping the surface of the ground level below the ball.

Royal Botanic Garden, Edinburgh.

JAMES MCNAB.

(To be continued.)

#### IDESIA POLYCARPA.

THE accompanying illustration of this interesting tree was made from a specimen sent to us last summer from the grounds of J. Luscombe, Esq., Combe Royal, near Kingsbridge, South Devon. It is a Japanese tree which was not known to science until 1866, when it was described by the Russian botanist Maximowicz, who met with it in cultivation at Nipon and Yedo, and ascertained that it was a native of the island Kiusin, at the foot of a mountain called Hikosan. Mr. Luscombe describes it as a handsome tree-like spreading shrub, with fine foliage; but, according to Professor Maximowicz, it attained in Japan the dimensions of a large tree. The leaves, which have crimson stalks, are irregularly serrate, slightly cordate at the base, the larger ones measuring about 6 in. across, bright green above, and whitish or almost glaucous beneath, with five prominent branching nerves, which are reddish towards the base. The

IDESIA POLYCARPA (NATURAL SIZE). Drawn by H. Hyde.

flowers are dioecious; the males, which are those represented in the accompanying illustration, have from four to six yellowish-green spreading sepals, and an indefinite number of pale green filaments with orange anthers. Each blossom is about  $\frac{1}{2}$  in. across; they form long, gracefully-drooping, branched racemes, springing from the axils of the upper leaves. The female flowers are similar in appearance, but are succeeded by very numerous orange berries, which appear, from dried specimens communicated by the discoverer to the British Museum Herbarium, to be about as large as a small Cherry. The flowers are deliciously fragrant, their odour resembling that of a Vanda; and although their colouring is not brilliant, their effect, combined with the red leaf-stalks, the varying green of the leaves, and their elegant drooping habit is extremely pleasing. The tree belongs to the Order Bixineæ (or Flacourtiaceæ), to which our gardens have not hitherto been largely indebted. It was named by M. Maximowicz in commemoration of a Dutch traveller named Ides; Mr. Luscombe's plant of it is upwards of 10 ft. in height.

**The Cherry Plum as a Hedge Plant.**—In reply to "Oxon's" inquiry about this Plum (*Prunus myrobalana*), see p. 92, as a hedge plant, allow me to state that my father first introduced it for that purpose nearly thirty years ago. I cannot say what induced him to try it in that way, but I presume it was on account of the following peculiarities that belong to the plant, viz., its very hard, unyielding wood, almost metallic in its texture, its formidable spines, and last, but not least, its capability of growing vigorously, even in soils of the poorest and most exhausted description, and its non-liability to the attacks of insects or disease. We have evidence of its value as a hedge plant on the driest and poorest soils, on wet bog lands, and on moist and rich fen lands. It has other merits besides; it is about the best stock in existence for almost all kinds of Plums and Apricots on poor soils. As it flowers very early in the spring, some have thought it would impart this habit to the kinds of fruit worked on it, but experience has proved that not to be the case. Were our English market gardens surrounded by fences of *Myrobalana*, with varieties of Plums suitable to the various districts worked at intervals along their tops, the fruit-producing capabilities of the country would be vastly increased, without its being necessary to devote any extra land to the purpose.—G. E. EWING, *The Nurseries, Norwich.*

**A Good Fence.**—A post and rail fence better than anything I have ever seen, patented or unpatented, is made as follows:—Set the posts 9 ft. apart, or 2 ft. less than the length of the rail used. Bore  $1\frac{1}{2}$  in. hole through the posts 1 ft. from the ground, and at right angles with the direction of the fence. Bore three holes above this on 9 in. apart, one above the other, and drive in wooden pins in all four holes to project 4 in. on each side of the post. Lay your rails on these pins, close to the post on each side. Bore a 3<sup>d</sup>th's hole above the top rail, and another one  $1\frac{1}{2}$  in. below the bottom pin. Take a piece of wire 10 ft. or 11 ft. long, and pass half its length through the top hole, and cross it under the top rail; cross it again under the second rail from the top; cross it again under the third rail, and finally cross it under the bottom rail by slipping the ends of the wire through the small hole, and bring them around in front of the post and twist them together. This makes a cheap strong fence, that will turn horses and cattle; but if sheep are kept, a board should be nailed at the bottom, or a fifth rail added.—"Albany Argus."

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Effect of Smoke on Trees.**—Mr. Acock, who for many years past has been making experiments with trees planted in the vicinity of his cotton mill, near Manchester, finds that the Plane, which does better than any other tree in London smoke, will not grow at all in that of Laneshire; but, on the other hand, he has been very successful with the Beech, Sycamore, Birch, Wych Elm, and Turkey Oak, but the Lime does best of all.

**A Good Example.**—Sir Horace St. Paul, of Ellowes Hall, Dudley, has consented to have about 30 acres of his waste colliery lands at Cosley levelled and cultivated, with the view of finding employment for a large number of men who are suffering great privations owing to the depression of trade. As there are thousands of acres in a similar useless condition in the Black Country it is thought the example will be followed by other land owners. At least, something as good as cluders will be got out of it. When everything has been tried and found wanting, no doubt we shall have others returning to the mother of all real wrenths—the earth.

## ORCHIDS.

### WINTER FLOWERING KINDS.

WINTER is certainly not the season when Orchids are at their best; in fact, they are now at their worst, for fewer species are in flower at this time of the year than at any other. Nevertheless, numbers of species are in flower this month, as the annexed list will show; moreover, those who cultivate Orchids in any quantity always have this advantage, that whatever the time of year may be, they always have something in flower—always something curious and interesting to observe. The subjoined list contains over a hundred sorts which flowered during the month of December. The first on the list are *Angreacm eburneum* and *sesquipedale*. There can be no question as to these two plants, with their fine bold spikes of ivory-white flowers, being worthy of a place in every collection, more especially *A. sesquipedale*, which is one of the most extraordinary-looking Orchids grown; some of its flowers have tails that measure as much as  $11\frac{1}{2}$  in. in length, and I have heard that they even grow sometimes longer than that. *Anguloa Clowesi* is another grand plant, its large, yellow, erect flowers reminding one of a well-grown Tulip. This is one of our most aromatic species, possessing, as it does, a very powerful odour of Aniseed, which I have never known any other plant in this Order to have. *Ansellia africana*! who could help admiring such a noble-looking plant as this is when well grown, its tall, gracefully-arching, pseudo-bulbs leafy at the top, and its great panicles of yellowish-green flowers spotted with crimson, showing well above the leaves, form altogether one of the most attractive-looking plants grown. *Barkeria Skinneri* is remarkable for its racemes of bright magenta-coloured flowers, which look quite gay at this dull time of the year. *Brassavola cordata*, with its long, thick, half-round leaves and elegant drooping spikes of green and white flowers, is more curious than beautiful, though it makes a good contrast to the brighter coloured species. *Bletia acutipetala* has pretty crimson-purple flowers, enlivened by a yellow crest on the labellum, as in *Barkeria Skinneri*. *Bletias*, however, will never become favourites, as they have the straggling habit so common amongst Epidendrams; still, they are well worth growing. I had almost overlooked an exceedingly pretty plant, one very rarely seen, but well worth growing—I mean *Bifrenaria racemosa*; the flowers of this are almost pure white, with broad recurved petals, three or four in a raceme, and they stand well above the leaves. *Bolbophyllum auricomum* is a pretty little gem, with erect spikes of white and yellow flowers; it must be seen through a magnifying-glass, however, if one wishes to observe all its beauties. What a contrast is our next on the list, *Bollea Patini*. Here we have a large, massive-looking flower, with sepals, petals, labellum, and column of a very pale dirty blue colour, relieved by a faint tinge of yellow; the most remarkable part of this flower, however, is the column, which is very large and shaped like a hood, overhanging a lip of which the greater part consists of a large, solid, ridgy crest; this is a bold-looking flower, but the colour is not decided enough for it ever to become a favourite, *Bollea Latindeli* being much prettier.

We now come to that wonderful genus *Catasetum*, all the species of which appear to have the same wonderful power of ejecting their pollen-masses on certain parts of the column being touched; and *C. viridi-flavum* is no exception to the rule. The flower is of a yellow tint, the labellum forming a large bag, completely enclosing the column, and at the bottom of these horns which form the irritable part of the flower, but I may here remark that these singular flowers are not irritable when they first open; on the contrary, it is nearly always a couple of days before they will answer to the touch and eject their pollen. The stigma of *Catasetum*, too, is also different, as apparently it is never viscid nor in a condition to receive the pollen, and this corroborates Darwin's idea, who remarks that in "*Catasetum* the sexes are distinct." Of Lady's Slippers (*Cypripediums*), thirteen species, hybrids, &c., flower in mid-winter. They are most useful plants, as they remain long in flower, and when out of flower, the foliage of many of them, like that of *C. venustum*, *C. pardinum*, *C. Swartzianum*, and *C. javanicum*, &c., is by no means unattractive. My favourite amongst them is the rosy-tinted *C. Sedeni*, a hybrid raised in

Messrs. Veitch's nursery by Mr. Seden. The last new species, *C. Boxalli*, has pretty, apple-green flowers, somewhat resembling those of *C. villosum* in colour, but instead of the upper sepal being veined with dark brown, it is covered with large, chocolate-coloured blotches, giving it a very distinct appearance. Let us now turn to *Cymbidium sinense*, a species that used to be much admired years ago when Orchids were rarely to be met with in cultivation; its spikes of brownish-yellow flowers, veined with crimson, have a pretty appearance, but it is now out of date, having had to make way for more fashionable plants. *C. Mastersi* is a species well worthy of a place in any collection, its elegant, drooping spikes of pure white flowers being very beautiful. Who, too, would be without the two *Calanthes*, if only to use the blossoms for bouquets? I mean the pretty white *C. vestita*, with its crimson or yellow eyes, and the pink *C. Veitchi*, one of Mr. Dominy's hybrids. *Colax jugosus*, too, has exceedingly beautiful flowers; this plant has the habit of a *Maxillaria* or a *Lycaste*, with large solitary blossoms at the end of radical peduncles; the sepals, which are pure white, are of good texture, and the petals and labellum are white, spotted with crimson; altogether a very attractive and distinct-looking flower. Of the genus *Cattleya* I have only one to mention, viz., *C. marginata*. This is a very handsome species, much like a *Sophrontis* in shape, but not so large as many of the grander sorts; it will, however, always be a favourite on account of its beautiful, broad, lilac sepals and petals, and rich crimson lip, frilled and edged with white; its compact habit, too, is much in its favour.

Let us now speak of the genus *Dendrobium*; foremost amongst winter-flowering species belonging to it may be named the beautiful *D. primulinum*; the colour of the sepals and petals is a lovely, soft, pale purple, which contrasts admirably with the lip, which is white in front, and streaked with crimson at the base. It is also compact in habit, the flowers being arranged alternately on each side of leafless stems, as in *D. cretaceum*, *D. ocellatum*, &c.; it is, indeed, so much like the latter, that Lindley said that perhaps they ought to be united; there are many points, however, in which they are decidedly distinct. Another beautiful species is *D. heterocarpum*, sometimes named *D. aureum*; this is a general favourite, not only on account of the unique colour of its flowers, which are produced from the ends of the stems, but also because of the delightful fresh scent of Cowslips which it diffuses around. There is, moreover, in flower now the new *Dendrobie*, *D. superbiens*, which promises to be a valuable addition to the genus. Its magenta-purple flowers, resembling those of *D. bigibum*, with their broad recurved petals, and a lip shaped like that of a *Lælia*, are arranged at the end of a long, erect, arching flower-stalk, and have a very graceful appearance. Then we have such well-tried kinds as *D. fimbriatum ocellatum*, *D. densiflorum*, and *D. Farneri* with its delicate colouring; also the ever useful *D. nobile* and *D. tetragonum*, about the last of which there is no great beauty; but it is worth growing on account of its neatness and singular appearance; the sepals and petals are yellowish-green edged and tipped with red, and the lip is white spotted with red; the lateral sepals are very long and attenuated and twisted at the base, so as to cross one another in front, whilst the dorsal sepal is bent down between them, giving the flower much the aspect of *Masdevallia gibberosa*. *Epidendrums* are, as a rule, not much cared for by Orchid growers, but still the different shades of rose and vermilion in such species as *E. elongatum*, *E. paniculatum*, and *E. Ibaguense* must not be entirely despised. *Lycaste Skinneri* is another well-known Orchid which, with its many varieties ranging from almost pure white to dark crimson, must satisfy everyone's taste; it is easily managed, too, for I have had one growing in an ordinary sitting-room for several years. It received little attention, but care was taken to keep the leaves quite clean by using the sponge pretty often, and the pot was placed over a pan always kept full of water. By these means it increased and flowered as well as in an Orchid house. *Cypripedium insigne* and *C. venustum* also succeed managed in this way; and I once saw in a cottage window as fine a plant of *Oncidium ampliatum* in full flower as one would wish to see. *Lælias*, with their large, rich-looking flowers, so much like those of *Cattleyas*, are exceedingly beautiful, *L. autumnalis*, with its soft rose-coloured blossoms, being very acceptable at

this season of the year; but what a pretty species is *L. albida*, with its pure white flowers! they are as odorous, too, as they are pretty, for they have a powerful scent of Almonds. *Maxillarias* are, now-a-days, much neglected; yet *M. picta*, with its orange flowers, almost white behind, and spotted with crimson within, is very pretty. *M. venusta* is, however, an exception, as its large, snow-white flowers cause it to be much sought after.

*Masdevallias* have lately become great favourites. *M. Veitchiana*, the finest of all *Masdevallias* as regards colour, reminds one of a scarlet coat with a crimson scarf over it; *M. amabilis* and *M. ignea*, too, are equally brilliant. How these three plants, with their blaze of colour, light up an Orchid-house; one does not think of winter whilst such flowers are to be seen. *M. tovarensis*, too, with its snow-white blossoms, and the purple-dotted *M. polysticta* and *M. melanopus*, are all gems, and one cannot wonder at their having become such favourites. *Mesospindium sanguineum* has warm, rosy-tinted flowers, but they are too small, and the flower-stalks are too straggling. *Neottia maculata* is a plant seldom seen, but it is well worth growing on account of the exceedingly bright crimson of its flowers.

As regards *Odontoglossums*, no one could help admiring *O. Alexandræ*, which is one of the finest Orchids in cultivation. Its near ally, *O. Pescatorei*, too, is very nearly as good, and another magnificent *Odontoglossum* just now in flower is *O. cirrhosum*. *O. Inseleyi* has grand flowers, more particularly the variety *leopardinum*, which is much finer in its markings than the old *O. Inseleyi*. Then there are *O. Rossi*, and our old friends *O. Bictonense* and *O. Uro-Skinneri*, the latter remarkably like the former, but double its size. From *Odontoglossums* to *Oncidiums* is but a step; in fact, it is a very difficult thing to say where one ends and the other begins. True *Oncidiums*, however, will never take one's fancy like *Odontoglossums*, as their panicles of flowers are mostly so very straggling. *O. cheiroporum* is the most compact of them all, and will be always welcome. *O. ocellatum* and *O. ornithorhynchum* are also very pretty, the rose and purple tints in these two species being very rare in this genus, in which the predominating colours are yellow and brown. That little gem, *Ornithidium Sophronitis*, has the largest flowers of all the *Ornithidiums*, and is a very pretty little plant, with bright scarlet flowers, though very rarely seen. Passing by *Phaius grandifolius*, a very old Orchid, we hasten on to the magnificent "Indian moth" Orchids, *Phalenopsis grandiflora* and *amabilis*. These two are, in their way, quite as lovely as *Odontoglossum Alexandræ*, but they have not the airy grace of the latter. They are very much alike, the only difference being that *P. amabilis* has more crimson round the crest of the labellum, and the leaves are of a darker green than in *P. grandiflora*. There is one other distinction, however, which I have noticed in these two species and it is rather a curious one. If the pollen-masses with their pedicel and gland of *P. amabilis* be withdrawn on the point of a pencil, the pedicel in a few minutes doubles itself backward on to the gland; whereas in *P. grandiflora* it bends forwards—a curious physiological fact. *Pleurothallis*, *Polystachias*, and *Rodriguezias* we must also pass over, as they are seldom grown, but must stop to give *Restrepia antennifera* a good word. *Restrepias* have an aspect peculiarly their own, caused by their extremely slender dorsal sepal and petals, and the connate boat-shaped lateral sepals. *R. antennifera* is one of the finest, the crimson markings on the white ground being very neat. What a useful plant is *Sophrontis grandiflora*, with its compact habit, and intense scarlet flowers just raised above the leaves; a few plants of this judiciously placed here and there in an Orchid-house have as fine an effect as the little old woman in a red cloak so often introduced in a landscape painting. I have nearly got to the end of my list, but I cannot possibly pass over *Saccolabium giganteum* and *violaceum*. How deliciously inviting do their close spikes of white and purple flowers look, and what a sweet scent they have. My last three are well-known plants, at least two of them, viz., *Vanda tricolor*, with its fine spikes of yellow and crimson flowers, and *Zygopetalum Mackayi*. What a useful old plant the latter is, and it has also the additional recommendation of being very sweet scented. The other *Zygopetalum* (or *Zygosepalum* as it

is now called) *Z. rostratum*, is seldom seen in collections, though I once saw it exposed for sale as a cut flower in Covent Garden, its large white blossoms having, I expect, obtained for it that distinction.

The following is a list of some of the best Orchids that flower in winter, including those just alluded to:—

<i>Angraecum eburneum</i> sesquipedale	<i>Dendrobium super-</i> <i>biens</i>	<i>Odontoglossum In-</i> <i>slayi</i>
<i>Angulos Clowesi</i>	tetragonum	<i>Bictoneense</i>
<i>Ansellia africana</i>	<i>Farmeri</i>	<i>cirrhosum</i>
<i>Barkeria Skinneri</i>	nobile	<i>claireps</i>
<i>Bifrenaria racemosa</i>	fimbriatum ocula-	<i>Pescatorei</i>
<i>Brassavola cordata</i>	tum	<i>Karwinski</i>
<i>Bletia acutipetala</i>	densiflorum	<i>Rossi</i>
<i>Bobophyllum aurico-</i> <i>mum</i>	<i>Dicrypta Baueri</i>	<i>Oncidium Cebolleta</i>
<i>Bollea Patini</i>	<i>Epidendrum ciliare</i>	<i>excavatum</i>
<i>Catasetum viridi-fla-</i> <i>vum</i>	elongatum	<i>suave</i>
<i>Cypripedium Sedeni</i>	cochleatum	<i>crispum</i>
javanicum	thagense	<i>haetatum</i>
concolor	variegatum	<i>chrysochorum</i>
venustum	paniculatum	<i>enclatum</i>
paradinum	equitans	<i>tripetrum</i>
<i>Roezli</i>	diffusum	<i>orthorrhynchum</i>
longifolium	<i>Isochilus linearis</i>	<i>retlexum</i>
<i>Harrisonianum</i>	<i>Lycaste Skinneri</i>	<i>Ornithidium Sophroni-</i> <i>tis</i>
<i>Schlimmii</i>	<i>Laelia autumnalis</i>	<i>Phaius grandifolius</i>
insigne	<i>Lindleyana</i>	<i>Phalenopsis amabilis</i>
<i>Boxalli</i>	albida	<i>grandiflora</i>
<i>Crossianum</i>	<i>Maxillaria picta</i>	<i>rosea</i>
<i>Swainianum</i>	foreata	<i>Pleurothallis prolifera</i>
<i>Cymbidium sinense</i>	variabilis	<i>ophiocephala</i>
<i>Mastersi</i>	venusta	<i>Polystachia luteola</i>
<i>Calanthe vestita</i>	<i>Masdevallia amabilis</i>	<i>grandiflora</i>
<i>Veitchi</i>	melanopus	<i>Rodriguezii secunda</i>
<i>Colax jugosa</i>	<i>Veitchiana</i>	<i>Barkeri</i>
<i>Cattleya marginata</i>	igna	<i>Restrepia antennifera</i>
<i>Dinema polybulbon</i>	polysticta	<i>Sophronitis grandiflora</i>
<i>Dichaea picta</i>	<i>tovarensis</i>	<i>Saccolabium giganteum</i>
<i>Dendrobium primidi-</i> <i>num</i>	<i>Mesophipidium sangui-</i> <i>neum</i>	<i>violaceum</i>
heterocarpum	<i>Neottia maculata</i>	<i>Vanda tricolor</i>
bigibbum	<i>Odontoglossum Uro-</i> <i>Skinneri</i>	<i>Zygopetalum Mackayi</i> <i>rostratum</i>
	<i>Alexandrae</i>	ARTHUR B. COLE.

**A Finely-flowered Odontoglossum.**—A plant of the beautiful *O. Alexandrae*, growing in a comparatively small pot in a villa garden at Clapton, is now bearing a spike of bloom 4 ft. long, furnished with eight large, crisp, beautifully-tinted blossoms. The house in which it is grown is but a few feet square, but this plant, as well as others associated with it, go far to illustrate how well the most valuable Orchids may be grown by villa residents, even where their glass structures are little better than a simple heated frame.

**Orchids in Flower at Tottenham.**—In the collection of Orchids belonging to Mr. Day, at Tottenham, there are just now several plants in flower of an attractive character. Notwithstanding the loss of a large number of buds of *Phalenopsis* through the heavy fogs which have lately been experienced in the neighbourhood of London, there is on these plants a fine display of bloom. The pure white *P. grandiflora* is bearing flowers very large in size, and which contrast effectively with the showy blossoms of *P. Schilleriana*, *P. leucorhoda*, and the beautiful natural hybrid *P. casta*, a kind intermediate between *P. Schilleriana* and *P. amabilis*. *Saccolabium* are also well in flower, especially the beautifully-scented white-flowered *S. Harrisonianum*. An excellent specimen of the useful and showy *Angraecum eburneum* is bearing three very large flower-spikes. In a cool conservatory are several well-flowered plants of the variety of *Odontoglossum Inslayi* called *Leopardium*, associated with *Dendrobium*, *Lady's-slippers*, and *Coleogyne*. In such a situation the flowers last for a longer period, and are much more enjoyable than when kept in a warm, damp atmosphere. In another house a good display is made with the chocolate and white-flowered *Miltonia cuneata*, the dwarf and beautiful white-flowered *Cypripedium niveum*, the sulphur-coloured *C. concolor*, *Laelia anceps*, *Lawsoniana*, and the ivory-like *Lycaste Skinneri alba*. With these are also associated good examples of *Laelia praestans*, the brilliant violet-pink *Barkeria Skinneri*, which forms such a striking contrast to the snowy flowers of *Odontoglossum Alexandrae*, the curiously speckled *O. blandum*, and *O. cirrhosum*. On a plant of *Oncidium orthorrhynchum albidum* are several graceful spikes of small white flowers with golden stamens; and a specimen of *Odontoglossum pulchellum majus* bears nearly thirty spikes.—C. S.

## PLATE CXIII.

## MASDEVALLIAS.

(WITH COLOURED FIGURES OF SOME OF THE BEST KINDS.)

Drawn by Mss. DUFFIELD.

A FEW years ago *Masdevallias* were almost unknown in Orchid collections, *M. fenestrata* (with singular-looking, brown flowers), *M. civilis* (with dull-coloured, disagreeably-scented blooms), *M. infracta* (with inconspicuous blossoms), and a pretty small-flowered kind called *M. maculata* (which, as far as I know, was at that time confined to the collection of the late Count Schiller) being all the varieties with which cultivators were acquainted; and, indeed, in appearance they bore so great a resemblance to the genus *Pleurothallis*, that little was expected of them. Travellers often spoke of the marvellous beauty of kinds which they had seen, and of their dazzling colours; but it was long before they reached us in the form of living plants. The annexed plate represents some of the handsomest species and varieties at present in cultivation; but it is impossible to do full justice to their rich shades and depth of colour on paper, beautifully drawn and coloured though the plate in question is. The great beauty in most Orchids lies in the labellum and petals; but in the *Masdevallias* these organs or parts of the flower are reduced to a minimum, and in many instances brilliantly coloured, and the points of the cup prolonged into slender tail-like appendages.

The following are a few of the best species, viz.—

**M. Veitchiana.**—The colours of this fine species are difficult to describe, the shading being so extraordinary. They consist of rich orange-scarlet and yellow, shot with intense purple. It is a native of the Cordilleras of Peru.

**M. ignea.**—This species comes from New Granada, and is remarkable for having the upper division of the calyx bent down over the throat; the colour is intense red, shaded with crimson-purple. It has already produced several varieties.

**M. tovarensis.**—The flowers of this species, which are usually borne in pairs, are as white as snow. The old stems should not be cut, as these develop new buds from the apex. It is a native of Tovar, in Columbia.

**M. Harryana.**—This grand species, which comes from New Granada, has produced many varieties, some much finer than the typical form. They vary in colour, from reddish-crimson to violet-crimson.

**M. coccinea.**—Of this the late Professor Lindley said: "The flowers are as red as a soldier's coat." Outside, however, they are tawny-yellow. It is a native of New Granada.

**M. Davisii.**—In this species the flowers are of a uniform, rich orange-yellow. It is a native of Peru.

**M. Chimera.**—The flowers of this do not depend so much upon gay colours for their attractiveness as upon their wonderful form. They are large, the points of the tripartite calyx being very much lengthened out into long, tail-like appendages. The colour is yellowish and brown, and inside the blossoms is a profusion of long hairs. It is a native of New Granada.

**M. Lindeni.**—In this species the flowers are medium-sized, and in colour a rich magenta. It is a most attractive and pleasing plant. A native of New Granada.

**M. polysticta.**—This is a small-flowered species, which bears numerous blossoms upon each spike; in colour they are white, beautifully freckled with crimson dots. It is a native of New Granada.

*Masdevallias* would appear to be the coldest of the cool Orchids, and to luxuriate in a soft atmosphere well charged with moisture, but yet with an abundant supply of air. The pot, in which they are grown must be thoroughly drained, and the compost should consist of rough peat and living *Sphagnum* Moss intermixed with just a small portion of sharp sand. They have no stout pseudo-bulbs in which to store up moisture, and therefore must never be allowed to get dry; indeed, they seem always to be growing, and if treated properly, they will bloom several times in a season. In fact, it may be said with propriety that they are perpetual bloomers, and their flowers contrast strikingly with those of *Odontoglossum*

A GROUP OF MASDEVALLIAS

Alexandra, O. Pescatorei, O. cirrhosum, and others, while as respects culture, they associate with them admirably.

W. H. G.

[Our plate represents a group of species gathered from Messrs. Veitch's Masdevallia-house at Chelsea.]

## GARDEN BOTANY.

### Introduction.

**GENERAL CONSIDERATIONS.**—The study of the phenomena of plant-life has been very much retarded and complicated by botanists and teachers of botany themselves, not willingly, of course, but none the less surely. Instead of its being popular, as a means of developing the observing powers of children, and adding to the pleasures of adults, it has come to be regarded as something too difficult for anybody with little leisure to attempt to take up, and as something consisting mainly of unintelligible names, and perplexing technical terms. Even many intelligent gardeners, who are obliged to acquire some knowledge of the names of plants, will have nothing to do with what they call botany, because they associate it with a bewildering terminology. It is the same with a very large proportion of amateurs, who cultivate extensive collections of plants for the beauty of their forms and colours, and the fragrance of their flowers. Many of them know a great deal about their plants, and ask, "what is the use of studying botany?" apparently unaware that they actually possess a great deal of essentially botanical knowledge, which a very little systematic study would render clear and profitable. On the other hand, there are many self-styled botanists, whose idea of botany is limited to making a collection of dried plants, and affixing their Latin names, wherewith they seek to mystify their sensible acquaintances, but only succeed in making themselves ridiculous. They know, may be, the plants by sight, and they know very little more. These collectors, whether of plants, butterflies, or birds, are very tiresome and objectionable people, for they ignore good English names of objects, and would shoot the last bird, or root up the last plant of a rare species, to put it in their collections. Knowledge of this kind by itself is worse than useless; it is not science, or botany, or natural history, and the possessors are in the same unfortunate condition as those persons who understand a number of languages without being able to converse in any of them on any intellectual theme. Yet the time they have devoted to the acquirement of this superficial knowledge of a subject would have been amply sufficient to obtain an insight into the life-history of some plants or animals. In effect, names are of secondary importance, given for the purpose of distinguishing objects; and therefore it is unadvisable to load the memory with the names of objects to the exclusion of knowledge of the objects themselves. A perfect appreciation of the external beauty of a plant or animal which appeals directly to the senses, is not incompatible with a serious interest in its structure, mode of growth, reproduction, &c. A surgeon or a painter may admire the human form, but an intimate acquaintance with the way in which it is built up is as necessary for the one to be able successfully to practice his profession as for the other to be able to produce really artistic pictures.

**OBSTACLES TO THE STUDY OF BOTANY.**—The assertion that botanists themselves have actually indirectly discouraged the study of botany is easily substantiated. Botany as a science has existed little more than a century; and, as researches proceeded, it became necessary to devise terms to designate different parts and modifications of parts. As was unavoidable in the infancy of a science, writers on the subject carried on their investigations independently, and each one proposed and employed what terms he chose. Some endeavoured to simplify as much as possible, whilst others seem to have made it their object to render everything as difficult and obscure as possible. Different botanists used some of the same terms to designate diverse parts or modifications, causing great confusion and contradiction. In course of time the accumulation of terms had become so great, and their application so uncertain, that reform was imperative. Reforms are proverbially slow, and in this case there were several causes to prevent their speedy

accomplishment; amongst them the impossibility of withdrawing from circulation the faulty text-books, and inducing authors to overcome their vanity, and devise a uniform system of nomenclature. By degrees, however, much has been effected, and a great many of the useless terms have been expurgated. So far as systematic botany (classification of plants) is concerned, the preparation of descriptive works, written in English, on the vegetation of our colonies has been the means of simplifying the terminology; and the translation into English of foreign works on vegetable physiology has served the purpose of introducing the terms generally employed by the principal labourers in this department of botany. Botanical teaching in this country is now tolerably uniform—taking the Universities and principal London hospitals, at least—and is based upon living specimens. The object of these paragraphs on plant-life is to set forth, in as simple language as possible, the structure and growth of plants, and their various vital processes so far as they are understood at the present time.

**NECESSITY OF CONSULTING RECENT WORKS.**—Here it may be observed that botany, especially physiological and anatomical, has advanced with rapid strides during the last quarter of a century, and important discoveries are constantly being made, upsetting earlier assumptions and theories; hence the necessity that great care should be exercised in the selection of a text-book, otherwise the student may have to undergo the difficult and disagreeable process of unlearning much to which he has devoted valuable time to acquire. Books only a few years old teach a great deal that is now known to be erroneous, and, therefore, the latest text-book, compiled by a thoroughly competent botanist, is the only one that can be safely used. But, although great progress has been made of late years, some of the functions and phenomena of plant-life are still very obscure, and we can only say that research points to this or that solution of these problems. To make these lessons, if they may be so termed, as perfect and trustworthy as possible, as far as they go, the writer has consulted not only the best English authors, but also the works of some of the foremost foreigners, such as Sach's "Lehrbuch der Botanik" and Duchartre's "Éléments de Botanique." With some few necessary exceptions, references to authorities and literature are omitted. Either of the works just named may be confidently recommended to the student who has mastered the elements, with the caution to be careful to procure the latest edition. There is an English translation of the third edition of Sach's "Lehrbuch."

**TECHNICAL TERMS.**—The set of terms employed by Mr. Bentham in his "Outlines of Botany," which is prefixed to most of the Colonial "Floras" hitherto published, will be adhered to as closely as possible, and used in the same sense. Doubtless some few departures from this rule will have inadvertently crept in, but these exceptions will not affect the whole. Moreover, it is a good many years since Mr. Bentham drew up his glossary, and he himself, one may safely say, would make some alterations in a new edition. In one respect these series of paragraphs will differ from most elementary works on botany, inasmuch as being addressed chiefly to persons whose avocation is the cultivation of plants, or who are familiar with living plants, everything that strikes the writer as bearing upon practical operations will be introduced. By way of illustration, independently of the woodcuts, repeated references are made to familiar common garden and wild plants. It is believed that this mode of treating the subject will not only relieve it of a certain amount of tedium, but also make it more instructive. Everything is as clearly and fully explained as appears requisite; but, as it is not specially intended for children or people unfamiliar with plants, it did not appear desirable to write down to their level. Without some application, nothing worth knowing can be learnt, though it may be safely asserted that any one starting with an acquaintance with the outward forms of plants, and knowing the names of a sufficient number referred to in illustration of certain facts, has very little serious study before him in gaining a general insight into the economy of plant life. The study of botany is really nothing more nor less than an arrangement of the plants, to which names have been given for the purpose of identification, according to their structural affinities, the way in which they grow, what their

food is, and what are the functions of the different parts, &c. As to the practical utility and the importance of the study of plants, it seems really unnecessary to say much; for do not plants supply, directly or indirectly, nearly every want of man? For food, clothing, fuel, artificial light, and pure air we are indebted to the vegetable kingdom. Coal is but the remains of vast prehistorical forests, silk is woven by the silkworm that lives upon the leaves of trees, and plants in their process of nutrition absorb noxious gases from the atmosphere and restore the oxygen necessary for the healthy development of animals. How some of these processes are effected is still a matter of conjecture, but what is known is none the less interesting because all is not known.

**DEFINITION OF BOTANY.**—In its widest sense botany includes all knowledge appertaining to the structure, life, products, &c., of plants, and is conveniently divided into the following branches, some of which will be separately treated in the sequel. I. Vegetable Morphology (sometimes called Organography and Comparative Anatomy), relating to the various organs and their external forms and modifications. II. Vegetable Anatomy, the internal or minute structure of the tissues forming the plant. III. Vegetable Physiology, the study of the various vital phenomena of plants and the functions of their different organs. IV. Vegetable Chemistry, the composition of the substances of the tissue and the products of assimilation. V. Systematic Botany, the description and classification of plants. VI. Economic or Applied Botany, the sources of vegetable products and their uses; and VII. Geographical Botany, or Phytogeography, which treats of the dispersion of plants over the surface of the earth. Some other special branches are distinguished as Vegetable Organogeny, the study of the development (growth) of the different organs; Vegetable Teratology, which treats of the anomalies and monstrosities that occur in the flowers and other parts of plants; and Vegetable Pathology, treating of the diseases of plants. Several of these branches will be but slightly treated upon, especially Anatomy, Organogeny, Teratology, and Chemistry; whilst others will be explained with considerable detail. But the divisions will not be rigidly adhered to, because it will save a good deal of space and repetition to state, for instance, what the function of an organ is when treating of its name and place.

**PREPARING PLANTS OR PARTS OF PLANTS FOR EXAMINATION.**—Fresh plants, in hot or dry weather especially, should be placed in water for a short time as soon as possible after cutting, when they will imbibe sufficient to keep them from withering for some time. This applies particularly to cut flowers or shoots to be sent by post, or otherwise, to a distance. Let them take as much water into their tissues as they will, but on no account sprinkle flowers with water, as it causes the parts to drop and decay, instead of preserving them. Pack them in as near air-tight tins as can be obtained, without any foreign material whatsoever. Flowers that have once withered never hold so long, other things being equal, as those which have not. Dried plants, or parts of plants, should be soaked in water or boiled for a short time previous to examination or dissection. Germination, or partial germination, will facilitate the determination of the nature of seeds and embryos. A simple microscope or pocket lens, a sharp penknife, and some needles fixed in small handles, are all the instruments necessary as aids in studying the external characters of flowering plants. To see their minute structure, and to follow the development of the cryptograms or flowerless plants, a compound microscope is indispensable, and some practical instruction in the art of preparing and mounting objects.

**HOW PLANTS DIFFER FROM ANIMALS.**—Organised beings—that is, animated beings—are divided into two kingdoms, the animal and the vegetable. In a general way it is not difficult to determine to which of the two kingdoms an organism belongs; but each kingdom includes a number of microscopic creatures of exceedingly simple structure; and on the confines, as it may be termed, of the two kingdoms, or a point where there seems to be a transition from one to the other, there are some of doubtful and debatable nature. The most ingeniously constructed definitions

break down somewhere in the chain, and it is not unreasonable to suppose that no such thing as a hard and fast line exists between the two kingdoms. But there is rather a formidable objection to the theory that there is actually a connecting link between plants and animals on the limits of the simplest forms of both, unless we assume that evolution in the contrary directions has taken place. It should be briefly stated here that some naturalists now believe in the possibility of all the present plants and animals having descended by evolution, or gradual change, from a simple form or forms to successively more complex structures. The fact that the simple organisms still exist side by side with the more complex is explained in this way, that evolution is effected by a process of natural selection. Other naturalists argue that because the progeny of any particular plant or animal exhibits a considerable range of variation, which may be still further increased by selection and isolation, it does not follow that there is no limit to it, and that, in course of a long series of years, the descendants will be totally different in form and structure from the parent. Neither does it seem certain that because species and genera and families pass into each other, with few interruptions, there is no other way of accounting for it, save by descent from a common stock. These are matters for individual thought and further research, and dogmatising on either side is inconvincent and fruitless. Whilst it is beyond all question that many existing very distinct forms in both kingdoms were not specially created, but have descended from others, the evidence adduced in support of the theory of evolution, as opposed to creation, is not conclusive. With this allusion to the diversity of opinion respecting the origin of species, &c., the theories may be left to take care of themselves; but whatever we accept or reject that cannot be supported by absolute proof, it should not interfere with our endeavours to solve the problems of Nature. Disregarding the lower microscopic organisms of doubtful nature, which do not come within our province, plants differ from animals most essentially by the manner in which they feed. The food of plants is invariably liquid or gaseous. Not the least particle of solid matter can enter their system; whereas, the food of animals is chiefly solid, and taken into a stomach, where it is subjected to a process of digestion to extract the nutrition from it, leaving a residuum to be excreted. Again, the food of plants is exclusively inorganic (except of a few leafless plants, destitute of green colouring matter), and is assimilated or prepared in all the young green parts. All parts of plants are built up of cells of different forms, and are homogeneous throughout, leaving nothing in their structure answering to the stomach and other internal organs of animals. The plan of growth in plants is totally different from that of the more highly organised animals, inasmuch as interstitial growth soon ceases; that is to say, each joint (internode) of a plant, makes its longitudinal growth in one season; and, although it may, and usually does in woody plants, increase in size, it does not increase in length. This may easily be verified by measuring, or even noticing, the height at which branches are given off from any tree with which we have been familiar for some years. If this were not so, our dwarf trees would grow into standards, and our trained trees would require new branches put on at the base as the stem lengthened. Plants are, as a rule, destitute of every power of movement. The vital principle in the two kingdoms seems to be indistinguishable, though animals are endowed with properties or faculties apparently not enjoyed by plants. Sensibility and instinct seem to be exclusively attributes of the animal kingdom, though some writers have sought to show that plants possess, the sense of feeling and display a kind of instinct. To anyone unacquainted with the singular mimicry of plant forms by zoophytes, it would seem almost superfluous and useless to say anything about these distinctions; but many of those curious organisms, or rather aggregations of individuals, might easily be mistaken for plants.

**INDIVIDUALISM IN PLANTS.**—Most plants are not individuals in the sense of being indivisible, and therefore some writers consider them as congeries of individuals. If we are so unfortunate as to lose a limb, even as a young baby, the loss is altogether irreparable; but each bud in a plant will develop into an independent plant possessing all the attributes of the

parent. Indeed, in some cases, as in *Bryophyllum* (fig. 1) *Begonia*, &c., the leaves themselves are capable of giving birth to new plants; and in many other plants, such as the Pilewort and some of the Lilies (fig. 2), little bulbs are formed in the

Fig. 1.—Leaf of *Bryophyllum calycinum*, with a plantlet developing from each notch. (Reduced.)

axils, and these, falling to the ground, grow into independent plants. This naturally leads us to the consideration of a

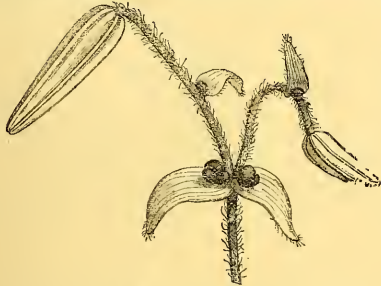

Fig. 2.—*Liliun bulbiferum*, with bulbets in the axils of the leaves.

whole plant, or an individual plant, as we shall term it in spite of its divisibility, without losing any of the properties of a perfect individual. W. B. HEMSLEY.

**Vegetation on the Shores of the Mediterranean.**—I have just returned from Naples and the south of Italy—to my favourite San Remo, and find vegetation, that has been battered and crippled by the dire Tramontana around Naples, here in gardens skirting the Mediterranean unscathed, and beautiful in its development and inflorescence. The garden of the Hotel Victoria stretches down nearly to the beach, the railway passing between the garden and the tidal-mark of the deep blue waters of the Mediterranean. It is a sheltered nook, and I am not surprised to see shrubs, usually grown under glass in England, here in fair flower in the month of January. I would especially mention the *Datura cornigera* (fl.-pl.) quite hung over with its long, fragrant flowers. *Abutilon album* and *Achania Malvaricus* are growing side by side, the *Achania* offering its sweets to the noble violet-bee, which hums past on rapid wing. The delicate colouring of the flowers of the *Abutilon* contrasts most happily with the green of the leaves. Everyone is at once interested in the dark flowers of the *Achania*. Then, what more glorious plant than the *Sparmannia africana*, with its parti-coloured stamens, that remind one in their tinting of the *Capparis* on the Lake of Como. There is something almost wonderful in the colouring of stamens! In both instances Nature has enhanced the beauty of the flower by her painting of the stamens. A fine climber, holding its own with beautiful effect, is the Cape *Tecoma*. Surely it could not be so full of flower at the Cape as it is in our garden at San Remo. Why, there is spray after spray of its ruddy orange blossoms. The *Eucalyptus globulus* is only partially covered with its fair flowers. A *Myrticort* in growth, it is the most rapid of all the tribe. Young trees soon

attain size and proportions. Its service, where malaria prevails, is now fully established. The *Salvia cardinalis* is very gay here all the winter, and is a general favourite. The same may be said of the *Cassia*, which is just now a perfect picture. These are the most conspicuous in the gardens of San Remo in the winter. It would be easy to supplement the list with as many more, but these flower more shyly, and I do not care to enumerate them with the others.—PETER INGBALD, *San Remo, January, 1878.*

## THE INDOOR GARDEN.

### WINTERING TENDER PLANTS.

Is it possible to keep tender plants in an unheated pit in winter? This question, which has often been asked, I answer yes, although many have no doubt failed in doing so. I suppose, however, no one would from choice attempt to keep tender plants in cold frames in winter; yet having the means of readily applying fire-heat to plants that can be kept in health in a low dry temperature, always provided the frost be kept out, is not altogether an unmixed good. True, too much fire-heat may not directly kill plants in the same way that frost would do; still, when a higher temperature is maintained than is necessary, it tends to exhaust plants, renders them unhealthy, encourages the presence of insects, and generally shortens life. One of the chief reasons why many fail to winter plants in a cold frame or pit is, they pot their plants or strike their cuttings too late in summer. Every cutting of such plants as *Pelargoniums* or *Verbenas* should be put in by the 1st of August or before that date, and all tender plants which it is desirable to lift and save should be potted early in September in light sandy loam, just merely shortening back the roots a little, cutting back any straggling branch, and taking off a few of the largest leaves. Unless this be done, the plants do not become sufficiently established to stand any hardship in the shape of either damp or frost. Some years ago I was asked, when clearing a flower garden in autumn, to give away any plants that were not required amongst the cottagers in the town and neighbourhood. The result was that the first year I had a good many applicants, but gradually they decreased, until at last none came. If I could have given away any plants well established in pots, they would gladly have had them; but many of them found that after buying pots the plants died during the winter—in some instances, no doubt, through frost, but mainly from want of that hardiness and maturity of growth that early potting and standing thinly in the sunshine always impart. In order to carry tender plants through the winter safely without fire-heat, they must have a careful preparation. *Verbenas*, *Calceolarias*, *Fuchsias*, and similar plants may be kept with little trouble, as it will take a very severe frost to hurt them when covered with litter; but in the case of *Pelargoniums* it is often the damp that kills, especially if the plants be imperfectly established. In wintering half-hardy plants, *Calceolarias* alone excepted, there must be freedom from damp, i.e., there must be a pure sweet atmosphere, and the temperature must not fall much below the freezing point. A degree or two of frost will not do much harm, provided the coverings are not removed too hastily after the weather breaks; but it must not be forgotten that if frost be allowed to enter at all, the plants are exposed to considerable risk. Making, however, every allowance for the difficulty of combating damp in cold pits, and for the thought and care required to guard against the admission of frost, yet neither of these objects is so difficult to attain as at first sight might appear. To secure a dry atmosphere, the floor of the pit or bed must be well drained; it must not hold moisture in suspension, to be drawn up by every gleam of sunshine that falls upon the glass. In the case of an ordinary brick pit with a brick bottom, like most of the old-fashioned forcing pits, all the manure that may have been used for spring forcing should be cleared out, and a temporary stage of boards erected, so that the plants may occupy a light position, and yet be at least 6 in. or 8 in. from the glass. The pit, when the spent manure is cleared out, will hold a much larger body of air; and the plants being placed in its midst, will run much less risk from damp settling on them than they otherwise would do. The smallest notch of air admitted from the outside will cause a rapid circulation, and much of the success will depend upon the attention and care bestowed upon the ventilation. No dead or decaying matter must ever be allowed to remain amongst the plants, and no plant should be watered until it is absolutely necessary to keep it from flagging, and not a drop should be heedlessly spilt. Should there at any time appear symptoms of damping amongst the plants, scatter dry dusty peat, wood-ashes, or sand amongst them; or, in bad cases, dress the affected parts of the plants with quicklime. If the pit cannot be provided with a temporary stage, and the plants have to stand on a coal-ash bed, there should be at least 6 in. or 8 in. of porous material beneath the ashes, to make sure of good drainage;

and, if at any time the precautions I have already named against damp are not sufficient, take the plants all out the first fine calm day, and spread an inch or two of the driest ashes that can be had all over the floor of the pit, at the same time lime-washing the walls; and, when all is finished, return the plants to the pit. This will be found a most effectual cure, and where plants have to be wintered without fire-heat, it is always advisable to keep a stock of dry ashes at hand. Keeping plants in cold pits is much a question of forethought—of trying to anticipate all difficulties before they arise. Any who puts things off or forgets them will fail, and had better not attempt it. I will now just briefly glance at the means employed to keep out frost. If the thermometer falls below 12° in the open air, it will penetrate through a 9-in. wall of brickwork; and it is as well to hear this in mind, for sometimes I have known thick coverings placed over the glass, and a sense of security indulged in, without thinking that the frost could enter through the brickwork. Therefore, when frost is apprehended, some means must be at hand for sheltering the walls, if composed of brickwork, as well as the roof; turf or earth walls are much better frost-resisters than bricks. There is nothing much better for covering pits during severe frost than long dry straw. When used in bulk it incloses a considerable quantity of air, and dry air, motionless, forms an almost impenetrable barrier to cold. When the straw becomes wet it is not nearly so good, as the water forces out the air and lets in the cold. I have known plants sometimes covered up for a month without taking any harm, but after a severe frost the coverings must be removed very cautiously; first let in a little light at the back, gradually increasing it as the foliage gets injured to it; air should be admitted in a similar manner. In fact, there is as much necessity for caution in these particulars as there would be in treating any case of deprivation in the human subject. Air must be given freely at all other favourable opportunities, in order to maintain the plants in a healthy vigorous condition.—“Field.”

#### BOMAREA CARDERI.

EARLY in the autumn of last year I noticed in Mr. Bull's nursery this fine new plant beautifully in flower. It belongs to the *Amaryllidæ*, but in its general habit and appearance it has nothing in common with the more generally known members of that family. It is a climbing, or more properly speaking, a twining evergreen plant, not unlike the *Vanilla*. The shoots spring from the base much in the way of those of a *Lappageria*, and they are about the thickness of those produced by strong specimens of that plant. It has handsome deep green oblong lanceolate foliage, 7 in. or 8 in. in length. The flowers are borne on the points of the shoots, and in form are not unlike those of a *Lappageria*, but instead of being reflexed at the points they are slightly compressed; the three sepals are pale pink, the petals, also three in number, are pink, suffused with green, and profusely spotted with black, a distinct and pleasing combination of colours; the cluster of flowers collectively forms a beautiful drooping cyme, not less than 15 in. in diameter. It is evidently by far the finest *Bomarea* that has yet flowered. As I understand that it is found at a considerable elevation in New Granada, I should imagine that an intermediate temperature would suit it. It is quite possible that ultimately it may be found to enocence in a greenhouse; in either case, it may be looked upon as an acquisition. It will be better adapted for clothing an end wall, or draping a pillar, than for running up the roof, as its natural disposition is continually throwing up fresh shoots from the bottom inasmuch as its being clothed with foliage down to the base. It succeeds in a medium-sized pot, but would, no doubt, be more at home planted out in a border of moderate extent, where its roots would have room to extend in a way that would insure vigorous top-growth, for in all plants that possess this habit of pushing up from the base the production of flowers is always proportionately augmented by the increase of strength. T. BAINES.

#### EARLY FLOWERING HARDY PLANTS UNDER GLASS.

I FIND no plants to yield at this early period of the year such rich tints in the hardy plant-house as the deep-coloured *Polyanthus* and *Primroses* that have been lifted from the open ground and potted for that purpose. It is easy to secure a good stock of these, as a packet of seed produces abundance of plants; and once a few dozens or hundreds are secured, there are plenty to lift for indoor decoration, and also enough still left for out-of-doors. Whether in a bed of seedlings or in a bed of propagated kinds, some plants will inevitably show bloom earlier than others, and these should be lifted into pots and placed in a cool house, in order that their blossoms may be

allowed to develop themselves without any check from bad weather. The Chinese *Primrose* certainly has the advantage of our hardy kinds; inasmuch as it produces larger trusses and larger flowers at an earlier period of the winter, but these cannot exist in frost; whereas the hardy *Primrose* or *Polyanthus* is in no danger, even if often frozen under glass. What the flowers lose in size by comparison they gain in richness and variety of hue, and can easily be grown by anyone, whilst the Chinese *Primrose* is much more difficult to deal with. Plenty of these hardy spring flowers are in bloom at the beginning of the new year; and as with a stock of plants a continuity of flowers can be had for four months, it can hardly be said that these do not repay any trouble that may be taken with them. *Hepaticas*, *Scillas*, *Snowdrops*, *Pansies*, and many others of the earliest gait to bloom are now fast pushing into flower, and are exceedingly gay in pots. The pretty *Myosotis* disitiflorus is already showing its buds, and, put under glass, will be in full bloom in a week or two. A box of this for a window, with a quantity of the scarlet *Anemone fulgens* planted amongst it, would be both rich and effective. This grand *Anemone* is fast showing bloom, and maintains its character as the earliest of its family. The two best *Violets*, *Marie Louise* and *Victoria*, though not effective as pot-plants, nevertheless diffuse a most delicious perfume throughout the house. A. D.

#### FOUR OPUNTIAS.

*Opuntia crassa*.—This is one of those plants that delight in sunshine, and the brighter and warmer it is the better they like it. It grows until its weight becomes too much for its base, when down it tumbles, and starts again from the bottom. The stems, which are very fleshy, are glaucous green in colour. I have had pieces of them 1½ ft. across and 2 ft. in height. I have seen it trained on a trellis 18 ft. high, and consisting of twenty pieces of flattened stems, that is, the widened-out parts between the joints.

*O. pubescens*.—This is a stout-growing plant of a curious metallic hue, and with sets of spines like little cushions, apparently inoffensive, but when they get into the skin they are very troublesome. Its flowers are handsome. A full-grown plant is about 1 ft. or 1½ ft. in height.

*O. clavarioides cristata*.—The spines of this singular plant are stellate in form, small, and harmless. Its skin is copper-coloured, and covered with grey scales, as its name implies. It is very variable, no two shoots being over alike. It is a fragile variety, and should be kept on a shelf near the light, and out of general reach.

*O. exuviate*.—This, the most formidable of all the genus, has a way of holding fast whatever touches it. If it be touched by the boot, one has to pull hard to get rid of it. Its spines are about 1½ in. long, white, like a quill; their outer cases can be pulled off, leaving the spine intact, which has a hook at the apex like a fish-hook. The plant itself grows about 2 ft. high. In California it is quite enveloped in spines, but in this country they do not grow so freely. It may be easily shaken to pieces; and to have a good appearance, young plants of it should be struck every year or so and grown on into specimens. J. CROUCHER.

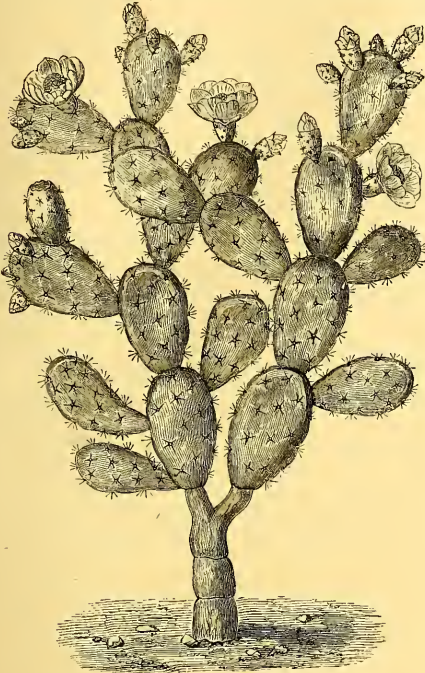

*Subury House, Hammersmith.*

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

*Epidemidiums for Forcing*.—Good established roots of these beautiful hardy plants in pots make excellent subjects for forcing into flower in March and April. They should be kept in a cold frame until the end of January, when they may be introduced to an intermediate-house and placed on a shelf near the glass. In a few weeks, if kept well supplied with water, they will come into flower, and their blossoms will be found to be very useful in a cut state.

*Eurya latifolia* as a Window Plant.—This is one of the most effective half-hardy shrubs which can be employed for window decoration. Its habit is good, and its leaves, being very smooth, are easily kept clear of dust. Even in unshelving positions, and during the duldest months of winter, the young growths assume a rich, bronze colour, which, in contrast with the white and green variegation of the older foliage, has a lively and pleasing appearance.

*Allium flavum* from Seed.—This may be easily propagated, by means of seed sown in autumn, as soon as it is gathered in small pots or pans in a cold pit or frame. The principal point requiring attention is preserving the seedlings from damp whilst in a small state. This can only be done by giving all the air possible whenever the weather is favourable. If planted out in March they will flower well the next year; *A. carinatum* may also be treated in the same way.—S.

*Opuntia crassa.*

*Opuntia pubescens.*

*Opuntia clavarioides cristata.*

*Opuntia exuvata.*

## GARDENING FOR THE WEEK.

**Orchids.**—There is no class of plants wherein cleanliness from insects is more necessary than in that of Orchids. That worst of all pests that infest them, white scale, should be diligently sought for, as, if allowed to increase to any extent, it does serious injury, especially to such as the different species of *Vanda*. It is difficult to get rid of. For down to the inner base of the leaves, where it is difficult to get at. For its removal I have found nothing equal to a home-made brush, consisting of a moderate number of long, stout bristles tied firmly to a thin bit of wood, with which the scale must be gently removed. If the plants are much affected, the operation requires care, without which the leaves get injured so as to cause their turning yellow and prematurely falling off. For the more exposed surface of the leaves a sponge will be sufficient. White scale is most difficult to eradicate from the greater portion of the scaly covering of the stems, where it is not easy to dislodge. Brown scale, although it is of a puny description, never attaining anything near the size on the thick, fleshy-leaved section of Orchids that it does on the generality of other plants, yet it is most injurious if allowed to get to any considerable head. It is much easier to dislodge, as it is more disposed to keep on the upper portion of the leaves than the base. I would caution those who have not had much to do with Orchids against being induced to use any form of the numerous insecticides recommended for the destruction of insect life, as I have never found any of them that would kill the insects without injuring the plants. A good and simple application of Scotch snuff may be dusted into the crowns of the plants when affected with thrips during the summer, but this should not be used until the leaves have made some progress, so as to be partially solidified; but where the plants are grown with sufficient light and air, without too much heat, they will usually bear syringing overhead enough to keep this troublesome little insect from finding a lodgment down at the bottom of the partially-opened leaves, without the water having the effect of injuring these, as it would if the plants are grown in a way to make them soft and tender. Means should be taken, whilst Orchids are now comparatively at rest, by repeatedly going over them, to reduce insects as low as possible. The atmosphere of the warmer Orchid-house, so long as the plants are at rest, should be kept sufficiently dry, but it is not well to carry this too far, or the effect will be that the pseudo-bulbs and leaves will shrivel too much. The different varieties of *Calanthe vestita* and *Veitchi* require a somewhat different treatment, as the case of the majority of plants, be kept in a temperature much lower than that of the majority of plants, so some parts of their growing season, as if kept too cool, young buds that are to form next year's growth do not grow plump and advance as they ought. The bulbs are also very liable to rot if the temperature is at all too low. It will shortly be time to commence potting; for this, preparation should at once be made by getting all the materials ready. Where there is a considerable number, it takes a much longer time to move them than the case of any other description of plants; but if a calculation be made of the quantity of peat that will be required, and this is broken in pieces and the Sphagnum wanted also prepared, the work can be got on with much quicker. A few words upon the preparation of these may be of use to those who have not had much experience in the cultivation of Orchids. Taking the Epiphyll Section collectively, growing naturally as they do with their roots in a great measure exposed to the full influence of the atmosphere, and their habit of adhering so closely to whatever they cling to, little reflection is needed to show that their roots are little calculated to bear confining in any material of a nature such as to become adhesive or confine them from the air, and they are likewise so constructed as to suffer more than other plants by removal; hence it becomes requisite to see that the material in which they are potted is of a nature that will last as long as possible without becoming decomposed. From this arises the necessity for its consisting of as much fibrous vegetable matter as can be obtained with the greater portion of the earthy part removed. The Sphagnum should be all carefully hand-picked, so as to clear out the whole of the bits of Grass and other matter that usually grow intermixed with it, for if these have got dry before the Sphagnum used, they will at once turn mouldy as soon as water is brought in contact with them, which, although it may not injure the roots of the plants, still looks unsightly, and hastens the decay of the Sphagnum. In potting the thick-rooted species, such as *Vandas*, *Aerides*, *Saccolabiums*, *Phalenopsis*, and *Angrecums*, it is necessary to be guided by the condition of the plants. If the pots or baskets in which they are growing are already large enough, and the plants in a healthy, thriving condition, they will be found to have quantities of roots firmly attached to the sides of the pots and baskets, from which they cannot, with even the greatest care, be removed without a great deal of mutilation. In the case of these, I have found it good practice to lay the plants down on their sides on the potting bench, work out all the old material, and then with the syringe and tepid water to wash the whole clean out, cutting up all dead roots; after which, replace the drainage, and fill it down moderately firm. This requires more time than taking the plants completely out, but if it is carefully performed, the check inseparable from total removal is avoided. Such as have to be removed altogether from the pots should be taken out with no more breakage of their roots than is unavoidable. The time of potting will, to a great extent, be regulated by that when the plants were put to rest, and the time that an

increase of heat and moisture will be applied, such as to induce growth; but with *Aerides*, *Saccolabiums*, and *Yandas*, it is essential that the potting be carried out before any progress is made in pushing up their flower-stems, or these are all but certain to receive such a check as to prevent their advancing further. *Vandas* and *Saccolabiums* do not require, nor will they bear, taking the different varieties collectively, so long a rest as many Orchids.—T. BAINES.

**Stoves and Green-houses.**—All *Allamandas*, *Bougainvilleas*, and *Clerodendrons* (climbing ones) should be cut back at once if not already done, and repotted very firmly as soon as convenient, using good loamy soil, enriched with a little decayed manure, but not encouraged to make growth. Keep the soil rather dry after potting, insert the principal stakes, and preserve the young growths from getting broken. Plants of *Poinsettias* and *Euphorbia japonica* (where done blooming) should be stored away on back shelves, under the stages, or in any other place where they can be kept dry in an intermediate house or the coolest end of the stove. *Aphelandras* done flowering may be treated in the same way, and those coming into bloom should have plenty of water, and a position near the glass. Do not allow any young plants to suffer from want of root room, but give them a shift as soon as they require it. Of stove bulbous plants at rest, start a few into growth, for early use, but it is too soon yet to start the general stock of these. A few *Nymphalises* should be introduced into a moist and temperature to encourage them to open. Placing igniconets in a little warmth will assist its flowers to open. Keep the plants near the glass, so that they do not become drawn, and tie them out neatly to a few thin sticks. Lilies that are pushing through the soil must have more water given them. Cuttings of *Verbena* and *Fuchsias* will root quickly in sandy soil if they can receive a little heat under a bell-glass. Old *Fuchsias*, that have been dried off in the autumn, may now be pruned. The branches should be cut well in, and the plants reduced in height. They may then be placed in heat, and, as soon as they have pushed a few roots, may be shaken out and re-potted. Soil if not under cover for the general potting of greenhouse plants, should be placed in a dry open shed, where it will receive plenty of air; lay it as open as possible for this purpose, and occasionally turn it over. Sand, also, should be placed where it will dry. Tree or perpetual *Carnations* are easily cultivated, and produce quantities of flowers for cutting. *Garibaldi*, *Life Guardsman*, *Valliant*, *Hubert*, *Vulcan*, *Clara Belle*, *Bewitching*, *La Belle*, *Miss Jolliffe*, *White Rival*, *Avalanche*, *Prince of Orange*, and *Golden Eagle* are all good winter-flowering kinds. In order to have good flowering plants in autumn and winter, select the best and strongest-rooted cuttings, which insert in a large 60-sized pot, placing from five to six cuttings round the edge. Plant them moderately firm, and place them in a bottom-heat of about 75°. In making the cutting or piping, the two lower leaves should be thoroughly peeled off the wood, leaving nothing but clear soft wood below the joint; then with a sharp knife, cut close up to the joint. The best soil in which to strike such cuttings is loam and leaf-mould, with plenty of sand. As soon as they are well rooted, pot them off in small 60-sized pots in a sandy loam free from wire-worm, and well mixed with plenty of sand. Place them in a frame with a bottom-heat unti again established, keeping them close to the glass.—H. G.

**Indoor Fruit.**—Vine's eyes which were potted a month ago should be plunged in a bottom heat of 30°. Squashes may be plunged in an early Pine bed or a heated frame. If deficient in number, peas may still be potted and plunged with the others. Turves 6 in. square should be cut, the Vine eyes placed in the centre, and a number of them set in a wooden box. Put the boxes on the top of the hot-water pipes in a warm house. Care must be taken that the turf does not get too dry; if this should happen, each turf should be lifted out separately and dipped in a pail of water. Another method is to fill a common propagating-box with soil to the depth of 4 in., place the eyes 6 in. apart in this, and treat them as in the former case, until the above stated height of 18 in., when a large knife should be run through between each row going down to the bottom at every cut; six days afterwards they should be cut similarly in an opposite direction. This forms them into squares by cutting all the long leading roots, which soon produce a host of rootlets. They should be taken out and potted before the roots again run into one another's squares. As time permits, the soil for Pines may be prepared for potting. Do not cut the turves with a spade or other implement, but tear them asunder with the hands, and divide about the size of hen's eggs. These turves, intended to supply later fruit, should remain in a low temperature, and the drier they can be kept consistently with health, the more certainly will they show fruit when desired. Avoid letting any water come in contact with or rest about the fruit while in bloom; inattention to this results in deformity. Holes and distorted development, which are sometimes seen in Pine fruit, arise from this kind of mismanagement, and nothing renders fruit more unsightly. In looking over suckers which were put in early in autumn, those with their pots full of roots should be intended to supply a fruit, and should be taken out into fruit prematurely. When re-potted, do not plunge them in a bottom-heat over 75°, as it is not yet time to encourage much growth in them. Smooth Cayenne and other kinds supplying fruits until the Queens are ready should receive careful watering and be otherwise closely watched. A little

air admitted during sunshine, and a slight damp overhead when shutting up, greatly helps the fruit to swell freely.—J. M.

**Flower Garden and Pleasure Grounds.**—All valuable kinds of Cupressus, Juniperus, Retinosporas, Thujas, Thujiopsis, Yews, Aucubas, Alaternas, Arbutuses, variegated Hollies, &c., should be planted at such distances from each other (say 15 ft. or 20 ft. at the least) as will afford sufficient space for the specimen to attain its natural form and dimensions; and in order to produce a finished or an immediate effect, the intervening spaces should be filled in with the more common varieties of evergreen and deciduous shrubs, such as the common and Portugal Laurels, Green Hollies, Lilacs, Spireas, &c., which should be gradually cut away from time to time, as found necessary, in order to give space to the more valuable specimens, as they continue to require the same. Examine clumps or belts of Rhododendrons and other American plants, and if any of the more delicate varieties are being overgrown by the more vigorous-growing sorts, let them be cut away to the necessary extent, or removed altogether. It is, in many instances, advisable to lift and re-arrange plantations of this kind about once during every three years, unless the plants have already attained dimensions which will not admit of its being done. Where, however, the plants are of moderate size, they may be moved at almost any season, with little or no risk, as their roots seldom extend far, and this circumstance renders it easy to transplant them. If the weather is favourable for the making of any alterations or improvements which may be contemplated in the grounds or gardens, which necessitate the removal of soil, and the laying of turf, &c., or the working of the soil, and the sowing of seeds, or the sowing of seeds, whether they may consist of the formation of flower-beds and borders, the making of walks, leveling and laying of turf or planting of Box, and other edgings. The planting of hardy herbaceous perennial plants may also be proceeded with. There are now so many really valuable hardy herbaceous and Alpine plants well suited to this purpose, that many of the tall coarse-growing species may with advantage be discarded. A somewhat liberal use, however, may be made with safety of such genera as the Delphinium, Dianthus, Myosotis, Penstemon, Phlox, and Iris. Where sub-tropical gardening is carried on, the seeds of various kinds of plants used for this purpose should be sown now, in order that they may be had sufficiently strong when the time arrives for planting them out. Sow in heat in seed-pans, pot the plants off singly as soon as they are large enough to handle, and grow on as rapidly as possible. They may consist of the various Ricinus, Cannabis gigantea, Nicotiana Würgandioides, Solanum Warscewiczii, while dry roots of the Cannabis, Brugmansias, &c., should be at once placed in heat with a view to increase by cuttings or divisions. *Humea elegans* may be sown in September, and potted off singly during the autumn, may now require to be potted into larger pots, as they are allowed to become root-bound, they will invariably lose their lower leaves. Pot off also rooted cuttings of choice Hollyhocks which may have been inserted during last autumn into pots some 4 in. in diameter; keep them close for a few days, and, when fairly established in their pots, they will only require the protection of a cold pit or frame until the time arrives when they may with safety be planted out where they are intended to flower. Cuttings of Verbenas, Petunias, Ageratums, Coleuses, Resines, &c., should be inserted in well-drained pots, or some 6 in. or 8 in. in diameter, using a soil composed of sifted leaf-soil and peat, or fine sand; place the pots containing them in a hot bed until fairly rooted, when they should be gradually inured to the temperature of an ordinary greenhouse, with the exception of the two last-named species, which will for some time longer require to be kept in a higher temperature. Spring-flowering plants and bulbs will soon begin to attract attention, so keep the beds and borders containing them free from weeds and littery matter of all kinds. Remove litter or worm-casts from the lawns by frequent sweeping, and pass a heavy roller over it as often as possible, while the same should frequently be done with gravel walks, in order to render them firm and comfortable.—B. G.

**Kitchen Garden.**—Peas, started in gentle heat under glass, should not be allowed to draw up weakly; but when about  $\frac{1}{2}$  in. high, should be removed to a cold frame. In sowing Peas on a narrow border, either draw the drill close to the wall, or form a bed, or run them obliquely across, so that the rows may range from south-east to north-west, in which aspect they will get the full benefit of the sun. Even early Peas should have plenty of room, at least 4 ft. from row to row, and two rows of Brown Cos Lettuce should be put in between each two rows of Peas. Autumn-sown Peas, that are now up, should have a ridge of earth drawn up on each side of them, and they should be sticks placed to them to form a protection; in addition, Spruce, Fir or Yew branches may be placed on the windward side of them, and a row of them in the middle. Scatter soot over and about them; this not only keeps sparrows and slugs at a distance, but also strengthens their growth. Draw the lights off Cauliflowers in frames every fine day, and give air freely to those under hand-lights during mild weather, dressing them at the same time freely with soot or wood-ashes. Cauliflower plants in pots or shelves in heat near the glass should be moved to cold frames to harden off. If there is space indoors, a few of the strongest might be shifted into larger pots for early use. Lettuces planted in slightly-heated frames or pits last November will now be turning in, and a row or two of them should be sown in a hot bed, or in a lit and shaded frame, in order to plant in gentle heat; also in a warm position at the foot of a south wall. Give air freely to forced Asparagus when fairly through the soil, to colour and flavour it; if the weather is sunny and drying, give a light watering, occasionally of weak liquid manure, in which about 2 oz. of salt to the gallon has been dissolved; continue to mat up at nights, as, although the days may be mild, the nights are uncertain. Where young Onions are

required for flavouring salads, sow the Queen, or the common Silver-skinned, in boxes in heat. Sow also, at the same time, the same kind on a warm border for accession; or a few roots of Chives may be lifted from the border, planted in boxes, and brought on gently in heat for the same purpose. Pot in succession Mint, Tarragon, Borage, Balm, &c. Sow a little Basil in heat for early use, and Sweet Marjoram, if no supply was secured in boxes in autumn. Make up a hotbed for early Turnips in the following manner: Dig out the soil, in a warm sheltered place, 1 ft. deep, and 6 ft. or 8 ft. wide, extending as far in length as is considered necessary, and casting the soil about equally on each side; fill the space so excavated with hot manure and leaves, treading it well down and laying the bed with a slope to the south; return about 6 in. or 8 in. in depth of the soil, and make it down fine; draw drills 6 in. apart, and sow the early Strap-leaved Stone Turnip thickly; fill in the drills with sifted soil. Where this mode of supplying earth-warmth can be assisted by top-coverings of glass, or light handy frames made of stout laths, thinly and neatly thatched with straw or reeds, success may be rendered certain, as the ground will be kept from freezing, and germination and growth go steadily on. The covers should be taken off every fine day after the young plants come up. Early Carrots, Turnips, &c., should be left much thicker than will be desirable further on in the season. As they will be used in a young state, the largest being drawn first, leave room for the remainder to grow.—E. H.

#### Diary.

**February 4.**—Sowing 100 pots of Osborn's Early French Beans. Potting off variegated Pelargoniums. Making a large hurdle-frame, and thatching it all round, ready for choice early Peas, to be sown over Pines, and watering them, where required. Beginning the pruning and making of Apricots. Making up another new Mushroom-bed. Covering up more Endive to blanch.

**Feb. 5.**—Sowing a box with Brussels Sprouts, and putting them into gentle heat; also a little Chervil, All-the-Year-Round Lettuce, and Capsicum. Potting off Cucumbers and Melons. Looking over Grapes in bottles, removing all bad berries, and filling up the bottles where required. Taking up all the Jerusalem Artichokes, and getting the ground heavily manured and dug for another crop.

**Feb. 6.**—Sowing Marrow Peas in boxes for making Green Pea soup; also Carter's dwarf crimson Celery. Putting in cuttings of Alternantheras and Coleus. Disbudding Early Black Hamburg Vines, and tying them down where required. Preparing ground for Parsnips. Springing early Peach-house night and morning where the fruit is well set. Thinning out Radishes, and renovating the things round the frames.

**Feb. 7.**—Sowing Cucumbers and Melons, also Parsnips in holes previously prepared for them. Putting in cuttings of Verbenas, Heliotropes, and Salvia. Removing Strawberries from pits to the Peach-house. Potting off the pits. Turning over Celery manure. Celery has been previously mixed with salt and soot, getting on with digging and trenching as fast as the weather will permit.

**Feb. 8.**—Sowing two rows of Fortyfold, two rows of G. F. Wilson, and two rows of James's Prolific Marrow Peas. Potting off autumn-sown Heliotropes and Verbenas. Putting a few sticks round the Early Ribbair, and covering it up with long litter to bring it forward. Cleaning up the pleasure grounds, and rolling down all newly laid leaf. Planting two three-light frames with Ashleaf Kidney Potatoes.

**Feb. 9.**—Potting smooth-leaved Cayenne Pines, and re-arranging first house. Turning over regularly the manure and leaves in Muscat-house, in order to produce moisture for softening the buds. Giving Early Black Hamburg inside Vine border a little warm water. Looking over fruit room, and clearing away any fruits that are bad. Cleaning up the kitchen garden. Fruit in use for dessert: Pines, Grapes, Pears, and Apples.—W. G. P., Dorset.

**Roses.**—The December number of the "Garden de Roses" reports that Messrs. Souper and Notting have, in the journals at Luxembourg, a collection of 1302 varieties of Roses. They comprise 15 Centifolias, 24 Provins, 15 Multifloras, 60 Moss, 42 Perpetual Moss, 150 Teas, 29 Noisettes, 41 Bourbons, 733 Hybrid Perpetuals, to which must be added Perpetuals of recent date, bringing the total of Perpetuals to about 1000.

**Tea Rose Cornelia Cook** is now, says the "New York Rural," one of the most popular of all the Roses used by the bouquet makers of New York during the winter months. The buds are long and much pointed, the colour being nearly pure white and the fragrance delicious.

**The Rice Paper Plant** (*Aralia papyrifera*), which is now being used so freely for ornamental purposes, is the tree from which in the Island of Formosa only, the Chinese make a choice kind of paper. The most common tree for paper-making is the paper Mulberry, an cocoran in many southern towns, Nashville especially, as a shade tree. All American trees have been apparently raised from one separate tree, as they are all named plants. In France a writer raised in the "Gardens Monthly" states that he saw female trees covered with immature fruit, and that thousands of seedlings are annually raised in the nurseries.

**ORCHARDS**, once so common in many parts of the country, seem to be passing away with the manor-houses of which they were the frequent appendages. Yet are not only useful but ornamental, and on this ground alone their gradual extinction is a matter for regret.

## THE KITCHEN GARDEN.

### FORCING POTATOES.

THERE are some who think that, because they have only a garden frame or a few old lights to spare, it is useless attempting to force Potatoes, but if they have these appliances, and a little stable manure or fresh-gathered leaves wherewith to impart the necessary bottom-heat, they are as well circumstanced for forcing Potatoes as they need desire to be. In order, however, to economise the fermenting material as much as possible, and impart a regular genial warmth to the soil, the best plan is to get together some rough hedge prunings, a few faggots, branches of trees or any rubbish that will lay loose and hollow enough to allow heat to pass freely amongst it. This collected, the next thing is to measure out a piece of ground a trifle larger than the frame, on which to build a foundation with such of the above-named gatherings as are available to set it on. If this is done to the height of about 1 ft. or 18 in., fresh fermenting material can be added at any time, and a much less quantity suffices than if the bed were built up solid in the ordinary way. Not only is this the case, but it often occurs with hot-beds after they get a weight of earth placed on them that the heat rapidly declines and soon ceases altogether, and that at a time when most wanted, whereas if formed with a base of rough stuff, a lining can be added at pleasure, by which means a uniform temperature may be maintained as long as the crop requires its assistance. Another advantage in making forcing beds up in this way is that the manure requires no previous preparing by being turned to sweeten it, which is a great thing considering the amount of labour such work involves, and that at a season when there is much else to be done. With a frame so made up, a barrow-load or two of fresh manure or leaves may be thrown around it at any time, and the waning heat thus revived and kept steadily on,

which could not be done were the bed close and solid, as then it is impossible to drive it in. In selecting a site for the frame, a sheltered, sunny spot should be chosen, so as to get as much benefit from the solar rays as possible, and prevent cold, cutting winds, that generally prevail during February and March, from blowing the heat out. To stop the soil from running amongst the faggots, or whatever material is used for the foundation, 6 in. or so of short litter or leaves should be scattered, and on this the mould for planting the Potatoes. The most suitable for this purpose is such as is of a light rich sandy nature, in which the Potatoes will not only produce a great number of tubers, but they will all come with bright clear skins, and this adds greatly to their appearance and quality when cooked. A soil containing lime rubbish or fresh crude manure is sure to spoil them by rendering them scabby or causing warty excrescences or other deformities, and should therefore be avoided where fine quality is aimed at. To make

the most of the room without unduly crowding, the tubers may be planted in rows at 1 ft. apart, and about 8 in. from each other, which affords ample space for the tops if they are kept sturdy and strong by giving plenty of air. Those who happen to have the convenience of a small forcing house or other warm place may considerably forward the sets by laying them in sifted leaf-soil in boxes to give them a start, and this is a capital plan, as a great many may be packed in a small compass and time saved while the frame and bed are being got ready. Many plant in small pots to commence, but they are in no way better than a shallow box, and take much more room and time to handle, as when laid in the latter they can be quickly transferred without the least injury. We are just moving some now that have been so treated, and they shift with masses of roots, and a tuft of leaf-soil as big as one's fist which will be a great help to them till they make further progress, and till they require something more substantial on which to lay hold.

In most gardens it is the practice to make up a hot-bed to sow seeds on, but the same thing may be done in a Potato frame, and valuable space thereby economised by making it serve the double purpose. Such things as early Celery, Cauliflower, Lettuce, and Brussels Sprouts may all be raised in this way, and pricked out elsewhere later, and when they require more room. When sown amongst Potatoes, it should be in rows midway between, as there they will get more light and air without interfering with the main crop or that with them, as would be the case were they scattered all over the soil. Even where a small frame is made up specially for the above-named vegetables, a sowing of Radishes may be made; the best and quickest of them in coming in is the Olive-shaped and Wood's Early Frame, the latter rather longer and larger, and always good and tender. If the seeds of these are soaked for twelve hours in warm water before sowing, they will germinate much quicker, and be ready for use out of the way

of the Potatoes before they want earthing up, which is very desirable, as the tops are apt to get knocked about during that operation. In sowing the Radishes or other seeds between it should be done thinly, as nothing is gained by overcrowding, for it is always better to have one strong plant than two weak ones, and especially is this the case with such things as Brussels Sprouts, Cauliflower, &c., that rarely do well unless their stems are stout and stocky. Although Potatoes succeed best with a little root warmth all through the growing period, top-heat, except what is afforded by the sun, is inimical to them, and should therefore be avoided by giving plenty of air on all favourable opportunities by tilting the lights at the back so as to avoid cold currents, which, if allowed to pass through the frame while the leaves are young and tender, cause them to curl, and thus injure the crop. A month or so later on in the season beds may be quickly made up by digging a shallow pit in the ground in which to put from 1 ft. to 2 ft. of fermenting

Garden Streamlet, with Groups of Yuccas and Water-side Plants.

material to give the Potatoes a start, and carry them on till the weather gets warmer to finish them off. Places of this kind answer admirably to keep up a supply after those forced early are over, and by turning the manure and adding a little fresh about the middle of May, the frames may be most profitably utilised for growing summer Melons, which, with early closing, ripen off well without much trouble or attention. Sunken beds such as these are well out of the wind, and therefore lie snug and warm, besides which, being low down, they are easily managed in the way of watering, covering up, &c., so that for late work they are all that can be desired. Even without such aid as a hotbed affords, Potatoes may be obtained at least a month or six weeks before they can be got from open borders, however warm and favoured their position may be. To do this, however, it is necessary to select a sheltered, sunny spot, where the soil is naturally light and dry, and then to make up a temporary frame by the use of any spare boards, to be either covered with straw hurdles or old lights for the purpose of warding off frost and keen winds. Where turf can be had, a better and more permanent structure may be easily made, and one which will be found to be exceedingly serviceable for many purposes, as, by the use of glass to lay on, any half-hardy plants may be safely wintered, or salads and a variety of other things grown in them. Next to brick, such frames are the handiest and most useful places anyone can have, and the present is a good time to build and turn them to immediate account, which can be most profitably done by starting with a batch of Potatoes and any other light crop that may be required between. The best Kidney varieties for frame culture are the old Ashleaf and Myatt's, the former a fortnight or so the earlier of the two, but not nearly so productive or hardy, two qualities that render the latter much sought after, as they are of fine flavour and excellent in other respects; indeed, for general purposes, they are the most useful Potatoes grown to afford a supply up to the middle of July, till which time there are none to equal them, either for growing on the open borders or under glass. Those who prefer Round to Kidney will find the Early Handsworth equal to any, and, having short, close tops, they are suited for frame work or growing close under the foot of a south wall. By planting these, or either of the foregoing, in a warm, sheltered position of this kind, a good supply of new Potatoes may be produced before the end of May, should the season turn out anything like favourable; and even if frosts occur, they can be easily protected by placing at night a few Laurel or other evergreen branches in front. However grown, the great thing is to select good, sound seed with strong, vigorous shoots, and these can only be obtained by laying the tubers out thin in some light, airy place, where they can come slowly on. Potatoes for sets should never be more than one deep, for if they are, those below must inevitably have long-drawn shoots, and these, under such circumstances, are sure to be bleached and tender, a condition in which they are easily susceptible of cold or wet, and this is one of the reasons why crops are so often defective. Anyone, therefore, having stores from which they intend to plant should see to them at once, as this is the time the tubers begin to sprout at a rapid rate; and unless allowed plenty of room and kept cool, they soon take harm. For Kidneys and all choice garden varieties there is no better way of storing them than that of having shallow boxes, with bottoms formed of laths nailed on 1 in. apart, between which the air has full play and strengthens the shoots as they form. Such boxes as these may be packed one on the other in any light shed, and a great quantity of Potatoes may be thus stored in a small compass. In order to keep them apart and admit air between, strips of wood should be nailed in the corner of each, or laid loosely across, so as to afford a distance of 2 in. or so, which, with the open bottoms, will be ample if the place in which they are set is kept as cool as possible.

It often occurs at the end of the season, after planting is over, that there are many more sets than are wanted, or that there are some left over from the general store, the largest and best of which may be turned to good account during the following winter. If these have the shoots rubbed out in the summer as they form, and are kept in a cool, damp cellar, they will, if buried in moist sand or fine soil, emit a quantity

of young tubers around them instead of forming any top growth; and although these are not equal, in point of flavour, to such as are grown in frames, they are a great rarity at or just after Christmas. A boxful buried and put into any warm place about six weeks before they are wanted will be found ready for use at that time; and as they do not require light, anyone may have them indoors in a cupboard, or the corner of any spare room. S. D.

**Leucocjum estivum as a Winter-blooming Plant.**—It may not be generally known that this Snowflake can be had in bloom in January, such, however, is the fact. But I would not recommend it to be forced so early, except when white flowers are required. By forcing so early, the spikes of bloom are smaller than those that open in February, when one can have them quite as good as those on plants grown out-of-doors. My plan is to lift the bulbs carefully in autumn without disturbing them much, and to pot them in such a way that the clumps just allow a little new soil to be put in the pots; after potting, I put them in a cold frame or pit until they begin to start, when they are forced as occasion may require. After blooming I harden them off, and then plant them out-of-doors; but, if need be, they can be divided before planting; they will then be ready for next autumn. If the bulbs be divided at potting time there will be no bloom; indeed, bulbs should not be pulled to pieces, except one wants to get up a stock.—JOHN CLEWS, *Headfort, Kells, Co. Meath.*

**Garden Streamlet.**—The well-formed little streamlet, shown on the opposite page, struck us not only by its beauty as being worthy of illustration, but from the handsome groups of Yuccas that are used along it so effectively. Generally watercress plants have not the fine, persistent leaves of these, but are such as die down in winter. Yuccas are more generally grown on dry ground, but in this case they thrive admirably along the water, intimately associated with Flags and other watercress plants. Such a streamlet offers excellent positions for a great variety of beautiful flowers. Such would easily make mixed borders far better than the old type.

**Swedish Turnips.**—Everybody complains of the dearth and dearness of vegetables at this season, and yet there is an excellent vegetable which we never use at our table, but give, by cartloads, to oxen and sheep—to wit, Swedish Turnips. At this time of the year, when they are fresh and sound, a single large Swedo Turnip will make a far better dish than white Turnips or Carrots. They must be mashed with milk and butter, Pepper and salt, and, if carefully strained, will be found to be of a good consistency, and particularly pleasant in flavour. But it does not pay the greengrocers to sell them, so they are very indignant at being asked for anything of the kind, and the reader had better ask a friend in the country to send him a hamper of them on trial. The price of the hamperful, containing enough for some twenty dishes, ought to be under half-a-crown.—"Truth."

#### NOTES FROM KEW.

ONE of the earliest and handsomest of all the vernal Crocuses is *Crocus Imperati*, from Calabria, which may now be seen in fine flower in the Kew collection. Both surfaces of the inner perianth segments, as well as the inside of the three outer ones, are of a fine, pleasing blue, prettily feathered with purple; the outside of the three outer ones are yellowish, each marked with three, deep purple, feathered lines. The yellow throat and anthers and the orange-coloured stigmas make an extremely attractive combination. Another recommendation possessed by this species is, that its leaves are produced and well developed at the same time as its flowers. Another most charming Irid is *Xiphion Histrio*, a native of Mount Lebanon, its nearest ally being *X. reticulatum*. The dark green, narrow leaves are about 1 ft. long; the slender scape is not so long as the leaves. In the flowers, which are 3 in. in diameter, yellow, grey-blue, and dark purple are represented. This very beautiful, hardy, bulbous plant should be extensively grown.

Among hardy shrubs, in addition to the yellow-flowered *Jasminum nudiflorum*, from China, and the fragrant, white-flowered *Lonicera Standishii*, also from China, a pretty little tree *Nitailia cerasiformis*, from California claims our attention. The white blossoms on its pendulous axillary racemes are already opening, in spite of the favourable weather. This neat-growing member of the Rose family ought to be much more frequently met with.

*Stapelia glandulifera*, a very pretty, small-flowered species, is in flower in the Succulent-house; the five corolla segments are so thickly covered with stalked, club-shaped, white glands as almost to hide the small reddish spots and bars and the yellowish ground colour.

The best greenhouse plants of this week are the following:—*Acacia dodonaeifolia* is a neat-habited, graceful bush about 6 ft. in height; the phyllodia are narrow, about 2 in. long, and the shortly-stalked, globular heads of yellow blossoms are produced freely from their axils either singly or in twos or threes. *Acacia Drummondii*, with its bi-pinnate leaves and catkin-like spikes, is too well known to need description; it is still one of the very best of that section of this beautiful genus. *Kennedya Lindleyana* is a handsome climber, with pinnate leaves and upright racemes of deep purple-blue flowers. With one or two exceptions, the *Kennedya* are natives of Australia, and nearly every one is well worthy of cultivation. *K. ovata rosea* has rather large, ovate leaves, and axillary racemes of rosy-pink flowers. Another variety of the same species, with white flowers, is also very pretty. One of the finest of all half-hardy shrubs is the New Zealand *Cianthus puniceus*. To the resemblance of the keeled petal to the beak of a parrot it owes its native name of Parrot-bill. From the axils of the pinnate leaves hang oval clusters of crimson flowers about 3 in. in diameter, measuring from the tip of the standard to the end of the keel. In tolerably sheltered spots, where some sort of protection can be afforded during winter, this is one of the most gorgeous of wall plants. *Triteleia uniflora* bears forcing readily, and is very charming with its narrow, Grass-like leaves and numerous starchy, whitish-blue flowers. The slight Onion-like odour the flowers emit is, however, somewhat against them.

In the Orchid collection are to be seen in bloom many species, the most interesting and beautiful of which we now mention. *Cattleya Trianaei*, from Mexico (as seen at Kew), has large flowers; sepals and petals white, suffused with rose; lip large, waved, and crisped, with yellow throat, and deep border of very rich crimson-purple at the apex. *C. Lindleyana*, from Brazil, has thick, fleshy, narrow-channelled leaves; its flowers, when first opening, are greenish-yellow, but turn to white when older; the apex of the lip is reddish-purple, and the whole of the flower is spotted and suffused with red. Although not one of the most handsome of the genus, this is well worth a place in the Orchid-house. *Laelia Dayana* is a very distinct, small growing, and free-flowering species; the sepals and petals are rosy-pink, the lip deeply bordered with purplish-red at apex, whitish at base, and furnished with several prominent dark purple ridges. The flowers of *L. alba* are white, with the exception of the three parallel yellow ridges in the centre of the lip; the base of that organ, as well as the under side of the column, is copiously dotted with reddish-purple. *Dendrobium Linawianum* is a very beautiful evergreen species, after the style of *D. nobile*; the delicate purplish-rose and white flowers are very charming. *Brassavola venosa*, from Central America, is a free-flowering plant, and grows best, as at Kew, on a block suspended from the roof of the house. It has thick, narrow, fleshy, channelled leaves, and several flowered spikes of large blooms; sepals and petals white, narrow, lip large, and bearing reddish spots at its narrowed base. The new *Grasdanan Odontoglossum Pescatorei* is a most beautiful plant; it is a pity that it is not more easy to manage. It does best in a cool house. The spreading sepals and petals are pure white, while at the base of the lip rosy-purple, reddish-brown, and yellow markings find a place. The long, arching spikes of the large, waved, and crisped flowers of *O. Blunii* are exceedingly handsome; every part of the flowers is snow-white, with the exception of two or three brownish spots at the apex of the lip, a yellow blotch at its base, and the reddish-brown markings of the column. *O. pulchellum* and its variety *najus* are well worth growing; the leaves are narrow, and the white flowers, which are produced on upright scapes, are, in spite of their small size, very attractive. *Dendrobium glaucum*, from the Philippine Islands, is a most desirable Orchid, and one, moreover, of easy cultivation; its drooping spikes of small, ivory white, very fragrant flowers, are exceedingly graceful. In its native haunts this is found on trunks and branches of trees; in cultivation, however, it seems to do best when treated as a pot plant.—†

**Camellia Blooms Refusing to Open.**—We have a large house planted with Camellias, which seem to be in excellent health, judging by the dark green appearance of their leaves; but I am afraid that something must be wrong with them, seeing that they make little apparent progress in the way of opening their blooms, while, on the other hand, they are in several instances pushing fresh growth. There has been little fire-heat in the house all winter, and air has been admitted on every favourable occasion—side air, at least—the top ventilation being so constructed, that when taken off in the autumn we cannot conveniently put it on till the following spring, when it is left on night and day. Several of the Camellias have shed a good many of their buds, though I am not aware that they have ever been dry at the roots. Indeed, from the luxuriant growths which they have made, one would almost imagine that they had had too much water.

Will someone conversant with *Camellia* culture kindly inform me in what I have erred? and if they think the flowers will expand, notwithstanding the fresh growth which the plants are making? If moderate-sized plants that are planted out be potted now, could we have them in bloom next Christmas? Last year they were in bloom about the beginning of January, and continued in that condition till well on in April; but this year they will at least be a month later, if not more. Should I give them a top-dressing? they have had nothing in that way for some years.—D. W.

## NOTES AND QUESTIONS—VARIOUS.

**Wistaria sinensis on Trees.**—In a semi-wild garden here we have two plants of *Wistaria* which, judging from the appearance of their stems, which are thick and corrugated, I should imagine to be nearly a century old. One has taken possession of a purple Beech, from which it hangs in festoons, and has a very pleasing effect; and the other, which has overrun two Laburnums, is still more attractive.—W. WILKS, *Usted Park, Galamian*.

—*Wistaria* may be seen here growing on trees—on the Laburnum, on Pines ponderosa, and on a Douglas Fir 40 ft. high.—A. WATERER, *Knap Hill*.

**Colletias in Sussex.**—The *Colletia cruciata* flourishes well at Ashburnham planted in a strong clay, in which it withstood the severe winter of 1869-70 without the least protection. What is the difference between this variety and *C. Bicktonensis*?—A. HOSSACK, *Ragley*.

**Destroying Woodlice.**—What is the best method of destroying woodlice in frames and greenhouses?—T. F. B. [In pits or frames woodlice may be destroyed by pouring boiling water round the walls to which they betake themselves during the daytime, but care must of course be taken that it does not injure anything. In greenhouses they may be trapped by placing slices of Potato on the stages amongst the plants, examining them every day, and killing such as have congregated under them.]

**Double Allamandas.**—Allow me to inform "E. H." (see p. 39) that some ten years ago a plant of *Allamanda* under my care produced several double flowers. I, however, failed to perpetuate it, and the following season not a trace of the sport could be seen. I trust that "E. H." will be more fortunate.—A. HOSSACK, *Ragley, Alecton*.

**Azalea Buds Drying up.**—I have tried for two seasons to grow a couple of *Azaleas* in a small greenhouse in my garden, but I find that, although new growth is made and plenty of flower-buds are set every spring, the buds never open at all, but the new growth begins again and the buds apparently dry up. Will any of your readers kindly say what is wrong in my management? I keep the temperature of the house at about 59° during the winter by means of hot-water pipes, and I sprinkle water on the pipes occasionally to prevent the air getting too dry. When the new growth is completed, I put the plants out-of-doors under a north wall till the autumn, and water regularly.—W. J. T., *Bristol*.

**Diseased Mushrooms.**—Will you kindly inform me what are my Mushrooms, two of which I send you, and if you think them fit to eat?—A. B. [The Mushrooms sent have their gills deformed by a parasite mould (*Hyphomyces lateris*). The mould is not uncommon; far too common in some places. When Mushrooms are diseased in this way they are not fit for the table, as a sort of decomposition has set in. Some persons (and with good reason) believe certain moulds to be very dangerous.—W. G. S.]

**Destroying Tree Stumps.**—What is the best way of removing or destroying roots and stumps of large Decid trees? Grubbing them up and blasting is too expensive, and for the firing obtained by rooting them up is not considered worth the power classes' while to do the work. I have been informed that by boring an auger hole in the stem, filling it with saltpetre, and leaving it so for a few months and then setting fire to it, that all will smoulder away. Can this be true?—"IRELAND." [Several methods of destroying tree stumps have been given in *THE GARDEN*, especially in Vol. I. Kerosene employed in the way you name is said to burn them up.—S.]

**Hotchkin Pippin.**—In answer to "W. G.'s" question as regards this Apple (see p. 92), allow me to say that it is sold by Messrs. Wood and Ingram, of Huntingdon, and by Mr. Henry Clark of Wing, near Oakham, under the name of the Rutland Foundling. Some years ago it was in the nurseries at Sawbridgeworth, but the late Mr. Rivers did not consider it good enough to put in his select list of Apples, and it never appeared in his catalogue. I am still using in the kitchen the Waltham Abbey Seedling, the Colini, the Blenheim Orange, and the Hotchkin, all excellent bearers, but though still sound, they have lost their freshness.—B. S.

**The Ball at Arundel Castle.**—At the recent ball at Arundel the magnificent apartment known as the Barons' Hall was appropriated for dancing, and was decorated in a beautiful manner by Mr. John Wills, who sent there a great number of choice plants and flowers from his stores at South Kensington. At intervals round the room were groups of stately Palms, springing from beds of Moss, Ferns, and flowers. There were many Lilies of the Valley in full bloom, also *Poinsettia* and lovely Orchids and *Camellias*, together with the more modest *Primulas* and *Cyclamens*, interspersed with a large variety of handsome foliaged plants. Mr. Gates' band from Brighton occupied a raised orchestra at one end of the room amidst a charming display of Palms and flowers.

No. 325.] SATURDAY, FEBRUARY 9, 1878. [Vol. XLII.]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### CAMELLIA BLOOMS REFUSING TO OPEN.

BUT for the fact stated by "D. W." (see p. 112), that his plants had shed a great many of their buds, I should have said that there was nothing the matter with them, only they were probably a month later than last year. That has been also the case with a house here this season. Last summer was, on the whole, dull and wet, and Camellias in cool houses were thus retarded in their growth. Neither, perhaps, ought a good many buds falling off to be accepted as any proof of much being wrong with the plants. Some good growers hardly thin Camellia buds at all; few, perhaps, do so to a sufficient extent. Bud-shedding is often nothing more than Nature taking that important duty into her own hands. As to present measures, remove all the fresh growths back to the old wood. This will hasten the development of the flower-buds, and often improve the plants by forcing them to push several shoots instead of one. Camellias in some localities, and some varieties in most places, manifest strongly this tendency to premature wood-making. The simple, strong, and effectual remedy is, to break it off sharp by the old wood. The sooner this is done the earlier the flowers close by the base of the shoot removed will expand. One of the most active causes of this wood-making in advance of the flowers arises from attempts to force the flowers to open by additional warmth and moisture. Camellias cannot be forced at the final stages with impunity. Anything like stimulating treatment causes them to shed their buds by wholesale. The sap that does not flow up the flower-buds shoots past them into the wood-buds, and is expended in premature growths. As these are mostly developed on the strongest and most vertical shoots, the result is an irregularity of wood growth alike in regard to place and time, as well as the loss of the flowers. Hence even for symmetrical growth, as well as uniformity of bloom, the removal of these early shoots is desirable. Yes; plants potted up now may be had in flower by next Christmas. If the flowers are very late, either pick them off or give them the chance of remaining on and expanding under forced treatment. Place the plants, as soon as potted, in a Peach house or Vinery at work, or other house where a temperature of from 50° to 60° can be maintained. Keep the atmosphere very moist, and see that the sun does not shine directly on the leaves while in a young and tender state. During the season of wood-making Camellias will bear sharp forcing well. As soon as the wood is made and the incipient buds formed on the ends of the shoots, cooler treatment must be adopted, or a second growth or the shedding of the flower-buds will be the consequence. If "D. W." has the means of warming his Camellia house, or will adopt a close, moist, forcing mode of treatment after his plants have finished flowering, and will continue it long enough until the wood is ripened and flower-buds formed, he may then have his house of Camellias in flower next Christmas, or soon after. By following a similar method for several years, Camellias may be timed to flower at any season from September onwards. From the description given and symptoms of health and vigour manifested by the Camellias in question, I would not recommend any top-dressing or stimulation with liquid manures. The plants seem overfed, if anything, and occasionally that will cause them to cast their blossom-buds in showers. Possessed of an exuberance of vital power, and relieved of the natural load of developing and supporting a crop of flowers, nothing is more likely; while few things are more provoking than that the plants should run prematurely into wood-making. D. T. FISHER.

Hardwicke House, Bury St. Edmunds.

### ANEMONE FULGENS.

IN a short article in THE GARDEN a week or two ago, the present was recommended as the best time to increase this Windflower, or to be more correct, if I remember it aright, as a good time to perform the operation of division. The writer stated that his plants would be shortly in flower, a fact which showed that they must be far advanced in growth. Now I respectfully beg to suggest a different course. I have under my charge a pretty good stock of this very beautiful plant (about 2000), and my experience is that it should always be lifted as soon as ripe, and that the roots should be kept dry until planting time comes round, which may begin in July, and be continued at intervals until December. The proper time to increase the

plant is at the time when it is planted; break the roots up into the smallest bits and plant at once; do not break them up any length of time before planting. It would, I think, be altogether wrong in practice to plant the roots whole, and after they have become established to take them up for purposes of increase. If they were divided at planting time they could not be again increased as soon as they are furnished with leaves; for although there is little doubt that they could be lifted with balls of earth, and with all their fibrous roots entire, and removed to some other position after growth had commenced, still the best practice is to leave them undisturbed after they are once planted in the form of dry roots until they have ripened off again. The advantage of successive plantings will be obvious on the principle that one cannot well have too much of a good thing. My first roots this season were not planted till the end of August, and now (Feb. 4) the first flowers are on the point of opening, whereas the last planted ones are only just beginning to peep above ground. T. SMITH.

Newry.

**Orchids at Tunbridge Wells.**—In the collection of Orchids now being formed by the Rev. R. Kinleside, at Sanbury House, I saw the other day the following in flower, viz., upwards of fifty plants of *Phalopsis Schilleriana*, varying greatly both in size and colour; one plant in particular had flowers of an unusually rich deep purple hue. There were also between fifty and sixty *P. amabilis*, some of the flowers of which measured  $\frac{3}{4}$  in. across; likewise fine masses of the snowy-white *Coleogyne cristata*, *Calanthe Veitchi* and *C. vestita rubro-oculata*, the comparatively rare *Odontoglossum Roezli* and its fine companion *O. Roezli album*, the beautiful *Cattleya maxima*, *Dendrobium moniliforme*, and the charming little *Leptotes bicolor*. There was moreover, a fine display of *Odontoglossum crispum* (Alexandre), some of the spikes of which bore as many as from twelve to sixteen flowers; and associated with it were *O. triumphans* (bearing twenty-two fully expanded blossoms), *Lesia anceps*, *Oncidium cucullatum*, *Odontoglossum roseum*, *O. Pescatorei*, and *O. glorieum*, the last bearing twenty-one flowers on a spike. *Lycaste Skinneri* and its many varieties were also in bloom; also the bright scented *Sophronia grandiflora*, which is quite a gem at this season of the year. The plants are all in good condition, and, as a collection, will probably be long rank as one of the foremost among the many that are to be found in various parts of the country.—JAMES BARNSHAW.

**The "Wild Garden."**—Illustrations for a re-written and beautifully illustrated edition of this book are now being drawn in black and white by some of the best artists in London and Paris. These illustrations will show some of the results already obtained, and suggest what is possible with many types of vegetation. This book is written in the interest of the most charming phase of picturesque gardening, and we should be greatly obliged to any persons interested in such for permission to see any photographs or sketches showing beautiful flower life in a wild or semi-wild state. What is wanted are not portraits of individual flowers, but wreaths, fringes, or colonies of them as they arrange themselves in a wild state, or are permitted to do so in the garden. American readers would also greatly oblige by letting us know if any photographs are obtainable showing flower life in the Northern, Eastern, Western, or Pacific States.

**Anemone blanda.**—Mr. Barr has lately had this early blue Anemone in his office in King Street flowering freely in a pot. It is probable that this Windflower would prove most valuable for blooming in pots or shallow pans in winter and very early in spring, when good blue flowers are often scarce. This Anemone is no doubt common in parts of Greece, and it is to be hoped that it will soon be among sorts readily obtained, being indeed the finest of all winter-flowering blue hardy plants; although like the Apeanine Anemone, it possesses great value in flowering so much earlier than that well-known species.

**Rhododendron Veitchi.**—This, one of the finest of tender Rhododendrons, has been for some time past in flower in the Exotic Nursery, Chelsea. Its blossoms are very large and waxy, and of snowy whiteness, with the exception of the lower petal, which is slightly tinted with yellow. The edges of the petals are beautifully imbricated, and the perfume delicious.

**Solanum Empress.**—This is the name given to a new and improved Solanum. It is dwarf and compact in habit, and bears berries in profusion. They are large in size, oblong, and bright scarlet in colour. Plants of it put out-of-doors in good soil early in spring, and lifted in September, make handsome specimens, which become covered with fruit. Mr. Williams, in whose nursery I met with it, finds that pinching out the points of the shoots in autumn has the effect of keeping the plants from making over vigorous

growth at the expense of fruit; the size of the berries is also thereby increased, and the plants themselves are rendered more bushy.—C. S.

**Dendrobium japonicum.**—This, which is one of the prettiest and most useful of Dendrobies, differs in habit of growth from all others of the genus. It is easily cultivated, and produces an abundance of pure white blossoms that are invaluable for small bouquets. It is now in flower in Messrs. Rolissons' nursery at Tooting, where there may also be seen the beautiful blue-flowered *Vanda cœrulescens* Boxalli, the orange-scarlet-flowered *Ada aurantiaca*, and several other water-blooming kinds.

**Hardy Flowers at Tooting.**—Beds of Crocus Imperati in Mr. Barr's nursery at Tooting are covered with blossoms, and at Mr. Parker's I saw the other day a few bright flowers on *Anemone fulgens*, also blooms on *Galanthus Imperati* and *Crocus Sieberii*. Helioleles in variety still continue to bloom freely, and the large blue flowers of *Gentiana acaulis* are being produced in abundance on well established plants.—S.

**Maadevallia ignea superba.**—This brilliant form of *M. ignea* is now in bloom in the Victoria Nurseries, Holloway. Its blossoms are very large and almost as high coloured as those of *M. Veitchii*. The plant, which is a free-grower, produces blossoms in profusion.

**Two New Ferns.**—In Mr. Wills' nursery at Anerley have been raised two new *Adiantums*, which, when they become known, cannot fail to be appreciated. One has light, slender fronds with drooping pinnae, reminding one of those of the sensitive plant when touched; the other has a dwarf, sturdy habit, and short, stiff fronds, resembling in size and appearance those of *A. Farleyense*, but they are much greener and harder, and more likely to stand better than those of that variety.—S.

**Chinese Primulas.**—There is now a fine display of these in Messrs. Carter & Co.'s nursery at Forest Hill, consisting of upwards of 1000 plants of the finest kinds. Amongst them may be seen the elegant Fern-leaved white and red varieties, Brown's Exquisite, a magnificent variety, with flowers the size of a five-shilling piece, the peculiar striped variety called Village Maid, and other equally good kinds. Messrs. Carter grow these plants annually wholly for the seed which they produce.

**The Double-flowered Epacris.**—Plants of this *Epacris* are now coming freely into bloom in Mr. Bull's nursery at Chelsea. It is a free-growing plant, sometimes making shoots from 18 in. to 2 ft. long, studded their whole length with small ivory-white blossoms. When plentiful, this double-flowered *Epacris* will doubtless be largely grown for market, as well as for other purposes.

**Tillandsia zebrina.**—For decorative purpose this *Tillandsia* is unequalled by any other of the genus. It is by no means difficult to grow, and, when furnished with their brilliant inflorescence, well-grown plants in 6-in. pots, set in vases and in similar positions, are strikingly effective. A quantity of well-grown plants of it are now in flower in Messrs. Rolissons' nursery at Tooting, and we also saw some hundreds of small plants of it being grown on for decorative purposes in Mr. Wills' nursery at Anerley.—S.

**Three Rare Orchids.**—*Aerides Huttonii*, a distinct species from Java, is now in flower in Messrs. Veitch's nursery, at Chelsea; its blossoms are bright rose-pink, spotted with white. *Epidendrum Wallisi*, a new species, has bright yellow flowers, and will, when established, be an acquisition. A large-flowered variety of *Angraecum sesquipedale*, in the same nursery, is now bearing four or five ivory-white blossoms, which, when fully expanded, will measure nearly 9 in. in diameter.

**Kentiopsis Lindeni.**—This is one of the most effective Palms for winter decoration which we possess. It has broad, massive, fan-shaped leaves, of a bright bronze colour, which, when associated with green-leaved kinds, produce a fine effect. We saw good specimens of it lately in Messrs. Rolissons' nursery at Tooting.

**Ageratum album.**—For supplying cut bloom in winter this *Ageratum* is extremely valuable. It grows well in pots, and established bushy plants of it produce abundance of white, button-shaped flowers for months in succession. It is grown by several London nurserymen for this purpose.

**The Botanical and Central Horticultural Societies of France** have agreed to hold, during the Exhibition, an International Botanical and Horticultural Congress. It will commence on August 16th, and will last a week. It will be held at the Central Horticultural Society's offices, 84, Rue de Grenelle, St. Germain, Paris. Other French and foreign societies interested in horticulture and botany are invited to send one or more persons (Members) to repre-

sent them. Excursions and visits to the different scientific establishments will take place in the intervals between the sittings of the Congress. Any persons wishing to be present are requested to send in their names, &c., to the President or to the Secretary of the Commission of Organisation, 84, Rue de Grenelle, St. Germain, Paris.

**Odontogoria (Davallia) aculeata.**—This pretty little deciduous Fern is not often met with, but it is one which is well worth culture, on account of the various uses to which it may be put. It has graceful fronds, from 1 ft. to 1½ ft. long, and finely-cut pinnae, the undersides of the fronds being armed with small sharp spines. Good plants of it may be seen in Mr. Ley's nursery at Croydon.—S. C.

**Pelargonium Lothair.**—Amongst scented-leaved *Pelargoniums* none surpasses this as to its beauty, and for clothing pillars or rafters in greenhouses it is most useful, producing, as it does, at every point trusses of pretty little, perfectly-formed, bright crimson blossoms, spotted with maroon. These, too, are produced without any forcing, and when gathered the petals do not fall nearly so soon as those of most *Pelargoniums*. It is grown in Messrs. Jackson's nursery at Kingston.

**In a Small Garden.**—The engraving of this subject (see p. 122) shows a type of garden which may be created on a very small space of ground, and yet one which gives as much satisfaction as many an extensive place. The small open lawn is fringed here and there with tufts of Grasses, choice Conifers, flowering and evergreen shrubs, and occasionally a strong tuft of a handsome herbaceous plant isolated in the Grass. These elements of the picture are not so changeable as the contents of the flower-beds, which are simple in outline, and arranged here and there round the outer walk.

**Finely-flowered Eucharis amazonica.**—A pair of plants of this *Eucharis*, in Mr. Williams' nursery at Holloway, are now very attractive. One plant is furnished with forty flower-spikes, and the other with thirty-five, and each of these bears five or six blossoms and buds. Altogether, therefore, the two plants will probably produce nearly 400 blossoms.

**Dendrobium luteolum.**—As a companion to the white-flowered *D. japonicum*, this well deserves attention. Its flowers are of a delicate sulphur colour, somewhat resembling those of *D. Pierardi*. It is robust in growth, and flowers freely. A number of plants of it are now in bloom in Messrs. Low's nursery at Clapton.

**A good Winter Tropæolum.**—The best *Tropæolum* which we have seen for furnishing bright flowers in winter is one used by Mr. Cannell, at Swanley, for covering the rafters of his greenhouses. It is a free-growing kind, which even at this season produces an abundance of flowers, with rich yellow petals, spotted with dark maroon. The edges of the blooms are toothed, and suggest the idea that this variety is a seedling the result of a cross between the well-known *T. canariense* and one of the scarlet-flowered kinds.

**Imnathophyllum miniatum princeps.**—This is one of the most beautiful forms of this valuable winter and spring-flowering plant. Its blossoms, which are large, are produced on stout, fleshy stalks, and usually open all at once. The petals are broad and waxy, and very delicate in colour, the inner portion having a rich creamy tint, whilst the tips are orange-scarlet. It is now in flower in Mr. Bull's nursery, where, contrasted, as it is, with the old form, its superiority to it in every way can at once be seen.

**Cypripedium insigne Maudslayi.**—A good display of this, perhaps the most useful of all the Lady's Slippers for general purposes may now be seen in Mr. Williams' nursery at Holloway. Its flowers are much larger than those of the well-known *C. insigne*, and the upper petals, which are margined with a band of pure white ½ in. broad, are spotted with delicate purple on the inner side. This variety flowers quite as freely as *C. insigne*, and is certainly, both in size and beauty of flower, greatly superior to it.

**Special Prizes at the National Rose Society.**—Among the special prizes announced for the meetings of the present year are a cup or piece of plate given by Rose growers for sale as the chief prize for the class for twenty-four Roses, single trusses (amateurs); a cup by Mr. Edward Mawley, for the best six Roses (amateurs); a five-guinea cup by Mr. W. Robinson, of THE GARDEN, for all Roses; and a cup by amateur exhibitors for the first prize for thirty-six Roses (nurserymen).

**Sycamore.**—It is well known that in England this name is given to a species of Maple, *Acer pseudo-Platanus*, while in this country the Button-wood (*Platanus occidentalis*) is the popular Sycamore. The true Sycamore (*Ficus Sycamorus*), a native of Egypt and Palestine, has oval, cordate, entire leaves, having no resemblance to either the Plane or the Maple. We have never been able to learn the history of this confusion of names.—"Bulletin Torrey Club."

## THE FLOWER GARDEN.

### A LIANE IN THE NORTH.

We often read of the beauty of Lianes or giant creepers that climb through the tropical forests, garlanding high trees with wreaths of leaves and flowers not their own. In visiting the nurseries of Messrs. Van Eden, at Haarlem, last spring, we were agreeably surprised to see a Liane, in the shape

A Liane in the North.

Aristolochia and Deciduous Cypress in Messrs. Van Edens' Garden at Haarlem.

of the well-known *Aristolochia Sipo*, or Dutchman's Pipe, which had clambered high into a fine old deciduous Cypress. Being much interested in this long-established companionship, we were able to procure, through the kindness of Messrs. Van Eden, photographs of the tree and its Liane, from which the engraving we now publish was drawn and engraved. When we saw it the leaves had not appeared on either the tree or its companion, yet the effect of the old rope-like stems was very picturesque. Messrs. Van Eden inform us that the *Aristolochia* ascends to "a height of 35 ft. 6 in. on the tree.

Some of the stems of the Liane are 7 in. in circumference. It is more than sixty years of age, and has always been in the same place and position—always friendly with the Cypress. For many years the tree has been known as a 'fine specimen;' but of late years it has suffered much from sea winds—the situation having become more exposed." We have had it engraved in the best manner as much for what it suggests as for what it represents.

R.

### ROSES AND ROSE SOILS.

ROSES are best moved before the close of the year, yet doubtless there will still be a good many to plant. With all kinds, excepting the Teas, no time should be lost in getting them into the places where they are to be grown; for not only do the buds after this time begin to push, but the roots commence to move also, after which transplanting has a more injurious effect upon their ability to make growth and flower during the ensuing spring and summer than when the planting was carried out earlier, when they were quite at rest. As to the places and positions in which Roses should or might be planted, a good deal has been said that is totally impracticable, such as covering the walls and chimneys of houses in towns, and other places of a like description, with them. It must ever be borne in mind that, in order to grow Roses successfully, the soil must be suited to their requirements; but, above all, the atmosphere must be moderately pure. All the art of the cultivator can never make them succeed where the air is charged to any considerable extent with smoke and gases inimical to vegetable life. Roses are more sensitive in this respect than most plants. Of this I have been long convinced by actual experience, when all that it was possible to accomplish had been done in the way of efficient drainage where required, and the introduction of soil best adapted to their wants, even to the extent of providing the hole in which they were to be planted similar to the practice generally followed in making a new Vine border; yet it was all to no purpose. In a smoky atmosphere they cannot live, much less grow satisfactorily. As a matter of course, the strongest-constituted varieties bear up against adverse atmospheric conditions better than the more delicate kinds; but, in their case, it is merely a lingering existence.

As is well known, Roses will succeed fairly well in the majority of soils where the land is not absolutely too wet or of too light and sandy a nature. Where the former is the case, it can always be remedied by efficient drainage; and where the ground is too light, this can be got over by the introduction of a sufficient quantity of good holding loam, or liberal additions of marl or clay thoroughly pulverised before being incorporated with the natural soil; but where the land is of a very sandy character, the additions recommended must be applied without stint. On such ground where Roses, even when worked on the Manetti stock, or on their own roots, could scarcely be made to live, by the application of 6 in. of heavy loam, added to 4 in. of marl or clay, I have been able to make them succeed satisfactorily. Of course, where the land requires such additions as these, only a limited extent can be planted; but Roses are such general favourites, that everyone possessing a garden is anxious to grow them; and as very many find themselves in localities where the soil is naturally of such a character as that just indicated, they are willing to incur any reasonable amount of labour and expense that will enable their culture to be carried on if only to a limited extent; but where such additions to the soil as the above are necessary, no time should be lost as regards preparing the ground. Where the soil is naturally deficient in strength, it becomes doubly necessary to discriminate as to the varieties which should be grown. It is much better to cultivate a score of vigorous, strong-constituted kinds than to extend the list to an indefinite number of weak growers. I look upon all the different stocks, both dwarfs and standards, on which Roses are grown as evils, though in some cases they may be said to be necessary ones, inasmuch as in the case of new varieties, if all were propagated on their own roots, the public would have much longer to wait and much higher prices to pay before they could possess them; and even with the commonest kinds budding and grafting facilitates the production of Roses in a way that effects saving

both in time and price; yet little else can be said for the use of stocks. No doubt where soil and climate are such as to fully answer the requirements of Roses, they will succeed almost any way; but the greater portion of the land in the kingdom is not of this nature, and in light soils especially I have found the Hybrid Perpetuals particularly to succeed on their own roots in a way not possible where a stock of any description was used; the Teas, of which there are now so many beautiful varieties, like a comparatively dry bed; they do equally well on their own roots, or when grafted so low that they ultimately emit roots above the junction with the stock. There is one evil connected with the use of stocks of all sorts more or less, to which Rose growers of the most limited experience can testify, that is, the production of suckers; the attentive cultivator always removes these as soon as they make their appearance, but this only limits the evil. More than half the energies of the plants are frequently directed for weeks to the formation and development of suckers, that often extend underground for 1 ft. or 1½ ft. before they make their appearance above the surface, and which, if even traced to the point from which they spring and removed, are so much lost to the plants; therefore I should advise all who grow Roses on a limited scale to gradually get their collection on their own roots.

As to the time of pruning Roses, a considerable allowance should be made consequent upon the different conditions under which they are grown. No greater mistake can be committed than indiscriminate early pruning, especially in mild winters, for, when such occurs, Roses begin to push the buds near the extremities of their shoots by the middle of January; these go on, leaving the buds near the base dormant. Such winters are almost invariably followed by severe spring frosts, that destroy these early-developed shoots, which, though no doubt they have, to some extent, weakened the plants by their production, may be said, nevertheless, to have acted as safety-valves by which the lower buds, that have to produce the wood and flowers for the ensuing season, have been kept in their wonted latent condition; whereas, if the pruning had taken place soon after the beginning of the year, these lower and only remaining buds, left to depend upon for the season's crop of flowers, would at once have been excited into growth, and subsequently suffered death or destruction by the spring frosts. Late pruning, no doubt, means comparatively late flowering, and in the most favourable parts of the kingdom it is well to, at all events, prune a few early, so as to have some flowers more forward, but even where climatic conditions render Roses less liable to suffer through cold nights in spring, it is a much safer course to defer pruning the greater portion until the middle or end of March. Roses, under fair conditions of soil and climate, will succeed well on a north wall; but, as might be supposed, from being so little in such a position under the influence of the sun, they are considerably later in pushing growth, hence it follows that they may with safety in such situations be pruned earlier; in fact, the sooner from the present time the better. On east and west walls, where the energies of the plants become excited sooner, it is well to defer the pruning a short time yet, although, as will be easily understood, plants under the protection of a wall on these aspects will not suffer through spring frosts to an extent that would occur if growing in the open ground. Tea Roses in pots ultimately intended to be turned out had better not be planted yet for a few weeks, keeping them in the interim as cool as possible, so that they may make the least amount of growth.

T. BAINES.

**White Christmas Roses.**—It is a mistake (see p. 93) to suppose that the only white variety of this plant "within the reach of all is more or less suffused with pink or a dirty purple colour," and that the flowers require to be "made white" by protection. I believe that the "dirty white" variety, as I call it, and which is perfectly useless as a decorative subject, is often supplied for the pure white kind; for I had a number of such plants sent to me by a respectable London firm, and though the plants were grown on a warm south border, and protected with hand-lights in winter, they did not change their hue in the least, and in the end I threw them to the rubbish heap. The variety which we have now I got out of a farmer's garden, quite exposed, where I found it producing an abundance of

almost pure white flowers. When the blooms are fully expanded a faint streak of pink is, in some cases, to be observed on the outside of some of the petals, but 3 ft. off the buds and flowers look as pure white as a Camellia. They have been very serviceable to us for the last six weeks, and there are a good many flowers to gather yet. I cannot see that the hand-light protection makes the least difference to the colour, for the flowers are no whiter with us than they were in the farmer's garden. I use the lights to prevent the rains from spattering the flowers with mud. The plants are growing in a heavy soil.—J. S., *Wortley Hall Gardens.*

### ALPINE AURICULAS.

WHAT is the difference between a "shaded" and an "unshaded" Alpine Auricula? and what is to be understood by these terms? These are questions that may now be put with advantage. A shaded Alpine has two tints on the marginal colour, the one dark at the base, the other paler on the edge of the pip; and so the deep colour shades the paler tint on the circumference. It will generally be found that these shades may be said to be related pretty nearly to the same colour, and maroon or claret-coloured flowers will be edged with red, or bronzy-red, or some such tint. In the case of flowers with violet, blue, or mauve grounds, the edging will be of much the same cast, but of a much paler shade. The more equally adjusted and clearly defined these two tints are, so much the nearer may the flower be said to approximate towards the florist's ideal of perfection, provided form and substance are also in combination. An unshaded Alpine Auricula is a self-coloured flower, destitute of shading, and this type is largely represented in the fine new varieties raised by Mr. C. Turner and others. Now the northern florists—or shall I say the rules of the National Auricula Exhibition held in Manchester every year—do not recognise these unshaded or self Alpines; they are there regarded as nondescripts, and would be disqualified in the Alpine classes. We may be disposed to disregard the rules which require a self show Auricula to be properly self in colour, and at the same time reject a self Alpine, and require that it be two-coloured or shaded; but they are none the less sacred in the estimation of the northern florists, and they stand by them. We owe much to these northern florists. They have held aloft the lamp of life of the Auricula at a time when it became almost extinct in the south. They inherit in perfect truth the opinions and predilections of a race of florists who in the last generation were past masters in the art of Auricula culture, and they have done good service to floriculture by the exercise of their floral faith. They see much of marvellous beauty in many flowers that do not come up to their ideal, but they reject them in consequence. They grow to admire and exhibit, and their admiration is most drawn out towards what would rank highest on the exhibition table. In the south, where the cultivation of Auriculas is just passing through a time of revival, the shaded and unshaded Alpines Auriculas can be shown together.

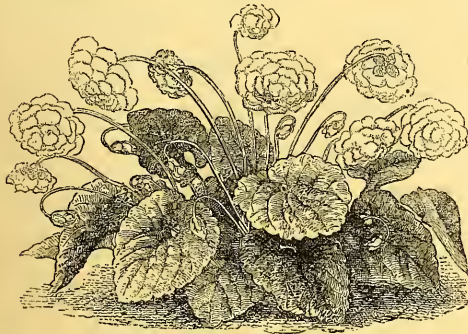

I shall not soon forget when I first saw Mr. Richard Gorton's beautiful new-shaded Alpine Mauve Queen in flower at Manchester. The base of the margin is violet-mauve, shaded off to a tint of silvery mauve. When these two shades are bright and distinct, without the base clouding the soft margin, the combination is perfect. The shaded Alpines require a great deal more skill on the part of the cultivator to get pips of fine character than the unshaded flowers. It is only occasionally that Gorton's Mauve Queen will shine out in all the perfection of its delicate beauty; it is a variety requiring to be grown in a rather poor soil to get it to flower in character, and then it should have a little stimulus to throw lustre and finish into the pips. Some other fine-shaded Alpines will be found in Turner's Bronze Queen, a distinct and beautiful variety; Dolly Varden, Queen Victoria, John Leach, Jessie, Novelty, Ovid, and Tennial, all from the same raiser; and Gorton's Diadem, a fine new-shaded flower raised in Manchester. Happy is he who can obtain a plant of each of these, for he will possess much to interest and instruct him. Alpine Auriculas are further divided for show purposes in the north into two other divisions—white centres and golden centres. Many of the most delicate-shaded Alpines have white, cream, or custard centres; while some of the darker-ground flowers have golden centres. The latter are the more attractive, because the centre is more radiant, and forms a more marked contrast to the marginal colour. It was found that the censors at the Auricula shows favoured the golden-centred in preference to the white-centred flowers; hence the creation of two distinct classes for show purposes. It is worthy of remark that, while the golden centre is regarded with so much favour in the Alps varieties, there must be no departure from the purity of the whiteness in the paste of the self-show Auriculas, and any approach to cream or custard would be regarded as a serious defect.

Last spring there was exhibited a remarkable break in the section of shaded Alpine Auriculas raised at the Bedford seed grounds, which

had great interest for cultivators. In this case dark-ground flowers were shaded with a clearly-defined band, like the regular edging to a Picootee, and generally this was white, or almost so. It was the well-defined character of the edging, and the marked contrast it presented to the body colour—the terms “ground colour” and “body colour” being synonymous—that attracted so much notice. The flowers were a little under-sized, but it was the first time that the seedlings had bloomed, and size is invariably discounted a little at the first time of flowering. When these new types are again seen, we shall be able better to appraise their value. Mr. Richard Gorton, Eccles, Manchester, one of the foremost of the northern Alpine *Auricula* cultivators, grows his Alpines in much smaller pots than cultivators of *Auriculas* generally do the edged varieties. The soil is also a little poorer. Some say, to get the shaded Alpines perfect, they must be grown in poor soil; but Mr. Gorton takes exception to this. There is always lustre about his flowers, as well as size and regularity of marking. He grows in a somewhat lighter soil than he does his show varieties, and in this the plants root with great freedom. Charcoal is freely mixed with the soil, and a free drainage is afforded to the pots. The Alpine *Auricula* so well repays attention, that it is especially commended to the notice of lovers of hardy flowers. D.

### NEW DOUBLE WHITE VIOLET, BELLE DE CHATENAY.

It is probable that no one looking at the annexed representation would recognise it, at the first sight, to be that of a Violet. The

New double White Violet.

flower of the single Violet is irregular, while in this new double variety all semblance to the usual structure of the Violet is lost, and we have in place of the normal flower a mass of petals, so arranged as to make a full double. M. L. Paillet, of Paris, the introducer of this novelty, asserts that it is the most beautiful of all Violets, a statement which we incline to the belief that the plant will warrant. Apart from growers who supply the demand of cities—and it is a large one—for Violet flowers, the choice varieties of the European Fragrant Violet (*Viola odorata*) are not much grown. Beyond a clump of the common single form in a shady place, to yield its sweetest of all flowers in early spring, we see but little attention given to the Violet in private gardens. With but little trouble one may, however, have Violets from January until May, when they bloom in the open ground. Plants, obtained by setting out runners in spring in rich soil, and giving all the water they need in dry weather, may be set early in autumn in a common cold frame. Allow them to grow until winter comes, then fill up with leaves, put on the sash, and over that a shutter. Of course, the plants must be treated like others under glass, and have abundance of air on mild days, and water as needed. A frame of three sashes, with boards to separate it into three parts, may be uncovered, one sash at a time at intervals of two or three weeks, and thus keep up a succession of flowers.—“American Agriculturist.”

**Dwarf Peony Perfection Aster.**—Every one admires Truffaut's Peony-flowered Perfection Asters, but to many their tall growth is objectionable. M. Ernest Benary, of Erfurt, is this season offering a selection under the above name, which, he states, has the large and perfectly-formed incurved flowers of the tall type, with a compact habit, the plants barely attaining 12 in. in height. These will form

good companions to the race of new dwarf *Victoria* Asters, which for some purposes, at least, will yet bear dwarfing a little more. For cuttings from it, there is no Aster which can compare with Boetzee's dwarf *Boquet*, which averages about 8 in. in height; it branches freely, and bears large numbers of flowers, which are produced successively. It is much to be preferred to the dwarf *Chrysanthemum*-flowered kind for cuttings from during the summer.—D.

### HARDY WINTER FLOWERS.

THE long-continued unseasonably mild weather, that has had such an influence in prolonging the blooming of autumn-flowering plants much beyond their usual time, has not had a similar effect in inducing the early appearance of such plants as do not show themselves until we get fairly into the new year. In fact, many of the earliest of these seem to be later than ordinary. In Mr. Ware's nursery at Tottenham even such plants as *Scilla sibirica*, *Snowdrops*, and *Crocuses* are not nearly so far advanced as usual at this time. The charming North American *Iris*, *Sisyrinchium grandiflorum* and its white variety, here are as much real winter-flowering plants as the Christmas Rose. Both varieties were in bloom last week, also a long bed, in a sheltered position, of seedling plants of *Helleborus abchasicus*, which showed every shade of colour from deep purple to white, and differed quite as much in the size and habit of the plants as in the colour of the flowers. Amongst the few really winter-blooming plants, if the present season is to be taken as evidence, is the Algerian *Iris alata*, the sky-blue flowers of which have kept on opening continuously since November, with more still to come. It is one of the most desirable plants that can be grown, and deserves a place amongst the most select of hardy flowers. The white blossoms of *Iberis gibraltarica* were just beginning to expand. In frames the white hoop-petticoat *Narcissus* (*N. Bulbocodium*), grown in pots, was well furnished with its chaste, delicately-scented flowers, contrasting beautifully with the true old double crimson *Primula*, also under glass protection. I noticed in one of the houses a large quantity of the Cape Orchid (*Disa grandiflora*) newly imported, fine masses just beginning to grow. They were just as they had been dug up in large tufts, with their native soil still attached to them. T. B.

**Campanula macrostylis.**—This fine bell flower grows about 15 in. or 18 in. in height, and has a branching, candelabrum-like habit; from the branches are produced numerous handsome-shaped cup-like flowers of large size, having a whitish ground colour, charmingly and deeply reticulated with violet. The stamens are large and prominent. I first saw this beautiful *Campanula* at the exhibition of the Weston-super-Mare Horticultural Society last August, where it excited much interest. Like many of the annual *Campanulas*, its seeds are very minute, and should be sown in a light, warm, sandy soil; they will not succeed in heavy ground. As this *Campanula* is very scarce, cultivators should take great care of it, until in course of time they discover by experience how best to manage it.—D.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Winter-flowering Begonias.**—I can fully endorse all that Mr. Cleve says in favour of *Begonia manicata*, and I would strongly recommend those who require flowers, at this season of the year, to give *Begonia hydrocotylifolia* more extended cultivation. Its habit is more compact than that of *B. manicata*, and the flowers, which are pinkish, are produced on strong stalks, and are more lasting than those of that variety. Last season I planted out all my old plants of *B. manicata* in the spare spaces in shrubberies, where they did well and formed quite a distinct feature in such situations.—A. HOSSACK, *Ragley*.

**Hyacinthus candicans Hardy.**—The beautiful *Hyacinthus candicans* is yet but little known, and its extreme hardiness has been unsuspected. Seed sown in the summer of 1876 in the open ground germinated freely, and the little bulbs were left exposed to the severe frosts of the succeeding spring, and were found to be quite fresh, and throwing out roots in the month of March. This proves that the *H. candicans* is not only hardy, but more hardy than most of our spring bulbs.—“Florist.”

**Making Plants Hardy.**—Nothing contributes more to rendering plants hardy, for enduring the sharp cold of winter, than a dry bottom. In the first place, a dry soil induces an early ripening of the wood, and we have known this early ripening to make more difference than 20° in temperature. A wet soil causes a late and watery growth, which is easily winter-killed. In the second place, trees and plants standing in a soil not soaked with water will bear greater cold than the same trees water-soaked at the roots. It is well always to bear these facts in mind and to act accordingly.—“Country Gentleman.”

## A FEW NOTES ON GARDENING IN GREECE.

We have received the following interesting communication (from Athens) from Dr. Xavier Landerer, Apothecary to the King of the Hellenes, Professor of Technology at the University of Athens, and Honorary Member of the Pharmaceutical Society of Great Britain :

The modern inhabitants of the Hellenic Kingdom are as great lovers of flowers as their ancestors. Flowers are abundant in every garden, the seeds and bulbs being brought from other parts of Europe, the poorer gardeners even being themselves conversant with horticulture. It will appear hardly credible to the inhabitants of more northerly climes that on the occasion of the festivals of Christmas and the New Year thousands of bouquets, containing Lilies and Roses of enormous size, are to be had for 3 fr. or 4 fr., such bouquets costing 20 fr. or 30 fr. in England or Germany. In all parts of Greece hot-houses are to be found, where the most beautiful flowers in the world are cultivated and improved; in fact, the art of horticulture is extending day by day. All kinds of European vegetables grown under the sunny sky of this classical land are as tender and as finely flavoured as those grown in other parts of Europe. The climate of Athens seems to suit trees from both the hottest and the coldest climates in the world, and in the gardens of the King's Palace we may see alleys of ordinary evergreens side by side with the beautiful Pepper tree (*Sobinus Molle*). Other branches of horticulture are also progressing greatly. Greece may also be called one great Olive garden, except where the Grape, the Lemon, and the Orange dispute the supremacy of the oil-giving berry. The Greeks have much to be thankful for to their soil and climate. The amount of wine made last year was valued at 50 millions of fr., while the amount of oil reaches nearly 80 millions in good years. Many thousands of wild Olive trees are scattered about the mountains, where they are dug up, replanted, and improved by cultivation. The Patras Currant also forms an important item.

All kinds of fruit trees are also found in this happy land, which seems to have been specially blessed by Nature. Greece produces about 100 millions of Lemons every year, which are exported eastward, some of them going as far as Odessa. It should be remembered that each Lemon sells retail at a penny or twopence. Millions of Oranges and Mandarins are also produced annually. A good Orange will cost from 2 lepta to 3 lepta (1d. to 1½d.), and a good Mandarin 1 lepton to 2 lepta (¾d. to 1d.), the whole of the Citron tribe being very plentiful. Citronelles and Adam's Apple from the Citrus decumana are grown in the Island of Naxos, pickled in salt and water, and exported to Odessa. Strawberries and other fruits are coming into increased cultivation day by day, thanks to improved systems of irrigation.

Hundreds of thousands of ornamental trees, such as the Pine, have been brought down from the mountains and planted in gardens; also the Arbutus, which in the days gone by was sacred to the goddess Aphrodite under the name Myrthos, various Mediterranean Heaths, sea-shore plants such as the Pancratium odoratissimum, whose tiny leaves speedily fill a room with the most delicate odour, and many others are beginning to play an important part among our cultivated flowers.

Wine growing is also making great progress, the vineyards increasing in size and number yearly, and excellent Greek wine is now exported to all parts of Europe. When grown in well-kept vineyards and cleanly made, this wine is very like Moselle. It is rich in astringent matter and phosphoric salts, hence it ought to be of great service to convalescents.

XAVIER LANDERER.

Athens, Dec. 27, 1877.

Frogs.—It is necessary to combat the absurd notion that frogs do any manner of harm in a garden. They are probably the gardener's best friends. The food of the frog—the highest authorities tell us—is wholly of an animal character, consisting of slugs, worms, and insects of nearly every kind. Wire-worms are its favourite diet. In the beautiful gardens of Monte Carlo, near Monaco, there are literally thousands of frogs; and the gardens in question are, perhaps, the most trimly-kept pleasure-grounds in Europe. So we learn from an abstract in a country paper.

**Euonymus as a Climber.**—We have been growing the climbing Burning Bush (*Euonymus radicans*) for several years past, unawares of its value for covering unsightly objects, as we use the Ivy. Now we are assured that it clings bravely to rough walls or to trees, and is preferable to any other plant available for that purpose. It has glossy, dark green foliage, and, what is better still, is evergreen. There is a variety with silvery-white variegations, and one similar to it with a pink tinge. The variegated forms have been found useful for edging beds and other ornamental work. It has been recommended as a climber where Ivy will not succeed. It is quite as easily increased by cuttings as Ivy, and it makes thrifty growth in almost any soil, although it seems to prefer a light loam.—"New York Tribune."

## THE FRUIT GARDEN.

## PEARS WHICH RIPEN FROM JANUARY TO MARCH.

SEVERAL bad seasons having occurred in succession, open-air fruit culture has come to be looked upon as doubtful work. Especially have good Pears been lacking; for even when the blossoms have escaped the frosts of May, the last two seasons at all events, there has been no sun in autumn to add flavour to the fruit; still, we must not give up in despair, but hope that better seasons are in store for us. When the seasons are at all favourable, the following are amongst the best Pears which ripen from now onwards to the end of

Fig. 1.—Josephine de Malines.

March. Let us begin with Josephine de Malines (Fig. 1), a well-known Pear, and one of the very best in every respect. It is the only real good Pear we have tasted since the beginning of the new year. The tree is rather straggling in growth, and requires to be well pinched in—summer pinching. The fruit should never be gathered till danger from frost makes the operation imperative, for if gathered too soon the flesh is sticky and dry; but when allowed to remain as long as possible, it is buttery, melting, and highly aromatic. The flesh is sometimes (always when good) of a pale salmon colour. Zephirin Greigore (Fig. 2) is also an excellent Pear, a very prolific bearer; but the blossoms, being more susceptible of injury than many others, tend to neutralise its free-bearing qualities. We have only got it in bush form, for which its habit is well suited, being of sturdy, short-jointed growth. Where wall-room could be spared for it, doubtless it would prove to be one of the very best of late Pears, the flesh possessing a rich vinous piquancy. Easter Beurré (Fig. 3) is too well known to require description. Unfortunately, the last two seasons the spring frosts have with us destroyed nearly all its blossoms, and fruit of it has been scarce, and what there has been has been spunky and kept badly. The tree is a vigorous ripener, is from Christmas to the end of March. The tree is a vigorous grower, and the fruit is finest on the Pear stock, but most fruitful on the Quince. Passe Colmar (Fig. 4) is another well-known and very generally grown Pear; and not the least of its good qualities is, that it has been constant through all the bad seasons, thus proving it to be hardier in constitution than

Fig. 2.—Zephirin Greigore.

many others, and therefore a desirable variety to cultivate. The fruit is medium-sized, very handsome, being, when fully ripe, of a bright lemon colour, with reddish russet on the side next the sun, and of a rich aromatic flavour. Beurré Gris d'Étver (Fig. 5) is a very handsome fruit of passable quality for a late Pear, but it should be grown on a wall. It does no good either in bush or pyramidal form, and is but a shy bearer even on a west wall. Ours is on the Pear stock; possibly on the Quince it would be more fruitful; its season for ripening is February. Ne Plus Meuris (Fig. 6) is not a good representation of the fruit, for though sometimes it is long, as shown, it is more frequently roundish-obovate, and very uneven in outline. It is a most excellent late Pear, ripening from February to April, the flesh being rich and piquant, if grown on a wall, as it always should be. If grown as standards or pyramids, it becomes gritty, and is only fit for stewing; it is a saro cropper, and a good grower. Besi di St. Waast

(Fig. 7) is an excellent, though little-grown Pear, about the size and shape of Flemish Beauty, but more uneven in outline. The flesh is juicy and sugary, and, though occasionally gritty, by no means unpleasantly so. The tree is of good habit and constitution, and does well, grown or trained in any form. *Beurré d'Areberg* (Fig. 8), is another most excellent December and January Pear, larger than the preceding, of handsome form, with light yellow and russetty skin. The flavour is rich and highly perfumed, quite equal to a good *Doyenné du Comice*. The tree is a good bearer, and though it does well as an espalier or standard, it merits a wall.

W. W. H.

#### A FEW NOTES ON POT-VINE CULTURE.

It is hardly worth while to go to the expense of growing Vines to produce ripe Grapes before the beginning of April, as *Lady Downes* can be had of excellent quality, plump in

stute *Foster's White Seedling*, as the best white for pot culture. I have a gentle bottom-heat, about 85° in one of the pits; the pots are plunged in that, and I do not apply any water until the buds have pushed through the ground. If the soil seems to be over dry, I merely syringe over it. When the young Vines have grown a few inches, I re-pot them into 6-in. pots. The pots are again plunged in the bed, and when the roots have reached the sides of the pots, these ought to be raised out of the beds, and be placed merely upon the surface. The next shift is into 8-in. pots, and by this time the season will be well advanced, and the temperature of the house by night may range from 65° to 70°. Water freely when the Vines are in active growth, and syringe the leaves with tepid water twice daily in the morning, and also in the afternoon, when the house is shut up. I generally contrive to have the young Vines in a sufficiently advanced state to be potted into

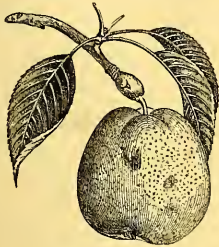

Fig. 3.—Easter Beurré.

Fig. 4.—Passe Colmar.

Fig. 5.—Beurré Gris d'Hiver.

Fig. 6.—No Plus Mours.

Fig. 7.—Best di St. Waast.

Fig. 8.—Beurré d'Areberg.

berry, with green foot-stalks, and covered with bloom at that date. There are few, however, who will not appreciate good *Black Hamburg* Grapes in April, and the best way to obtain them at that date is a question of considerable importance to gardeners. Of course, where expense is no object, early Vineries can be built to succeed the late house, and the size of them be regulated by the supply. There are, on the other hand, many gardens well furnished with *Cucumber* and *Melon* houses, or rather pits, which could be spared to grow a crop of early Grapes. This is my own case. I had *Melon* and *Cucumber* houses built, but we do not require the whole for that purpose. I found that they were also well adapted for growing Vines in pots. I could not purchase the Vines, and had no alternative but to raise them from eyes.

In January, or the first week in February, I put the eyes singly in 3-in. pots, in pure turfy-loam, with a little sand. The varieties were *Black Hamburg*, with a few *Duckland Sweet-water*; but if I had to do the same thing again, I would sub-

stitute *Foster's White Seedling*, as the best white for pot culture. I have a gentle bottom-heat, about 85° in one of the pits; the pots are plunged in that, and I do not apply any water until the buds have pushed through the ground. If the soil seems to be over dry, I merely syringe over it. When the young Vines have grown a few inches, I re-pot them into 6-in. pots. The pots are again plunged in the bed, and when the roots have reached the sides of the pots, these ought to be raised out of the beds, and be placed merely upon the surface. The next shift is into 8-in. pots, and by this time the season will be well advanced, and the temperature of the house by night may range from 65° to 70°. Water freely when the Vines are in active growth, and syringe the leaves with tepid water twice daily in the morning, and also in the afternoon, when the house is shut up. I generally contrive to have the young Vines in a sufficiently advanced state to be potted into

their fruiting-pots by midsummer, or, at the latest, by the second week in July. After this their growth is exceedingly rapid. It is a race against time, and they ought to have as much heat as they will bear with a moist atmosphere. In hot weather in July the temperature in the afternoon may rise to 90° or 95° without injury, but I always ventilate early in the morning, admit a little air at six o'clock, increasing the ventilation as the sun's rays act upon the glass. With this treatment the canes will be brown and hard by the end of August, and they will also be exceedingly strong, with large, plump eyes.

After this time I gradually decrease the amount of atmospheric moisture, and admit more air, leaving the ventilators open a little at night. During October I allow the ventilators to be freely open night and day, and by the end of that month the Vines will be ready to place in the forcing house. I find that they start best if the pots be plunged in a very gentle bottom-heat, say 80°; a bed of leaves is as good as anything.

The temperature of the house should be about 50° at first, and it may range from that to 55°. When the buds are fairly started, raise it at once to 60° or 65° in mild weather. I do not care to have the temperature higher than 65° at night until the Vines are in flower. During this time a higher temperature is desirable, and it may range from 65° to 70° until the Grapes begin to colour. The pots I use for fruiting are 11-in. and 12-in. ones, and the compost merely consists of good turfy loam, not too much rotted, but sufficiently so to kill the Grass; this is torn to pieces by the hand, and a 9-in. potful of crushed bones, with as much charcoal, is added to each barrowful. In potting, press the compost in firmly with a wooden rammer. I do not plunge the pots after the Vines have fairly started, but have been most successful with those that have been placed on a stage about 6 in. above the hot-water pipes. Each Vine will furnish about six bunches of Grapes, and finish them off well. I never use Vines a second time, but have given them away, when they have been planted out and succeeded well, bearing a crop of fruit the next season.

J. DOUGLAS.

### FRUIT CULTURE IN THE UNITED STATES.

TO THE EDITOR OF THE LONDON GARDEN.

In this country, at the present time, there is no other branch of horticulture receiving so large a share of public attention as that of pomology. This is especially true in all our fruit-growing regions, and I speak advisedly when I state that we have more capital and labour employed in this interest than in all others pertaining to the garden. About twenty years ago the great cry all through the land was, "plant more fruit." The press took up the earnest refrain, and reiterated it in every village and hamlet in the Union. Nurserymen enlarged their facilities to an enormous extent and with wondrous rapidity, and the business suddenly expanded beyond all precedent. The people had heard the advice, and were resolved to act upon it without delay. The ordinary business of farming, as commonly applied to tillers of the soil, had become an old story to them; it was hard work, incessant toil, with profits small, and uncertain at best. They read of Bartlett Pears bringing from 5 to 10 dollars per bushel in New York; of Plums selling by the barrel at the price of a ton of hay. They were told that this bushel of Pears could be grown on any soil, and in almost any location, and from a small tree a few yards from the graft; and that from 100 to 150 such trees would grow on an acre; and all this with very little labour after the trees had once become fully established, and that then they would continue to increase in productiveness each year, and attain to a great age. Downing said this was so, Wilder and Thomas endorsed it; and the whole circle of pomologists agreed to it. And it was so; every word of it was true. Who can look back over those years without feeling and knowing that those promises have been more than realised? Thus it was that the people plunged into the fruit business from Maine to California. They bought trees, Vines, and plants, raised, increased, and propagated them; calling into existence such large and extensive nursery firms as Ellwanger and Barry, with 700 acres of land, and over 2000 varieties of fruit; and scores of other prominent firms in different sections. Thousands, yes, millions of acres were thus speedily converted into fruit gardens and orchards. Many of these received careful and intelligent culture; some, of course, were sadly neglected, and rewarded their owners in proportion, for surely it was not promised that they would succeed without some care and attention. Those who were earliest to embark in the business, together with others who used special care in cultivation, were, of course, first in the field. They grew fine fruit, obtained highly-remunerative prices, and at once increased their acreage. Then, in regular succession, as the skill and labour of each had succeeded, came the thousands of other growers with their large supplies. The market literally teemed with the luscious load; but it proved expansive and elastic. Our rapidly-increasing population, and a growing popular taste for fruit, absorbed it all, and paid fair prices without a murmur. But, as the years rolled by, these millions of trees grew very rapidly; and trees that a few years previous produced one bushel, now gave three; and each year the long rows were

being extended, until the amount of fruit grown in the United States has become simply immense.

Some idea of the magnitude of our fruit culture may be formed from the fact that we now have 4,500,000 acres devoted to it, upon which it is carefully estimated there are 112,000,000 Apple trees, the same number of Peach trees, 28,000,000 Pear trees, and 141,000,000 Grape Vines. The value of the produce of the above for the past year has been placed at 50,000,000 dollars for Apples, 56,000,000 dollars for Peaches, 14,000,000 dollars for Pears, 2,000,000 dollars for Grapes, 5,000,000 dollars for Strawberries, and 10,000,000 dollars for other fruits. Marshall P. Wilder estimates our fruit crop at nearly one-half the value of the Wheat crop. In 1875, the Maryland and Delaware peninsula alone produced between 7,000,000 and 8,000,000 baskets of Peaches; and during the past season over 3,000,000 quarts of Strawberries were shipped from Norfolk, Virginia, 1700 pickers being seen in the fields in one day. These statements will serve as a general basis for an intelligent estimate of our present productive capacity. Our late war carried with it half a million consumers; cheap and rapid transit is bringing foreign and tropical fruits in more active competition with our own; and now, for the past year or two, the whole aspect of the fruit business is gradually changing, and, except in particular instances and special localities, the supply frequently exceeds the demand. Car-loads of Peaches are annually thrown from the docks in New York for the want of consumers; and last summer whole fields of Strawberries were allowed to rot on the plants for the same reason; which will be more easily understood, perhaps, when I state that over 10,000 bushels were received at New York in a single day; Cherries barely paid for marketing; Pears were slow and dull, resulting in heavy losses from decay while awaiting sale; and in 1876 Apples were almost unsaleable, large quantities rotting in the orchards, simply because it would not pay to market them.

The past year the Apple crop was very light, from the fact that usually, in this country, the Apple tree bears a full crop but once in two years, whether from bad management or whatsoever cause, and this being the off year, prices have ruled higher; and thus I might go on down the entire list of Raspberries, Blackberries, Currants, Grapes, &c., with some few trivial exceptions, and show how fully we are supplied. But the question arises, then, in view of these facts, shall we still continue to increase our already enormous productive capacities? or cut down and plough up a portion and devote it to better-paying crops? or shall we simply fill up rows decimated by the ravages of insects, disease, and death? I would not, however, counsel the adoption of any very radical measures at present, for the obvious reason that the wonderful provisions of Nature can usually be relied upon in such contingencies; for even now many of our trees and fruits are becoming infested with insects and maladies, concerning the habits and causes of which we know very little, and each year we are introduced to a new lot of these strange creatures, that baffle our skill and puzzle our brains to a very large degree. The old enemies of the Apple are reappearing with augmented force and vigour, and the villainous knight of the crescent leaves his unwelcome autograph in our Plum orchards more abundantly than ever. Our once thrifty Pear trees are struck as if by lightning, and die by the hundred; the most vigorous branches frequently blacken in a day, the leaves droop and wither almost while we stand watching them; we ply the saw and shears promptly, removing all affected parts, but in a few days we are dismayed to find other and larger portions. At first we could remove the parts without seriously disturbing the symmetry of the tree, but now it has laid hold of a prominent branch. Still, we saw it out, giving up form, and only hope for life. But, alas! a few more weeks of sawing out, and the battle is over. The shrivelling enemy has crawled down the trunk, the black flag is out; and, instead of the saw and pruning shears, we resort to the axe and the spade. We ask our pomologists and scientific men about it, and they tell us it is "blight;" and to-day that is all we know about it. Theories are promulgated by the volume, but our Pear trees die annually by the thousand from this disease; and I am fully confident that the real cause thereof is yet wholly unknown. Up to this time no reliable information has

appeared, and I think we may justly regard the Pear blight as the most profound problem now presenting itself to the pomologists of the nineteenth century; and the man who succeeds in solving the mystery and prescribing a remedy will be a benefactor in the garden of mankind. It will thus be seen that Nature is doing much to balance our operations in modern fruit culture, and the business has been elevated from a mere occupation to the higher plane of science. We must study now in order to raise fine fruit successfully; it will not grow without the ingredient of brains existing somewhere in the management. We are now canning and drying fruits very largely, besides exporting to an increasing extent. Even many of our perishable fruits, by means of improved appliances, are arriving across the water in good condition; hence the apparent over-production is doubtless in a fair way of speedy adjustment.

Kingston, N.Y., U.S.A.

H. HENDRICKS.

## THE KITCHEN GARDEN.

### SEED POTATOES.

It is now desirable that Potato stores should be thoroughly overhauled, and the tubers picked and turned carefully. As a rule, Potatoes are keeping well, especially where placed on a dry bottom or in boxes. No seed tubers should now be in pits, or in heaps or bulk in any shape, as their eyes will push, and once that is the case, the productive power of the tuber is largely diminished. In all good gardens this work will be seen to without reference to weather; but it is too frequently the case that it is left until wet days come, and sometimes before these occur much mischief is done. There are few growers who will not find some diseased Potatoes amongst their stock, as even with the greatest possible care in the selection of seed sound and healthy, some will turn out rotten after a few months' storing. Broad open shelves, placed somewhat closely one above the other, admit of a large quantity of seed Potatoes being stored in any fair-sized shed; and if plenty of air be given when the weather permits, the tubers will remain firm and almost dormant until planting time. It is an undoubted fact that a seed tuber, if kept dry and in an airy place, will never throw a shoot above an inch or so in length, and with it a few partly-developed roots. It is only when kept seceded from light and air, or where there is moisture, that this growth is made, and then it must be either pulled away or the sets planted with these shoots attached; but if done so, it is most probable that such shoots will decay, and perhaps the plant will altogether perish. Those who have to purchase their stock seed tubers instead of having saved some for the purpose, should obtain it at once, both to make sure of being supplied and also to get good samples. There are indications that the seed stocks of many good kinds are this year smaller than usual, therefore the first-comers will be both first and best served. It is also a great benefit to the grower that, having his seed-stocks early to hand, he can get them exposed and matured before planting. As regards planting, gross culture for the production of heavy crops and large tubers is an undoubted mistake. A healthy, clean crop is better than a diseased one of twice or even twenty times the bulk. Raw manure should never be applied to land intended for the growth of Potatoes, but the deeper the soil is worked the better. Let all redundant moisture get freely away from the roots, and the plants will be a medium-sized, hard-wooded haulm than a coarse, succulent one. The comparative freedom from disease that has in years past characterized certain kinds arises from the fact that the haulm is of a firm, fibrous nature; and if such kinds be grown in soil of but moderate quality, and free from raw manure, a sound crop may be almost assured. For a first early kind intended for early market or home consumption, good soil, with a liberal dressing of manure, may answer, as the crop generally is thus forced and lifted for immediate consumption; but for all main crops manure should be avoided.

A. D.

**Scarcity of Vegetables.**—Living in the midst of market gardens where hundreds of acres are devoted to the growth of vegetable produce for the London market, I read with surprise the quotation given in your column, from "Truth," as to the assumed scarcity of market vegetables. Never, perhaps, was there greater abundance, and rarely have growers had to complain that winter crops sold so badly. All kinds of greens have been growing from the time they were first put out until now without check, and much faster than they could possibly profitably be got rid of. There can be no greater

mistake than to assume that growers hold back their produce to get an exorbitant price; so far from that being the case, they are only too glad to sell at a reasonable profit. In all directions acres of fine Savoy Cabbages are literally bursting from want of sale, and it may curiously be remarked that it is to be regretted that so much good food should be thus wasted; but it is not the grower's fault. When prices are so low that it will not pay to cut a crop and send it to market, it can hardly be expected that the grower should be so indifferent to his own interest as to lose by it. The great want is a more intimate connection between grower and consumer, not so many middle dealers, fewer profits, and quick returns. London is very deficient in the matter of vegetable markets. Instead of one there ought to be twenty, where the consumer may purchase of the grower retail, and get the vegetable produce of our gardens fresh and cheap. Growers would be delighted to get 2d. for a bunch of Turnips, or for heads of Cabbages or Coleworts that now cost 4d. As a rule, however, they get about 1½d. out of that sum, and the rest goes into the pockets of the dealers. Garden vegetables, when fresh and good, rank truly amongst the most healthy and valuable of all forms of food.—A. D.

### WATERCRESS IN FRAMES.

I HAVE been gathering Watercresses at the rate of three bunches daily from a two-light frame for these last three months, and I could now gather twenty or more bunches, if needed. I find that Watercress is esteemed more than all other salads at this time of the year, and fortunately none of them can be produced more easily. About one-third of the frame mentioned is filled with plants in 24-sized pots, which are placed in Saakale-pot lids turned upside down; a little stingle is placed in the bottom of the pans, which are sunk in ashes to keep them firm, and they are then filled with water (rain water I find the best), which is replenished as it wastes. A second batch grown in 48-sized pots, placed in some old evaporating troughs, answered admirably. Single was placed in the troughs to stand the pots upon, and the troughs were filled with water, as before mentioned. The remaining portion of the frame was filled by pricking Cress out in soil, which was merely placed upon the ashes. I found the 24-pots the most productive, although the Cress from the 48's was the first ready for gathering, being a week or ten days earlier than that pricked out in the frame; but the latter forms a good succession and is more productive than the former. I shall certainly adopt the planting-out system more extensively next autumn, for I believe the Cress to be better flavored than that grown in pots. I do not suppose that this system would answer in the summer months, as it would be difficult to provide enough moisture to give satisfaction. The position of the frame is on the north side of a Thorn hedge about 4 ft. 6 in. in height, which increases in height as the summer advances, which is just what is wanted for affording shade. The soil I employ for pricking out the Cress in the open frame is composed of very strong loam with a small admixture of decayed manure pressed rather firmly to hold the water as long as possible. For pots I use a compost made lighter by adding decayed leaf-soil and a little river sand. The worst enemy I have is the slug; I, however, manage to keep them pretty well at bay by placing a little salt round the base of the frame outside. I find the brownning of the Cress depends chiefly upon the amount of air and light given during the growing period. In favourable weather the lights are tilted about 1 in. at the back, which is not allowed more than four hours in the middle of the day during the winter. As the temperature increases, more air is admitted after the outtings are established, but the frame is closed early in the afternoon, giving a thorough watering overhead.—J. P., in "Journal of Horticulture."

**White Worms in Celery Plants.**—What is the best cure for these? Would salt, which is extensively used for Asparagus beds, be equally available? Mine is very light sandy soil; that, perhaps, may induce worms.—E. [The best preventive for worms in Celery is to mix plenty of salt, soot, and lime with the manure that is to be employed in trenches. They should be added to the manure some weeks before it is used, during which time it should be turned now and then. The mixture just named also benefits the growth of the Celery, which will lift clean and spotless compared with that grown in the ordinary way.—S.]

**Lost, Stollen, or Strayed.**—What has become of the famous Tycoon Radish, asks M. Carrière in the "Revue Horticole," that enormous Radish which, either on account of its size, form, or good qualities, was named after the first prisoner in Japan, and about which the whole horticultural press was speaking some time since? I may as well say at once that it has not quite been forgotten, and that if the first seeds which were introduced did not respond to the opinion which had been formed of them, there are others which have been imported since which are much more promising.

## PLATE CXIV.

## A GROUP OF FANCY PANSIES.

Drawn by Miss DUFFIELD.

THE term "fancy" is applied to that section formerly known as the Belgian Pansy, first introduced into this country about twenty years ago, at which time the flowers were remarkable only for their peculiar and fantastic colours, but very deficient in both form and substance. Since that time, however, and more especially during the last six or seven years, florists have devoted much attention to their improvement, and have succeeded in so thoroughly changing their character that one can now scarcely recognise in them a single feature of the original. In 1871, the Scottish Pansy Society, seeing the necessity for having some points of perfection fixed as a guide both for judges and exhibitors, drew up the following properties as a standard;—First, form to be a perfect circle; second, texture to be thick and velvety; third, colours to be clear and well defined, and not to run into each other; fourth, smoothness, the petals to lie close and evenly on each other, and the edges to be smooth and not fringed; fifth, size, any flower under  $1\frac{1}{4}$  in. in diameter to be disqualified. As in the show Pansy, the eye should be small and compact, not running into the blotch, and placed exactly in the centre of the bloom. The blotch should be solid and circular, and the larger the better; indeed, the large blotch, more than any other point, distinguishes the fancy from the show Pansy. At the same time, the society just named encouraged the cultivation of this class by offering prizes, the result of which has been most satisfactory; and now there are flowers combining the most beautiful

In a small garden (sunset).

and brilliant colours with the fine form and regular marking of the show Pansy. Pansies, on account of their easy cultivation, have always been grown chiefly by cottagers, but since the introduction of the fine fancy varieties, they have become fashionable border plants everywhere; and this is not to be wondered at, as nothing can be more attractive than a collection of their varied and brilliant colours.

The habit of the fancy Pansy is more robust and vigorous than that of the show Pansy, and it can be grown successfully in localities and soils where the other would barely exist. Cuttings from the side shoots and centre of the plants can be got in abundance in August and September, and should be put in a shady bor or cold frame in soil composed of loam, leaf-mould, and sand, where they will root freely, and with a little protection they may be left there until planting time in March or April when the weather is suitable. Care must be taken to leave the cuttings uncovered, except during frosty weather, as damp is perhaps the worst enemy with which they have to contend. When blooms are wanted in May the plants require to be put out in October or November, and slightly

protected during frost. Fancy Pansies will succeed in any good garden soil; but when grown for exhibition, the ground ought to be well prepared, if possible the previous year, by trenching, manning, and green-cropping. The situation should be open, and sheltered only from the north and east, but not under the shade of trees. They may be planted 9 in. apart each way, and during dry weather in summer an occasional thorough soaking with water, and where convenient a mulching of old manure, spent Hops, or Cocoa-nut fibre will considerably prolong their season of flowering, and keep the plants in better health. A small stake to each plant is useful to keep them from being shaken by the wind. In shading for a show, great care must be taken to cover the bloom only, and not the plant, as no plant is so easily drawn as the Pansy. Blooms should be collected every morning for three or four days before a show, and kept in cold water in a cool airy shed or cellar.

Pansies are easily raised from seed sown in pans in August or September, and kept in a cold, well-ventilated frame during winter, or in the open border in spring, and if planted out when fit to handle they will flower well in summer and autumn.

Of course, when particular varieties are wanted, plants must be procured, as they do not come true from seed. Beginners, when ordering plants, would do well to state whether they want them for decorative or competition purposes, as for the former robust habit and free-blooming properties are of more importance than the fine quality of the individual flower. As a guide to those unacquainted with the latest improvements, we append a list containing a collection of the finest in their different classes, and we think the Scottish Pansy Society should now classify them under different colours, as they have already done

with the show varieties, so that growers of a limited number might be able to have as great a variety of colour as possible. Some of the selfs show merely a narrow margin of the ground colour round the petals, all the rest of the flower being covered by the blotch.

WHITE SELFs.—Countess of Strathmore, John Hampton, Miss McMicking, Mrs. Cree, Mrs. Felton, and Miss Wallace.

YELLOW SELFs.—Buttercup, Duchess of Edinburgh, George Bryce, Gretchen, Miss Darling, Mrs. Taylor, and Queen of Yellows.

BLUE SELFs.—Blue Jacket, Camperdown, Robertson Munro, True Blue, William Blackwood, and Zimmerman.

RED, CRIMSON, AND AMARANTH SELFs.—Andrew Dougall, Edward Moir, George Wood, James Grieve, John Boyd, Louise Milne, Major Molesworth, Mrs. Birkmyre, Redbraes, and Thos. Grainger.

FINE SHADED AND RETICULATED FLOWERS WITH RICH COLOURS.—Bessie, Cairngorrum, D. Cavin, J. B. Downie, Louisa, Mrs. Black, Mrs. Whitton, Nelly Thomson, Wm. Nimmo, and W. E. Gumbleton.

FANCY PANSIES AS THEY ARE.

**WHITE PICOTEE EDGES.**—Auntie Cuckoo, James Skinner, Maggie Paterson, Mrs. Crawley, Mrs. J. T. Fleming, Mrs. John Welsh, Mrs. Neilson, and Wonder.

**YELLOW PICOTEE EDGES.**—John Currie, Monarch, James Robert Welsh, Mrs. Alexander Ingram, P. W. Fairgrieve, Wm. Melville, William Robinson, and William Ziegler Welsh.

The Pansies represented in the annexed plate were drawn by Miss Duffield just as they appeared on their arrival from Edinburgh, whence they were sent to us by Messrs. Dickson, of Waterloo Place, who cultivate these and many other hardy flowers to a large extent. As many of our readers are aware, it has long been the custom to exaggerate and distort flowers of this kind in plates published in illustrated periodicals devoted to horticulture. We believe this system to be as prejudicial to the interests of the commercial growers as it is distasteful to all who love flowers. Many may have seen plates showing Pansies as large as tea-saucers, drawn perfectly round by the aid of the compass, and as hard as if made of tin. We do not say that Pansies are not often larger and finer than those shown in our plate; the present state of colour-printing will not always allow of preserving the softness and delicacy of colour of well-drawn designs of such flowers; but we will always endeavour to secure designs drawn after Nature, and never instruct the artist to follow arbitrary rules as to form, outline, and size. These Pansies, then, have no pretensions to be the ideal beauties desired by certain cultivators, but they will be none the less interesting to those who love flowers on broader principles.

## GARDENING FOR THE WEEK.

### Hardy Flowers.

**Carnations and Picotees.**—If these have continued in a healthy condition thus far, the probabilities are greatly in their favour that they will not be injured by spot or damping off now. If the weather is fine, the glass lights should be removed entirely from dawn until dusk, and on mild nights the lights should be tilted; a free circulation of air is conducive to the continued health of the plants. The damp, thick atmosphere prevalent about large towns, charged, as it is, with sulphur, is much more hurtful to the plants than frost. They are not so easily injured by gales as Auriculas, but it is as well to avoid exposing them to cold east winds. Clear the plants from dead and decaying leaves, remove weeds from the pots and stir the surface. Have the soil properly prepared for potting, and put in a dry place. It is not wise to keep the soil under cover always so that it becomes dusty-dry, but in winter it ought to be placed under cover long enough to bring it into good condition for use. I mix it up at once, so that it is ready for use when required. A good compost is loam of a turfy nature five parts, one part rotten manure, and one of leaf-mould. The heat pots are those of 7 in., 8 in., and 9 in. in diameter. Many persons use 10 in. and 11 in., but they are not necessary, although it is probably much easier to layer the Grass when the pots are large. See that the pots are washed and placed ready for use.

**Pinks in Beds.**—We have just gone over the beds, picking out the weeds and carefully removing the withered leaves at the base of the plants. The surface of the ground has been stirred over to the depth of 1 in., pressing the plants into the ground at the same time with the fingers. Alternate frosts and thaws throw the plants out of the ground, and the leather-coated grub pays nocturnal visits to the plants. They eat voraciously, and must be watched at night with a lamp, or they may be found by day buried near the plant just under the surface of the ground. A practised eye can detect the presence of the grub by the appearance of the ground above where it is hid.

**Pansy Beds.**—These were looked over at the same time, and the surface stirred up in the same way. This work should now be done, taking advantage of the first opportunity when the weather is fine. If Pansies have been wintered in pots, they should now be planted out. The soil should be rich, and it ought also to be deeply trenched, so that the plants may be able to carry themselves bravely over the hot weather in summer. Many persons complain that Pansies do not succeed about London and in other districts of the south of England. They certainly do not thrive so well as they do in Scotland and the north of England during the summer months, but in spring and autumn they do equally well. By planting in rich soil deeply trenched, and placing manure on the surface of the beds, and watering directly hot weather sets in, they will do very well in most seasons.

**Cuttings of Herbaceous Phloxes.**—These should be put in if they are sufficiently long. I pot the cuttings singly in thumb pots, and place the pots on a gentle hot-bed. They root very quickly, and, if well managed, will flower the same season. The cuttings may be put in in handlights out-of-doors, but they do not form roots so quickly, and will not do so well. If the plants have been wintered in frames, they may be planted out in beds of rich soil at once 20 in. apart. The early flowering section *P. pyramidalis* does not succeed well in hot districts in the south, but the late-flowering section *P. decussata* makes a glorious display either in beds or planted in the back rows of the herbaceous borders.

**Propagation of Dahlias and Hollyhocks by Cuttings.**—The Dahlia roots may be placed thickly together in boxes, and just covered over with fine soil. Place the boxes in a house with a temperature of 55°, and take the cuttings when they are 2 in. long. They strike freely in small pots plunged in bottom-heat in the same temperature. I generally pot my choice Hollyhocks, and from each stool a number of growths will start; these are taken off with a heel attached and potted in light soil, the same as Dahlia cuttings. The Hollyhock is also propagated by grafting the cuttings on a small portion of the root of another plant. It is best not to water for a few days. Keep them shut up in a close frame. The bottom-heat for Hollyhocks should not be more than 85°; a higher temperature generating steam causes the cuttings or grafted plants to damp off.

**Top-dressing Auriculas.**—This must be attended to early this month, especially if they were potted in May. Plants that were potted in August or September are not much improved by top-dressing. This work must be done in a careful manner, else more harm may be done to the plants, from injury to the roots, than they will receive of good from the fresh stimulant. The pots may be taken into a shed, and the work could be done in wet weather, but the plants must not be uncovered while it rains. About 1 in. or 2 in. of soil may be removed from the surface, working it out carefully with a label; a portion of prepared soil may be put on the surface at once, and be pressed down firmly with the fingers. During this operation all decaying leaves and other matter likely to cause decay should be removed. Green-fly is a troublesome pest, and this should be cleared off with a small camel-hair brush. If the plants have been much infested with aphid, a careful scrutiny must be made for it, and, as a further precaution, the plants may be fumigated with Tobacco-smoke after they are put back in the frame. The soil for surface-dressing should be richer than that used for potting. I sometimes use the compost that had been prepared for Hyacinths; if there is any of it left, by adding more rotted cow manure to it, just enough to make the material about equal parts loam and manure, a little pounded charcoal added keeps the soil sweet. Many of the trusses are now appearing, and from this time the plants must be protected by the frames being covered with mats on frosty nights. If the frosts are severe, double mats may be used. Those who have the advantage of heated pits for their plants will be able to defy frost, and it is much easier to preserve the plants from injury. Low pits where the plants can be placed near the glass are best for Auriculas. The temperature need not fall below 35° on any occasion. Air the frames or pits as freely as possible, but if high winds prevail, the lights must be tilted on the side opposite to that from which the wind is blowing.

**Gladioli.**—These are such useful flowers for cutting to decorate large vases and for other purposes, that it is very desirable that their flowering period should be prolonged. It is a good plan to pot a number of the largest roots of the earliest flowering sorts. Place the pots in a cold frame where they are protected from frost; and after they are started, plant them out on an early border. I manage to protect them from frost by inverting a flower-pot over each plant. Should frost threaten at night, the pots are removed in the morning, when the danger is over. The soil used to pot the bulbs should be good loam, to which is added a fourth part of leaf-mould. A little clean sharp sand should be placed under and over the bulbs.—J. DOUGLAS, *Loxford Hall, Uford.*

### Orchids and Orchid Houses.

The effect produced in an Orchid house by the position and arrangement of the plants is a matter worthy of consideration. Far the greater portion of these plants are epiphytal, and, consequently, they are in a more natural position when grown on blocks or in baskets, and suspended from the roof than otherwise, and the situation is much more in accordance with their naturally grotesque appearance. Another advantage to plants individually so treated is, that they are placed in the most favourable position for making strong, robust growth, consequent upon their being nearer the roof glass, and thus under the influence of a greater amount of light than when placed upon stages in a lower position. There is one considerable drawback to the principal bulk of the plants in a house being grown in this way; it is that without care the drip from them after the operation of watering acts injuriously upon such plants as occupy the stages underneath; but with care this can generally be avoided with

comparatively little loss of space. There is also another disadvantage, especially in houses that are so constructed as not to admit a maximum of light to the inmates; the suspended plants necessarily shade those below them to a considerable extent, but this is a great measure may be rectified by having the houses in situations where there are no objects existent to intercept light, a condition of the greatest importance, and one to which, if due consideration had been given, half the Orchid houses now in existence throughout the country would have been differently situated. Of equal importance is the construction of the houses, so as to have them built in a way to admit all the light possible. The low, dark erections too generally seen, either lean-to, or run up against existing walls to save cost, and the side-roofed, the side-and-end-roofed, the roof only being of glass, are a result of the most short-sighted economy which it would be possible to imagine in providing places wherein to grow these, the most valuable of all plants. True, there are some species that will not succeed under the influence of strong light, but these are comparatively few, and if a good number be suspended from the roof, these may be made to do duty in reducing the amount of light to such as only require it in limited quantities.

**Evils of Shading Orchids.**—In the case of the few Orchids that will not bear full exposure to light, it is a very easy matter to subdue it in keeping with their requirements. This is a subject I have before urged, yet it would be difficult to refer to it too often. If ever an individual plant of any Orchid is seen possessing more than usual strength and substance in either bulb or leaf, as is generally the case both combined, it will almost invariably be found to have been grown in close proximity to the glass, either near the roof or up to the side-lights or end of the house. The attempt, under artificial cultivation, to imitate the dense shade existing in the evergreen forests, the scene of the species are found indigenous, and the impression that this was necessary in a cultivated state, has been most fatal in its results; the difference in our too often leaden atmospheres, contrasted with the all but continued cloudless sky in tropical countries, has not been sufficiently taken into account, combined with the totally different effect produced upon the plants by the necessary more or less confined condition of the atmosphere of the house in which they were grown, as compared with the open air, even where this was reeking with moisture. This most essential element of light is so potent in its influence, that it often goes far to equalize the other conditions of an adverse nature to which plants may be subjected. For instance, I have seen such species as *Vanda corulæ*, indigenous, as it is, to the high cool district of Khasya, continue to grow strong and vigorous in a temperature many degrees too hot for any Orchid when suspended with its head within a few inches of the glass in a very light house; and this is only one instance out of many that I have seen bearing out this view.

**Modern Orchid Houses.**—We seldom now meet with an Orchid house pleasing in appearance, as was usual when these plants were less generally grown. Many who only commence with a few gradually go further, until they appear to be satisfied with nothing less than the possession of almost every known species, amongst which there are numbers in nearly every genus so far inferior to others as to deserve a place; the result resulting from this, are that the labour attending the whole becomes so great, that none receive the attention they require; the next is, that the plants are crowded together often as thick as the pots will stand, which is seriously detrimental to the whole. It is no uncommon occurrence now to see whole houses filled with *Odontoglossums*, *Masdevallias*, *Lycastes*, and the like huddled together as close as a bed of winter Onions, with nothing to break the monotony of the even surface except the few plants that happen to be in flower. In Orchid growing, as in all other things, selections of the best, and only the best, are always the most satisfactory. Where a large number of plants are suspended from the roof, their weight is a considerable strain upon the rafters, to meet which it is necessary to have these well tied together with iron rods; but it would be no difficult matter to introduce a moderately light iron framework immediately under but independent of the roof, yet so placed as to exclude little or no light, on which to hang the plants. In addition to the numerous *Dendrobies* that are naturally of a drooping habit usually grown in baskets, most of the *Phajans*, such as *D. J. de Vriesei*, *D. J. de Vriesei*, *D. J. de Vriesei*, and others of similar habit are seen when the flowers, or better, the plants hanging over the sides of a basket than when tied upright in pots in the more ordinary way; the growth they make and flowering capabilities grown in such a position are far in advance of what are made when further from the roof. There are some species, such as *Dendrobium albo-angueinum*, that generally refuse to grow altogether unless suspended. There are no plants with which I am acquainted wherein the substance and enduring properties of the flowers are so much influenced by the conditions under which growth is made as Orchids, frequently to the extent of their lasting quite double the length of time.

**Orchid Baskets.**—When Orchids are to be suspended in considerable numbers, it becomes necessary to choose a material which will support the baskets made that is light, will look well, and last long. The objection to iron wire is, that even when galvanised, it soon becomes rusty, in addition to which the roots getting interlaced round it, the plants cannot be got out without these roots being broken when it becomes necessary to renew the material. Copper wire baskets are expensive, and with them the same objection exists as to the roots. The rustic earthenware baskets, though handsome and enduring, are considerable in weight; the nice-looking baskets made of maple and ash or woods of a like nature, and others of a like perishable character, are so far objectionable that they soon rot, and when far decomposed the roots force their way right into the wet, spongy mass, often causing their destruction. The best baskets I have ever tried or seen are made of fossil Bog Oak. They are light,

easily made, will last long, and are unexceptionable in appearance. This wood is easily worked; it splits up readily; and if used 1 in. in diameter, it will last a dozen years or more. One of the greatest advantages in its use is that it does not rot right through like other timber; the decayal fall from the outside, and it will hold together till gradually reduced in thickness to that of an ordinary pencil. The most effective collection of Orchids I have ever seen was a very select lot, the greater portion suspended in baskets made of this material, with a moderate number occupying the stages below, consisting of such plants as *Lycastes*, *Zygopetalums*, *Vandas*, *Miltonias*, and others of similar character. Even such species as *Calanthe vesicata*, when grown in baskets from the roof, will attain a size of growth and flowering capability such as I have never seen more than half equalled by this plant when set on stages in the usual way. Bog Oak can be obtained from most of the north of England peat districts at the cost of ordinary firewood. Spring-blooming *Cattleyas*, such as *Mossie*, *Warneri*, *amethystina*, and any that flower after a rest from the preceding season's growth, as also *Lælia purpurata*, *elegans*, and others of a like description often suffer at this season through the flower-sheaths decaying; they usually turn black and become wet and rotten; and if nothing is done to prevent it, the flowers, now in the shape of small terminal buds on the extremity of the bulbs enclosed by the sheaths, frequently are destroyed by the wet, putrid mass. As soon as ever the sheaths are observed to be thus affected they should be split open from the top down about one-half their length, which will very soon cause them to dry up. I have tried splitting them down to the bottom, or cutting them off altogether, but when so treated the flower-bud frequently dies—I believe, through the cause of sudden exposure to the light, as it is no uncommon occurrence to see *Calanthe vesicata* from the buds that have been enclosed, but simply been furnished with the small terminal bud unenclosed.—T. BAINES.

### Conservatories.

These should now be gay with Dutch bulbs, Cyclamens, Chinese Primroses, *Cinerarias*, *Camellias*, *Azaleas*, forced shrubs, *Epericeras*, *Heaths*, *Acacias*, and a few other plants. The pretty water plant *Apongeton distachyon* now in full flower both in the coolest part of the greenhouse and in cold frames is so easily grown, that a large inverted bell-glass, or flower-pot, or pan with all holes stopped up forms a sufficient home for it. Pot, out back, and start into growth in the warmest corner of the greenhouse some *Fuchsias* and *Lemon-scented Verbenas*. Some *Cineraria* seed may be sown in gentle heat, to furnish flowers late in autumn; and young *Cyclamens* may be pricked off into pots or pans. *Mignonette* should now be sown in pots for early blooming; plants of it that are up should be thinned, and *Tree Mignonette* should be trained and tied into proper form. *Propagolus* should be trained twice a week, and as soon as their flower-buds are well set, weak manure-water may be freely given to them. Remove dead leaves from all plants in pots, and stir and top-dress the soil. Divide and re-pot plants of *Isoplepis gracilis*, and place them for a time in a moist heat. *Selaginellas* may also be separated and potted in a mixture of loam, peat, and leaf-mould in equal proportions, with a good admixture of sharp sand. Borders of these little plants may also be renovated. If a good stock of seedling Ferns be at hand, one or two of a sort may be inserted in a pot containing *Hyacinths* and *Tulips*; they hide the surface-soil, and render the pots more pleasing in appearance. Greenhouse Ferns should be kept as dormant as possible yet, especially such as are deciduous, and also hardy Ferns in pots, but a dust-dry condition is injurious.

### Indoor Fruit and Forcing Department.

**Pines.**—Prepare a good stock of soil for potting these, and lay it under cover for some time prior to using it. Water the plants but sparingly, avoiding too much drought, or, on the other hand, a sodden condition of the soil. For stock plants maintain a night temperature of 70° and a bottom-heat of 80°; 10° lower temperature will be quite enough for succession plants, which should not be excited till the end of the month.

**Vines.**—These should not be allowed to carry any of last year's fruit till now, and if any bunches are still hanging on them they should be cut off at once, with pieces of the wood attached to them, inserted in bottles of water and kept in the fruit-room; this allows the vines to be sparingly pruned, and to be got in readiness for starting into growth at any time when required. Give some manure-water to pot Vines that are swelling fruit, and keep them in a brisk, moist temperature; 65°, with a dry atmosphere and a little air, are necessary for such as are in bloom.

**Peaches, Nectarines, &c.**—Syringe trees of Peaches and Nectarines that have set their fruit, and attend to disbanding and watering, whether the plants are in pots or borders. Keep Figs in pots in a bottom-heat of from 75° to 80°; if maintained by means of fermenting material, so much the better. Syringe daily and supply water moderately. Keep those for late work in sheds or turned on their sides under stages quite dry.

**Cucumbers and Melons.**—In preparing for Cucumbers place a little mound of good soil in the middle of the bed over the manure, and let it rise to within 6 in. of the glass; one mound under each light is sufficient. Shift seedling Cucumbers into larger pots, and a day or two afterwards pinch out the top of the leading shoot. Maintain a night temperature of 70° both in pits and frames for Cucumbers and newly-planted-out Melons.

**Strawberry Plants.**—Keep up a succession of these; early Peach houses or Vinerys will be good positions for the earliest batch; succession fruit houses for the next earliest crop, and frames for a late supply.

### Hardy Fruits.

**Fruit-Buds and Birds.**—During this month birds often greatly damage the bloom-buds of bush fruits. See that the trees that were threaded over some time since, or syringed with lime and soot-water, are effectually protected; if the thread has become black, or been removed by the wind, run a few more strands round each bush, or apply more of the lime mixture with the syringe. Such appliances cost little in labour or material compared with the loss of a crop of fruit, and permanent injury to the trees by the bloom spurs being destroyed.

**Standard Apples or Pears** that have been planted through the autumn and winter, even if staked at the time, should be examined to see that it has been effected before the March winds begin to blow, for they will be injured if not well secured.

**Peaches, Nectarines, and Apricots** on open walls will require immediate attention in the way of pruning and nailing, for if these operations are deferred too long, the buds get so prominent as to be knocked off in quantities during the progress of the work. Apricots, bearing, as they do, a good deal on spurs, do not require so free a use of the knife as the others. On the contrary, as much of the wood should be nailed in close to the wall as possible, as on a frosty night the bloom thus situated will frequently escape, where such as is further from the wall gets destroyed. Do not leave the shoots of Peaches and Nectarines too crowded, and in pruning reduce them to something like two-thirds their original length, as near as may be, always cutting back to wood buds, which are easily discernable from their long pointed shape as compared with the round blossom buds. If the shoots be strong, they will contain numbers of double bloom buds, with a wood bud in the middle; this centre bud will form a leader, without which the fruit will not swell freely. Sufficient foresight should always be exercised in pruning Peaches and Nectarines to see that provision is made to supply the trees in all parts with young wood for the coming year, that is, by cutting a sufficient number of the shoots out to make room for the new wood. In the spring, and where there usually exist several wood buds, the best placed of which should be grown on to form a shoot for tying in the following year in place of older wood, which it may be advisable to remove. For the same reason, in pruning at the present time, it is well to cut out any long, straggling branches that have no bearing wood upon them, except near or at their extreme points. In pruning these trees, obviously the first consideration must be the current season's crop, but at the same time, by a little forethought, the operator will easily see where it is advisable to encourage a shoot for next year's bearing. It is the want of this kind of attention that reduces the numbers of these trees to nothing, but strong, bare wood, unfruitful except at the points of the shoots. Young trees are in the same way often spoiled by leaving the strong shoots too long, instead of shortening them well back. It should always be borne in mind that at whatever point the shoots of such trees are cut back to from that point, several young shoots will usually push, but not lower down nearer the base; consequently it will readily be seen where next year's shoots should be induced to spring from, so as to properly furnish the future tree.

As soon as a tree is pruned, nail it at once. The right way to proceed in this is to begin in the centre of the tree, taking a branch straight upwards, selecting for this, as near as the eye can decide, the one that will leave an equal portion of the tree on each side, and nail this in regularly over the allotted space. This applies, in pruning and nailing, to both dwarf and standard trees of the above-named fruits. There is another matter to which trainers should attend, and that is, never to nail the shoots too tightly. Every shoot ought to have double its thickness of room allowed in the sheds, so as to admit of its thickening. It is also most essential not to bruise the bark, as there are no trees so liable to gum, if the bark be bruised, as Peaches and Nectarines.

### Kitchen Garden.

When the mornings are frosty, manure may be wheeled on to open quarters; the remains of spent crops, such as Cabbage or Brussels Sprouts, should be cleared off, and preparations made for other crops. Make new plantations of Strawberries, if such was not done in autumn. Make new plantations of Jerusalem Artichokes, Early Garlic, Early Garlic, Shallots, and Boscabeau in rows 1 ft. apart, and 6 in. asunder in the rows. Tansy, Tarragon, and some other herbs should have their crowns divided, and fresh plantations made, if necessary, with the divisions. A bed of Parsley should be hooped over expressly for winter use, and immediately on the appearance of frost some Pea-stakes, evergreen boughs, mats, or any other material at hand, should be thrown over the hoops; and should very severe frost set in, some Fern should even be placed over the mats. Some Onions for seed may likewise be protected; also some Parsnips and Jerusalem Artichokes, in fact, the two latter should be lifted altogether, the first to be stored and the room given to other crops, the last to be replanted. Turn manure heaps at the same time, saving the roughest litter for protecting vegetables and for covering frames; the more decayed part can be used for spring cropping. Manure and leaves for hot-beds should also be turned and well mixed together. Tools should be repaired, baskets mended, canvas screens for protecting fruit trees put in order, nets for placing over seeds got ready for that purpose, and many other things done for which time cannot be spared hereafter.

**Walks and Weeds.**—Where gravel has got black and unsightly, 3 in. or 4 in. of the surface should be turned, and, if deficient in gravel, some should be added to the top, giving the whole a thorough rolling as the work proceeds. The walks in a kitchen garden, where anything

approaching an orderly system of gardening is attempted, should be as well drained and constructed as those in the pleasure ground. Now is the best time to go over walks generally, and hand-pick all weeds, whilst the surface is soft. Market gardeners who grow for profit and who no doubt calculate the return they expect to get for every shilling they expend in labour, set an example in respect to weeds that amateurs and others would do well to follow. With them it would be a difficult matter at any season to find a bushel of weeds on an acre; their system is to destroy every weed as soon as it vegetates, by frequently stirring the ground.

### Forcing Early Potatoes and Carrots.

Look to those seed Potatoes placed in shallow boxes for sprouting and planting next month; they should now be pushing strong sprouts hard and green, that is if they are in a place in which they can receive sufficient light. They will generally get enough if the boxes are placed under a greenhouse stage or on the floor of a cold Vinery, or in a shed or empty room of any sort where there is enough light to prevent their drawing up weakly. Some stable manure and leaves in equal quantities, if the latter are at hand, should be got ready to make up slight hotbeds for early Potatoes and Carrots. Let these fermenting materials be well shaken together and allowed to lay for ten days or so, turning them over once during that time to sweeten, then make up the beds about 2 ft. thick, and at once apply the frame, in which put about 10 in. of soil in a moderate dry state, and plant about 4 in. deep any early Kidney varieties. These are the most suitable for forcing, as they do not make such large tops as some others; place the tubers 10 in. asunder in the rows, which should be 14 in. apart; room will thus be left for a thin crop of Radishes, which should be sown at once over the surface, raking in the seed. There is not much danger of a bed of this kind getting too hot, yet over-heating does sometimes occur, thereby injuring the Potato plants that are in the centre. When the bed is made and soiled, insert a stick trial right down in the middle of it; this can be drawn out daily for a week or two, and felt so as to ascertain the heat, which should not rise above 70°. If there is any doubt about the temperature, plunge a thermometer in the bed, and if it indicates more than the heat just named, get a stout stake and drive it right into the side of the bed to the centre in several places, leaving the holes so made open for a few days, so as to allow the heat to escape.

**Carrots.**—A bed for Early French Horn Carrots may now be made, and soiled to the same depth as for the Potatoes. Let the seed be sown at once in rows 8 in. apart, covering it with  $\frac{1}{2}$  in. or so of soil. If a good body of warm leaves is at hand, the manure may be dispensed with altogether, or not more than a fourth of it need be used, in which case the beds may be made up once without further operation of the materials, as leaves are not liable to get too hot. Give air every day as soon as the crop appears above ground. If there happens to be a deficiency of autumn-sown Cauliflower or Lettuce plants, a few seeds of these may be sown in pans or boxes, and placed in beds such as the above, where they will soon vegetate, and when large enough to handle they should be pricked out in a frame or under hand-lights, from which they should be afterwards transferred to the open ground.

### Diary.

**February 11.**—Sowing on early borders Early Short Horn Carrots and Radishes. Putting in cuttings of Tomatoes and of Solanum capsicastrum. Re-potting a late batch of herbaceous Calceolarias. Earthing up early Potatoes in frames, and renovating the linings. Levelling down and preparing ground for the main crop of Parsnips. Breaking up loam and peat for potting Pines, and putting it into Vineries to warm.

**Feb. 12.**—Potting smooth Cayenne Pines, and re-arranging another house. Sowing Cucumber and Melon seed, also a little more Sweet Basil and Borage. Forking over and levelling down Celery ground for Peas. Planting a frame with Potatoes that had been previously brought forward in boxes. Looking over all trees and shrubs that are staked, and supplying them with new stakes and ties where required.

**Feb. 13.**—Sowing the main crop of Parsnips, consisting of the following sorts, viz, the Student, Maltese, and Hollow Crowned. Potting Lilian anarum, and putting it into gentle heat. Putting in cuttings of Coleus, Alternantheras, and a few more Vine eyes. Thinning out Radishes. Forking amongst herbaceous plants, and digging flower borders.

**Feb. 14.**—Sowing a box each of Carter's Dwarf Crimson and Sandringham White Celery. Putting in cuttings of Fuchsias, Crotons, and dwarf Ageratum. Potting off Cucumbers and Melons; also Coleus and Alternantheras. Removing Cyclamens, Primulas, and Cinerarias from Melon pits to late Vineries. Stopping and tying down young shoots in the early Vinery. Getting all digging and trenching finished up as fast as the weather will permit.

**Feb. 15.**—Sowing a few rows of Prickly Spinach; also Mammoth Long-pod Beans and a box of Golden Preshum. Emptying Cucumber and Melon pits, and refilling them with fermenting material. Getting Peas that had previously been sown in turf planted in rough frames. Disbudding Peach trees in the early house. Cleaning up the pleasure ground, and rolling down all turf and gravel that require it.

**Feb. 16.**—Sowing Mustard and Cress. Potting of Heliotropes, Fuchsias, and Tomatoes. Shifting Humae elegans, also a few pots of Musk, and getting in a good batch of Lily of the Valley. Giving the early Vinery and Peach house a good watering with warm water. Passing a sack of hair brush over Straw-beds, and blowing to assist to rot. Looking over Grapes in bottles, removing any bad berries, and filling up the bottles where required. Fruit in use for dessert—Pines, Grapes, Pears, and Apples.—W. G. P., Dorset.

## GARDEN BOTANY.

(Continued from page 105.)

## The Plant.

THE fact that a perfect plant will spring from a detached shoot, or bud, or even from the margin of the leaves of another plant, under certain conditions, as well as from a seed, is a great aid in comprehending the significance of the transformations to which different parts of a plant are liable, and enables the student to accept without hesitation the theory of the nature and morphological affinities of the different organs as explained further on. Taking the whole of the vegetable kingdom, including the lower cryptogams, or what are popularly termed flowerless plants, it presents an inexhaustible diversity of forms, varying from 1-10,000 part of an inch, as the Bacteria, mentioned again below, to 450 ft. in

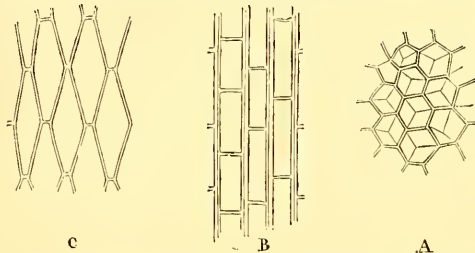

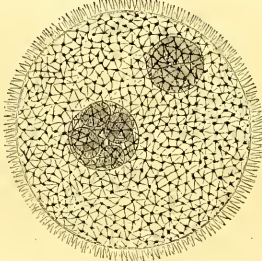

Fig. 3.—Some of the varieties in the shape of cells forming vegetable tissues.

length or height, as some of the Australian Gum trees. Each of these organisms is in itself a perfect plant, endowed with vital phenomena. The minute structure or anatomy of plants will be treated separately, but it may be useful in rendering more intelligible what follows to give a few words of explanation in this place. All parts of all plants are built up of various modifications of cells or hollow sacs (fig. 3), which may remain hollow, and independent, or eventually become filled with solid matter, or the partitions between some of them may disappear, resulting in the formation of long cylindrical cells. The cells collectively constitute the vegetable

Fig. 4.—A colony of *Volvox globator*, a spherical union of hundreds of separate plants, the ordinary diameter of the whole colony being about one-third of an inch, and the separate plants about one-five-hundredth of an inch in diameter.

tissue, of which different kinds are distinguished. Broadly speaking, vegetable tissue differs fundamentally from animal tissue in that each of its constituent cells contains the vital principle which may or can give birth to a separate plant. It is true that not all modifications of cells are known to possess this property, though it is possible that they do at some stages of their existence. What takes place in the leaves of *Bryophyllum* (fig. 1) occasionally occurs in other parts, instances of which will be given in treating specially of the reproduction or propagation of plants.

MINUTE PLANTS.—Beginning at the bottom of the scale of vegetable life, where the individuals are so minute as to be

absolutely invisible to the unaided eye, and whose forms can only be detected by the most perfect and powerful microscopes hitherto constructed, they are extremely simple in structure, many of them consisting of a single cell only; others of chains of cells, with every gradation up to the most complex structures. Among the most minute are the Bacteria, an obscure

Fig. 5.—A very highly magnified figure of *Liemophora splendida*, a one-celled alga.

race of organisms, often associated with diseases of men and animals; whether they are the cause or consequence of disease is still, perhaps, an unsolved problem. The microscopic unicellular organisms are many of them exceedingly elegant and beautiful, and are of some simple form or variously branched; they live separately or in colonies. *Volvox globator* (fig. 4), for instance, is social, and lives in families or colonies enclosed in a common membrane. Each of the individuals is provided with two tails,

Fig. 6.—A very highly magnified representation of *Heliopelta Mikii*, an elegant one-celled alga found in Guano.

or cilia, which penetrate the membrane, and give the whole colony a revolving motion. Figs. 5 and 6 are highly magnified representations of two members of a numerous family called the Diatomaceæ, which are remarkable for their siliceous beautifully marked coatings. Ascending in the scale of plant-life, a gradually greater complexity of structure is met with, and greater differentiation of organs, associated with a greater

distinction and separation of functions. But although some of the sea-weeds are almost trees both as regards size and form, they present no differentiation of parts into stem and leaves, &c. It is the same with the fungi (figs. 7 and 8). Some of these live entirely underground, as the Truffle; whilst

Fig. 7.—*Boletus edulis* (reduced), the spores very highly magnified. No distinction of stem and leaf in the plant.

others have an intricate underground growth called the mycelium (spawn), but the spore-producing part appears above-ground—the Mushroom, for example. Passing without notice some of the smaller groups, the Mosses are the first in which we find a differentiation of stem and leaves (fig. 9). In the

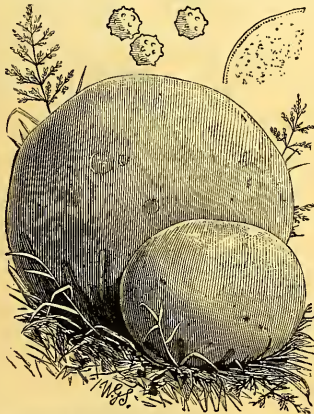

Fig. 8.—*Lycoperdon giganteum* (reduced), and the spores very highly magnified.

Mosses we also find a distinct kind of fruit, but it does not come within our province to describe its nature here, especially as it is very complicated. This passing allusion to the lower cryptogams is for the purpose of directing attention merely to the existence of forms exhibiting a gradual transition, as it were, to a more highly-organised condition, such as we find in most cultivated plants.

**FERNS.**—The first group of plants, or the lowest as regards organization, which concern us more closely are the Ferns (fig. 10). In most Ferns there is a distinct stem and leaves. The stem may be erect, as in the accompanying figure, or it may be creeping, either above or beneath the

surface of the soil. Sometimes it is almost obsolete, and the bases of the leaves crowded together close to the ground. The leaves vary very much in form and manner of division,

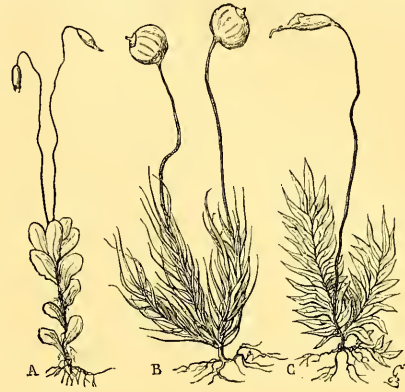

Fig. 9.—Various forms of Moss, showing distinct stems and leaves.

being many times divided, as in fig. 10, and having the appearance of branches bearing numerous small leaves, or they are undivided, as in the Hart's Tongue Fern. For reasons, more fully explained elsewhere, the leaves of Ferns are termed fronds. The principal reason is that they bear a kind of fructification, usually on the under surface or margin, but sometimes on differently shaped ones. Thus in Ferns, although there is a more or less marked differentiation of the plant into stem and leaves, the latter are clearly not of exactly the same nature as those of Fennel, for example; but what is important to note is the absence of flowers. Nevertheless, a Fern produces something analogous to seed. An examination of the fructification, such as we find on the fronds

Fig. 10.—*Alsophila excelsa*, or Tree Fern, much reduced.

of Ferns, with the naked eye reveals little; but with an ordinary pocket lens we are able to distinguish clusters (naked or covered with scales) of bodies as represented in fig. 11. Each of these is a spore-case (sporangium), and when mature, bursts

open, freeing a fine powder. The granules of this powder are very minute, and differ so materially in their nature from the seed of flowering plants, although they play the same part, that they have received the distinctive appellation of spore. Under the head of germination the differences in the development of plants from spores and seeds are pointed out.

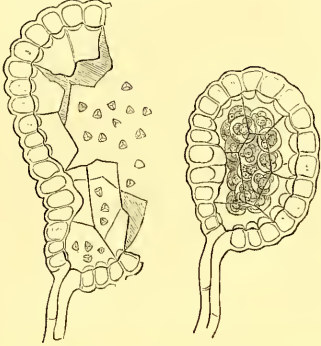

Fig. 11.—Spore cases (sporangia) of a Fern, many times magnified. The figure to the right represents a closed sporangium; the other has burst, allowing the spores to escape.

**DIFFERENT TYPES OF FLOWERING PLANTS.**—The next step takes us to flowering plants, three types of which will be cursorily examined for the purpose of pointing out the names of the principal different parts and organs of plants. Exceptions will be left out of consideration in this place, because they will be better understood after we have dealt with each of the organs separately, and because a very large proportion of

Fig. 12.—Sorghum, an example of a graminaceous plant, very much reduced.

flowering plants belong to one or the other of these types in so far as the nomenclature of their different parts is concerned. All three of these plants, it will be observed, possess certain characters in common, although in habit and general aspect they are totally different from each other. Each of them has its root, stem, leaves, and flowers; the roots offer no striking dissimilarities, but the leaves of figs. 12 and 13 are, in general

features, alike, and very different from those of fig. 14. These three plants, then, present two types of foliage, characteristic, it may be said, in general plan of two large divisions of the vegetable kingdom, and associated with other important differences, especially in the structure of the flowers and fruit. The flowers of the Grass (fig. 12) are comparatively inconspicuous, taken separately, and are of much the same colour as the foliage, and the envelopes are chaffy scales. This figure is introduced here for the purpose of contrasting with the others, and for giving a general idea where important characters are

Fig. 13.—*Tritileia uniflora*, one-half natural size. (See text under Perianth.)

to be found, and therefore we need not enter into particulars of the floral structure of Grasses at present. Moreover, it would be confusing at this stage. Neither will the flowers of *Tritileia* (fig. 13) be examined in detail; the only part to be noted now is the floral envelope, or petals, as the parts of it are termed in popular language. In this plant the floral envelope consists of six pieces, three inner and three outer, alike or similar in shape and colouring. This kind of floral envelope is called a perianth, and is common to a large number of familiar plants, as Hyacinths, Tulips, Crocuses, Lilies, and their allies. The parts constituting the perianth are spoken of as segments

or leaves. The reasons for a special name to designate this kind of floral envelope will become apparent as we proceed, because in speaking or writing of it as a perianth, a distinct and tolerably well-defined meaning is conveyed, and repetition is avoided.

EXAMINATION OF A BUTTERCUP PLANT.—Let us now take a Buttercup (figure 14) and examine it a little more in detail, as it presents all the parts the most highly-organised plant contains, though some of them are rather small. It is from modifications of these parts or organs that

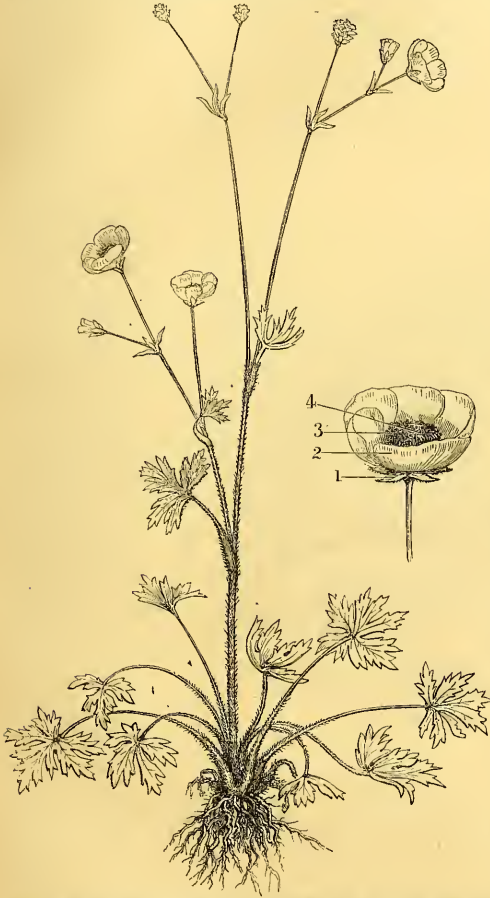

Fig. 14.—*Ranunculus acris*, Buttercup or Crowfoot, in flower and fruit, one-third natural size. A flower, natural size; 1, calyx; 2, corolla; 3, stamens; 4, pistil. The arrangement (estivation) of the petals is not quite correct.

characters are obtained whereby plants are distinguished in conversation or in written descriptions, hence the necessity of thoroughly comprehending at the beginning of our studies the correct use of the terms employed to denominate the organs. The familiar Buttercup (fig. 14) will serve as a model plant, and a knowledge of its structure the foundation for comparisons with other plants. In the first place we note that there are two essentially different systems, the root-system and the stem-system; the former avoids the light and grows in a downward or underground direction, whilst the stem grows in the atmosphere and seeks the light. Taking the parts

growing on the stem from below upwards, at the base there is a tuft of leaves crowded together near the crown of the root, and therefore called root-leaves, or radical leaves. These leaves consist of two distinct parts, a stalk and a blade. The stalk of a leaf receives the distinctive name of petiole. Passing upwards, the stem and its branches also bear leaves, with gradually shorter petioles, until the blade is seated close upon the stem, sessile. Continuing upwards, the blade itself becomes more simple, and those of the joints of the last ramifications of the stem are reduced to small, scale-like, undivided organs, and are called bracts. An important fact to bear in mind is that on many plants, including the Buttercup, the passage from leaves to bracts is so gradual, that it is impossible to distinguish between them beyond calling the uppermost ones bracts, though for descriptive purposes it is useful to make this distinction. Each branch terminates in a cluster of organs, termed collectively a flower. On examination, without the aid of any magnifying power whatever, a Buttercup flower will be found to consist of four sets of organs, easily distinguished from each other; they are not mixed up indiscriminately together, but those of each kind form one or more circles or whorls, always the same in position in relation to the other kinds. The floral envelope, or covering differs materially from that of *Triteleia*, being, in fact, double, and consisting of differently formed and coloured series of

Fig. 15.—Section of a flower of Buttercup, showing the position of the sepals, petals, stamens, and carpels of the pistil.

organs. The outer series is called the calyx, and the five pieces of which it is made up the sepals. The calyx is usually green and smaller than the inner floral envelope, or corolla, the five components of which are petals. Within the corolla is the third series of organs, which are altogether different from the sepals and petals, and very numerous. They are slender bodies, enlarged at the top, from whence they emit, through two longitudinal fissures, at some stage of their existence, a powdery substance. This is the pollen, and the organs bearing it stamens, by some writers given the collective name androecium. The centre of the flower is occupied by a group of organs (carpels) forming the pistil, or gynœcium. Each of these carpels, as may be seen in fig. 15, has a hollow cavity (ovary), containing a solitary young seed. Long after the sepals, petals, and stamens have fallen away the carpels will be found adhering (see fig. 14) until the seed is ripe, when they, in their turn, drop. This rapid sketch of a complete plant is introductory to the study of the different organs, their modifications and functions separately. W. B. HEMSLEY.

The Manure called "Le Floral," first noticed in THE GARDEN some two or three years ago, has been proved to have a remarkable effect in promoting rapid and sturdy growth in plants. It is in the form of a powder, readily soluble in water, and is said to contain all the elements essential to plant growth. Messrs. Sutton & Sons, of Reading, are the sole agents for it in this country. Not the least part of its value is the ease with which it can be applied both to plants in pots and to those out-of-doors.

Killed Seed.—At a recent prosecution under the Seed Adulteration Act a lawyer explained that the admixture of killed seed was formerly a practice not limited to fraudulent persons at all, but adopted by many under the guise of competition, and did not become fraudulent until so stigmatised by Act of Parliament, a statement which might appropriately end with a whole row of !!

Ms. JAMES LLOYD collected during his lifetime the material for building two large conservatories, modelled after those in the Kew Gardens, London. A party of liberal gentlemen have just purchased the property and presented it to the city of San Francisco, to be placed in one of the parks.—"Anglo-American Times."

## TREES AND SHRUBS.

## TRANSPLANTING TREES.

*(Continued from p. 98.)*

WHERE large plants must be moved to a distance, and no proper lifting machine is at command, it is not unusual to open up a plant and surround it with a box, afterwards working a bottom under it by undermining. During the year 1842 a large Decidua was removed from Rosepark, Edinburgh, to the estate of Milfield, near Falkirk, a distance of 25 miles. The tree was 20 ft. high, with a stem 2 ft. 5 in. round, and the circumference of the branches before being tied up was 60 ft. A pit 4 ft. deep was first formed on one side of the tree, quite straight, and smoothed down perpendicular, cutting off all the large roots that would not submit to bending, but retaining carefully all fibres. At 2 ft. below the surface an excavation was commenced. A number of boards were prepared, each 6 ft. long, 6 in. broad, and 2 in. thick; these were put under the

bottom one by one while the excavation was proceeding. After the first bottom board was placed, the sides being all previously prepared entire, one of them was put on and securely ranced against the bank. Each bottom board, when placed, was strongly supported below with an upright post placed within 8 in. of each end. This went on till the undermining was a half-way under one side. The opposite side was done in the same manner till the plant was quite open below, the box side being also put to and ranced. Stout 8-in. broad planks were next put below, to support the ends of the bottom boards, but

outside of the temporary supports first placed under each. Two of the same size were also placed along the middle, and secured with iron straps to the ends. At the four corners very strong square posts were fixed in the ground, and placed so as to support the two 8-in. broad planks placed longitudinally under the bottom boards. During the first part of the operation, viz., the undermining, the soil right and left was not disturbed. The next part of the business was to lower the soil down to the base of the box on one side, then placing against it the board prepared for it, and securely fixing it with iron straps to the bottom, as well as to the ends. The soil on the opposite side was also removed, and the board prepared for it secured likewise. The box, 6 ft. square and 2 ft. deep, now stood entirely on the supports put under the corners and sides. After putting heavy planks below in a sloping position, the uprights were then withdrawn and rollers introduced. On these rollers the plant was drawn out of the hole by means of two fixed windlass crabs, and by the same contrivance was drawn on a low four-wheeled Lawrie. Being present during most of the above work, I was delighted on witnessing the operation, and particularly observing the forethought dis-

played in every movement by Mr. Hepburn, the gardener at Milfield. I have since seen the tree in its new situation (four years after the removal), and I am happy to say it was then looking well.

The next kind of transplanting which I shall allude to are those systems done on a gigantic scale, but chiefly on the screw-raising principle. For this particular branch of transplanting, the palms due to Mr. William Barron, of the Elvaston Nurseries, Derby, a gentleman who has done more for the transplanting of very large trees, both evergreen and deciduous, than any other planter in this country. Mr. Barron's heavy transplants are all removed in an upright position, and in all cases with great success. The balls of all are previously prepared, and all made of a square shape. Planks and chains are worked below the mass of roots; a large four-wheeled machine is then put round it, previously removing the heavy screw bars from behind. After being properly adjusted, the chains supporting the bottom planks are fixed to the powerful screws, which are wound up, and the tree stands suspended in the machine sufficiently

high to clear the ground, and in this position it can be taken along the public roads, guyropes in all cases being necessary, as well as in all stages of the lifting. The late Mr. Stewart McGlashen, whose portable transplanting apparatus I have previously described, has also a transplanting machine for lifting large trees with heavy balls, but instead of preparing the balls, as is usually done, a strong iron oblong frame, hinged at the corners, is laid on the ground round the tree; a series of solid iron spades are then driven into the ground immediately inside of the iron frame, and securely fixed to

Old Judas tree in the Garden of Plants.

it with powerful screw tension-rods. Strong battens are then placed longitudinally on the top of the frame, and securely fixed at the ends with chains. A large and heavy machine on four wheels, two large and two small, is then put round the tree, previously removing the back part of the apparatus. After everything has been put in working order, the screws are fixed to the chains, and the mass is screwed out of the ground, and the tree hangs suspended in the machine, and is conveyed by horses to its destination. Mr. McGlashen's heavy transplanting machine is rather complicated and expensive; it, however, answers the purpose, as I have myself seen, the chief drawbacks being tap roots and stones; the latter are often very troublesome while inserting the spades.

The only other kind of transplanting which I shall notice is the Janker system. This method has been long in practice, and was extensively employed in the Royal Botanic Garden here by my late father during the years 1821-22-23 while transplanting a number of the taller deciduous trees from the old Botanic Garden at Leith Walk. The trees most suitable for Janker lifting are those between 25 ft. and 45 ft. in height. In all cases the roots were prepared the year previous to lifting.

At Allanton, Lanarkshire, the late Sir Henry Stewart did good service by this mode of transplanting, as fully described in his *Planters' Guide*, published in 1828, and where a representation of the Janker system may be seen (p. 251, plate 3). As no balls of earth can be lifted by the Janker system, it is necessary, in order to secure safe transplanting, to have all the tree roots prepared the previous year; and if done for two years, so much the better for the safety of the plants. This opening up is accomplished by digging a trench from 4 ft. to 6 ft. from the base of the stem all round, care being taken to save all the roots that it is possible to do. This can only be effectually done by forking out the soil with a close-fined fork either all round at once, or one-half at a time, the latter method being preferable. When one-half of the circumference is done, working to within 1 ft. of the stem, and after cutting away any injured roots, fill in with some prepared soil for the better development of new roots. When one-half has been completed, prepare the other side in the same manner. A little water may now be given with safety. During the following year some of the trees may put out comparatively few healthy leaves; the roots, however, will be making progress, but infinitely better during the second. Three guy-ropes are fixed to the top of the tree and temporarily secured to posts. Strong planks are put across the hole exactly the width of the Janker wheels. The Janker for transplanting purposes is generally prepared with broad, high wheels, and with a strong frame on the upper side immediately over the axle. This frame must be well cushioned on the upper surface for the protection of the bark. It must also be supplied with several strong books and rings. A stout rope is fixed to the ring at the extremity of the Janker pole previous to its being placed upright against the tree. When so placed, it is necessary to fix the top of the tree securely to it, a ladder being used for the purpose, care being observed to surround the bark, in the various parts where tying is necessary, to prevent chafing. The chief securing being to the cushions immediately above the axle, a strong rope is generally put under the root, and fixed to a ring at each end of the Janker axle. When all is ready, the rope attached to the end of the Janker pole is drawn down, and, if properly balanced, it will rest on the Janker, men being placed to attend to the top, either by holding up or drawing down during its progress along the gravel to the new hole, which is done by a horse, chains being fixed to the Janker axle for the purpose. After the hole is reached, planks are again put across it; the Janker is then drawn to the middle so that the roots shall be immediately over the hole; secure the wheels in their places with stones, to prevent them moving while the work is going on. By means of the three guy-ropes originally fixed to the top, and the one at the Janker pole, the tree is drawn upright. Care is necessary in this stage that the guy-ropes be carefully attended to, particularly if the hole should be too deep for the roots. When upright, by means of the ladder, untie all the fastenings from the Janker pole, secure the guy-ropes, and fill up with prepared soil, spreading the roots carefully out while the filling in is going on.

From the number of partial failures which I have seen by the Janker system of transplanting, particularly those removed without root preparation and with all their branches entire, I prefer having the branches of Janker-moved trees foreshortened when the tree is laid on its side. It will generally be found, after two or three years, that such foreshortened trees, although they are made to look a little bare for a time, will ultimately make excellent specimens; while the branches of many of those planted entire, and in many cases root-prepared, are often covered with dead wood, and after-branching has often to be resorted to in order to get them to break out from the old wood, often taking many years to make up, all from the want of branch-foreshortening at the time of transplanting.

Botanic Gardens, Edinburgh.

JAMES McNAB.

**An Old Judas Tree.**—This ranks amongst the best of flowering trees, but when old it is not much valued for beauty of form. The engraving on the opposite page shows an old specimen of it that has always seemed to us remarkable from the point of view of form alone. It is, of course, when in full flower, an object of great

beauty. The Judas Tree is one of the most neglected in modern planting, though there are good specimens of it to be seen here and there in old gardens. The one which we figure grows in front of one of the buildings in the Garden of Plants.

#### NOTES FROM KEW.

SEVERAL of the very fine Himalayan *Rhododendrons* are opening their blossoms in the winter garden. A very lovely variety of *R. arboreum*—noted a month ago—has a broad, rose-coloured limb which gradually fades into a pure white throat marked at the base with a deep, blood-red blotch; it is called *R. arboreum* var. *limbatum*. The under surfaces of its leaves are silvery white. One of the hardiest of all the Himalayan *Rhododendrons* is *R. nilagiricum*, with bright rose-coloured flowers. *R. argenteum*, a native of Sikkim, and growing at elevations of from 8000 ft. to 10,000 ft. above sea level, is a noble species; its large leaves are about 1 ft. long, and broad in proportion, silvery white beneath. The heads of large flowers are pink in bud; as these expand they gradually whiten; a blood-purple spot surrounds the stamens at the base of the tube. Perhaps the most beautiful of all the Australian *Acacias*, where unlimited space can be afforded it, is *A. dealbata*, the delicate foliage and the large, drooping, branched panicles of bright yellow, globular flower-heads being without equal for grace and beauty combined. For the foliage alone this is well worth growing in a small state. Another noteworthy *Acacia* is *A. hybrida*, a plant distinct from, but similar in habit, &c., to *A. armata*. Besides possessing all the good qualities of that well-known favourite, in my opinion it is a more graceful plant. *Tetranthera*, *Tremandra*, or *Tetratecha hiruta* (for it bears all these names) is a very free-flowering Australian shrub. Its Heath-like foliage sets off its numerous saucer-shaped, reddish-purple flowers to great advantage. All the members of this genus are charming plants, and worthy of every general cultivation. *Hedroma* or *Genetyllis fuchsoides* is a most lovely greenhouse shrub with small neat foliage, and branches terminated by small heads of inconspicuous flowers; the lack of show in these latter is fully made up for by the large, beautifully-coloured involucre which surrounds them.

Among hardy flowers one of the most desirable is *Milla Leichtlini*, a pretty little Liliaceae, bulbous plant with shortly stalked heads of white flowers just above the ground. The individual flowers are similar in form and to about as large as those of *Triteleia uniflora*. When it is stated that this blooms in company with the Snowdrop and the Winter Aconite, enough has been said to prove its importance as a hardy, herbaceous, spring-flowering plant.

This week we note several Orchids that have not been mentioned before in connection with Kew. *Lycaste macrophylla*, from Peru and Venezuela, is a sturdy-growing, free-flowering species; the strongly ribbed, broad leaves are shortly stalked; the sepals are brownish, the petals white, the lower portion of the lip tinged with red and the upper suffused with yellow. *L. Reichenbachiana* is a handsome plant with a considerable resemblance in habit, size, and structure of flower to *L. gigantea*, noted in THE GARDEN for January 19, 1878; the sepals are green, the petals and the beautifully ciliated lip being pure white. A broad-leaved form of the tropical American *Epidendrum ciliare*, bearing the varietal name *latifolium*, is very well worth growing; the middle lobe of the lip is almost thread-like, the lateral lobes beautifully cut up into fine fringes. When the flowers first open they are somewhat greenish, but soon become white. *Dendrobium Freemani* is a very showy species, much in the style of the old *D. nobile*; the sepals are narrow, white suffused with rose; the petals are much broader, and deeper in colour; the throat of the somewhat trumpet-shaped lip is deep purple-red, the spreading portion pure white, with the exception of a narrow border of rose colour at the recurved apex. *Odontoglossum cordatum*, from Central America, is a distinct and beautiful species; the sepals and petals are a rich cinnamon-brown, barred with yellowish towards their bases; the lateral lobes of the cordate lip are whitish, the remaining portion being of the same colour as the petals. *O. crocidipterum* is a very pretty plant, totally different from any *O. ontoglot* hitherto noted; the ground colour of the sepals and petals is very light, almost approaching white, and is blotched with chocolate; the lip, which is yellow at the base, bears one chocolate blotch, and is prolonged into a tail-like process at the apex. *O. constrictum* is a narrow-leaved species from Venezuela with narrow sepals and petals of a yellowish-green colour, dotted with brown; the white base and crest of the lip are followed by reddish-brown bars, and then by a whitish-yellow border at the apex. *Antis latifolia* is a terrestrial Orchid from tropical Asia, having in habit much in common with some of the *Bletias*, the tall, erect scape for the upper third of its length bearing numerous flowers of a uniform brown, with the exception of the

white column and lip. This species, however, is more fit for the botanical garden than for general collections. *Oncidium cucullatum* var. *grandiflora* is a very charming little plant from Peru and New Granada; the lip is very large in proportion to the other parts of the flower, and its whitish ground is thickly spotted with rich purple. The very variable *Cattleya labiata* is represented by several varieties, the best of which is one called *purpurea*.

*Calliandra bromatocarpa*, a most lovely stove shrub, the native country of which appears to be unknown, is in flower in one of the warm compartments of the New Range; it has pinnate leaves with from seven to ten pairs of opposite pinnules about 1 in. long, and heads of small flowers, of which the calyx and corolla are almost concealed by the large number of long, brilliantly-coloured filaments which radiate from a centre, and form a ball of scarlet threads. A Gesneraceous plant (*Tydeea Mille. Hefne*) is also very striking; the tube of the flower is red, and the limb and throat are thickly spotted and barred with rich claret colour on a greenish-yellow ground.

In the Palm house several specimens of *Brunselia latifolia* enliven the tropical American shelf. This is a neat growing shrub with entire, alternate, green leaves, and flowers of all shades from blue to white. When first opened, these are deep slate-blue with a white eye, they then turn lavender-blue, and end by becoming white, with only a trace of colour. *B. eximia* is similar to *B. latifolia*, but is larger in all its parts.—†.

**Gentiana Andrews.**—This Gentian, as it grows in my woods behaves differently from what it does as described by your correspondents. The flowers do not last a long while, if by flowers are meant individual flowers, or the corolla. There is a long succession of flowers, but in my locality the individual corolla soon begins to fade. The ovary, however, continues to grow, and soon pushes itself through the mouth of the corolla, exposing the stigmatic surfaces, which remain in a receptive condition for some time after exposure. An insect could cross-fertilise it, when in this condition, wholly from the outside. The only difficulty with me is, that I do not see where the pollen to cross-fertilise is to come from. Mr. Darwin teaches that pollen from the same plant, or from plants growing under similar conditions, is practically no cross-fertilisation; but with them, bees or other insects do not go into one flower or one plant, and then away to another many yards away, then returning, and again going back, continuously going and coming, as a zealous cross-fertiliser, so beautifully arranged by Nature, should do, but they go from flower to flower on the same plant, or on plants in the vicinity, till all are done; at least this is the case with me, whatever they may do elsewhere. However, it is well to recognise the fact, that plants and, no doubt, insects behave differently in different places. For instance, Mr. Darwin, from English experiments, utterly denies that *Linum perenne* can fertilise itself by its own pollen. He says we may as well "sprinkle over it so much inorganic dust." But a single plant, which I brought with me from Colorado in 1873, bears fruit freely in my garden every year. It shows that how a plant may behave in one place is no rule as to how it will elsewhere.—THOMAS MEHAN, in "Bulletin Torrey Club."

**Hardy Plants for Pot-culture under Glass.**—I am pleased to see "A. D." (see p. 106) direct attention to this subject. Any one who has but a garden of a few yards can do something in this way; for nothing can be easier than the transference of a few patches of Primulas, Polyanthus, Daisies, Pansies, Hepaticas, Auriculas, Forget-me-nots, Violets, &c., from the open bed or border to pots. Common bulbs, such as Snowdrops, Crocuses, Scillas, Anemones, Tulips, Daffodils, Crown Imperials, Lilies, are equally amenable to removal and acceleration in this easy way. This plan possesses many obvious advantages. Many of the earliest spring flowers are much improved by the shelter of glass, as shown recently in the case of the Christmas Rose. Double hardy Primroses and the earliest Forget-me-nots and Anemones are additional examples of greater purity and delicacy, or a larger development of beauty under glass. Again, this mode of forwarding or protecting hardy spring flowers under glass anticipates and intensifies the pleasures of the spring-tide, the most enjoyable season of the year. It is something, much indeed, to snatch a week, it may be a month, from the hard, cold embrace of flowerless winter, and add so much to genial, cheerful spring. Not only does this simple mode of potting up hardy plants prolong the spring, but it gives us two, as it were, instead of one. We have the same flowers at this season as we shall have by-and-by. We thus, in a sense, double the pleasures of our spring; perhaps more than double them to many, for spring flowers in the window are brought nearer, and are, consequently dearer to many than the same flower in bed or border. Besides, how much better and how much newer they all seem. We have to go to see the flowers in most gardens. The flowers in the window come to see us. They also stay.

The spring flowers thus protected from climatal accidents in the window abide with us; they are not flying visitors, but abiding ones; and when at last their beauty fades, all they need to enable them to resume their places of vantage and of favour another season is, that they be carefully returned to the places from whence they came. What could equal a box, vase, pan, or pot of *Myosotis dissitiflora* fringed or studded with golden Aconites in January? Even this is within reach of most readers, and is only a trifling sample of the wealth of beauty that hardy flowers place within reach of all.—D. T. FISH.

**Early Flowers in Ireland.**—Some of those who read THE GARDEN may be interested in the following list of plants which blossomed here since the first of the year. I give the date of the opening of the first flower of each species:—January 22, *Galanthus Imperati*; 3, *Helleborus niger*; 5, *Helleborus purpurascens* and *H. atro rubens*; 10, *Tussilago fragrans*, *T. alba*, and *Jasminum nudiflorum*; 12, *Vinca minor*; 15, *Daphne* (Dauphine); 17, *Pyrus japonica* and *Prunella vulgaris*; 20, *Galanthus nivalis* and *Primula elatior*; 22, *Hepatica triloba* and *Mahonia glauca*; 24, *Scilla sibirica* and *Anemone coronaria*; 26, *Crocus vernus*, *C. luteus*, and *Rhododendron hybridum* var.—F. W. MOORE, Curator, College Botanic Gardens, Dublin.

**Gaultheria Shallon at Balmoral.**—During August, 1861, I paid a visit to Balmoral, and was surprised to find plants of the *Gaultheria Shallon* growing on the moorland ground on the summit of the hills above the Castle. During autumn of the same year the Queen and the late Prince Consort paid us a visit, and while passing a clump of the *Gaultheria Shallon* in the garden, the Prince remarked that he grew it extensively in the woods at Balmoral, and that the fruit was readily eaten by game. I stated that I had recently seen plants of it growing on the places alluded to, the berries having evidently been eaten and the seeds passed by birds on the situations where they were found. They were generally in seed masses, a few inches square and 2 in. in height. A circumstance which I was not aware of till recently, is the process now adopted by nurserymen of moistening trees and other seeds with water, and then sprinkling them over with red lead before sowing. The birds seem to have an aversion to the foreign colour thus given to such seeds, and therefore they are rarely meddled with.—JAMES McNAB, Botanic Gardens, Edinburgh.

**Adiantum Farleyense in Loam.**—This Fern is seldom seen in a luxuriant condition, and I believe that the failure arises from the mistaken notion that it should be grown in peat and sand. The best soil for it, in my opinion, is a mixture of good turfy loam, leaf-mould, and silver sand, to which may be added a liberal quantity of crushed bones. The plants should not be too densely shaded, as when that is the case, one loose the fine rose-coloured tints that appear on the young fronds. Last autumn I put one in a hanging basket, and it promises to be an attractive feature this season.—A. HOSSACK, Ragley.

—Most Ferns can be raised from seed, but, as far as is known, *A. Farleyense* has not seeded in this country; therefore, it can only be propagated by division of the roots, and as a cultivator once remarked in reference to it, "it does not mind being cut up." The best time to divide for propagating purposes is in spring, when the pieces divided root quickly, and get rapidly into growth. Between large and small pieces, the grower for market is enabled to have plants for sale almost all the year round. Just now, and during early spring, beautiful plants of this Fern are being sent into market. Enormous numbers of plants are grown only for their fronds, which are laid on the cloth in the case of dinner tables, and choice Orchids, like *Odontoglossum Alexandræ*, &c., are placed on them.—D.

**Buttercups and Daisies** may sometimes be found in the Nottingham meadows beautifully variegated with cream colour, white, and yellow. *Cherophyllum sylvaticum variegatum* may also be found sparingly in the ditches hereabouts; it is one of our most cheerful winter and spring fine-foliated plants.—W. ELLIOTT, Stapleford Hill, Notts.

**Leucojum æstivum Forcé.**—A correspondent has sent me some forced flowers of *Leucojum æstivum*, and informs me that annually this Snowflake is one of his winter-flowering plants. To a house of *Ginerarias* and *Cyclamens* at this season of the year this plant must be a charming addition.—P. B.

**The Winter Heliotrope** (*Fussliago fragrans*).—I should be greatly obliged if any of your correspondents who are endeavouring to extirpate this *Tu-lu-gio* would send me a few roots to the undermentioned address.—J. STEWART HARR, Camden Hill, Staplehurst.

Old Woman (peeling Potatoes)—"What a lot o' eyes these 'taters have got!" Old Man—"I specs they's extra, so as to look arter the Colorado beetle."

## THE SIZE OF GARDENS.

Most gardens are too large. This may seem a strange assertion; but it is nevertheless true. No one has ever attempted to measure out pleasure from paintings by the foot or yard square of canvas. Nine out of ten gardens are too large to be enjoyable. Size is the smallest factor in artistic pleasure—if, indeed, it be one at all; good keeping, appropriate furnishing, are of far more moment. Now both of these, however essential to an extreme degree, hence either or both are often seriously neglected to the loss of all true pleasure. And if not so bad as this, the struggle of keeping up the garden is such a strain upon our means that the exertion often exceeds the pleasure, and there is not the slightest need for these serious drawbacks. There is no more necessity that the art of horticulture should be dragged out over a great extent of land than the art of painting over so many square yards of canvas. Large pictures are, indeed, held by some to be vulgar on account of their mere size. This may be carrying art criticism to extreme lengths, but assuredly the canon holds good in regard to many gardens. Let those who are fond of horticulture boldly face facts, and cut their gardens down to their means if they would thoroughly enjoy them. Gardening may be either made a pleasing recreation—a delightful pastime for spare hours—or it may become a burdensome, oppressive, enervating luxury, and eat out a good many of the higher pleasures and nobler enjoyments of life. The springs of the pleasure which it yields lie hidden not in the width of its walks, the number and height of its walls, the grandeur of its slopes or terraces, the size of its beds or borders, the broad expanse of its velvety lawns, nor the perfection of its specimens or mass of trees, shrubs, flowers, or plants, but in the spirit in which it is prosecuted, and the pure delight which its pursuits inspire. Horticulturists must be humble, gentle, reverent, earnest, grateful, if they would be happy in their pursuit. And all these qualities may be as fully developed in small gardens as in large ones. Only disappointment can come of disguising the fact that high keeping is costly. It is not the mere matter of one digging and one hoeing or planting and filling, but many. The farmer may reap profitable crops with a minimum amount of labour; the gardener cannot, for his best crop of pleasure is really reaped every day, from having his garden kept in a perfect state. Bad workmanship, or weeds, or a look out of place, may mar a whole day's pleasure, just as the most exquisite picture begets a sense of pain when seen in a bad light, or through a blinding screen of dust. It should never be forgotten that a garden is, or should be, a charming picture, not stored in a lumber room, but displayed for exhibition all the year round; hence the importance of high and perfect keeping at all times. Then, again, a garden is a finished picture. A great many seem to forget this. Some people's gardens are ever being painted in or done up in new frames. It is impossible to enjoy any sense of repose owing to the bustle of busy workmen—to see the effects of light, shade, or play of colours, of fountains and bushes. The fussy activities and unfinishedness of gardens are fatal to all artistic pleasure. They are easily avoided, if one would only exercise forethought. The rule in some of the finest gardens is, no workmen visible after certain hours. All the work on prominent points is done early in the morning, and repose and finish reign over the garden undisturbed throughout the remainder of the day. So possible is all this, that the questions have often been asked, when is the work done? where are the workmen? or have you any? Gardens should show results, not processes. One plant grown well, suited for its place, may give tenfold the pleasure a thousand large specimens would do, packed into, rather than well arranged in, the most magnificent conservatory. And it is exactly the same in all other branches of horticulture. A patch of the vernal Forget-me-Not, so artistically posted as to form the eye of the drawing-room window, may confer more real pleasure than the thousand spring bulbs piled up in gay magnificence in beds or borders. But enough has been advanced to show that size is of far less moment in gardens than either good keeping or skilful arrangement. Fortunately, too, these latter are within reach of all, while the former, and the means and ability to do justice to large gardens, must ever remain the heritage of but very few indeed.—“Country.”

**Garden Fences.**—The English and Americans seem to have an insane love for fences. We fence the roads from the farms, and then divide the farms into little apartments, like enlarged checker-boards. We fence our village and city lots, and even disfigure our cemeteries by costly and unsightly fences. Every owner of a little lot in the City of the Dead must fence his 20 square ft. of property, but whether for the benefit of the living or the dead is not clear. The English carry this folly to a still greater extreme, and most of the costly mansions with their elegant grounds, in the vicinity of London, and, in fact, everywhere, are surrounded by brick or stone walls, from 6 ft. or 8 ft. in height, and even these are sometimes surmounted by broken bottles, or something of the kind, to make a passage over them dangerous, if not impossible. The front gates, too, are solid and massive, and anyone desiring admission must ring the bell or go “tapping at the garden gate.” The English law maxim, that “Every man's house is his castle,” seems to be fully believed by the people, and many residences look as though they might endure a formidable siege. The people of this country have begun at last to realise the folly of spending such vast amounts of money, not only uselessly, but to the actual injury of their property, both in appearance and productiveness. Farmers are using fewer fences, while n

many of the finest places in the neighbourhood of our large cities front fences, and even division fences, have been mainly discarded. An objection is that the destruction of fences destroys all privacy. This is in a measure true, but we have not yet seen the person who considered this a serious objection, or who would be willing to restore the fences when once removed. Some are apt to think that passers-by will take unwarranted liberties, pick flowers, &c., but this is not so. Remove your fences, place confidence in the people, and you put them on their good behaviour. Nothing will be harmed. We have in our mind a place near this city, planted with shade trees. Three years ago it was divided into three lots with hedges and fences, now all are removed, and we know of no prettier piece of lawn in the world.—“Vick's Magazine.”

**Experiments with Potato Sets.**—A French journal describes the results of some experiments in Potato growing recently conducted by scientific men in Germany. The principal conclusions arrived at seem to be two in number. The first of them is that the vigour of the Potato plant is always in direct proportion to the weight of the tuber used for sets—a theory which certainly finds some support in common sense, considering that the young shoots for some time draw their sole nourishment from the seed Potato. The second conclusion is that there is a great variety in the productive power, not only of different tubers, but also of different eyes in the same Potato. It is found that the eyes at the top of the Potato produce a much more vigorous offspring than those in the lower part, and the consequence is, that those who cut their Potatoes in half before planting them are not well advised in cutting vertically, but should always divide them horizontally, planting the upper half and using the other as food. But the best plan of all is to plant the tuber whole, cutting out, nevertheless, all the eyes except those in the top part. The experiments were conducted in a garden soil by Prof. Gantz, the amount of crop produced by several different settings being accurately estimated in statistical tables. It appeared that from tubers divided vertically only 5 tons were produced per acre, and from whole Potatoes  $7\frac{1}{2}$  tons. The third sort were Potatoes horizontally divided, which are set down as having produced 9 $\frac{1}{2}$  tons. In this particular, however, some of the other professors do not agree with Herr Gantz, but maintain that, other things being equal, the whole Potatoes will always produce more than halves, however cut. On the fourth result, however, all agree, and that is, that the whole Potatoes from which the lower eyes have been cut out produce 11 $\frac{1}{2}$  tons per acre, or more than double the result shown by the sets first mentioned.

**Opening Kew Gardens in the Forenoon.**—The following are Mr. Gerard Noel's reasons, given in the House of Commons, for not opening Kew Gardens in the forenoon.—“What is asked could not be conceded without a large increase of expenditure, and without materially interfering with the daily work in the gardens. In fact, I may say, the change demanded would involve the consideration whether Kew could continue what it originally was intended to be—a scientific utilitarian institution—or merely a resort for pleasure-seekers. [Why does not the Dublin or Edinburgh or Paris gardens suffer from opening them in the forenoon?] The present arrangements, I really believe, satisfy everyone but those who live in the immediate neighbourhood. [Not so. London people, and these at greater distances from the gardens, are practically debarred from visiting them in the winter time.] The visitors from the metropolis and elsewhere, as a rule, never arrive till long after the gardens are opened, and sometimes days and weeks pass without any visitors. [People do not go to stand outside locked gates.] What a waste of public money would be incurred, therefore, were the gardens always opened at ten in the morning, and we consequently had to maintain an additional staff of men all the year round. [The gardens lose half their value if they are shut more than half the time people might visit them.] Kew is open every day gratis to all, Sundays as well as week days. Christmas Day is the only holiday, the only closed day in the year. No institution in the country, I may say in Europe, is so freely open to the public every day from 1 p.m. till dark. Notwithstanding this, the authorities are so anxious to meet the reasonable demands of the public, that for the future we are prepared to open the gardens at ten in the morning on Bank holidays. I trust this will be satisfactory to my hon. friend. He will see from what I have stated that more could not be conceded without altogether altering the character of the gardens, without doing away with the original intention for which the gardens were from the first established, and without largely increasing the annual expenditure. [As to the statement about no institution in Europe being so freely open to the public, we propose collecting a few facts, of which one is given here. Until the present year, the Botanic Garden at Glasnevin has been open to the public from noon to 6 o'clock p.m. on week-days;

conservatories from 1 p.m. to 6 o'clock p.m. on week-days during summer; during winter, from noon till 3 o'clock p.m. On Sundays the gardens are open at 2 o'clock p.m.; the conservatories at 2½ p.m., then remains open until sunset, summer and winter. At the beginning of this year the hours have been altered. The gardens are now opened at 10 o'clock a.m. on week-days, and remain open until 6 o'clock p.m. The conservatories are opened at noon, and remain open until 6 o'clock in summer, and sunset in summer. Sundays the same as previous years. It should be noted that the Royal Botanic Gardens at Dublin are within a mile of crowded parts of that city.]

**Ivy Edgings in Shady Places.**—We have a walk here running through one of the shrubberies which is very much shaded by large Beech and other trees. On each side of this walk, and separating it from the shrubby borders, were Grass verges some 18 in. wide. I, however, always found it impossible to keep those verges in good condition, owing to the dense shade in the summer, and the almost continual drip in winter. At last, after having put down fresh turf six times in as many years, it occurred to me to give Ivy a trial instead; and I am happy to say that the result has been highly satisfactory. The formation of these Ivy edgings was a very simple affair indeed, and occupied but a short time. I allowed the Grass verge—or rather the sod on which the Grass had grown—to remain, and along the centre of it I opened a cut some 2 in. deep, and in this I placed quite close together well-rooted plants of Ivy, covering the roots with a little fine soil, and returned the portion of turf which was removed in making the cut, pressing it down firmly. It is now just two years since this edging was put down, and it has formed a complete carpet the full width of the original verges, and I need scarcely say that its appearance is in every respect contrast to that presented by the original verge, even when at its best. There was no difficulty whatever in obtaining an abundance of plants, as there are acres of wood here in which Ivy forms a thick carpet all over the ground. Indeed, there is no place in which there are woods where this plant may not be found, and in a suitable form for turning to account in the way just alluded to.—“Gardeners' Record.”

**Tall Trees.**—It appears that there were some very remarkable sections of North American timber trees shown at the great International Exhibition at Philadelphia in 1876. The dimensions of some of them come near that of the “Big trees” (*Wellingtonia gigantea*) of California. A section from an Oregon Red Cedar (*Thuja gigantea*) measured 23 ft. in diameter, the tree from which it was cut being 325 ft. high. A section of *Abies Menziesii*, taken 98 ft. from the ground, was 6 ft. 10 in. in diameter, and the tree was stated to be 318 ft. high and 16 ft. in diameter at the base. Two sections of the Yellow Pine (*Abies grandis*), from Oregon, measured, one 6 ft. 10 in. in diameter, exclusive of bark, taken 130 ft. from the ground, and the other 5 ft. 10 in., taken 200 ft. from the ground. Both these sections were cut from one tree, which gave a diameter of 15 ft. 9 in. at the base, and a height of 321 ft.

**Public Parks.**—Two national parks only have been made in North America by authority of the Government. These are the Yosemite Valley and the Yellowstone National Park. The former was granted by Congress to the State of California, June 30, 1864. This tract is in the county of Mariposa, at the head waters of the Merced River, and is about 15 miles long and a mile in width from the main edge of the precipice on both sides. At the same time the Mariposa Big Tree Grove was set apart under like legislation. This comprises an area of about four sections. The Yellowstone National Park is located in the extreme north-west corner of the territory of Wyoming. It is 65 miles in length from north to south, and 55 in breadth from east to west. The Act of Congress setting it apart as a public park was approved by the President March 1, 1872. Probably no area of equal dimensions on the globe contains so many objects of wonder as hot-springs, geysers, waterfalls, and canyons. Professor T. V. Hayden is the authority quoted in this paragraph.

### GLASS COPINGS FOR WALLS.

HAVING devoted many years to the cultivation of Peaches and Nectarines in low-lying situations, liable to be affected by early autumn and late spring frosts, I have found that the use of glass copings, combined with the Trentham system of frequent lifting, and re-planting in pure loam, furnish the most successful means of ensuring satisfactory results. Where glass copings have been tried during the season of 1877 for the first time, their condemnation would be unfair, as half-ripened wood never produces good crops of fruit. Some years ago I placed glass copings over four Peach trees on a wall 80 ft. in length; and although I have lost crops of fruit and the trees also on other walls protected by boards and fishing-nets, I have never missed gathering a crop from the glass-coped trees. Last year, so fatal in many places, their foliage was quite clean and free from curl. The fruit set well, and required frequent thinnings, and the trees are again furnished with promising wood. The other set of trees to which I have referred, on a higher level, consequently a better wall for resisting the effect of cold, was so much injured by blight and curl, that the crop so failed, and many of the trees have had to be removed. Glass copings should be light, portable, and inexpensive. Mine are 12 ft. long, of plain deal, grooved and painted, the glass (21 oz.) being slipped into the grooves, and the last square fastened by a small screw. They are placed over the trees before the blossoms open, and remain on until all danger from spring

frost is over. They are then taken away to the store-house, and the trees are well syringed, mulched, and watered. In elevated gardens enclosed with high walls, slight protection is all that is required for securing crops of fruit. At Madresfield Court, the magnificent set of Peaches and Nectarines was last year laden with fruit, and the only protection Mr. Cox uses is two or three folds of fishing-net; but then his walls are high and well coped, and he has wisely selected an open, elevated position for his new kitchen garden. In making a selection of trees for low, damp situations, I have discovered that short or half-standards on the Muesel stock are hardier and last much longer than the ordinary dwarf tree, which is worked a few inches above the level of the ground.—W. COLEMAN, in “Florist.”

**Scottish Horticultural Association.**—The usual monthly meeting of this association was held at 5, St. Andrew's Square, Edinburgh, on Tuesday, the 5th inst. There were over 100 members present. The President occupied the chair. Thirteen new members, proposed at the last meeting, were duly admitted, and fifteen new names were announced. The subject for discussion was “Vine borders,” opened by Mr. William Priest, Newbattle, who read a short paper, in which he set forth in a plain and practical manner his experience in their construction. He laid great stress upon having a good depth of border, say 2 ft. 6 in. to 3 ft. 6 in., and sloping from back to front, and that the soil should consist of a good loam, lime-rubbish, crushed bones, and charcoal. The paper gave rise to an animated discussion, in which many members took part, the general feeling being that the principles advocated by the essayist were sound and thoroughly practical, but that cultivators would require to be guided by the circumstances of their individual cases. During the discussion the experiments of Mr. Hunter, Lambton Castle, were adverted to. The proceedings terminated with a vote of thanks to Mr. Priest for his paper.

### NOTES AND QUESTIONS—VARIOUS.

**Roberts' Gros Guillaume Grape.**—It is more than probable that Ireland will continue to retain the credit for years of having produced the heaviest bunch of black Grapes on record, as we have not as yet heard of any to equal the large bunch produced last autumn of Roberts' Gros Guillaume, grown by the raiser of that variety, Mr. Roberts, of Charleville Forest, Tullamore, which weighed 23 lb. 5 oz. The more we see of this Grape the more we are convinced of its distinctive character and genuine worth.—“Gardeners' Record.” [We understand this Grape will be sent out by Messrs. Tait, of Dublin.]

**A New Apple.**—The editor of the Germantown “Telegraph” remarks that the Albemarle Pippin looks very much like his progenitor, the Newtown Pippin, and is about the same size, but in point of excellence it far exceeds it, in his estimation, as it does every other Apple he has ever tasted—a pretty good compliment, we should say, for the Albemarle Pippin.

**Abies Patoniana.**—Allow me to direct the attention of planters of Coniferous trees to this, which is one of the finest of all of them, and yet one of the least planted, i.e., so far as my own observations have gone. It has beautiful light green foliage, which contrasts admirably with such sombre kinds as *Picea cephalonica* and *P. Nordmanniana*. It seems nearer allied to the Larch than to any other Conifer, but it is evergreen. It is perfectly hardy, and of free yet compact growth. I have been told on good authority that its timber is of more value than that of many Conifers which are more largely grown.—W. W. H.

**Self-watering Flower Pot.**—Mr. Matthews (see p. 62) is in error in stating that the above was described in *The Gardener* of December 19 as a new invention. The writer merely alluded to it as patented by Mr. Levetsov; as since, as manufactured by the latter—it meets with a good sale, whilst Mr. Matthews' pot finds few purchasers, some improvement in construction or material has probably been introduced.—T. S.

**Gas Tar on Trees.**—A writer in the *London Gardener* says he has used gas tar on his Oak, Ash, Larch, and other trees for twenty-five years without injury. His object was to exclude rabbits. As we have repeated instances reported in this country where it very promptly killed every tree to which it was applied, we conclude that in the instances where this result was not produced, the trees were large enough to have produced dry and hard bark through which the tar did not penetrate. Something is obviously due to the time of year when the application is made, as green bark during the growing season is more sensitive than in the dormancy of winter, the tar gradually drying and hardening in the course of months.—“Albany Country Gentleman.”

**The Late Mr. Rivers.**—At a meeting of the Massachusetts Horticultural Society, on the 24th ult., action was taken, with reference to the recent death of Mr. Thomas Rivers, of Southwicksworth. The venerable Col. Wilder offered appropriate resolutions, prefaced by an adequate tribute to the memory and services of Mr. Rivers.

**Testimonial to Mr. James Drummond.**—Mr. Drummond, over 35 years gardener at Blair Drummond, was presented the other day with a testimonial of his subscribers connected with the Stirling and Kilmacdock Horticultural Societies on the occasion of his retirement. The testimonial consisted of a handsome timepiece, a beautiful silver bread or cake basket, a solid silver snuff-box, and a splendid parlour copy of Burns' Poems, very elegantly bound in Bannockburn wood.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### OAK STUBBS IN GARDENS.

Few are aware of the great value and importance of old timber and other stubbs in picturesque gardening. Of these there are several kinds. Those most readily obtained, especially by people who possess woods, are such, which, after the trees have been felled for "flawing," are immediately and carefully grubbed, with sufficient fibrous roots to ensure their existing in a living state, when all round the margin, under the bark of the stubb, multitudes of fresh, vigorous shoots spring forth, bearing immense leaves, often 1 ft. in length, and forming as handsome a dwarf shrub as one could desire, especially in autumn, their golden and russet leaves remaining far into the winter. Another kind of stubb is that of an Oak or Holly which has been exposed for years to the drip of a damp wood; it becomes well rounded, and densely clad with the liveliest-green velvety Moss, Lichens, minute fungi, and drooping polypody, a perfect picture of beauty. This being a dead stubb, it is too beautiful to last, and can only be depended upon for a very few years, decaying very rapidly. Most difficult to obtain, and the most desirable for durability, but for another purpose, viz., for forming a rootery, is the ancient Bog Oak root, which we exhume from beneath the surface, where it may have been buried for many centuries; all the outer sappy portions have been decayed, leaving only the angular stellate centres, hard as iron, often of a deep reddish-black, and when built up on the surface of a mound or bank reminding one of mountain peaks very similar to the Aiguilles of Mont Blanc. In forming a rootery, it is necessary that the foundation should be composed of a large quantity of stones, clinkers, or brick-burrs, to ensure perfect drainage; commencing with the base, which should be made as irregular as possible, the stubbs must be jammed down firmly upon each other on a surface of rooty-peat and loam, small broken stones and sand, leaving valleys and bays and pockets or open places in which almost any plant will thrive, as, for instance, Alpine and rock plants, Ferns, small Vines and Ivy, and delicate Grasses, such as Briza, and many of the Orchises. It need scarcely be named that such a stubbery should not be isolated like a tumulus on a plain, but must grow out of some natural hollow or nook in a cliff of rock or high background of old stems of trees, or Ivy-clad wall in a somewhat retired spot, and not to form part of a scene from the windows of a house. Ants are, however, great enemies of these places, the dryer portions of the wood internally becoming rapidly converted into a kind of sawdust, in which their countless eggs are hatched, the pungent odour of the formic acid being most disagreeable. Here Sir John Lubbock might with advantage study in a natural way the habits of these interesting creatures. It would be desirable to observe what wood might best resist their attacks. Doubtless an ancient Yew or Holly stubb would prove more efficacious and durable than even Bog Oak. Oak grown in poor sandy soils, though not attaining large dimensions, is very close-grained, hard, and sound, and for "postes," as my carpenter assures me, is better than all other timber, for though Elm underground resists dampness, it much sooner perishes where exposed to the vicissitudes of wet and dry air than heart of Oak. And of hearts of Oak, are we not as islanders and mariners justly proud and nationally enthusiastic? E. W. COOKE.

*Glen Andrea, Sussex.*

during the Saturday evenings of June, July, and August till 8 p.m. (for the benefit of the working classes). During the winter months it is open from daylight till dusk. The hothouses are open every Wednesday and Saturday from 12 till 4, but during the long days till 5 p.m. Strangers not resident in Edinburgh can get admission to the houses on other days of the week by satisfying the porter that they are strangers. On open days men are stationed in the houses, but on other days (when not open) a man is sent round with visitors. Besides the ordinary open days, the garden and houses are open during all holidays and to people coming by excursion trains to Edinburgh, although not on an open day."

### ARTIFICIAL TREE FERNS.

I FIND these very useful as ornaments for the dinner-table, especially at times when one is puzzled to devise a change. The following are a few details of what I mean by "artificial" Tree Ferns, together with the names of a few Ferns which are suitable for such purposes. These consist of *Lomaria gibba*, *Blechnum brasiliense*, *Dioikonia antarctica*, *Alsophila australis*, and *Pteris tremula*. As regards the mode of procedure, I get a healthy young plant of *Lomaria gibba* in a 4-in. pot, take it out, and shake off as much of the soil as I can without breaking the roots; what remains can be got rid of by washing the roots under a tap or pump. The next thing to decide is the height of the stem, which I usually make about 1½ ft. high. I get four straight stakes, place them at equal distances round the base of the plant, and secure them with small copper wire; then I get some pieces of rough peat and loam, and begin forming the stem from the plant downwards, taking care not to destroy the roots, and as I proceed I bind the whole with fine wire. I then cover the whole over with Moss, obtained from the roof of an old shed. This is preferable to what is found growing under trees, because it is not so liable to break, and, having no soil adhering to it, it looks much neater. I then place the stem in a 4-in. pot, filling the same pretty well with potsherds, merely putting a few pieces of loam on the surface. I then cover with Moss, similar to that with which the stem was clothed. I then have a hand-light in readiness to put them in, and attend well to the watering and shading for a few weeks, when, if all have gone on well, young roots will be emitted through the Moss. They may then be gradually exposed to the ordinary temperature of a Fernery, but avoid putting them in a draughty position. They will now require an abundant supply of water, and the best way to apply it is to put the hand round the stem and pour it from a watering-pot without a rose. It is always well to make these artificial Ferns in pairs, and to avoid making the stem too bulky. Some of the coarser-growing Ferns are not so tedious to deal with—*Alsophila*, for instance; these ought to have the stems made proportionately stout to their growth and longer—say 3 ft. the first season. Some may object to this mode of making one's own tree Ferns as an innovation on Nature; granted. But are we not placed in a position to assist Nature? And I do not find that these artificial Ferns look unnatural, but quite the natural brown one. Plants of the description just indicated may be used on the dinner-table in a variety of ways, but I much prefer them set on a flat plate, and the pot mounded with some healthy plants of *Lycopodium denticulatum*. A few flowers may then be inserted among the Lycopod. One colour is preferable; say out blooms of *Abutilon Boule de Neige*, scarlet *Pelargonium*, &c.

*Razley.*

A. HOSSACK.

**Hyacinthus candicans in Holland.**—This very ornamental plant has been cultivated by us for several years, and has invariably proved to be quite hardy. We have several times left large flowering bulbs of it in the ground during winter, planting them in autumn, and they never sustained any injury from frost. We, however, prefer taking the bulbs up in autumn and replanting them in spring, keeping them dry and out of the reach of frost during winter, like the Gladioli. Those in our seed beds are not taken up in autumn until the bulbs are two years old. We do not doubt that this *Hyacinth* will soon become as popular as it deserves to be.—J. H. KRELAG, Haarlem.

**Snowdrops on Stoncrop Turf.**—I wished to have a small strip of ground covered with verdure, and yet I did not want to have it frequently mown. Early in autumn it was broken up, levelled, and made smooth on the surface, and into it were dibbled a quantity of bulbs of the double Snowdrop; the entire surface was then covered with small patches of the creeping green *Sedum Lydium*. This latter now forms a carpet of rich green foliage, through which are peeping the lily-white blooms of the Snowdrop, and the effect will soon be most charming. The leaves of the Snowdrop will look unsightly for a short time, but as soon as they are ripe, they can be

**The Opening of Kew Gardens.**—In reference to Mr. Gerard Noel's statement (see p. 133) that "no institution in the country is so freely open to the public as Kew," we last week gave the hours of opening of the Dublin Botanic Garden; this week we publish those for the Royal Botanic Garden at Edinburgh. "It is open to the public every lawful day—in summer from 6 a.m. to 6 p.m., also

cut away, and the Sedum will remain green and neat until next spring. This arrangement, if occasionally treated to a top-dressing of finely-sifted soil, will remain good for several years.—A. D.

**Newtown Pippins.**—The past has been a very bad season for this popular Apple, the fruit being as a rule scarce, poor in quality, and worm eaten.

**Rose Cornelia Cooke.**—Mr. George Paul informs us that this Rose, so popular in America, owing to its firm buds, has been tried in this country in the open air, and proved to possess no qualities that would recommend it for cultivation.

**Nephrolepis Duffi.**—This new and distinct Fern, which may be seen in Mr. Bull's nursery, has long, slender fronds, closely beset with small and elegant pinnae. When well established, it will doubtless be found very useful and ornamental for placing in vases and in similar positions.—S.

**The Creeping Forget-me-Not** (*Omphalodas verna*).—Permit me to direct attention to this as a winter-flowering plant. I potted several young plants of it in November from the open ground, and they have been in beautiful flower in my rather cold greenhouse ever since the beginning of the year. Nothing can exceed the beauty of the shade of blue which distinguishes this little plant, so often overlooked.—H. B.

**A Winter Carnation.**—A new winter-flowering Carnation named *Alegatere* is now making a fine display in Mr. Turner's nursery at Slough. The plant possesses a free-branched habit, and produces a profusion of bright scarlet blossoms during the winter months. It is of French origin, and must ultimately be grown in preference to any other kind of the same colour for market.

**Hardy Flowers at Tooting.**—Mr. Barr has sent us, from under glass, specimens of *Allium neapolitanum*, bearing umbels of pure white flowers, and of *Senecio pulcher*, with rich magenta-coloured blossoms. Both are well-suited for culture in pots for blooming during the earlier months of the year.

**Snowdrops in Covent Garden.**—The beautiful white flowers of the early Snowdrops play an important part in even the choicest of bouquets in Covent Garden. They are also employed with good effect fastened to sprays of common Box. The drooping white blossoms are placed in such a manner as to allow the green, stiff leaves of the Box to peep between them. In bunches of Violets, too, a few Snowdrops are introduced, and, being allowed to droop over the Violets, form a pretty combination.

**Andromeda floribunda for Forcing.**—Boshy plants of this *Andromeda*, potted and forced into flower in Messrs. Osborn's nursery at Fulham, are now furnished with a profusion of clusters of Lily of the Valley-like blossoms, which are much whiter on forced plants than on those in the open ground. Associated with scarlet *Cydonia*, Ghent Azaleas, &c., the value of such shrubs, in an ornamental point of view, at this season of the year cannot scarcely be overestimated.

**Hemerocallis Kwano variegata.**—Allow me to recommend this as a most desirable plant for many purposes at the present time. Clumps of it potted in autumn, and introduced into a house of only moderate warmth, are now very beautiful, and much more graceful and superior in every way to either of the variegated *Pandanus* so frequently used for table and other decorative purposes. It is quite hardy, and, after doing duty now, it can be planted out by-and-bye in the border, where it will take care of itself.—T. SMITH.

**The Great Brownsea** (*B. macrophylla*) at Lakeland was in gorgeous beauty when I paid it a visit the other day, having three of its brilliant fiery orange Rhododendron-like bloom trusses open, all coming out of the hard wood of the trunk at distances varying from a few inches to 1 ft. from the ground. It has been now blooming almost continuously for over two months, having already produced over 100 of its gorgeous bloom-heads, and having several more still to expand.—W. E. G.

**Rosa polyantha.**—Mr. George Paul has just told us of the beauty of this Rose as a vigorous climber in Mr. J. Sibley's garden at Lyons, we, in reply to an inquiry, received the following note from that veteran amateur, who has enriched our gardens with so many good varieties of plants:—"As to the principal object of your letter, I can say but very little. I have possessed *Rosa polyantha* since it has been introduced from Japan. It is a very hardy shrub, having stood with me the severe winter of 1870, when we had, in December, 21° Centigrade below freezing point. The flowers are white, small, and single, but they are borne in clusters, like the Lilac. It seeds freely. It needs no pruning; quite the contrary. I have obtained from its seeds several varieties with double flowers, which are about the form and size of those of *R. multiflora*. They are generally white, but some are tainted yellowish or pink. I must suppose that the mother

plant has been fertilised, through insect agency, with the pollen of other *Roses*, because my son, who is an engineer in Japan, wrote to me that in the neighbourhood where he resides, where the *Rosa polyantha* grows wild on the hills, it always comes true from seed, but that may happen because there are no other *Roses* in the neighbourhood."

**Chinese Primroses.**—A coloured figure of *Primula sinensis fimbriata coccinea* has been sent to us by Mr. B. S. Williams, of Holloway. It represents a beautiful, deep crimson form of these Primroses, various improved varieties of which have been introduced by Mr. Williams.

**The Fulham Nurseries and New Lines of Railway.**—In consequence of a railway being about to be formed through Messrs. Osborn's nurseries, at Fulham, active preparations for the moving of trees and shrubs in its way are being made. These are not confined to the moving of ordinary nursery stock, but to that of full-grown Magnolias, Azaleas, and similar hardy trees and shrubs for which this nursery has long been celebrated. The roots of the largest of the trees to be moved have been cut ready for transplantation next year.

**The White Lycaste.**—One of the best examples of the beautiful white variety of *Lycaste Skinneri* which we have seen is now in bloom in Mr. Williams' nursery at Holloway. Its blooms are very large, and quite as chaste and pure as those of the well-known *Cymbidium eburneum*, which is, even at the present day, somewhat rare. Flowers of the white *Lycaste* are as freely produced as those of the rose-coloured varieties, and for cutting they are invaluable.

**Orchids at Messrs. Veitch's.**—Among rare *Orchids* now in flower in Messrs. Veitch's nursery are mentioned *Ocidium Orestodi*, which produces small pure white flowers, with a yellow throat, set on short stalks; the brilliant orange-coloured *Lælia harpophylla*, with several spikes of blossom; the white-flowered *Cattleya Trianae*, and a variety of *C. Trianae* called *Penelope*, the latter bearing a magnificent flower with petals 2 in. broad, of a delicate transparent violet colour, and a claret-coloured lip with rich golden throat. To these may be added *Epidendrum Wallisi*, *Odontoglossum Chestertonii* and *protonites*, the latter being furnished with upright spikes of flowers having chocolate sepals and prettily-marked petals. Several new *Lælia*'s *Slippers* are also in bloom, and the large-flowered variety of *Angreum sesquipedale* is still in good condition.

**Closed Gates at Kew.**—We understand that the Kew Gardens Public Rights Defence Association have determined to make an application to Parliament, and to persevere until the object desired is achieved. An appeal is made to the public for the necessary funds. The secretary is Mr. Charles Colman, jun., and his address is Cumberland House, Kew.

**Ghent Horticultural Exhibition.**—We have received the programme of the Ghent exhibition, to be opened on the 31st of the coming month. It promises to be a most important horticultural meeting. Copies of the programme may be obtained from M. Ed. Claus, 20, Rue digne de Brabant, Ghent.

**The Orchid House at Glasnevin** is at present quite a treat to look at, and even to a person unacquainted with the value of the plants it would amply repay a visit. The following is a list of such as are in flower, viz., *Cypripedium barbatum*, *C. Dominianum*, *C. hirsutissimum*, *C. Harrisianum*, *C. Lowii*, *C. longifolium*, *C. Roezli*, and *C. villosum*. *C. Harrisianum* is very fine; *C. Lowii* is also in excellent condition. Associated with these are *Odontoglossum grande* and *O. cariniferum*, *Lælia anceps* and *L. superbiens*, the latter very fine, the blooms being large and well-coloured; *Calanthe Dominiana*, *Neottia maculata*, *Dendrobium nobile*, *D. densiflorum*, and *D. Wardii*. *Cattleya Trianae* is also finely in flower, as are also *Angreum virens*, *Ocidium spheacelatum*, and *Aerides giganteum*. The two gems of the collection are, however, a noble plant of *Phalaenopsis Schilleriana*, with over fifty beautiful blooms on it fully expanded; and a very fine specimen of the very rare and beautiful *Vanda Cathcartii*, the flowers of which measure over 2 in. across; the lip is white, with a rich cream-coloured edging, with two somewhat inconspicuous chocolate stripes down the middle; the petals are large and fleshy, and are barred irregularly all over with stripes of a light chocolate colour.—F. W. MOORE, *College Botanic Garden, Dublin*.

**Kentipossia Lindeni**—It is stated (see p. 114) that this Palm has massive, fan-shaped leaves. Is that really the case? If so, it can hardly be a *Kentipossia*. The fronds of Palms are generally considered under two terms as to shape, the one fan-shaped, the other feather-shaped, which, as a loose general rule, holds good through the whole family. The *Kentias* and *Kentipossias* should belong to the latter group, hence the reason of this query. If *Kentipossia Lindeni* belongs to the former group, it is a very distinct plant from what it is generally supposed to be.—M. D. [*Kentipossia Lindeni* belongs to the feather category.]

## VASE OF ROSES BY REGNIER.

It has been truly said that the highest art is that which renders most correctly the spirit of the subject without condescending to photographic detail, since we never can attain to both at once. When gazing on the charming group, the subject of the accompanying engraving, we cannot but observe how fully this remark has been fulfilled, for while recognising the graceful shape of the Cabbage or Provins Rose, still dear to many a Rosarian, it is obvious that the closely-packed petals are indicated rather than minutely copied; but as the likeness is not lost thereby, the gain in lightness and grace much more than compensates for the absence of detail. Our modern cultivators, in their endeavours to improve (from a gardening point of view) the queen of flowers, have almost succeeded in banishing the light and but semi-double Damask Roses forming the top of the group from our gardens; but to a painter's eye they will always furnish a spray of bloom, such as he delights in. This is not even in these days forgotten by modern French artists, who tread worthily in the "spirit" rather than the footsteps of Regnier, the light and delicate sprays of Tea and Noisette Roses being very favourite subjects with them, while the massive blooms of a Pierre Notting and Maréchal Niel are sparingly used, and only as a counterfoil to some rich drapery, such as that before us.

E. H. W.

Vase of Roses by Regnier.

## CLIMBING ROSES.

THE desire for the varieties of Roses that produce the finest formed individual flowers is so contagious, that in far the greater number of gardens many of the Roses best adapted for particular purposes are completely lost sight of. Even where lists are given of what may be termed garden Roses, it rarely happens that there is anything to be found in them but a selection of the freest-growing Hybrid Perpetuals, with a few Noisettes, Bourbons, &c., a whole host of distinct kinds being left out much more appropriate for planting in many positions in any garden—large or small—than those recom-

mended. Take, for instance, the Banksians, both white and yellow. What can be more beautiful than the innumerable bunches of full, yet not formal, flowers that these produce when well established in a warm situation? but how comparatively rarely are they seen. All they require is either a naturally dry bed, or one that is sufficiently drained to make it so, with plenty of rich soil, and in other respects they should be left undisturbed, except to shorten any over-strong shoots, and to nail or tie others, so as to regularly cover the space which they are required to fill. A good washing two or

three times in the spring with weak Gishurst water, allowed to dry on the leaves, is a great assistance in keeping down red spider and green fly. By the sides of shrubby walks, away from the more dressed part of the garden, where any particular object has to be covered, the Ayrshire and Boursault Roses are generally very much more in keeping with the surroundings than the kinds that produce finely-shaped flowers. One of the most effective objects imaginable in such a situation is the trunk of a dead tree with its upper branches partly shortened and covered with Ivy, from amongst which hang pendent, long, untrained shoots of these Roses in flower, with no further tying in than just sufficient to disperse them irregularly over the upper portion of the stump. Such a combination is easily obtained where the soil is suitable and plenty of manure is

dug in; the Roses must also be well supplied with it afterwards, or the Ivy, being a gross feeder, will impoverish the soil to an extent that will prevent them getting sufficient sustenance. Where this combination is attempted, the Ivy should have two or three years' start, otherwise the Roses are such free growers that they will monopolise the whole space. The same arrangement on a wall looks equally well; but, if a successful effect be expected, the Ivy and the Roses must not be left to fight out a war of extermination; on the contrary, whichever is found to be unduly taking the lead must be kept within bounds, and the Roses must be annually manured, for

if this be not done, while the Ivy would grow on without any assistance, the Roses would die of starvation. Even under such conditions, the evergreen Roses (*R. sempervirens*) alone are often much more suitable than those with finer shaped flowers; they are also well adapted for covering arched trellises over walks, or for divisional screens to shut out anything which it is desirable to hide, or for overrunning wooden fences anywhere not overhanging with trees, and where the soil is not only in the first instance made sufficiently rich to promote free growth, but is continuously kept in that condition afterwards. The Noisettes are equally useful for intermixing in the way above recommended; their great advantage is their disposition to flower profusely late in the autumn. The Teas, *Gloire de Dijon*, and climbing *Devoniensis*, are unsurpassed for use in this manner; where they have plenty of head-room, the long, unformal branches of the last, with its great clusters of flowers hanging from the points, and the ever-blooming disposition of the former, are not equalled by anything in their way. In the case of these, again, the principal matter is to see that the roots are well sustained and to use the knife as little as possible. Where a single object, like a very large-headed drooping standard Rose, is required in such a position as a distant corner of a lawn, nothing answers the purpose better than the old variety *Blairi*; where soil and situation suit it, and a strong support is used, it will grow to a very large size. In its case, again, the knife must be sparingly employed, or the result will be sure to be a large crop of shoots, but few flowers.

Nothing is more common than planting rows of standard Roses along the sides of walks, a practice by no means conducive to an improved appearance in gardens; but where there is a determination to plant them in that way, much might often be done to render them more interesting than they usually are—here and there a plant doing well, and the rest mere starvelings. For such situations nothing but the freest growers should be chosen, and the soil ought to be such as is naturally suited to the growth of Roses. The small pieces of unfurfed space immediately round their stems, left for the purpose of supplying manure, are simply eyesores, for if the Roses make their wonted progress, in a year or two their feeding roots would be far beyond the parts left unfurfed. Where Roses are grown in such a position, it is best to lay turf right up to their stems; and when assistance is required in the way of manure or new soil, strip off the turf during the winter, or, if more convenient, at the present time, remove some of the old earth and add new soil. Then make all firm and replace the turf.

T. BAINES.

**A Rose for the Wild Garden.**—Few plants make more beautiful objects in the wild garden than many of our British Roses. Their graceful and wild luxuriance of growth and native vigour enable them to hold their own with most hardy plants. We now recommend to our readers one which has all the beauty of our own combined with a strength of constitution which equals, if it does not surpass, that of many of the species of our English hedges and commons. It is from Nepal and Kamoon, and bears the name of *Rosa Brunoniiana*. Its large, stout branches, which are beset with rather strong, hooked prickles, often attain a height of 12 ft. or 15 ft., and are tolerably thickly clothed with pretty bright green leaves; the pure white, fragrant flowers have five roundish petals, and are borne in large corymbs. When in flower nothing can well exceed the charming appearance presented by this Himalayan Rose. Where its bare stems might be an eyesore during the winter months, plant it behind not very tall evergreens, &c., and allow its long branches to droop naturally from among the twigs of low trees, such as the *Laburnum*, &c. Being perfectly hardy in this country, it ought to be much more generally grown.

**Rose Gardens of the Future.**—Mr. George Paul suggests that the plan adopted of growing *Lilacs* in *Rhododendron* beds might with advantage be extended to the Rose. In that way the early bloom of shrubs and *Lilacs* would be succeeded by the still more precious summer and autumn Roses. Apart from this advantage, however, the plan and similar ones are desirable, if only to save, or partially save, the Rose from the dismal and stiff Rose gardens that are seen in many places.

### CHRYSANTHEMUMS IN TRENCHES.

In the *Chrysanthemum* we have a plant of such a hardy, enduring nature, that it not only grows, but may be said to flourish amid soot and smut, if now and then they are washed from its leaves, as there it is they do the mischief by stopping the breathing pores. If those who live in and around towns and cultivate *Chrysanthemums*, as nearly all do if they have the least bit of ground, only knew how important it is that they should be kept free from dusty deposits, their success would be much greater than it now is, as when the respiration of any plant is impeded, its whole system becomes disorganised, as would be the case with ourselves did we suffer in the same way. The leaves are to them what lungs are to us, and it is therefore obvious that if they become clogged in any way, it is at the expense of their health. This being the case, those who would have them thrive should not fail to give them a good drenching overhead at least once or twice a week during the summer and early in autumn; if they do this, the return will be a much finer display of bloom and plants in such a condition of health as to be a real pleasure to look on. This watering overhead is almost of as much importance as a supply of moisture at the roots, especially if the plants are growing near dusty roads or where the atmosphere is not clear and pure, as it seldom is in the vicinity of large towns and cities, where *Chrysanthemums* are perhaps more appreciated than anywhere else. In applying water to cleanse the foliage it is best done through a good syringe, as then it can be used with some considerable force. Failing this, a good shower from the rose of a water-pot will answer the purpose; but, however carried out, the washing should be thorough, as a slight sprinkling would only aggravate the evil by moistening the dusty deposit, and making it stick all the tighter. One of the reasons why we so frequently see *Chrysanthemums* in the naked, shabby condition they are at the time they should be looking their best, is from lack of water at the root, a state that generally brings on mildew, and if not this noxious parasite, the leaves become so starved that they die from inanition. This will be apparent to anyone, as it is always those low down the stems which get the least sap that go first; but if the plants are well fed, they will retain these till they become exhausted by flowering, when they die away naturally. When in active growth, it is surprising the quantity of water or liquid-manure *Chrysanthemums* will take, and to ensure thorough soakings, it is a good plan to have the crowns of the plants slightly lower than the soil, that a small basin-like receptacle may be formed round them, that each may get its due share without any loss. Where large specimens are required for pots, or for transferring to positions in open borders, to take the place of summer-flowering plants, a purpose for which they are well adapted, the best way is to grow them in shallow trenches, for the same reason as that explained above, and if, in addition, they receive a slight mulching, there will not be the least difficulty in keeping them in the most perfect health. Plants treated in this way do well for lifting and transplanting under sunny walls of dwellings where it would be much too hot to grow them successfully during the summer, but where in autumn when in bloom the shelter is just what they require. With a very little trouble, therefore, the beauty of a garden may be considerably prolonged, as all that is necessary when the summer occupants are over is to lift the *Chrysanthemums* with good balls just after they have formed their buds, and if this is done during a dull, showery time, they will scarcely feel the removal. The finest and best plants I have ever seen in pots were managed in this way, and it is a plan of growing them I can strongly recommend, saving, as it does, a vast amount of labour and time in watering, besides yielding better results. Before taking them up, the thing is to see that they are thoroughly soaked a day or so previous, which will cause the soil to adhere to the roots better than it otherwise would. In potting, well-enriched loam should be used for the purpose, and the plants afterwards set for a few days on the north side of a wall, where they can be frequently syringed or watered overhead to prevent flagging. The rapid way they form roots, and their naturally great recuperative powers, soon enable them to set to work and get re-established, after which they bear the air and sun in a greenhouse or conservatory just as well as if they had been grown in pots all the season.

### Propagating Chrysanthemums.

Much has been said and written on this subject, but there can be no question that if large plants are required, it must be done early; and the practice of all the best growers of these popular flowers is to begin at the latest by the turn of the year, and those, therefore, who are ambitious to excel next autumn should at once set about getting a first batch in. The best cuttings are those that are stout and short-jointed, plenty of which may generally be obtained now if a plant of each kind from the old stock has been kept in cold frames for the purpose. It is the custom with many to shake these out and take off the rooted suckers; but, except for planting in borders, cuttings are much the best, and as these strike readily at any time after this, they should have the preference for pot culture. The most suitable place to propagate them is a Vinery or any forcing house at work where they can get a gentle heat, but in order to keep them from flagging, the aid of a hand-glass is necessary, under which they can be kept close and moist till rooted. A situation of this kind will be found to agree with them far better than a hotbed, where they get a much higher temperature, as there they are more apt to become drawn and damp off, and if weakened at this stage of their existence, they are never so satisfactory afterwards. In whichever position placed, they should be well up to the light, and not allowed to remain longer without fresh air than is absolutely necessary, as, from their hardy nature, they are very impatient of close confinement, which is a frequent cause of mildew, to which some of the sorts are particularly liable. Where only a limited number of plants is required, and space can be afforded, it is much the best way to put each cutting separately in small pots, as then there is no further check or disturbance of the roots in the way there is when numbers are put in together; but if this has to be done, the thing is to pot early before the roots become interlaced and liable to injury in effecting a separation. If afforded a very gentle heat for a week or so after being potted off, to give them a start, they will be ready for removal to a cold frame, in which they should be placed on a solid bed of coal-ashes within a few inches of the glass, so as to enjoy all the benefit of the sun, light, and air that can be afforded them at this dull season. There they will come slowly on, making short-jointed, stubby growth—just what is required for a good foundation, which with these, as with most plants, is the stepping-stone to success. Towards the end of March, if all goes well, they will be ready for a shift into 6-in. pots, which should be done, using only one crock at the bottom, and on this a pinch of soot, which not only acts as a fertiliser, but keeps out worms that otherwise are often most troublesome. The most suitable soil for Chrysanthemums is good, sound, fibry loam, rather inclined to adhesiveness than otherwise, and if this can be had tolerably fresh, they will succeed best without any admixture whatever, except a little thoroughly decomposed manure; but even this should not be strong, as it is always more satisfactory to give most of what stimulates they require in a liquid form, the advantage of which is, that it can be applied when the plants most need it, instead of being unduly forced in their infant state, as many are by having too rich a soil to start with. By the end of May they will be ready for their final shift into 10-in. or 12-in. pots, and should after that be plunged on a firm bottom in loose littersy material in an open, sunny spot, where, if well attended to with liquid manure and clear water, they will make grand plants by the autumn.

The most suitable sizes, however, for amateurs and others who only require them for greenhouse decoration may be had from cuttings struck later, say towards the end of March; this affords ample time to grow fine little specimens in 8-in. pots, and such as these are generally the handiest for most purposes. Beautiful little plants may be had by propagating as late as May or June, and these come in capitally for window decoration indoors, or for the fronts of stages among others to fill in vacant spaces and afford more variety. In all cases the treatment and culture they require is much the same, as, unless planted out, they all do best plunged in sunny spots, well sheltered from the wind, which otherwise is sure to break them down. To prevent any risk of that kind, they should be staked and tied early, but not in such a manner as to give them a stiff, formal appearance, which spoils half their beauty.

If the main branches are firmly supported, that is all they require, and every stick used should be out of sight, as at best they are necessary evils and never any ornament, although, by the way they are frequently employed, many would appear to think otherwise. It should be borne in mind that to have the flowers of Chrysanthemums perfect, they need early protection from frost, as they are very liable to injury in the bud state; and if allowed to stand out exposed then, a whole season's care and attention may be lost in one night. If housed, they should have an abundance of air during the day, and be kept as cool as possible.

S. D.

### WINTER-FLOWERING PLANTS.

It is generally taken for granted that flowers must necessarily be scarce during the dark and sunless months of winter. This is, however, only partially the case, as when the matter is duly considered it is found that there are many species of plants in cultivation whose natural period of flowering is during the depth of winter. In enumerating a few of the more common, although most useful, species, let us begin with the Christmas Rose (*Helleborus niger*), a native of Austria, but long cultivated in this country, and perfectly hardy. After mild autumns this frequently commences to bloom in the open air early in December, and continues to do so until the end of January. During unfavourable weather, however, the pearly whiteness of its fine large flowers is apt to get more or less tarnished, and to obviate this drawback, plants of it are frequently taken up and potted during the autumn; and when placed in a greenhouse, or any other light, cool structure, they continue to bloom from the middle or third week of December until the end of the following month. The stalks of blooms produced under glass are of increased length, a circumstance which renders them better suited for the purpose of cutting; and the colour of the blooms is at the same time increased in purity. All these advantages, however, can also be secured by leaving the plants in the soil, and placing a light frame or hand-glass over them early in December. The Christmas Rose is readily increased by division, and this should, when necessary, be done early in spring. There are several other species of the genus *Helleborus* that are very ornamental and only a little less early in their time of flowering, and to all of which similar treatment is in all respects applicable. Among these may be named *H. niger grandiflorus* or *maximus*, a fine variety with large greenish-white flowers, and *H. atrorubens* with dark red blooms.

The Winter Aconite (*Eranthis hymalis*) is a lovely little yellow winter-flowering plant, belonging to the same Natural Order, viz. Crowfoots. It is a native of Italy, and is quite hardy. It commences to flower about the end of December, and continues to do so until at least the end of January. Patches of it taken up and potted about the beginning of December and placed under glass soon become exceedingly effective, as will likewise patches of the yellow-flowering *Sternbergia lutea*, sometimes called the "Lily of the Field." The well-known Snowdrop (*Galanthus nivalis*), a native of Britain; *G. plicatus*, or the Crimean Snowdrop; together with the beautiful Snowflake (*Leucojum vernum*), are all impatient of heat, and only require the aid of a glass roof to induce them to come into bloom at or soon after the commencement of the year. Potted plants, too, of some of the *Aubrietias* and *Forget-me-Nots*, hardy Primroses, &c., will follow very close upon them. The white Roman Hyacinth is also exceedingly useful as a winter-flowering plant, producing, as it does, an abundant supply of pearly-white, sweet-scented blossoms at a season when such flowers are generally much in request. The bulbs of this Hyacinth should be potted early in September, three bulbs being placed in a pot of 5 in. or 6 in. in diameter, or five bulbs in pots of larger size. After being potted, the pots may with advantage be covered with finely-sifted cinder-ashes to a depth of 6 in. or 8 in. In about three weeks they will be found to have started into growth, and should then be placed under glass, say in the front of a greenhouse, or in a light pit, where, without the application of artificial heat, they will come into bloom about the beginning of January, and, if desired, at an earlier period. A very slight amount of forcing will accomplish this desideratum.

Conspicuous among hardy or nearly hardy evergreen shrubs that flower in winter stands the *Laurustinus*, a native of Southern Europe, which, although generally considered and treated as a hardy plant, is, nevertheless, not unfrequently more or less injured during hard weather; and as the flowers are naturally produced during the depth of winter, they very often become tarnished and disfigured by the inclemency of the weather, even during seasons when the depression of temperature may not be remarkable. Consequently, in large establishments, where a supply of flowers during winter is a *sine quâ non*, it becomes expedient to have a portion of these plants in pots, and on the approach of wintery weather to give them a place in the greenhouse or the conservatory, where they will soon be found to be well worthy of this distinction. Under such conditions their flowers will generally be produced in profusion, as well as greatly improved in character, almost rivalling in purity of colour the blooms of a white *Camellia*. Plants well set with bloom buds should be selected early in October, potted and placed under glass in any convenient structure, and they will mostly be in flower by Christmas. Suitable plants may also be retained in large pots or tubs, and trained into any desired form, such as that of a pyramid or standard with clear stems. Such plants should be grown in the open air during summer, while in the winter they form very effective objects in the conservatory. *Chimonanthus fragrans* and *C. grandiflorus* are both well worthy of a place in every garden, for they are remarkably useful, sweet-scented, winter-flowering plants. The first-named was introduced from Japan about the year 1776, and the latter is probably a seminal variety from the first, both being perfectly hardy, and closely allied to the sweet-scented *Calycanthus*, or *Carolina Allspice*. To secure in perfection, however, their delightfully-fragrant flowers, which are produced long before the foliage appears, and which are of a pale yellow or straw colour—the large-flowered variety being the most showy in appearance, but possibly less fragrant than the other—it is necessary to select for them a somewhat sheltered situation if they are intended to be grown as standards. They will, however, generally succeed best when trained to a wall. At some places I have seen each of the varieties trained to walls some 12 ft. high, under a wide glass coping, facing the south, and sheltered also at each end by a glass structure; thus circumstanced, they succeed admirably, producing annually an immense amount of bloom from about the middle of December until the beginning of February, and such blooms are always in great demand, as their fragrance is considered equal to that of the *Violet*. If a few of them be merely dropped into a vase and placed in an apartment, they will continue their perfume for several days. Each variety, treated as just described, not only flowers profusely, but will also produce thoroughly ripened seed in abundance; and this, when sown in heat as soon as it is gathered, vegetates quickly, and soon forms plants suitable either for pot-culture or for planting out. These two kinds of *Chimonanthus* can also be increased by layers, but they do not strike readily from cuttings. When trained to a wall they are treated very much like trained *Pear trees*, *i.e.*, all the young shoots which have borne bloom are cut in as closely as possible, with the exception of such as may be required as leaders, which are of course nailed, or in some way

secured to the wall. This pruning is generally done about the middle of February, or when the plants have ceased to flower. And as the season advances, young shoots are developed in abundance; these produce flowers the following winter. It will thus be seen that all that is required in the way of summer management are the nailing in of leading shoots, and the rubbing off or stopping any gross or over-strong ones which are occasionally produced. *Jasminum nudiflorum*, like the *Chimonanthus*, produces its bright yellow blooms during the depth of winter in great profusion upon the young shoots while they are yet destitute of leaves; hence its appropriate specific name. It is indigenous to the north of China, and was introduced to this country by Mr. Robert Fortune about the year 1845 or 1846, and has proved to be not the least worthy of his many valuable introductions. It is perfectly hardy, but severe frost, or rather inclement weather, has not unfrequently the effect of bleaching the colour out of its clear, yellow blooms, so that the most suitable situation for this plant is a south wall, under a somewhat wide coping, in order, if possible, to keep the flowers dry, as, if this condition be secured, no amount of cold will injure them. This *Jasmine* succeeds well when grown in pots, and only requires the protection of a glass roof during the months of December and January, when it will be in full bloom. Its habit of growth, however, is somewhat too straggling for pot-culture, and it appears nowhere more at home than when allowed to ramble at will over a block or stone in some rough part of the garden. It can, however, be made to submit to any system of training, and where the flower for the purpose of cutting is an object of importance, it is advisable to subject the plants to a certain amount of training or restriction, in order that they may more easily be protected from the effects of the weather. It looks well trained horizontally to a wall facing the south, the principal shoots being kept at a distance of 6 in. from each other. These shoots during summer produce a vast number of small sprays, which should be allowed to droop or fall over the surface of the plant. During the summer care should be taken to twist off any gross or over-luxuriant shoot, and to nail in the leaders

A Contrast—Clipped Trees in Little Trianon.

where they may be required. The drooping spray will seldom fail to clothe the surface of the wall with a profusion of flowers, and that during the most wintery months of the year; but, unlike most of the family to which it belongs, it is entirely destitute of fragrance. As soon as its flowering season is over the spray should be cut in as closely as possible. This *Jasmine* is very easily increased by cuttings or otherwise, the young shoots seldom failing to emit roots into the soil whenever they chance to come in contact with it.

Among other winter-flowering shrubs, possibly less extensively grown than the above, is the sweet-smelling *Honeysuckle* (*Lonicera fragrantissima*). This is also an introduction from China by Mr. Fortune, and is worthy of more extensive culture than it appears to have yet obtained. In a favourable situation the blooms, which are of a pale straw colour, and which precede the foliage, begin to unfold during the month of January, and although somewhat small and not remarkably ornamental, are nevertheless so exceedingly fragrant, as to render them extremely useful for the purpose of cutting for bouquet making. Although the plant is of a somewhat stiff habit of growth, it nevertheless readily submits to training

upon a wall. It is also easily induced to form a bush, and in the latter form it is very suitable for pot-culture, and the delightful fragrance of its flowers fully entitles it to this consideration. It may be increased by layers or by cuttings of the young shoots, inserted in a mixture of sand and finely-sifted leaf-soil, plunging the pots containing them in a slight bottom-heat, in a close frame or cutting case. *Lonicera Standishi*, also an introduction from China, bears considerable resemblance to the above, and similar treatment may in all respects be applied to it.

Many other early-flowering, or what, during mild seasons such as we are at present experiencing, may be considered winter-flowering plants, are to be found among such genera as *Berberis*, *Daphne*, *Coronilla*, *Forsythia*, *Magnolia*, *Rhododendron*, *Andromeda*, *Kalmia*, &c. The *Mahonia Aquifolium* is now—end of January—in full flower, and *Erica mediterranea* and other hardy *Heaths* and *Menziesias* have been so for some time. Even the common *Laurel* is already putting forth its racemes

## THE FLOWER GARDEN.

### IMPORTED LILLY BULBS.

THANKING Mr. Stewart Hardy very much for his courteous reply (see p. 49) to my queries, and waiting for his further report, which I trust he may be able to give without much inconvenience, I shall now proceed with what I had in view when I took the liberty of putting my questions to him. As a heading to his catalogue of Lilies, Mr. Ware says:—"This is the grandest and most gorgeous group of bulbous plants in cultivation. There is no class of plants so stately in their habit, so profuse in flowering, possessing such lovely and delicate colours, and so much fragrance. They stand pre-eminently far before any other hardy border plants. There is hardly a situation in which more or less of them will not thrive, and yet how rarely do we see them grown." Another writer says:—"By this time no moderate-sized garden ought to be without them. But what is the fact? They have been bought by thousands upon thousands and planted, but where are they now? Except in the gardens of com-

A Contrast—Untortured Trees in Little Trianon.

of bloom-buds. I have also seen a plant of the *Coronilla glauca*, in full flower, trained to a wall—in a somewhat sheltered situation, it is true, although facing the east. But this *Coronilla* is, properly speaking, a greenhouse plant, and an exceedingly useful winter-flowering one it is,

*Culford.*

P. GRIEVE.

**A Contrast.**—The small cut on the opposite page shows the trained and clipped trees on the French garden-side of the Little Trianon; the larger illustration the untortured trees in the English garden there. Comment on either is needless.

**The Garden the Nation's Safety.**—Twelve years' experience in the occupation of a farm have satisfied me that Great Britain and Ireland might be turned into gardens, and that work might be found therein for every able-bodied man in the country. . . . Nothing but a reform of our whole social system, commencing with the land system, can save this country from ruin.

. . . Nothing can save us, as said the late noble teacher, Frederic Robertson, but a return to simpler habits and purer lives.—HARRY ATKINSON, in the "Industrial Review."

paratively a few, they are all dead and gone!" A writer in a contemporary says:—"In the autumn of 1874 I bought two dozen of the finest-imported aratum bulbs, and planted them out. In 1875 thirteen turned purple just before flowering, and then died; the remainder grew up, and bloomed very fairly. In 1876 these grew up again, but, after showing flower, all died but one. Last summer this one also died." Many similar reports could be quoted, but they would only add to the same complaint. Dr. Wallace, however, who has had considerable experience in connection with imported Lilies, contributes some extra and valuable information on the subject. Alluding to a disease among the aratum group, which has been closely observed by him during three years, he says, "The signs are as follows:—When the Lily stem is from 1 ft. to 2 ft. high, and the flower-buds are just perceptible to the touch or sight, after a hot day in June some of the lower leaves turn brown, then other leaves higher up, and so on, till all are browned; then the stem browns also, the leaves wither, and the buds drop off or dry up. If the bulb be taken up the roots are found to be unhealthy, few in number, and discoloured, the bulb sometimes unscathed, but if apparently sound, it often happens that it becomes subsequently unhealthy, and breaks up or rots. Thousands of bulbs have in this way died annually, and

not only freshly-imparted bulbs, but those that have stood two or three years undisturbed." We may well ask, "What is the cause of such wholesale falling off?" Before attempting to answer the question, let us first endeavour to ascertain what a Lily bulb really is. Drs. Hooper and Klein Grant, writers on the animal and vegetable kingdoms, both say:—"The term bulbous is, in botany, applied to roots, but improperly, for a bulb is not a root." So far as the Lily is concerned, I entirely agree that the bulb is not the root of the plant. If we lift a Lily bulb in the autumn and cut it in two, right down from the apex to the base, it will be observed that it is composed of a core or fleshy part, more or less conical in the upper portion, and truncated below. This core gives rise, at its upper face, to fleshy scales pressing one against the other, and to a central short stem formed of leaves and rudimentary flowers, whilst from its lower face spring the root-fibres. These root-fibres, if closely examined, will be seen to emanate from the base of the stem itself, and pass down through the core or fleshy part, thus preserving a distinct connection between the stem and the roots without interfering with the scales of the bulb, for these scales, if carefully picked off, will be seen to have no connection whatever with the root-fibres. The bulb itself, composed of the scales, is, in fact, nothing more or less than the cradle, or nursery, of the legitimate seed-bud, which inhibits its nourishment from the scales through the core, until it has grown and become a fully-developed bulb, capable of flowering the next year.

#### Lily Bulb Disease.

We now come to the most important part of the subject, namely, the disease alluded to by Dr. Wallace; and about the cause of which he seems to be somewhat doubtful. I may, therefore, say at once that, in my opinion, the cause of so much loss in imported Lily bulbs is a parasitic fungus constituting a kind of mould of foreign origin, of a most destructive character, and, as in the case of the infected bulbs, causing the disease to become hereditary, descending from parents to their offspring. Before, however, entering into particulars, I think it desirable to quote the opinions of some others with reference to the evils attendant on the exposure of the bulbs when lifting and transplanting them. The late manager of the Herbaceous Department at Kew says:—"When lifting and transplanting Lilies, the roots should not be allowed to lie about exposed to the weather, but kept as short a time as possible before being re-planted, as they suffer very much indeed by continued exposure, and hence the frequent failures in bought bulbs, which may have been long and badly stored. If they are not allowed to lie too long out of the ground, they may be lifted every year." Another writer, who is even more particular, says:—"Generally speaking, the months of August, September, and October constitute the season for planting Lilies, and the longer they are kept out of the ground (no matter how carefully they may be packed), the worse will be their condition when planted. When they are transplanted, the site they are to occupy should be prepared for them before they are lifted, if possible; but if they are to be planted again in the same spot, the work should be done quickly, and the bulbs be in the meanwhile covered with moist soil to protect them from the destructive influence of the atmosphere." Dr. Wallace says:—"Some of our friends would have wintered their Lilies in pots in a dry corner without moisture, had we not remonstrated; others were even drying off their Lilies for the winter, as they would Hyacinths in July. We believe this to be a common custom, but against such treatment we protest most strongly. A Lily ought never to be dry. Never let it be out of the ground longer than necessary. Never let it be dry." These writers all agree—and to what they say I most heartily subscribe—that Lily bulbs should never be kept out of the ground a moment longer than is absolutely necessary. It will be seen, however, that there are some who thoughtlessly advocate a season of rest, overlooking the fact that bulbs exposed to the atmosphere, even for a day or two, will become discoloured, and that this discolouration is undeniable evidence that disease is just beginning to perform a part that would, in no very long time, ruin the plant. Dr. Hooper has illustrated such a case by saying, "That if an arm or a leg were to become so discoloured, it would be high time to apply to a physician, plants, like animals, being organised and living beings." Those who recommend a period of rest out of the ground must certainly imagine that the bulbs they would thus treat are those which bloomed last summer; whereas the bulbs that bloomed last summer are by this time dead and already at rest. The bulbs they would thus mistakenly lift as the old bulbs are in reality the new bulbs, which should be encouraged by every possible means to go on with their growth, instead of having it certainly checked and possibly ruined. Those who advocate such ruinous experiments cannot be aware that the whole existence of a Lily bulb is comprised within two years, and may be divided into two distinct parts. From the period of its germination

until it has become a fully-developed bulb, that is, until it has become a parent bulb, is just twelve months. From this time until it has bloomed and decayed, is just twelve months more. During the first six months, its growth is very slow and gradual compared with the second six months. During the second six months its growth is no less than 5000 times greater than during the first six months. This may surprise many, but it is a carefully calculated experimental fact. During the second year its growth is more apparent than real, for it has within itself a growing young bulb that enlarges the bulk of the parent bulb. Facts like these should teach Lily growers to look to Nature as their guide, and not to tamper with her dictates; to transplant soon after the flowers have faded, when growth is slow and gradual, and not to wait until every part of the bulb is increasing with so rapidly an accelerating growth, as consequently subjects the numerous and healthy roots to a most pernicious check if moved late in the season.

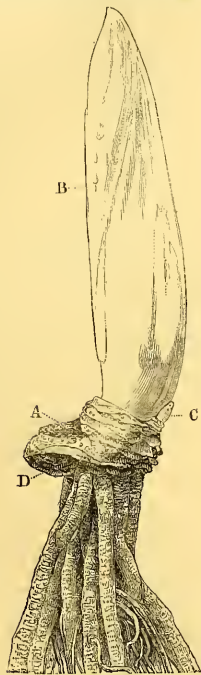

#### Lily Bulb Collectors' Instructions.

Let us now turn to the instructions that are given to the agents abroad who collect Lilies for transmission to this country. They are as follows:—"The time to collect Lilies is after the flowering season is over, when the leaves turn yellow and fall off, and the stems die down. Bulbs that are to be sent a month's journey or upwards must be taken up when ripe, as aforesaid, thoroughly dried, but not to such an extent as to become flabby. It is well, also, to expose the bulbs to the sun for a few days thoroughly to ripen and dry them; they then acquire a tinted colour, varying from yellow to purple. The roots and stems should be cut off close to the bulb, and a dry material prepared for packing. For a month's journey, sawdust, Moss, Coconut fibre, or other dry material will answer well, but for a two months' journey or upwards this mode of packing is not safe, the object being to exclude light and air, and thus prevent, so to speak, the bulb and deprive it of all vital action." When I read these instructions, my surprise was, not that so many thousands upon thousands had perished, but that a single bulb had continued to struggle for existence even for one year. That many have done so, can only be accounted for by the supposition that some collectors do not carry out these instructions in their entirety. I shall now endeavour to account for the disease in imported bulbs, to which Dr. Wallace alludes. The minute microscopic root-like filaments of the mould-like fungus that I have mentioned insinuate themselves into the epidermis of the bulb, and, acting as parasites, draw nourishment from the tissues, and ultimately poison the plants. The minute germs of this fungus are dispersed everywhere throughout the atmosphere, and are ready to alight on any substance in which they can find a nidus. The tender scarf-skin of the Lily bulb, freshly lifted out of the soil, is particularly favourable to their growth. In one day thousands upon thousands of Lily bulbs, in fact, any number that can be mentioned, if exposed to the sun, will be covered with myriads of this minute fungus; so that, from a fresh clean colour, the bulbs will be changed to a dirty yellow, a purple, and then to a dirty brown; and, as the parasites increase in number and destructiveness, they penetrate into the interior of the bulb, as may be seen by the sapless, gaping scales of those imported, more like withered Pine-cones than living, healthy bulbs. And yet the collectors, or many of them, are actually directed to subject the bulbs, before they are packed, to all this ruinous treatment.

#### How Lily Bulbs become Affected by Disease.

In order to illustrate the peculiar aptitude in the organisation of Lily bulbs for transmitting disease to the second, third, or even to the fourth generations, I have sent a photograph (from a drawing) of one of six skeletons, the bulbs for which purpose I had lifted on the 1st of January, and dissected in the presence of a Lily grower; so that there cannot be a doubt of its being a genuine representation of the underground interior parts of a Lily, exhibiting plainly the phenomenon, or mystery, of "three generations in one," to which I have formerly alluded. By looking at the annexed woodcut, it will be seen that the seat of the stem that bloomed last summer is on the left, at A. The mark underneath this part, at D, will show where the roots of last summer have been, but now both stem and roots are entirely gone. In the middle, at B, is the new flower-stem that was destined to bloom next summer; and on the right, at C, is the young seed-bud that was destined to grow up and flower the following year, that is, in 1879. The healthy, strong, and numerous roots which spring from the new bulb, and are here truly represented as those of the 1st of January, ought to convince anyone that it would be ruinous to their growth and harmful to the plant itself if disturbed and checked late in the season by lifting and transplanting them. As regards the disease, it is acknowledged by botanists that "seed from diseased plants will produce a diseased offspring," that "fungi new to this country have been introduced by

means of the parent plant," and that "fungi are capable, when once established, of spreading to other plants which are perfectly sound." All this is admitted, and to this may be added the more than ordinary aptitude of the offspring of the Lily to be infected, and the fact that it has been infected, even to the second, third, and fourth generations, at any one of which periods the plants may be seen to decline and die off entirely without any apparent cause. By looking at the woodcut, it will easily be seen that if the parent bulb had been infected, it would have been next to a miracle if the new stem and the young seed-bud could have escaped, so closely do they stand in connection with one another; springing, too, as they do, from the same core or fleshy part. We cannot help observing, in the columns of THE GARDEN, the unanimity that appears to exist among Rose growers in reference to their knowledge of all that pertains to the plant they patronise. On the other hand, opinions differ so widely among Lily growers, that we seldom meet with two who agree to take their stand entirely on the same ground. There are certainly exceptions here and there; but among the many hundreds who call

Lily Bulb from a Photograph.—A, the leaf of the stem that bloomed last summer; B, the new flower stem; C, the young seed-bud; D, the mark where old roots have been. Want of space prevented the roots being shown in their length and abundance, as in the photograph.

themselves Lily growers there are comparatively few who have any correct knowledge of the underground action of the plants they profess to cultivate. How is this? In April last, on the occasion of my sending in a specimen seed-bud, the readers of THE GARDEN were told by a correspondent that "it could be seen at a glance that it was nothing more than one of the axillary buds which exist at the base of each scale in nearly all Lily bulbs." Had the writer supported this statement with any evidence, even the slightest, that he had ever seen an axillary bud in the inside of a Lily bulb, he would have added some weight to what he then said. I knew that he was wrong, that it was a groundless assertion, likely to do harm, coming, as it did, from one who professed to know all about it. I felt that it was a duty incumbent on me, and I now embrace the opportunity to state distinctly that the seed-bud has no connection whatever with any scale, as it rises alone and independently from the core or fleshy part of the bulb. This is easily proved; first, by picking off the scales from the outside of it, as in the woodcut, and then by

breaking off the young flower-stem at its base. By this means the seed-bud will be seen to stand alone, adhering to the fleshy core. I admit that if the scales were picked off separately, and properly cultivated, some of them may be made to germinate, to grow, and, in course of time, to bloom; but I venture to deny that any man has ever seen such a thing as an axillary bud in the inside of a healthy-growing Lily bulb. As regards the legitimate seed-bud, it is altogether different. The man who has made himself acquainted with the underground action can point to the very spot, before the bulb is dissected, where the seed-bud can be found. And I may now add, for the information of inquiring readers, that it will always be found opposite to the old flower-stem, the young flower-stem standing between them, as in the annexed illustration.

[This paper was closed before I had an opportunity of seeing the remarks of Mr. Groom, "T. D.," and "H.," so that they must stand over for my next paper. With respect to Mr. George F. Wilson, my best thanks are due to him for the very kind invitation he has been pleased to convey to me. I have never seen him, that I know of, but fame has told me a great deal about his doings in the Lily world.]

### CLEMATIS PITCHERI.

This species, which has been recently introduced from North-Western America, has not only the attraction of novelty, but it is also a very ornamental plant, which is sure to be much sought after on account of the brilliant hue of its flowers. These form a somewhat rare exception to the rule which governs the colour of the flowers of the genus Clematis, which pass generally from white to dark violet, but rarely approach even a pink hue. It is, however, especially distinguished by the beautiful deep vermilion hue of its flowers, as well as by its thickish, rounded, drooping leaflets, of a pale bluish, sea-green tint. The petals of the flowers, of which there are four, are very thick and fleshy, and are carried on a long, coloured stalk. The flowers themselves are wide at the base, but narrow suddenly near the top, where the petals bend backwards to form the opening of the flower. Being a native of North-Western America, the Clematis Pitcheri, being hardy, will be a valuable addition to the ornamental plants of our gardens. It is also probable that it will thrive in pots, which would lead one to suppose that its growth is rather weak than strong. With regard to this possible defect, we ought to state that the plants grown from seed are not all that can be desired, being somewhat weedy. It is, however, most probable that this defect will disappear under cultivation, and that, grafted on a vigorous subject, its own vigour would be increased. It commences to bloom about the end of spring, and lasts in flower for a long time. Besides being valuable for the beauty of its flowers, this Clematis will be of great service for producing new varieties; in fact, we cannot help thinking that its true worth will be found in this direction. This part of the subject is deserving of the earnest attention of all growers. It cannot be doubted that, by means of judicious artificial fecundation, we shall succeed in growing varieties with large flowers, and capable of being almost continually in bloom, or something near it; or, in other words, to transmit to the varieties we now possess the brilliant colouring of the petals of Clematis Pitcheri. In any case, we repeat that it is already a plant of great merit, which ought to be in the possession of all those who like beauty coupled with originality. The Clematis Pitcheri may be procured at the nurseries of Persan-Beaumont (Oise).—E. A. CARRIERE, in "Revue Horticole."

*Centaurea rutafolia*.—This interesting plant appears to have been discovered by a Russian botanist, in the neighbourhood of the Balkans. It is a hardy perennial, growing to the height of 2 ft., with branching stems amply clothed with deeply pinnatifid foliage, the entire plant being covered with a dense white tomentum, as in *C. ragusina*. It is, however, of freer growth than that popular species, increasing in size throughout the summer till checked by the cold of autumn. The flower-heads are pure white, about one-half the size of those of *C. ragusina*, but much more abundant. The plant derives its ornamental value from the persistent whiteness of its foliage, which suffers less from rain than that of the species previously named. It succeeds in any soil, but its growth is more compact in rather dry soils, or on rock-work, where it will probably be quite at home. It is a sterling addition to the class of white-foliage plants.—W. THOMPSON, Ipswich.

*Saxifraga Burseriana*.—This is now flowering beautifully, and is, without doubt, one of the most charming of Saxifrages. Like many other plants, it varies considerably both in size and in the number of flowers which it produces, some of the blossoms being at least double the size of others. In some cases they are produced

very sparingly, while in others one can scarcely put a pin's point between the blossoms. None of these differences can be attributed to cultivation, for the same occurs in a wild state. It is not a plant at all difficult to grow in warm, dry spots on the rocky; with plenty of grit and stones mixed with the loam, and a good-sized stone or two resting on the surface to keep the soil cool, it is less liable to suffer from drought than when planted on a plain surface.—A. F.

**Dividing Anemone fulgens.**—In reply to Mr. Smith, of Newry (see p. 113), in reference to this matter, permit me to say that I allow my roots to remain in the ground all through the summer, and lift and divide them when the earlier leaves are well through the ground. This is comparatively easy work, and is productive of no harm whatever to the plants; it also facilitates the finding of the roots, as not one is either damaged or overlooked. My plants, so treated, are now throwing up flowers, but the season is cold and unseasonable, and for this reason the flowers are quite a month later than last year. Mr. Smith lifts his ripened roots in the summer, and divides before planting. I do not see any reason for lifting them or keeping them out of the ground, but it is quite a matter of opinion; as, however he lifts his roots in the summer, of course his mode of propagation under the circumstances is correct.—A. D.

**Fancy Pansies.**—It is impossible to withhold one's meed of praise for the beautiful plate of fancy Pansies issued last week in THE GARDEN. In all respect they are exact reproductions of these richly coloured flowers as they grow in the open ground, and anyone who may be able to secure seed of a good fancy strain will be in possession of just such flowers as those represented. There is not a rigid florist's flower amongst them; the true florist's Pansy, if shown as such, is generally the produce of pot culture or frame growth; further, when exhibited on the painted stands they are usually flattened out either by means of gum or pressure, and thus the peculiar irregular formation of the flower is often lost. My experience of these Pansies so far has been that the flowers of the finest qualities are generally produced on plants that have constitutions not too robust, whilst others equally rich in colouring, but not quite so large or round, are produced plentifully on strong growing plants. In the remarks which accompany the plate it is recommended to winter the plants in frames, but that is doubtless written from a northern point of view. Here in the south the Pansy will stand our worst winters, and thrive far better through the summer, and bloom much earlier if planted out in the autumn. Seed might be sown at any time under glass as soon as obtained, but to secure extra strong plants to stand the winter and flower early I prefer sowing in pans under glass early in July. Seedlings thus raised should be pricked out into a frame or into boxes until well rooted, and then they can be planted out in a strong condition, and with good hills of roots either into beds or borders, as may be desired. The timely publication of this beautiful plate ought to attract special attention again to this once highly esteemed border flower.—A. D.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Hamamelis Zuccheriniana.**—This is now in full flower here, and is a desirable species to cultivate as a companion to *H. arborea*. The flowers, which are pure yellow, are destitute of the bright red-brown sepals seen in the *arborea*, and I think that the plant now under notice is a little more robust in habit than the last named kind. We have had very sharp frosts here for the last few days, which have failed to injure the flowers of either.—T. Sarrin, Newry.

**Spring Flowers.**—Notwithstanding the mild weather which we have had, spring flowers are scarce; many are opening, but not with freedom—similar, in fact, to what they would do after a severe winter followed by mild weather. Saxifraga Barseana, Narcissus Otusii, Sisyrinchium grandiflorum, various kinds of Christmas Roses, Galanthus plicatus, Crocus Sieberi, Anemone Pulsatilla, Anemone Robinsoniana, and Cyclamen Atkinsi, embrace the best of them. Of course Primroses, Hepaticas, and many others are out, but these are well-known spring favourites.—Amos Psaar, Tottenham.

**Clematis Otto Fröbel.**—One of the finest of the pale-coloured hardy varieties of Clematis is Otto Fröbel, which last season bloomed splendidly with Mr. G. Jackman, in his nursery at Woking. The plant appears to be remarkable for vigor, and the flowers are of immense size and perfect in form, the sepals being sufficiently broad to be well imbricated. The colour is a French white, and therefore somewhat wanting in purity, but the fine qualities of the flower in other respects amply stone for this deficiency, and no one who plants it could possibly be disappointed if the plant thrives. It is by no means a novelty, being a Continental variety sent out some years since.—"Florist."

THE Schedules for the National Anticilia Show, Southern Section, are now ready, and may be obtained of Mr. E. S. Dodwell, Chatham Terrace, Clapham, S.W.

## PLATE CXV.

### THE LARGE WHITE JAPAN QUINCE.

ONE of the many merits of the Japan Quince is its variability. A shrub most precious in its ordinary form, it becomes doubly valuable from its enabling us to make it produce good effects from new forms with certainty, the character of the shrub being so well proved. Among the various forms seen in our gardens a large white one is the most promising. This was raised in France, and from the "Revue Horticole" our figure is taken. Messrs. Veitch also have a stock of a new and handsome white kind. Where a shrub is of such thoroughly proved merit as this, the gain of new varieties distinct in colour is more than usually valuable. It frequently happens that varieties of fine hardy shrubs are much more abundant on the Continent than with us—the Weigelas, the Lilacs, and this also, for example. M. Charles Baltet, of Troyes, sends us the following list of the kinds he knows to be in cultivation in France, marking the most important thus\*. We can fancy nothing more promising than these for forming groups wherever bright flowers are desired in the open air in spring, the Cydonia being without doubt the most valuable of all early spring-flowering shrubs:—

C. alba	gandavensis	*princeps
* „ semiplena	*Ganjardi	*rosea plena
* „ grandiflora plena	inermis	rosea semiplena
*atrosanguinea plena	*Mallardi	*rubra aurantiaca
*aurora	macrocarpa	* „ grandiflora
*cardinalis	*Moerloosi	*sulphurea perfecta
carnea	*nivea coccinea	*sanguinea multiflora
coccinea	Papeleui	plena
chrysea	*Princesse	*umbilicata
*eximia	Soutzo	versicolor plena

**The Chicago Botanic Garden.**—We learn from the "Bulletin of the Torrey Club" that this promising enterprise has come to an untimely end. The managers solicited contributions from the principal gardens of the world, promising to make suitable returns as early as possible. The total number of packets of seeds and living plants received up to July 1, 1877, was nearly 15,000; the number of similar packets returned about 5000; the number of species under cultivation in the garden over 6000. Nevertheless, the board of commissioners voted in July, on account of the expense, to terminate the operations of the garden, and place all its plants, seeds, &c., under the charge of the general superintendent of the park. The managers, supported by many citizens, sought in vain to have the matter reconsidered. They are, therefore, rendered powerless to fulfil the promises made with the sanction of the commission.

**Rotten Row.**—I have been at some trouble to learn authoritatively something about Rotten Row. Last year a portion of it was renovated, under a contract, with one of the principal firms of road-makers. This year the other portion has been renovated. The system has been to make a hard, impermeable bottom, with a slight curve, so that the water drains off to each side. On this, a thick layer of sand is laid. In the sand laid last year a vein of clay existed, but pure sand is now used. From all that I can make out, it is impossible that Rotten Row can ever be in a better condition than it is now. If the bottom were not impermeable, the rains composing it would churn up under the feet of the horses. If the sand were not so thickly laid, the Row would not be so soft enough, whilst, after heavy rain, with an impermeable bottom, and a thick layer of sand over it, there must be mud. A Rotten Row, in fact, fit to ride in when the weather is dry, involves a Rotten Row, unfit to ride in when the weather is wet. Official ingenuity has failed to get over this difficulty. If you, my friend Edmund, can solve the problem, let us have your solution by all means. Otherwise, I am greatly afraid that, when you ride in Rotten Row on wet days, you are likely to find it somewhat muddy.—"Truth."

**The Willow-pattern Plate.**—A contemporary gives this description of the Willow-pattern plate. To the right is a mandarin's country seat; in the foreground is the pavilion; in the background an Orange tree; and to the right a Peach tree in full bearing. The estate is enclosed by a fence. At one end of the bridge is the famous Willow tree, and at the other a gardener's cottage. At the top of the plate, left-hand side, is an island with a cottage on it. The birds are doves. The three figures are the mandarin's daughter, with a distaff in her hand, the lover, and the mandarin. The story is as follows:—The mandarin had an only daughter, Li-Chi, who fell in love with Chang, her father's secretary, and he lived in the island cottage at the top of the plate. The mandarin forbade the match, and the lovers eloped, and lay concealed for a time in the gardener's cottage, and from there made their escape to the island home of the lover. The father pursued them with a whip, and would have beaten them to death had not the gods changed them into turtle-doves. It is called the Willow pattern because at the time of the elopement the Willow began to shed its leaves.

THE LARGE WHITE JAPAN QUINCE. *CYDONIA JAPONICA* (PERS.) VAR. *ALBA GRANDIFLORA*.

GARDEN BOTANY.

(Continued from page 129.)

The Spore and Seed.

INTRODUCTORY REMARKS.—The unusual course of describing the seed first is adopted, because the seed seems to be the beginning or phase of plant life most likely to interest those engaged in practical cultivation of plants, inasmuch as the rearing of plants from seeds is one of the most important operations coming within the gardener's wide field of labours. Furthermore, this particular branch of botany is rather superficially treated in most text books, and it will, therefore, receive more attention from us. Spores and seeds are of the same nature, in so far as both contain a germ or the vital principle of a future plant, which lies dormant until exposed to certain external conditions that cause it to start into active life; or it loses its vitality or power of germinating by being subjected to other unfavourable influences.

THE SPORE.—For the sake of brevity, the spore (of Ferns) will be treated of under the same head. It has already been stated that the spore or reproductive body of a Fern, &c., differs materially in its nature from the seed of a flowering

small Liver-wort. On the under surface of the prothallium a number of filiform, one-celled rootlets, or root-hairs, appear, and interspersed amongst them one or two kinds of microscopic organs are produced. These organs contain the male and female elements, the conjunction or fusion of which results in the fertilization of an embryo, which, under favourable conditions, develops into a young Fern (figs. 17 and 18), like

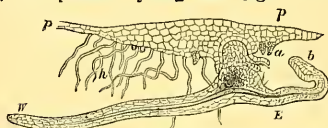

Fig. 17.—*Adiantum Capillus-Veneris*. A vertical longitudinal section through the prothallium *p*, and the young Fern *E*; *r*, root-hairs; *a*, archegonia of the prothallium; *b*, beginning of the first frond; *w*, of the first root of the young plant. (Enlarged about ten times. After Sachs.)

the plant that bore the spore from which the prothallium was produced. Until the act of impregnation is consummated, there is no development beyond the prothallium stage. As it sometimes happens that a prothallium bears only the organs of one sex, and that the male, its existence ends as a prothal-

Fig. 16.—Various Fern spores, very highly magnified to show the ornamental surface. *A*, *Gymnogramma calamelancas* in different positions; *B*, *Allorsora*; *C*, *Aspidium*.

plant, though its ultimate result is the same. A spore being lower in the scale of organisation than a seed, and the history of its structure and development being essentially the history of the Fern itself, it may be considered first. A spore differs from a seed in the simplicity of its structure, and in the circumstance that it does not directly give birth, or grow into a plant like that which bore it, but, in the course of its development, passes through two distinct phases. These phases are not exactly analogous to the transformations insects undergo, though it is not easy to find a better comparison. Ferns, it has already been stated in the general consideration of a plant, do not bear flowers; but on some of the fronds, usually on the under surface, there are clusters (sori) of capsules containing a snuff-like powder. The anatomical development of this a powder cannot be described here beyond stating that it is by process of cell division and separation that the individual grains or spores originate. They are one-celled, extremely minute bodies, consisting of a nucleus, or vital germ, and a wall, which is differentiated into two distinct layers, an inner (endospore) and an outer (exospore), the outer surface of the latter often being embellished with most delicate and elegant markings or appendages (fig. 16).

GERMINATION OF SPORES.—In germinating, the spores develop into a flat, cellular plate (prothallium, fig. 17), resembling

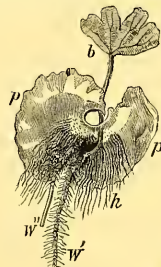

Fig. 18.—The same in a more advanced stage; the prothallium seen from below with the young Fern attached to it; *b*, its first frond; *w*, *w'*, its first and second roots. (After Sachs.)

lium; or should it produce the female only, and there be no male near at hand to effect fertilization, the result is the same. The development of these two kinds of organs, and the process of fertilization, can only be seen by the aid of a good microscope, and that in the hands of an expert manipulator; there-

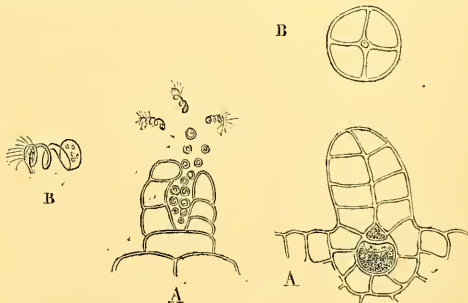

Fig. 19.—Antheridium of a Fern. *A*, Antheridium open, allowing the antherozoid to escape. *B*, Antherozoid dragging its vesicle on the last coil of its spire. (Magnified 300 diameters.)

Fig. 20.—Archegonium of Fern. *A*, archegonium, showing the oosphere and canal-cell. *B*, section of the neck.

fore, a brief description will not be out of place. Figs. 19 and 20 represent the male (antheridia) and female (archegonia) organs respectively. They both arise from the superficial cells of the prothallium, and are of very simple structure.

SEXUAL REPRODUCTION OF FERNS.—An antheridium (fig. 19)

is a cellular outgrowth consisting usually of a single layer of cells enclosing a central cell in which a number of exceedingly minute bodies are generated. When the antheridium opens these bodies escape as tiny one-celled spheres, which at once burst, releasing the antherozoids. The antherozoids are spirally coiled and furnished with a tuft of motile hairs (cilia) at the thinnest end; and attached to the other end there is usually a small vesicle. The latter is supposed to have nothing to do with fecundation, and soon falls off. Thus freed, the antherozoid swims about in the water, turning upon its axis, and violently agitating its cilia until it finds the entrance to an archegonium, or loses its power of motion. The structure of an archegonium (fig. 20) is not unlike that of an antheridium. It is a cellular nipple-like projection of four rows of cells, with a basal portion in which a central cell appears. The contents of this cell soon divides into two portions, the lower eventually forming the cavity (oosphere) in which the germ or embryo-sac appears. The upper portion grows out between the four rows of cells, thus forcing them apart, and forming a mucilaginous canal; a part of its substance escaping at the apex of the nipple and remaining collected around the aperture it has effected in making its exit. The antherozoids coming in contact with this mucilage are detained. A number of them force themselves into the neck or nipple, and some of them reach the oosphere, where they disappear in and fecundate its contents, which now gets the name of oospore. This fertilized body develops into a Fern; an early stage of this phase is shown in fig. 17, and fig. 18 represents the same in a more advanced condition. This Fern in its turn produces spores, completing the cycle of changes which the plant undergoes. It will be seen that Ferns present two distinct generations in the course of their development, namely, a sexual (the prothallium state) and an asexual, or the perfect Fern to which the fertilized oospore gives birth. This kind of reproduction, in which the generations which succeed each other and proceed from each other are unlike, is called alternation of generations. Some of the fungi and algae are produced in three or four dissimilar generations; and these different generations were formerly supposed to be distinct plants belonging to different genera. Thus the yellow fungus often found in the leaves of the Barberry in the spring, and the rust of Wheat, are now known to be different generations in the cycle of development of the same organism.

**THE SEED.**—The structure and properties of a true seed are very different from those of a spore, and, being in all cases much larger, and, in many instances, very large, there is little difficulty in following their external development. The anatomical development of seeds will not be touched upon here, and their origin will be considered in another section. The composition and external forms of seeds, their various modes of germination, and other noteworthy features, will form the subject of these paragraphs. Taking the mature seed fit for sowing for examination, and subsequently watching its development into a plant, we shall then be in a position to follow the development of each successive organ plants produce, and their various modifications in different plants.

**GENERAL DESCRIPTION.**—A seed of a plant is the counterpart of an egg of an animal, inasmuch as it usually leaves the parent in an inactive though living state. Its vitality is latent or dormant, and this vitality is retained for a longer or shorter period, according to the external conditions to which the seed is exposed, and according to the nature of the seed itself, for different seeds vary very much in this respect. A special paragraph on this part of the subject follows. A seed differs from a Fern spore, in the first place, in always giving direct birth to a plant in the likeness of its parent, providing, of course, that cross-fertilization with another plant has not taken place; but, even in this case, the progeny is essentially the same, there being no alternation of sexual and asexual generations in flowering plants. Something similar, however, occurs in flowering plants, many of which present a barren and a fertile state. The Ivy, for instance, when trailing on the ground, never (?) produces flowers, and rarely when climbing until it reaches the summit of the object on which it is climbing, or meets with some other obstacle to its further progress. With some important exceptions, seeds are enclosed in a

covering in addition to their proper coats. The general term fruit is applied to this case and its contents, whether it hold one or more seeds.

**DISTINCTION BETWEEN SEED AND FRUIT.**—Many one-seeded fruits especially bear a strong likeness to a seed, and in popular language are designated as such. A little practice and a knowledge of the general plan of the production of seeds will enable anyone to distinguish between fruit and seed, no matter how strong the resemblance may be. Little will be said on this point here, because it would involve much explanation, or assume an amount of previous knowledge that the reader might not possess. Under other sections, especially that treating of the fruit and its modifications, more precise

Fig. 21.—Fruit of Salsify crowned with a feathery calyx-limb (pappus), resembling seed of Epilobium (Fig. 22).

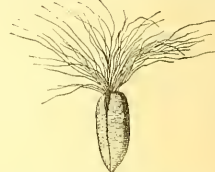

Fig. 22.—Seed of Epilobium, crowned with a tuft of hairs. (Magnified.)

definitions will be found. Here some general indications may be useful. For example, the one-seeded fruits of most of the plants of the large family to which the Dandelion and Lettuce belong are commonly called seeds. This has arisen from the fact that the seed, as it approaches maturity, adheres closely to the fruit covering (pericarp), and thus it is the fruit we sow. Often, too, the resemblance to the seeds of other families is very striking (see figs. 21 and 22). The so-called seeds of the Parsley, Celery, Parsnip, &c., are simply parts of fruit, each containing a solitary seed more or less confluent with the pericarp. In a young state the seeds are easily separated from the fruit, as may be seen in the section of a flower of Parsnip (fig. 23). A fruit of the Sweet Chestnut, again, is so much like a seed of the Horse Chestnut, as to deceive almost anybody seeing them only in the state in which they are committed to the ground, and knowing nothing of their development on the tree. The Acorn, or fruit of the Oak, is another instance in which a novice may easily be mistaken. The nature of the Acorn may be proved by making a transverse section of a quite young example, when it will be found to contain three

Fig. 23.—Vertical section of a flower of Parsnip, showing the young seeds (ovules) free from the pericarp.

cavities, with the rudiments of two seeds in each cavity. Only one of these comes to maturity, as a rule, and that fills the whole interior of the fruit. Further particulars on this subject are given under the heads *Involucres* and *Fruit*. The winged seeds of Pine and Fir trees are not unlike the half of a fruit of Maple or Sycamore (figs. 24 and 25). It should be mentioned that the seeds of the Pine family are exceptional in being destitute of a pericarp. They are borne on the upper side of the scales of the cones, as may be seen on breaking a young cone across, and examining it with a magnifying glass. With the exception of the Coniferæ (Pine family) and two other small families, the seeds are protected by a covering or pericarp, in which there may be one or more compartments, and one or more seeds; sometimes an exceedingly large

number (see figs. 26 and 27). A seed may be sessile or borne on a stalk (funicle), which in the Ash is very long.

**PARTS OF A SEED.**—A perfect seed consists of two parts, an

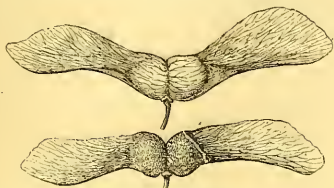

Fig. 24.—Fruit of Maple.

integument or shell and a nucleus, and varies in size from 5 in. or 6 in. in diameter, as the Cocoa-nut, to the almost invisible

Fig. 25.—Winged seed of a Pine, resembling one half of the fruit of a Maple.

Fig. 26.—Flower of Rhubarb, the pericarp removed to show the single seed. (Enlarged.)

seed of Musk. The integument usually consists of two layers, which are not always easily separable or distinguishable; and it is

only the outer coat (testa) that is of importance in descriptive botany. The substance, surface, colour, appendages, &c., of

Fig. 29.—Embryo of Almond as it is found in the seed. c, cotyledons; r, radicle.

Fig. 30.—Embryo of Almond from which one cotyledon has been removed to show the plumule.

the testa present a great variety of characters useful in distinguishing the seeds of different plants. The inner membranous coat is the tegmen, which is rarely mentioned. Coming

to the nucleus itself, this will be found to present two principal modifications. It may consist wholly of a plant-germ (embryo), or the embryo may occupy only a part of the interior of the seed, the other part being filled with a substance, varying in its nature in different plants, but always called albumen. Seeds are, therefore, albuminous or ex-albuminous. The embryo also, independently of size, exhibits two distinct types, often, however, indistinguishable until germination takes place.

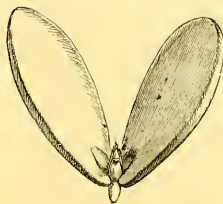

Fig. 31.—Embryo of Almond, with the cotyledons spread open to show the plumule.

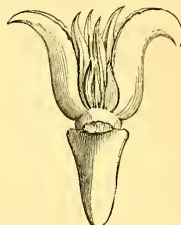

Fig. 32.—Embryo of Almond from which the cotyledons have been removed. (Enlarged.)

It consists of a short stem bearing two lobes or seed leaves (cotyledons), usually face to face, and enclosing a little bud

Fig. 33.—Seed of Kidney Bean.

site cotyledons, there may be only one, but this usually has a broad base encircling the stem, and often enclosing the plumule like an extinguisher. The number of cotyledons is one of the important characters by which flowering plants are divided into two great classes, monocotyledons and dicotyledons, according as their embryos have one or two seed leaves. The Almond (figs. 28 to 32) and the Kidney Bean (figs. 33 to 35) are examples of dicotyledons having exalbuminous seeds and large embryos, the parts of which are easily distinguished. The indigenous *Euonymus europæus* has a relatively large

dicotyledonous embryo in the centre of albumen (fig. 36), and the Meadow Rue has a minute embryo embedded in the copious albumen at one end of the seed (fig. 37). The cuts illustrating germination show many other modifications of the embryo, &c. The Cocoa-nut is an example of an albuminous monocotyledonous seed. As in some other Palms, there is a central cavity in the seed containing a quantity of milky fluid. The

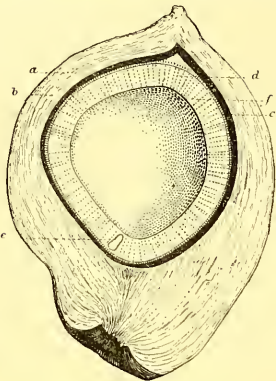

Fig. 38.—Vertical section of a fruit of the Cocoa-nut Palm, showing the solitary seed with a large central cavity, and a minute embryo at the base; a, b, pericarp; c, testa; d, albumen; e, embryo; f, milk cavity. (Reduced.)

embryo is very small, and seated opposite one of the three round holes at the base of the fruit. Exalbuminous seeds in the monocotyledonous class are somewhat rare and usually so small, that it is not easy to separate them into their constituent parts. The seeds of all Orchids are, however, destitute of

Fig. 39.—Seed of *Euonymus europæus* partially covered with an arillode.

albumen, and some particulars of their structure will be found under germination. We will next proceed to the examination of some of the modifications of the different parts of seeds.

W. B. HEMSLEY.

**Lime Juice Biscuits.**—An important contribution to the art of food-preserving has recently been made by Dr. Campbell Morfit, who in the first instance applied his invention to Lime-fruit juice. Dr. Morfit's preservation is gelatine. The manufacture of biscuits under Dr. Morfit's patent has been undertaken by Messrs. Carr & Co., of Carlisle, and they will presently appear in the shops as a regular article of commerce. What has been found practicable with Lime-juice is obviously equally practicable with the juices of other fruits, such as Lemons, Currants, and Plums; and soon we may have a series of biscuits in which fruit juices are conserved in their natural delicacy.—“Sanitary Inspector.”

**The London Cemeteries.**—The principal Metropolitan Cemetery Companies have recently entered upon a dispute with the monumental masons, in which the public are very largely interested. A few months ago they gave notice by circular, that in future a scale of fees should be charged on all work executed by the masons in the various cemeteries belonging to the various companies. The fees were to range from 5 to 20 per cent. on ordinary monument work, whilst on that of a superior class the mason was either to name the price he received for his order, or submit to have its value estimated by the superintendent, the fees to be assessed accordingly. I note also that the London Cemetery Company is seeking to impose a fee of 2s. 6d. in all cases where a gardener is sent to the Highgate Cemetery to attend to the flowers on the graves. This grasping policy is unwise, because it is certain to turn out unsuccessful.—“Truth.”

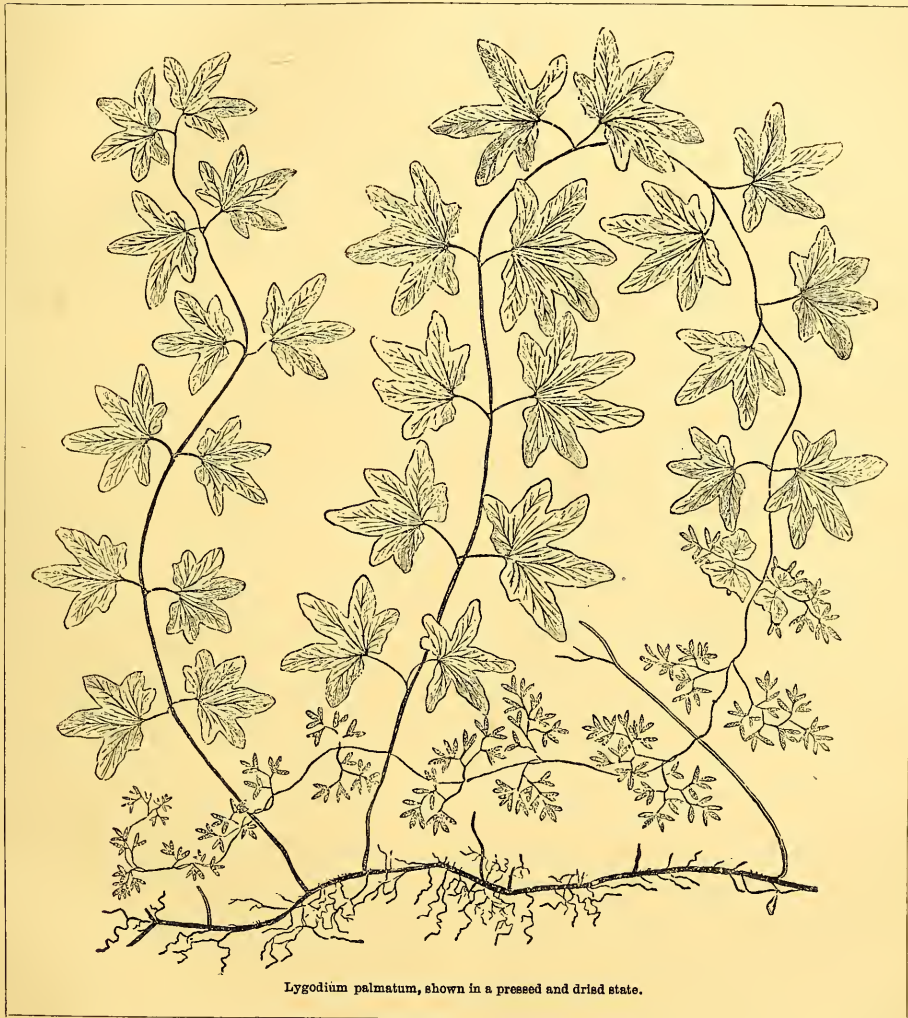

### LYGODIUM PALMATUM IN A DRIED STATE.

WHENEVER pressed Ferns are used for decorative purposes, the *Lygodium palmatum*, more commonly known as the climbing, or New England Fern, takes precedence, commanding a high price, with a constant demand. To the name “climbing” we protest; we have carefully examined the manner of growth, and find it to be rather a creeper, if not upon the ground, from shrub to shrub, weaving them together over yards of space. The genus *Lygodium*, however, includes many climbers, but all are of semi-tropical growth and habit. *L. flexuosum*, *L. scandens*, and *L. polystichum* come from the East Indies, *L. japonicum* from Japan, and *L. monophyllum* from the Philippine Islands. These are rarely sold pressed, as they are easily grown in pots, and, as living specimens, are scarcely to be equalled for beauty. The annexed illustration of *L. palmatum* is that of a pressed specimen, selected to show in full every stage of growth, and the irregularities that characterize the species. It is rare, indeed, as our search for this specimen proved to us, to find in a single plant an illustration that shall show the whole. At the base we have the wiry root, turning neither to the right nor left, but continuing one steady, straight course. It is this peculiar growth of root, we think, that prevents success when the attempt is made to grow the Fern in pots. The root meeting the side of the pot, unable to turn either to the right or to the left, at first languishes and then dies; other reasons, however, may be adduced, such as the plant being taken when partially matured, the disturbance and cutting of the root, the attempt to make climb that which was designed to creep, as the *L. scandens* does not thrive when permitted to droop or lie upon a flat surface. Since last summer we have cherished a *L. palmatum* in a 4-in. pot among house plants. Through the autumn and winter it existed, neither losing nor gaining. In February a new frond started, having two pinnae; a month later a second frond appeared, having seven pinnae; and then a third made its appearance, 1-in. from the side of the pot. Near the base are new fronds starting from the root, the involucre being so slight as to be scarcely distinguishable by the unassisted eye. There is also rachis from which the pinnae have been broken, and a barren frond, bearing but one perfect pinna; while some are in perfection. In examining the perfect frond it will be noticed that the pinnae are irregularly lobed. Six-lobed being the greatest number in natural growth, we conclude that to be of the perfect specimen. In our house-grown plant, however, though the original pinnae were five-lobed, the new pinnae number seven lobes, while they are larger and more regular in outline than any we have found growing under natural conditions. Not only do the lobes differ in number and size, but in shape; the colour and texture alone being uniform. The fertile pinnae are narrow, finger-like spikes (under a magnifying glass resembling bits of braid-work), composed of little pockets, each containing a seed vessel. Rich, heavy, and a beautiful brown, they contrast finely with the broad, green, barren pinnae, and form one of the chief beauties of this Fern. Professor Gray locates the Fern from Massachusetts, through Virginia and Kentucky, and sparingly southward. We have heard of it in Florida, Maine, near Philadelphia, and other parts of Pennsylvania. Connecticut may, however, be considered the richest field. American wit, that Midas-like, must turn what it touches into gold, took this in hand. Forthwith people became *Lygodium*-seekers, and the Fern's very existence was threatened. Like a horde of Vandals, they poured upon every locality where trace of it could be found, and by their injudicious and wasteful spilling, would soon have compassed its extermination, had not a few “selfish owners” called the aid of the Legislature for its protection.

American enterprise has made of the pressing of this single Fern a business, employing many hundreds of hands, commanding a sale of many thousands of dollars' worth annually, and with a market extending from California east to St. Petersburg. Mr. E. W. Clark, of Springfield, Mass., one of the largest dealers, writes to us:—“This Fern, found over all of the New England States, is most abundant in cold and moist localities in the Connecticut River Valley. In gathering, care must be taken in removing it from the shrubs and other Ferns to which it clings. The time of gathering begins about the middle of August, and continues until the last of Novem-

ber. They are tied in bunches, thirty strings in a bunch. Fruited specimens are always preferred, and bring the highest price. In pressing, the Ferns are put between the leaves of large books, where they remain for about two days. They are then transferred to sheets of paper, to be changed again and again until all the moisture is absorbed. During the season we

Their cultivation, if specimens indigenous to the climate be secured, is the simplest imaginable; and the interest, once excited, is unquenchable. In-doors, no costly Fernery is necessary, unless the more delicate kinds are sought, and even then extemporised arrangements may be successful. The delicate filmy Fern we have grown under an inverted tumbler.

*Lygodium palmatum*, shown in a pressed and dried state.

employ several hundred hands at this work. Several attempts have been made to cultivate and grow the *Lygodium* in pots, but so far all have proved unsuccessful."

We would recommend Fern culture to the notice of our readers. There are few places that have a damp corner, or secluded shady spot, in which Ferns will not thrive. Some are hardy, others delicate. Their beauty is beyond question.

The *Trichomanes* have thriven upon a bit of limestone inserted in a flower-pot, the earth filling the pot being kept constantly moist, with none reaching the plant. The character of the situations in which the specimens are found is only needed to be observed, and as far as possible supplemented, in order to make the artificial growth perfectly successful.—"Fanciers' Journal."

## GARDENING FOR THE WEEK.

## Orchids.

Where a large collection of Orchids exists a good deal of discrimination is needed to keep them sufficiently but not too dry. According to the requirements of particular species. In order for the majority of Dendrobies well, it is necessary to be very careful as regards giving water when the bloom-buds begin to swell. For instance, the beautiful little *D. pulchellum*, if watered more than very slightly at the roots, and that not above once or twice when in the state just alluded to, the flower-buds are almost certain to run off into growth. If the atmosphere of the house be moderately moist, that will be sufficient until the individual flowers are clearly visible. The *D. nobile* section are also subject to run off into growth in the same way, and also the tall-growing species, such as *D. Dalkhoasianum*, *D. Calceolaria*, *D. fimbriatum oculatum*, &c. *D. Devonianum*, than which there are few more lovely Orchids, is often kept too warm during both winter and summer. I have found it to succeed much the best by not encouraging growth in the spring nearly so soon as the plant evinces a disposition to start. The best plan is to keep it through the winter and spring from 45° to 48°, with a little water once a fortnight or so after the young shoots have begun to push, but it must not have either moisture or sufficient heat to induce a pushing more than a very slight extension of the young growth until the end of April. This Dendrobe should always be grown in baskets suspended near the light, and the same remark also applies to *D. Warlianum*. These, being strictly drooping plants, are completely out of character when grown in pots with the shoots tied upright, as one sometimes sees. *D. Pierardi* will now be pushing up its flowers, and should be kept in a fairly moist condition at the roots. *D. densiflorum* and *D. Parnaci*, where wanted to flower late, should be kept dry at the roots, and in a night temperature a few degrees under 50°.

**Winter-blooming Plants.**—One of the best white-flowered winter Orchids is *Cologyne cristata*, but this, again, is a plant that does not succeed well in a very high temperature, but, being a native of the moist hill regions of Nepal, it cannot bear much drought. When in a strong, healthy condition its leading bulbs soon get beyond the limits of the pot or basket in which it is grown, and in this case there is nothing for the roots to lay hold of, the result of which is that the bulbs formed under such conditions are deficient in size and ability to produce strong spikes. In order to remedy this it is necessary to reduce the plants I have found this best accomplished by cutting the leading piece with about three bulbs attached to each, leaving the remaining roots to break back. The severed pieces are best arranged in pots or baskets, in sufficient numbers to make an effective display. In no way does this *Cologyne* grow better than fixed on a large piece of cork, on which is placed 2 in. of good, fibrous peat, covered with a little Sphagnum. In this its roots will luxuriate, and when suspended near the glass it makes the strongest possible growth. Now, or immediately after flowering, is the best time for performing this operation. The different varieties of *Cypripedium* habitans, *C. ensatum*, *C. Patricium*, *C. villosum*, *C. leucodatum*, *C. Lowi*, *C. Dayanum*, *C. hirsutissimum*, and *C. Stonei* must not be kept too dry at the roots, as the flowers will shortly begin to show themselves; the four latter kinds being natives of hot countries, require more warmth in winter than the first-named sorts, as where the temperature is not sufficient their roots generally decay. *Chysis bracteosa* and *Limninghea*, where required to flower later on, should be kept at the coolest end of the Mexican house, and a little water should be given them as soon as the young shoots commence to grow. Thus treated, they will make little progress until more warmth and moisture is applied. In this way a good display of flowers is distributed over a longer time than under ordinary treatment, and I have never found the plants suffer by it in the least where no extremes were attempted.—T. BAINES.

## Indoor Plant Department.

**Conservatories.**—In addition to Hyacinths and other bulbous plants, these also contain blooming plants of Camellias, Azaleas, Chinese Primulas, Cinerarias, Solms, some small Pelargoniums, Dalrymples of different kinds, Cytisus, Zieria Smithi, several Acaecias, Heaths, Epimediums, Libanths floribunda, Tremandra verticillata, Correa cardinalis and Brilliant, Monochetum sericeum, multiflorum and ensiferum, Lachenalia, Roella collata, Oldenburgia Deppiana, Pyrethrum uliginosum, Leucopogon lanceolatus, and Luculia gratissima. Amongst climbing plants, Hibbertias, Kennedys, Hardenbergias, Brachysemas, &c., are now coming beautifully into flower. Amongst dwarf climbers nothing is prettier at present than good plants of *Mysyrhyllum*, Verbenagoldes, loaded as they are with a profusion of little, reflexed white flowers, being of a very orange-coloured conspicuous tawny. This is a plant that may be readily raised from seeds sown in a hotbed, pricked or potted off singly when up, and kept growing in moderate heat or in a cool house; either will do, only when a little warmth is employed good plants are sooner obtained than by cool treatment. Pot such roots as remain of *Primula cortusoides* in a compost of good loam two parts and leaf-mould one part, with a little sand. Those previously potted and beginning to grow, keep on a shelf as near the glass as possible. Give a final shift to the *Calceolarias*, and also to some of the bushy ones intended for conservatory decoration. Cinerarias required for late blooming should have plenty of water, and be kept in a cool, airy house. A few Balsams and Cockscombs for early flowering should be sown in a hotbed, and pricked off before they become spindly. Of *Amarantus saffordiana* a few seeds should likewise be sown for conservatory ornamentation, as well as for flower garden decoration. To succulents starting into growth water should occasionally be given.

**Specimen Plants.**—Large Heathbs, *Chorozemas*, *Boromias*, *Apheleandras*, and similar plants should now be staked and tied into such shapes as it may be desired they should assume. A position near the glass is best, and especially one in which all sides of the plants may be subjected to an equal degree of light. In training plants of *Draacophyllum*, unless the long shoots are twined round the base of the plant, and only the points of last year's shoots allowed to grow upwards, a symmetrical or handsome specimen cannot be obtained. Many train the old wood of this plant over a trellis and allow the blooming points to project outwards a little, but the result of such a method is not satisfactory. Show and fancy *Pelargoniums* keep in a cool well-aired house and in close proximity to the glass. If the stages do not permit of them being near enough to the glass, raise them upon inverted pots, blocks of wood, bricks, &c. Although wirework for training purposes was refixed when the plants were cut back, no attempt should be made to tie down any of the shoots yet; on the contrary, a slow and stocky growth should be encouraged, which is the most productive of flowers; no fire-heat should therefore be employed for these plants in winter beyond what is necessary to expel frost. If required for early shows a little fire-heat may be applied after February.

*Allamandas* may be re-potted, cut well back, and allowed to break freely, keeping them moderately dry. *Dipladenias* will now be producing their young wood, which should be trained to fine string run across the rafters inside the stove. If the pots in which they grow are plumped, or partially so, in a moderate bottom-heat, it greatly assists their growth; and if the wood is produced early without check, and by free exposure to light made firm, abundance of flowers will doubtless be the result. If not already done, bring down the shoots of *Clerodendron Balfouri* and splendens, and train them around the trellises fixed on the pots. As *Clerodendrons* produce their flowers from the old wood, none of it should be removed at present; but after they have done blooming they may be pruned, re-potted, and encouraged by bottom-heat and a high temperature to produce their young growths, which should be trained along the sides of the stove, in the same manner as recommended for *Dipladenias*, with the exception of the difference of season, viz., *Dipladenias* from the middle of January until they begin to come into bloom, and *Clerodendrons* from the time they have done blooming until they form and thoroughly mature their young shoots, which will be the blooming ones of next season. *Stephanotis* may now be unfastened from the cords on which they have been supported and trained around their trellises; if required early, raise the temperature of the house or transfer the specimens to a warm, moist stove. To high temperature in winter, however, more caution should be taken. It deprives them of their proper rest; but it must not be allowed to fall under 55°.

**Stoves.**—Where there is the convenience of stove-heat, there are many things that will shortly require attention. If it is now time to start growth in a moderate bottom-heat, and it is better to excite the roots into growth at once, for although the plants will keep throwing up flowers more or less through the summer, still the heads of bloom produced after the first and principal flowering are much fewer in number, and not so effective. If a portion be at once potted and placed in heat, they will soon begin to push. Do not overpot them; an 8-in. pot will grow a large bulb, especially if it be assisted with manure water; good sandy loam is the best material for them, with one-fifth of rotten leaf-mould. Use 1 in. of crocks in the bottom of the pots, and do not, as is so common, ball, but allow its surface to rest to appear above the soil. Pot moderately firm, and place in heat at once. Some Achimenes should be started at the same time; these are better placed thickly in shallow pans, covering the bulbs with  $\frac{1}{2}$  in. of soil. When they have pushed shoots 1 in. or 2 in. long, they can be transferred to the pots or baskets in which they are to be grown. They are fine decorative plants grown in this way, either for a large or small house; use baskets proportionate in size to the house they are intended to grow in.

**Bedding Plants.**—Hotbeds should now be put up for the propagation of these where hot-water heated structures are not available for that purpose. A little extra warmth may be communicated to ordinary frames by means of a Glazebank, and the contents may be covered with straw; this additional heat will induce the plants to start into growth and to soon begin to yield material for cuttings. Where two, three, or more *Pelargoniums* were placed together in one pot in the lifting season for convenience of storage, they may now be separated, potted singly, according to size, and kept without water for some days after the operation. Keep the house or frame rather close for some little time after potting. Lose no time in obtaining and striking as many cuttings of all plants as possible, for the stronger they are, and the earlier propagated, the harder and the more vigorous will they be when turned out in the latter end of May. *Calceolaria* cuttings seldom root well in spring; nevertheless, the tops of autumn-saved plants may be economised for that purpose in the event of an otherwise deficient supply. If struck in a cold frame early this month, in the same manner as autumn cuttings are, they sometimes root very satisfactorily. *Verbenas*, *Heliotropes*, *Ageratums*, *Tropaeolums*, *Petunias*, *Lobelias*, *Colsenes*, *Alternantheras*, *Iresines*, &c., when rooted, should be potted singly or transferred to boxes, and still be kept in a hotbed, and they may be taken off for the same purpose, and also their side shoots, so that, with plenty of heat and convenience, a large supply may be obtained before the end of the next two months. Sub-tropical plants must also be increased as expeditiously as possible. Side shoots taken off for cuttings soon make good plants. Seeds of the various kinds commonly raised by that means should now be sown in a brisk hotbed or warm pit. *Acacia lophantha*, *Wigandias*, *Cannas*, *Ferdinandias*, *Richnuses*, *Zeas*, and many others can be readily raised from

seeds. Canna roots saved from last year should now be divided and started in heat. Dahlia roots may also be started. If beds be dug out about 18 in. or 2 ft. deep, and filled with leaves trodden firmly, so as to be covered by a frame, and some light rich soil be placed therein, they will form excellent positions in which to plant *Calceolarias*, *Verbenas*, or *Heliotropes*, so as to have good plants before they have to be set out in beds.

#### Flower Garden.

Where hardy material can be spared for replenishing flower-beds and borders, planting may be proceeded with. Pansies, Daisies, Arabis, Alyssums, and similar early-blooming plants transplant as well now as later in the season; indeed, if carefully removed, they suffer little or no check in the operation. Ground for the reception of hardy herbaceous plants should be trenched and heavily manured, but the subsoil, unless good, must not be incorporated with the surface soil. Where *Lythrum roseum* is used in ribbon-border making, it should now be lifted, cut up into good crowns, and replanted in a line about 15 in. or 18 in. apart. Sweet Peas should now be sown where they are to bloom, and some should be put in beds from which to make up deficiencies in case of failure; sow a few in a box decomposed manure to beds where late plants, such as those of *Ricinus*, *Perdanidia*, *Wigandia*, and other gross feeders, are to be grown, *i.e.*, if the beds are now empty. If this soil last year was found to be too moist, turn it out, and place a layer of stones, broken bricks, &c., in the bottoms of the beds. Mulch all newly-planted shrubs or trees, and affix strong, but neat, stakes to such as require support. Prunae bark pretty hard some *Clematites* for early-flowering; some of the hardier *Rose* plants may also be pruned for the same purpose. Tree *Peanies*, *Myrtles*, the Japanese *Quince*, and several other tender plants should have a little protection now next; for, although their roots and principal stems might escape unharmed, their young shoots might be considerably injured.

#### Indoor Fruit Department.

**Pines.**—The end of this, and the whole of next month, is the recognised period for the general spring potting of Pines. Have, therefore, a good stock of material at hand, including turfy loam, charcoal, and 3-in. bones. Pot suckers at once, if necessary, but if they be weak allow them to remain for a time on the plants, even after the fruit is removed. Increase the temperature a little, and apply water more plentifully.

**Cherries.**—For these a high temperature is ruinous, especially before the fruit has set well. A night temperature of 45° is sufficient, and water should be given only moderately.

**Vines.**—Thin Grapes as soon as they are large enough to admit of the performance of that operation; thin and stop shoots also, and regulate growth generally. Tie up to the wires such Vines as are intended soon to be started, but leave undisturbed such as are to be permitted to come naturally into growth. Sprinkle plenty of water on the paths and on other bare surfaces, in order to maintain a moist atmosphere.

**Strawberries** colouring should be kept near the glass, in a moderately dry house, at a temperature of 60° or 65°. Water carefully, for too much would impair the flavour of the fruit. Bring in or shift from a cool house to one that is warmer plants for succession. Cucumbers and Melons sown last month will now be sufficiently strong for planting out. Keep up for them a steady bottom-heat, either by means of hot water or fermenting material, and water them with tepid water. Sow a few more seeds for a later crop.

**The Early Peach House.**—The fruit will now be set in the earliest house, and syringings morning and evening will be required in favourable weather. Attention should likewise be paid to the thinning of the fruits where they are set thickly, but this rarely happens when forcing commences so early. The disbudbing of the shoots is a process best performed by taking off only a few of the strongest at different times, so as not to give a check to the roots. The temperature at night may be maintained at about 60°, with a rise to 70° by day, and by sunbeats 6° or 8° higher. Green-fly will begin to make its appearance, and the infested shoots must be picked off; but fumigation with *Tobacco* will have to be resorted to at the last. Some of the new patented fumigators are very efficient for the purpose, for by making a hole in each door of the house for introducing the nozzles from the outside, the house can be soon quite filled with smoke, and kept so for any length of time required.

#### Kitchen Garden.

**Early Radishes.**—If the weather keeps mild, Radishes sown in the open ground, and covered with litter, will very soon vegetate. See that they are not kept covered in the day as soon as up, or they will be drawn and weakly. The litter should be carefully taken off in the morning, and again shaken over the bed in the evening, until the plants have got sufficient strength to bear full exposure. As soon as the first sowing is up, a second bed should be sown to give a succession, to ensure which, during the spring, great care should be taken, as this crop is generally held in very high estimation in the early season, and, without the closest attention, Radishes cannot be had crisp and uninterruptedly.

**Birds and Seeds.**—The seeds of Radishes, Turnips, and all the Cabbage family are particularly subject to the attacks of birds, more particularly in small gardens. In the market gardens, where Radishes are sown by the acre, a boy is regularly employed to keep off these marauders. In the small breadth required in a private garden it would not pay to employ labour in that way, yet, if nothing be done, a very few

finches would, in a single day, destroy a crop. For many years I have, previous to sowing, dressed all seeds of the above description with red lead, and I have never found any bird touch them—except the greenfinch, from which nothing will preserve the seeds but covering them with mats. This dressing, to be effectual, must be done thoroughly. The best method is to place, in a large tea-saucer, as much seed as fits the intention to sow, on which sprinkle a very few drops of water, for, if they be made too wet, the seed and the lead will all stick together in a mass; then take a tea-spoonful of dry powdered red lead, and stir the whole thoroughly until all the seed is well coated with the lead; let it stand for a couple of hours to dry before sowing—this is necessary, or the lead will wash off with the rain; whilst, if laid on with the right amount of moisture, and well dried, it will adhere to the outer covering of the seed, even when it appears above ground. With a little practice in the preparation of the various seeds that thus fall a prey to birds, the operator will soon be able to judge when he has hit upon the right degree of moisture required before applying the lead, and upon which depends the thorough preparation. Half a pound of lead will last a season, and the trouble is nothing when compared with blank crops.

**Seakale.**—Put in more Seakale roots for successional supply, treating them as advised for the earliest forced. If there be at command more of this vegetable than is required for forcing, it will, if the crowns be covered with 8 in. of fine ashes or sand, blanch well when it grows naturally with the warmth of the spring. To be managed in this way it should be planted in rows, so that the covering material can be placed over it in the shape of a continuous ridge, removable as the crop is gathered. In taking up this vegetable for forcing, the whole of the long roots, from the thickness of a finger to that of an ordinary pencil, should be forked out of the ground, and laid in soil until the time comes for planting. This is better and more certain than raising the plants from seed.

**Rhubarb.**—If some more roots of this be now put in any building where the external air in a great measure can be excluded, it will spring fast, and come in before the outside crop, and be better in quality than that which has been forced. If a few inches of stable litter be placed over the crown of the roots outside, it will act as a protection from spring frosts, and induce them to push a fortnight earlier than such as are fully exposed.

**Potatoes.**—Late Potatoes, required for use from the present time through the spring, should be gone over as soon as they commence to sprout. Rub the sprouts off before they have attained any considerable length, for if allowed to remain on, they spoil the quality of the tubers for cooking. Keep them in as cool a place as possible, so that they are not exposed to frost, but quite in the dark.

**Carrots, Beet, and Turnips** should be gone over in like manner, rubbing the young growth off them. The sand, soil, or ashes in which they are stored should be as dry as is consistent with not absorbing the natural moisture from the roots, for if at all wet, growth is promoted, which it is the object to discourage as much as possible.

#### Diary.

**February 18.**—Sowing Red Cabbage and early Savoy in boxes, and putting in the gentle heat. Potting Black Jamaica Pines, and rearranging the pit in which they are growing. Giving first crop of Broad Beans a little earthing. Forking over the surface of the ground amongst Cabbage plants. Planting a four-light pit with Telegraph Cucumbers, and another with green-fleshed Melons.

**Feb. 19.**—Sowing Marrow Peas in boxes for making Green Pea soup. Potting Cucumbers and Melons. Looking over early Vineries, thinning out the berries, and tying down the shoots where required. Thinning out Radishes and Carrots in frames. Clearing out early forced Asparagus, and re-filling the frame with another lot. Sticking early Peas with short sticks, and earthing them up a little. Covering up Endive to blanch.

**Feb. 20.**—Potting off Chrysanthemums and Lobelias. Pricking off Celery plants in boxes. Disbudbing Peaches and Nectarines, and thinning out the fruit where set too thickly. Stirring the soil amongst Lettuces and Endive in frames. Looking over Cucumbers, picking out all false blossoms, and stopping the shoots where required.

**Feb. 21.**—Sowing Cucumbers and Melons. Putting in cuttings of *Pelargoniums* of different kinds; also those of scented *Verbenas*. Potting *Adiantum Farleyense* and other Ferns; also a few *Caladiums*. Emptying another Melon pit and refilling it with fermenting material for bottom-heat. Looking over Cauliflower plants in frames, picking out all dead leaves and button-headed plants, and stirring the soil amongst them.

**Feb. 22.**—Potting Tomatoes, and putting in cuttings of *Gesneras* and *Salvias*. Getting another box of Mint into gentle heat. Renovating the linings round manure frames. Clearing litter used for covering off Celery ground. Getting guards put over Peas just coming up. Looking over Grapes in bottles, removing any bad berries, and filling up the bottles where required.

**Feb. 23.**—Putting in cuttings of *Coleus*, *Iresine*, and *Mesembryanthemum*. Looking over *Pelargoniums*, picking off dead leaves, and stopping the shoots where requisite; also *Calceolarias*. Weeding all Box edgings and kitchen garden walks. Clearing out all decayed leaves amongst Brussels Sprouts and other Greens. Looking over the fruit room. Fruit in use for dessert—Pines, Grapes, Pears, and Apples.—*W. G. P., Dorset.*

## THE FRUIT GARDEN.

### HOW FAR APART SHALL WE PLANT APPLE TREES?

There is a great difference of opinion on this subject. When the land is poor and thin the roots will be less numerous, and must spread for long distances in every direction to get the nourishment needed. Our poor soil it is very necessary to give the trees plenty of room. Our densest forests and thickest turf grow on soil which is very rich. In planting an Apple orchard, as in most other operations, it generally pays to do the work well. When properly taken care of, after, say a lapse of twenty years or so, many varieties of Apple trees will spread 20 ft. in each direction, and some spread further. The rapidity of growth and the longevity of the trees depend much upon the soil and climate, as well as on the variety of fruits that happen to be planted. I have several orchards in mind in which the trees were planted closely together within 15 ft. or 20 ft. of each other. Some of these were so planted because the owners had a theory that the trees would the better stand the rigours of severe cold winters and hot summers. One

of the orchards was set twenty years ago on sandy land. The trees grew well for a few years, till they shaded all the ground. They were well cultivated, but never bore very well. After shading the ground they began to run up for more air and more light. At present the orchard is of no value, and never will be, except for fire-wood. It was a poor investment, chiefly because the trees were planted too near each other. One of the other orchards was planted on good, rich land. The trees behaved much as in the previous case, though they bore good fruit in considerable quantities for some years, when they crowded, died, or split down, and to-day, when only about twenty-eight years old, the orchard is of little value. On a neighbouring estate with similar soil, another orchard was set at the same time. The latter has borne the most fruit, and is still apparently good for many more years of profit to the owner. In ordinary

good loamy soil, or in poor light soil, the roots of an Apple tree, when fifteen years old, extend at least 25 ft. or 28 ft. in all directions. This is not mere fancy, but a fact, as I have repeatedly seen the roots as described while putting in tile or while digging for the purpose of examining the roots. The feeders of the roots—the root-hairs—are renewed every few weeks during the growing season. The small roots from which the root-hairs grow are also often renewed. I mean these die, and others take their places, or other places not far away. In this manner roots are all the time feeding on new ground. Doubtless, after a time, much ground is fed over again and again. Roots do not search for food as animals search for it; but they grow where they find the best soil, and they will there multiply in the greatest abundance. For long-lived trees and the best results, I am satisfied that large varieties of Apple trees should not be planted nearer than 40 ft., if they are set in squares. This gives not a whit too much air and light for the tops, and, as has been shown, the roots will soon occupy all the ground and make good use of it. While the Apple trees are young, if desired, other crops may occupy the intervening spaces. I prefer to set trees in squares, because it is the simplest plan, and because it is easier for the cultivation. As mentioned, the roots will run all through the soil, even

crossing one another at long distances between two trees. If the trees are of varieties which do not grow fast or become large, they may be planted nearer together than 40 ft. If, like the Wagener, they begin to bear young, and are allowed to bear and get ready to die by the time they are fifteen years old, they may be planted only 20 ft. or 25 ft. apart. Trees are often injured by planting too closely, seldom by having too much room. One tree does not protect another by growing very near it; on the contrary, one robs the other. Our strongest, finest ornamental and forest trees grow in open spaces where there is plenty of room, and where the soil and climate are suited to their natures.—*Rural New Yorker.*"

**Tall Trellises for Espaliers.**—Having before spoken of the well-trained and in all ways well-managed espalier trees in the School of Horticulture at Versailles, we now give an engraving, showing the general effect of a portion of the square in winter. The trees are all trained vertically, and the tall trellises mutually support each other by rods running across them. Cordun Apples are grown between the lines, and sometimes, on the ground, Strawberries.

The effect of a large square completely furnished with these handsome and well-formed espaliers is very good, particularly when the high trellises are from top to bottom a sheet of level bloom in April, or when well hung with handsome fruit, in no danger of being blown off these firm trellises by autumnal gales. The espalier trellises are formed of thin galvanised wire, supported by T iron, the vertical lines on which the shoots are trained being Pine wood rods  $\frac{1}{2}$  in. square.

**Retarding Peach Blossoms.**—This, no doubt, is entirely a question of temperature; therefore, leaving the trees untrained, with their branches as far as possible from the wall, till the last moment offers the easiest and best means of retarding the flowers. Moreover, under this treatment the buds are stronger and hardier than when trained earlier, and shading resorted to to keep back the blossoms. The trees should be loosened from the walls

early in autumn, the sooner after the leaves fall the better, as this thorough exposure, accompanied by the gentle motion of the branches by the movement of the air, is beneficial in many ways. It is unnatural to keep trees of any kind always tightly braced up to the wall, and certainly shortens their lives. Of course the main branches must be sufficiently secured to prevent high winds injuring the trees in exposed situations. As soon as the blossoms begin to show colour the trees should be trained as carefully as possible, but if they are healthy, Peaches will always set a much larger number of fruits than can possibly be allowed to remain on, so that if a bud or two should be displaced it will not be of any serious moment. The chief thing is to delay the opening of the flowers, as the longer this can be put off—nine seasons out of ten—the greater will be the chances of securing a crop of fruit.—*E. HOBDAV.*

**Fruit Prospects for 1878.**—As the critical season for fruit crops is rapidly approaching, it is satisfactory to observe that at present the condition of the trees is highly favourable; not only are the flower-buds abundant and strong, but, what is of greater importance, they are not unusually advanced, for, although the winter has been an open one, without much frost or snow, we have hitherto had but little unseasonable elevations of temperature to excite growth.

Tall Espalier Fruit Garden.

All kinds of fruit trees, both on walls and in open quarters, promise to yield good crops; and should the coming spring prove propitious, fruit returns will compare favourably with those of previous years.—*J. Groom, Henham.*

### FRUIT TREE PROTECTION.

It is somewhat early to write about fruit prospects, and perhaps, instead of fruit, it would be wiser to write about buds, which are plentiful and of average quality. Bullfinches, I find, are already attacking the buds of Plums—a sure sign that growth has commenced; for I have noticed for years that these pretty songsters, but most reckless bud destroyers, never touch them till growth begins. Probably the starting of buds, like the sprouting of Barley in malting, develops sugar, and the birds wait for the buds to be thus sweetened. If this be so, it seems that buds vary in sweetness, which they assuredly do, and that the order of merit in bird estimation is about as follows, viz., Plums, Gooseberries, Apples, Apricots, Peaches, and Pears. This order, however, may vary in other places. Here the birds evidently think there is nothing like Plums, and hence they are at them already, though the Gooseberries, which are more forward, are not touched. Pears and Apples seem to be rather later than usual, and Peaches and Apricots are moving but little. The wood of these is greener than is customary, and not in the best form for encountering a severe spring, which it is more than likely we may have after so much wet. It will therefore be wise to see to all protective expedients early. With a glass coping, or a movable wooden one, on the top of the walls, the trees may generally be left to shift for themselves. Still, it will be wise to take extra precautions this year. We cannot yet afford to have another fruit failure; therefore woollen nets, mats, old fishing-nets, thin canvas, frigi-domo, &c., should be had in readiness with which to fight the frost when it comes. The old-fashioned plan, too, of drawing a few Fern fronds or old Asparagus tops—harvested and kept dry for this purpose—or small Spruce, Yew, or other boughs under the branches, affords one of the most effective of protections against frost and cold winds. They are fixed over and amongst the flowers, and are sure to protect a few just where they are wanted. The gradual process of defoliation is also one of the chief merits of these simple and homely protectors. They likewise shade out the sun as well as conserve heat. Some of these rough modes of protection, like the old-fashioned one of loose straw bands run along the wall horizontally, a foot or so apart and a yard from it, are rather unsightly; but that matters little should they prove effective. We can afford to lose sight of our trees for a month or six weeks if they will only come forth by-and-by laden with fruit. The most sightly, and at the same time one of the most efficient means of protection, is a glass coping, 18 in. wide, on the top of the wall, and a woollen net stretched down from within 6 in. of its lower edge to nearly the bottom of the wall. The netting, being thus overhung by the glass, will be kept dry, and the two together will preserve the blossoms of Peaches, Nectarines, Apricots, and Plums against 10° or 12° of frost.

D. T. FISK.

**Two Orchards—A Contrast.**—We have seen two orchards in Western New York, standing within half a mile of each other, which very nearly corresponded with the following description of two orchards at South Haven, Michigan, given by Prof. Beal. One of these orchards he pronounces as bearing the best crop the past season which he had seen in the State. The ground has a perfectly natural drainage, but has not a strong soil; hence the necessity of the triennial manuring and cultivation given it. With this treatment the annual shoots are not over 1 ft. long. The owner raises fine fruit, and makes it a rule to send to market only the very finest in quality. It is no wonder, then, that he cannot fill all the orders he receives. His neighbour set his orchard the same year (seventeen years ago), and allows his trees to stand in Grass. He had no fruit of any value the past season. The two orchards are separated only by a line fence. The last-mentioned trees are mossy, with yellow leaves, and out by the borer, and make little growth. A specimen tree in this orchard measured 14 ft. through the top, that is, the limbs were 7 ft. long with seventeen years' growth. The tops of the trees in the good orchard were 22 ft. through.—“Country Gentleman.”

**Fruits at High Elevations.**—What fruits can be grown on a brick wall, looking south and south-west, at an elevation of say 930 ft. above the sea? Will some of your correspondents favour me with an answer to this question?—*D. J. M.*

**The Vine Pest in Australia.**—The discovery of the *Phylloxera* in the Vineyards of Victoria, for the “*Mark-lane Express*,” is a sad blow to the hopes of the colonists, for a successful development of their wine-growing industry. The pest has been rapidly increasing in Geelong for two years without attracting any general attention, although the insect was found to be infesting a few small patches of Vines as long ago as 1872.

## THE KITCHEN GARDEN.

### WHERE TO PLANT THE POTATO CROP.

At p. 46 will be found some excellent advice on this important subject, and as I have had abundant opportunities of confirming the writer's views, I venture to offer a few supplementary remarks on the subject, not with the idea of furnishing a cure for a malady that has hitherto defied all our efforts, but with a decided impression that by judicious culture, and, above all, by selecting favourable situations as regards elevation, and studying the character of the soil where into plant our main crops, we may at least get sounder tubers, if we should miss sensational results. During the last ten years I have had the opportunity of inspecting a great number of cottage gardens and allotments; also of attending the annual autumn exhibitions of roots in connection with several local societies for promoting cottage gardening, where Potatoes form the most important crop; and such a marked advantage have the cultivators of light or mixed soil lands over those who have heavy, retentive, rich soils, that separate classes are provided, otherwise the light sandy lands would invariably claim every prize offered, the quality and clean even sample of Potatoes raised on them being so much superior to that off heavy soils. Fancy varieties are not much sought after for main winter crops, but the old Rough Reds, Flukes, and Regents are as much grown as they were twenty years ago; and as regards quality, it is difficult to say where in newer sorts the improvement is to be found. In this neighbourhood every cottager has a large allotment in addition to a good-sized garden, and, destructive as the disease was last year, they unanimously aver that no crop pays so well as Potatoes; and when fine crops in gardens and highly-manured land have been a mass of rotteness, the allotments almost invariably produce good, sound Potatoes, with little loss from disease. This is certainly not attributable either to richness of soil naturally or artificially, or to any skillful routine cultivation. Indeed, the fields selected for allotments are such as farmers would not offer much competition for, being mostly light land, with plenty of stones and sand, on which the water drains away as rapidly as it falls; yet from the depth of loose, friable soil, such land does not suffer so quickly from drought as might be expected. The manure employed is very limited in quantity, but most of the land intended for Potatoes is well broken up before winter, so as to get the full benefit of rains and frosts. I may also remark that the most successful exhibitors of Potatoes which we have ever had occupy land reclaimed from adjoining barren wastes, that being situated close to Oak woods have been annually dressed with great quantities of Oak leaves, until a deep light soil has been obtained, and fine Potatoes, without spot or blemish, have been the result. The sandy soils here are mostly liberally mixed with a white sand, almost equal to silver sand. But perhaps the most striking instance of freedom from disease was afforded by our field crops, which escaped with scarcely any loss in that way. The situation was an old wood of Fir trees that was felled the year previous, and the land was deeply trenched, and no manure of any kind has ever been applied to it, and the soil, which is of the lightest description, is also undulating. No matter how much rain may fall, it is always in good working order. The sets we dropped in after the plough and earthed up in the ordinary way, and, as before remarked, there was scarcely a diseased tuber in a hundred. The crop was not a sensational one, but it consisted of more sound Potatoes than if it had been planted on richly-manured level land. People cannot, I know, always select so favourable a site, but last year was an exceptionally destructive season, and the attack was as sudden and rapid as it was destructive; it is, therefore, but reasonable to suppose that medium crops might be obtained in all seasons if strong retentive soils and highly-fertilising and moisture-retaining manures were avoided; for instance, salt is frequently recommended for insuring good results as regards Potatoes. It is, however, the very last ingredient one would think of for promoting dryness of the soil, and, with regard to Potato crops, nine out of ten seasons are too wet for them. In order to produce good crops of medium-sized tubers fit for table use,

no fresh manure is necessary if the land has been manured for a preceding crop, and well broken up before the winter's frosts, so that rain can pass readily through it. This is one of the secrets of successful cultivation. It is useless reducing the labour bill one-half if the productive power of the land be reduced in an equal ratio. It has, I think, been pretty clearly shown that there are no "disease-proof" Potatoes; but as regards combating the evil with anything like success, I believe, if we could compare notes from different districts, we might at least clear up one important point, viz., "Where to plant." The after culture is simple enough; and although I have not tried Peas as a means of drawing off the superabundant moisture, I have frequently observed that the soundest tubers were found where strong-growing weeds had acted in that capacity.

JAMES GROOM.

Henham.

#### WHITE WORMS IN CELERY PLANTS.

In last week's GARDEN some sound advice is given (see p. 121) as to the mixing of soot, salt, and lime with the manure used for Celery, alike as a means of reducing the pest of worms, and of increasing the value of the manure as a suitable stimulant for that crop. This is well as far as it goes, but other means may also be adopted with the view of reducing the numbers or wholly extirpating worms in Celery. The abolition of the progressive system of earthing up is one of those means. Worms seldom enter Celery until it is covered with soil and blanched. Hence it follows that, if grown to full size first and blanched afterwards, the worms will at least have much less time in which to ply their vocation, for Celery can generally be thoroughly blanched in six weeks or less. Another means of reducing the number of worms is to either tie, or compress the Celery together as tightly as possible during the process of earthing up. It may seem absurd to suppose that the plants or the soil around can be made so firm as to exclude worms by sheer mechanical force; but, be that as it may, the closer the leaves of the Celery are forced together, and the firmer in reason the earth can be packed round them, the fewer will be the worms in the sticks, as a rule. Worms, indeed, seem to favour a confused or disorderly arrangement of leaves and stems. In most cases of careless earthing up in which the earth may have got into the hearts of the plants, or some of the leaves have been broken, there are more worms than in the perfect sticks. Before earthing up it is a good practice to remove all suckers and dead leaves from the stems, and to apply a slight dressing of equal parts of soot and lime, with a small quantity of fine salt to the plants overhead, and a heavier dressing to the soil in the trenches. Unless rain should follow in a few days, water this dressing in with a thorough flooding; when this has subsided, and the plants have become quite dry, earth up, say the second day after the watering. This dressing generally prevents the worms ascending from below. Of course they may exist in the side soil and be brought into contact with the plants in the process of moulding up; and this brings us to another, and perhaps the most radical cure of any for worms in Celery—that is, thorough cultivation during the previous winter, accompanied with liberal dressings of lime, burnt earth or marl, and charred refuse. These render the mass of earth distasteful to worms, and insure a sweet and mellow tilth, which is most favourable to the growth of clean, sweet, crisp Celery. On wet soils thorough drainage must be the first step to high cultivation, and the removal of stagnant water is often associated with the diminution of the number and almost practical extinction of worms in rich kitchen garden soils. What may be called specific local remedies consist in the use of spent tan, saw-dust, Cocoa-nut fibre refuse, and coal-ashes for blanching instead of earth. Of course, these are somewhat costly and troublesome remedies, but they are effective, and such materials, after blanching a fine crop of Celery and preserving it free from worms, can be mixed and incorporated with the mass of earth, adding to its bulk and improving its quality.

D. T. FISK.

#### POTATOES FOR POTS AND FRAMES.

It is singular to note the hesitation that cultivators display as regards the utilisation of the newer and better kinds of Potatoes for frame and pot culture, whilst they grow all sorts of garden kinds by the acre without much special regard to their respective table qualities. Perhaps this hesitation may be owing to the undoubted fact that a forced frame or pot crop of Potatoes must of necessity be a limited one, and that, therefore, it is doubly dangerous to run the risk of failure by growing sorts that have not been thoroughly tested. Frame and pot Potatoes, however, enjoy one advantage over crops grown outside; they are not affected with disease, and in

that respect, at least, there is less risk of loss of crop. The disease exercises none of its destructive influences on Potatoes grown under glass, because the foliage is not exposed to rain and to the mists and dews that fall during summer; indeed, so far as experience has gone, it has shown that the only absolute safeguard against disease is to grow the Potato under glass, but then that is an impossibility where thousands of acres are concerned. The Ashleaf family of the Potato still remains the most favoured section for early culture and for general purposes yet; probably it is the best. It is, however, unfortunate that any attempt to set up sections in this family should be made, as it is apt to mislead growers. The Potato trials made at Chiswick a few years since proved that there is no difference between one Ashleaf and another, except distinctions in name. Myatt's, Rivers', Veitch's, Gloucester Kidney, and a host of others are all the old Ashleaf, nothing more or less, and any distinction in reality is to be found only when the Ashleaf and Walnut-leaf sections are mentioned; but the latter kinds have never been greatly favoured, and enjoy but a moderate amount of popularity. The Walnut-leaf has for aliases Moua's Pride, Prince Teck, Melbourne Hero, and a few others. There is yet plenty of room to find improved kinds of frame Kidney Potatoes, as we want sorts with dwarfier haulm and whiter and more fleshy flesh than characterises the Ashleaf sorts. That such will presently be forthcoming there can be little doubt. Our labours in the work of raising seed Potatoes of late have been generally directed to the procuring of kinds that should be disease proof, an *ignis fatuus*. Now some attention is being paid to the raising of sorts that shall be productive of crops of good tubers within the shortest possible space of time, and I am hopeful that some unusual crosses with a new early white Kidney and the American Extra Early Vermont, undoubtedly the earliest Kidney in general cultivation, will presently produce what is so much wanted. A few years since Mr. Robert Penn endeavoured to distribute a white Kidney, having very short haulm, named Little Gem, which he specially commended for pot and frame culture. This kind produces tubers having the whitest flesh and of the finest quality. Grown both in a frame in rows 1 ft. apart and in 9-in pots in a Vinery, it produced crops of the most delicious quality, and gave the grower the most entire satisfaction; but somehow it was not inquired for, and it has been withdrawn from commerce. Alpha, one of the white American section, is also a most valuable kind for this mode of culture, and is an undoubted boon to those who have to provide first early Potato crops. The tubers are white and of excellent quality; but that, too, is hardly grown. The very best round kind for general frame cultivation is Early Market, as it has a dwarf top, and produces an abundance of good-sized, handsome tubers of the finest quality. This kind ought to be universally grown, both for frame-work and as a first early in the open garden, where, planted upon a south border in rows 1 ft. 5 in. apart, it produces an excellent crop.

A. D.

**Storing Roots.**—For many years the plan of keeping Carrots here was taking them to a cellar or outhouse, and building them up; with every layer of Carrots was put a layer of sand which kept them fairly well until about Christmas; but after that date they were always far from being satisfactory. My practice now is never to put more than two ordinary barrow-loads together, building them outside, head upwards, and covering them with straw and soil. We are now using Carrots taken up in October just as fresh and good as when taken up, and they will keep so until the end of May. These Carrots are used before the growing ones, which we always sow in July, and pull from the beds all the winter. The latter are much sought after, being mild, tender, and delicious. In order to keep Onions sound and free from growing, we tie them up in small hand bunches, and hang them in a draughty passage, where they are always cold. In this way we find them to keep perfectly sound and good. Parsnips we leave in the land until they begin to grow, when we lift and store them as we do Carrots for late spring use. Beet-roots should be lifted before the frost touches them, and stored precisely in the same way. An advantage belonging to this plan is, that it takes up no shed-room, which at all times is needful, particularly in winter, for storing Lettuces, Broccoli, and many other things.—R. GILBERT, *Burghley*.

**Scarcity of Vegetables.**—"Truth" does not speak truly when it says (see p. 111) that vegetables are scarce. For my own part, I never knew them so plentiful in any season of the year as they are at present. From open quarters we are eating young spring Cabbages, Purple and Snow's Broccoli, Brussels Sprouts, Savoys, Cotagers' and Curled Kale, Spinach, Lettuce and Celery for salads, while indoors we have Mushrooms, Seakale, Asparagus, French Beans, Cucumbers, and Rhubarb, &c. In fact, this is a good year for cooks, who have merely to ask and have.—R. GILBERT, *Burghley*.

## THE JUDAS TREE (CERCIS SILLIQUASTRUM).

I was glad to observe the favourable notice of this tree which appeared in your last issue (see p. 131). Permit me to state some particulars of the oldest and largest Judas tree with which I am acquainted—probably the largest in England. It is growing at Bath, on the premises of an ancient chapel, called St. Mary Magdalene. This remarkable tree I should guess to be not less than 300 years old (the chapel dates several centuries back). It was probably planted in the first place as a wall plant against the gable end of the chapel, for the base of its trunk is close to the wall; the stem and head have been gradually drawn away from the building, and are now in a leaning position, being supported by one of the arms resting on the boundary wall adjoining the street. The stem girths 6 ft. 1 in. at half-way up to the crown; at 10 ft. up its head has evidently been cut off some years ago, in a rough and unworkmanlike fashion. Notwithstanding the mutilation, however, three or four upright branches have shot out of the crown, and are now from 12 ft. to 15 ft. high. This specimen, although so old, still forms an attractive object every spring, when covered with its little clusters of Pea-shaped, gay-coloured flowers. The origin of the name Judas, applied to this tree, is, so far as I am aware, unknown. It is said to have been given it by Gerard, who stated that "this is the tree whereon Judas did hange himself." It is indigenous to Turkey, Greece, and Judea, where its flowers, owing to their agreeable acidulous flavour, are highly esteemed for mixing in salads, and they are also frequently pickled for use in the same way when fresh flowers cannot be had. Its foliage is very distinct from that of most other trees in shape and colour, the latter being bluish-green on the upper surface and Grass-green underneath. When old, the Judas tree forms a broad, round, flattish head, somewhat similar to that of an Apple tree. The wood is not considered valuable, although it is hard and capable of taking on a good polish. As an ornamental tree in spring, it ranks as one of the most attractive, owing to the singular and beautiful appearance which it presents when its old, as well as young, wood is literally covered with its purplish-pink blossoms clustered together in small bunches before a leaf is visible; and when associated with Laburnums, Lilaos, Flowering Currants, Azaleas, and other spring-blooming subjects, it forms a charming contrast in colour, blooming, as they all do, at the same time. The Judas tree is also well suited for planting on a lawn, either to form a standard bush as an isolated specimen.

Longleaf.

GEORGE BERRY.

*Retinospora ericoides* a Misnomer.—I am sorry that I wrote the note on this subject which has so interested Mr. Syme (see p. 533). It was simply written because I thought that the information on the subject which seemed to abound here might possibly prove acceptable to him. I only write now to say that *R. ericoides* is very common here, as is *Thuja ericoides*, T. Tom Thumb (*Ellwangeriana* of some), and many other similar forms, and that I may be pardoned for supposing that Mr. Syme meant *R. ericoides*, as the beautiful engraving is of the form *ericoides*, and not of the *juniperoides*, whatever Mr. Syme may have meant in the text. *R. ericoides* has been in the trade for nearly fifty years, and it was pardonable in old times to regard it as a *Retinospora*, because the polymorphic conditions of *Arbor-vitae* and *Junipers* were not understood. These polymorphic *Junipers*, however, are easily known when carrying on through life their juvenescent form, by having their leaves in whorls of three, which Mr. Syme's engraving has not; while the *Arbor-vitae* have their leaves in pairs, as Mr. Syme's drawing has. In short, the *R. juniperoides* of the trade is a *Juniper* which has simply retained its juvenescent character, while *R. ericoides* is simply *Thuja occidentalis* under the same abnormal conditions. If Mr. Syme is really not ironical in his being "so grateful to any 'intelligent American' for an explanation of the 'biological law which induces dimorphism,' and yet does 'not require to consult' the American works to which I have referred him, he may read with profit the article "Conifers" in Sach's "Text Book of Botany," though, with all due respect to that remarkable work, I think the references I first gave make the matter clearer morphologically, though not equal to Sach's, of course, in the minuteness of detail in the structural work.—THOMAS MEEHAN, *Germanstown, U.S.*

A Grand Myrtaceous Tree.—In the director's recently issued report of the Botanic and Domain Gardens, Melbourne, we find the following allusion to *Syzygium Moorei*:—"Lot no.," he writes, "I firstly describe one or two species of this Order (Myrtaceae) as an indication of the effects to be produced with such materials at command. First is the *Syzygium Moorei* (of which I have seen whole forests in Northern New South Wales and Queensland), attaining a height of 70 ft., or 80 ft., and affording when in full bloom one of the most gorgeous spectacles imaginable; its every branch and even a part of the stem being clothed with one mass of royal purple blossoms, having the appearance of rich pile velvet."

## NOTES FROM KEW.

*VELTHEIMIA VIRIDIFOLIA*, a Liliaceous plant, introduced from the Cape of Good Hope more than a century ago, is well worth growing. It succeeds under very diverse conditions, doing equally well in either a warm or a cool house, and requiring very little care. The broad, arching, wavy, bright green leaves form a kind of rosette, from the centre of which springs the rather tall, stout scape, surmounted by a raceme of long, rosy-pink flowers, green tipped when in bud. When planted out in a cool house *Datura sanguinea* forms a most beautiful object, the light green foliage setting off to great advantage the numerous, large, tubular, red flowers. Seemann says that this is one of the most dreaded of the poison plants of the Isthmus of Panama, and that it appears to have played, and still continues to play, a prominent part in the superstitions of tropical America. The Indians of Darien, as well as those of Chocó, prepare from its seeds a decoction which is given to their children to produce a state of excitement, in which they are supposed to possess the power of discovering gold. In any place where the unhappy patient happens to fall down digging is commenced, and, as the soil nearly everywhere contains gold dust, an amount of more or less value is obtained. In order to counteract the bad effect of the poison, some sour *chica de maiz*, a beer made from Indian Corn, is administered. *Prunus sinensis* fl.-pl. is one of the most valuable of all white-flowered plants for forcing purposes. *Hebeclinium ianthinum*, a Mexican Composite, is very useful and attractive for decorative purposes; the long-stalked, opposite leaves are coarsely serrated, and the flowers, which are produced in large corymbs, are remarkable for their very long, purple styles. *Acacia longifolia* var. *micronata* has narrow, almost linear phyllodia, about 2 in. long, and catkin-like spikes of clear lemon-coloured flowers; it is a very pretty plant. Another variety of *A. longifolia* (not named) has orange-yellow flowers and phyllodia about the same length as, but fully double the breadth of those of the last named.

In the Palm house may be seen in flower *Rondeletia cordata* from Guatemala. It is a neat, close-growing shrub, with leathery leaves and dense panicles of flowers about the size of those of *B. speciosa*; the colour is a warm flesh, the throat of the tube being entirely closed by numberless primrose-yellow hairs. *Strobilanthes Sabiniana* is a very pretty Acanthoid from the East Indies, every shoot being terminated by a tall, leafless spike of blue, Gloxinia-like flowers. The only drawback is the short time which each individual flower lasts. *Toxicopilea Thunbergii*, though not so handsome as *T. spectabilis*, is still worthy of notice from a gardening point of view. It has opposite, dark green, leathery leaves, and axillary bunches of a very fragrant white flowers. *T. spectabilis*, the Winter Sweet, a specimen of which is in the stove, is a very handsome Cape plant, with clusters of pure white, deliciously-scented flowers. A coloured plate of this desirable shrub was issued with THE GARDEN for July 7 of last year.

The most noteworthy Orchids in flower are those mentioned below. *Cypripedium Boxalli*, one of Mr. Low's recent introductions, is evidently closely allied to, although quite distinct from the well-known *C. villosum*; the leaves and flower-stalks are clothed with hairs; the upper sepal and petal are greenish white, spotted and blotched with dark purple. *Trihopilia sanguinolenta*, from Central America, has one-flowered scapes; the sepals and petals are greenish with light brown marks and blotches; the ground colour of the crisped and waved lip is pure white, the base bearing a line of a bright vinous-red colour. The East Indian *Ocleya cristata*, with its large flowers, snow-white, with the exception of the beautiful yellow crests on the lip, is and always will be a great favourite with Orchid growers. *Epidendrum cochleatum*, from tropical America, is a small-growing species of very easy cultivation; its compressed pseudo-bulbs bear two or three leathery leaves, and a raceme of rather large green and purple flowers, the narrow sepals and petals being of the former colour, and the large shell-shaped lip of the latter. *Ornithidium coccoineum* is a West Indian species with small pseudo-bulbs, and leaves from 1 ft. to 1½ ft. long and ½ in. to 1 in. broad. From the sheathing bases of these leaves spring clusters of scarlet flowers, the small size of which, in comparison with the leaves, causes the plant to be less generally cultivated than it otherwise would be. *Maxillaria punctata* is a very charming species with narrow, curved leaves and short roundish pseudo-bulbs. The leaves taper off towards the base, so the one-flowered scapes, though considerably shorter than the foliage are not at all hidden; the flowers are large for a *Maxillaria*, the sepals and petals are citron-yellow, the column red-brown, and the base of the lip striped and suffused with the same colour. *Leelia cinnabarinia* has petals and sepals nearly uniform in size, and of a reddish-orange colour. Dr. Lindley remarks of this plant that what the flowers want in size is amply compensated by their peculiar colour and the graceful manner of growth. The clustered pseudo-bulbs are clothed with acute striated scales, and bear at their extremities one or two linear-

oblong, reflexed, leathery leaves. *Rodriguezia crispa*, a Brazilian epiphyte, has a drooping spike of waved flowers of an uniform greenish colour; the species is more of botanical than of horticultural interest. Two very fine *Dendrobiums* conclude our list, *D. fimbriatum* and *D. densiflorum*; the former has upright stems and long drooping racemes of extremely handsome flowers of a bright golden-yellow colour, with the exception of a blotch of deep maroon at the base of the beautifully fringed lip. *D. densiflorum* is a small-growing species from Nepal with light yellow sepals and petals and an orange-coloured lip.—†.

#### AURICULAS AND POLYANTHUSES IN POTS IN FEBRUARY.

A DECIDED movement towards active growth is just now taking place in Auriculas; and even in Manchester, where the weather is pretty generally made up of snow, sleet, rain, fog, smokes, and a consequent continual darkness, the Auriculas are stirring. With this movement comes the necessity for top-dressing. Young roots are put forth near the surface of the soil, and it is necessary to give these something good to feed upon and assist the formation of the trass of flowers. The best top-dressing is made up of cow manure that has been laid aside and becomes dry, some good leaf-mould, and a little ordinary Auricula soil. But as it is certain that grubs and other enemies to plants will have taken up their abode in the manure, it is best to put it into an oven and subject it to a high temperature after being broken to pieces, or to pour boiling water on it, taking care to put it into some vessel, so that the water, which will carry down with it some of the goodness from the manure, may be saved. This is useful for the purpose of giving the plants a good watering before top-dressing is done. In top-dressing, the surface soil should be carefully removed, being particular not to injure—and, indeed, as little as possible, disturb—the root-fibres near the surface. Then add the dressing, leaving space for water to be given when required. At the time of top-dressing, it is well to wash the outsides of the pots, and clean them of dirt and stains; also to brush the foliage with a camel's-hair brush to rid the leaves of green fly, which at this time of year is apt to gather thickly about the young leaves.

Polyanthuses should be similarly top-dressed. They are more advanced than Auriculas, for it can scarcely be said they have rested at all during the winter; *Cheshire Favourite*, *William the Fourth*, and *Exile* are already showing flower. In the open ground, gold-laced Polyanthuses have been blooming all the winter. The plants in pots should have an abundance of air while the mild weather lasts, but cover them up securely in time of frost. Some plants in pots that have stood out of doors on an ash bottom all the winter, are forming very strong crowns, and they are decidedly backward as compared with those plants that have had the protection of a frame. On no account should the plants in frames be kept so close as to allow them to become drawn. D.

#### ROYAL HORTICULTURAL SOCIETY.

The annual general meeting of this Society was held on Tuesday last in the Council-room at South Kensington, the President, Lord Aberdare, in the chair. His lordship pointed out to the Society had improved during the past year, and remarked that the forthcoming four days' exhibition in May next would probably surpass any show yet held at South Kensington. The business of the meeting included the election of members of council, officers, committeemen, and auditors. The report of the Council referred to the temporary suspension of the Society's journal, owing to the death of its editor, Mr. Andrew Murray. It is expected, however, shortly to re-appear. Mr. Samuel Jennings having been appointed editor, as well as assistant-secretary to the Society. The state of the Chiswick Garden is reported to be most satisfactory. This year collections of Peas, Lettuces, Beets, and Leeks will be subjected to critical examination in it, and experiments will be made on the comparative value of artificial manures. The collection of herbaceous plants has been rearranged and largely added to. The Council have also procured collections of some of the more ornamental kinds of these plants and flowers; including *Delphiniums*, *Pononias*, *Pyrethrums*, *Iris*, *Ranunculus*, *Crocus*, &c., which have been separately planted. A rockery, for the stones of which the Council are indebted to their treasurer, Mr. Henry Webb, has been formed opposite the entrance to the Great Vinery, and planted with rock plants, many of which of great interest were presented by the Royal Gardens, Kew; the Royal Botanic Gardens, Edinburgh; Mr. G. F. Wilson, Mr. George Maw, and others. Trials have been made of various kinds of Zonal *Pelargoniums* (which were successfully grown both in pots and planted out in the open border), also of various varieties of *Canna*, *Hegonia*, *Euphorbia*, *China Aster*, *Stocks*, and various sorts of hardy annuals, of which full reports are being prepared. During the past year 255 new Fellows and 231 Guinea Members had been elected, as against a loss of 79 Fellows by resignation and 69 by death. The revenue from all sources for the year was £4886, and, deducting the expenditure, there was a balance in hand of £747, but of this amount life compositions figure for £737. The income from subscriptions was in-

creasing, as well as that from garden produce. The Great Vinery, probably the finest of its kind in the world, the Vines in which are twenty years old, produced an abundant crop, which, at the reduced prices at which the Grapes were sold to Fellows, realised £320. The report was unanimously adopted, and 25 new Fellows were then elected.

#### THE SCHEDULE OF THE SOCIETY'S MAY SHOW.

WHEN this schedule was in preparation it was currently reported that its arrangement was placed in the hands of a few of the principal London nurserymen. That the Council should deliberately ignore its own professional advisers, and almost its own existence, certainly seemed at the time incredible, but it is only necessary to cast one's eyes over the schedule as placed before us to see that its concoction not only has a strong smack of the trade about it, but further, that it is almost exclusively made in the interests of just a few notorious plantmen who keep on hand a regular stock of prize-winners that are as well known to the London sightseers as the Horse Guards are to the frequenters of Whitehall. The Council offer a grand total in prizes of £693 7s.—a fine lot of money, that ought to produce a truly noble exhibition. That it will bring fine examples of the few kinds of plants invited there can be no doubt, but it seems to have been overlooked that there are a few other things that bloom in the month of May that are quite as worthy of cultivation and as attractive for exhibition as the few plants invited by the schedule. Out of a total of thirty plant classes Orchids get four, with prizes amounting to £114; stove and greenhouse and fine-foliage plants get six classes and £154; Azaleas three classes and £67; Roses three classes and £64; *Pelargoniums* four classes and £68; *Ericas* two classes and £44; *Ferus* four classes and £43; new plants (stove and greenhouse, of course) two classes and £30; *Palms* one class and £23; and for a miscellaneous group of plants occupying a space of not exceeding 300 square feet—that is to say, 10 ft. wide and 30 ft. long, a total of £23. Thus, we have only ten distinct sections of plants of the regular show order invited, whilst the group which is not of the nurseryman's order, but is rather intended as a sop to the market grower, and would take about 300 market plants to make it effective, gets just the same amount offered for it as is given for— heaven save the mark!—nine fine-foliage plants. What extraordinary liberality! Collections and dishes of fruit get the small crumb of £53 7s. allotted to it, and quite enough too for a lot of gardeners who are already as rich as Jews, and know nothing of the hard times to which the poor London nurserymen are subjected; whilst vegetables—oh, tell it not in Gath!—get £12 in all for one collection, and precious lucky must vegetable growers think themselves when they hear that the Royal Horticultural Society deigns to notice them to such an extent. There are some other things that could be shown that do not require stoves and greenhouses to bring them to perfection—plants that the million, from the Queen downwards, love to admire and linger over, but which it would, of course, be invidious to name, that are both beautiful to look upon, and the cultivation of which is worthy of encouragement; but these are not of the select order—they are not kept on hand ready made for show, and fit to be trotted out for the gaze of an admiring public at a moment's notice. Perhaps they are reckoned of the vulgar herd, good enough for Lambeth or Whitechapel, but not fit to be seen in Royal Kensington; and yet I remember it was told me that when Her Majesty visited South Kensington last May, both herself and Princess Beatrice expressed high admiration for these simple hardy plants. I may be told that since the Queen has forsaken the Palace of Buckingham and the society of the fashionable world for the wilds of Balmoral, that her taste has become vulgarised. Perhaps so; in any case there will be little danger of such a disaster happening to the visitors to South Kensington next May the 28th.—“Gardeners' Chronicle.”

**Apparent Sterility of *Cochlostemma's* Jacobianum.**—Having seen a fine specimen of this curious and beautiful Bromeliad, with three fine bunches of its ornamental bluish blossoms, growing in an intermediate stove in the rich collection of Mr. Crawford, at Lakeland, near Cork, when visiting it a few days since, I was informed by the gardener that, being very anxious to increase and propagate this still somewhat rare plant, he had done everything in his power to get it to produce seed, but hitherto unsuccessfully; and though all the parts and organs of the flower seemed perfect and fully developed, and though pollen was to be found in abundance concealed in a kind of small pouch in the centre of the flower, yet though carefully taken out and placed upon the style with the point of a camel's-hair brush, there had never been any sign whatever of fertilization or setting of seed. Perhaps some of the readers of THE GARDEN who have been successful in getting this plant to seed, or in propagating it by any other means, will give me the benefit of their experience in the matter.—W. E. G.

**Cucumber Duke of Connaught.**—This is one of the best of Cucumbers either for exhibition or for general use. It is indeed most prolific, producing frequently three fruits a joint, very asymmetrical in shape, and averaging 24 in. in length.—F. Donne, *Middlesexhill, Suffolk*.

A finely-flowered *Oenothera glauca*.—At p. 102 an *O. Alexandræ* in a villa garden at Clapton is said to have borne a spike 4 ft. long, furnished with eight flowers; it should have been eighteen.

To Correspondents.—“T. S.,” Highgate, “A. R. C.,” Grantham, Mr. Larcombe, Lea Hurst, and other correspondents will oblige by sending their addresses, which should always accompany enquiries.

No. 327.] SATURDAY, FEBRUARY 23, 1878. [Vol. XIII.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

**Loranths from Australia.**—A gentleman from Australia has recently arrived in England, bringing with him to Kew living plants of some of the Australian Loranthaceæ growing on the common Oleander. As many of the species of the large genus *Loranthus* are exceedingly handsome, and would be great favourites with everyone, it is to be hoped that this venture may be followed by many equally successful ones. So far as can be ascertained from the notes of collectors, there seems no evidence that particular species affect particular trees; they are found almost indiscriminately on the *Eucalyptus*, *Casuarina*, *Acacia*, *Banksia*, *Melaleuca*, and many other trees. Representatives of all these genera are to be met with in our conservatories, so that we may expect one day to see them act as host plants to some of those gorgeously-flowered parasites which take the place in Australia of the *Mistletoe* of England. The tubular flowers of some of these are about 2 in. long and splendidly coloured, crimson, yellow, and bright green being sometimes most attractively combined in a single species. In the West Indies and throughout the Tropics generally there are numerous species which would be heartily welcomed in any collection of decorative plants. Some commentators, who take no heed of the miraculous side of the question, but attempt to find a natural explanation for everything mentioned in Holy Writ, have suggested that the burning bush seen by Moses was the *Acacia Farnesiana*, thickly covered with a scarlet-flowered *Loranthus*. Although there is no record of this growing on the *Acacia* trees in the desert of Midian, it is so abundant in some parts of Syria, as to give the trees on which it grows the appearance of being on fire.

**Fruit Prospects for 1878.**—In this locality (North Notts) there is at present a very favourable prospect of good fruit crops should the spring frosts not be too severe. Although the weather all through January and up to this date in February has been open, there have been at times some sharp snaps of frost, especially in the last week in January and beginning of February, which have prevented unduly excited growth in fruit trees. Last year the months of January and February were excessively open and rainy, so that the buds of fruit trees began to be so forward that the severe check given to them by the ungenial spring months caused a general failure all over the kingdom. The summer of 1877 had a temperature below the average, but the autumn months were favourable for ripening the wood of fruit trees, and from their bearing thin crops of fruit, there is an abundance of blossom buds formed for this year's crop. Both on walls and on standards in open quarters this is now apparent on all kinds of fruit trees. Mr. Fish, on fruit tree protection (p. 153), gives the soundest possible advice to be prepared with all kinds of protecting materials for covering the walls where the most valuable kinds of fruits are grown, such as Peaches, Nectarines, and Apricots. Where the retarding process can be carried out, the blossoms are often safer from spring frosts if only rendered a week or two later in their expansion.—WILLIAM TILLEY.

**Lectures at South Kensington.**—With a view to render the meetings of the Royal Horticultural Society more interesting, the secretary (Mr. S. Jennings) has decided to deliver a lecture in the afternoons of the days on which they are held on the history, classification, and culture of different kinds of plants in season. The first of these lectures was given on Tuesday last, the subject being the *Cyclamen*. The lecturer, beginning with the hardy kinds, remarked that, as a genus, the *Cyclamen* is confined to the borders of the Mediterranean—South Europe, West Asia, and North Africa; and it could therefore scarcely be considered an English plant; but it could be found in a perfectly naturalised state in some Kentish woods. Two of the hardy species, *C. coum* and *C. hederifolium*, were cultivated in Gerard's garden as long ago as 1596, and *C. persicum* was introduced by Sibthorp from the Isle of Cyprus in 1731. The original *C. persicum*, although very beautiful, was far eclipsed by the magnificent examples shown at this meeting. After alluding to the confusion existing in the nomenclature of the species, Mr. Jennings remarked that for all practical purposes their number might be reduced to six, namely, *C. coum*, *C. ibericum*, including *C. Aikinsii*; *C. vernum*, including *C. repandum*; *C. europæum*; *C. hederifolium*, with its geographical forms of *C. africanum* or *macrophyllum*, *C. græcum* or *latifolium*; and *C. persicum*. After explaining how each kind might be distinguished, he made allusion to the most important of all, *Cyclamen persicum*; observing that a few years ago,

when the drying system of *Cyclamen* culture was carried on, we never obtained anything like the results either in the quantity or quality of flowers as were to be seen exhibited in the Council room that day. Instead of drying off the bulbs, it was found that by growing the plants steadily and naturally on, giving them at all times, even during their season of rest, sufficient water to keep the roots and leaves in a fresh and healthy state, that grand flowering plants could be obtained in a very short period. The improvement of the *Cyclamen* had been very great in every way during the past few years. Whilst some cultivators had striven to obtain quality of bloom, others had endeavoured to secure quantity and size. Some growers had confined their operations to the improvement of the habit of the plant, others to the colour of the flowers; and although each one had in his own way made great strides, yet what was really wanted was all these improved qualities combined, and the lecturer had no doubt that some day these results would be attained. At present, however, it was found that if we improved the size of the flower we destroyed the scent, and we did not get such a profusion of blossom; it was remarked, too, that often seed saved from a given plant would produce plants, some of which would possess a beautiful perfume, whilst others would be completely scentless. Altogether, the lecture was an instructive one, and was evidently so considered by most people present.

**Lapagerias in the Isle of Wight.**—Both the white and red varieties of *Lapageria* grow freely here on a wall in the open air. For the red kind a site was selected on the west side of an ornamental wall, adjacent to the back wall of the conservatory, on which it was planted about five years ago. The wall in question is about 9 ft. 6 in. high, 3 ft. 6 in. of which form the basement, the upper 6 ft. consisting of pillars and arches. The red *Lapageria* covers this wall thickly from bottom to top for a length of 23 ft. The white kind is much younger, but it is succeeding equally well, completely covering a portion of wall about 3 ft. by 4 ft. In autumn both plants are covered with their beautiful waxy flowers. *L. rosea* has been producing blooms in succession for these last five months. A shoot of it made since last May measures 18 ft. in length, young and succulent, but as yet uninjured by frost, which has this winter been sharp enough here to freeze the soil in our cold houses quite hard. On the same wall on which the *Lapagerias* are growing is a large plant of *Rhynchospermum jasmynoides*, which grows and blooms freely.—Wm. STANBURY, *Appby Towers, Ryde, Isle of Wight.*

**Scilla sibirica in the Greenhouse.**—I am so fond of the glorious blue of *Scilla sibirica*, that I every year grow a number of bulbs in a box for the sake of the flowers they supply. Last autumn I was desirous of saving a few store plants of *Mesembryanthemum cordifolium variegatum*, and, being short of pots, planted them in the soil of the box containing the *Scillas*. The box was then put on the top shelf of the greenhouse near the glass, that being one of the warmest and driest spots in the house. The *Mesembryanthemum* has grown and covered the surface of the box, and now the blue blossoms of the *Scilla* are just emerging from the green sheath of leaves which appear above the charming variegation of the *Mesembryanthemum*. It is a mistake to keep the *Mesembryanthemum* too dry during the winter if you can maintain a sufficient warmth to keep frost at bay. I watered the *Scillas* somewhat freely all the winter to get them into growth as early as possible, and the *Mesembryanthemum* has thriven on the moisture so supplied.—D.

**Horticulture at the Coming Paris Exhibition.**—An enterprising firm at Marseilles has offered to place at the disposal of the Exhibition authorities a garden of Bamboos planted in the form of an alley or avenue of some hundred yards in length. It is feared that this offer cannot be accepted, as such a share can hardly be devoted to the purpose without taking from the general effect of the Trocadero. But it is hoped that the administration will be able to utilise the plants by furling them in groups, which cannot fail to produce the finest effect, if properly arranged, which they are sure to be. Another offer, coming from Belgium, proposes to place an immense parterre of rare-flowering plants beneath the central dome of the grand vestibule of the *Champs de Mars*, on the side of the *Pont d'Iéna*. This spontaneous offer has been unconditionally accepted. The requirements of the exhibitors for plants in the parks and gardens of the Exhibition are so numerous, that the Minister of Agriculture contemplates being obliged to rent large spaces in the immediate vicinity of the building, where these floral collections can be carefully stored in reserve, under careful cultivation, until such time as they may be required for display in more prominent positions. One of the greatest floral attractions is expected to be the grand bed of Tulips planted out in November by the Haarlem Florists' Club. Upon this space of ground, some 15 by 17 metres in extent, about 40,000 Tulip bulbs are set, to represent when in bloom the arms of the City of Haarlem, with the word "Haarlem,"

"Holland," underneath. The Tulips used for this purpose are the Rex rubrum and La Candeur, surrounded by a broad border of the double brown flower known as Princess Alexandra.

#### NOTES FROM KEW.

AMONGST cool greenhouse plants the following—all found in the House No. 4—are the most striking:—*Acacia Sophora* is a handsome species with leathery phyllodia, about 2 in. long, and from  $\frac{1}{2}$  in. to 1 in. broad; the bright yellow flowers are borne in spikes about  $1\frac{1}{2}$  in. long. *A. leprosa* has drooping branchlets and narrow, almost linear, phyllodia; the peduncles are short, generally in pairs or clusters, and bear each a globular head of numerous showy flowers. For the decoration of the cool conservatory, these two *Acacias* can be strongly recommended; they are extremely dissimilar in appearance, the one being a stiff, erect grower, the other a light, airy, graceful bush. Both should be allowed to attain a height of 5 ft. or 6 ft. *Correa Harrisii* is a neat-growing species bearing an abundance of very pretty, large-sized flowers of a uniform red colour. *Diosma capitata* is a Heath-like shrub with heads of pinkish flowers. The leaves, when steeped in vinegar or brandy, are—in Cape Colony—universally used in domestic practice, and held to be a certain remedy for most of the ills that flesh is heir to. *Hardenbergia Comptoniana* is a charming West Australian bright purple-flowered climber. *Kennedya rubicunda* has leaves somewhat similar in form to those of the last-named plant, but of a dull, not shining, green and short racemes of large flowers, the standards of which are ruby red, with a paler blotch at their bases, and the keels blood red. *Zieria Smithii* var. *macrophylla* is a pretty Ratæaceous white-flowered shrub; this plant does well in sheltered positions in the open air in the south and west of England. *Clematis indivisa*, from New Zealand, is one of the most beautiful of woody, greenhouse climbers, and, on account of its flowering so freely and so early in the year, it is invaluable for the decoration of the cool conservatory; a coloured plate of it was issued with THE GARDEN for October 27 of last year. *Akaha quinata*, from the Chacana Archipelago, has pretty leaves and dull purplish-brown flowers, the delicious fragrance of which, combined with the graceful festoons formed by the freely-running stems makes up for their lack of brightness.

In the Kew Orchid collection this week there are very few species to note when we except those that have already been recorded in these columns. There are two very beautiful *Dendrobiums*, *D. aggregatum majus* and *D. Hillii* in flower; the former, an elegant and graceful species, is a small one with one-leaved, elongated, channelled pseudo-bulbs and pendulous racemes of flowers of a pale yellow colour, with the exception of the central portion of the large lip, which is a shade or two deeper than the other parts of the flower; the latter—a noble species from Australia—has long stems and thick, leathery leaves of considerable size; the many-flowered raceme, about  $1\frac{1}{2}$  ft. long, springs from the top of the stem, and the great number of yellow flowers more than makes up for deficiency in individual size and beauty. *Epidendrum nutans*, from tropical America, has tall, stout stems, bearing large, coriaceous leaves and dense panicles of rather large, whitish-green flowers; this plant, however, will hardly be found outside a botanic garden.

In the Winter Garden are two plants which deserve mention; they are *Trymalium Billardieri* var. *biratum* and *Anopterus glandulosus*, both natives of Australia. The first is a Rhamnceaceous shrub with roundish, hairy leaves and much branched, terminal panicles of small white flowers. The second is a handsome evergreen shrub with shortly-staked, coarsely-serrated, oval, leathery, shining leaves and upright racemes of white flowers about  $\frac{3}{4}$  in. in diameter, pink-tipped when in bud; this member of the Saxifrage Family attains in some of its native localities a height of 30 ft. or 40 ft.

A fine specimen of *Crimum asiaticum* may be seen in the Palm House. This handsome East Indian *Amaryllid* is a tall-growing species with long strap-shaped leaves and tall, stout scapes surmounted by umbels of pure white flowers.—†

**Apples in Covent Garden.**—The best-looking Apples in Covent Garden just now consist of a kind named *Dieu Donne*, middle-sized fruits, very plump, and well coloured. They realise from 2s. to 3s. per basket of eight or nine fruit. There is still abundance of the American Lady Apple, White Calville, and Reinette du Canada in the market, but Newtown Pippins are nearly over for this season.

**Hardy Flowers in Bloom.**—The beautiful *Irises reticulata* and its variety, *Krelagei*, are now finely in bloom in some of the nurseries about London. *Sisyrinchium grandiflorum album* and the White Hoop-petioled *Narcissus* (*Corburnii* monophylla) are also in flower, together with *Scilla precox*, *Primula denticulata*, and the

pretty white *Saxifraga Burseriana*. Large beds of *Bulbocodium vernum* are now very attractive; as are also those of *Galanthus plicatus* and other Snowdrops.—S.

**Crocus minimus.**—A bed of this rare *Crocus* was in bloom on the 17th inst. in the York Nurseries. Its colour is pleasing and rather novel, being pale purple, inclining to cobaltum pink internally, with sepals brightly veined externally with deep purple. The blossoms are in form much like those of *C. Sieberi*. It is earlier than most species of *Crocus*, a circumstance which gives it additional value.—B.

**Golden Juniper.**—One of the best coniferous plants which we possess is *Juniperus chinensis aurea*, which, unlike most of its class, retains its true character throughout the winter. Good specimens of it may be seen in Mr. Turner's nursery at Slough.

**Sechium edule.**—Messrs. Gair's, of Covent Garden, have favoured us with specimens of this curious Cucurbitaceous fruit, which, as tested here appears to have no merit or distinction beyond that of any tasteless half-succulent vegetable substance.

**Japanese Chrysanthemums.**—In order to encourage the culture of this most beautiful section of this popular winter-flowering plant, Messrs. Dixon & Co., Amhurst Nurseries, Hackney, provide in the schedule of the show to be held in the Royal Aquarium, Westminster, in November next, special classes for them, in which valuable prizes are offered.

**A Finely-flowered Dendrochilum.**—A large plant of *Dendrochilum filiforme*, growing in a pan in one of the Orchid houses in Messrs. Veitch's nursery, at Chelsea, is now furnished with no fewer than seventy strong flower-spikes. Though not one of the showiest of Orchids, yet, when so well grown and flowered as this is, it is both graceful and effective.

**A Good Azalea.**—One of the most showy and useful of early-flowering Indian Azaleas is *S. Ruoker*. Its blossoms, which are very large and waxy, are of a violet-pink colour edged with white, the upper petals being blotched with deep crimson. Plants of it in bloom in the nurseries round London are just now very attractive.

**Two Spring Flowers** are now in great beauty at Glasnevin, viz., *Iris reticulata* and *Rhododendron præcox*. The former is on a south border, and is producing an abundance of blooms, which, as regards colour and beauty, might favourably compare with many Orchids. As to the *Rhododendron*, even at this season of the year, when good flowers are scarce, it is one sheet of bloom. It is, however, rather delicate, and is liable to be spoiled by spring frosts.—F. W. MOORE, *College Botanic Garden, Dublin*.

**New Crocuses.**—We have received from the Colchester Bulb Company a novelty in the shape of a crimson and white *Crocus*, colours which we do not remember to have met with together in the same flower before. It ought, therefore, to be the forerunner of a new race of *Crocus*. It was discovered in an importation of *C. alatavicus*, and the name of *C. alatavicus porphyreus* has been suggested for it. *C. alatavicus ochroleucus* is another new form which was also found in the same importation. It is, as the name implies, pale yellowish-white.

**Narcissus minor.**—About London none of the *Daffodils* in the open air, except this little early kind, has as yet flowered. It is, as it was in Shakespeare's time, one of the most beautiful and interesting of our early spring flowers. Mr. Parker, of Tooting, showed some healthy little tufts of it the other day at Kensington.

**Garden Depredations in Kent.**—Attention is being called to garden robberies in various districts. A correspondent of a metropolitan contemporary states, that on Monday night his garden at East Peckham, Tunbridge, was stripped of its Snowdrops and Hepaticas, which were taken up by the roots. Within a few days many of his neighbours' gardens have shared the same fate. He attributes his loss to the itinerant sellers of flowering plants, and says those who buy from this class of men are encouraging a system of robbery which is extremely annoying to their country brethren.

**Begonia ornata.**—For clothing pillars or bare walls in greenhouses and similar places, where *Cissus discolor* will not succeed this *Begonia* forms an excellent substitute. It grows freely in any cool house either in a shady or sunny position, and its large stiff green leaves, marbled with white veins, are very ornamental. It is easily kept free from insects, and, being a plant of rapid growth, bare walls can be hid by it in a very short time.—C. S.

**Niphobolas Heteractis.**—For rockwork in greenhouses, or for growing on dead trees, Fern stumps, this is one of the best Ferns which can be employed. It is a rapid grower, and having creeping rhizomes and long, smooth, strap-like leaves, it soon covers whatever it is required to conceal. Cones or pyramids of it might also be introduced into rooms with good effect.—S.

## THE FLOWER GARDEN.

### MOLOSPERMUM CICUTARIUM.

THERE is a deep green and Fern-like beauty displayed profusely by some of the Umbelliferous family, but I have rarely met with one so remarkably attractive as this species. It is a very ornamental plant, with large, deeply-divided leaves of a lively green colour, forming a dense irregular bush. The flowers, which are insignificant and of a yellowish-white colour, are borne in small roundish umbels. Many of the class, while very elegant, perish quickly, get shabby indeed by the end of June, and are therefore out of place in the tasteful flower garden; but this is firm in character, of a fine rich green, stout yet spreading in habit, growing more than 3 ft. high, and making altogether a most pleasing bush. It is

*Molospermum cicutarium.*

perfectly hardy, and easily increased by seed or division, but rare as yet. It loves a deep moist soil, but will thrive in any good garden soil. It is a fine subject for isolation or grouping with other hardy and graceful-leaved Umbelliferous plants.

R.

### HARDY FERNS IN PLEASURE GROUNDS.

IN most gardens there are situations which, owing to perpetual shade through buildings or trees, are found extremely difficult to embellish satisfactorily. Places of this description occur frequently in the neighbourhood of the dwelling-house, and are often a source of vexation, as the majority of flowering and fine-foliaged plants will not thrive therein. For such localities hardy Ferns are the most suitable occupants, inasmuch as the self-same conditions which prove so fatal to the well-being of the majority of ornamental plants are just those which enable them to maintain themselves in health and luxuriance. The construction of a Fernery is often supposed to entail a considerable amount of labour and expense, and it is this consideration which deters many from undertaking the culture of hardy Ferns. The Fern tribe is a large and varied one, and if it is desired to cultivate a large variety, then, undoubtedly, a good amount of forethought and care will be necessary to ensure success. There is, however, a considerably large class which is really hardy in every sense of the word, inasmuch as they will thrive in almost any situation, and require but an ordinary amount of care to be taken in planting. And amongst these are fortunately to be found great variety and exquisite beauty; they are, therefore, all that can be desired for our purpose. Many varieties of *Lastres*, *Asplenium*, *Scolopendrium*, and *Polypodium* will flourish in the most ordinary garden soil, and can hardly be excelled in elegance of form and diversity of growth by the more tender kinds. They may be easily procured at a cheap rate of

any nurseryman, and some of them, such as the common *Poly-pody*, the male and Lady Fern, are to be found plentifully in moist hedgerows, from whence they may be safely removed in early spring before growth commences. These varieties are mostly strong growers; they should, therefore, be so planted that they are not stinted in the way of nourishment. Ferneries upon a small scale are apt to dry up in hot weather, and the occupants fail to obtain that luxuriance which constitutes one of the greatest charms of the Fern tribe. Although something in the way of burrs, stumps, or sandstone is necessary to keep the soil open, yet this kind of material should be introduced in the present instance merely to effect that purpose, leaving as great a bulk of mould as is consistent with good drainage. The cheapest material that can be employed is the root stumps of trees. In country districts hedges are being grubbed up occasionally, and a good cardoam may be purchased for a few shillings. Those living in the neighbourhood of populous towns could arrange with some friend in a rural district to consign a load to them as an opportunity might occur of procuring them. They are admirably adapted for the purpose, and not only serve to efficiently drain the soil in which they are placed, but appear to retain in themselves a certain amount of moisture, even in very dry weather. Root stumps are often objected to on the ground that they ultimately rot away. That is, however, no detriment in the present case, as by the time they do so, the plants are well established, will have filled the soil full of fibre, and eager to feed upon the decaying matter which is thus presented to them. As to soil, there is no necessity to be at all particular. If some turfy loam or rough peat can be easily procured, they will be benefited by an admixture of it. Ordinary garden soil, with some of the roughly-sifted portion of the refuse heap will meet their requirements. No garden can be considered properly furnished without Ferns of some sort, and many a dark, dingy corner may be simply and almost inexpensively beautified by them. Where winter verdure is desired, the evergreen kinds need only be employed. In a general way, however, they should be used with the deciduous ones, as they contrast so beautifully when bursting into growth in spring.

JOHN CORNHILL.

*Byfleet.*

### FANCY PANSIES.

THE coloured illustration in THE GARDEN of Fancy Pansies, done with so much fidelity to Nature by Miss Duffield, carries me back to a time when they were quite new to English florists. That was about the year 1859. For many years past raisers of English Show Pansies from seed have been familiar with the fact that, along with these seedlings, there were constantly occurring Pansies of such eccentric colouring and curious markings as to deserve the title of Fancy Pansies. But they were invariably rejected, because it was felt that such forms would render impure the fine varieties then being raised for show purposes. Mr. John Downie, of Edinburgh, however, did take a few of these in hand with a view to their improvement, but it was left to a Continental florist, the late M. Miellez, of Lille, to take the first decided step forward in the march of their improvement. The Continental seedlings were named, and some of the London nurserymen—notably Messrs. E. G. Henderson & Son, then of the Wellington Road—imported a quantity of them and offered them in their catalogues.—The earlier varieties were named Bobo, Eva, Eckard, Carberus, floribunda, &c. Then followed something decidedly superior, such as Prince Imperial, Ali Bey, Parpailot, Miracle, Agnes Sorrel, Napoleon III., Masaniello, &c. These came to England about 1858 or 1859. In 1860 still finer kinds made their appearance; amongst them were Belle Equermeuse, Louis Miellez, Distinction, Levathan, Princess Mathilde, Michael Ange, Dandie Dinmont, and Belle Lilloise. I well remember the sensation which these produced, and there was this advantage about them, that they were of a decidedly vigorous constitution, and stood better than the more delicate high-bred English Pansies. In 1861 two other varieties came over from France, from M. Miellez, viz., Noemé Demay and Octavie Demay, and these were the last of his productions, for he died soon after. By some means, the two last-named proved of more delicate constitution than any that preceded them. Meanwhile, English-raised seedlings were raised, and soon distanced those received from the Continent. The cultivation of Fancy Pansies was then generally taken up, and up to this time they have remained highly popular and attractive border flowers.

D.

*Mirabilis multiflora*.—Botanical tourists and collectors in Colorado narrate that among the more remarkable features of the Flora of Canon City, the abundance of the *Nyctaginaceæ* or *Marvel* of Peru Family is specially noteworthy. Of these probably the most remarkable are the *Mirabilis multiflora* and the *Abronia fragrans*.

*M. multiflora* differs somewhat in habit from the common Marvel of Fern, being a diffuse trailer, with much branched glabrous stems, thickened joints, and heart-shaped, rather pointed foliage. The flowers are produced both from the extremities of the branches and from their upper axils, and arise from a cup-shaped involucre about 1 in. long, from four to six blossoms being produced from each. The funnel-shaped calyx, for such is the coloured perianth in this genus, and not a true corolla, is about 2 in. long, of a pleasing mauve-purple colour, with an Ipomœa-like aspect, which doubtless suggested Torrey's name of *Qumœlidion* formerly given to this and the allied *M. oxybaphoides*. It produces a tuberous root, which is perennial and quite hardy in dry soils, though, like that of the *Mitribilla jalapa*, it may be taken up in autumn and preserved in a pot of dry soil. In favourable seasons it blooms the first summer, when raised early in a frame. A coloured illustration of this plant appeared in the "Botanical Magazine" for 1876.—W. THOMPSON, Ipswich.

### SEED BUDS OF LILIES.

MAY I ask "Dunedin" if he experiments and writes on *Lilium auratum* and supposes that his observations apply to all Lilies? *L. auratum* and all the varieties of *L. speciosum* form at the base of the flower-stem, in the heart of the bulb, two Lily buds, one on either side of the stem. This is readily proved by carefully removing the surface earth, when the flowers fall, and cutting the stem close to the bulb without disturbing the large roots that fill the pot, when the following year two strong shoots will push up, and the original single bulb be split into two large bulbs; but there is no such thing as any part dying away or decaying but the flower-stem. That the bulb is forced open by two Lily buds springing from a common centre is evidenced by the two shoots or stems coming up the following spring divaricating, and not vertical, to one another. If but one Lily bud comes up, it is certain proof of the plant not having sufficient of the requisite elements in the soil for its full development; and the roots decaying and the leaves turning yellow and dropping off are certain indications that sufficient vitality cannot be maintained to resist chemical action. The disease, mould, or fungus he talks of is the result, not the cause, of the decay of the plant, and any dead vegetable matter in the same earth would be doubtless found covered with the same species of mould. The bulbs of *L. longiorum*, again, are very different. They come up (with me) in a cold house, much earlier—six weeks at least—and as soon as the flower-buds show early in spring, I cut the stems down to the surface of the earth; four or five shoots will then come up and bloom with far finer flowers in September and October than would otherwise be the case, and continue in perfection very much longer. The Lily buds from which these sprang I consider to have had their origin at the base, but outside of the original single bulb, as I find on turning out the pot in December as many bulbs as shoots, all of the same size. And I suspect this is the case with *L. Humboldtii*, *Washingtonianum*, *negligerense*, *Brownii*, *Kramerii*, *superbum*, &c., as I find small plants come up in a slanting direction some inches from the large bulb which sends up the flower-stem. But that the large bulb annually decays, I know is not the case from personal observation. I am inclined to think that we shall never grow Lilies to their full perfection until a very careful chemical analysis has been made of their seeds, especially as regards *L. auratum*; and as yet I have never been able to procure sufficient for the purpose. We must therefore trust to experience till this is done; but if any of your readers who grow *L. auratum* very strongly (that is 7 ft. to 8 ft. in height, with enormous heads of bloom) would state the nature of the soil and where it came from, it might be the means of detecting the elements requisite for its full development; and that there is some special requisite for this Lily is certain, for whereas we see it so often stunted and sickly, it may be found thriving vigorously in the lightest peat and the stiffest loam. I find I must add *L. tigrinum splendens* to the bulbs of *L. speciosum* with two internal buds, for in the autumn I cut down a large one in a pot close to the bulb as an experiment, and now there are two shoots considerably thicker than my thumb pushing up with extraordinary vigour, which has very much surprised me. I do not know that it is anything new, but I got some of my best bulbs of *L. auratum* from cuttings. The small shoots which frequently come up round the bulb, if off a little below the surface of the earth, readily strike and form a bulb, and, as more shoots come up, I continue the operation during the summer. I have got some of these to bloom the following year.

ANATEUR.

"Dunedin" says, "While one bulb is flourishing (p. 27) in its first and only bloom, another bulb within it—mark these words, 'within it'—not outside, as offsets of any description whatever, another

bulb, a new bulb within it, is progressing in its growth so as to be enabled to bloom next year in place of the one now blooming, which will then be dead, thus keeping up a yearly bloom from successional bulbs *ad infinitum* if properly cultivated. . . . Every year witnesses a birth and a death, that is, the birth of the seed-bud and the death of the flowering bulb, being the youngest and oldest of the 'three generations in one,' the new bulb being always an intermediate between these two." Now "H." at p. 86, seems to think he invalidates this theory by taking the case of a bulb grown from seed. He says, "I hold in my hand a Lily bulb grown from seed sown last year. If this Lily were an annual, this little bulb, which is about the size of a Pea, would surely flower. But, no; it will continue to grow for a few years to come, and then flower." But if "H." keeps his small bulb growing, he will find it will throw up a stalk next year, not strong enough, it is true, to bear flowers, but yet partaking of the nature of a flower-stem; the old bulb will pass into that stem, and the new successional bulb will be fed by that stem, by the scales that form it, and by the new roots, and so on year by year till the successional bulb is large enough to bear a flower on its stalk and strong enough to be parent and foster-nurse to a still greater bulb. The small bulb, no bigger than a Pea, doubtless contains within itself a tiny seed-bud for the future successional bulb. I hope I agree with "Dunedin" about Lily bulbs from seed, as no doubt their mode of reproduction is not so clear when the bulbs are only a year old in the seed-bed. I could wish "Dunedin" had not implied that there is no certainty about imported Lilies flowering the first season, as out of a hundred or more planted in the open border in March, I have found every one produce flowers. Of course, they were all fine bulbs; but most imported bulbs are rather large and pretty sure to flower. I do not think that imported Lilies are thoroughly established till the third season, as the first season they flower well from the strength of the bulb, which is exhausted thereby and by the long voyage, and so the successional bulb for the next summer's flower is not properly fed; the third year they may be considered thoroughly established and proved.—FRANK MILES, Bingham, Notts.

### CHRISTMAS ROSES.

I HAVE frequently wondered why the *Helleborus* is not oftener made a subject of special culture in gardens than it is, considering its value as a winter flower, and its easy management. We have a pretty extensive and well-selected stock of herbaceous plants here, but amongst them nothing is thought more of than the Christmas Rose, which produces its pure white flowers in the depth of winter, and without forcing or attention. A good deal has lately been said about the white *Abutilon*, *Boule de Neige*, as a handsome white flowering plant; but we have had both it and the Christmas Rose in flower here at the same time, and we certainly give the preference to the latter. Though they resemble each other a good deal, the *Abutilon* is poor and frail compared with the Rose, the waxy and pure white flowers of which are far better adapted for decorative purposes than those of the other. Indeed, the flower-buds, just before they fully expand, are quite equal to those of the white Rose as far as appearance goes, or a *Camellia* bud, and they are often used instead of them for button-holes, set up in a Fern frond or green leaf. I notice that they are extensively used for such purposes in towns about Christmas time; but the supply is by no means abundant seemingly. I would strongly recommend every possessor of a garden to plant Christmas Roses extensively; but they must be careful to get the pure white kind, for there are numbers of species and varieties. *Helleborus niger* is the best kind, and the Scotch variety of this, which is semi-double, is said to be much the finest; but I doubt if it surpasses the single one, which is so particularly attractive in the bud state. *Helleborus atro-rubens*, which has red flowers, is also described as a handsome kind, but I do not think that it is worth growing; and the same applies to *H. orientalis*, which has flowers of a dirty greenish hue, altogether inferior to those of the pure white kind. The latter is extremely hardy, and will grow in almost any soil and in any situation, but it deserves a good position in order to have it in flower early, for its blooming at Christmas depends a good deal upon the weather. This winter, owing to the long continuance of soft, mild weather, the flowers were well up by the new year, but in some seasons they do not expand till the month of March. A good sunny position on a south border, however, hastens their progress; a hand-light placed over each plant helps also to push them on, and at the same time keeps the flowers clean—an important matter, for they get so bespattered with mud when exposed to heavy showers as to be almost unfit for use, and attempting to clean them only makes matters worse. For this reason it is best to grow the plants in isolated patches, about 2 ft. across or less, for the sake of protecting them conveniently, and the lights or cloches should be put on them in November. The

Christmas Rose is propagated by means of seed and by division, but the latter plan is the best and most expeditious. Single crowns detached and planted in good soil will make large plants in a short time. It is an excellent plant for shrubberies, and should be planted freely in all warm and sheltered corners. In such situations it should be planted as extensively as Daffodils, Crocuses, Snowdrops, &c., which it just precedes in flowering, and, being an evergreen with handsome foliage, it is interesting at all seasons of the year. CHEE.

### LIFTING ANEMONE FULGENS.

I CANNOT agree with Mr. T. Smith, Newry (see p. 113), as to the advisability of taking up the roots of this Windflower after the tops have died away, as these, like all plants of a similar nature, do best when left in the ground undisturbed. At least, this is the case where the soil is anything approaching a friable nature with free drainage, so that they may be moderately dry during the winter, as then there is no shrinking or loss of weight through escape of sap stored up to enable them to start away vigorously again when the proper season arrives for their doing so. It is a well-known fact by those who have anything to do with hardy bulbous or tuberous-rooted plants that taking them up annually tends much to weaken them, as it is impossible to keep them in that plump, healthy condition they always remain when allowed to stand where they grow. Nothing shows this in a more striking manner than *Gleditsia*, which, if dug up and wintered in the way they generally are, lose at least half their weight, and are weakened in a corresponding degree. Of course, it would not be safe to leave these out in some places, but if the soil were properly prepared at planting time and a good sprinkling of sharp sand placed around the crowns, it would be so in the majority of cases, and I am convinced that those who once try them in this way will never again resort to the practice of taking them up. For the purpose of getting a succession of bloom it is all very well, as different plantings may be made, but if really fine spikes are desired, the best plan is to leave them alone, as there is no loss in size, health, or vigour. It is the same with Anemones and all other plants of a kindred character, and the closer Nature is followed with these, as with anything else, the more satisfactory will be the results. In the case of those of doubtful hardiness, it is a good plan to lay a shovelful of coarse coal-ashes over the top, as these ward off sharp frost, and at the same time admit plenty of air, while, being absorbent and porous, they drink up moisture and part with it quickly, thus rendering plants under them in a snug, comfortable condition. As to the proper time of increasing *Anemone fulgens*, I agree with Mr. Smith's remarks, for to take the roots up after the leaves have made their appearance above ground would be a most improper proceeding, and cause such a check, that the plants would be some time in recovering. The best time for dividing all roots of this kind with a view to increase is just as they are breaking, as then they start away quickly, and the injured parts heal rapidly over, in which process they are greatly assisted by the foliage and young feeders then forming. The modern system of bedding has had much to do with the proofting and storing such plants as the above, as, unfortunately, they are torn out to make room for the summer display; but if small tubs were made of heart of Oak, they would last many years, and might be used to mark the sites of each patch, so that there need be no risk of disturbance; or better still, perhaps, would be some pegs made of stout galvanised iron wire turned at the top so as to form a loop or ring large enough to put the finger through. These would then have an exceedingly neat appearance, and be less conspicuous than anything else, in addition to which they would last a lifetime. If bulbous and tuberous-rooted plants were cared for in this way, they need not be so frequently disturbed, and there would not be the annoyance there now is by such continual losses arising either through repeated lifting and bad storing, or from injuries resulting through workmen digging and cleaning the borders. S. D.

### NOTES ON VEGETATION TO JANUARY 31, 1878.\*

It has been observed by many that the year 1877 has been remarkable for the untimely flowering of many vegetable productions, a circumstance probably arising from different causes. In the case of shrubby plants, the unripened state of the wood at the proper time, occasioned by the recent sunless summers, might induce such a result; and in the case of herbaceous and bulbous plants, the undeveloped state of their roots, caused in most cases by excessive moisture, might bring about the abnormal conditions just referred to. The comparatively mild state of the weather during autumn and early

winter has been the means of inducing many plants to produce blossoms at later periods than usual; even bouquets of hardy flowers have been sent to us from various quarters to show what has been produced in many gardens different from former years. At the present time (31st January) the leaf-buds of Lilacs, Scarlet Ribes, *Cydonia japonica*, and Roses are all far advanced, the latter still flowering in the open air, and in some places near the sea particularly fine. This unnatural state of matters will be much against the reports on open-air vegetation which I am annually in the habit of drawing up. During most seasons, a period of rest between autumn and the spring months takes place, sometimes owing to long and severe frost and snow, or continued drought, all of which are essential to vegetation, particularly after a good and productive summer. If all is favourable, spring plants advance regularly and successively, and their dates of flowering can be recorded. This winter many plants have been flowering more or less continuously since autumn, but particularly during December and January, as, for instance, *Veronica rupestris*, *Lithospermum fruticosum*, *Pentstemon alba*, *Gentiana acaulis*, *Helleborus* of different sorts, *Heptacodium triloba*, *Aubrietia grandiflora*, *Primula vulgaris*, *Polyanthuses*, Stocks and Wallflowers, *Arbutus Unedo*, *Erica carnea alba*, also *Senecio pulcher*, which has been particularly fine this winter, and is still flowering on the rock garden. During 1877 the Hazel was in full flower all through January; no fruit, however, was produced, in consequence of the male catkins being destroyed while in perfection. This year, although the Hazels are covered with catkins, not one flower expanded during January; the *Garrya elliptica* (male) has been in flower since the 25th of December, while last year few flowers were produced, and none before the middle of January. The *Jasminum nudiflorum* is also in flower, and has been so during most of the winter months. Several herbaceous plants, which are usually noted as being in bloom during January, are not yet out, such as *Tussilago fragrans*, *Sternbergia lutea*, *Lencojum verum*, *Crocus Imperati*, *C. susianus*, also the common Snowdrop, *Galanthus nivalis*, except a few on the lawn close to the Palm house, where no frost ever reaches them. Many thousands of this plant exist in the garden, both in beds and on Grass lawns, but not one is yet to be seen in bloom (Jan. 31). This is rarely the case with Snowdrops during January, except where their roots have been long covered with snow or frozen in, and they may not be able to flower before February, but which was not the case this year. Several shrubby plants are also late—kinds which are usually seen in flower about the middle of January—such as *Laurustinus*, *Daphne Mezereum*, *Rhododendron atrovirens*, *R. Nobileanum*, and *Cornus mas*. At the present time it is difficult to say, with any degree of certainty, what the fruit crop may be for the present year. Fruit-buds on many trees seem to be well formed, and, in all likelihood, the smaller kinds will ripen freely, but the prospect is more doubtful in the case of the larger fruits, such as Apple, Pear, and Plum, although blossom-buds have the appearance of being copiously produced, probably in consequence of having little or no fruit to mature last year. The seeming immature state of the wood, however, from the recent sunless summer, followed by recent frosts, may operate against the proper ripening of the fruit, as has been the case in many places for the last two years, and may be so this, unless the season should prove to be exceptionally fine. It has often occurred to me that when a large amount of blossom is produced, and all allowed to open, this excess of bloom generally assists to deteriorate the strength of the wood, independent of the weakness engendered by recent sunless summers. In several instances I have recommended parties to have a quantity of the blossoms cut off while in the bud state, leaving only what may be considered sufficient for the trees to mature. When all the buds produced are left to open, much of the bloom falls off from weakness or gets ruined by caterpillars; whereas, if fewer blossoms be left on a tree, the blossoms are more likely to open and ultimately come to maturity, besides saving the wood, which a crop of immature fruit from unripened shoots must necessarily damage.

To continue the meteorological tables carried on by me during the last twenty-three years, showing the amount of frost each month from October to April, I have to add the following observations:—In October, 1877, the thermometer was six times at or below the freezing point, amounting collectively to 15°. The lowest markings were on the mornings of the 3rd, 9th, 12th, 17th, 18th, and 19th, 31°, 31°, 32°, 27°, 24°, and 32° being respectively indicated; while the six highest morning temperatures were on the 7th, 14th, 15th, 22nd, 30th, and 31st, when 50°, 53°, 55°, 49°, 45°, and 45° were indicated. During November, 1877, the thermometer was six times at or below the freezing point, amounting collectively to 32°. In 1863 110° were registered, the lowest during 1877 being on the 21st, 24th, 25th, 26th, 28th, and 30th, when 23°, 24°, 25°, 28°, 31°, and 29° were respectively indicated. The six highest morning temperatures were on the 1st, 2nd, 4th, 5th, 6th, and 15th, when 44°, 44°, 41°, 44°, 45,

\* Read the other evening by Mr. James McNab before the Botanical Society of Edinburgh.

and 41° were indicated. During December, 1877, the thermometer was fourteen times at or below the freezing point, making in all 63°. In December, 1876, 43° were registered; in 1875, 81°; in 1874, 277°; and in 1859, 337°. The lowest temperatures in December last were on the mornings of the 3rd, 14th, 25th, 26th, 27th, and 28th, when 28°, 28°, 21°, 17°, 26°, and 23° were indicated; while the six highest morning temperatures were on the 10th, 16th, 17th, 19th, 21st, and 22nd, when 43°, 40°, 44°, 40°, 44°, and 46° were indicated. In January the thermometer was seventeen times at or below the freezing point, indicating collectively 101°, 73° being registered during 1877, and 103° during 1876, while in January, 1864, no fewer, than 39½° were registered. The lowest markings during January, 1878, were on the mornings of the 10th, 11th, 22nd, 25th, 30th, and 31st, when 22°, 23°, 22°, 14°, 21°, and 23° were indicated; while the highest morning temperatures were on the 4th, 6th, 14th, 15th, 16th, and 20th, when 40°, 40°, 41°, 41°, 41°, and 40° were indicated.

#### HARDY PLANTS FOR POT CULTURE UNDER GLASS.

In addition to the plants named for this purpose by Mr. Fish (see p. 132), I would strongly recommend *Lonicera fragrantissima*, which is one of the best hardy winter-flowering plants in existence; not that its blooms are particularly striking or showy, but they are so deliciously fragrant that one or two sprays added to a glass or spyglass are sufficient to perfume a large room. Grown in pots and plunged in a sunny situation, so as to get it well ripened, and kept in a somewhat stunted condition, it is of an exceedingly floriferous habit, so much so that every joint is crowded with buds that keep on expanding for many weeks in succession. The first blossoms make their appearance towards the end of the year, a season when they are doubly valuable, as it is admittedly a dull time in gardens, even in large establishments, for just then *Chrysanthemum* are over and forced things are not in. A half-dozen or so of *Lonicera fragrantissima* dotted about in a greenhouse would do much to give it a cheerful aspect, while they would render it most enjoyable by the sweet odours exhaled. Even those who have not the convenience of such a structure may have a plant on the walls of their dwelling, or in some sheltered sunny nook, as a shrub, or in pots in their windows, for the latter of which purposes it will eventually be highly prized in towns and cities, as it is not of that fleeting nature peculiar to many plants, the beauty of which is over almost as soon as purchased. Honeysuckles, too, have a charm of their own, carrying one in imagination to woody scenes and hedges where its native congener climbs, clothing bare stems and twigs with such perfect grace and beauty. Although introduced by Mr. Fortune many years ago, *Lonicera fragrantissima* appears as yet to be little known, which, considering its time of flowering and its usefulness for working into bouquets, is a matter of surprise, seeing the great demand there is for blooms of the choice sweet character this is, and so well adapted for mounting. Those who are not so fortunate as to have the above-named Honeysuckle will find the present the best time to get plants of it, as, being deciduous, it will not transplant well later in the season. Where desired, an increase may be readily effected by taking off the young shoots with a heel when they have attained a length of 3 in. or 4 in. These, if inserted in sandy soil and placed in close moist heat, will soon root and form good plants by the autumn, if stopped once or twice meantime so as to induce them to break and grow bushy. On walls, the thing is to coax up the main shoots so as to get them to the required height as speedily as possible, and then encourage plenty of small breast wood on which most of the flowers are borne. As these suffer from the inclemency of the weather, a south aspect, where they can have the friendly shelter of a coping or overhanging eaves, should be chosen. S. D.

**Gymnoloma Porteri.**—This genus will probably be new to most people. It belongs to that apparently inexhaustible Natural Family, the Compositae, and is limited to the North American Continent. One species, *G. multiflora*, is a native of Colorado, and is not without some claims to notice, but has the serious defect of flowering too late to mature seed in this climate. *G. Porteri*, now first introduced, is an exceedingly rare plant, occurring only on Stone Mountain, Upper Georgia. It grows from 2 ft. to 3 ft. high with a very bushy habit, neat lanceolate to linear, alternate, entire foliage, and a profusion of bright yellow Coreopsis-like flower-heads nearly 1 in. broad. It is in perfection about the middle of September, at which time the flowers completely cover the plant. The disk of the flower is conical, as in the *Rudbeckias*, and it was in that genus that the plant was first placed by Prof. Gray. Both species also share the questionable advantage of a synonymous designation, that of *Heliomeris*, under which name the *G. multiflora* occurs in Porter and Conlter's Synopsis

of the Flora of Colorado. Of the ornamental value of this plant there is little doubt, and although it may not mature seed in this country, France and Italy are close at hand, and will lend us their sunny skies. It will need the treatment of half-hardy annuals, and should be sown early.—W. THOMPSON, Ipswich.

**Seeding Plants of *Lilium auratum.***—Anyone growing this Lily from seed must be prepared to exercise patience, if my experience of its reluctant powers of germination be general. Some good seed was taken when fully ripe from the pods and sown in a pan, and placed in a cool house last April. During the summer and autumn no signs of growth appeared, but as I found the seeds to be still firm and sound I allowed it to remain undisturbed through the winter. My reward is at length assured; the seed has germinated, and the minute green spears are piercing the soil. Perhaps in a gentle heat they would have shown sooner, but they were in a cool house. I would have liked them to have remained dormant for another month, but in the hope of preventing the damping-off of the young plants, I kept them rather dry, and have covered the surface of the pan with dry silver sand.—A. D.

***Gillenia stipulacea.***—Most cultivators of the choicer hardy perennials are more or less familiar with the *Gillenia trifoliata*, a plant figured by Curtis in the 14th volume of the "Botanical Magazine" under the name of *Spiraea trifoliata* and justly termed by him, as being, when in perfection, a most delectable plant; *G. stipulacea* differs but slightly from it, chiefly in having leafy, ovate, serrate stipules, those of *G. trifoliata* being small, linear-pointed and entire. Like its congener, it grows from 1½ ft. to 2½ ft. high, with sparingly branched, slender stems, bearing trifoliate leaves above, the lower ones being almost pinnatifid, all lanceolate and nearly stalkless. The flowers are borne in loose panicles on long foot-stalks, each flower having five very long narrowly-lanceolate petals arising from the mouth of a tubular-campanulate calyx. In the bud the petals are deep rose, and they retain a tinge of rose after expansion. It loves a north or north-east exposure, and succeeds best in peaty soil with a small admixture of loam. The seeds are best left to spontaneous growth in a cold frame. It is a native of the States bordering on the Mississippi; *G. trifoliata* being found chiefly in the Eastern States.—W. THOMPSON, Ipswich.

**Keeping Down *Lilium.***—There are few who have gardens and I plants in pots who do not require at some time or other to place them out on the ground—perhaps in the shade during summer, or plunged in ashes or in a frame in winter. Worms in such cases are often troublesome, and to keep them from entering the pots is a desideratum. Having, during the past winter, to set a large quantity of plants in small pots in a frame placed on the ground, I first levelled and flattened down the soil, and then strewed all over it fine slaked lime to the thickness of about ½ in.; over this again was placed ½ in. of fine ashes, and on this bed the pots were placed. As a result, although three months have elapsed, not a worm has given sign of its presence in any of the pots, and I feel that the plan has proved entirely successful.—A. D.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Propagating Violas.**—I find all kinds of Violas to strike by far the best in the form of short, stubby cuttings put in in September. Cliveden Yellow, a great favourite here, we struck by the thousand in an east border, and just now (Feb. 15) they are all fairly started and beginning to grow and flower.—R. GILBERT, *Burghley*.

**Gladioli in Rose Beds.**—Allow me to supplement the suggestion of Mr. George Paul (see p. 138) by adding the Gladioli as desirable to plant among Roses. They come into bloom when the first Roses are over, and help to prolong the gaiety of the beds. I may add that I left my Gladioli in the Rose beds all through last winter, and they turned out much better than I expected. As it will soon be the season for planting out Gladioli, may I suggest that some of the readers of THE GARDEN will try the above, and the result I am certain will prove satisfactory.—J. T., *Elghaston*.

**Double Pelargoniums.**—Many of the double-flowered Pelargoniums of recent introduction possess the compact habit and free-flowering qualities of the best of the single varieties. One of the most free-blooming is the semi-double Wunderful, which is of the same habit and colour as *Vesuvius*, from which it is a sport; and one of the most useful is Madame Thibaut, a grand rose-pink. *Député Anelou*, deep rose-purple, *Litré*, another rose-purple, and *Le Nord-Est*, bright scarlet, are also fine. *Candidissimum* is said to be the best white.—"Florist."

**Hardy Flowers at Tooting.**—*Allium neapolitanum* and *Senecio pulcher*, stated (see p. 136) to have been grown at Tooting, were grown here in a greenhouse, and I doubt if either of them will stand out-of-doors. I took Mr. Barr a much more uncommon thing, a blooming bulb of *Aclis trichophylla*, which might be worth mention. It is figured as *Lencium trichophyllum* in Bot. Reg. vii., 544, and is more curious than pretty.—A. R., *Bromley Common*.

GARDEN BOTANY.

(Continued from page 148.)

THE TESTA.—Disregarding size, the seeds of all plants present some external differences by which they may be determined either in the appendages, colour, surface, density, or other characters of the testa. Whole families are characterised by certain peculiarities, and, on the other hand, in some families the seeds are very various. Some of the outgrowths or appendages of the testa are exceedingly beautiful, and some of them are amongst the most valuable of vegetable productions.

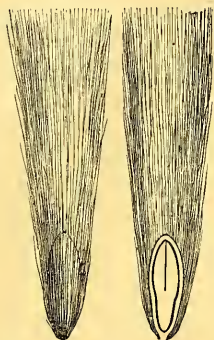

Fig. 40.—Enlarged bearded seed of Willow.

Fig. 41.—Section of the same, showing the straight embryo filling the whole cavity.

Botanists have given distinctive names to some of these outgrowths according to their origin. Thus an outgrowth of the funicle or point of attachment (hilum) of the seed, as the fleshy covering of the seeds of Passion-flower, is termed an aril. In *Strelitzia* and other members of the Banana family, the aril is of a most brilliant colour as, orange, blue, &c. An outgrowth from or near the micropyle is termed an arillode or false aril. The Mace of commerce is an arillode which invests the Nutmeg seed, and the orange-coloured fleshy outgrowth on the seed of *Euonymus europæus* is of the same origin, but there are numerous outgrowths for which no special names have been arrived at; in fact, they are so numerous, that it is more con-

Fig. 42.—Seed of *Hibiscus syriacus* with the hairs in one line.

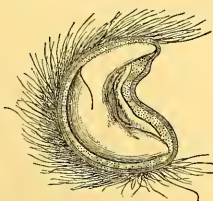

Fig. 43.—Section of the same, showing the large embryo surrounded by a thin layer of albumen.

venient to describe them than to invent names to designate them. Thus many seeds have hairy appendages. Cotton is obtained from the seeds of various kinds of *Gossypium*. In this case the woolly hairs proceed from the whole surface of the testa. The seeds of *Epilobium* have a plume of hairs at one end, and in Willows (fig. 40) the hairs spring from the base, and eventually completely invest the seed. In *Hibiscus syriacus* (fig. 42) the hairs are in one line around the outer part of a crescent-shaped seed, and the seeds of nearly all the *Asclepiadææ* (ex. *Stephanotis*) are plumose from the hilum. The seeds of the *Oleander* are densely woolly, and in some other *Apocynææ* they are plumose at both ends. An almost constant character of the *Bignoniaceæ* (ex. *Ecceprocarpus* and

*Tecoma*) is found in the seeds, the testa of which expands into a membranous "wing," often of a very delicate and beautiful texture. Nearly all the *Caryophyllaceæ* (ex. *Silene*, *Saponaria*) have elegantly pitted or tubercled seeds (see fig. 44, seed of Corn Cockle), and the seeds of different *Solanaceæ* are marked and sculptured in a great variety of patterns. Colour, as in flowers, is a less constant character of the testa than some others noted, and may be said to characterise varieties rather than species. Thus, of the *Kidney Bean*, for example, there are white, cream, yellow, red, brown, black, and almost blue-seeded and an indefinite number of variously spotted and streaked varieties. In density and texture the testa is leathery in the *Horse Chestnut*, bony in *Nelumbium* and some *Acaciæ*, crustaceous in the *Brazil Nut*, and membranous in the *Cocanut*: the outer hard shell of the latter, as it is usually seen, being one of the layers of the pericarp, called the endocarp, in contradistinction to the fibrous exocarp or outside coat. In rare instances the testa is obliterated or absorbed as the seed advances towards maturity, and the embryo is found naked in

Fig. 44.—Seed of *Agrostemma Githago*, enlarged, showing the tubercled testa.

Fig. 45.—Seed of *Nyctipha alba*.

Fig. 46.—The same, in section, as in Fig. 45, showing the minute embryo enclosed in an amniotic sac or fleshy albumen at the apex of the seed.

the ripe fruit. This is the case in *Pelliciera Rhizophoræ*, a curious Mangrove, native of the muddy seashore of Central America, which has large exalbuminous seeds.

THE ALBUMEN.—It occupies nearly the whole of the interior of the seed (figs. 46 and 47), or forms only a very small portion of the contents, as in *Hibiscus* (fig. 44). Between these two extremes there is every intermediate gradation. In the seeds

Fig. 47.—Section of the albuminous seed of *Carex maxima*, showing the minute embryo at the base.

of *Nymphææ* (fig. 46) there is a kind of double albumen. In consistence and composition the albumen is starchy or farinaceous in *Wheat* and other cereals, horny or ivory-like in the *Vegetable Ivory* (*Phytelephas macrocarpa*), fatty in *Castor Oil* (*Ricinus communis*), fleshy in *Euonymus*, and partly liquescent in the *Cocoa-nut*. Sometimes it contains a poisonous principle, as in the *Nux Vomica* (*Strychnos*); in the *Nutmeg* it is pleasantly aromatic; in *Coffee* stimulating; and in *Pepper* highly pungent. The albumen of the *Nutmeg* and *Ivy* is partially traversed by darker plates proceeding from the tegmen, and is said to be ruminated. In *Coffee* seeds the albumen is convolute, and many other curious modifications of it occur in various parts of the vegetable kingdom. The use of the albumen is to nourish the nascent embryo, and the only essential difference between albuminous and exalbuminous seeds is, that in the one case the embryo remains relatively small until germination takes place, whilst in the other it absorbs the albumen, or what would go to form albumen, into its own body before commencing active life; and the embryo is often large, especially the cotyledons, and contains a store of nourishment for the germinating plant.

THE EMBRYO.—It has already been explained that the embryo consists of radicle, plumule, and one or two cotyledons. The relative size of these parts, the form of embryo, its position in relation to the albumen in albuminous seeds, &c., are

characters of importance in systematic botany, and interesting to the cultivator. In some cases the parts are not easily distinguished until germination begins, on account of the small size of the entire seed; and in others there is not so perfect a differentiation of the parts as in the examples given in illustration. The position of the embryo in the seed, both in

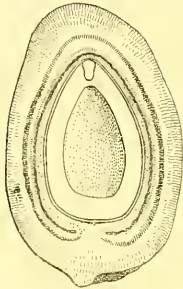

Fig. 43.—Fruit of the Date Palm (*Hyphæne thebaica*), cut longitudinally, showing the solitary seed resembling a miniature Cocoa-nut, but the embryo is at the summit. (Slightly reduced.)

relation to the hilum or point of attachment of the seed and the base of the seed-vessel, is, to all intents and purposes, constant in the same species, but very varied in different species. In the Cocoa-nut (fig. 38) the minute embryo is near the base of the fruit, and in the Date Palm it is at the apex (fig. 43); in the Pine (fig. 49) the embryo is in the axis or

Fig. 49.—Seed of a Pine cut vertically, showing the embryo in the axis of the albumen.

Fig. 50.—Seed of *Mirabilis jalapa* (Marvel of Peru).

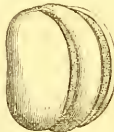

Fig. 51.—The same denuded of its testa, showing the embryo which almost encloses the albumen.

centre of the albumen. The embryo of the Marvel of Peru (figs. 51 and 52) encircles the albumen, which its broad, flat cotyledons almost enclose; in the Corn Cockle (fig. 53) the nearly cylindrical embryo is curved around the outside of the

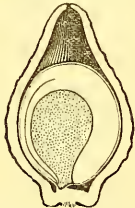

Fig. 52.—Section of the ovary and seed of the Marvel of Peru, showing the position of the embryo with regard to the albumen and the base of the seed-vessel.

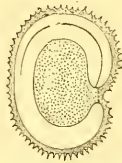

Fig. 53.—Section of the seed of the Corn Cockle, showing the embryo surrounding the albumen.

albumen. The reverse of this obtains in *Hibiscus syriacus* (fig. 42), where the embryo is enclosed within a thin layer of albumen. In the Onion (fig. 55) and the Ribgrass (fig. 55) the embryo is wholly embedded in the albumen, that of the Onion being curved, and of the Ribgrass straight. The embryo of the latter is parallel to the hilum, as shown in figs. 57 and 58;

whereas in *Chamærops* (fig. 59) and *Asparagus* (fig. 60) it is oblique. In *Bellevalia*, a Liliaceous plant near *Muscari*, it is spirally rolled (fig. 61). The embryo of the Coffee is a good illustration of another variety of position; in this the embryo,

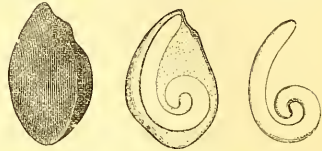

Fig. 54.—Enlarged seed of Onion. Fig. 55.—Section of same exhibiting the curved embryo. Fig. 56.—Embryo of the same detached.

though small, is easily seen on the outside of the albumen near the base on the anterior side of the seed when in the fruit. Usually the embryo lies free, unattached, in the seed, but in

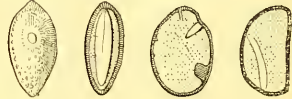

Fig. 57.—Seed of Ribgrass showing the hilum. Fig. 58.—The same in section, the embryo parallel to the hilum. (All enlarged.) Fig. 59.—Section of a seed of *Chamærops*, the embryo oblique to the hilum. Fig. 60.—Section of seed of *Asparagus* with oblique embryo.

the Cycadæe (fig. 61) and the Coniferæ it is attached at the radicular end by a long folded cord or suspensor to the albumen. Particulars respecting this and the origin of the embryo

Fig. 61.—Spirally rolled embryo of *Bellevalia*.

generally are given under the section devoted to the ovule or young seed. The position of the embryo can rarely be determined without making a section of the seed, but in many

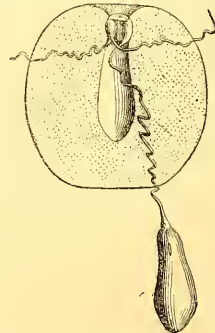

Fig. 62.—Albumen and embryo of *Cycas*. The embryo removed from the cavity and hanging by its long suspensor. (Magnified.)

Palms, even those with a very dense albumen or hard endocarp, it is indicated by a small depression or projection on the outside of the testa or endocarp where the wall is very thin, thus facilitating germination. Homogeneous or undifferen-

tiated embryos are common among true parasites—Loranthaceæ (Mistletoe) and Orobanchaceæ (Broom-ropes); also in the Orchidaceæ.

**NUMBER OF EMBRYOS IN A SEED.**—With few exceptions, there is normally only one embryo in each seed, but in the seeds of the Mistletoe there is usually more than one, and in the Orange there are often as many as six in the same seed (figs. 63 to 66). In many other seeds two embryos are occasionally found; and this occurrence has been recorded for *Allium fragrans*, *Asclepias nigra*, *Carex maxima*, &c.

**COLOUR OF THE EMBRYO.**—The embryo is almost invariably white or pale yellow, but in *Lathyrus Nissolia* it is a golden-yellow, in Mistletoe green, violet in *Theobroma Cacao* (Cocoa),

Fig. 63.—Seed of Orange denuded of the testa. (Enlarged.)

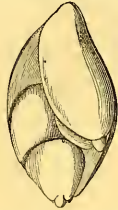

Fig. 64.—The same divided into two parts to show that it contains several embryos. (Enlarged.)

Fig. 65.—Portion of the seed represented in fig. 64 with one detached embryo to the left.

that some botanists distinguish the part found in the seed as the tigellus, and the root developed from it when germination begins as the primary root, and in seedling plants the space between the cotyledons and the beginning of the root is sometimes called the tigellus, or caulicle. The reasons for this distinction will be better appreciated after studying the germination of various seeds. In some families the position of the radicle with regard to the cotyledons furnishes important characters. Thus in the Cruciferae (Cabbage tribe) the flowers are so much alike in all members of the family, that few generic distinctions can be drawn from them. The radicle of the embryo of *Isatis* and many other genera is turned up and closely applied to the back of the cotyledons (fig. 68), whilst in others it is folded upwards against the edges of the

cotyledons; in the former case the cotyledons are said to be incumbent, and in the latter accumbent. There is one other particular respecting the radicle that should not be omitted, because it is constant and almost without exception. All seeds have on some part of their surface a minute aperture, which

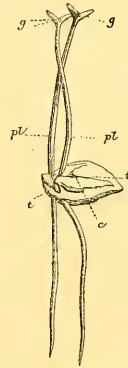

Fig. 66.—Germinating seed of Orange, from which two plantlets are issuing. *g*, first leaves; *pl*, plumule; *c*, one of the cotyledons of each embryo, the others remaining enclosed; *t*, the testa.

may be more easily found after the seeds have been soaked in water for some hours, though a lens of considerable power would be necessary to enable one to detect it in most cases. This aperture is termed the micropyle, and the radicle almost invariably points in the direction of the micropyle, through which it pushes itself in germination. It should be added that all roots which are not produced from the direct prolongation of

Fig. 67.—Section of seed of *Coussarea multiflora*, showing the embryo surrounded by albumen. Detached embryo of the same with relatively large club-shaped radicle. (Magnified.)

Fig. 68.—Enlarged embryo of *Isatis tinctoria* in which the radicle is closely applied to the back or under surface of one of the cotyledons; the latter are termed incumbent.

the lower extremity of the embryo are termed adventitious, because they appear at no fixed or determinate points; not because their production is altogether accidental.

W. B. HEMSLEY.

**Azalea narcissiflora.**—I am pleased to endorse "C. S.'s" high estimate (see p. 94) of this useful *Azalea*. It is one of the very best for early forcing, and may easily be had in bloom at or before Christmas. The flowers are also admirable for bouquet work, and when tastefully mounted might readily be mistaken for a somewhat ragged flower of the lovely double white *Narcissus*. The lasting properties of cut blooms of this *Azalea* are wonderful. I have known the self-same flowers made up in several bouquets in succession, and still appear quite fresh, without speck or flaw.—D. T. F.

**A Vegetable Disinfectant.**—Mr. E. Rimmel has introduced what is called an "Aromatic Ozonizer, or Natural Air Purifier." It is a fragrant powder composed in great part of the concentrated active principles of the Pine and Eucalyptus, and by simple slow evaporation in dwellings or places of public resort, it generates a healthy and healthy atmosphere somewhat like that produced by Pine and Fever Gum trees. It is stated to be the first agreeable disinfectant ever produced.

## GRAPES AND ROSES:

GRAPES are valuable when they can be got good and free from all the ills to which the Vine is heir; but when mildew becomes an overpowering nuisance, and the crop, if ever so good, will not pay to market, then Grapes result in a loss instead of a gain. If good Grapes be required, a crop of those only must be expected from the same house, for when it is attempted to associate the growth of hardy plants with them, the Grapes will soon come badly off. I have a large span-roofed house in which it has for several years been attempted to combine these two things, but only to result in failure; the hardy plants would do very well, but the Vines would not, and I came to the determination to let the Vines "go to the wall." In the same house, however, a strong plant of *Maréchal Niel* Rose has long been growing, and this has borne so many flowers, been free of blight, and, in spite of the regular appearance of mildew on the Vines, still keeps free from that fungus, that I determined to root out the Vines, that were planted in outside borders on either side, and to replace them with Roses. This was done early in the winter; the borders were well trenched and manured, and recently the Roses were planted. These latter are all 30-in. standards, to admit of their being easily introduced through the brickwork to the inside wire trellis. The plants were carried through from the inside, roots foremost, and planted, care being taken to so arrange as that those of robust habit and those having a more compact growth should alternate. The old plant of *Maréchal Niel* is just covering all the centre of the house, and the newly-planted Roses will be, as they grow, brought up to meet it, and in a year or two I look to have a perfect bowyer of Roses. The sorts planted were a selection by an experienced grower, and consist of *Maréchal Niel*, *Safrano*, *Niphetos*, *Catherine Mermet*, *Madame Berard*, *Lamarque*, *Homer*, *Marie Guillot*, *Madame Margottin*, *Anna Oliver*, and *Paul Nerou*—all kinds well adapted for house culture, and likely to produce flowers that will be acceptable in the market. Whilst the weather remains so mild as at present, extra protection outside is not required; but, should severe weather ensue, I shall afford such to both roots and stems. With these Roses kept properly thinned and comparatively leafless during the winter months, hardy plants will not suffer, and as the sunny days come on, an agreeable amount of shade will be afforded. Roses so planted in an old lean-to Vinery are a great success at Syon Gardens; but in this case the outside border is up to the level of the brickwork, and thus none of the stems are exposed outside. Mr. Woodbridge has his plants on the seedling Brier, and during the year or so in which they have been planted, they have made a wonderful growth, some of the more robust kinds having already gone to the top of the house. *Maréchal Niel* has made a marvellous growth, the main stem having swelled to the girth of a man's wrist. In this house a gentle heat is given, and no doubt by this time flowers are being out. The Rose likes a rich deep soil, plenty of moisture, and I expect will, under outside planting, produce a more permanent and robust growth than when existing on an inside border, where all watering is artificial. Perhaps even a more rash experiment has been to pull away a number of old Peach trees from a south wall, trench the ground, and plant it with Tea Roses. Peaches have of late become such an uncertain crop, and, when a good one, fetches such comparatively poor prices, that I have thought Roses may prove more remunerative. In any case it is worth trying. I think that Roses are not subject to so many ills and diseases as are Vines and Peaches.

A. D.

**Fungus in Cocoa-nut Fibre.**—I have sent you a small quantity of Cocoa-nut fibre that is completely over-run with some kind of fungus. The fibre in question is in a propagating frame at one end of a stove. Can you kindly inform me what the fungus is, and how to destroy it, as it works up the pots and damps all off with which it comes in contact, even old roots of *Clorodendron* and *Dipladenia*?—M. C. [The fungus on the Cocoa-nut fibre is the mere mycelium, and no one can tell to what it belongs without seeing the perfect fungus itself. It is probably the spawa of some mould, but it may be something quite different. We cannot give a certain remedy. Mycelia flourish in moist warm air, and often perish when the conditions are reversed.—G. W. S.]

**Spot on Pelargonium Leaves.**—Will you kindly say what is the cause of spot on Show Pelargonium leaves?—A. D. [It is supposed to be caused by damp and insufficient ventilation.]

## PLATE CXVI.

## DENDROBIUM SUAVISSIMUM.

Drawn by F. W. BURBRIDGE.

For the opportunity of figuring this handsome Dendrobe we are indebted to Messrs. Low, of Clapton, in whose nursery it flowered last summer. In habit it resembles a strong-growing form of *D. chrysotoxum*, from which, however, it is entirely distinct, not only as regards the pseudo-bulbs, but also the flowers, the lip of which is much rounder than that of *D. chrysotoxum*. Its blossoms are borne eight or ten together on a gracefully-drooping spike, of which two or more are borne at the apex of the spindle-shaped last year's bulbs. Mr. Boxall, who collected it, states that he has seen a plant of it bearing 10 spikes and as many as 160 blossoms. As regards size and colour, the flowers come nearest to those of *D. Cambridgeanum*. They measure 2 in. or more in diameter, the petals being broad and having a glossy, waxy-like appearance. The lip, which is crispulate, is fringed, and has a bold, crimson-black spot in the centre. In every respect it is a desirable addition to the fine genus to which it belongs, and one of the best Orchids which has been imported of late years. Its culture is identical with that of *D. chrysotoxum*. It grows well in either baskets or pots in peat crocks and Sphagnum. A temperature of from 60° to 65° suits it perfectly during winter, and being evergreen, it requires a good supply of water at all times. As a basket plant it will, no doubt, be greatly appreciated, as when grown in that way its rich pendent blossoms can be seen to the best advantage. It comes from Upper Burmah.

C. W. S.

**Our English Orchids.**—Why should these not be more grown than they are? One now and then meets with a few solitary specimens in a rock garden, but their beauty is entirely lost, as they are so far removed from the eye. I once came across a large mass of *Orchis maclata* near Basingstoke; there was a space of at least an acre completely covered with these plants growing as thickly together as Buttercups, and in full flower. The effect was astounding, and it struck me at once that this was the way it should be grown—in large masses. This plant, too, is very accommodating as to soil, as I have seen it growing in almost pure chalk, and also in the wettest bog on a gravelly subsoil, along with that exquisite plant, *Equisetum sylvaticum*, of which, to my great surprise, I saw a quantity for sale at Stevens's some time ago. The colour of the flowers of *O. maclata* varies a great deal, some being a dark lilac spotted with purple, and some pure white, though the latter is very rare; the purple markings on the leaves also vary with the flowers. Another pretty plant is *Orchis* or *Anacamptis pyramidalis*, whichever you may like to call it. In some parts of Kent during the month of August the chalky hillsides are quite gorgeous with the magenta-coloured spikes of this pretty flower, and it grows in such quantities that it may be mown down like Grass. Unlike *Orchis maclata*, this seems to flourish nowhere but on the chalk. Then there are the marvellous insect Orchids, *Ophrys apifera*, *muscifera*, and *arnifera*, in which nature imitates nature. These are certainly quite as wonderful in their mimicry as the well-known butterfly Orchids, *Oncidium Papilio* and *Kramerii*. There are several other species besides these, but those I have mentioned are the best.—C.

**Lopezia coronata in Winter.**—This old Mexican annual is now seldom heard of, and yet it makes a capital plant for blooming in the greenhouse at mid-winter. The small reddish flowers are not much individually; but, as they are freely produced, this deficiency is counteracted. I have recently seen some examples of this plant 3 ft. in height, and as far through, literally loaded with blossoms from head to foot. The plants were raised from cuttings struck in March last, and, when rooted, potted on, and transplanted in the open ground in June for the summer, and lifted and repotted in September, treating them, in fact, as one would berry-bearing Solanums, there would be no difficulty in this way in getting plants 4 ft. or so through. The more liberally the plants are treated during summer, the larger will be their size in September. When repotted, they should be put into a gentle heat, to assist in developing the flowers; and then they may be taken to a greenhouse for the winter, where they come in and prove most useful for cutting from. There are many fine things that want bringing forward once more; among them *Linum trigynum*, *Canarina campanulata*, &c. They are occasionally met with well grown, thereby adding intensity to the feeling of regret that they are so little regarded generally by plant cultivators.—D.

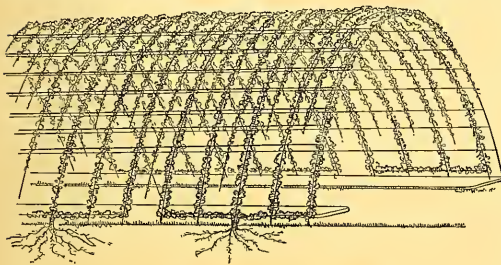

DENDROBIUM SUAVIS

## THE FRUIT GARDEN.

### ARCHED FRUIT TRELLISES OVER WALKS.

I MUST congratulate Mr. Hobday (see p. 11) on his remarks upon this subject. Arched fruit trellises over garden walks have been a subject of interest to me for years. Espalier fruit trees are rarely seen managed in a truly satisfactory way. In the generality of cases the energy of the trees seems expended in attempts at extension (notwithstanding all the thumb and finger work that can be allowed them); the result, as too often seen, is fruit tree hedges that bear no fruit. I am not finding fault with espalier trees, when the espaliers are properly made and the trees are properly managed; in every large, well managed, and well supported garden every kind of fruit would be benefited by being trellised. Imagine a low trellis 120 ft. to 180 ft. or so, covered with White or Red Currants, or dessert Gooseberries—how simply these could be netted over, shaded by matting or bunting, and retarded! and what a breadth of wall this would give for more important fruit! I would even have a slight wire trellis for Raspberries. But to return to the point. There is something grand in utilising the space occupied by garden walks for fruit culture. It would, in fact, be converting the space occupied by the walks into a kind of orchard house. Let us suppose the garden to have a main central and two side walks, and these walks arched over with a well-made trellis, the central one somewhat higher than the side ones—what a sustaining, balancing kind of effect these arches would give to a contiguous range of glass! what a delightful, cool

Arched Fruit Trellis over walk.

promenade these covered walks would be in summer. In the last place in which I lived as gardener a new kitchen garden was contemplated, and one walk (the central one) was intended to be trellised, as just described, for Pears alone, and those only of a free and vigorous growth, as the more delicate kinds of Pears, especially in these northern parts, require a wall. The accompanying sketch will give some idea of this walk. It will be seen that each tree has five branches (including the central one), each trained 2 ft. apart upwards, over, and downwards to the bottom on the opposite side, and that the trees on this side are so planted that the branches alternate, or are trained over between the others, just as if the rod of a Vine, when reaching the top of a rafter, were trained downwards between two others on the back wall—giving, in fact, the trees on the trellis the benefit of the extension system, as a branch trained over a trellis 7 ft. or 8 ft. high would, as an arch, give a length of branch from 16 ft. to 18 ft., just what a vigorous-growing tree wants—room for extension. I would not, as Mr. Hobday recommends, plant flush with the walk; on the contrary, I would have a narrow border, 1 ft. wide, on each side. These borders would be eminently useful for such things as required coolness in summer and slight protection in winter—say Parsley or Lettuce—and no places would equal them in which to strike cuttings. No objection can be made to the above plan as regards shading. What will give shade will give shelter; and there are always crops in a large garden that require both. I have given the height of the trellis as 7 ft. or 8 ft. This is optional; the larger a garden is the higher should be the trellis—nothing under 7 ft., however, should be attempted. I have,

so far, had only a trellis for Pears in view, but many kinds of fruit would do equally well—Plums, Cherries, Apples, and even the Vine in very warm localities; nor would it be necessary in the case of dwarf free-bearing trees, such as the Hawthorned Apple, to adopt the above interlacing method. And one thing must not be forgotten—these trellises, in whatever direction they may run, will always give two aspects, nearly equivalent to both sides of a wall. I have been speaking of these arched trellises as adapted for large gardens, but there is no reason why any place worth calling a garden should not have one, and for all I know they may be common in many places. There is scarcely a vicarage or parsonage or villa in the kingdom but has its wire arches striding unmeaningly over walks in many parts of the grounds; but if this matter be taken up in earnest, every kitchen garden will have its arched fruit trellis as well as every flower garden its arches for Clematises and Roses.

THOS. WILLIAMS.

Ormskirk.

### MOVABLE SHELTERS FOR FRUIT TREES.

M. TOURASSE, of Pan, who has lately been rendering himself famous by exhibiting Apples and other fruit from seedlings of three years old and upwards, has devised a movable shelter for fruit trees, which ought to receive extensive application. M. Courcier, a member of the Société Centrale d'Horticulture, has visited M. Tourasse's establishment at Pan, and read the following account of these appliances before a recent meeting of the Society. After giving a description of M. Tourasse's method of inducing seedlings to bear by systematic root-pruning, M. Courcier goes on to describe these appliances. It seems that, although the climate of Pan is very hot, it is subject to extreme and unexpected variations. Rain is frequent and sometimes abnormally heavy, and is often succeeded by a burning sun. To remedy these inconveniences, M. Tourasse has had constructed an immense movable shed, so that his trees may be sheltered from the sun, rain, or cold at any given moment without work being interrupted. This movable shed is 85 ft. wide and 35 ft. deep; it consequently covers about 3000 square ft. of ground. It is high enough to allow a man to walk about under the tie-beams of iron, which keep the uprights in their proper positions. It is supported in front by three posts, terminated at their lower extremities by rollers, which run in grooved iron rails. In consequence of its great breadth, the roof is formed of two gables supported by three rows of cross pieces, which rest on nine posts provided with rollers at their lower extremities. These rollers run in grooved rails, which lie on sleepers resting on the ground, with pegs driven in here and there to keep them in their proper position. The rails are fastened to the sleepers by chairs bolted to them on each side by strong screw bolts. The shed is moved backwards and forwards by a fixed windlass, but three men can move it one way or the other by levers. This shelter allows the labourers to work during any weather, and to keep the soil in a good condition during the heavy rains. It also serves to shade any seedlings that have been recently planted out. The architect under whose direction this shed was constructed gave M. Courcier the following particulars respecting its various parts: The cross pieces, pegs, and uprights are all of Oak, all the rest being of deal, with the exception of the tie-beams, rods, and bolts which unite the posts of each row, which are made of iron rods. The rollers, with their bearings, are in cast iron. To make the shed as light as possible, everything that could possibly add to its weight has been dispensed with. An intermediate set of uprights has been placed between the principal supports. To these thin boards have been nailed, the whole being covered with tarred felt. With these improvements it may be very easily moved. This shelter stretches across a space of ground 330 ft. wide; it consequently covers an extent of about 25,000 square ft. It is moved by a fixed windlass, the outside and middle uprights of each row being held firmly together and the whole perfectly rigid, the pull being equally felt by the outside and the middle uprights. The girder in question is formed of a flat piece of wrought iron, about  $\frac{1}{2}$  in. in thickness, to which is rivetted another similar piece, the whole giving a T section. This shelter has now been in constant use for five years, and has been found fully to answer the purposes for which it was intended. The total cost was about 6000 francs (£240)—a comparatively small sum for such a valuable appliance.

C. W. Q.

**Fruit Trees for High Elevations.**—My experience in this matter may, perhaps, be of service to "D. J. M.," as I have for twenty years past been seeking, practically, a solution of this very question. My garden lies 880 ft. above the sea on the edge of moor-

land, exposed to south-westerly winds, on a hillside with a southern slope. To begin with Apples, and first as standards, I find that few table sorts are to be depended on for regular bearing, but I can recommend as trustworthy—Irish Peach, King of Pippins, Northern Spy, Court of Wick, Kerry Pippin, and Margil. Kitchen sorts, for standards, are more numerous; here are twelve regular bearers, and thoroughly good—Lord Suffield, Cellini, London Pippin, Small's Admirable, Norfolk Bearor, Cockpit, Greenup's Pippin, Normanton Wonder, Jolly Beggar, Tower of Glamis, Forge, and Yorkshire Greening. For a south wall I would recommend Red Astrachan, Golden ReINETTE, ReINETTE du Canada, Court Penda Plat, Melon, Pineapple Russet, Dutch Mignonne, Ribston Pippin, Hereford Pearmain, and Sturmer Pippin. Of Plums, few will bear as standards, except such as River's Early Prolific, Doney's Victoria, Diamond, and Damon. For a wall also—July Green Gage, Transparent Gage, Denniston's Superb, and Kirke's. The list of Pears is smaller still, Hazel and Crawford being the only standards for a wall—Jargonelle, Williams' Bon Chrétien, and Darondeau. If an exceptionally good wall—Bourré d'Amanlis, Bourré Hardy, and Bourré Diel. These fruits I have proved, and only these, to be depended on at this elevation; others are good, but I am not sufficiently certain of them.—W. FEATHERSTONHAUGH, *Edmundsbury Rectory, Blackliff, Durham.*

—“D. J. M.” does not state whether his garden is in the north or the south, but the following information as to what can be done here, in South Yorkshire, from 700 ft. to 900 ft. above the sea, may be useful to him:—On a south wall, 700 ft. above the sea, early Peaches, like the Royal George, and Nectarine, like the Elcuge, ripen in October. Forty years ago or more this garden was celebrated for its Peach crops ripened on heated walls, and an account of the same was published in the “Transactions of the Horticultural Society” at the time; now all our Peaches are under glass, except a tree or two, but the above date refers to fruits ripened without artificial aid; on the heated walls they ripened much earlier. On the same aspect (south) Apricots ripen about the end of August, and Plums, like the Green Gage, in September, and the later kinds, like Jefferson's, Coe's Golden Drop, &c., towards the end of the same month, but the time varies according to the season. Pears like the Marie Louise and Louise Bonne come to first-class perfection on a south wall, and they also ripen on espaliers, but not so well. Later varieties are seldom good, but the earliest kinds, like Williams' Bon Chrétien, ripen well in open quarters on standards. Many of the better sorts of Apples succeed on west and south walls, and so do Cherries, but the earliest sorts are seldom ripe before the middle of July on a west wall. On an east wall the best dessert Plums are seldom ripe till late in October, and last season they did not ripen at all. Higher up on the hillside, 900 ft. above the sea, my neighbour trusts to a good, well-glazed orchard house for his Pears; and, unless it be Apricots, I am not aware that he has ever had crops worth speaking of from his outside walls, which are, however, not extensive. I do not suppose, indeed, that he tries much, knowing the climate with which he has to deal, but he has good fruit from his orchard-house trees. I should say, however, that Pears (that ripen as early as Marie Louise and Louise Bonne, which are unsurpassed for excellence, and which keep till January in late situations), Cherries, Apricots, Plums, and some of the better and hardier dessert Apples might be grown with tolerable success on south and south-west walls 900 ft. above the level of the sea.—J. SIMPSON, *Wortley Hall Gardens.*

## GARDENING FOR THE WEEK.

### Orchids.

Vandas of the suavis and tricolor section must not be kept too dry at the roots, as their lower leaves are almost certain to suffer to an extent that causes their premature falling off if they shrivel much, but their ability to bear dry treatment will always be found commensurate with the stout leathery state of the leaves, or the thinner, less substantial character consequent upon the different conditions under which they have been grown. Their flower-stems will now be about ready to appear down in the axils of the leaves. Care must be taken that the plants are not placed in a position where they will receive drip from the roof, or it will accumulate at the bottom of the leaves and rot the advancing flower-stems. Any plants concerning which it is necessary to renew the potting material should have the old Sphagnum worked out from amongst their roots without detaching them from the pots, or the check they will receive is almost certain to stop the further development of the advancing flowers. The beautiful and distinct Vanda téves needs exceptional treatment to flower it well. After being grown as near the light as possible, and somewhat cooler than most of the other species, it requires a long season of rest in a temperature not more than from 50° to 55° in the night, with the atmosphere comparatively dry, and no water at the roots for three months, otherwise it never ceases growing, in which case it is useless to expect flowers. Managed in this way through the winter until the middle or end of March, with at that time 5° more warmth, it will then show a few, and water may be given to the roots, but the plants should not be submitted to a high temperature until the flower-stems are a little further advanced, or they frequently go blind.

*Trichopilia suavis* will now be fast pushing its flower-spikes, which come from the base of the lower side of the bulb, often in contact with the potting material. Care is necessary that in giving water it does not reach the advancing flower-stems, or they are very liable to rot; the same holds good with *T. coccinea* and *T. crispata*, although these are not quite so impatient as the first-named sort. The varieties of *T. tortilis* are later in flowering, and must be kept dry for some time yet. The beautiful *Thunia Bensoniae* should be kept moderately warm and moist, so that the growth in process of formation may receive no check. Stanhopeas at the present day are held in little estimation by the generality of Orchid growers, yet in the whole family of Orchids there are none that bear flowers more gorgeous in colour or singular in formation. *S. tigrina*, *S. eburnea*, and *S. usneigis* deserve a place in any collection, for although the individual flowers are of short duration, still, where they are well managed and have attained a large size, they will produce sufficient spikes in succession to keep up a display for a month. They require a considerable period of rest, and should be kept all but dry at the roots for some time yet. *Sophronitis*, and some small growing plants, with comparatively large, intensely-colored flowers, are amongst the most attractive winter bloomers. Where subjected to somewhat cool treatment the flowers will yet keep fresh, for some time, but as soon as the blooming is over any that require placing on fresh blocks—virgin Cork and a little Sphagnum suits them as well as anything—should be attended to directly; after which, place them in a night temperature of 55° or 60°, with a moderate amount of moisture. T. B.

### Roses.

Where a house or pit exists for forcing Roses proportionate in size to the quantity required some Hybrid Perpetuals should be brought in from the positions in cold pits or frames that they have occupied, the protection of which, when they are intended to be forced, is much preferable to their being left out in the open air, as, in common with all other plants the roots of which are confined in pots, even when the drainage is as perfect as it is possible to make it, and when the pots are all plunged in some material sufficient to protect the balls from being frozen, still they are always liable to suffer when outside from getting too wet. A temporary covering of a few loose lights placed over them is sufficient to throw off rain. It is well to observe that the slower they are brought on by not using too much heat, the finer they may be expected to flower; and with most of the Hybrid Perpetual section it is well not to submit them to so much warmth as the Chinese varieties, that have been forced earlier through the winter. To have prepared these pots and to have a way to give the best results, they should have been grown in pots for at least twelve months preceding, as when not forced too hard, and their requirements are properly attended to, pot Roses when used in this manner will not only continue for a long time fit for the purpose, but will go on improving. If room can be found to accommodate some plants in a house or pit where no more heat is employed than is sufficient to keep out the sharp night frosts that may be still looked forward to, they will supply a quantity of the finest flowers before outdoor Roses come into perfection. The most satisfactory results, these should have been grown for at least a season in the pots which they occupy, although if potted early last autumn, with as little mutilation of their roots as possible, they will bloom fairly when not subjected to any forcing more than being gradually brought on in an ordinary greenhouse temperature. Before starting all such Roses as the above, whether green fly can be detected upon them or not, I have always found it good practice to syringe the plants with Tobacco water or Fishurex; the latter mixture I prefer for this purpose, as the sulphur it contains will be found beneficial in destroying any trace of red spider or mildew that may be about them.

Pot Roses now flowering, and particularly such as were started early and making growth after the production of their first blooms, will be much benefited by a liberal use of manure water. One of the greatest

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Glass Coping for Fig Trees.**—There are two large Fig trees here growing against a west wall. Last spring we had a glass coping erected over one of them, and the result was decidedly successful, for we gathered at least six fruit from the tree beneath the glass for the results of this experiment. My employers are so thoroughly satisfied with the results of this experiment, that they propose having the other tree done in a similar manner. The shoots were neither thinned nor stopped the whole year in either tree, and I do not intend to do either this year. As far as I can judge by appearances at present, there will be a good crop this season.—T. LLOYD, in “Gardeners' Chronicle.”

**A New Mode of Getting Rid of Phylloxera.**—Madama Amélie de Bompar, a lady residing in the Canton of Pesse, makes known, in a pamphlet just issued, her discovery of a simple method of getting rid of the Phylloxera. To ensure this happy result it is only necessary to set Strawberries at the foot of the Vine-stocks. These plants are infested by the Phylloxera and its eggs, who makes it his business and pleasure to sip out of the genus Trombidion, so greedily that the reproduction of the pest is scarcely possible. Unfortunately, practical experts appear to receive the announcement of this discovery with some degree of incredulity, and the Phylloxera commission is not likely just at present to discontinue its labours.

essentials in the cultivation of pot Roses is to regularly supply them with sufficient nutriment to enable the young wood that is being formed to grow stout and strong. Weak wood will never produce anything but comparatively small flowers, whereas when the successional shoots that are being made contain plenty of substance, they do not fail to produce not only flowers in greater numbers, but larger and fuller also; and size, with the Chinese varieties particularly, is a matter of the first consideration. If not already done, I should recommend without any delay a sufficient number of plants being potted to grow on out-of-doors through the summer, with the view of preparing them for next year's blooming; and I would urge upon those who have not had much experience in this department of flower-growing the desirability of securing a sufficient supply of the small varieties. To the list given a short time ago, I would add the fresh-coloured Mr. Bosanquet ought to have been included as a fine kind for forcing; it does not possess the long, Cahagne-like buds of many of the Chinese varieties now held in so much estimation, but the individual blooms are sufficiently full, and produced in large quantities.

**Marechal Niel** is now so generally known as to need nothing more said in its favour, but though of the most vigorous possible habit, in some soils it appears very liable to go off at the collar, just on a level with the soil, forming large protuberances, which show a disposition to omit roots in quantity, as if they were deficient in these below, but which ultimately do not go on, the plants usually cankering right off. This often occurs when the plant is on its own roots, and yet there is no stock on which I have seen it worked that appears sufficiently strong to support it, as is evident by the stem above that buds generally attaining a much greater thickness than the stock. To meet the loss occasioned when it goes off in this way, successional plants should be from time to time introduced to take the place of those that die. This variety may, with the best results, be grown thinly on the roof of a Camellia house, either planted out or with its roots in a large tub. Where convenient the former is the best. In such a position the shade it affords through the spring, at the time it is making its growth and flowering, will be more beneficial than otherwise to the Camellias that at the same time will be making their growth underneath it. The necessary free use of the syringe or garden engine to keep down red spider and green fly on the Rose will do no injury to the Camellias, a circumstance that often occurs when plants of a less water requiring nature than Camellias are grown under Roses. Another advantage is that the Camellias are less likely to suffer through the above insects being communicated to them from the Roses grown overhead than most other plants.—T. B.

### Stoves.

There are many plants in stoves that will now want re-potting, and amongst others it will be well to give the majority of the ornamental-leaved varieties a shift. Crotons need more drainage than most hard-wooded plants; they should also have a good layer of fibrous material put over the crocks. If the drainage be not very good the soil soon gets too wet, as these plants want a good deal of syringing to keep down yellow thrips where they exist. *Bertolonia* and *Flemingia* are small plants well worth cultivation; the *Flemingia*, especially, will succeed in places where few plants will prosper. It is time now to start *Caladiums*; they should be taken out of the old soil and re-potted in fresh material, consisting of good loam, to which has been added a little sand and some leaf-mould. Where desirable, they can be increased by dividing the bulbs, leaving to each piece part of the crown with buds. For all decorative purposes, plants of a comparatively small size will be found most useful; put them in heat as soon as they are potted. Where sufficient space can be afforded for its full development, *Medinilla magnifica* is a fine plant for decoration; the temperature of an intermediate-house, say 50° by night, will be the best for it at the present time; if it be kept too hot it will be likely to cause numbers of the flowers to drop, neither should it have as much moisture in the atmosphere as many stove subjects require. Plants that were well ripened in the autumn will break out and bloom from the back wood as well as from the points of the shoots. Those who are fond of strange-looking flowers will do well to give *Aristolochias* a place; they grow rapidly, and can be had in a blooming state in two months from the time of the cutting being struck, and they do not need much care. Plants that are in little pots ought to have a shift; they may have 6 in. or 8 in. more room; pot in good loam, to which add some leaf-mould and sand; they need a liberal supply of water; syringe every day, as they are liable to the attacks of red spider if allowed to become too dry overhead. Their flowers show to advantage trained over a path, in which way they can be grown; or the shoots may be trained round a trellis, taking care to keep the points higher than the other parts; if they do not do this they will stop and break out into fresh growth, which generally is not desirable if the plants be not weak and so need strengthening.

### Ferns.

A commencement should be made in potting Ferns, for if this operation be deferred too long, the young growth gets checked and becomes deformed. Whether we take into account their beauty, or their value for mixing with cut flowers, *Gleichenias* have few equals. Fully-matured ferns, when well supplied with water, will last in a cut state for an almost incredible time, but, of course, the young immature fronds will, as in the case of other Ferns, shrivel very soon. It is not advisable to cut plants that are small, but they are not very difficult to grow, and when they attain a good size they will in a comparatively short time, there need be no fear of cutting to a reasonable extent. In getting in

young plants it is necessary to be extremely careful that they are perfectly free from both scale and mealy bug, for if either of these pests exist on them, they cannot be grown in a way to show their true character. Whilst the plants are small, the insects may, by uncaring attention, be kept down, but as they get larger, the sponge and brush, however carefully applied, prevents their progress satisfactorily. If healthy plants be treated as hereafter recommended, they will grow quickly. The soil in which they are grown ought to consist of five parts of the best fibrous peat, broken into pieces about the size of hens' eggs, one part clean sand, and one part coal-cinders about the size of Acorns. As they have creeping rhizomes that will extend a long way in all directions, broad and somewhat shallow pans are better than deep ones in which to grow them. 6 in. to 10 in. of the rim with drainage, pressing the soil moderately firm. They must not be syringed overhead, but the roots need a good supply of water; they succeed best in a drier atmosphere than that usually allotted to many Ferns. Let them be placed where there is plenty of light and not far from the glass. They do not want to be kept very hot—from 45° to 50° night temperature in the winter, and 5° higher by day, will do, with 10° or 15° more in the summer, admitting a moderate amount of air and slightly shading them.

### Greenhouse Plants.

A general potting of these should now take place. Some of the *Fuchsias* from under the stages should be turned out of their pots, have the old soil shaken from their roots, and then re-potted in fresh soil in the same sized pots. Do not water them for a time nor prune them closely until they begin to break. Of *Lilium auratum*, a few of the most forward should be placed in the stove, and on a shelf near the glass, for flowering in May. Be careful in applying water at first; it is the safest to pour it gently round the inside of the pot, not over the whole surface of the soil. No water should be given to such as are still in the greenhouse until their shoots appear. *Tritonia aurea* is now beginning to grow; therefore, such as require shifting should be re-potted in a compost of two parts good loam, one of leaf-mould or rotten manure, and some sand. The coolest part of the greenhouse is sufficiently warm for them. Plants of *Nerine* should now be re-potted and placed in rather a warm, moist temperature, to encourage growth. A compost like that for *Tritonias* suits them perfectly. Of *Convolvulus mauritanicus*, the old plants may now be divided, potted in small pots, and kept in the warmest corner of the greenhouse. These plants are particularly suited for suspended baskets, but when grown in pots and then transferred to the baskets, they form better flowering plants than such as are wholly kept in baskets. A few of the finest *Cyclamen* blooms should now be fertilised, and the plants should be placed on a side shelf. Only a few, say six flowers, should be fertilised on one plant, from which all other flowers must be removed as they appear, otherwise the seed will not be so satisfactory. Some of the finest *Zonal Pelargoniums* ought to be re-potted and placed in gentle heat, to encourage them to form fine specimens for the conservatory.

### Frame Ground.

Heaths and other greenhouse plants in frames should be well ventilated on every favourable opportunity, but protected from frost when it occurs by having mats spread over the glass. The sides of the frames should be protected by means of a lining of straw. *Ivies*, *Rhododendrons*, *Jasmines*, *Clematisses*, *Skimias*, *Magnolias*, and other plants in pots, but not in frames, should be protected from frost by means of a framework of hoops covered over with mats. Everything at all tender out-of-doors in pots should be plunged in coal-ashes, Cocoa-nut fibre, or other material, even although unprotected in other respects. Any somewhat tender small *Coffeers* or other evergreen or deciduous plants grown out-of-doors and likely to be injured by frost should have some straw strewed over them at night, and if the frost abates in the morning it should be removed and again applied at night.

### Sub-tropical Plants.

Sow seeds of *Acacia lophantha* on a brisk hot-bed, and prick off and pot singly the young seedlings as soon as fit to handle. Prune back old plants, and permit them to start slowly in a pit or greenhouse. These have a fine effect in the sub-tropical or flower garden, mixed with flowering plants, or used in clumps in the centres of beds. Sow *Solanums*, *Wiganthias*, *Fernandas*, *Abutilons*, &c. in pots of sandy soil in brisk hotbeds, afterwards to be pricked off and potted as they require it. Old plants of the same that were sved from last year's collection should be forced in a pit or hotbed, in order to induce young growths for cuttings. Sow *Castor-oil plants*, *Tobacco plants*, *Hemp*, *Udeas*, *Chilian Beet*, *Amarantuses*, variegated *Maize*, and a few others in brisk heat, and attend to them as regards timely thinning, pricking off, potting, and watering; grow them on in a warm temperature for a time, and, towards the end of April in May, gradually harden them off prior to planting, which should be done in June. *Erythrinus* may now be started gentle, and, if required, the young shoots may be used as cuttings; these will make nice little plants by May or June, and next year they will bloom well. Propagate *Aralia papyrifera* by means of root cuttings, but do not start the old plants into growth until next month. Plants of *Aralia japonica* raised from seeds last year will make fine plants for bedding-out next summer, provided they are grown on slowly, as, for instance, in an intermediate house. Sow a few more seeds of *Abutilons* in pots, in glass pans, inasmuch as a stock of this sort cannot be obtained from roots, as in the case of *A. papyrifera*. *A. spinosa*, a showy and pretty plant, is

hardy, and only requires pruning back to a plump eye in March or April. In the case of frosty weather, however, the ground containing the roots should be mulched, and the stems encircled with straw or hay-bands. Cannas may be started into growth like Dahlias; and, when they begin to grow, they may be divided into as many pieces as there are shoots, on each of which a piece of the old root should be retained. Canna seeds may be sown in a hotbed or pit; and, if they are steeped for a night in tepid water they will germinate sooner than they otherwise would do. If the stock of *Caladium esculentum* is short, start some roots, and propagate every offset as a cutting. Propagate *Ficus elastica* by means of cuttings or eyes, with a leaf attached to each, and held upright by means of a wooden peg. Cuttings of *Meliantbus major*, struck now, make fine plants for next summer's use. New Zealand Flax, both green and variegated, may be divided, and each division potted separately in a loamy soil, and placed in a hotbed or frame. Plunged or planted in flower-beds, they are very effective, and old specimens are most in vogue. In lawns, or as centres to beds. The general stock of Cycads, Palms, Musas, Bamboos, Ficuses, Dracenas, and other perennial tender sub-tropical plants will now be starting into fresh growth; therefore, such as require fresh potting should be attended to in that respect, so that the plants may form a good supply of fresh roots before summer sets in. Hard forcing should not be practised in the case of those not potted, a slow and hardy growth being best.

### Plants for Carpet-bedding.

As carpet-bedding continues to be so fashionable, some forethought must be exercised as to the quantity of plants of the various kinds that are likely to be wanted. The foremost among these will be *Alternantheras*, which will be required to be now subjected to a temperate heat, in order to cause them to grow, when abundance of cuttings that strike freely may be obtained; highly-coloured shoots do not strike so freely as green ones, which, afterwards, become coloured. Seeds of Golden Feverfew should now be sown in a hot-bed; last year's saved plants are sure to "run" during the summer, therefore, this plant is always best treated as an annual. Sow seeds of *Lobelia pumila*, and also propagate it by means of cuttings; its compact habit and bright blue flowers make it very valuable for carpet-bedding. The variegated *Mesembryanthemum* should be increased by means of cuttings; this plant, although harder than most greenhouse plants, thrives well, and does not lose its compact character in a stove. *Ajuga reptans sanguinea*, a good dwarf plant, furnishes a dark bronzy colour, and may be propagated in cold frames or out-of-doors by means of offsets, but more readily in heat. All dwarf *Echeverias* are useful for this purpose, and may be kept in boxes in a cool house or frame, and, when the light, rather dry at present, and perfectly free from all decaying matter. The young plants raised from seeds, offsets, or leaves are best grown in a gentle heat, in order that they may be strong by bedding-out time. Various kinds of *Sempervivums* and *Sedums*, both tender and hardy, may be treated in the same way as the *Echeverias*, but in the case of the hardy ones, unless increase of stock is necessary, they are best wintered out-of-doors. *Coleuses* and *Fresnes* are also useful for forming central masses to the beds, and if a few old plants were saved to produce cuttings, these should be started into growth at once, and their propagation proceeded with, because well-hardened-off young plants are much more desirable than old ones. *Centaureas* have a fine effect used with dark-leaved plants, therefore have a stock of them for that purpose, either raised from cuttings in the autumn, or from seeds or cuttings now. Keep old plants pretty dry, and in cool airy pits. The variegated *Thymes* make fine edgings or carpets, and can now be raised freely from cuttings, or by means of division. The *Santolinas*, too, may be readily propagated by the same means, and as they submit to severe clipping in summer, they are very useful for this kind of work. They may also be increased freely by means of division in the open border. An old white variegated *Pelargonium*, called *Dandy*, is of such dwarf habit as to be very suitable for this purpose; but although it strikes freely from cuttings, these are twelve months old before they make much show. There are many hardy plants that can be used for this purpose, such as the Mossy *Saxifrages*, the creeping *Veronics*, *Pyrethrum Tobiatchewi*, the variegated *Arabis alba*, and several others, besides a few such as *Polemonium aceruleum variegatum*, that form nice specimens when studded here and there in the carpet.

### Hardy Fruit Garden.

All fruit trees should be pruned before this time, and their trunks and main branches cleared of Moss and Lichens. Young trees may yet be planted. Prune back to 15 in. above ground stocks on which grafts are to be put. Mulch the roots of lately-planted trees, and affix strong stakes to all that require support; see also that espaliers are sufficiently staked and tied. Have all trees on walls properly pruned and nailed. A good syringing with sulphur and water will mix the soil and be found beneficial to wall trees. Collect all prunings and other rubbish, and burn them, saving the ashes resulting from the operation for manurial purposes. Hoe over the Raspberry beds, and remove any weeds, after which give the surface a good mulching with manure. From the nature of this fruit in completely renewing its wood yearly, it takes a great deal to support it, and requires, to grow it well, a greater amount of manure than any other fruit will grow. Have all the inches of good solid manure, placed on the surface every year, is not too much, and will be well in repay for extra outlay. When the plants are strong, half the bread often devoted to this fruit will suffice, and they rarely fail in yielding if grown in suitable soil, that is, of medium strength, neither too heavy nor too light. The young shoots must be thinned out in the spring to some-

thing like the number required for fruiting the following season, so that all the strength of the roots is concentrated in producing the canes only that are required and no more. If kept clear from weeds the plants will last for a lifetime, instead of requiring re-planting, as is often the case. Gnano is an excellent manure for Raspberries, applied to the surface with a little vegetable soil, or as an assistant to a light dressing of stable manure, and if there is a deficiency of the latter, a few cwt. of good guano will be an excellent substitute; but in the purchase of this it is necessary to be careful, remembering that there is no such thing as a cheap article under the same. When it is offered below the ordinary price, either wholesale or retail, the chances are that it is not worth as many pieces as you are charged shillings. There is one thing to be observed respecting this manure. If, after trying a sample, it is found good, there need be no hesitation in purchasing a supply that will last for years, for, if kept in a moderately dry shed, it will be just as good in every way at the end of a dozen years as on the day it was imported. We have had it much longer than this, and could not detect the slightest diminution in its strength.

### Kitchen Garden.

Where advantage has been taken of the open weather which we have had for trenching and ridging every available piece of ground, satisfactory results may now be realised. Quarters not so treated are often so cold and damp, that seeds sown in them perish, whereas well-trenched ground in almost all cases will be found in good condition. Draw earth to rows of Peas, and at the same time stake them. Sow a succession of Marrow kinds, with one or two rows of Round Spinach between the rows. A plantation of early Potatoes should now be made in some warm quarter and in rather light soil; those in pits should be examined, rotten or diseased ones removed, and all sprouts rubbed off. Of Jerusalem Artichokes, a plantation may be made in any odd corner, and all tubers of last year's crop yet in the ground should be lifted and housed. Any other roots of Parsnips, Beet, and Carrots may be lifted and housed, but should be lifted, for although their flavour is maintained if kept in the ground during winter, unless they are lifted now they begin to grow, and their quality is consequently greatly reduced, for they become stringy. Some of the finest roots of Parsnips, Beet, and Carrots may be transplanted to a favourable position for seed. Sow some early Turnips in a light, warm soil. Of Cabbages, sow some of the early sorts for summer produce; also some Red Cabbage, some Walcheren Broccoli, and Savoy seeds. Savoys sown early grow much larger than late-sown ones. A sowing of Onions should be made as soon as the ground is ready. Onions are sometimes grown year after year on the same piece of ground, but that is a practice which cannot be recommended, better results being obtained from rotation with other crops on deeply-trenched and well-manured ground. Make a good sowing of Marshall's Dwarf Beans, some Leeks, Chervil, Fennel, Dill, Parsley, &c.

### Extracts from my Diary.

**February 25.**—Sowing Mignonette in pots; also Walcheren Broccoli in boxes for early autumn use. Potting off Sweet Basil. Putting Dahlias into gentle heat to start them. Planting early Ashleaf Kidney Potatoes in cold pits. Cutting out William I. Peas sown in turf and brought forward in heat. Cutting down overgrown Lantanas, and layering some of the lower branches to make a good thick bottom. Giving the Onion ground a top-dressing of soot, and forking it over ready for sowing.

**Feb. 26.**—Sowing 100 pots of Osborn's Early Forcing French Beans. Digging out new Asparagus beds, and refilling them with good manure, burnt vegetable refuse, and a liberal supply of leather shavings and soot. Looking over early Strawberries, and picking off all the late and useless flowers. Getting into the early Peach house all plants infested with green fly, and fumigating them.

**Feb. 27.**—Sowing Cucumbers, Melons, and Vegetable Marrows; also a row of Sweet Peas. Putting in cuttings of *Verbenas*, *Heliotropes*, *Iresine*, and *Coleus*. Potting off autumn-struck *Pelargoniums*. Putting a mixture of loam, manure, and soot into the Melon pits ready for planting. Looking over Grapes in bottles, cutting out all bad berries, and filling up the bottles where required.

**Feb. 28.**—Sowing Early Snowball and Early White Stone Turnips. Putting in cuttings of *Dracenas*, *Pelargoniums*, and *Alternantheras*. Potting off *Fuchsias* and *Ageratums*. Getting into gentle bottom-heat another batch of Strawberries. Preparing a rough frame into which to transplant *Calceolarias*. Covering up Seakale. Earthing up French Beans in pots, and covering up Endive to blanch.

**March 1.**—Sowing the following sorts of Peas in the open ground, viz., William the First, Dr. Hogg, G. F. Wilson, James's Prolific Marrow, Dr. Maclean, Commander-in-Chief, Giant Emerald Marrow, and Duke and Duchess of Edinburgh. Planting early border with Ashleaf Kidney Potatoes. Getting into the Mushroom house a few more roots of Rhubarb, and a little more Chicory and Dandelion to blanch. Giving Mushroom beds a little warm manure water.

**March 2.**—Potting off Cucumbers and Melons; also cuttings of Hathaway's Excelsior Tomatoes. Pricking out all the Year Round Lettuce and Celery in boxes. Trenching Grapes in early Vinery, and tying down the shoots where required. Disbanding Peaches and Nectarines, and thinning the fruit where too thickly set. Cleaning up the pleasure ground and kitchen garden walks. Watering the Pines all through. Fruit in use for dessert:—Pines, Grapes, Peas, and Apples.—W. G. P., Dorset.

TREES AND SHRUBS.

PINUS EXCELSA (WALLICH).

THE merits of this Pine consist in its hardiness, beauty, and free growth when placed in suitable soils and positions. In its native state, in the uplands of India, it is said to be highly valuable as a timber tree, as well as for the amount of limpid fragrant turpentine which it produces. It is to be hoped that it may prove to be proportionately valuable here. As yet, however, we can only speak from young and adolescent plants, which are peculiarly beautiful from the way in which the long, narrow, shimmering, silver-grey leaves depend from the up-turned extremities of the branches. In summer there are the leaves of three seasons' growth, in winter only two; but the extended, almost nude, branches are nearly hidden by the veil of leaves which hang from the edges of the gradually-narrowing tiers of branches as they bend gracefully over one another, forming a broad-based, airy, silver-grey cone of beauty. Such plants are most frequently seen on the wooded

Cone and Leaves of Pinus Peuce.

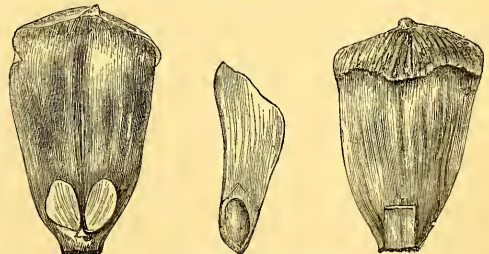

slopes of hills where the soil is of a light, open texture, and otherwise naturally drained, and where ample room and sufficient shelter are furnished by their equally fast-growing nurses. Planters will save themselves money and much disappointment by not planting it in heavy, low-lying, even though pretty well sheltered ground. The opinions of others compel me to consider here the *P. Peuce* of Griesbeck. Sir Joseph Hooker and the late Professor Parlatore have treated it as a synonym of *P. excelsa* (see *Proceed. Linn. Soc.*, vol. viii., p. 145, for 1864, and "*Prodromus*," vol. xvi., pp. 404 and 405). After careful comparison of the different parts of many plants of different ages of both forms, I am enabled to substantiate the following botanical differences:—The leaves of *P. excelsa* have generally three resin canals, are finely and closely toothed on all three angles their whole length. The leaves of *P. Peuce* have generally two resin canals, are distinctly toothed on their edges—as one to three on a given space as compared with *P. excelsa*—and the upper or inner angle is entire nearly its whole length, there being only from four to six teeth near the point. The male catkins of *P. excelsa* are greenish-yellow, those of *P. Peuce* pale pink. The accompanying illustration correctly

represents a cone of *P. Peuce* which grew here last year. The difference between this and the cone of *excelsa* is, I confess, very little, except in point of size, the latter being from 6 in. to 10 in. long, with a foot-stalk from 1½ in. to 2½ in. long; but allow me to call the attention of botanists to the scales and seeds of both forms as here represented. The point or

Scales and Seed of Pinus Peuce.

angular process on the edge of the scale of *P. Peuce* seems to be unnatural; but if so, it is the fault of the cone, for all its scales are so formed, a circumstance possibly owing to imperfect development. The seed leaves of *P. excelsa* are from nine to thirteen in number; those of *P. Peuce* from seven to ten. To those who care to distinguish between growing plants of *P. Peuce* and *P. excelsa*, or, indeed, any other known five-leaved Pine, the bright glossy green of its bark will be sufficient. The young bark of *P. excelsa* is a dull glaucous grey. Practically considered, the two trees differ greatly. *P. Peuce* is at all stages of much slower growth than *P. excelsa*—so slow, indeed, that planters ordering *P. excelsa* with a view to plant for timber would not thank nurserymen for substituting for it the comparatively slow-growing *P. Peuce*. As an ornamental tree it is probably not less effective than the other, but it has a slightly different habit. It is of a narrow, conical outline, with the branches denser and less spreading than those of *P. excelsa*, and its leaves, which are of a dull green, are but little expanded. It reminds one more of *P. monticola* than of any other Pine. It is perfectly hardy in England, but not at all hardy in the warmer parts of Germany, where *P. excelsa* luxuriates. It inhabits the mountains

Scales and Seed of Pinus Excelsa.

of Roumelia and Macedonia, where it forms an erect tree, never exceeding 50 ft in height. Everything considered, it is probably only a variety of *P. excelsa*, but sufficiently well marked to deserve a name to distinguish it from the *P. excelsa* of Wallich, as, for instance, *P. excelsa* Peuce.

GEORGE SYME.

TRANSPLANTING LARGE TREES AND SHRUBS.

THIS requires forethought and preparation, but when alterations and improvements are decided on, they are, as a rule, so speedily commenced that there is little or no time for preparation; therefore the best must be done by means of careful transplanting with large balls. The system generally adopted is to dig a trench all round at an equal distance from the butt of the tree, cutting all the roots clean through. This seems right, but when we reflect that it is the minute extremities of the roots that absorb and manipulate the nourishment, we

are led to the conclusion that if a few roots of good length with their numerous rootlets could be taken up entire, they would support the tree while new roots were put forth from those cut closer in. A few years ago a difficult operation brought these things to my mind, and led to my adopting the novel plan of cutting out with the tree a block or parallelogram of earth three times the width of the stem on each side as far as the branches reached. In this way we get two lots of long roots, one on each side, with numerous undamaged rootlets; while the shape enabled us to grasp the projections with a home-made rough-and-ready pair of timber tongs with half-box ends, not less than the block in length, nor more than half its width, binding the mass of earth and root together, and keeping all safe from being shaken asunder *in transitu*. During the month of February I moved great numbers of standard Portugal Laurels, Evergreen Oaks, Hollies, and Deodars, from fifteen to twenty years old, from a sheltered situation into one much exposed. Several, in my absence, were moved during frost, yet, to my surprise, they did not subsequently show any ill-effects therefrom; nor a tree entered more than it would have done from preparation for future transplanting. Directly they were placed in position, a little manure and leaf-mould were mixed with the earth and placed all round, care being taken not to plant so deeply as they were before. They were then thickly mulched with leaf-mould and manure, and the second season they were all in robust growth, and many bearing abundance of flowers and fruit. The length of the parallelograms should run from the light to the heavy side of the tree, and when placed in its new position the heavy side should be set to the stormy aspect; this induces the tree to grow symmetrical in shape.—P. Love, in "Field."

#### ROOTS OF TREES ATTACKED BY FUNGI.

Most cultivators have, doubtless, occasionally had to deal with or prescribe for trees (both fruit-bearing and ornamental), the roots of which are so infested with the spores or long, thread-like filaments of some species of fungi as to endanger their lives. They are insidious pests that slowly but surely poison their victims. Being of so dangerous a character, every precaution should, therefore, be taken when planting rare or valuable trees that fungus germs are not introduced by using any half-decayed vegetable substance, such as leaf-mould or the sweepings from old faggot heaps. Planting a young tree in the site just previously occupied by an old one without thoroughly trenched and intermixing the soil, at the same time picking out every bit of soot, no matter how small it may be, is a dangerous proceeding. The best plan to adopt, when it is necessary to plant a young tree where an old one previously stood, is to open out a good hole, say 6 ft. square and 2 ft. deep, and cart the soil away bodily, and bring back fresh material from a position where no trees are growing. Many a young and valuable tree has been lost from want of this care, and if many a tree that has an unhealthy tinge were examined, fungi would be found on its roots. Trees infested with fungus will in nearly all cases be found dry at the root; it cannot exist in a damp soil. I have known trees planted on a heap of stones, with a view of securing a well-drained site, so subject to it, that it was necessary to lift and replant. The best and surest remedy is water strongly impregnated with soot; the latter acts as a check upon the growth of fungi, and is beneficial and strengthening to the tree. Trees of only moderate size could be taken out and have their roots carefully washed in a pond or large tub, and then be carefully replanted in fresh soil. Those too large to be lifted should have a trench opened at a suitable distance from the trunk, so as not unnecessarily to mutilate the roots, and the trench to be kept full of water until every particle of soil is thoroughly moistened; in fact, it is impossible to overdo it, as it must be drowned out, and the soaking with water ought to be repeated two or three times. If the soil be poor or exhausted, some of it should be removed and replaced with fresh material, at any rate, the trench should be filled with fresh earth, and some fresh loam should be used as a mulching or top-dressing. Just before growth begins will be a suitable time for ascertaining the condition of evergreen trees. Deciduous trees should be seen to at once if there be any suspicion of fungi being among their roots.

E. HOBDAY.

#### RE-PLANTING SACKVILLE STREET, DUBLIN.

SOME time towards the close of last year Mr. Niven generously offered to supply trees gratuitously for re-planting this street in the autumn of the current year, the trees being in the meantime selected by him and properly prepared for their transfer from Garden Farm to their urban homes. This offer was made subject to certain conditions, some of which, as to transport, providing fresh soil and labour, were fair enough; but there were others calculated to nullify Mr. Niven's good intentions. One of

these was that the flagway on both sides of the street should be widened, in order that the trees, when in position, would stand well inside instead of, as now, outside the kerbstones. Another condition was that neatly-fitting, open gratings should be provided for covering a certain portion of space left undrained round each tree for the purpose of aeration and watering. There could be no question (says the "Irish Farmers' Gazette") that if financially feasible these things would be highly advantageous; but then the expense would be very heavy, and in the present state of the municipal exchequer the Corporation could scarcely be expected to go in for it. Weighed against this cost, the free gift of the trees would be only as dust in the balance. As a consequence, we at the time suspected Mr. Niven's offer would fall through, and Sackville Street for another spell present the most unhappy example of municipal horticulture to be found in Europe. We are glad to perceive, however, from a report brought up at the Corporation meeting the other day that Mr. Niven's offer, renewed, but unhampered by the conditions mentioned above, has been thankfully accepted. The only conditions now imposed by Mr. Niven is that the trees be planted in October and be removed from his entrance-gate to their destination at the cost of the Corporation, that body also undertaking to procure suitable soil and pay all expenses incurred in planting. So far so good, and there is now hope that the second planting will not be like the first—a wretched failure. Our grounds for this hope are, that there will this time be carefully-selected and prepared trees, young, tidy, well-rooted, and planted at the right time: not ancient rumples, all but destitute of feeders, and planted at a season when the chances of success were all against them. As regards the mere planting of the present trees, it was well and carefully done, and had nothing whatever to say to their subsequent sorry figure. Besides the quality and condition of the trees, the advanced period of the spring in which they were planted, the wholesome influences to which town life is subjected there, and which will, we apprehend, be always a difficulty in the way of success, and also a want of due care and attention after they were planted, helped towards failure, while later on a ruthless and grossly-ignorant mutilation gave the coup de grace to such of the poor *miserables* as were making a struggle for life.

**Abies Regiæ Amaliæ.**—Most species of *Abies* and *Pinus* when cut down to the ground are virtually killed, and never recover themselves, as some other trees do, by throwing up fresh shoots. On Mount Malevo, however, a mountain belonging to the Arcadian range, there is found a species of *Abies* which must be taken out of the above-mentioned category, for, no matter how closely it may be cut down, it will throw up a shoot which will ultimately form a fine tree. This species of Pine was named after the late ex-Queen Amalia, the wife of the unfortunate King Otho, who was an ardent patroness of horticulture during her residence in Athens. Many thousands of these trees, which were formerly cut down and have since sprung up again, are to be found on the slopes of Arcadian and Peloponnesian ranges.—X. LANDEKER, Athens.

**How the Trees Suffer—White Mites.**—During the month of June, 1877, while driving in the country, I observed a Black Poplar tree evidently suffering from the ravages of insects; I therefore stopped the vehicle, and got out to examine. I found the tree bored in many places by the larvae of the goat moth (*Cossus ligniperda*), three of which I secured. A considerable portion of the bark was loose, and the sap kept this quite wet, the peculiar smell produced by the larvae being very evident. On removing a portion of the bark where it was moist with sap, I found it covered with a moving mass, consisting of myriads of very peculiar white mites. About the middle of August I again visited this tree, and found upon and with the white mites a number of hypopi, but whether these were parasitic on the white mites, or merely residing with them, I was not able to determine. I passed this tree on several occasions during the summer, and frequently saw wasps and red admiral butterflies enjoying the sap, which kept some parts of the tree continually moist.—C. F. GEORGE, Kirton Lindsey, in "Science Gossip."

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Leptospermum bullatum.**—This is a rapid-growing, tree-flowering wall shrub, the blossoms of which are produced on the old wood only. Its singular little seed vessels also render it interesting.—T. SMITH, Newry.

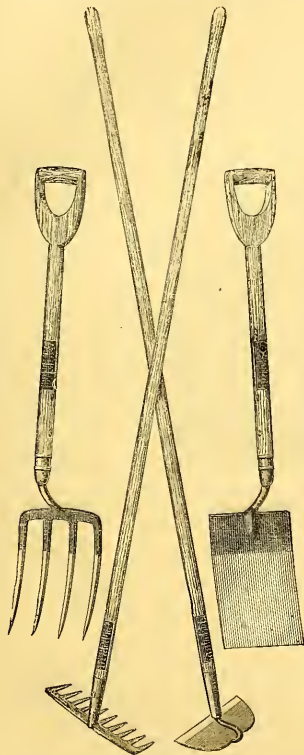

**Large Trees.**—The following is the circumference of trees at Mamhead, the seat of Sir Lydstone Newman, Bart., the measurements taken at 3 ft. from the ground: Oak tree, 14 ft. 6 in.; Yew, nearly 40 ft.; Oak, 18 ft.; Ash, 21 ft. 10 in.; Elm, 18 ft., and 23 ft. 6 in. at its largest girth.—F. D.

**Senecio elaeagnifolius.**—This is a very distinct and handsome shrub quite hardy here at Newry, where it grows rapidly. Its foliage, which measures 2 in. one way and 1½ in. the other, is glossy green above and silvery beneath.—T. SMITH. [Some very beautiful foliage was sent us with this notice—light glossy green above and silvery beneath.]

## THE KITCHEN GARDEN.

### GARDEN TOOLS.

A set of garden tools, consisting of a spade, a four-tined digging-fork, a rake, and a draw-hoe, called Andrew's patent "Paxton" gardening implements, of which the annexed is an illustration, has been manufactured by Messrs. Spear & Jackson, of Sheffield. The following advantages are claimed for them:—The iron straps with which the hand in ordinary tools continually comes in contact is abolished in these implements, and a smooth handle, better adapted and more suitable and agreeable to the hand while in use, is substituted; the cofer and rivets on the face of the spade is also dispensed with, thus securing a smooth level surface, which prevents all accumulation of earth, and allows the spade to work easier and to keep more cleanly. Being divested of the iron straps and shaft at the

neck, the earth is penetrated deeper and with greater ease, and there being no clogging, the work is accomplished with greater facility and less labour than would otherwise be the case. Altogether they are improvements on anything of the kind which we have hitherto seen. They are made of solid cast steel, are convenient to use, and have the appearance of being excellent tools.

**The Witloof or Flemish Endive.**—At a recent meeting of the French Société Centrale d'Horticulture several members exhibited specimens of the Witloof or Flemish Endive, a new variety of salad plant lately introduced into France. M. Poinet-Delau, gardener to M. Ledue, of Puteaux, showed a dozen fine heads, the leaves of which had grown in a fortnight under a layer of dead leaves. M. Poinet-Delau gives the following account of the method of cultivating this plant which he has adopted, and found to succeed admirably: From

May 15 to June 15 he sows the seed in lines 8 in. apart in good garden soil, previously well manured, for it is necessary that the roots should be well developed in order to obtain a good result. When sufficiently grown the rows are thinned out, leaving spaces of about 4 in. between each plant, taking care to leave only those which are of a globular habit. Hoeing and watering should be performed when necessary. In the course of the month of August M. Poinet-Delau cuts off the outer leaves. When wanted for use the plants are taken up, the roots trimmed down to about 8 in. in length, and the leaves to within from 2 in. to 4 in. of the collar, according to the growth of the plant. They are then planted upright in a frame in a bed of dead leaves, covering them over with a layer of rotten manure to the depth of 8 in. The frame is then shut, and covered up with straw-mats should the weather be cold. In a fortnight the plants will be ready for gathering, the transplanting being kept up every fortnight throughout the season. The waste leaves and roots may be given to rabbits. These little animals are excessively fond of all parts of the Witloof, and thrive well on this kind of food, so that every part of this plant may be utilised. M. Poinet-Delau was awarded a second-class prize by the Society for the excellent specimens which he exhibited. M. Sirry also showed some fine heads of Witloof which had simply been placed in sand in a cellar for six weeks, in which time they had produced an excellent ball of succulent leaves. The ease with which an abundant supply of good salad material may be obtained at any time, almost without expense or trouble, ought to make the Witloof one of our most popular and widely grown salad plants.

### SPRING-SOWN ONIONS.

THE most favourable season for sowing main crops of Onions being now at hand, and as much of their future success depends on the previous preparation of the soil, a few remarks on the routine which I have found to be successful may be serviceable. Although, as a rule, I find hard and fast methods, as regards rotation of crops, neither profitable nor practicable, we make an exception in the case of Onions; we invariably follow the main crop of Celery with them, as the preparation necessary for that crop leaves the ground in good condition and vacant at the proper season for sowing. The ground, after a crop of Celery, owing to the deep cultivation and exposure to atmospheric influences which it received during the winter, is in the very best condition for being levelled down by the end of February, when a dressing of pigeon's manure or other thoroughly rotted manure is applied and forked in, the surface being left rough, until the first or second week in March, when, choosing a fine dry day, a good dressing of soot is spread on the ground and raked in; the ground is then trodden firmly all over and raked level, the rows are marked off 1 ft. apart, and very shallow drills are drawn with a triangular hoe. If the seed be good, it can scarcely be sown too thinly, for all superfluous growth that has to be removed at thinning time is so much loss to the main crop. After sowing, the drills are trodden in and the beds lightly raked over. As soon as the seedlings show themselves, a Dutch hoe is run between the rows, and repeated at intervals, to keep down weeds; the rows are hand-weeded, and the plants thinned to their proper distance apart, which must be regulated according to whether large specimens are required or only a full crop of medium-sized bulbs for ordinary use; the latter is preferable, and in that case the plants may be left from 3 in. to 6 in. apart in the row. When in full growth, a top-dressing of soot is highly beneficial, and by adopting the above routine we seldom have any loss from the Onion fly, although it has of late years been exceptionally destructive in the neighbourhood. We have grown the following sorts with good results, viz., James's Keeping, one of the very best, Nuneham Park, Reading, Deptford, Bedfordshire Champion, and Dauver's Yellow. As soon as growth is quite completed, the whole crop is pulled up and thrown into beds, keeping them stirred with a wooden rake on fine dry days until the outer skin is thoroughly crisp and dry, when, a favourable period being selected, they are stored in cool, airy lofts or sheds, and cleared and sorted as required. If well ripened, the late sorts will keep until the autumn-sown crops are fit for use. After the crop is cleared off the ground a good dressing of manure is applied and dug in deeply, and the main crop of Cabbages is planted on it about the first week in October.

JAMES GROOM.

Henham.

## SEED BEDS AND SEED SOWING.

The majority of kitchen gardens, owing to the wetness and mildness of the season, are already so fully stocked with slugs, that there is little chance for the growth of seeds. It is astonishing how intensely conservative most cultivators are in all matters relating to sowing and planting. Seeds are not seldom sown on the same day and in the same place, be the weather or the conditions and circumstances what they may. This is altogether wrong. All such matters should be more determined by conditions than times. The more haste the less speed is often verified in the sowing of seeds in the open air, and for this obvious reason—that the loss of a crop is always a loss of time as well as of seed. Every day that seed lies longer in the ground than is necessary for its germination, through being sown under unfavourable circumstances, increases the risks of its injury and final loss. The greatest seed-killer in the world is a cold, ungenial, wet seed bed, filled full of black slugs and other seed-eating pests. But what easier or wiser than to at once baulk the slugs and forward such plants as Cauliflowers, Cabbages, Brussels Sprouts, Lettuces, Peas, Broad Beans, Potatoes, &c., by sowing them in pots, pans, boxes, or in the soil itself in pits, frames, the floors of orchard houses, or other places? Whilst such seeds are vegetating in safety under these favourable conditions, the seed beds and their living occupants should be treated to a few dressings of hot lime, bitter soot, or sharp coal-ashes or burnt marl. These will help to clear the soil of pests and improve its condition, so that by the time the plants are sufficiently advanced to be planted out, the ground will be fit to receive them. Fortunately, such main crops as Onions seldom suffer much or at all from slugs. On some wet soils they are, however, injured by worms, which drag them underground in a young state in great numbers. In such localities Onions may be treated in the same way as other seeds specified, and planted out when well up. Parsnips, Carrots, Turnips, and Radishes do not transplant well, and fortunately the first does not dislike the wet, and slugs are not so fond of Carrots as of Peas, Brassicas, Lettuces, &c.; besides, April is time enough for the main crop of Carrots. Peas have suffered exceedingly this winter; so much so, in fact, that those sown in November have disappeared almost wholly in some gardens. This is really of little moment, except as regards the loss of the seed. Peas sown now, and planted out when a few inches high early in March, will generally be fit to gather quite as early as those sown in November. The crop, too, will, as a rule, be more regular and equally prolific. The soil is much fresher, sweeter, drier, and in all respects more favourable to vegetation than such as has been under crop all winter. Of course such seeds as the first crop of Celery, Tomatoes, &c., are always raised in heat. The object of these remarks is not to suggest what to sow, but to urge a departure from the usual mode and place of sowing hardy vegetables at this season. Time, strength, money, and health are gained by sowing in artificial seed beds when the earth is stocked with slugs, chilled by cold, and soaked with water. Seed beds in open quarters for such main crops as Carrots, Onions, Parsnips, Early Turnips, Spinach, Radishes, Potatoes, &c., may also be vastly improved by careful earth culture. Early autumnal cultivation and thorough drainage are the best preparations for a good spring or summer seed bed. Ground laid up rough in autumn forms a distasteful lair for slugs and worms, and becomes warm, dry, and mellow, in a word, a model seed bed under the first breath of spring. Even this favourable state may be heightened by the addition of a few loads of burnt earth or charred refuse. Bottoming the seed drills or seed beds with such matters, and also applying a heavy sprinkling of similar substances over the seeds, is the best antidote for insect pests, as well as the most kindly and genial help to the germination and early growth of seeds. No doubt all this is more trouble than the mere casting of seeds from the bags

into the ground, whether it be sour or sweet, wet or dry, warm or cold, clean or foul. But in the matter of seed-sowing it is emphatically true that what is worth doing at all is worth doing well. Success in furnishing a continuous supply of vegetables rests upon the proper rearing of seeds, and this can hardly be achieved in seasons like the present without the adoption of some such conserving and stimulating expedients as those here noted. D. T. FISH.

**Vegetable Plants of Greece.**—Besides the ordinary vegetables grown in gardens, amongst which the Artichoke holds the first place, in company with ordinary Potatoes, Sweet Potatoes (*Convolvulus Batatas*), Tomatoes, Aubergines, &c., a large number of vegetable plants growing in the fields and on the hills round Athens are collected by poor women and children and sold in the streets and markets as Chickweed and Groundsel are in London and Paris. They are bought largely by the common people, and either stewed with meat in the national *pot-au-feu*, or eaten as salads. Amongst them are several plants used medicinally. The most common of them are Chicory (called "Radikia" by the modern Athenians), Common Mallow, *Raphanus sylvestris* (a kind of Radish), Spinach, Caulis, Sorrel, Fennel, Water Mint, Asparagus, Cress, and Portulaca oleracea, the latter being a favourite escul with all classes of the community. It sometimes happens that, through the ignorance or carelessness of the gatherers, poisonous and wholesome plants are plucked together. Some time since, in one of the small islands off the coast of Greece, four children were poisoned through eating a quantity of *Hyocyamus* which had been gathered in mistake for a salad plant. *Conium maculatum* does not seem to be as poisonous in the East as it is in the West. The porters of Constantinople eat it in large quantities as a salad with oil and vinegar without feeling any bad effects.—X. LANDERER, Athens.

Nook in Pleasure Ground with Weeping Spiphora, Dracæna, and Day Lilies around Tree.

on the produce of their own country, and when there comes a scarcity prices range higher. It is from Bedfordshire, and especially the districts of Sandy and Bedford, that the chief supplies of Onion seed are drawn. There are some growers on a large extent, and many cottagers and others grow their piece of Onions for seed. When there happens a good season, and the sample is of the best quality, a bushel of Onion seed will weigh from 37 lb. to 39 lb., inferior samples 35 lb. to 36 lb. To show the large amount of seed required to meet the demands of the trade, it may be mentioned that twenty years ago one of the wholesale seed houses, and that not the largest, used to put together 250 bushels of seed as the first bulk. This would be done early in December, and be quite exhausted by the end of February.—D.

**How Celery is Blanched.**—Those who follow the advice given by Mr. Fish at p. 154, to grow their Celery to full size first and blanch it afterwards, will think, in the end, that it had been better if they had put up with the worms than attempted to combat them by such means. Mr. Fish does not seem to be aware that Celery cannot be blanched, or made fit to eat as a salad if the plants are allowed to grow to their full size first. To recommend the abolition of the progressive system of earthing up simply means no crop. It is not the leaves that are covered at the time of earthing up that are blanched fit for use, but those that push afterwards, and which never see the light, and this, I thought, every practical gardener was well aware of. I would not recommend earthing up too soon, but it should be commenced long before the plants have grown to full

size. If better authority than mine be needed on this point, I refer your readers to Mr. Robert Thompson in the "Gardeners' Assistant," where, in speaking on this very subject, he says, "So it is with Celery. The part of it which we do not grow in the dark cannot be blanched, as it should be, white, crisp, and tender, by any subsequent exclusion from the light. This, we think, is sufficient proof against the practice of allowing Celery to grow nearly to its full, and then earthing it up at once." I fail also wholly to see how the late earthing up of the plants can in any way prevent the white worms he speaks of, and by which I apprehend he means the maggot of the Celery fly or those of some of the other enemies of the Celery, leaving out snails and slugs. The first begins its ravages almost as soon as the plants are put out or as soon as the eggs of the fly are hatched, and which are deposited upon the leaves in the first instance; hence it follows that the longer the plants are left unearthed the greater the destruction is likely to be from the worms.—*CHER.*

### STORING ROOTS.

MR. GILBERT'S remarks (see p. 154) on this subject are quite right. To maintain roots sound in quality and sweet in flavour, store them in moderate quantities in the open air. On the other hand, mass storing in dry earth or sand is the surest means of drawing out quality and ruining flavour. Roots stored in masses frequently undergo a species of decomposition, while dry earth or sand extracts no small part of their sweetest juices. This applies to Potatoes as much, or more, than to Carrots, Parsnips, Turnips, or other roots; in fact, many of the marvellous differences in quality observed among Potatoes of the same varieties in different localities originate as much, or more, in modes of storing as in varieties of soil or diversities of culture. The nutty flavour so much prized in Potatoes cannot be long preserved unless they are stored in the earth. The old-fashioned mode of storing in narrow pits was far preferable to the modern ones of cellar, loft, or bin storing. The only mistake about the pit was the covering with straw immediately over the Potatoes, which often imparted a musty flavour. Of course the straw covering was convenient as regards facilitating the removal of the Potatoes from the pit. But better far spend a little more time in removing the Potatoes than ruin their flavour. If straw be used at all, it should be over a layer of earth, to exclude wet and frost; not under the soil, next the Potatoes. As to the earth running through and among the tubers, the more in reason that occurs the better. It separates the Potatoes, and thus conserves their flavour, and also, perhaps, preserves them from disease. It may also be added that it is a great mistake to air-dry Potatoes when lifted. The Potato rind is sensitive to the touch and largely porous to atmospheric air when first turned out of the ground; the air thus sweeps quality out, and is often loaded with fungus spores and other germs of disease, which could hardly find a more favourable seed-bed than the moist surface of a newly-raised Potato rind. To prevent such seeds from being sown, and also the flavour of the tubers from being dissipated, cover them with earth the moment they are lifted, and keep them covered till eaten. D. T. FISHER.

### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Early Sown Brussels Sprouts.**—We do not find that Brussels Sprouts are much appreciated before October, and they can be easily had in fine condition then from sowings made in the open border in March. There is no necessity for sowing them under glass, and the space may be better utilised with tender crops.—*J. G.*

**Early Peas.**—William I. and Ringleder are now from 3 in. to 4 in. high. They were sown on the 15th of November, and have received no protection of any kind, except what was needed to be done. The seed had to be rolled in; it had to be coated with red lead to keep off mice when breaking;  $\frac{1}{2}$  in. of coal-ashes had to be put into the ground to keep off slugs; and, lastly, bre strings of worsted had to be used to keep away the sparrows.—*R. GILBERT, Burghley.*

**The Wrong Ideal.**—A writer in one of our contemporaries, in an otherwise excellent article on Brussels Sprouts, says, "My best ideal of a plant of Brussels Sprouts is as follows:—It should be fully 4 ft. high and studded with Sprouts the size of a small Orange." In the native land of the Brussels Sprouts, and in other places where this vegetable is a favourite, it is preferred small and green. A hard little body, the "size of a small Orange," is far from what the Brussels Sprout ought to be; some harm is done in the aim to get everything as big, as full of sugar, or as circular as possible.—*V.*

**The Conqueror Tomato.**—Prof. Beal finds the Conqueror the earliest out of a large number tried at the Michigan Agricultural College. The form and ripening of the Hathaway are almost perfect, but it has proved a moderate bearer. He prefers the Trophy for a late sort.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 19.

THE most attractive subjects shown on this occasion consisted of groups of Orchids from Messrs. Veitch, Williams, and Wills. With these and other choice plants, together with large quantities of well grown florists' flowers, the whole of the available space in the Council room was completely filled.

**First-class Certificates** were awarded as follows:—

**Hæmnanthus rupestris** (Ball).—A species furnished with large heads of flame-coloured inflorescence, borne on stout stalks from 6 in. to 9 in. in height.

**Cyclamen White Beauty** (James).—A good-habited kind, belonging to the Persian section, bearing large, pure white blossoms, beautifully scented.

**Primula sinensis fimbriata coccinea** (Williams).—A fine variety, bearing whorls of deep rosy-crimson blossoms.

**Cyclamen Rosy Morn** (H. B. Smith).—A fine kind, bearing large flowers of a rosy-pink colour.

**Cyclamen persicum rososum grandiflorum** (Edmonds).—A dwarf-growing variety, with marbled foliage and large and beautiful rose-coloured blossoms.

Botanical commendations were awarded to Messrs. Veitch & Sons for *Aerides vandarium*; also to Messrs. Rollison & Sons for *Saccolabium Calceolare*, a rare Orchid, bearing small waxy flowers from the base of the plant.

**Miscellaneous Plants.**—In Messrs. Veitch's collection of Orchids was a fine example of *Angraecum sesquipedalesuperbum*, bearing very large ivory-white flowers; a richly-coloured *Cypripedium Harrisianum*; a magnificent example of the beautiful white-flowered *Cattleya Trianae*; *Odontoglossum Bechii album*; *Laelia Elchei alba*, and a richly-coloured variety of *Oncidium Forbesi*. Associated with these were also well flowered examples of the peculiar *Masdevalla Chimera*, *Cyrtocloium maculatum*; and the unique *Angraecum citratum*; from the same firm also came a good plant of the brightly flowered *Hæmnanthus cinnabarinus*, in good condition, and the beautifully-spotted variety of *Odontoglossum Alexandræ*, called *maculatum*. Mr. John Wills, Onslow Crescent, South Kensington, sent an attractive group of Orchids, Palms, Ferns, and Mosses. In Mr. Williams' group were good examples of *Dendrobium superbiens*, *Cypripedium Marlei*, *Dendrobium Wardianum*, and the curious but beautifully-coloured *Trichopilia suavis*; *Odontoglossum odoratum*, and several good varieties of *O. Alexandræ*. A panful of plants of *Habrothamnus elegans argenteus* was also shown by Mr. Williams, who had, moreover, a group of *Solanum hybridum* (Empress), some beautiful Chinese Primulas, and a brilliantly-coloured plant of the new *Croton falcatum*. From Mr. Winn, Wood Street, Birmingham, came one of the most beautifully-spotted varieties of *O. Alexandræ* we have yet seen; and Mr. Johnson, gardener to P. Clarke, Esq., Uxbridge, sent four finely-flowered specimens of *Daphne indica rubra*. A brilliant and curious but beautifully-coloured *Trichopilia suavis* was shown by the Hon. and Rev. J. P. Boscawen, and was awarded a vote of thanks. Mr. Cannell furnished examples of the salmon and white-coloured varieties of *Yasuvium Pelargonium*, and also the scarlet-purple kind called Dr. Denny. Several good seedling Snowdrops were shown by Mr. Melville, Dunrobin Castle, and a white-flowered *Camellia* named *Ninfa Egeria* came from Messrs. W. Paul & Son, Waltham Cross. An excellent group of Persian Cyclamens was furnished by Messrs. Veitch & Sons, and exhibitions of the same plant also came from Mr. H. B. Smith, Ealing Dean Nursery, and Mr. Charles Edmonds, Hayes. Messrs. John Standish & Co., Royal Nurseries, Ascot, sent well-flowered specimens of *Chorozema cordatum splendens*, several Palms, Roses, and a dozen potsful of Lily of the Valley, each containing no fewer than 100 well-developed flower-spikes. Mr. James, gardener to W. F. Watson, Esq., Isleworth, furnished an attractive group of seedling *Cinerarias*, remarkable for their bright colours and dwarf habit. From Messrs. W. Paul & Son came an extensive collection of cut blooms of *Camellias*, consisting of all the best known sorts of all colours. Mr. Ollerhead, gardener to Sir H. Peck, Bart., sent a plant of *Odontoglossum Alexandræ*, on one spike of which there were thirteen unusually large waxy-looking blossoms. A beautiful plant of *Kentia macrocarpa* came from Mr. Bull, of Chelsea.

**The Fulham Nursery.**—It is stated (see p. 136) that we are preparing trees for removal on account of the ground being shortly required for a railway. This is not quite correct. It is true there is a project in hand to bring a railway to Fulham, which, if it comes, will take a small portion of my nursery, but not all in the direction in which we are now preparing trees for removal. This we are doing for quite a different purpose, viz., because in the course of a few years my lease of the "portion of the ground which is not my own expires, and may not be renewed, and I am anxious that a few of our fine and scarce specimens may then be in a fit state to transplant."—*ROBERT OSBOEN.*

MR. GRANSTON considers Yew the most difficult tree to fell; next come Beech and Ash. Oak, though very hard, fells well; but the easiest of all is Spanish Chestnut.

## RETINOSPORA ERICOIDES A MISNOMER.

I would again remind Mr. Meehan (see p. 155) that I heartily agree with him in considering the above name a misnomer for the Rochester seedling, *Thuja occidentalis ericoides*. What is known in Britain as *R. ericoides* was considered by Parlatore to be a variety of *R. squarrosa* (Sieb. and Zucc.), and in so classifying it he may have been right. They, however, differ considerably in their juvenescent conditions. The leaves of *squarrosa* are generally in opposite pairs, but occasionally in whorls of three; those of *ericoides* are generally in whorls of three, but not infrequently in opposite pairs—according to the vigour of the branch or branchlet to which they are attached. I may also state that the male flowers of the latter are of a beautiful red colour. Has Mr. Meehan ever seen a red flower on any of the varieties of *Thuja occidentalis* or on any Juniper? The *R. ericoides* of the United States is known here as *Thuja occidentalis ericoides* of which a twig was sent me, received from Mr. Meehan. Its leaves are similar in shape and disposition on the branch to the illustration of the plant (*R. juniperoides*) which gave rise to this discussion. But, independent of that, they are essentially distinct. There are other forms belonging to distinct genera—aye, belonging to different tribes—that have juvenescent leaves similar in shape and disposition to those already named. Such an one is *Widdringtonia cupressoides*. So closely does it resemble *Thuja occidentalis ericoides*, that even people well informed in such matters would have some difficulty in saying which was which. This being the case, why does not Mr. Meehan call this plant *T. occidentalis ericoides*? "Arbor-vitæ have their leaves in pairs, as Mr. Syme's drawing has." A one-year-old seedling of *T. occidentalis*, now before me, has its leaves in fours, threes, and twos; and the juvenescent leaves of *T. gigantea* are nearly always in fours; but, as in all the *Cupressinæ*, the number of aggregate leaves varies in proportion to the vigour of the species, the individual, or, indeed, the vigour of the individual twigs of a plant. We are told that "polymorphic Junipers are easily known, when carrying on through life their juvenescent form, by having their leaves in whorls of three." If this were a constant character, there would be less difficulty experienced in determining them; but, although three in a whorl is the normal number, four and two are not uncommon. A branch of *J. communis* before me has its leaves in whorls of four, while on the weak laterals they are in threes. Mr. Meehan may, perhaps, learn some day to place less faith in the number of leaves in a whorl on the branches of the *Cupressinæ*, as a specific or generic character, than he seems to do at present. Those who have studied these matters most find that the number varies in proportion to the vigour of the portion of the plant on which they are found, and therefore they place little reliance on this point as a character for classification. With such, the shape and internal structure of the leaves take precedence to the number of them in a whorl. Contrary to what I have written, Mr. Meehan states that "*R. juniperoides* of the trade is a Juniper which has simply retained its juvenescent character," i. e., that it has leaves in whorls of three. It would be interesting to know the name of the species of Juniper represented, also where it is a native of, or, if a garden variety, where and when it originated.

Geo. Syme.

**Closed Gates at Kew.**—I cannot understand why the authorities at Kew object to opening the gardens early for this reason: they admit they are for public instruction, and therefore the more the public can see of them the better. Yes, but, say the authorities, that is all very well; but when is the work in the houses to be done if the public be admitted early? Now, I know from six years' experience in the houses at Kew, that there is no validity in this objection. When I first went to Kew, I re-potted the whole of the plants in the Cactus House, and never stopped for the public; neither did they hinder me. The same, I know, is done in the Palm House, the Fern House, the new Range, and the new Temperate House. If at any time we were obliged to stop up a part of a walk, the public did not complain. As to extra labour, anyone acquainted with Kew knows that there is always enough; for what two men have to do in a private place, three are provided at Kew. Then, as to the scientific work done in the gardens for the colonies, that is all done in the propagating pits, and they are always private.—J. CROUCHER, late Foreman of the Propagating Department, &c., Royal Gardens, Kew.

**Azalea mollis.**—I have at present a quantity of seedling *Azaleas* of the *Mollis* section crossed with *Azalea sinensis*, and they are showing fine trusses of flower that vary in colour from golden-yellow through the intermediate shade of copper and buff. By crossing with *A. sinensis*, the flowers are larger and better shaped than those of the type that I grow, which consist of *Consul* *Pecher*, *Isabella Van Houtte*, *Madame Legrele*, *Baron Rothschild*, *Ebenezer Pyke*, and

*Madame Van Houtte*. I had these varieties from Belgium when they were first sent up. I have now grown them for several years, and I find that as decorative plants during the winter months they are invaluable. They can be had in flower with very little forcing in the depth of winter, and in a cold greenhouse they will flower early in the spring, keeping up a succession; and amongst other plants their showy trusses and peculiar colours make a grand display. As they are perfectly hardy, they ought to be planted in borders and shrubberies in quantities along with Ghent *Azaleas* and *Rhododendrons*. In pots I find them to grow well in a light loamy soil mixed with leaf-mould, but I have no doubt that any good peaty soil that would suit *Rhododendrons* would likewise suit them.—WILLIAM TILLEY, *Welbeck*.

## OBITUARY.

JOHN KEYNES died at Salisbury on Sunday last, the 17th inst., in his seventy-third year. Mr. Keynes, an enthusiastic lover of flowers, commenced his career as florist by cultivating Pinks and Carnations; and well do we remember the fine examples of both which he showed at Chiswick in days gone by. He next directed his attention to Dahlias, of which he was not only a skilful cultivator, but a most successful raiser of new kinds, many of his earliest seedlings still occupying foremost places in even the best collections of the present day. No longer ago than last year eight of his seedling Dahlias obtained certificates. Of late years, however, his attention has been for the most part devoted to Roses and Rose growing; and in order to show how well he succeeded with the queen of flowers, we may mention that one year, not very long ago, he carried off first prizes at the Crystal Palace in every class in which he showed. Both in public and private life Mr. Keynes was much respected for his straightforwardness, and for the earnestness and vigour with which he carried through whatever he undertook.

The death, at Orleans, is announced of M. de Laage de Meux, aged ninety-three. He it was who first introduced the cultivation of the Pine on a large scale in the desert region of the Sologne.

## NOTES AND QUESTIONS—VARIOUS.

**Antirrhinum procumbens.**—This, when grown in pots, pans, or baskets suspended from the roof of a greenhouse, has a pleasing appearance, and yields numerous whitish blossoms all through the winter.—S.

**Cochlostema Jacobianum.**—"W.E.G." must have fallen into more than one error respecting this very beautiful plant. In the first place, it does not belong to the Pine Apple family (Bromeliads), but to the Spiderworts (Commelinaceæ); secondly, that it does not seed freely I admit, but I have raised young plants from both self-fertilized seed, and also from seed obtained by means of artificial fertilization. Seed-bearing, therefore, cannot be so great a rarity as your correspondent would lead us to believe.—W. H. G.

**Artificial Manure.**—Will you kindly inform me what proportion of guano, ashes, and soot you think most suitable to make a manure for general gardening?—A. S. [To every barrowful of sifted ashes put one shovelful of guano, and two of soot; you will thus make a good mixture for general purposes.]—S.

**Rosa Brunoniæ.**—Will some reader of THE GARDEN kindly inform us where this Rose can be procured; also seed of *Rosa polyantha*? Is *Brownia macrophylla* a hardy shrub?—Sux. [The *Brownia* to which you refer is true.]

**Propagating Willow Trees.**—Will someone kindly tell me how to raise Willow plants for renovating coppices, &c.? I have tried cuttings, but cannot succeed, possibly because they were taken in an improper way, or at the wrong time.—K. [Willows may be easily propagated by cutting up long shoots of last year's or older wood into slips from 1 ft. to 15 in. in length. They should be planted in a slanting direction in moist soil, if near a pond or river so much the better. If planted during mild weather in March or February, and made firm in the soil, they will commence to grow in January or April, and become well established during summer. Pieces of Willow as thick as a broom-handle driven into the ground like pegs will also root and grow freely.—S.]

**Wide Copings as Fruit Tree Protectors.**—I desire to follow the recommendation frequently given in THE GARDEN of having a removable coping for fruit walls, either of wood or of glass, but the estimates which I have procured make them come too costly for practical use. I am sure that some of your correspondents would greatly oblige me besides myself if they would, at this season, when it is high time to get them ready for this spring's blossoms, give particular directions, sufficient to enable a carpenter, or at any rate a horticultural tradesman, to work from. It is chiefly the elaborate iron fastenings which seem to make my estimates so high. I imagine some sort of iron support from beneath will be necessary, lest the coping should be blown away by gales from below. As to width, would 18 in. be sufficient? These copings seem common in France, and I am sure they are economical there. How do they fasten them effectually and cheaply in France? Nearly every spring late frosts kill the Pear blossom on my walls.—E. Aigburth. [18 in. would be a good width for walls not exposed to heavy cold rains. A thin board or felt in very light frames ought to be easily arranged by a carpenter and blacksmith. Well-made straw mats are generally used in France. Can any of our readers advise?—En.]

"This is an art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

**Tea Roses at Syon House.**—The method of growing Roses adopted by Mr. Woodbridge is one well worth practising by anyone who has space at command, and who requires to have quantities of flowers during the winter months. The house in which they are grown is a lean-to one, which was formerly a Vinery, the border being outside. In this the Roses were planted; the main stems were brought through the front wall and the branches trained on a trellis near the glass; and, although they have only been planted little more than two years, they completely cover the roof. The principal kind grown, and the one which succeeds best, is *Maréchal Niel*. This was first tried on its own roots, but was found not to succeed satisfactorily; it was, therefore, budded on the seedling *Brier*, on which each year it has made fine growth. The main stem near the base is as thick as a broom-handle, and the shoots are as large as a good-sized walking-stick, whilst the smaller branches bear a profusion of golden blossoms. *Cheshunt Hybrid*, *Devoniensis*, and several other kinds are grown in the same house, but they do not come into bloom so early by several weeks as *Maréchal Niel*; moreover, they neither grow nor flower so freely. For succession, Roses are also grown here at the back and sides of Peach houses or Vineries, and, besides yielding a plentiful supply of bloom, they help greatly to beautify the houses.—C. S.

**Primroses.**—These are in bloom this season at least a month before the usual time, and it is with regret that I find it necessary to lift and out the plants to pieces because of the inexorable exigencies of propagation. Those who can plant their Primroses in borders or beds and allow them to remain undisturbed for two or three years are indeed to be envied, as here, where all the choice kinds get transplanted twice in the year and all others once, it is impossible to have those beautiful heads of bloom that are seen in borders in which the plants are well established. I get the best display from Primroses every spring by lifting some three or four single crowns into 6-in. pots and keeping them in a frame or cool house; thus treated they form fine heads of bloom, and are most beautiful during the month of March, which is, as a rule, the best month for Primroses. *Virginia*, snow-white; *Brilliant*, rich vermilion-crimson; *Lustrous*, intense deep crimson; and *Rosalind*, rose-red; and others, are now in bloom, and show off their fine florists' qualities and solid colours to advantage. The singularly-coloured seedling kind shown at South Kensington on the 19th ult. by Mr. Wilson is a novel and really valuable addition to these beautiful hardy flowers. All who know the so-called *altaica* have but to picture it transformed into a plant having flowers of a bluish-purple hue to understand what the new Primrose called *Scott Wilson* is.—A. D.

***Isolepis gracilis* for Surfacing Pots.**—This is a most useful plant for surfacing large pots in which Palms, Camellias, &c., are grown, and it should be cultivated by the thousand for such purposes. Small plants of it in thumbs, or 3-in. pots, can be readily dibbled in over the surface of large pots, or planted so as to form a fringe hanging over their edges. A few plants, or even a row hanging down in front of the stages in greenhouses or conservatories, have a charming effect. In very large conservatories, Camellia houses, Orangeries, &c., where large woody, and sometimes rather bare specimens are met with, a very pretty effect may be produced by means of this plant by shaking out a number of them, tying them in Moss, and fastening them with fine wire here and there on the bare branches. They will need no other care than syringing now and then to keep them damp. The numerous drooping culms will hang down and hide the Moss, and have a pretty epithelial appearance. Another method with this plant is to place it in small pots; under the rim of these pots is placed a stout wire, with a portion of it turned up to form a loop. In most old conservatories or on the back walls of old-fashioned plant-houses, where Camellias and various creepers are usually grown, there are almost sure to be bare naked places, in which a nail driven here and there, and a pot of the *Isolepis* with its wire collar placed on them, will have a novel and refreshing appearance. Under such circumstances the plants will soon hide the pots, and give a character to otherwise uninteresting places. I need scarcely add that the plant is nearly hardy, and that it revels in damp and shade.—T. WILLIAMS, *Ormskirk*.

**Precoity of Vegetable Crops.**—If the present mild weather should continue through March we shall have to contemplate something approaching a green crop famine a little later in the season. It

is a fact that all kinds of Greens are now pushing on with remarkable rapidity, and throwing up flower-stalks as fast as if it were the month of May. Turnips have made 1 ft. of growth, and at the present rate will be soon over. Nothing but dull, cold weather can hold these and other vegetables in check, for bitter easterly winds or sharp frost would kill the young tender growth wholesale. With such an abundance of Greens and a poor sale, Turnip-tops will scarcely pay for gathering, and doubtless many acres that otherwise might find their way to market will either be food for sheep or be ploughed in as manure. With this evident precoity in all green vegetables it will be found difficult to tide over the interval that elapses between the cutting of the latest white Broccoli and the gathering of the earliest Peas. For the supply during this interval we have generally to depend upon autumn-planted Cabbages; but a mild season now may in large quantities of these to "bolt," and thus the anticipated supply will be lessened. In private gardens Asparagus and Seakale are serviceable, but such vegetables as these are out of the reach of the masses for whom the general market grower has to cater. The precoity of the green crop, as now seen, will, of course, enable the ground occupied to be cleared and re-cropped at an earlier time than usual; but with a glut of Greens the sale is so poor, that any grower would prefer that the incoming of the crops should be spread over a longer period. Success in market gardening does not depend upon the quantity of the crops produced; a good remunerative price at the market is what is wanted.—A. D.

#### NOTES FROM KEW.

AMONGST hardy shrubs the most striking is the European *Cornus Mas*, whose leafless branches are now studded with clusters of small, bright yellow blossoms; the pulpy fruits, which are in shape and size somewhat like Olives, and resemble a cornelian in colour, have obtained for it the name of Cornelian Cherry. *Acer dasycarpum*, the Silver-leaf Maple of the Eastern United States, is also bright with thousands of small red flowers. This species, sometimes cultivated under the name of *A. eriocarpum*, is one of the most beautiful of Maples, and is much used in America as a shade tree on account of its rapid growth and handsome foliage. The following are the most interesting and noteworthy of the hardy herbaceous plants to be seen at Kew:—*Xiphion reticulatum* (perhaps better known as *Iris reticulata*) and its variety *Krelagei* are invaluable for spring flowering; the variety is the earlier to bloom by a week or more, but the type is perhaps the more beautiful. Their general colour is a deep violet, and they exhale a delicious fragrance of Violets. *Galanthus plicatus* is a very pretty Snowdrop, differing from the common one in its plaited leaves. The Spring Snowflake (*Leucojum vernum*) is similar to the Snowdrop, and is one of the most charming of all hardy flowers. It may not be generally known that this forces readily, thus differing considerably from the Snowdrop, which does not lend itself at all easily to any such purpose. *Helleborus colchicus*, with its purple flowers, is, at present, the most showy member of this very ornamental genus. *Bongardia Ranwolfi*—the only known species of the genus—is very rarely met with, although it is a long time since it was first introduced to this country; it has a wide geographical distribution, being found from Greece to Persia and Afghanistan. This peculiar herbaceous Berberis has an underground, Potato-like root-stock, a few pinnate leaves—the lower portion of each lobe being purple-red, the rest a dull green—and a stout-branched scape bearing golden-yellow flowers from  $\frac{1}{2}$  in. to 1 in. in diameter. In the Crocus collection many very pretty species may be seen, one of the best being *C. Sieberi*, a native of Crete, Greece, and Asia Minor; this is a lovely little species, with its golden-throated, pale blue flowers just over-topping the leaves. *C. etruscus*, from Italy, of which no figure has as yet appeared in any English work, is near the last named, but is of a paler and more delicate blue colour. Among yellows, the brightest is *C. Olivieri*, a handsome little plant from Greece and Asia Minor, with faintly-smelling, golden-orange flowers. The Crimean *C. asiaticus* comes next, and is remarkable for expanding its blooms in all kinds of weather; the three outer segments roll back, and continue so even when the flower is closed in the evening, never returning to a straight position. *C. luteus* and *C. aureus* are similar in size and colour; they inhabit the same countries as *C. Olivieri*. *C. biflorus* and its varieties, *argenteus*, *Waldenii*, *pulsillus*, and *estriatus*, are all very desirable kinds.

Besides many previously-noted species, several fresh *Orchids* are in flower, the best of which are given below. *Epidendrum Lindenii* is a tall, leafy plant from Central America, nearly allied to *E. xanthinum* mentioned in Notes from Kew several weeks ago; the flowers of this species are sulphur-yellow, and not orange as in *E. xanthinum*. *Dendrobium densiflorum album* is a very striking *Orchid* with tall, ribbed stems and pendulous racemes of flowers, the sepals and petals of which are white and the lip orange. *D. semulum* is a small

species from Australia; it has small, cylindrical pseudo-bulbs and short, upright racemes of small white flowers. *D. barbatulum*, from Western India, has lateral, many-flowered racemes borne on graceful, slightly-curved stalks; the flowers, which are about 1 in. in diameter, are almost pure white, with the exception of the green spur. *Batemanii* Colley has a pendulous inflorescence of three or four rather large flowers, which are described in books as handsome; their dull colour, however—greenish tinged with purplish-red—and somewhat disagreeable scent will not recommend them to cultivators. *Lycaste lingnilla* has greenish sepals and petals and a pure white lip, the end of which is curiously twisted; this is a very free-flowering species. *Odontoglossum luteo-purpureum* concludes our list of Orchids; it is a remarkably showy, as well as curious, species from New Granada; the long scape bears several large flowers, the sepals and petals of which are similar in form and size. *Tillandsia xiphioides*, a most charming South American Bromeliad, has small, somewhat twisted, silvery leaves and a scape bearing several large, pure white, deliciously fragrant flowers. This specimen is not attached to anything, but is suspended by a piece of wire from the roof. Along the bases of the *Cordilleras* it grows on trees and rocks, and on account of the delicate perfume of the flowers it is much prized.

*Clerodendron villosum*, from the Indian Archipelago, is a shrub with stalked oval leaves and terminal panicles of sweet-scented flowers, white, faintly suffused with rose. *Amphiscofia Pohlana*, a dwarf Brazilian Acanthad, has shining leaves and purple flowers springing from the spike of large, rosy-purple bracts. Both these plants are to be seen in the Palm House.—†

### NOTES OF THE WEEK.

THE effect of what the papers call the new villa in Hyde Park is very bad—we mean from a landscape point of view, and without reference to the space thus taken away from the public in the very spot that ought to have been preserved in a quiet green state. If such structures were necessary in a park, the place for them is the outer corners, or by the entrances or boundary roads, and not in the centre of the park. Wrong anywhere in the park, they do far more harm in the centre than if placed towards the margin, where they would be seen in connection with other brick and chimney-pot effects.

**Rockwork at Kew.**—At the head of the Herbaceous Ground there has just been completed a piece of rockwork, which most people will acknowledge to be the most successful attempt yet made in that line in the Botanic Gardens at Kew. The semi-circular outline has apparently been varied as much as the existing beds of *Narcissus*, &c., and the raised bank which forms the background would allow. By means of a few large stamps, shaded and sheltered nooks have been formed, presumably for subjects which require those conditions. If this piece of work receives anything like attention, the "rockwork," which, with its tent-like covering, has been the laughing-stock of all classes of visitors, will soon be deserted.—†

**Hardy Plants from the Cape.**—Several species of *Albica*, *Montbretia Pottii*, and *Sedum alpestre* have stood the cold of this winter, which here has been tolerably severe. *Montbretia Pottii* is a new species, which bears graceful spikes of little but numerous bright orange-brown flowers. *Sedum alpestre* is a neat little plant with white flowers, very desirable for edging flower-beds with or for planting on rockwork.—MAX LEICHTLIN, *Baden-Baden*.

**Primula purpurea.**—I have this fine Himalayan *Primrose* now in bloom. A strong plant of it has thrown up a stout stem crowned with an umbel of delicate lilac-mauve flowers. It is several days earlier than *P. denticulata* and *P. pulcherrima*, but that is no doubt a mere accident. Generally speaking, *P. denticulata* is the first to flower of the trio. The two former are doubtless only natural selections of the latter, with the slight differences that will manifest themselves in seedlings. Of all early-flowering plants these hardy *Primulas* are the most satisfactory in pots. *P. nivalis* and *P. intermedia* will soon be in flower, as will also *P. farinosa*, *P. spotsblissii*, and *P. marginata*. These will be succeeded by *P. amœna* and its varieties, and the later-blooming *P. Parryi*. Some good strong plants of *P. denticulata* would be found very useful for growing in pots for cutting from at this season of the year.—D.

**Vegetation in Kensington Gardens.**—Among your numerous readers there may be some who would like to compare the advent of vegetation in their own gardens with that in the flower walk at Kensington. I should premise that the plants quoted are the most forward of their several kinds, and that the young leaf or young blossom is indicated by *l* or *b*. *Cheiranthus Cheiri*, *b*; *Euonymus japonicus*, *l*; *Ribes sanguinæ*, *l*; *Cydonia japonica*, *b* and *l*; *Photinia serrulata*, *l*; *Kerria japonica*, *l*; *Laurostima*, *b*; *Spirea prani-*

*folia*, *l*; *Mahonia Aquifolium*, *b*; *Ribes Diacontha*, *l*; *Jasminum fruticosum*, *l*; *Mahonia repens*, *b*; and *Deutzia gracilis*, *l*. From the above it would appear that we are indebted to foreign countries for our earliest spring vegetation more than to our native plants.—M. MOGGIDGE.

**Vanilla at Syon.**—The large plants of *Vanilla* at Syon, which have on several occasions been alluded to in THE GARDEN, are now literally loaded with large clusters of pods. The plants are growing on each side of a glass partition separating two houses which have just been planted with Bananas; the moist heat which it is necessary to keep for the perfect growth and fruiting of the Bananas suits the *Vanillas*, which, through their blossoms being carefully fertilised, yearly bear clusters of from ten to twelve long straight pods.—S.

**Griffinia Blumenavia.**—This is one of the prettiest of the Griffinias, and although it has long been in cultivation, it is not very commonly met with. Its flowers, which are not so large as those of *G. hycinthina*, are of a delicate blush colour, the throat being veined with deep violet-purple. They are found to be useful in a cut state in vases, &c.; and when on the plants, associated with Ferns or similar plants, so that their pots and naked stems can be hidden, they are very effective. It is now in bloom in Messrs. Henderson's nursery at Pine-apple Place.—S.

**Phylloxera at Gunnersbury.**—In consequence of the injury committed in the Vineries at Gunnersbury by the *Phylloxera*, strenuous efforts are being made to exterminate that pest. All the Vines on the place have been rooted out, and the soil removed from the borders. No Vines whatever will be grown at Gunnersbury this year. In other gardens in the neighbourhood similar operations are, we hear, also being carried out. It is therefore to be hoped that such radical measures will be attended with satisfactory results.—S.

**Musa Cavendishi.**—A plant of this dwarf Banana at Wilderwick, East Grinstead, is now bearing a fine cluster of fruit, which promises to be exceptionally heavy. The plant is eighteen months old, and the cluster measures over 3 ft. long and 4½ ft. in circumference, and consists of over 170 pits not yet ripe.—A. J. O.

**Hardy Plants in Bloom at Tooting.**—Readers of THE GARDEN who are interested in hardy plants may like to know what is in flower at the present time in our grounds at Tooting. *Cyclamen ibericum* and its varieties, white, flesh coloured, rose, and red are now in flower, as are also *C. coum* and its varieties, bright red, white, flesh coloured, and rose. *Hepaticas*, double red, single red, rose, mauve, pale, white, and blue are likewise in blossom, also the double blue in large quantities. Of *Hebeles* or Christmas Roses we have niger and its varieties, oolotions and its varieties, abuchianus, white and red; orientalis, with its large, coriaceous leaves and bold, handsome flowers; and viridis, with its curiously-coloured blossoms. *Anemone blanda*, the loveliest of all blue spring flowers, is also in bloom, as are likewise *A. fulgens*, scarlet; and *A. coronaria* and its varieties. Its reticulata, with its rich violet-gold blotched fragrant flowers, and *I. raticulata* var. *Krelagii*, with its plum-coloured blossoms, are now in perfection, and the same may be said of *Scilla bifolia*, with its rich ultramarine flowers, and *S. sibirica*, with its bright blue blossoms. The three giant forms of *Snowdrop* are very beautiful; they consist of *Galanthus Imperati*, the largest; *G. plicatus*, the Crimean *Snowdrop*; and *G. Elwesi*, a distinct and beautiful kind. *Sisyrinchium grandiflorum*, with its rich purple flowers; *Narcissus (Corbularia) albus*, the beautiful white Hoop-petticoat of Algiers, are also in blossom. *Crocus vernus*, from the Nottingham meadows, and its rich Dutch forms of every shade, from bright yellow through all the grades of purple and the variations of stripes to pure white, are just now in great beauty. Of the species of *Crocus*, *aureus* is perhaps the most attractive, the yellow being deeper and richer than the Dutch yellow *Crocus*, and as the blossoms precede the foliage somewhat, nothing is seen but a mass of golden-yellow. *C. aureus* is succeeded by *C. sulphureus oncolor*, a pale but decided sulphur-yellow, and its variety *sulphureus striatus*, with the outer petals beautifully striped. The little pale creamy-white *C. sulphureus pallidus* is a rare and beautiful kind, and *C. susianus* and its variety *striatus*, with their reflexed petals, are both striking sorts of *Crocus*. *C. stellaris*, the striped yellow *Crocus*, is now in great beauty, as are also *versicolor* and its varieties, biflorus, ranging from the handsome Scotch *Crocus* through its various grades to the little variety of the Roman Campagna, and the beautiful *estriatus* collected by Mr. Maw. *Imperati* and its form *saravolens*, the latter delightfully fragrant, are likewise now in flower, as are likewise *Sieberi*, with its purple blossoms; *lacteus*, with its small, creamy-white flowers; and *Wildeni* and its beautiful forms *albus* and *tinctus*. *Chrysanthus tinctus*, with its golden blossoms, has been beautiful for a long time; and *vulcanicus* is now in full beauty. We have, moreover, a large piece of *Winter Aconite* in bloom, and very beautiful it is.—P. BARR.

## IN JAPAN.

HALF a century ago, as I am reminded by Mr. Hemsley's excellent article on the plants of the China-Japan region, which appeared in *THE GARDEN* on December 15, how limited was the knowledge which we then had of the treasures in store for us from this part of the world. It is extremely interesting, when looking back, as one sometimes does, towards the close of the year, or the beginning of a new one, to find that the word "Japonica" meant to our fathers and grandfathers nothing more than the *Pyrus japonica*, which brightens now, as it did then, in spring many a garden wall, or at most included the *Camellia*, then making a sensation in their greenhouses; now-a-days it is almost impossible to remember how many times this word occurs as a specific name among our garden plants, until it is brought directly to one's mind by visiting the country that has sent us so many beautiful garden ornaments. Still more vividly is it brought before one when exploring some ravine or steep green mountain-side in Japan, where each moment we hail with delight some well-remembered plant at home. On one rocky bank, the typical *Pyrus japonica* glows still more brightly than with us, and a responsive fire shines from the red *Camellia japonica* on the next, that is somewhat in shade. One pauses to admire the lovely sight, or thoughtlessly sits down to contemplate the scene at leisure, in a bower of *Aralia japonica*, when the sharp spines of its constant and most thorny ally, *Aralia spinosa*, remind us unpleasantly that

the motto "Nemo me impune lacessit" applies to plants in this country even more forcibly than to the Scotch Thistle left behind us. Spurred on to further exertions, the next few steps bring us in sight of the green *Aucuba japonica*, the pretty, but scentless, *Citrus japonica* (trifoliata) or the golden-flowered *Kerria japonica*, in their native haunts on the mountain side, which owes its peculiar greenness not to the Grasses with which we connect that colour, but to an undergrowth of dwarf Bamboos, which entirely take the place of nutritious Grasses, and give a richer and more velvety green to the mountains than can be seen elsewhere. To prolong the list of "Japonicas" is unnecessary, but before dismissing the subject, it is worth while mentioning that the epithet must not always be trusted implicitly, as the Japanese noblemen or Daimios, as they style themselves, have from the earliest epoch been accustomed, when returning from some war expedition—may be, to the Corea, North China, or the Island of Formosa—to bring back with them some new plant or tree they had seen and admired, which they planted in the courts of the temple where they worshipped. It is now believed that many of the trees common throughout Japan at this time were introduced in this way, and it is very difficult to arrive at a satisfactory conclusion as to where they originally came from. As we scramble up the valley, the wealth of *Wistaria*, that almost smothers the bushes, and the abundance of the lilac *Azalea* just showing its first flowers, and colouring many an acre with a faint lilac shade, recall in effect moorlands in autumn, and make one wonder that two plants that are especially abundant and beautiful in Japan should have escaped the affix that tells of their country

while the Japanese themselves regard the former as in some sense sacred, as the name "Fugi" shows, applied, as it is, to both the *Wistaria* and their sacred volcano Fugi-yama, to express their sense of the heavenly beauty common to both. Their devotion to the *Azalea* as a decorative plant I have before mentioned; and with such assiduity have they dug up and transplanted to their gardens all those that are of the more brilliant shades of colour, that it is only where inaccessible, or growing among great rocks that forbid transplantation, that a glowing mass of red or rose-coloured *Azaleas* can be found growing wild. On every rocky mass exposed to sunshine *Rhynchospermum jasminoides* takes the place of Ivy, covering the ground as with a carpet, mantling the rocks with its dark green oval leaves and slender stems, but never vouchsafing so much as one single flower until it reaches the top of its support, or seizes some friendly shrub, twining itself round till it gains a more open and airy situation, when at once the plant changes to such a degree, that it is hardly possible to recognise it. The roundly-oval leaves become slender and pointed, the stems become sturdy and upright, and a cloud of starry, Jasmine-like flowers scent the air each returning spring. The flowering form alone is common in our gardens in England, but the form which, like Ivy, climbs by the aid of adventitious roots, has only lately been introduced; both are, however, identically the same, though useful in different ways, and I am persuaded that it is a plant that will be found hardy anywhere in England where a light soil and sunny situation can be given it, growing closer than Ivy, requiring no clipping, and in course of time, when allowed to grow off from the wall, rewarding one with its sweet white flowers. But what a wilderness of beauty! *Deutzias*, with yard-long sprays of flower; *Weigelas* of all shades, from white to deepest purple-red; Japanese *Honeysuckle*, with pale yellow flowers, showing at every joint; *Iris* of many colours—all seem as if they were anxious to outvie their neighbour, and show how much floral beauty can be crowded into a short period of the year. It is, however, some consolation to find that the *Rose* type of beauty in our gardens is so poorly represented, that here, at least, we may congratulate ourselves at home. *Rosa polyantha* would be called a Bramble by many an Englishman, and is strangely inferior to the beauty of the Chinese variety of the same species, abundant all over the neighbourhood of Shanghai, while neither attain the blushing beauty of our *Dog Rose*, a corruption, by-the-by, I believe, of the German "Tag" *Rose* (the day *Rose*) a name that impugns its durability rather than its beauty. But to return to our valley, from which we have wandered so far, and plunging down into its deepest recesses, where the spray from the stream, as it tumbles from one rocky pool to another, encourages a growth of *Ferns* as wonderful in its ways as the flowers above, we find the great *Woodwardia orientalis* hanging its heavy head, as if weary with the weight of its pale green, massive fronds, in such profusion as almost to bar progress; and on looking upwards for a clearer path, a ray, as of gold, flickers in the sunny shade, and causes an instant diversion in its favour. Nor are we disappointed. Gold it is, but vegetable, not mineral, that greets our astonished eyes—a *Fern*, not covered with a powdery dust, such as we are familiar with in the silver or gold *Ferns* common to so many gardens, but a *Maiden-hair*, that has been, as it were, dipped in a liquid solution of gold so transparent as to allow its green colour to shine through the metallic wash, and yet so golden, that in the glancing sunlight the freshly-developed, but full-grown fronds shine as if pure gold. So exquisite is the *Adiantum monochlamys* in its native state, that if, under cultivation, it shows one-half of the beauty belonging to it, it will become a rival to the *Adiantum cuneatum*, now that it has been introduced to England, for it adds yet another charm to its graces of form and colouring in that when bruised it gives out a delicate and sweet perfume. A little higher up the hill, and in a dry but sheltered nook overshadowed by *Pinus masoniana*, grows the well-known *Adiantum pedatum*, with flat fans of pale green, side by side with another American type, the ostrich-like plumes of *Struthiopteris pennsylvanica*, both outposts of the American *Fern* army; while a tangle of *Gleichenia dichotoma*, so dwarfish and thick as to make an elastic couch on which to recline, links us with the Australian

types of vegetation. A little farther on, *Lastrea erythrosora*, with its bright red young fronds and crimson sori, covers the banks in company with a still more common Japanese Fern, *Davallia pilosella*, whose downy and slender drawn-out fronds differ widely from European species. Dwarf *Azaleas* of small growth, with tiny white flowers of the *Azalea amoena* type, bend down over the stream, where numbers of things rare, beautiful, and familiar are to be found which need hardly be mentioned now, unless it be an unnamed *Polystichum*, with firm evergreen leaves, and a habit of growth strangely resembling that of an Oak Fern (*Polypodium Dryopteris*) in its long stems and flat, triangular-shaped fronds, set on at right-angles to the stems. If by good fortune this were to withstand our climate, it would furnish our hardy Ferneries with a most distinct and bold-habited Fern, and increase the debt of gratitude which we already owe to those who, by exertion and energy, have introduced so much new beauty to our gardens.

E. H. WOODALL.

### SHOW PELARGONIUMS IN MARCH.

A MILD autumn and winter, during which plants have had no period of rest, but have continued to grow without interruption, is a trying one to the amateur cultivator of the Show Pelargonium. They must be kept fairly moist at the roots, or they will lose their lowermost leaves, leaving naked stems to view, and, once lost, they are never regained. The most robust of the plants, having a stocky growth, should be allowed to grow on for flowering early; those of taller growth, and having the appearance of becoming drawn, should be stopped and induced to break again. They will soon do this, and if they flower later they yet yield a greater amount of bloom. March is an important month with the Pelargonium. The plants should be near the glass, but in an airy position, at the same time not subject to cold draughts of air. This is a point of importance, and respecting which the growers of Pelargoniums for market are very particular. Fungus must be particularly attended to, for when the days are bright and sunny aphides will make their appearance, and closely infest the points of the branches, and they need to be kept under. Watering, too, at this season requires more than ordinary care and judgment. Enough is required to merely moisten the balls of earth about the roots and keep the foliage green and fresh, but no more. A superabundance of water in dull, sunless, cold weather leads to material harm. When the sun is warm and the atmosphere drying, a syringing overhead will be found of great value. Any shifting required should be done at once, but a large shift should never be given just now; a plant requires the next largest sized pot only so that the roots may speedily reach the sides. By tying out the side shoots, so as to give space in the middle, the plants can be trained into even shape, and the foundation of good specimens laid. The more delicate Fancy varieties—the “ladies’ Pelargoniums,” as they have been termed—require similar treatment, but much care in watering, and they should have the warmest part of the house in which they are growing.

D.

*Iris reticulata* under Glass.—I have just had a bunch of this beautiful *Iris* sent me by a clergyman who grows it at this season of the year in his greenhouse. It is not the freest flowering variety of the *Iris* tribe, but he informs me that he has a quantity of it in flower at the present time. I need hardly state that *Iris reticulata* is, perhaps, the most beautiful of its class; but I have never seen such fine and perfectly developed flowers of it as those just referred to, and I should say the plant would be of some desirable addition to our forcing plants, if growing it in a greenhouse can be called forcing. The flowers are of a deep blue colour, with a bright golden blotch on the lip, shading off to white at the edges, and also spotted with purple. It is even superior to some *Orchids*.—J. S.

*Hepatica angulosa*.—I would recommend all lovers of spring flowers who have not yet grown this *Hepatica*, either on account of the damage it receives from slugs, or because the soil of their garden is unsuitable, to try it at once. I have possessed it for some few years, but until now never knew its real beauty. Having taken Mr. Wilson’s advice concerning the perforated zinc protectors recommended in your paper some time since, I am this spring most fully repaid, in every plant is bearing a profusion of pale blue flowers, and each bloom is the size of half-a-crown. The flowers, too, are not only ornamental on the border, but useful also for cutting for small glasses; and the exquisite green of the foliage lends to contrasts well with the gorgeous lines of the *Tulips* and *Hyacinths*. I firmly believe that, in most cases, it is not the soil but the slugs which prevent people from growing this exquisite *Hepatica*.—E. F., *Petford Hall, Swaffham, Norfolk*.

## THE INDOOR GARDEN.

### IMANTOPHYLLUM MINIATUM AS A FORCING PLANT.

THIS is one of the most useful of winter-blooming plants, and its flowers, which are produced in great profusion, are greatly improved by forcing. It is an invaluable plant for either large or small gardens, not only because of its rich green foliage or the sparkling attractiveness of its flowers, but also on account of its vigorous habit and constitution. During the dull winter months a handsome specimen or two of it arranged with other plants in the conservatory are always objects of interest and admiration, and in the form of cut flowers it stands pre-eminently the foremost of its type for certain purposes. It is seen to best advantage by itself in single glasses, proportionately fitted to the sizes of the spike, accompanied by a spray or two of Fern, or, if needs be, the individual flowers may be used in a variety of ways to suit any conceivable purpose. This plant is often found prolonging a miserable existence in stoves, but these are not the places for it. Plants of it kept in heat during the greater part of the year may flower, but not with certainty, and if they do, the flower-spike is not half its normal size or strength, nor is there the same substance in the flowers themselves, which is, of course, the natural sequence of diminished growth from want of a proper season of rest. This plant is about as accommodating as many of our hardy shrubs; the natural character of root and leaf will almost indicate how it should be treated as regards compost. It is a vigorous grower, and its thick fleshy roots show that to grow it well the compost should be rich and heavy; good loam and cow manure rubbed between the hands with an admixture of horse-droppings and charcoal will answer well, or indeed any ordinary soil will do, provided there is a free course of drainage, so that if the soil should lack the necessary elements, these may be added in a liquid state. Perfect drainage is important in the case of this and similar plants which flower best when pot-bound, and which do not, therefore, come within the annual routine of potting. Large specimens of this plant are useful for various purposes; but I prefer smaller plants, as being best adapted for general purposes, either for cutting from or as “brilliant dots” amongst fine-foliaged plants when flowers are not over plentiful. The best time to pot is after flowering. If large plants be pulled to pieces, that operation should be carefully performed, and also the potting; the leaves should be sowed over at the same time, and the pots plunged in a bed of leaves at a temperature of from 75° to 80°. Keep the plants syringed daily, *i.e.* if the weather will permit of it; they delight in an atmosphere almost at saturation point at this stage, which is all the watering that is necessary till fresh roots are formed and the plants are re-established. Plants that are plunged for a time in this way are best removed by degrees, say by lifting the pot partly up or by shaking it, so as to leave a vacuum between it and the plunging material, and then by placing it, after it is lifted, on the surface of the bed for a few days. When growth is progressing towards final development, the plants may be removed to cooler houses, till by degrees they are turned out-of-doors altogether, where they should be partly shaded from the scorching sun. They should stand out-of-doors till November, when, on the appearance of the flower-spike pushing up, they should be taken indoors and plunged in a brisk top and bottom-heat, with plenty of atmospheric moisture. The flower-spike is not only hastened, but the flowers themselves are so improved in colour by this treatment, that if the blossoms of a plant that is forced and those of one flowered in a cool house be compared, the latter would, in all probability, be discarded as useless. I would recommend, therefore, all who grow this plant, whether it is flowered in season or out of season, to put it in heat a few days before the flowers begin to expand, in order to improve their colour. No doubt many people grow this plant successfully out-of-doors in the south of England, and I am not quite certain that there are not many nooks and corners in many a garden in the north of England and Scotland also (especially in sheltered places near the sea coast) where it would thrive and make a sprightly companion for *Aralia Sieboldi* and similar subjects. W. HINDS.

Otterspool.

## PERESKIA LYCHNIDIFLORA.

This is a plant seldom seen in collections, and yet it is the best of the genus to which it belongs. "Oh, but," says someone, "it won't do for bedding," it is not a fine-foliated plant, and its flowers won't do for cutting." True; but it is nevertheless a useful plant in other ways. Our ancestors seem to have had a more refined taste as regards plants than we have, for the plants which they grew were good of their kind and well varied; therefore their collections possessed an interest which those of the present day often fail to yield. This plant

*Pereskia lychnidiflora.*

will succeed in a greenhouse; it resembles *P. Bleo* in foliage, but it is not so vigorous.—J. CROUCHER, *Sudbury House, Hammersmith.*

## CAMELLIAS AND THEIR CULTURE.

ALTHOUGH the Camellia is fairly hardy, and thrives in the open air in many parts of England, it can scarcely be recommended as a plant for outdoor culture. Our spring climate is so precarious and variable, that it is only in exceptionally favourable seasons that the blooms arrive at their proper development. In its native habitats the flowering season is dry and fine. In order, therefore, to derive real enjoyment, and to realise fully its capabilities as a flowering plant, we have to imitate those natural conditions by affording it the protection of a glass roof. There are few plants that enjoy such universal popularity as the Camellia does. Its glossy, deep green foliage renders it always attractive, and the suitability of the flowers for bouquets and decoration generally is too well known to need description. In spite of this well-merited popularity, however, we find the Camellia, as a rule, but indifferently cultivated, a good collection in robust health being but seldom met with. It is, to a greater extent than any other greenhouse plant, a source of wonder and perplexity to amateurs, who are often at their wit's end to understand why buds drop instead of expanding, or why the

foliage will not assume a healthy hue, and no satisfactory growth is made. Many of the failures which take place are due to the fact that the true nature of the Camellia is but imperfectly understood by the grower. In its native land the winter is cold, the spring dry, and the growing season warm and moist. What we have to do, therefore, is to imitate these natural conditions as nearly as possible; we have, in fact, to consider the glass protection merely as a means of correcting the great variability of our English climate. Anything more than this, anything approaching to coddling or forcing, will certainly be attended with disastrous consequences.

## Soils and Potting.

The choice of soil for the Camellia has ever been a fertile source of discussion amongst practical men, and there would appear to exist considerable divergence of opinion upon that subject even at the present time. Loam, peat, and leaf-son have each their warm advocates, some preferring either one or the other in a pure state; others, again, recommend a mixture of two or all the kinds enumerated. Very fine plants have been, and are now, grown in loam or peat alone, and they do equally well in a mixture of both soils. I have been informed that the Messrs. Chandler grew theirs in two parts loam and one part peat; whilst Messrs. Loddiges used both loam and peat separately or mixed for their once fine collection. The Belgians pot their Camellias principally in leaf-mould, which is collected in the forests and used by them in a pure state. This leaf-mould is hardly to be compared to that with which English gardeners are accustomed to, as it is the accumulation of many years, and contains a large proportion of decayed wood. It may be used, as collected, without any previous preparation, and does not appear to bind or become sour when confined in a pot. This description of soil is very valuable when it can be procured as above described, and it is not only valuable for the Camellia, but it is well suited for many kinds of hard-wooded plants. With respect to loam, judgment must be exercised in the selection of it, as, although in some kinds of loam the Camellia will flourish and make perhaps stronger growth than in any other soil, yet there are many varieties of loam commonly used for potting, the employment of which, in a pure state, for our present purpose would be most unwise. It is, in fact, rather to the mechanical than the chemical properties of the soil employed that we must pay attention, for unless we secure a free and unimpeded action for the roots, we cannot expect our plants to pass through the various phases of growth and bloom with that amount of vigour which is desirable. As the Camellia is liable to remain in the same soil for years, it will be easily perceived how highly necessary it is to ensure for its porosity and freedom from sourness and stagnation. It is often from want of properly recognising this fact that many of the failures at the blooming period are to be attributed. All soils of a close tenacious nature must be rejected, and if loam cannot be procured fulfilling the above-mentioned conditions, it will be better to rely upon a compost which, if somewhat deficient in stimulating properties, will preserve the fibre in a healthy condition. Nutrient can always be given by means of liquid manure when the necessity for it is perceived, which will be during the growing season, and occasionally whilst the flowers are expanding. This will be a safe method for many whose experience in soils may be somewhat superficial, or who may not have had much experience in Camellia culture. Amateurs whose object it may be to grow but a few plants, and who naturally desire to attain excellence, should procure both plants and soil from a good grower. As quality rather than quantity is in their case the great desideratum, it is absolutely necessary to secure a soil of the very best description. The compost which I would recommend should consist of one-third loam, one-third peat, and one-third leaf-mould, crushed charcoal, and silver sand. In this mixture we have all the elements necessary to promote vigorous growth and to ensure lasting health; and, provided the ingredients be properly sweetened, it may be relied on to remain in a sweet, wholesome condition. The peat, I may add, should be fibrous, and pulled to pieces with the hand, sifting the dust away from it, and being careful not to employ any of a sour description. In planting out permanently, it is of equal importance to pay strict attention to the quality of the soil employed. A larger

proportion of loam may be used than for potting, but in that case the utmost care must be taken to ensure free drainage, as, unless the *Camellia* can be copiously watered during the growing period, the buds will fail to attain that substance which is absolutely necessary for the production of perfect flowers. Nothing is more fatal to their well-being than stagnant moisture at the root; from it proceeds a long train of evils, such as yellow foliage, stunted growth, and premature casting of the buds.

#### Potting and General Treatment.

One point must be especially kept in view by the *Camellia* grower, and that is never to over-pot. *Camellias* may be kept perhaps longer in perfect health without change of soil than the generality of flowering plants. If a plant shows symptoms of ill health, it is better to turn it out and replace it in the same pot with fresh drainage, extracting as much of the old soil as will come away without injury to the roots, and dusting the ball round with silver sand. This treatment, with occasional root waterings, during the growing season will often re-establish old debilitated plants and induce healthy growth. It is therefore impossible in the matter of repotting to lay down a hard and fast rule; each plant must be treated according to its merits. If the pot be well filled with healthy fibres, and the general appearance of the plant indicate that it is in a thriving condition, there need be no hesitation in transferring it to a larger receptacle. Should the roots, however, present a blackened or discoloured appearance, and have not thoroughly permeated the soil, then the better way is to treat it in the manner above described, and defer the shifting until the following season. It is necessary to pot firmly, working the soil down evenly between the old ball and the pot. I do not, however, approve of such hard ramming of the soil as is frequently practised; extremes are always dangerous, and there is a vast difference between insuring proper consistency and bringing the soil into the state of a garden path. I have seen plants potted so hard, that when turned out the balls presented the appearance and had assumed the consistency of half-baked bricks. This is simply bad treatment, and must by no means be indulged in in the present instance. In purchasing plants for growing on it is essential to secure them in a perfectly healthy condition, and it is well to begin with 4-in. pots. There are many thousands of *Camellias* imported annually into this country from Belgium. These plants are remarkable for their vigorous, healthy appearance; the foliage is of a deep hue, and is generally of handsome proportions; they give the idea, in fact, of containing an enormous store of vitality. This description of plant, however, often fails to realise the expectations that are naturally formed concerning it; they seem to need a great amount of care to maintain them in health. These plants are, in fact, grown under peculiar conditions, which cannot well be maintained when they come into this country; they consequently sustain a check which debilitates them to a serious extent. It is preferable for the amateur to choose his plants from English-grown stock, as, if they are not quite so large and handsome, they may be more depended on. March may be considered the best period to repot, when the plants must be placed where they can be shaded from the sun, and can be attended to in the way of syringing, for the *Camellia* delights in moisture, both atmospheric and at the root, when making its growth. \* Abundance of air must, however, be given, as undue confinement will both cause weakly growth and enfeeble the whole plant. A moist and warm, but not a close atmosphere is that in which the *Camellia* will thrive during the growing period, for we must remember that we have to deal with an almost hardy evergreen which merely requires the glass protection to ensure a regular growing temperature. When growth is completed the plants may be placed in the open air, a situation in which they catch the morning sun and are sheltered from that of midday, being best adapted to them. There they may remain until the end of the summer, to be housed before the advent of the heavy autumnal rains. It is of great importance to give free ventilation when the plants are first housed, and to see that they do not remain dry, as a few days' neglect just at this time in these respects will do irretrievable mischief. The ventilators should remain open night and day for some time, only closing them in frosty

weather. Bud-dropping is often caused by the change experienced in the removal from the open air to the close quarters of a glass structure.

#### Propagation.

Propagation is effected by means of cuttings, grafting, and inarching. Although most varieties of the *Camellia* strike fairly well, the most satisfactory results are obtained when they are grafted upon the common red, inasmuch as it insures a healthy constitution to those kinds which are naturally inclined to be weakly and uncertain in their growth. Many of the highly-bred, fine-flowered kinds would not attain any great degree of vigour if grown upon their own roots. Cuttings of the common red are inserted in August in sandy peat surfaced with silver sand, and placed in frames until September, when they are removed to the propagating house. They there make root, and are potted off in the spring, grown on in frames during the ensuing summer, and are fit to be worked the following season. Pieces of the past season's wood are taken and placed in the ordinary way of side grafting. The grafted plants are kept in close frames in the propagating house, admitting air daily for an hour or two until they have taken, when they are removed to more airy quarters and gradually hardened off. The best time to graft is in August, when the wood is ripe; they then get well established by the following spring and are ready to grow away strongly. Inarching is now only practised when it is desired to introduce a newer or better variety upon an old-established plant. The operation consists in simply paring away a portion of the bark of the stock and fitting the branch of the plant to it which it is desired to establish thereon—the wood of the graft to be pared away similarly to that of the stock. Tie them firmly together, placing the plant which furnishes the grafts so that it cannot move. They will soon unite, when the branch may be severed and will become part of the old plant. This is a good method to renovate old planted-out specimens which may have become bare and leggy and deficient in vigour. The placing upon them of fresh branches from young fresh plants infuses new life into them, and, in addition to re-clothing the plants, often has the effect of causing an increased circulation of the sap and inducing a more healthy root action. JOHN CORNHILL.

*Byfleet.*

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Tillandsias on Fern Stumps.**—*Tillandsias* succeed perfectly planted on Tree Fern stumps cut into lengths of about 9 in. A few small Ferns or Mosses may also be planted round the base of the *Tillandsias*, and be allowed to cover the stumps. Such arrangements answer well indoors where flower-pots are often objectionable. They may also, if required, be suspended by means of a piece of wire. Other plants might likewise be grown in this way with equally good effect.—C. S.

**The Double-Flowered *Dentzia crenata*** is a remarkably fine variety of *Dentzia* far too seldom seen, either in the forcing house or the shrubbery. It is a much stronger grower than *D. gracilis*, and it produces longer racemes of flowers, which are quite double and pure white; they also last much longer and are far better adapted for cutting than those of the single kind. We have forced it here for the last two or three years, and find that it succeeds quite as well as *D. gracilis*. I do not consider it at all inferior to the best of the *Bouvardias* for any purpose, and I would strongly recommend it as a forcing shrub.—J. S. W.

***Pteris serrulata cristata major*.**—Few Ferns are more valuable for decorative purposes than this. Mr. Wills grows at his Anerley Nursery hundreds of small plants of it for vases and similar purposes, as well as large specimens. In a small state it is exceedingly pretty, and when grown into a large specimen 3 ft. to 4 ft. through, its beautiful created pinnae droop gracefully from arching fronds 2½ ft. to 3 ft. in length. This variety produces spores readily, but they seldom produce anything like the parent plant. Division is therefore the only sure way of propagating it.—C. S.

**A Simple Shading for Plant Houses.**—A correspondent of "The Gardener" states that he has tried lime and whitening with most unsatisfactory results, both as regards appearance and fitness to resist heavy rains. He has found plain butter-milk, laid on with an ordinary paint or whitewash brush, to be most efficient for the purpose. When put on in this way it has "the appearance of ground glass, and forms a light shade, sufficient to throw off the burning sun, and not darken the house to an injurious extent, even in dull weather." As to its enduring property, he states that some of this shading put on early last June, and recently washed off, stood the rather severe test of something like 1½ in. of rainfall.

## LONDON CHURCHYARD GARDENS.

It has often occurred to me that churchyard gardening is greatly neglected in this country. We appear to wait until some benevolent person furnishes the necessary funds before any attempt at embellishment is made. This is, to say the least of it, unfortunate, when so much might be done in so little time, and that at a trifling expense. I am confident from experience that a well-kept park or pleasure ground has great influence in improving the condition of the inhabitants in its neighbourhood. It is impossible to give directions which will prove suitable to all situations, as they are so numerous and variable, but, generally speaking, the mode of procedure may be the same in all cases. I do not think it necessary in carrying out a scheme of churchyard improvement that we should adopt an elaborate plan of landscape or floral decoration, these being more suited to private residences and public parks; what is really required is some simple and natural arrange-

ment (which, by-the-by, is perhaps the highest and best art of the landscape gardener), something which cannot fail to please without being too artificial. Nature, even under the most adverse circumstances, has provided us with the means whereby we may fill many blanks. The chief point is to know how to treat her. A churchyard should not be a playground, neither should trees preponderate, inasmuch as they have a darkening effect, nor should it be a glaring flower garden; it may, however, combine these in a modified sense, viz., it should afford scope for decent recreation, and trees, flowers, and Grass should be so balanced as to tone down and relieve each other in the proportions best suited to the locality. Turf should, in all cases, form a principal feature, the relief afforded to the eye by a beautiful green velvety sward being incomparably greater than that produced either by flowers or rockwork. Trees and shrubs are most desirable, but they should be sparingly planted in small areas. There are, of course, many instances in which tombstones will interfere with arrangements; in fact, some churchyards are so full of

them that little can be done, except planting a few trees and climbers. Our business now, however, is more particularly with open spaces, in which few inconveniences occur. Assuming a church to stand upon a rectangular plot of ground, with entrances from the street in front only, besides the entrance, roads and walks will be necessary, and much depends upon the directions which these take. Walks should never be straight—a series of graceful and natural curves being a pleasing feature in landscape gardening. When the walks are formed the work may be said to be half over. Their width should be in proportion to the area of the ground upon which they are laid out, and also to what parts of the building they are intended to lead. Their width may, however, be variously stated at from 5 ft. to 16 ft. Turf from 10 ft. to 30 ft. in width should run along the sides of the building, and in front there should be a lawn as large as the area will permit, reserving a belt for trees and shrubs along the boundary fence or wall next the street. Upon the turf just mentioned should be planted Catalpas, Ailantus,

Robinias, Sumach, Yuccas, and Enonymus. Ivy, Virginian Creepers, Clematis, and any other varieties of climbing plants may be trained upon the walls of the church, always, of course, taking into consideration the locality. We should never attempt to construct rockwork adjoining the building. Under such circumstances it is unnatural and altogether out of place; rockwork rising out of sheltered nooks cannot be objected to; but to pile stones and bricks against the walls of a church is an unparadoxable mistake. Where practical, a line of trees may be planted round the margin, and plantations formed with curved outlines may be made where it is necessary to shut out unsightly buildings or other objectionable features. In this matter our churchyards and cemeteries are greatly behind those in America, some idea of which may be gleaned from the annexed illustration. When the lines of walks have been decided upon, a practical eye would at once see the best positions for the plantations. During summer it would of course be desirable to enliven the place with a few flowers, and here again great judgment is requisite. I should most certainly deprecate any attempt at forming an elaborate system of beds; what is wanted are a few beds placed here and there without formality, and filled with the most unostentatious flowers, such as Ivy-leaved, Pink, and White Pelargoniums, Lobelia, Gazanias, and Tropæolums. Where possible, too, hardy herbaceous plants and perennials should be freely introduced in the shrubby borders; upon the Grass also, especially upon sheltered slopes, may be planted bulbs of Snowdrops, Daffodils, &c. Primroses are exceedingly pretty in such positions, the colours being varied and decidedly beautiful. Clumps of Fennel, Acanthus, and other hardy ornamental plants may, with good effect, be planted on the Grass, and in the plantations Heracleums and Verbascums. The list might be greatly extended, but, perhaps, enough has been said to show the class of work advised. I may now mention some of the best trees and shrubs which may with safety be planted in the more densely populated districts of London. Of

A Churchyard Garden.

course, greater latitude is available in more open situations. The Plane, Poplar, Lime, Sycamore, Acacia, Elm, Willow, Thorn, and, as before mentioned, Ailantus, Catalpas, Aucubas, Privets, Lilacs, Euonymus, Ribes, and dwarf Hypericums all succeed. This list may also be much increased, but only with a thorough knowledge of the peculiar constitution of the trees and shrubs employed, and also the surrounding atmosphere. It must not be forgotten that trees and shrubs have their enemies in the shape of insects, and these must be diligently hunted for and destroyed. The probabilities are that in course of time the only trees that will remain will be the Planes and Poplars. Still, some variety is desirable; and as some trees die or are destroyed by insects, it may be found necessary to plant others. A good guide in choosing trees and shrubs for London is to select those which grow most vigorously, and which lose their leaves and bark freely in winter; in other words, those which thoroughly clean themselves once in each year; without this success is difficult, if not impossible. It is probable also that the turf will require

great attention, for that too has its enemies. The ground should in all cases be thoroughly drained, and if breeze or cinder-ashes can be got, a good layer about 1 ft. below the surface will materially assist in keeping the Grass in good condition. A good and effective plan, however, is to sow thinly a renovating mixture of Grass seeds in autumn and spring, thoroughly raking the surface with a wooden rake, adding soil where necessary, and rolling. The cost would be trifling, and success would be tolerably certain. Dressing the surface with artificial manures and other means may also be tried in some localities.

C. DENNIS.

*Southwark Park.*

## THE FLOWER GARDEN.

### "DUNEDIN'S" REPLIES TO QUESTIONS ON LILIES.

Mr. WILSON observes that it seems to him that Lilies like *Lilium giganteum*, where the old bulb clearly dies, and *L. superbum*, where only the new bulb flowers, give facts in my favour; but that *L. tenuifolium* rather points the other way. I hope, however, he will be able to settle to his own satisfaction in what way he thinks this Lily differs from the others, as I have not found that there is in it any departure from the general organisation of other Lilies. With respect to *L. Thomsonianum*, M. Leitchlin, of Baden-Baden, says: "The bulb of this plant is annually formed anew; the old one entirely decays. This latter serves for some time as nourishment and support for the shoot, which soon makes its growth independently of the decaying bulb." Dr. Wallace, of the Colchester New Plant Company, says: "We have constantly observed, when Lilies are taken up, that there are two sets of scales—the outer irregular discoloured portion, which represents all that is left of last year's bulb, and an inner regular, plump, white set of scales, representing the growth of the previous and the inflorescence of the coming season." These remarks all hover so very near the verge of my discoveries, that if carried a little further by inquiry in the interior of the bulb, they would, I think, have corroborated everything that I have said on the subject. On the other hand, Mr. Baker is represented as having said, in connection with the "Old World species of *Lilium*," that a bulb, after having bloomed for the first time, "goes on living for an indefinite period, sending out each year a flower-stem from its centre, and shedding off old scales with buds in their axils." The readers of THE GARDEN will see that this idea of the "bulb going on living for an indefinite period, and sending out each year a flower-stem from its centre," is entirely contrary to the facts which my experimental investigations have disclosed, and may, therefore, have been the means of confirming many in the mistaken notion that it is "the same bulb that continues to bloom year after year."

### Lifting and Transplanting.

At p. 83 Mr. Groom says:—"Although 'Dunedin' positively asserts that Lily bulbs do not suffer from being cut down in full bloom, will he go so far as to recommend such a course as being likely to assist the perfect maturation of the succeeding year's flower-spikes?" I fear there must be some misunderstanding here, as I am not aware of anything like "perfect maturation" being required at such a time, nor do I know what is meant by the phrase, "perfect maturation of the succeeding year's flower-spikes." If Mr. Groom will oblige me by referring to p. 28 (Jan. 12), he will there see that, in order simply to illustrate the independency of the new bulb at the time when the parent bulb is in bloom, I said:—"I have cut down the stems when the plants were in full and fresh bloom without in the slightest degree affecting the growth of the new bulbs, which at this time are themselves sending down roots, by which they can gain subsistence sufficient to make them independent of the parent bulbs." I stated this merely as the result of certain experiments, as I thought it might interest some of the readers of THE GARDEN, and I added:—"Those who have carefully studied the connection that exists between the old and the new bulbs will understand this." As regards the date or time for transplanting, if Mr. Groom will turn to p. 557 (Dec. 15) he will find that I have said, "It is a fact,

which science has placed beyond a doubt, that if Lilies do not all bloom at the same time, they should not be all transplanted at the same time. Beginning, therefore," I continued, "eight or ten days after the Lilies which flower first, have shed their bloom, we go on lifting and transplanting, from time to time, until October, during the most agreeable part of the year, and during a period, too, when amateurs have a good deal of spare time on their hands, which might be turned much to their own advantage, and, at the same time, to the advantage of our professional growers." This is my idea of what transplanting, in a scientific point of view, ought to be; that is, transplanting each class soon after the bloom of that particular class has faded, and not all the classes at one and the same time. In dealing with the Lily we should never overlook the fact that it is, in its organisation, totally different from all other bulbous plants. When a Lily has once bloomed, all that Nature intended is accomplished; and nothing afterwards remains for it but to droop, decay, and die—stem, bulb, and roots all perish. The new bulb at this time requires no maturation, for within two weeks after the bloom of its parent has faded it is itself fully developed, and is become a parent bulb. The new bulb, like all its progenitors, is charged with the function of liberating a germ, which vegetates as soon as brought into a condition fitted for its growth; and this is the time it is fitted, and also the time when the transformation takes place. This is now also the most appropriate time—that is, when the new bulb is in its most quiescent state—for lifting and transplanting it, with the best prospect of a successful bloom next season. He that asserts the contrary, and continues to transplant at a later season, can know nothing correctly of the organic structure of a Lily bulb; and, consequently, he continues to act in opposition to the dictates of Nature, and also to his own detriment. I quite agree with Mr. Groom when he says:—"Is it not safer to postpone the period of transplanting until after blooming?" But then he appears to have made this remark under the impression that I had advocated something different. As regards the leaves fading, if the flowers have faded, it is of no consequence to the new bulb whether the leaves of the old flower-stem have faded or not. This is characteristic of the Lily, apart from all other bulbous plants. With respect to "the bulbs soon commencing to rot afresh," this remark also appears to have been made under some misapprehension, as the old bulb never roots or flowers again, and the new bulb is sending down its own roots long before the bloom of the old bulb has faded. It is these new roots being mixed up undiscovered with the old ones that have led many superficial observers to entertain mistaken notions on the subject. As to "pot culture," I candidly confess that I know little or nothing about it, my experimental researches having been principally confined to the open ground, in order, if possible, to induce Lily growers to unite in one understood and general system. I flatter myself, however, if Mr. Groom can adapt some of my views to his pot culture, they may be of benefit to him, as I have pronounced nothing that is not founded on experimental facts.

### Imported Bulbs.

We now come to "T. B." At p. 86 he says that I questioned the accuracy of Mr. Stewart Hardy's statement. I beg leave respectfully to deny having even entertained the idea of questioning the accuracy of any statement he has made. My questions were put to him "in all sincerity," for this special reason: A few days after his note of December 22, 1877, appeared, I called at a place in Cheapside, and obtained a supply of newly imported auratum bulbs, upon which I operated by dissection, in order to collect evidence of certain facts before making them known to the readers of THE GARDEN. This is the head and front of my offending. But what did "T. B." himself do in order to confirm Mr. Hardy's statement? He says: "For the last three years I have purchased annually four or five dozen of imported bulbs. The sizes ran from 2½ in. to 3½ in. in diameter, and all grew satisfactorily, and produced from five to nine flowers on each bulb, though two bore respectively twenty-seven and thirty-eight on one stem. I made the purchases in Jan., and had them potted and placed in a cold Vinery till they started, soon after which they were put into a frame under a north wall till the inclement weather was passed. When their

growth was completed they were transferred to my conservatory. Those purchased last year began to bloom in August, and the last of them is now only fading (January 26)." The reader will see here that there is no confirmation whatever of Mr. Hardy's statement, for, though Mr. Hardy's Lilies did not grow very high, it appears they were all planted out, and bloomed in the open air. Instead of confirming Mr. Hardy's statement, "T. B." supports mine in all essential particulars, for he shows clearly that, as a general rule, it would be a waste of money to buy imported bulbs to be planted at once in the open ground. In fact, he distinctly acknowledges this, for he says: "I have not had satisfactory results from those planted outside." I daresay "T. B." and I would agree very well if he would draw a broader line of distinction between culture under glass and culture in the open grounds of England. In reply to "Amateur" (p. 160), I am able to inform him that *Lilium auratum* and *L. speciosum* have had as fair a share of my attention as any other class, and I have not yet met with any peculiarities in them that are not at times to be found in others. If "Amateur" will turn back to p. 260, March 31, 1877, he will find something described and explained there, under the head of "twins, and three at a birth," that may perhaps induce him to review his present article, as a great part of it is, as he himself must admit, mere speculation where facts are really wanted. If he does this, I shall be glad to read his further remarks. With respect to Mr. Frank Miles, I wish he would try to ascertain under what circumstances his bulbs of *L. auratum* were gathered, packed, and transmitted to this country, as I believe their success in a great measure depends on this. I shall also be glad if he can throw any light on the admitted fact that, though hundreds of thousands are annually imported, the complaint is still, "Where are they now?" Mr. Groom has said, and I entirely agree with him, "In reference to imported bulbs, one fact must be decidedly clear, viz., that, under our enormous annual importations, the whole country would soon be a bulb garden if the bulbs did not speedily die out; the cause of which must be attributed to the drying-off process, the pernicious effects of which are annually everywhere visible." To this I may add that the difference of opinion which exists among collectors themselves clearly shows that, until the organisation of a Lily bulb is better understood, we may look in vain for a better and an earlier supply. I am prepared to prove that planting in the open ground so late as February or March, though not apparently deteriorating from the bloom of the first season, is most destructive to the young and tender germ in its incipient state, and consequently to successional bulbs, causing them to die out at a very early date.

#### Do Lily Bulbs Grow Annually Larger?

With respect to "H.'s" remarks. At p. 86 he says:—"The origin of a Lily is a germ or seed-bud, we are informed; but would it not be better to trace the Lily from the seed and follow it through its various stages up to maturity, its flowering period?" Now here I must say that I have always found my greatest difficulty to be in dealing with those who have already formed prejudiced opinions in favour of some fanciful theory. It is very clear that "H." is not aware that the germ within the bulb is the true origin of the Lily and of all that belongs to it. It is impossible that we can go further back than the germ. If we can trace the plant from that point "to its flowering period," it is all we can do; and this I have done, and attempted to describe over and over again in the most elaborate manner. If I have not succeeded in making myself understood, I can only say that I regret it very much. "H." asks:—"If a Lily dies annually, how is it that the bulb grows larger year by year?" In reply, I say that the same bulb, most assuredly does not grow larger year by year. And on this ground I take my stand; for in the correctness of this doctrine lies the whole gist of the matter. If "H." had read my former papers carefully, he must have seen that I have stated distinctly that a Lily bulb blooms only once and then dies—stem, scales, and roots all perish; and that it is the successional bulb that blooms the following year, and so on. So that, if the successional bulb grows "larger year by year" [until it reaches its maximum], it is simply owing to superior culture and congenial soil. We more often find that the suc-

cessional bulb grows less year by year; and this, again, is owing to neglected culture and the want of good and suitable soil. Dr. Wallace relates several instances that have come under his observation where the bulbs grew larger, and also where they grew less. To the experimentalist this is nothing new. If "H." could banish from his mind the idea that it is the same bulb that blooms year after year, much that is now obscure and unaccountable would appear to him as clear as the light of day. I am, indeed, sorry to differ from him on any point. Will he, therefore, oblige me by looking at the drawing of the photograph at p. 143, and my remarks which accompany it, and then say, after due deliberation, whether he still believes that the bulb (at A) that bloomed last year will ever bloom again, supposing that it had not been removed from the ground? If the block on which the drawing is engraved were put aside until the 1st of January next, and another half-dozen bulbs were then taken up and dissected as before, the same block would do for the printer, as the representation in the fresh bulbs would be the same as the present, but the actors would not be the same, that is, the site of the present A would be gone. B would have taken the place of A, C would have taken the place of B, and a new and fresh seed-bud would have taken the place of C. This was so last year, and will be so again and again for an indefinite number of years, provided the culture is good. "H." closes his remarks by saying: "Common sense tells me that the Lily is a perennial; that the germ or seed-bud constitutes one of the modes of reproduction; but I cannot look upon it as the origin." Common sense is a variable quantity in the minds of different persons, and is, therefore, not admitted to be a correct guide in such a case as this. But if "H." will refer the matter, in a proper form, to Science and Nature, they will tell him that the Lily is decidedly not a perennial, and that the germ is really and truly the origin of the Lily—that from which the stem, the leaves, the flowers, and the flower-seed itself springs.

I have said that the Lily is not a perennial, and that it is not an annual. I have also said that there is an annual bloom, but not from the same bulb. Then what is the Lily? for it is certainly not a biennial. This question I propose, on another occasion, to answer by placing before the readers of THE GARDEN the details of a course of experiments, the most interesting of all that I have made, tracing the growth of the Lily month by month from the birth of the germ until the death of the flowering bulb, this being all comprised within a period of two years.

DUNEDIN.

#### WALLFLOWERS AND VIOLETS FOR MARKET.

Those who are fortunate enough to possess a few acres of these sweet-smelling flowers are getting for them better prices than can be obtained for vegetable produce, and, enormous as is the supply of them, it is none too large to meet the requirements of vast flower-loving London. Violets and Wallflowers bring to all alike the one touch of Nature—a love and desire for something that is beautiful. The recent sunny days and dry weather have brought Violets and Wallflowers on apace, and their gathering keeps myriads of hands busy, whilst not a few poor women and children in our crowded cities have good reason to rejoice in a good Violet season. Wallflowers, unchecked by frost, are blooming gloriously, and are of that deep crimson hue so dear to purchasers. It is curious to find that the bright golden and yellow selfs will not sell—at least growers declare that no one would purchase them if they grew them; and if this be true, it tells forcibly that sweet perfumes have more charms for the poor than gorgeous tints. Effective as the Belvoir Yellow and the Golden Tom Thumb kinds are for spring bedding, they will not be grown for market unless the tastes of the people undergo a considerable change. The flowering of all Wallflowers can be accelerated by transplanting them late in the autumn, but it would not be desirable to do this to any very great extent. Where used for spring bedding such transplanting is unavoidable, but, in that case, earliness as regards flowering is a great desideratum. It is useless to expect pure colours where the seed is sowed from plants grown near each other. Insects of all kinds, bees especially, frequent the Wallflower in abundance, and the pollen is carried in all directions. It is necessary to isolate distinct colours as far as possible, in order to secure the required self hues. No doubt owing to the fact that only the dark blood-red kind is universally grown about London is largely

due the rich self colour of the flowers of the popular market kind. For market work seed is sometimes sown in the autumn, and the seedlings remain in the seed bed, and are planted out in the spring, but as a rule it is sown during one of the first two months of the year, in order that strong plants might be ready to get out early in the summer, the object of the grower being to get large plants that will produce a good head of flower earlier than late-sown plants. For bedding it is early enough to sow in March, and the seedlings should be planted out in poor soil to keep them dwarf and compact. That grandest of all single Violets, Lee's Victoria Regina, is not cultivated so extensively as it ought to be. I have had it in fine condition under glass this winter, and next year, with a good stock, I hope to have a thousand strong plants to flower in frames. All side shoots taken off old plants in November, and planted thickly in rows, will give a very fine lot of plants next autumn if replanted more thinly in April.

A. D.

### HARDY CLIMBING ASPARAGUS.

SOME of the hardy species of Asparagus are worthy the attention of the "curious gardener." Even from the point of view of ornament only, a healthy tuft of the common kind looks

A Hardy Climbing Asparagus.

well among low shrubs. There are few more graceful plants when in its summer green or when in fruit. The species we now figure is one of the hardy climbing ones noticed in the Garden of Plants (*A. verticillatus*), which grows in a twining manner about 10 ft. high, and forms a very distinct plant with much grace. It is a native of the Caucasus.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Snowdrops in Masses.**—These delicate harbingers of spring are now in full beauty; but to be able to see them in perfection they must be allowed to thoroughly establish themselves in masses. On ground that has been dug their purity of colour gets dimmed through heavy rains, but in permanent position, carpeted by Moss, Grass, or Ivy, they are simply exquisite.—J. GAOON, *Henham*.

**Primula denticulata and Veronica Blue Gem.**—This *Primula* is just now in its first flush of beauty; its round heads of lavender blossom and stems thickly powdered with yellow dust are perfectly delightful; and, as I have been away so many springs, its beauty strikes me afresh. Too much cannot be said in praise of *Veronica Blue Gem*; though for a short time frost cut the flowers, it is now again opening fresh blossoms, and makes, with *Snowdrops*, *Crocuses*, and lingering *Arbutus* berries, quite a glow of colour.—E. H. WOODALL.

### PLATE CXVII.

#### THE ACANTHOLIMONS.

(WITH A COLOURED FIGURE OF *A. GLUMACEUM*.)

Drawn by H. HYDE.

The small Order *Plumbaginaceæ*, or *Thrift* tribe, yields its full proportion of ornamental plants to our gardens. The old-fashioned *Thrift* (*Armeria maritima*), with its rose-coloured or pale lilac flowers, is still not unfrequently met with as an edging plant. With various species of the *Sea Lavender* (*Statice*) we are familiar, both in greenhouses and in winter bouquets of dried flowers; while the exquisite pale blue blossoms of *Plumbago capensis* hang in rich profusion from the roof of many a conservatory. The genus *Acantholimon*, albeit less known than any of these, is a worthy associate of them, and has almost equal claims upon the practical cultivator. It is an Eastern genus, extending from Syria and the east of Greece to Western Thibet, and having its head-quarters in Persia. The flowers resemble those of the *Statice* and *Armeria*, but the habit of the species of *Acantholimon* at once distinguishes it from either of these. The *Acantholimons* do, indeed, form branching, cushion-like tufts, somewhat after the style of *Thrift*; but the leaves, instead of being soft and Grass-like, are rigid and sharply pointed, or even spiny. From among the foliage arise flower-stems, which are sparingly leafy or quite without leaves; they are simple or slightly branched, or, in some exceptional cases, elongated and divided into two toward the apex. The blossoms are small, but numerous and showy, either rose-coloured or white, and of a dry, chaffy texture, like those of the *Sea Lavenders*. The calyx is usually white, surrounding the corolla in a frill-like manner. As many as eighty-four species have been described by Bunge, while Boissier has only about half as many; it is probable that the higher number is capable of considerable reduction. The species so much resemble one another, that anything like a detailed account of them would be too technical to interest the readers of *THE GARDEN*; but their attention may be drawn to one or two which are useful and striking plants for rockwork, although not often met with in such situations. They are not difficult of cultivation, but do not grow readily from seed, the best mode of increase being by dividing the plants, or layering the shoots towards the end of the summer.

**The Grassy Acantholimon** (*A. glumaceum*, Boiss) is a pretty little plant of Grass-like habit, with green, spiny, needle-like foliage, and a short scape about twice or thrice as long as the leaves, formed of small dense spikelets, each containing from seven to nine rose-coloured flowers. It is a native of Armenia, blossoming during the summer months, and is a very useful and ornamental plant for rock-work.

**The Beautiful Acantholimon** (*A. venustum*, Boiss) is or was recently in cultivation at Kew. It is a beautiful perennial, with radical tufts, narrow grayish leaves, and rather large flowers of a beautiful satiny rose colour, which are arranged in long scorpioid racemes rising above the leaves. The spikelets forming these racemes contain from twelve to twenty flowers, which are longer than those of *A. glumaceum* and of a brighter hue. This species is a native of Mount Taurus, and flowers in June and July.

As far as I am aware, no other species of *Acantholimon* is in cultivation, but the introduction of others is much to be desired. *A. Kotschyi* is a handsome species, with long spikes rising well above the leaves and numerous white flowers; *A. melananthum* has short, very dense, capitate spikes, the limb of the calyx being bordered with dark violet or black; *A. Phrygium* is in the way of *A. venustum*, but is a more robust plant, with longer spikes; *A. androsaceum* is a pretty, compact little plant, with numerous branches and very short spikes of intensely purple flowers, enclosed in a white calyx with purple ribs.

JAS. BRITTON.

[The plant figured was sent to us by Mr. W. Thompson, of Ipswich.]

**Hardy Plants in Flower at Fulham.**—The following plants are now in flower here, viz. :—*Bulbocodium vernum*, *Eranthis hyemalis*, *Iris reticulata* (various), *Leucogonum*, *Scilla bifolia*, *Hepaticas*, and *Helleborus orientalis*.—OSMOND & SOXS.

## GARDENING FOR THE WEEK.

## HARDY FLOWERS.

**Auriculas.**—Attention was directed a fortnight ago to the surface-dressing of Auriculas. If this has not been done, as then directed, no time should be lost in doing it now. The plants have started early and strongly, and give promise of a good bloom. They must not suffer from want of water at the roots after this, and it is very desirable to thoroughly moisten the old soil. During the winter the soil becomes very dry, and if it be not thoroughly saturated before the dressing is applied, it is very difficult to do so afterwards. The weather has been favourable for the development of decay, to which a close, muggy atmosphere is always conducive. I have found it necessary to cut the decayed portion of the stem from several varieties, afterwards dressing the wound with freshly-slaked lime. I recently read an article on Auriculas, wherein it was stated that all the trusses formed up to February should be removed. The writer could not have had any practical experience, or he would have known that the best trusses are those that are formed down amongst the leaves so early as November and December. Such trusses will gradually develop themselves, and they will flower the earliest, but not too early for the Auricula show. What grand trusses I have had of Lancashire Hero (Lancashire), Smiling Beauty (Heag), Alderman Wisbey (Healdy), Geo. Lightbody (Healdy), Arabella (Healdy), Glory (Taylor), and many others from autumn-formed trusses! The pipes are more regularly formed, and the edging more perfect; besides, they are nearly double the size of late formed trusses.

**Carnations and Picotees.**—Those in pots require attention; and unless the largest proportion of the plants are grown in pots, the blooms will not be so good as the best of those exhibited at our flower shows. Many of the weakly varieties will die off during the winter if they are exposed to the atmosphere of our large cities without a glass protection; and one advantage which the grower of these flowers, and also of Auriculas, possess is, that they can be grown in smoky cities almost as well as in the free air of the country. Mr. Simonie told me that St. Paul's Churchyard, at the top of Ludgate Hill, was a more favourable situation for Auriculas, Carnations, &c., than his own garden in Sheffield; and anyone who has visited him must have come to the same conclusion. Standing in his garden on a clear day in June, you can look at the sun at noonday as if you were gazing through smoked glass, and yet Mr. Simonie carries off first prizes at the national shows. The lights should be removed every day when the weather is fine. See that perfect cleanliness is maintained in the frames, remove all decaying foliage, and destroy green fly by brushing it off, dipping the leaves in soft soapy water, or, if practicable, the frames may be fumigated with Tobacco smoke. A gentle shower of rain will do good if the plants are nearly all dry, for they are not usually all dry at once, and it is not wise at this season to allow rain to fall on plants that are sufficiently wet. The leaves should not be allowed to remain wet very long; tilt the lights, and allow the air to circulate amongst the plants afterwards. Many are troubled with sparrows eating the hearts out of the plants. In our garden they prefer to pick off every bud of Primroses and Polyanthuses at which they can get, not to eat them, but to drop them on the ground in mere wanton mischief. If they attack Carnations in frames, they must be kept from them by stretching a net over the plants in such a way that it does not touch them.

**Dahlias.**—If Dahlia roots have not yet been put into a house where there is a gentle heat, they ought now to be placed there, as previously recommended. There is plenty of time yet if a large stock of plants be not required, and it is very undesirable to force on the growth in too much heat. The cuttings should be taken off when they are 2 in. long, and each cutting should be placed in the centre of a 24-in. pot, and the pots should be set close together in a frame or pit over a bed where there is just a gentle bottom-heat. The slender cuttings form roots most quickly. Very stout cuttings will remain a long time before they do so. When the small plants begin to grow, they must be removed from the bed, and be placed near the glass, and when fairly rooted, may be potted in 5-in. pots. It is not necessary to start pot roots for a month yet; if started too early, the plants become pot-bound or drawn up weakly before planting-out time.

**Hollyhocks.**—These are not so easily propagated as Dahlias; the cuttings take longer to form roots, and are more liable to damp off instead of forming roots at all. If they be managed as previously directed, when the cuttings or grafted plants have formed roots, they should be potted into 5-in. pots, keeping the plants near the glass in a house where there is a little heat. In two weeks after potting the plants will have rooted sufficiently, so that they may be transferred to a cold frame. Keep the frame rather close at first, and

use mats on frosty nights; afterwards give air freely. Such plants will flower well, and usually produce better spikes than autumn-struck cuttings. Autumn-struck outtings wintered in small pots should now be potted into larger pots. If the plants become pot-bound, they seldom give satisfaction.

**Pansies in Pots.**—Some years ago the Royal Horticultural Society offered prizes for Pansies in pots, and I have a vivid recollection of the fine group of plants exhibited by Mr. James, of Teddes, Isleworth. It is to be regretted that the prizes were not continued, as Pansies succeed remarkably well in pots; and what a refreshing change it would be to introduce them at the March or April shows! If the plants have not yet been potted into their blooming pots, no time ought to be lost in doing so. They do well in a compost of good turfy loam, four parts; rotten cow manure, one part; leaf-mould, one part, and a little river sand added to keep the soil open. The plants must be placed very near the glass in cold frames, the Pansy being impatient of the restrictions of a heated structure. Admit air freely, and see that the plants are kept free from insect pests. Green fly attacks the plants when in confinement, and slugs are particularly fond of half-opened flowers or tender young leaves.

**Tulips.**—These did not appear through the ground so early this season as they did last; but they are now all above ground. Our beds will have the surface-soil stirred over with a pointed stick; the weeds will be removed by hand. I am not at all anxious about them suffering from cold at this season. Our soil is of a dry nature, and it is well drained; in wet soils and heavy loam the plants would suffer from wet, if frost should set in after rain. J. DOUGLAS.

## Roses.

Tea Roses that have been grown on in pots with a view to turning out in the open ground may now be planted where they are to remain; they are much more suited for covering walls, particularly low ones, than other kinds often used for such purposes, inasmuch as their habit of flowering in succession through the season, and especially up to the latest period in autumn that the weather permits, is a decided advantage, although the quantity of bloom which they produce at any particular time may not be equal to that of some of the hybrids. The soil in which they are to grow should be made very rich with manure before they are planted, otherwise their progress will be comparatively slow, and in such situations they need more attention as to water at the roots during dry weather in summer than they otherwise would do, for at the foot of a wall the soil seldom gets moistened by rain so effectually as where fully exposed. This is one of the reasons why Roses on walls are frequently met with in a stunted state. The manner in which Roses are too often trained on walls is also the cause of their often getting into an unsatisfactory condition with nothing but bare old branches, devoid of either foliage or flowers for several feet from the base upwards. This results from the whole or greater portion of the stronger shoots being nailed in an upright position; whereas if they were spread out, especially the strongest, fan-fashion, stout young growths would annually be emitted near the bottom that would keep the surface evenly covered with flowering wood. In the case of established Roses that have got in this way in such situations if they be now loosened from the walls, and the lower part of their strong branches for some feet be bent and secured in a horizontal position, the lower dormant eyes will start and furnish the required growth. In narrow borders close to buildings in which the roots of climbing Roses are confined, the soil, as elsewhere, in time gets exhausted, and does not present such facilities for digging in the requisite quantity of manure as in more open situations, the result of which is weak, puny growth. Where this happens some of the old surface soil should now be removed, and a good layer of manure or new soil substituted, forking it in as far as possible without disturbing the roots or the soil. In the case of the extremities or main feeding roots of Roses on buildings from which they get into gravel walks that run near and parallel with the buildings; in such cases the best way of feeding them is frequently during spring and summer to soak the gravel with strong, clear manure water. A thorough application so as to moisten the whole mass at the present time will be of material assistance in enabling the plants to push vigorously in their first spring efforts at growth. All pruning of Roses on walls yet to be completed should be brought to a conclusion without delay, and the nailing and tying should be finished, or the now fast advancing buds will be partially destroyed.—T. B.

## Orchids.

The temperature of Orchid houses may now be raised 5° at night, as the increased length of daylight and the disposition to make growth will require this. In the day temperature, as a matter of course, the variation will be considerable; when it is bright and clear the thermometer will now frequently rise to 80°, but when the weather is cloudy there should be no attempt at keeping it so high as this by fire-heat. For the East India house, 65° by night and 70° in the daytime without sun will be sufficient; in the Mexican house from 50° to 55° at night, with 5° higher without sunshine during the day, will be enough. The cooler Odontoglossum house may now be kept at night from 48° to 50°; with a corresponding increase during the daytime. It is now also quite time to get the blinds on, for although the sun may not be bright and clear for

more than three or four hours during the day, still even at the beginning of this month it is often so powerful as to do serious harm if allowed to shine directly on the plants; in fact, I have seen the leaves of *Aerides*, *Succoboliums*, *Angustans*, and *Vandas*, especially the latter, when near the roof, much injured by the sun coming in full force on flaps in the glass, causing them to act as scorching lenses, whereby the leaves were literally burnt off, the effect of which was at an hour's neglect in this matter took years to rectify. But although recommending caution in this respect, I wish it to be clearly understood that I do not recommend the blinds being down for a single hour, particularly at this early season, when there is not an absolute necessity for it. Correspondingly more moisture may be kept up in the atmosphere, but this should not be increased too rapidly, and even comparatively little be given to the roots of the some plants, it will be of great service, and will be of great use as quickly as to either wholly or partially prevent their flowering. This will be more likely to follow when the plants have been grown under conditions of too much shade and moisture. A little air during the brightest part of the day should be given, but this should be confined to the roof. The system of air-giving to Orchids by shutter-boxes and flaps in the walls, where the air admitted before reaching the plants would first come in contact with the hot pipes, is a plausible and taking proposition, but in practice I have found it very injurious, as when the roof ventilators are at the same time open, even ever so little, it produces a dry, arid current, expelling the moisture from the house at a time when, through the heat of the sun, it is most wanted. We frequently hear the remark made, that Orchids succeed better in houses where the roof is composed of small squares with many laps than they do under large squares in houses of more modern construction. The cause is obvious; the many openings in the laps allow of more even and gradual admission and diffusion of air at the top than where the laps are few and close.

**Calanthes.**—The different varieties of *Calanthe vestita*, and the hybrid *C. Veitchii*, should be largely grown wherever cut flowers are required in winter in quantity, but to do them well they need a comparatively high temperature. Such as have bloomed early will want immediate attention as to potting, as this operation should in all cases be carried out as soon as the young growths at the base of the old bulbs have begun fairly to push, yet before they have made any attempt to emit roots, as if the young fibres first emitted be at all injured, which is certain to occur if potted after they have begun to push, the season's growth will be thereby seriously affected. I have tried different kinds of potting material wherein to grow these plants, such as all fibrous peat, all fibrous loam, and equal proportions of both, in each case with and without the addition of dry slaty manure. I have also tried them in manure alone, such as had lain out in a heap, and lately, reaching a wire border or an Asparagus bed; as a matter of course, in every case a good sprinkling of pot shreds or broken charcoal, with a little sand, was added, yet I have found little difference in the growth of the plants traceable to the material in which they were grown; but, more than most Orchids, they are favourably influenced by a maximum amount of light. The best I ever had were grown in earthenware pans made to fit inside ordinary wire baskets, suspended so as to elevate the leaves of the plants when fully grown to within 2 ft. of the roof; for appearance sake a thin layer of Spagnum was placed inside the wire baskets so as to hide the pans. Grown in this way, with a thin shade to protect the leaves when the sun was full upon the glass, the bulbs formed were double the size I ever could get them to when set upon the stages, and it will almost invariably be found that the flowering capabilities are proportionate to the size of the bulb. In addition to the growths that spring from the base of the old bulb, they will generally push one or two from the upper portion; where a sufficient stock of the plants exist, with no necessity for further increase, I should advise all these upper breaks being rubbed off as they are formed, by which means the principal growths from the base will produce a much larger bulb. The old bulbs in existence twelve months ago, and from which last year's growth was produced, so long as they retain their vitality will be found to have a great influence in increasing the size and strength of the bulb formed during the coming season. I mention this from a knowledge that many growers discard these old back bulbs under an impression that they are useless, but from actual observation I have proved that the influence, on what we may term the second growth, is very considerable. In potting these plants, I have found it better to shorten the old roots at the base of the bulb now dead to within 1 in. of the bottom than to remove them, as by retaining them thus far, and pressing the potting material firmly round them, the bulbs are kept in their place until the new roots get firm hold of the soil. On no account should they ever be allowed to remain a second year in the old soil, for however fresh it may now appear, it will be in a condition unsuitable for them before the season is over.—T. B.

#### Greenhouse and Stove Plants.

Remove some of the most backward *Cinerarias* to a wire house so as to preserve their lateness; water those that are in bloom freely, and occasionally with manure water; keep them free from insects by fumigation. Chinese *Primulas* required for seeding should not be burdened too much, therefore reduce the quantity of flowers on each plant to one or two, and increase the strength of the plants. Keep the bluebonnet *Calceolarias* growing gently, by supplying them liberally with water and keeping them in a light and airy house and near the glass. Violets that were bloomed in pots during the winter may now be transferred to a warm border. Hyacinths and Tulips should be kept as cool as possible, and in light houses. *Lachenalis* are now blooming pretty freely; keep them near the glass and treat them liberally. Statice should be re-potted and

kept in the warmest part of the greenhouse. Save seeds of *Solanum capsicastrum*; cut down the old plants and use the young shoots for cuttings. Re-pot and remove for the same purpose the suckers of *Calla californica*. Cut off the ends of the branches, and thin plants of *Veronica* *Andromeda*, when they start them into growth. *Kalanchoes* *coccinea* should be re-potted in a compost of good loam and some thoroughly decayed manure. Cut back *Borvardsias* that have done flowering, and use the young shoots for propagating. Cut back, re-pot, and start into growth some plants of the lemon-scented *Verbena*. Turn out into frames young *Chrysanthemums*, and see that none suffer for want of potting. Re-pot and stake choice *Petunias*, and sow some seeds in light soil in gentle heat for conservatory blooming; the surplus may be economised for bedding purposes. Train *Tree Mignonettes*, and admit plenty of air to dwarf-growing plants, such as the *Veronica* of the fine varieties, as well as *Musk*, which may be potted in two parts loam and one of decayed manure, with some sand; they soon grow and form neat flowering plants. Wire baskets containing the latter, and also others planted with *Saxifraga sarmentosa*, may now be made up either for the window or for suspending from the roof of the conservatory.

**Euphorbia jaquiniflora.**—Plants of this that have done flowering should have their flower-pots pinched off. They should then be encouraged, by means of additional heat and moisture, to make fresh shoots, which, taken off with a heel, and inserted under a hand-glass like ordinary stove-plant cuttings, strike as freely as *Verbenas*. The stems of these plants are commonly cut up into little pieces, each having one or two eyes, which will strike like *Cinistatas*, *Vines*, &c., but they do not form such good plants as those obtained by the former method; besides, they root so quickly nor grow as fast as cuttings do, and the earlier the latter are rooted, and the stronger they become before their flowering period, the finer will their inflorescence be.

Pot singly rooted cuttings of *Lyons*, *Dracenas*, *Aphelandras*, *Eranthemums*, *Hoyas*, *Gardenias*, &c., as they become fit for that purpose, and keep them in a moist, brisk temperature. Make a little incision in the stems of *Dracenas*, *Diophysias*, &c., just below the crowning tuft of leaves at the summit of the naked stem, and tie around the incision some damp Moss mixed with silver sand, so as to induce the plants to callus and emit roots before they are separated from the parent stock.

**Azaleas.**—Any of these that have been forced for the purpose of flowering early should, directly they have ceased blooming, be placed where they will begin to grow; if put now in a cold house the growth, which the heat to which they have been subjected to bring them into flower will have excited, will receive a check; if this occur, the plants will be injured. Be very careful to see whether there are any thrips upon them; should these be found, give a good washing with Tobacco water. This is not only necessary for the well-being of the Azaleas, but also on account of the insects, for if the insects be only few in number, they will quickly spread to the subject in the next month, and they will live upon; the safest plan is to wash, whether any thrips are discovered or not. It sometimes happens that Azaleas that occupy pots as large as desirable get into a weak state through the soil becoming exhausted. When in this condition they are generally thrown away; this need not be done, as in a couple of years they can be brought into a thoroughly satisfactory state. The present is a good time to begin; allow the soil to become rather dry, but not so much so that the plants would need watering for several days; then cut them well into the old wood, reducing them to about half the size they were before they were operated upon. Give them a good cleansing if they have had any insects on them, and put them in a moist heat of about 60° by night. Syringe overhead once or twice a day, but the soil must not be permitted to become too wet. If all go well, they will break in the course of four or five weeks.

**Saracénias.**—The want of success often experienced with these plants is generally attributable to the mistake made in treating them indiscriminately with the ordinary occupants of the stove, not only in the amount of heat to which they are subjected, but also as to water and soil. The advice often given as to their requirements has been such as to induce those not experienced in their cultivation to keep them in too great heat, especially in the winter time, which has the effect of preventing their getting the rest they require; it also induces weak, soft, elongated growth, and many of the leaves being found developed into their wanted pitcher-like form, a condition which, owing to the anomalous singularity. The different species will succeed well with similar treatment as to soil, moisture, heat, and air. From the middle of November till the end of February they should have a temperature of 50° by night and 5° more in the day; after this time increase 5° night and day; during the spring and summer it may run from 60° to 70° in the night, and from 75° to 80° by day, according to the state of the weather. Whether they seem to need it or not, each year in February get all the soil gently away from them, re-potting them in a fresh compost, consisting of equal parts of the best fibrous peat with all the earthy matter abstracted, and chopped Spagnum liberally mixed with crocks or charcoal broken moderately fine, adding to the whole a good sprinkling of sand. If they be potted late in the season, the pitchers often come crippled. *S. Drummondii* alba and *S. Drummondii* rubra are exceptions to the others in the time of potting, as about July, when their spring growth is finished, is the best season to move them. The pots should be one-third filled with crocks; the growing stems must be kept just above the soil. They must be watered every day from the time they begin to grow freely until autumn, and twice a week in winter. All the varieties of *Saracénia*, except *S. purpurea*, must not be syringed, as it renders them soft. They should have a shelf of unplanned wood to stand on; this will hold

moisture, and it ought to be damped two or three times every day during the time the plants are growing. Let them have a place at the south side of the house near the glass, or else elevated till they nearly touch the roof; they should occupy a moist corner, and though they like a moderate quantity of air, it ought not to be admitted close to them. They must not be stood in pans, as their roots are liable to rot when so treated. A very thin shade is necessary when the sun is on them. The flowers ought to be nipped out directly they appear, at any rate whilst the plants are small, as they weaken them. All the flower-stems that are thrown up divide the crowns that produce them into two; by this means they increase, but until they get a good size they ought not to be separated. Scale is very troublesome to them, and it will seriously injure them if allowed to remain. They are also subject to green fly and, above all, thrips. These latter especially get under the rim of the mouth of the pitchers, and if not soon destroyed the pitchers will be ruined. Before they have lasted half their properties they will have newly imported the almost general mistake is to keep them too hot at first, the result of which is to cause them to make leaf-growing without any corresponding root-action, the latter very often never making any progress during the first summer. When this is the case they almost always die the ensuing winter. As soon as the plants arrive, they should at once be placed in pots that will only hold their roots with a moderate quantity of soil. Keep moist, but if they come in the autumn they should not be subjected through the winter to more than from 46° to 50° in the night, increasing the heat a little as the spring advances, and in the summer give them no warmer treatment than an intermediate house will afford.

### Flower Garden.

The replenishment of flower-beds from our reserve stock must now occupy attention; all spring flowering plants may be transplanted with impunity according to convenience. Several of the autumn-sown annuals too may be transplanted from their winter beds to where they are required for blooming, and to fill up vacancies between perennials. Hollyhocks and Foxgloves from last year's sowings should now be transplanted permanently in good rich soil; indeed, a spadeful or two of well-decayed manure mixed with the soil in each hole is an important addition. Iry, Jasmines, Clematises, Honeysuckles, Crataeguses, Magnolias, and similar plants on walls should be thinned or pruned, if necessary, and neatly trained. Form edgings of the variegated Queen of the Meadow, Arabis Polemonium, Grasses, Daisies, Golden Feverfew, Eryngium radicans, Santolinas, &c. Some of these, such as the Golden Feverfew, are only fit for spring gardening when sown from the previous year's sowings, and to be repeated again in April or May from spring-sown plants which do not so readily run to seed during the summer and autumn months. Various kinds of flower seeds should now be sown for early blooming, but the main crop of hardy annuals is best sown in the first week of April. When the weather is dry, add some turfy loam and well-decomposed manure to beds where large plants, such as those of Ricinus, Ferdinandia, Wigandia, and other gross feeders are to be grown, i.e., if the beds are now empty. If the soil last year was found to be too moist turn it out, and place a layer of stones, broken bricks, &c., in the bottoms of the beds. Mutch all newly-planted shrubs or trees, and affix strong but neat stakes to such as require support. Prune back pretty hard some Clematises for early flowering. Tree Peonies, Myrtles, the Japanese Quince, and several other rather tender plants should have a little protection from frost; for although their roots and principal stems might escape unharmed, their young shoots might be considerably injured. Prune and tie up climbing plants. Where new lawns are intended to be made, the ground should now be cleared of all superfluous trees and shrubs, and the soil should be trenched over, turning all rough material into the bottom of the trenches, and making the whole perfectly level, smooth, and firm by means of raking and making. The seed should be sown in the latter half of this month.

### Shrubberies.

In the shrubbery and its surroundings the state and position of deciduous trees should be inspected, especially those planted near the boundary with a view to give shelter or privacy. It is a matter of frequent occurrence to find such trees planted without the slightest regard to the space they will ultimately occupy, and merely placed so as to give immediate effect. Even where the trees have been planted with a due regard to their future proportions, and the intervening spaces filled with others to act as nurses for those intended to be permanent, there is nothing so common as to see the nurse plants retained until they have completely ruined the trees by crowding. The whole of the under branches, which were intended to act as a break, and upon the vigorous presence of which the beauty of the trees depend, are completely destroyed. The object of these nurse trees is only to afford the necessary shelter to those intended to stand, and to assist in filling up the intervening spaces. These temporarily planted trees should, the moment they interfere with the well-being of the others, be either removed altogether, or cut in with no sparing hand; it is often considered time enough to do this when the branches touch; but this is a mistake, for when they have grown to this condition, very serious harm will have occurred to the permanent trees from the exclusion of light and air, thus making them draw up weakly, and rendering them unable to develop their proper growth. Thousands of amateurs' gardens throughout the country suffer in this way. The present is a good time for reducing the branches, unless the trees are still of a size to be removed and it is the intention to replant them, in which case no time must be lost, as the buds of many will soon begin to swell.

### Indoor Fruit Department.

**Pines.**—Increase the day and night temperature of Pine pits, in accordance with the weather, and give a little extra moisture to the roots, especially those of plants swelling fruit; but such as have nearly finished swelling should be kept moderately dry. Shift into fruiting-pots all plants requiring that attention, and take off and pot suckers as they become ready. Do not starve young growing plants, for, if once checked, they are almost sure to produce small and premature fruit. Syringe with tepid water the surface of the beds and about the necks of growing plants, especially on fine days.

**Vines.**—Thin and stop the shoots, thin the berries, and keep up a steady moist temperature.

**Peaches.**—Thin these where too thick, but do not make the final thinning until after the stoning period is over, and until that time maintain a steady and moderately low temperature. Regulate an thin the young shoots, and syringe morning and afternoon with tepid water on fine days, and once every day, regardless of the weather. If a little top air can be left on at night, and artificial heat given to maintain the requisite temperature, it will be of material importance to the crop.

**Cherries.**—A temperature of 50° or 55° will be sufficient for these until the fruit has stoned afterwards the heat may be increased 10° by sun-heat and when the fruit is colouring a night temperature of 60° and a day one of 75° or 80°, with sun-heat, will not be too much for them. An airy house and a position near the glass is of the utmost importance in Cherry forcing, and a high temperature either by night or day before the fruit has stoned is ruinous.

**Figs.**—Give manure water occasionally to Fig trees swelling their fruit, and syringe them freely until they begin to ripen. Pot Figs are commonly used for the earliest crop, and, where houses are not specially devoted to their culture, they may be successfully ripened in the Pine stove or early Vinery. Stop the young shoots at the third or fourth joint, and remove all root suckers, unless a few are wanted next winter for fresh plants.

**Strawberries.**—The earliest will now be ripe or ripening, therefore they are best kept moderately dry and airy. Introduce plants of them for succession into Peach houses or Vinery shelves, or into houses built purposely for them.

**Cucumbers.**—Keep up a bottom-heat of 75° for these, and an atmospheric one a few degrees lower; but in the event of bright weather, an extra 5° would be rather beneficial to them than otherwise. If the bottom-heat is not sufficient, and the plants are wanting, apply fresh linings or mix fresh manure with the old fermenting material. Sow a good successional crop of Cucumbers and Melons.

**Forced Vegetables.**—Kidney Beans should be sown in succession fortnightly, or according to the demand; a Cucumber house, Pine stove, or early Vinery suits this crop perfectly, and the plants must be freely syringed, to keep down red spider. Sow a few Tomatoes at once in a moderate hot-bed, or propagate by cuttings from old plants saved in pots during the winter; plants from these cuttings fruit earlier than from seedlings. Rhubarb will soon be obtained abundantly from the open air, i.e., if a forkful or two of litter be placed over the crowns; but a few roots for succession may still be taken into the Mushroom house. Keep up a constant succession of forced Asparagus, either by placing roots in moderately heated frames, or by filling trenches between the beds with fermenting material. Start a few more Sealake roots. A temperature of 60° and a humid atmosphere should be maintained in the Mushroom house. Protect Lettuces in frames from wet, and plant some out as convenience and weather may permit; sow some seeds for succession. Sow a few Capsicums in boxes, and pot them off singly, or prick them off when they are fit to handle. Sow some Celery seeds in a gentle heat. Sow some New Zealand Spinach in a brisk temperature for summer and early autumn use. Thin Carrots in frames; keep them dry, and shelter them from rain, but expose them freely in favourable weather.

### Kitchen Garden.

**Potato Planting under Slight Protection.**—Few crops are of more importance than the Potato crop, and means should, therefore, be taken to obtain it out-of-doors as early as possible, for although Potatoes grown in pits and frames are very acceptable, still, unless brought on in such places very slowly, they are rarely equal in quality to those grown in the open air. If there exists a good south wall, this will no doubt be occupied with fruit trees; but, without in any way interfering with these, a row of Potatoes may be grown at the foot of the wall that will come in, with a little care, a fortnight earlier than they can be grown without protection, even in a sheltered border at a greater distance from the wall. Fork the ground over 15 in. wide from the wall, not going so deep as to injure the roots of the trees, and if the soil be poor, add a little rotten manure; then open a trench 8 in. from the wall and about 4 in. deep, drawing the soil forward. Take some Potatoes that a short time back were prepared by sprouting, reduce the sprouts on each tuber to two, and, in planting, cover them with the soil very carefully, so as not to injure them; 9 in. will be far enough apart, as they will be taken up as soon as large enough for use. Where there does not exist a wall that can be taken advantage of in this way a few square yards of a warm, sunny border should be selected; this should have the assistance of a temporary frame made of light boards, with strips of wood nailed across, so as to admit of being covered at night with mats, when the crop appears above ground, which it will before spring frosts are over. Crops thus produced

will be found to be well worth the labour bestowed on them, as Potatoes raised in this way will come in after those that have been grown in frames are used, and before those in the open ground that have received no protection. Potatoes in frames must receive plenty of air on all occasions when it is not absolutely frosty, or they will become drawn. The lights should be raised at both ends, so as to let the plants have air equally all over.

#### Extracts from my Diary.

**March 4.**—Sowing Henry's Prize, Aytton Castle Giant, and other Leeks; also a Little Borage and Chervil. Potting off Capsicums. Putting in cuttings of Heliotropes, Pelargoniums, and Gazanias. Thinning out and cutting back Ivy on walls. Preparing three-light manure frames for Melons. Looking over Cucumbers, stopping them and picking out all false blossoms. Covering up Eadive to blanch.

**March 5.**—Sowing Canadian Wonder French Beans in pots. Potting on Cucumber and Melon plants. Earthing up Potatoes in frames. Pulling up and clearing out Early Brussels Sprouts stumps and getting manure on the ground ready for digging. Cleaning up the pleasure grounds, and rolling down all newly laid turf and gravel. Fumigating Cucumbers, and covering up Seakale.

**March 6.**—Sowing Marrow Peas in boxes for Green Pea soup. Earthing up Beans in pots. Potting off Coleus, Alternantheras, and Verbenas. Clearing manure and leaves out of Muscat houses, the Vines being well broken. Tying in some of the forward Peach and Nectarine shoots, and disabding them where required.

**March 7.**—Sowing All the Year Round and Carter's Giant White Cos Lettuce; also Early Horn Carrot and Early Frame Radish. Potting off Petunias, Heliotropes, and Gazanias. Getting into boxes a quantity of Lily of the Valley, and putting them into gentle heat. Clearing away all the wet litter from Globe Artichokes, and putting a little more dry litter round them, in order that they may not feel the check all at once.

**March 8.**—Sowing Mustard and Cress, also a border of Spinach. Picking out Lobelias and Golden Pyrethrum. Cutting back and thinning out dwarf Laurel shrubs. Getting a mixture of leaf-mould and old Pine soil into frames in which to transplant *Calceolarias* 6 in. apart. Commencing to prune and nail Peach trees on open walls. Looking over Grapes in bottles, removing any berries that are decaying, and, where required, filling up the bottles.

**March 9.**—Planting early Potatoes, consisting of the following sorts, viz., Early Ashleaf and Gloucester Kidney, Penn's Early Market, Porter's Excelsior, and Lady Page Kidneys. Planting Wheeler's Imperial Cabbage plants, also Jerusalem Artichokes. Looking over fruit room, and removing any that are useless. Thinning Grapes, and tying down shoots in early Vineries. Fruit in use for dessert: Pines, Grapes, Apples, and Pears.—G. W. P., Dorset.

#### GRAPES AND ROSES.

ANYONE unacquainted with English gardens would imagine, on reading "A. D.'s" remarks (see p. 166), that fruit growing, more especially Grapes and Peaches, subjects so interesting to cultivators, was at a very low ebb; but the fact that anyone with an ordinary Vinery should fail to winter hardy plants and produce a good crop of Grapes as well is surely against our experience of good cultivators. What would gardeners do with their stock, not only of hardy but of tender plants, if their fruit houses could not be utilised for the purpose of wintering it? We should all like to have separate houses for different subjects; but "A. D." is mistaken if he considers plant growing and mildew Grapes to be inseparable companions. All our Vineries here, both early and late, are used for all kinds of plants, according to the season of the year and the temperature at which they are maintained. The only season at which they are entirely free from plants is when the crop is approaching maturity, when a dry atmosphere is necessary in order to ripen and keep it until required for use. And yet we have no mildew. Thrips and scale may be imported into Vineries if due care be not exercised as regards subjects introduced. But hardy plants, properly so-called, are not subject to the attacks of these, and need never be under glass when Vines are in a growing state. I have on numerous occasions seen good collections of plants, including Orchids, that had always been grown in Vineries, but I by no means recommend such a course. As regards Peaches, I consider them a more difficult crop, both on walls and under glass, than Grapes. With a Vinery and border ready made Roses might certainly be grown by any intelligent labourer; but Roses, however abundant, will never supersede choice dessert fruits, and anyone who has failed to winter plants in Vineries and grow Grapes fit for table as well, I would strongly recommend not to attempt fruit culture under glass at all, being thoroughly convinced that they have mistaken their vocation.

Henham.

J. Groom.

#### GARDEN BOTANY.

(Continued from p. 165.)

**THE COTYLEDONS.**—The curious extinguisher-like cotyledon of many Palms has already been described, but monocotyledonous embryos are very variable. When they are not sheathing, the base at least extends all round the radicle, as in figs. 69 to 71, thus differing from the exceptional dicotyledonous embryos, in which one of the cotyledons is so small in proportion to the other as to escape observation or, as is occasionally

Fig. 69.—Monocotyledonous embryo of *Dioscorea villosa* with a thin flattened cotyledon and a short obtuse plumule.

Fig. 70.—Embryo of *Dioscorea cordifolia*.

Fig. 71.—Monocotyledonous embryo of *Rajania hastata* with a relatively large, flat cotyledon.

the case, entirely suppressed. The Walnut, which is a one-seeded fruit, with an exalbuminous seed, has large, sinuously-lobed cotyledons. The base of the fruit has partitions, dividing it into two or four compartments, into which the cotyledons grow, and the upper part is one-celled. At the upper or pointed end of the shell (endocarp) the small radicle may be discerned, and in breaking the kernel in longitudinal halves, the relatively large plumule will be found. In the large, exalbuminous seeds of *Pachira* and some other *Bombacæ*, for example, one of the cotyledons is very large and fleshy, and completely enfolds the plumule, radicle, and the second cotyledon, which is comparatively small; and in germination its folds are pushed apart by the growing plumule and radicle. The cotyledons of the embryos of some plants, whose other characters associate them with dicotyledons, are quite obsolete, as in the genus *Garcinia*, mentioned in the foregoing paragraph on the radicle; in other members of the same family the radicle is very minute and the cotyledons large, as is also the case in the Almond (fig. 31) and the Kidney Bean (fig. 35). Sometimes the cotyledons adhere together by their inner faces, as in *Tropæolum*; they are then termed conferruminate. Usually they are very different from the succeeding leaves, especially in being thick and fleshy, and in having no visible nervation, but in some embryos the cotyledons are thin and distinctly veined; they are then called leafy or foliaceous. The Castor-

Fig. 73.—Embryo of Lime, spread out to show the lobed cotyledons. (Enlarged.)

Fig. 74.—Embryo of Scotch Pine, with six cotyledons (c).

oil tree and *Enonymus* seeds are examples of the latter kind. We have alluded to the suppression of one or both cotyledons, and given an instance of the latter condition. *Cyclamen* furnishes an example in which only one cotyledon is fully developed, and this grows to a relatively large size, resembling one of the ordinary leaves which follow.

**PERMANENT COTYLEDONS.**—*Streptocarpus polyanthus* is a singular plant, in which only one cotyledon is developed, and this grows out to 1 ft. or more in length, and several inches broad, and is the only leaf the plant possesses. In *Welwitschia*

*mirabilis* (fig. 72) only the cotyledonary or seed-leaves are developed, growing to a length of several feet. As a rule, cotyledons are entire on the margin, but in the common Cress (*Lepidium sativum*) they are deeply three-lobed, in fact, almost trifoliate; and in the Lime they are folded and five-lobed (fig. 73). Sometimes the number of cotyledons exceeds two, and this is a very common occurrence in the Coniferae, where the number varies from two to fifteen. In nearly all the Pines and Firs there are several. The embryo of the Scotch Pine has usually six (fig. 74), and the Stone Pine twelve. But the Coniferae differ so much in other respects from dicotyledons (exogens), with which they are often associated in classification, that many modern botanists regard them as forming, with Cycads and Gnetaceae (*Ephedra*, &c.), a distinct class between Ferns and monocotyledons.

**THE PLUMULE.**—It is not until germination commences in the majority of embryos that the plumule becomes visible, though the beginning of its formation may be found by the aid of a microscope. There is, however, very much diversity in the degree of development of the plumule before active germination begins. Thus in the Kidney Bean (fig. 35) two distinctly formed leaves, visible to the naked eye, will be seen in a dormant seed on separating the thick cotyledons. In the Almond, also

exhausting it; but meanwhile its succeeding leaves become green, and thereby fitted to perform their special function, which is defined and described in detail in the section just named. Usually the stem of a plant and all its ramifications proceed directly from the plumule, but occasionally, or indeed one might say frequently, in some plants buds appear below the insertion of the cotyledons on what is sometimes termed the caulicle or tigellus.

**GERMINATION OF SEEDS.**—This phenomenon depends upon certain conditions, varying in degree, intensity, and relative proportion for different seeds, but essentially the same for all. The modes of germination are various, and there are many attendant circumstances deserving of our attention. It may be necessary for the reader to consult the sections on minute anatomy and nutrition, in order to fully comprehend some of the processes accompanying germination, because for the sake of simplicity they are merely mentioned here. For practical purposes the germinative period may be defined as commencing as soon as the testa bursts, or some part of the embryo begins to emerge from the seed, and as terminating when the supply of nutriment either in the cotyledons or albumen, as the case may be, is exhausted.

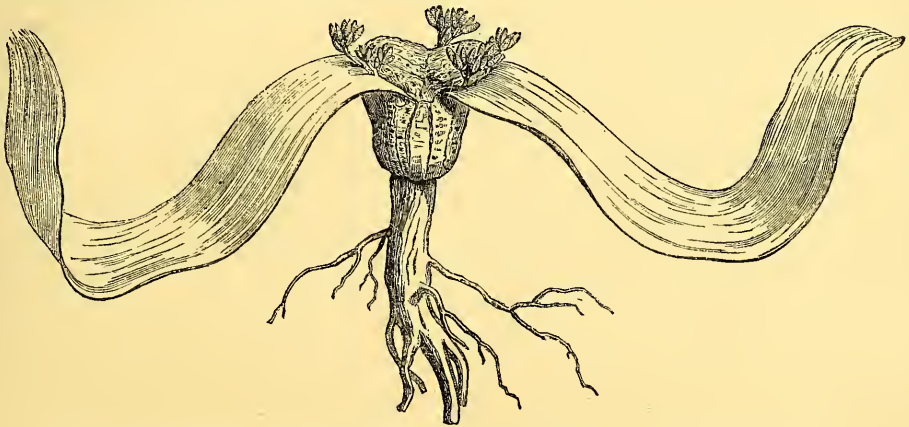

Fig. 72.—*Welwitschia mirabilis*. An example of a plant which produces no leaves beyond the two cotyledonary or seed leaves.

(fig. 31), the plumule is fully formed in the seed. The plumule of the singular Mangrove (*Pelliciera Rhizophora*) is very large in the ripe seed, and pierces the fruit sometimes before the radicle, and attains a considerable length before the latter starts. On the other hand, germinating seeds of garden Cress (*Lepidium sativum*) exhibit no visible trace of the plumule for some days after the seeds have germinated and the cotyledons have appeared above ground. But it is worth noting the different conditions under which the embryos of the Cress and Kidney Bean develop into plants. The embryo of Cress is small, the cotyledons are thin, and the seed contains no albumen, hence there can be little nutritive substance stored up for the use of the plant in the earliest stage of its growth. As there is almost no provision of food in the embryo itself, or within its reach, in the form of albumen, it follows that soon after its start into active life it must be able to absorb and assimilate the materials necessary for growth. This it is able to do, for the seed-leaves (cotyledons) assume the form of ordinary leaves, and become quite green. The significance of their becoming green like ordinary leaves will be perceived on referring to the section on the nutrition of plants. In the thick cotyledons of the Kidney Bean there is a large store of food for the growing plant, therefore it is not necessary that the cotyledons should acquire the power of assimilation. The highly developed plumule feeds upon this store of food, finally

**CONDITIONS CONTROLLING GERMINATION.**—Given a good seed that is, a seed which has not lost its vital properties, a certain amount of warmth and moisture is necessary to stimulate it into growth; and to enable the young seedling to attain perfect development as an adult plant, there must be within its reach certain substances which it requires for food. Further, the atmosphere must contain oxygen, and, as a rule, sunlight is indispensable. Only those agencies actually determining germination will be considered here. The chemical changes, so far as they are known, which the contents of the seed undergo in germination are explained in the "Chemistry of Plants."

**MOISTURE.**—The primary process in germination is the absorption of water by the seed or embryo, which distends the tissue of the latter, causing a rupture of the testa, or the growth and consequent protrusion of some part of the embryo through the micropyle. As we shall presently see, it is not always the radicle that first breaks through, though this, it is stated in many text-books, is the usual way in which germination begins. The relative quantity of water necessary to even initiate germination depends, to a great extent, upon the nature of the testa, and frequently too of the pericarp, when the latter does not split open to free the seeds. Stone fruits (drupes), for example, like the Cherry and Plum, having a hard bony endocarp, will remain in a moist place for a long time before the water penetrates to the seed itself, and the same

holds good for seeds with a very dense testa, as in many species of *Acacia*. This dense endocarp or testa seems to act as a protection to the embryo, by preventing it from germinating at an unfavourable season of the year, and from being devoured by animals. The hard endocarp or stone of such fruits as the Cherry, Sloe, &c., serves as a protection to the embryo, inasmuch as when the fruit is eaten by birds or animals, the stone passes through the stomach undigested. Instances are on record of Plum seeds and Raspberry seeds having germinated after the fruit had been boiled into jam, but it should be remembered that it is the seed, plus its pericarp, or portion of its pericarp. But in whatever light we regard it, it is a fact that by breaking open the stone of a Cherry or softening the testa of an *Acacia* seed by soaking it in very hot water, so that water is absorbed by the embryo, germination is greatly accelerated, or even commences at once. An instrument has been invented in France for cracking the hard bony endocarp in which Olive seeds are enclosed without injuring the seed, and treated thus they quickly germinate. With old seeds, also, much time may be saved by soaking in warm or hot water, according to their nature. Some seeds will even bear boiling for a short time without injury, but this extreme measure is not recommended for practical purposes without being first tried experimentally. There are, moreover, many seeds which are not provided with such a preventive to the quick penetration of water into the embryo, but which lie dormant for a long period when fully exposed to the influence of such an amount of moisture as the soil may contain. In many cases seeds that are shed in autumn appear to await the return of a greater amount of heat before they are stimulated into germination. The spores of some Ferns, too, are many weeks before they show signs of vegetation when under the influence of a sufficient amount of moisture and heat, that is to say, when a larger or a smaller amount of heat and moisture would not exercise a greater accelerating influence.

**EVIL EFFECTS OF TOO MUCH MOISTURE.**—A superabundance of water exercises a retarding influence on the germination of most seeds, and finally destroys their vitality by dissolving their soluble substances, and facilitating chemical changes of their insoluble substances. The embryo swells, but the nutriment which it requires for development is drawn from it by the fluid. Broadly speaking, only the seeds of true aquatic plants germinate and grow freely when completely immersed in water, but many benefit, by being partially immersed, and will grow when suspended just above the surface until they have exhausted the nutriment the seed contains. It is often found difficult to maintain the proper degree of humidity for small, delicate seeds, which will only germinate if upon or very near the surface of the soil. This is more or less overcome by covering the seed-pots with panes of glass, which prevent rapid evaporation, or better still, by a thin layer of Moss, and keeping the pots standing in shallow water. Indeed, the little Bog Orchis, *Malaxis paludosa*, seems to germinate and grow upon the Sphagnum of the bogs, which conveys the necessary water to it.

**THE PART OF THE SEED WHICH ABSORBS THE MOISTURE.**—Various experiments have been made to ascertain through what part of the seed the water is absorbed, with the result that in seeds having a very dense testa it appears to enter only by the micropyle, whilst it is absorbed through the whole surface of a soft, permeable testa. The principal things to bear in mind respecting the influence of water on the germination of seeds are, that an excess is almost invariably injurious, and that alternations of wet and dry states are soon fatal. But this, according to some experiments carried out by De Saussure, is not invariably the case. He found that the germination of the seeds of Wheat, Rye, Barley, Maize, Cress, Mustard, Cabbage, Lettuce, Hemp, &c., if interrupted by drying, recommenced on the application of water; whereas the seeds of Kidney Bean, Broad Bean, Poppy, &c., were killed by the drying. Some of the first retained the power of completing their germination after having been exposed to the utmost degree of desiccation attainable in the open air, in the shade, or in an artificial heat of 95°. Wheat, Rye, Cabbage, &c., in course of germination may be dried, then submitted to a temperature of 158°, without losing the power of reviving on the return of moisture. It

is true, however, that seeds possessing this remarkable quality suffer in vigour from desiccation, as the radicle perishes; and the more advanced their germination before drying, other things being equal, the longer they are in recovering from the check. When a seed has once been thoroughly saturated with moisture, the probabilities are strongly against its germinating if permitted to become dry again, because the extension of the tissue by the fluid absorbed is incipient germination. This process, having once begun, cannot be easily stopped without killing the embryo, or permanently injuring the seedling plant; but it may be retarded by embedding the seeds in slightly moist earth.

**ALTERNATIONS OF WET AND DROUGHT.**—The seeds of many tropical plants especially will not germinate if once allowed to dry, as they normally germinate as soon as they fall from the tree, or as soon as they are mature, or as soon as the next rainy season sets in. The only way in which such seeds can be successfully sent long journeys is by packing them in some dense earth which is not quite dry, nor sufficiently moist to induce growth in a high temperature, or decay in a low temperature. On the other hand, there are many seeds, particularly those having a starchy albumen, which can scarcely be kept too dry, and in a dry state retain their vitality for years unimpaired. This brings us to the fact that the seeds of different plants require different amounts of heat, associated with a proper degree of humidity, to cause them to grow healthily.

**HEAT.**—Most seeds will retain their germinating power in a moderately dry atmosphere for a considerable period, varying, however, from a few weeks to several years, and buried in a moderately dry soil for much longer periods; and the desiccating process seeds undergo in maturing leaves them in a condition to withstand greater intensities of both cold and heat than their species can bear in active growth, or even as plants at rest. As an instance of the extreme cold seeds will bear when in a dormant state without injury, it may be mentioned that the English Arctic Expedition, which returned in 1876, brought home some Wheat left in the Arctic region five years previously by an American expedition. This seed germinated perfectly, but it is uncertain to what degree of cold it had been exposed, although it was left there to ascertain whether the cold would injure it. Possibly it was sheltered to a great extent by a thick layer of snow. And, as already mentioned, some seeds will bear boiling for a short time, or a dry heat of 213° without injury. Edwards and Colin relate that Wheat, Barley, Rye, and Beans retained their vitality after being exposed to about 70° of frost. But to effect germination, or promote growth, the temperature must range between certain restricted limits, varying for different plants; and midway between the extreme limits of temperature under which a plant will grow is the most favourable to its perfect development. The upper limits of temperature which plants will bear with impunity, or flourish under, are not, perhaps, so easily defined as the low temperature, which will certainly injure plants in active growth. It should be remembered, too, that the same degree of cold that would destroy the leaves and young shoots of a tree would have no injurious effect upon it in winter, or when not growing actively. The new shoots or growths of trees and shrubs in temperate climates, after growth for the season has ceased, pass through a phase called ripening or lignifying, and the more perfectly this is accomplished, the less moisture there will be left in the shoots, and greater in proportion the intensity of cold they will bear without injury. Herbaceous plants die down to the ground annually, and the living portion left is less exposed to the influence of cold. Travelling into gradually colder countries than our own, we observe that arborescent vegetation becomes scarcer, until it dwindles quite away; and, what is more important, the roots of herbaceous plants, as well as the branches of the dwarf woody vegetation, are protected during the rigour of winter by a more or less thick layer of snow. Therefore, the hardness of a plant is not always in direct relation to the climate of the country in which it grows. For instance, a plant hardy at St. Petersburg, where the winters are very severe, but where vegetation finds a natural protection in the snow, might succumb if exposed to the influence of the comparatively mild but almost snowless winters of London. There is, however, a great diversity in

the constitution of plants in relation to temperature, though by no means so great as one would imagine without reflection; but there are many peculiarities in the constitution of plants inexplicable in the present state of our knowledge. Whilst we know that if the shoots of trees do not ripen in the autumn, and are overtaken by frost while they are in a herbaceous, sappy condition, they are sure to suffer, it is not so easy to explain why such soft, fleshy plants, as the common Groundsel and purple Dead Nettle, will bear very severe frosts of many hours' duration and several times repeated, and others less succulent are blackened by two or three degrees of frost continued for an hour or two only.

W. B. HEMSLEY.

THE NUTRITION OF DROSERA.

An objection is frequently raised to the modern view of the "carnivorous" habits of the Sundew and of some other plants on the ground that they do not benefit by this habit, but appear to carry on quite as healthy and vigorous an existence when deprived of this source of food. According to the Darwinian theory of natural selection, no habit can be acquired by an organism unless it is of some benefit to it. In a paper recently read before the Linnæan Society, Mr. Francis Darwin pointed out that the statements that animal food supplied to the leaves of *Drosera* is not advantageous to it rest on vague or unreliable data, and he described a series of careful and elaborate experiments, from which he appears to have proved that it is distinctly advantageous.

For this purpose about 200 plants of *Drosera rotundifolia* were transplanted on June 12, 1877, and cultivated in soap-plates filled with Moss during the rest of the summer. Each plate was divided in half by a low wooden partition, the plants on one side of the partition being fed by supplying each leaf with one or two bits of roast meat, each weighing about 1.50th of a grain, while the plants in the other half were starved. The feeding was performed at intervals of a few days from the beginning of July till the early part of September. The benefit of the feeding on the plants in one half of each plate was soon apparent. By July 17 the leaves were evidently of a brighter green, showing that the increased supply of nitrogen had allowed a more active formation of chlorophyll grains to take place; and from this time the flower-stems on these plants were distinctly taller and stouter. On August 7 the ratio between the number of starved and fed flower-stems was as 100 to 149.1, and by the middle of August the proportion of leaves on the two sides was as 100 to 136.9. At the beginning of September, the seeds being ripe, all the flower-stems were gathered, and the following comparisons were arrived at as the result of counting, measuring, and weighing the various parts of the two sets of plants:—

Ratio between the number of starved and fed plants	as 100 to 101.2
Ratio between the weights of the plants exclusive of flower-stems	as 100 to 121.5
Total number of flower-stems	164.9
Sum of the heights of the flower-stems	153.9
Total weight of flower-stems	231.9
Total number of capsules	194.4
Average number of seeds per capsule	122.7
Average weight per seed	157.3
Total calculated number of seed produced	241.5
Total calculated weight of seeds produced	379.7

The most important feature in the general result is that the advantage gained by the fed plants is far more conspicuously shown in all that relates to the seeds and flower-stems than in any other part. Thus the ratio between the weights of the plants, exclusive of flower-stems, is as 100 to 121.5; while the weights of the flower-stems, including seeds and capsules, were in the proportion of 100 to 231.9. The highest ratio is seen to be between the total weights of seeds produced, viz., 100 to 379.7; and this is intelligible, says Mr. Darwin, because a source of nitrogen is laid by in the albuminous seeds. Another point is, that the difference between the starved and fed plants is more clearly shown in the comparison of weights than in that of numbers or heights. It is clear that increase of weight is a better proof of increased assimilation than any other character. It may fairly be said that the above experiments prove beyond a doubt that insectivorous plants are largely benefited by a supply of animal food, and it can no longer be doubted that a similar benefit is gained in a state of nature by the capture of insects.—"Pharmaceutical Journal."

DEEP CULTIVATION.

A few remarks on this important subject, as regards the future well-being of kitchen garden crops, may not be out of place at this, the season of preparation; for although we have lately heard doubts expressed as to the beneficial effects of frequent and deep cultivation—and others go so far as to quote instances of soil that has been injured and rendered less productive by it—I must, from my own experience, come to the conclusion that in all such cases the waste of labour was due to an utter disregard and in defiance of anything approaching scientific cultivation; as it must be obvious to the most casual observer that, although the manual labour attending the act of trenching the ground does not require any great skill to direct it, yet its utility may be more than counteracted if done on a haphazard plan, without any regard to character of soil, the nature of subsoil, and whether freshly broken up or old, and what is sometimes termed "worn out" from repeated cropping. I have no hesitation in saying that the worn-out theory is entirely brought on by substituting shallow surface-stirrings for good deep and thorough cultivation, and in some measure by lack of attention to the proper rotation of crops; for, although land may be destitute of the elements necessary to perfect one crop, it may be rich in what another requires; and when the surface is cropped repeatedly with crops nearly allied to each other, it may only yield moderate results, whereas if fresh soil were brought to the surface by deep cultivation the very elements that are wanting may be restored, and substances converted into food for future crops by atmospheric action that would never have been available if buried deeply, as the more solid the land becomes, the more is the soil closed against the action of frost or air. Forland of this description trenching by merely substituting the bottom spit for the top is best, and fresh unrotted manure will be more beneficial worked in at the bottom of the trenches than thoroughly decayed materials; and the earlier it is done in the autumn or winter the better, as the winter frosts and rains will pulverise and sweeten any crude substances brought to the surface, and furnish abundant food for bringing succulent crops to perfection in all seasons, as in exceptionally wet seasons the thorough drainage insured renders the land warmer by admitting the air, and during periods of drought there is no remedy half so successful as a good depth of thoroughly pulverised and enriched soil, where the roots can descend and find plenty of soluble food at all times. No amount of labour expended on watering or surface-stirring will do more than mitigate the evil arising from shallow cultivation at such periods, for it is the lack of food that deprives vegetable crops of their succulence. If they can find it, there is no fear of their being able to withstand the highest temperatures we ever experience in this country, as most of our best vegetables and salads are natives of warmer climes than our own. And if we come to the question of economy, I am convinced that better results will be attained by reducing the area under cultivation to the limits of available labour, as it is a questionable policy to reduce the labour bill one-half if the returns are reduced at the same rate. When we come to deal with freshly broken-up land, or where a bad subsoil exists, the manner in which the trenching is performed must be modified according to circumstances; but I never yet saw land that could not be made fit for first-class garden produce by the addition of substances in which it was deficient. When the subsoil is exceptionally poor—either clay, sand, or gravelly—but a small portion should be brought to the surface at a time. With heavy land, such substances as leaf-mould, ashes, or sandy dressings, to promote a friable condition of the staple soil, will prove more beneficial than heavy farmyard manure, which will be more advantageously employed on lighter descriptions of soils; but it is better in such cases not to bury it so deeply, as, when the subsoil is gravelly, the manurial properties are liable to be wasted by the superabundant drainage. The land should, in all cases, be allowed a considerable period to elapse before cropping, for which reason autumn or early winter offers the greatest facilities, as it is then in good condition for spring cropping. Surface-stirring will then be of great benefit to keep the surface clear of weeds, and in such condition as to receive the greatest advantage from solar heat and air. By taking a certain portion in hand each year, and doing it thoroughly, the oldest gardens may be kept in the highest state

At a recent meeting of the Leicester Town Council it was decided to buy the Abbey Meadow, on the north side of that town, for a people's park.

of productiveness; and any additions to the vegetable area may be eventually brought into the same condition, however uninviting their appearance. I would say to all who are halting between two opinions, as regards deep cultivation v. surface-stirring, try the former thoroughly in winter, and follow it up by the latter during the growing season, and you will have no reason to complain of the results.

J. GROOM.

Henham.

## TREES AND SHRUBS.

### TRANSPLANTING WITHOUT BALLS OF EARTH.

SOME remarks on this subject that have lately appeared in THE GARDEN (see p. 171) may prove useful to those who are changing the sites of their trees and shrubs. Mr. Love's method, however, omitting his machinery, is very much like that of the late Sir Henry Stuart, who, it is well known, was most successful in removing trees even of larger dimensions than those alluded to by your correspondent. The late rector of Oakham, the Rev. Heneage Finch, carried out that system in the laying out of his grounds, and failure rarely attended his operations. My own experience leads me to think that an equally successful result would have been arrived at by Mr. Love had he been content with merely following the roots to their extremities in the way he recommends, and protecting the rootlets from injury. Sir Henry Stuart's system, I believe, did not find favour with the public because so many failed in their attempts to carry it out. But their want of success was in most instances owing to their not attending sufficiently to the details of his method, and the men employed did not understand their work. Mr. Finch found it no easy matter to train the labourers whom he employed. I have been surprised of late to find the antiquated notion revived that when a tree is moved it should always carry with it a mass of the soil in which it grew. The earth itself greatly adds to the

weight of the moving mass, and the only possible good it can do is to preserve the rootlets imbedded in it; and there is always fear of the adhering earth breaking away during the transit and carrying with it the fibres on which the life of the tree mainly depends. But a square mass of soil surrounding roots devoid of fibre is absolutely useless, and if the portions beyond it have been severed the tree must die. Nurserymen, it is well known, usually transplant every second year the trees they wish to sell, and when this rule has been attended to, there is little trouble in lifting them; but when a tree has stood for many years in one place, the extremities of some of the roots should accompany the tree to its new quarters. Among the trees that I have at various times transplanted there is one, a variegated Sycamore, the circumference of which at 4 ft. from the ground measures 5 ft. 3 in. This tree was moved to its present site in 1840 from a plantation in which it had stood undisturbed for at least ten years. It took two strong men to carry it on their shoulders, and the roots only just cleared the ground as it was borne along. All the earth was shaken from the roots to

diminish the weight at their end of the trunk; but there were plenty of them, and I had no fear whatever for the life of the tree. Great attention was given to the distribution and arrangement of the roots when the tree was set up, a process on which much will often depend, and which is but too often thought not worth the trouble. A failure which followed the removal of a Jargonelle Pear will further illustrate the principle which I am defending, namely, that the life of a tree does not depend on the earth about its roots when it is transplanted. It is true that in this instance I did not expect to save the tree, for it had been left undisturbed for a dozen years or more, and had nearly filled the space of wall allotted to it; but I thought I would give it a chance, so I began by making a semi-circular trench round the tree at 5 ft. from the stem, a distance which I thought would be sufficient to ensure a supply of branch roots growing from the main roots within that distance; and by underminings here and there I was able to cut through most of the roots beneath the tree. In this condition

it was allowed to remain till the following autumn, when it was taken up and moved to its new quarters; but I saw at once that the case was hopeless. The vitality of the tree almost entirely depended on the portions of the roots beyond where the severance had been made the preceding season; and, indeed, there were indications that the tree had suffered from the amputation even before the removal took place. It was the excision of the vital portions of the roots that caused its death. In the case of trees that have stood many years on one site, Mr. Love's method, whether with or without his machinery, is the only one that is likely to ensure success. B. S.

The Jujube Tree.

**Pinus Laricio v. Rabbits.**—One who has planted this Pine extensively informs me that, unlike other Pines in a young state, rabbits do not molest it, or if they do so once they will not repeat the experiment; and so satisfied is he of this, that he partly attributes the comparatively high price of young plants to its being rabbit-proof. Its timber is known to be of excellent quality. The rats at which it grows when properly treated is equal to if not greater than that of any other of its tribe, and, if I may be allowed to make the suggestion, the naturally narrow spread of its branches ought to be a material consideration in its favour when cultivated as a forest tree; if, moreover, what my correspondent has said be true, that circumstance alone ought to add much to its value.—GEO. SIME.

**The Jujube Tree.**—Lovers of curious trees may be interested to see a portrait of this as it grows in the Garden of Plants at Paris, where it is a vigorous, compact tree. Anyone who knows the climate of Paris in winter and spring will not think it a very tender tree. We should like to know if it thrives with any of our readers. The tree in question is between 20 ft. and 30 ft. high, and the engraving is from a photograph made last summer.

**The Sun-ray Pine (Pinus Massoniana variegata).**—This bird fair to become one of the most desirable of Conifers. It has proved perfectly hardy at Flushing for two winters. It is propagated by grafts on seedlings of the species, or upon the Scotch or any other two-leaved Pine. It never burns under summer suns, as nearly all other variegated-leaved Pines do. P. Massoniana does not sufficiently differ from the Scotch or Austrian Pine to render it of any special

value, except it may be as one in extensive collections, but its variation is that which gives it the one charm that wins all who see it. When the buds first break in spring the leaves are all green, with the exception of a mere line or dot of variegation; but it would seem that the leaves lengthen in this very part, so that when fully grown nearly the entire "needle" is a golden yellow, tipped only at the end with green, presenting in thick clusters a really brilliant appearance. The leaves are occasionally striped alternately yellow and green, like the new Zebra Eulalia, but most of them are as first described. If the theory that variegation is a disease needed any invalidation, we think that this Pine, as well as the Eulalia Grass, would furnish it. Both are vigorous plants, and the green portions of the foliage are none the less vigorous for lying between or upon the variegated portions. We have many times alluded to the beauty of the Golden Retinosporas, and it has seemed unaccountable to us that, notwithstanding their extreme hardness and accommodating habits they should yet creep like snails into general use, for which, no doubt, they are ultimately destined. But we think our Sun-ray Pine—as we should like to call it—will take a quicker and stronger hold upon the affections, and that a popular demand is awaiting it that few others of its class have ever known.—*Moore's Rural.*

**Propagating Willows in Coppices.**—Although Willows are easily propagated (see p. 176), and will grow in or out of the ground, it is not so easy to get them well established in coppices or as underwood. I have found the following plan to be most satisfactory in reference to the growth of Willows in rough ground: Cut out a clean notch on the surface with a spade in lock-spit form; then put in the spade in a slanting form about 3 in. and raise the ground a little more than the thickness of the cutting; slip in the cutting on the flat, not on end, and press down the surface raised with the foot, which is all that is required. The selection of Willows for planting in coppices is a matter of some importance. I have found that Willow cuttings from  $\frac{1}{2}$  in. to 1 in. thick and about 1 ft. long are the best.—*CHAS. McDONALD, Stokesley, Yorks.*

**Top-dressing Fruit Trees.**—In 1876 some Peach trees in a house here made very weakly shoots, and their general want of vigour indicated a deficiency of nourishment at the root. Early in the spring of 1877 all the soil was removed from the roots for more than 1 ft. below the surface. For this was substituted a rich mixture of loam, cow manure, and old lime rubbish; one barrowload each of the two latter being mixed with three of the former. Shortly after the trees began to grow, it was evident that they were taking advantage of the fresh material, and by the end of the season the wood was three times stronger and healthier than it was at the end of the previous one. At the present time these trees are more promising than any of the others, and we are so well pleased with them that we have done every one of our wall trees in the same way this winter.—*CAMBRIAN.*

**Seeding of Cochlostema Jacobianum.**—With regard to the apparent sterility of this fine plant, as experienced at Lakelands, I may say that, so far as my experience goes, the shortcoming in question is more apparent than real; at least I have never found any difficulty in getting it to seed freely; and that too without taking very much pains in the way of fertilising the flowers. Indeed, I have a plant under my charge which has more than once borne seed without any artificial assistance whatever. I have had it six years, and the second year after I got it it flowered. To insure success, I had recourse to artificial fertilisation, and that, too, after a very rough and ready fashion. When I thought the flowers had reached the best stage for the operation (which as they individually only last one day) requires careful attention, I merely picked out the small cone-like receptacle containing the pollen, tore it in two, thus exposing the pollen fairly, and touched the point of the style lightly with it without the aid of a brush or anything else, much in the same way as we operate on Melons or Cucumbers. My first attempt produced, I think, four pods, which ripened satisfactorily. I retained the seeds till the following spring, when I sowed them carefully, but not one seed germinated out of some two or three dozen; therefore, when the plant flowered again, which it did the following summer, I managed to secure a few pods of seeds, which I sowed as soon as they were ripe. From these I managed to raise three plants, which I have now growing in 15-in. pots; they flowered last season profusely, and I again managed to secure a few pods of seeds, which have produced eighteen young healthy plants that I am just now potting. These make my stock to consist of twenty-two plants, a result which, considering the care and attention which I have exercised in the matter, is by no means discouraging.—*A. H. Tarr, Carlisle.*

The best action which has appeared in "Punch" lately is the out of the "Double-acting Electro-Magnetic Extractor," to remove old nails, &c., from the recently levelled portion of Rotton Row—a hint to Mr. Gerard Noel.

## THE KITCHEN GARDEN.

### POTATO CULTURE IN DORSET.

For some years I have made the cultivation of Potatoes in garden and field a matter of close observation, it being of some importance, as I prepare ground for myself, labouring, and other tenants to the amount of nearly three acres. Let us, therefore, consider the subject as to preparation of ground, season for planting, and as to the varieties which I have found the best for all purposes.

**Preparation of Ground.**—Fresh manure, if possible, should be avoided. The land, if in field, should be chosen as rich as possible, from sheep having been fed off roots, and if oilcake, all the better. If possible, the ground intended for planting should, after ploughing as deeply as the nature of the soil will permit, be exposed to atmospheric influences for some time. Now, the soil in a garden requires very different treatment; or, on an average, three-fourths of the space are allotted to cultivation of the Potato, and among the poorer classes even a greater proportion; therefore the drain upon the land must be great, and met by constantly keeping up a succession of crops, the heavy manuring for all such edibles as Early Broccoli, Savoy, Cabbage, &c., restoring the land to a fit condition to receive the Potato crop; and where, for want of stable manure, this cannot be done, a good change for the ground will be found by sowing Turnips late, so as not to come to draw, and in the spring digging in the greens when "shot out." Of course, I might say much more as to kinds of dressing, viz., lime, rotted leaves, decayed vegetation of all kinds, but different medicines and different diseases.

**Planting.**—As to the proper season for this, I need say but little. All amateur and professional gardeners wish to dig from the open ground about the last week in May. I conceive there is not any gain in planting on the warmest border before February 1, and as to the general crop, the first fortnight in March, both in garden and field, will be soon enough.

**Varieties.**—For a warm border, Myatt's Early Prolific Ashleaf; for the general crop (second early), I strongly recommend Neat's Kidneys (I know not any other name); they come from fortnight to three weeks later than the Ashleaves, are of yellow flesh, boil splendidly, of excellent flavour, and I have often eaten them in thoroughly good condition at Christmas; in short, I consider it the most valuable Potato I grow, as I can raise them ripe before the disease comes. Then, for succession, the Red Emperor, or, as called by Messrs. Carter, the Main Crop, an excellent-flavoured Potato, very heavy cropper, and one of the least wasteful in paring. Next comes the king of all main crop Potatoes, the Red Regent, a kind that is good in every soil; it is a first-class boiler, and keeps well until May, and even if disease sets in, still it yields fair remuneration for planting, and is still good. For late sorts I only mention the Apples Potato, whose only fault is its deep eye. It is an excellent cropper, capital as regards flavour, and for baking, the best I know. Last, but not least, is my old friend the Flake—I do not mean his wretched caricature the Hundredfold Flake, but the genuine old Flake, with strings in it like darned cotton, but one bad of meal, and all that could be desired as to flavour. It is equal to most late kinds in weight of crop, and one of the least wasteful in the paring; good, in short, all round. EUGENE E. P. LEGGE.

*Lilton Cheney, Dorset.*

### POTATOES FOR POTS AND FRAMES.

"A. D." (see p. 154) says, "A few years since I endeavoured to distribute a White Kidney, having very short haulm, named Little Gem, &c." The fact is, I did not endeavour to distribute this variety, notwithstanding that it gained a first-class certificate at the Royal Horticultural Society's Potato trials at Chiswick, along with another of its class named Alice Fenn. I withdrew both of them, publicly stating at the committee table that I felt honoured by their appreciation, but that I did not consider the varieties sufficiently productive to become appreciated by the general public during the then great demand for large-cropping sorts. I have occasionally distributed them amongst my friends, and I still keep them for my own eating. What "A. D." says about my seedling, Fenn's Early Market, is true; and perhaps I may recall to his memory a seedling called Early White Kidney as being a sort worthy of mention for early frame and border culture, as both this and Fenn's Early Market are in commerce. They also both gained first-class certificates at the Chiswick trials. Forthcoming is a new seedling of mine, named Worthington G. Smith, which I consider a very first-class variety for early frame and border culture. I never attempt to admit a Potato in commerce till I have thoroughly proved its constancy and quality. I know there are sorts of mine in distribution which have "crept out" against my wish, and others of my seed-

lings are grown whose raiser the world is as likely to remain ignorant of as of him who raised the old Early Ashleaf. I have now between 300 and 400 new seedlings under probation, some of which, I hope, in the time may become acknowledged acquisitions.

UPWARDS AND ONWARDS.

Cottage Farm, Sulhamstead, Reading, Berks.

**Onion Seed.**—A correspondent (see p. 174) refers to the comparative scarcity of Onion seed at present, and to the fact that home-saved seed is chiefly grown in Bedfordshire. It may be of interest to know that a Bedfordshire grower of seeds has land in this locality, and grows here a considerable crop of Onion seed annually. He plants the bulbs in rows, running from east to west, about 6 ft. apart, and utilises the intervening spaces for the growth of ridge Cucumbers or Gherkins, but the latter chiefly, enormous quantities of which are supplied by him to a well-known pickling firm. The Onion bulbs are planted in the rows as close together as is consistent with good growth, and when the stalks are fully grown they form shelters both from hot sun and wind for the Cucumber plants. When the centre pods are ripe the heads of the Onion seed are cut and dried off in the sun, the stalks being allowed to stand until the Cucumber season is over.—A. D., Bedford.

**Cutting Down Lilies in Full Bloom.**—I am surprised that anyone should say that Lily bulbs do not suffer from being cut down in full bloom. We have found, after 30 years' constant experience with thousands of bulbs of *Lilium speciosum* and its varieties, *Melpomene*, &c., that the bulbs are injured or killed outright, just in proportion to the time at which cutting down is performed. If a plant be broken off in June when 6 in. or 7 in. high, the bulb will die. If cut down in July it will go off into divisions of small bulbs, and if cut down in September the bulbs will only be about half size. Our autumnal exhibition always takes place about the middle of September, and we usually cut from 50 to 100 spikes, an operation which weakens the bulbs so much, that they only produce a very few flowers the following year. In the case of any rare or choice kind, we do not allow them to be cut on any account, and such as we do cut will be done only to get a "first," as Mr. Reynold Hole's gardener says in reference to Roses. Mr. Groom's remarks (see p. 83) are invaluable to lovers of good Lilies.—C. M. HOVEY, Boston, Mass.

**Lilium auratum.**—With reference to the remarks of "Amateur" (see p. 160), may I offer the result of my small experience in the culture of this beautiful Lily? At the commencement of 1876 I began with two bulbs, which may be called No. 1 and 2. No. 1 was planted in a 6-in. pot, in a mixture of yellow loam (from the neighbourhood of Croydon), some garden soil, well-rotted manure, and a little sand. In due time one flower-stem appeared, and produced eighteen blooms, three of which were blown off by the wind, but the remainder were fully developed. The plant grew about 6 ft. high. On proceeding to repot in the autumn, I found the bulb much reduced in size, and, in order to give it a good chance of recovery, I thought it best to plant it out in a border. In the spring of 1877 it produced a feeble flower-stem which, however, soon died, and thus ended No. 1. No. 2, a smaller bulb, was planted in 1876, in a smaller pot, but in the same soil as No. 1, and in due course produced three blooms. It was repotted about September in that year, in a 6-in. pot, as it appeared to have increased in size, and in 1877 it produced six blooms—from one stem only as before. It was again repotted in September, and now this year, 1878, judging from the thickness of the new flower-stem, which is about 1 in. above ground, it seems likely to produce a larger number of blooms than it has yet done. I do not venture to express an opinion on the question of the renewal of the bulb so ably discussed by "Dunedin," but I may say that when repotting I have never discovered traces of a decayed old bulb.—W. J. T., Brixton.

**A National Entomological Exhibition** is to be opened at the Royal Aquarium, Westminster, on March 9, and already several thousand square feet of space have been applied for. The exhibition will not only include selections from the chief collections of insects in the kingdom, but also many adjuncts of interest to the general public.

**Royal Botanic Society, Regent's Park.**—We have received the schedule of prizes offered by this Society at its exhibitions to be held in the gardens during the year 1878, and at each show the prizes, as well as the classes, appear to be of a satisfactory character. The exhibitions are to be held as follows:—May 22, June 12, and July 10.

**Begonia Froebeli.**—In addition to this *Begonia* being attractive when planted out-of-doors in summer or when grown in pots, it also forms an excellent winter-flowering plant for the conservatory. Dried

bulbs of it are now plentiful, and if started early in heat they will supply a fair amount of brilliant scarlet blossoms in winter or early in spring, and they will last longer in a cold state than those of most other *Begonias*.—S.

**The Phylloxera in France.**—According to some statistics given in the "Ecomomiste Francais," Vine culture in the Department of the Hérault was practised, prior to the attack of the Phylloxera, over 420,000 acres, yielding on an average 264 millions of gallons. At the present time 141,974 acres of vineyards have been abandoned, so far as the Vine culture is concerned, so that the produce of the department has diminished to the extent of 88,000,000 gallons of wine, which at the average cost of 10s. per hectolitre, or a little over 5s. per gallon, represents £1,920,000, or nearly £2,000,000 sterling. In 1877 the loss is estimated at £3,200,000, the price of the wine being calculated at 15 francs the hectolitre, or about 7d. per gallon.

**Allium neapolitanum.**—"A. R." Bromley Common, whose note occurs on p. 162, may be assured that this plant is perfectly hardy, and would probably take as good care of itself in one of the copses about Bromley as it does in the orchards of Southern France, though, of course, it would flower much later in England.

## NOTES AND QUESTIONS—VARIOUS.

**The Judas Tree.**—There is, I believe, still standing a fine tree of this kind in the grounds of Frogmore House, overhanging the old Dutch garden, which was every spring a beautiful sight when abundantly covered with its clusters of purple-tinted flowers.—J. G.

**Bedding Viola Yellow Boy.**—This very early bedding *Viola* has never been fortunate enough to secure the attention which it deserves. It is quite distinct from any of the forms of *Viola lutea*, and has a more compact and dense habit. The flowers are stouter, of a bright yellow hue, and are borne in great abundance. Perhaps its chief merit is its exceeding precocity, being the very earliest of all yellow bedding *Violas*.—A. D.

**Fruit Prospects in Cleveland.**—The fine dry winter which we have had in this district has been favourable to the maturity of fruit buds. The occasional frosts which we have experienced have not penetrated deeply into the ground, and the present appearance of fruit trees indicates an early bloom. Gooseberry bushes are unusually forward. Apricots, which are very generally grown in this district, are not unusually forward. On warm walls Jargonelle Pears are showing flower. Between the appearance of fruit trees now and at the same time last year there is a striking difference in the Cleveland district.—C. M. D., Stokesley.

—Apricots, Peaches, and Nectarines show bloom in abundance, but Pears both on walls and standards are thinner of bloom-buds than I ever remember to have seen them. Apples are, however, thickly set with good plump buds.—B. GILBERT, Buryleigh, near Stamford.

**Christmas Roses.**—"F. G. P." will be glad to know the best place to obtain good plants of the largest sort of white Christmas Rose; also what soil suits them best. [The largest sort of White Christmas Rose may be procured from any nursery where herbaceous plants are grown. We presume you mean *Helleborus altifolius* (usually called *H. nigry* maximus), which, however, is often slightly pinkish. It grows in any ordinary good garden soil.]

**Quercus heterophylla.**—This Oak is very nearly hardy, and it retains its leaves here until January or February; in fact, it never loses them until we have a sharp nip of frost. Its flexible shoots, graceful habit, and diversified foliage make it a desirable addition to collections of hardy trees. It is sometimes called in catalogues *Q. agrifolia*.—T. SMITH, Newry.

**Winter Nelis Pears not Ripening.**—I have a fine Winter Nelis Pear tree trained on a wall. It bears freely, but does not ripen; on the contrary, it keeps tough, and is of no use. I have been thinking of cutting it down. What should I graft on it?—R. MARTIN, Trifalgar, Cork.

**Barr's Criterion Cabbage.**—This excellent Cabbage, sown on July the 17th and planted out on September the 2nd, is now producing beautiful little hearts, which we are cutting at the rate of from fourteen to twenty dozen a week. Of Carter's Heartwell Dwarf Imperial, sown and planted at the same time, we have now sturdy plants, which, however, will not be fit to cut before the end of April—thus losing a crop, and that the best of all kitchen garden crops, viz., Myatt's Potatoes. The ground on which the Criterion is now growing will be dug between the 20th and 25th of March, and planted early in April with Myatt's Prolific Potato.—R. GILBERT, Buryleigh.

**Treatment of Heaths after Flowering.**—I have recently purchased some Heaths. They have done blooming. What treatment do they require? Should they be cut down? If so, when? should they be reotted?—ROBERT P., Eastham. [Cut your Heaths consist of such kinds as *hyemalis*, *Willmoreana*, *gracilis*, or similar sorts, they should be cut back after flowering. Place them in a light airy situation, and when they break forth, give them a slight shift if they require it. Use peat and sand, and well rsm the new soil round the sides of the old ball. Also take care that the ball is not dry before it is potted.—S.]

No. 329.]

SATURDAY, MARCH 9, 1878.

[Vol. XIII.]

"This is an art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### DAISIES IN TOWNS.

In densely inhabited districts where other spring flowers do not flourish these will grow and yield a continuous round of blossoms for a lengthened period. As gorgeous colour they combine every shade from the purest white to the deepest crimson; they are plain and quilled, and often singular as regards growth, as, for instance, Hen and Chicken Daisies. Hyacinths, and Tulips are beautiful, but short-lived, a remark which also applies to many other spring flowers. Anubrietas, Arabis, Pansies, and many others often damp off under the dull smoky atmosphere of London; therefore when we possess such a staunch friend as the Daisy we should make as much use of it as we can. During ordinary winters Daisies are seldom without flowers, and in such winters as that which we have just experienced they are literally in full bloom, and will continue so until removed to make room for summer bedding plants. A packet of seed costing a mere trifle will produce hundreds of plants. The seed should be sown in shallow boxes in light sandy soil any time during June, and the boxes should be placed in cool shady frames after a good soaking of water has been given them. The young plants soon make their appearance, and when sufficiently large to be handled they should be pricked out in the open ground 2 in. apart, giving them at the same time a thorough watering. Daisies love water, and are very tenacious of life. They rarely die even if thrown on the surface of the soil, provided there is an abundance of moisture. They grow rapidly and soon become a solid mass, when they can be taken up like turf. They should then be divided and planted in the beds where it is desired they should bloom from 4 in. to 6 in. apart. In February they commence to grow, and by the first week in March they are in full flower; and, as already mentioned, continue so incessantly until removed in May to make room for bedding plants. It will thus be seen that our beds might be carpeted with flowers at a season when blossoms are extremely scarce, and that at little trouble or expense.

*Southwark Park.*

CHARLES DENNIS.

**Perpetual Carnations in Open Borders.**—Having a large stock of these, and relying on young plants for winter blooming, we last spring planted out in mixed borders a quantity of the best varieties. They soon made flowering shoots in abundance, and during the summer and autumn months their blossoms proved very acceptable. Owing to the mildness of the weather, too, they have continued to expand their blooms all winter, and during the fine weather last month (February) we out several perfect blooms. These Carnations, therefore, are desirable plants for those who appreciate out flowers during winter, and who have but a limited amount of heated glass structures, for although they expand their blooms more readily in a temperature of from 50° to 55°, they will yield satisfactory results in cool houses, and even out-of-doors.—*J. GROOM, Henham.*

**Camellias in the Open Air.**—Readers of THE GARDEN have more than once heard of the luxuriant growth and fine-blooming qualities of the Camellia in the gardens at Glen Eyre, near Southampton, and elsewhere, and enough has been said from time to time to show that the Camellia can be made a grand outdoor shrub if properly treated. Mr. Cornhill, in his otherwise admirable paper (see p. 181), asserts that "it is only in exceptionally favourable seasons that the blooms arrive at their proper development." If such be the case, the seasons at Southampton must at all times be exceptionally favourable, as the numerous plants at Glen Eyre flower most abundantly every spring; and let me add that not a plant at any time receives the slightest protection. If anyone doubts this, or would like to obtain information as to the situation, soil, and sorts of Camellias grown, they cannot do better than pay Glen Eyre a visit and judge for themselves. For my part—after what I have seen in the gardens in question, where the situation is elevated; in the gardens of the centenary rector of North Stetcham, Mr. Bendon, near the river Itchen; and in the gardens of Mrs. Fleming, at Chilworth—I have not the least doubt that the Camellia might be grown as an outdoor hardy shrub in hundreds of gardens, especially if for the purpose

young robust plants that had not been previously pampered in heat were used. As long as it will thrive well in mid-Hants, so long might it be expected to succeed throughout the southern counties of England.—*A. D.*

**Cypripedium Lowi.**—This is one of the best of our winter-flowering Orchids; in fact, it blooms at all times of the year. I have a plant of it bearing three flower-spikes, of which two, with five and six flowers on them, were in bloom before Christmas, and they are still in good condition. They are upwards of 4 ft. long, gracefully arched, and the flowers measure more than 7 in. across. The third spike, on which the flowers are, as yet, undeveloped, is about 1 ft. in length. I grow it in a shady, moist pit, in which there is an average temperature of 68° in winter and 75° in summer. It is potted in broken crocks, peat, and Sphagnum Moss, well drained half-way up the pot by an inverted pot and crocks. Its leaves, which are evergreen, are some 18 in. long and 2½ in. wide.—*J. GARLAND, Kellerton.*

**Lilium auratum v. Sulphate of Lime.**—The particulars given by "W. J. T." (see p. 196) regarding his culture of this Lily are most interesting, and tend to support the theory that sulphate of lime in the soil is detrimental to the growth and full development of the plant. It would be interesting to know whether he applied manure water or soft water, for it would account for the larger number of blooms, and increased size of bulb the second year, from the simple reason that such water containing ammonia would convert the sulphate of lime to sulphate of ammonia, which, being a soluble salt, is gradually washed out. Messrs. Barr and Sugden state in their catalogue that they saw "plants of *L. auratum* grown in Rhododendron beds (I presume in peat) with stems from 3 in. to 4 in. in circumference, and attaining a height of 11 ft., surmounted with large heads of flowers with from fifty to upwards of 100 blossoms." I should like to know in what part of the country this was, for common peat in the neighbourhood of London will not support such growth; it contains the requisite iron, but is deficient in the phosphates. I have a rough account as to the results of experiments which I have made with various soils and fertilisers, which I shall one of these days send you.—*AMATEUR.*

**Auriculas in the Open Ground.**—Showy border kinds of the Alpine section of Auriculas have done well in the open ground this winter; so well, indeed, that they excel in robust health, vigour, and earliness all similar plants kept in pots and under glass. Planted on the west side of a low wall in rather stiff loam, they show that they prefer that to the finer and lighter compost in which pot plants are usually grown. Has the fact that the roots are thus in the open ground kept moist and plump anything to do with their fine, healthy development? It seems that it is not desirable to keep the balls so dry during the winter as some recommend, but the danger lies in the possible rotting of the crowns. I shall certainly try some of the choicer Alpines in the open ground during the ensuing year.—*A. D.*

**Newtown Pippins.**—A friend of mine having received a barrel of these celebrated Apples from America, gave me half-a-dozen, which were tasted by myself and several friends who take an interest in Apple growing. We were much disappointed with the flavour, and considered them inferior to several of our own favourites, such as Blenheim Orange, Pimston Pine, Cox's Orange Pippin, and Ribston Pippin. The Apples answered fairly to the description as to size and appearance given in Lindley's "Orchard" (1831) and Scott's "Orchardist," recently published. Lindley says:—"Juice saccharine, and possessing an exceedingly rich and highly aromatic flavour." Scott describes the flesh as "very juicy and crisp, with a fine aroma and an exceedingly high and delicious flavour. This Apple stands at the head of the list in America, where it comes to the highest perfection. It is largely imported into this country, and commands a high price in our markets." We were disappointed with the flavour, and having doubts about the accuracy of my samples, I took two to Messrs. Carter, Page, & Co., of London Wall, who showed them to the foreman of their nursery. His verdict was "True Newtown Pippins." If so, my faith in these Pippins is gone. Will any reader who is familiar with the Newtown Pippin give me the benefit of his experience in regard to it?—*C. G. Addiscombe.* [The Newtown Pippin has come to us in bad condition this year; but when good it is one of the best Apple known.]

**Dandelion Salad.**—The unusually fine weather which we have lately had has brought Dandelions rapidly forward; in fact, they are now at their best; little difficulty will therefore be experienced in either finding or preparing a bowl of this excellent salad. In passing through one of our vegetable markets a few days ago I noticed a quantity exposed for sale; they were, however, very coarse-leaved, and not at all the kind which I should recommend. They are also best used, if possible, freshly cut, as, if allowed to lie for any length of time after being gathered, the leaves become leathery, and lose their flavour.—*CHARLES DENNIS, Southwark Park.*

## CALLA ÆTHIOPICA PLANTED OUT IN SUMMER.

It is difficult to overrate the usefulness of this plant all the year round, for while its highly ornamental foliage renders it serviceable all seasons for mixing in groups, its season of flowering may be easily made to embrace the whole year round by having successional batches of it in store. Amongst the most prominent uses for which this plant is eminently fitted is that of furnishing large vases in entrance halls or corridors, associated with stately, or by the margins of fountains, and, perhaps, best of all, in church decoration, the cut spathes being especially sought after for Easter. We also find the white spathes effective in trumpet vases associated with Poinsettias and other brilliant colours. For winter and spring supply we find the plants much benefited by being planted out in rich garden soil during the summer months. About the end of May we take such as are exhausted with flowering, remove all their side growths, and then plant the strong single stems in rows 2 ft. apart. The offsets, when put in beds at distances according to their strength, make serviceable-sized plants for the following season, while the largest plants, if liberally treated as regards rich soil and plenty of moisture, make sturdy specimens with stems as thick as those of a Caroon. By September the majority of them will be showing flower, when they must be lifted and potted carefully, and well watered and shaded from direct sunshine for a few days. The conservatory or intermediate house will be quite warm enough in which to flower them in perfection; for if forced in too much heat, the leaves become long and weak, and the flower spathes lack substance. When planting out the stock for succession, propagate as much as possible from those plants that have produced the finest spathes. As a rule, the longest and darkest green leaves indicate the best kinds, plants with rounded, pale green foliage having small spathes. Selection in this way, therefore, may do much to improve the stock; for, although the size of the flower is greatly influenced by good cultivation, it is desirable, in the first instance, to get a good strain. Callas will also grow vigorously and flower freely during summer and autumn with their pots plunged in water in tanks or on the margins of lakes or ponds. So wide, indeed, is the range under which they thrive, that good specimens are by no means uncommon in the arid temperature of ordinary living rooms; and where moisture is but irregularly supplied, either at the roots or in the atmosphere, their vigorous roots and shining foliage, so easily freed from dust, seem to defy unfavourable conditions, a fact which accounts for their popularity. A moderately stiff loam, enriched with thoroughly decayed manure, suits them admirably.

J. GROOM.

Henham.

## LILIES AND THEIR REPRODUCTION.

THE discussion raised by "Dunedin" as to the propagation of Lilies seems to interest a vast number of people, and the question is really well worth investigation. His theory, as I understand him, is briefly this—

"All bulbs that perish, other bulbs supply,  
By turns they catch the vital breath and die."

He states (see p. 185) in last week's GARDEN that a great part of my previous communication was mere speculation. I know not to what point he may refer, but my only object is to increase our knowledge of such matters; and I think I have advanced nothing but the results of personal observation. However, the main questions to be decided are, whether or not the bulb after flowering decays; and, secondly, whence springs the flower-stem or stems of the succeeding year. Your correspondent "W. J. T." (see p. 196) so far corroborates my experience that he has "never discovered traces of a decayed old bulb." But in order to settle the question beyond dispute, I will grow in pots different bulbs so close to the surface that the tops of the bulbs may be readily exposed and watched during the season; and in October or November I shall be most happy to turn them out and show "Dunedin" the results. I did this last year with *Lilium giganteum*, and it is now shooting up from the precise centre of the bulb as previously, and there can, I think, be no mistake, as the large scales are 1 in. above the ground, and have been so for three years; and yet it is stated (see p. 184), according to the experience of Mr. Wilson, that the old bulb of *L. giganteum* "clearly dies." It really makes one despair of the truth amongst so many irreconcilable and indisputable facts; but if facts, we must then seek the cause of such discrepancies, as the vagaries of plants under dif-

ferent modes of treatment and varieties of soil are truly wonderful. My theory as to all bulbs and corms has been that there is a stool from whence the roots descend, the scales (or underground leaves, bulbs, or abortive accumulations of sap—corms), emanate, and from the centre of which stool the flower-stem is thrown up. This flower-stem has buds at the base, one or more; if but one, the same bulb (or underground leaves) continue; if two or more, additional scales are thrown out to make each bud a circular bulb, thus breaking up the one original bulb, as may be seen in the Crocus, by growing a large one in water, when, if three or four blooms come up, the one corm will, before the end of spring, be found, on removing the outer skin, to have formed three or more circular corms. If a Lily be grown in a soil containing a full amount of the neutral salts required for the full development of the plant, or say more than it requires (being an extraordinarily greedy plant when supplied with the requisite moisture and light), this superabundant food will be developed, not as in say Wheat in large quantities of seeds, but in buds or bulbs at the axils of the leaves, or where leaves have been, and even on the roots (as in *Lilium longiflorum*), where I have observed small bulbs formed on the large roots all round the exterior of the pot. Now anything to gainsay these views will be doubtless as valuable to a great many of your readers as it will be to myself. I have not referred as yet to *Amaryllids*, from which I find much to learn. In most of mine the offsets spring from the exterior circle of the stool, whilst in *Valloia* they commence at the axil of a leaf at the stool, and the leaf dying and binding the bulb tightly, the little bud or bulb is gradually brought up so high, that when the leaf or sheath round the parent bulb bursts from the expansion of the bulb, the young bulb will actually fall out on the ground. One *Hippeastrum* which I wanted to grow very strongly, and put in a 13-in. pot, has sent up ten strong suckers at the side, all round the pot; but whether they emanate from the roots or the large bulb (which seems almost impossible) I can only decide when I shake it out in autumn.

AMATEUR.

**Preserving Flowers in Their Natural Colours.**—In the last volume of the "Proceedings of the American Pharmaceutical Association" there is a simple receipt for the preservation of the natural colours of flowers in herbaria. The whole plant is drawn through a solution of salicylic acid in spirits of wine contained in a shallow basin or deep pie-dish, and afterwards swung backwards and forwards to remove the excess of liquid, dried between blotting-paper, and pressed in the usual manner. Care must be taken not to leave the plants too long in the solution, as a prolonged immersion discolours delicate flowers. The blotting-paper, too, must at first be removed frequently. Plants treated in this manner are said to dry rapidly and furnish specimens of superior beauty, retaining their natural colours in greater perfection than by any other process. The salicylic acid, which may be obtained at any chemist, must be dissolved in the spirits of wine in the proportion of 2 grains to 3 ounces. Methylated spirit must not be used, as it contains a certain amount of resin dissolved in it, which would render the plants sticky.—C. W. QUIN.

**Horse Chestnut Liquor v. Worms.**—Do grated Horse Chestnuts, mixed with ten times their bulk of water, expel, as it is said, worms from the soil in pots?—Q. [I have given this receipt a trial, and certainly there is something nauseous or disagreeable to the worms in the solution in question, for they quickly make their exit from the soil, and if left in the liquor soon die. The grating is, however, a tedious operation. I should recommend crushing the Horse Chestnuts, and steeping them in order to extract their strength in scalding water, allowing the liquor to get cold before using it. This remedy is, however, by no means equal to Messrs. Rutley & Silverlock's soap cure, the effects of which I described in THE GARDEN of October 6, 1877 (p. 318), and which is decidedly the most expeditious and safe remedy with which I have ever met, either in the case of lawns or that of plants in pots.—JAMES GROOM, Henham.]

**Cement for Aquaria.**—The "Polytechnisches Notizblatt" gives two recipes for a cement for joining glass, wood, and metal. The first consists of a mixture of equal parts of shellac and powdered pumice-stone, to be used while warm; the second is obtained by melting ordinary brimstone in a ladle, and adding an equal proportion of powdered pumice-stone. The pumice-stones in both cases must be thoroughly dried before mixing, as it is apt to absorb moisture from the air.—C. W. QUIN.

**Roses and Vines.**—Mr. Groom (see p. 190) cannot be so well acquainted as I am with the peculiar circumstances that induced me to cast out a quantity of diseased Vines in favour of good Roses. The Vines were planted in a harsh sour clay, no border having been made. There is no heating power in the house, which has, as a first important use, the growing of some thousands of hardy plants in

small pots during the winter and spring for trade purposes, and the keeping of which in check during mild weather renders it necessary to open the house, producing all sorts of cold draughts that would bring mildew on any Vines under such conditions. The Vines were a failure, and the Roses a success.—A. D.

### NOTES OF THE WEEK.

**Crocuses in Hyde Park.**—A really beautiful effect has lately been produced in Hyde Park, near the "corner," from white Crocuses coming through the Grass. As we have always pointed out without reserve the blemishes in our public gardens, so we wish to praise this and like efforts. If the managers of our parks will only go on this way in securing natural and artistic effects from simple hardy materials, the parks of London will soon become a great source of pleasure and instruction. By the way, we hope these numerous Crocuses and all others in our parks will be allowed to spread into old-established tufts. We notice now that while many gardens have Crocuses, by far the most beautiful are in small gardens, where they are allowed to form strong tufts undisturbed.

**Fritillaria pudica.**—We have to thank Messrs. Backhouse, of York, for some specimens of one of the most novel and beautiful hardy spring flowers we have ever seen, viz., *Fritillaria pudica*. It grows nearly 6 in. high, and has bright golden-yellow flowers peculiarly graceful in form and drooping like a Snowflake.

**Orchids at Gunnersbury.**—There is just now a fine display of Phallopis in one of the houses at Gunnersbury. The plants, which are growing in wooden baskets, are suspended along the front of a lean-to house, and underneath them is a narrow stage which is planted with Mosses and *Panicum variegatum*. These, being kept continually moist, grow vigorously, and the moisture benefits the roots of the Phallopis. Though many of the blooms have been out, there still remain some dozens of large, gracefully-drooping spikes of fine flowers. In another house there is a plant of *Odontoglossum Alexandrie*, with one of the largest bulbs which I have ever seen, furnished with two branching flower-spikes, each of which bears no fewer than thirty bulb-buds, and a plant of *O. Pescatorei* is furnished with a gracefully-arched spike bearing upwards of sixty expanded blossoms.—S.

**Narcissus monophyllus.**—This is one of the Daffodils of doubtful hardiness and great beauty which all must desire to see plentiful in our gardens. Mr. Elwes called our attention to a pot of it the other day, at South Kensington, bearing over fifty of its fair flowers in a 5-in. pot. The specimen was grown in Mr. Hammond's garden in Kent in a greenhouse. This and other supposed half-hardy species are charming for growth in pots, though we believe they will eventually be found quite hardy in suitable soils and properly sheltered among plants of like stature. Indeed, we believe this to be harder than the Peacock Iris, which is quite hardy and flowers freely in sunny sheltered borders in Kent.

**Dondia Epipactis.**—This interesting little flower, now in perfection in the front row of herbaceous borders and on rockwork, deserves to be better known than it is. Even those who dislike its colour cannot but be pleased with its umbels of yellow flowers ensigned in bright green leaves. Possibly rockwork may be its proper place, but I find that it looks perfectly at home and thrives well on a border. It is a most companion for the Iris reticulata, Scillas, Sisyrinchiums, and Dog's-tooth Violets, which have now begun to beautify the spring garden.—E. F., *Petygards Hall, Swaffham, Norfolk*.

**Rare Hardy Plants.**—We learn that a very rare and pretty plant, *Chionodoxa Forbesi*, is now flowering probably for the first time in European Mr. Elwes' collection at Crichester. It is, we believe, one of Mr. George Maw's introductions from Asia Minor. In the same garden there is also a wonderful Turkestan Tulip, white with an orange centre, now in bloom, which is expected to be new.

**Habrothamnus Aubletii.**—This fine greenhouse climber has been making a good display for some time past, trained against a back wall in the greenhouse at Impney Hall, Droitwich. It has, I believe, only been planted out about twelve months, and it blooms at every joint. It has very dense foliage, and the blooms are much larger than those of *H. elegans*.—T. W. S.

**Iris reticulata and its Variety Krelagei.**—Last year I complained in your columns that *Iris reticulata*, as grown by me, had failed altogether in the open ground, and that its blossoms in the greenhouse were exceedingly short-lived. Thanks to the courtesy of your correspondents, I received some useful hints as to the culture of this lovely plant, and in consequence I have this year to report that it has bloomed beautifully both in the house and in the open border ;

in fact, it has bloomed here before the Crocus and simultaneously with the Snowdrop. I should like to call the attention of nurserymen who offer this bulb for sale to the necessity of keeping the two varieties *I. reticulata* and *I. reticulata Krelagei* distinct. The latter is, in my opinion, greatly inferior to the former, and it is disappointing to receive a consignment of the inferior plum-coloured variety instead of the more beautiful violet-blue *I. reticulata*. Spring flowers here in Worcestershire are all too promising, and the gardens are already ablaze with Crocuses, and starred with blossoms of Daisies, Aubrietias, and Violas. *Anemone fulgens* is full of buds, while Wallflowers have been in blossom ever since October. Indoor Hyacinths may be pronounced a comparative failure this year ; evidently the bulbs suffered from the cold spring and wet summer of 1877. Will anybody tell me how to grow *Hepatica angulosa* successfully?—HEBERT MILLINGTON, *Bromsgrove*.

**Claytonia caroliniana.**—This pretty modest American spring flower is now in bloom in Mr. G. E. Wilson's garden at Weybridge. It is in a cold frame, but it is probably quite hardy, and when plentiful enough to risk in the open air will no doubt flourish among the many rare hardy plants in the same garden.

**Saxifraga oppositifolia.**—We have some plants of this Saxifrage on rockwork in full bloom just now ; they are literally smothered with flowers, and are greatly admired by all who see them.—W. M. THOMSON, JR., *Tweed Vineyard, Clovenfords*.

**Anemone blanda.**—Mr. P. Barr finds this Anemone to vary in colour, there being a light as well as a deep blue form, the last much the best. He has also in bloom in the open air the beautiful winter-flowering *Iris stylosa*.

**The First Rose of the Year.**—On March 1 a lady, the resecta daughter of an old Rosarian, wrote to me that a plant of *Maréchal Niel* Rose was in flower upon the wall of her house (in the neighbourhood of Danmow) ; and, upon my suggesting that the house referred to must be a greenhouse, I received by return of post a lovely bloom of the *Maréchal*, quite perfect in form, colour, and fragrance, and with it the following remarks : "Seeing is believing ! This *Maréchal* Nil ten minutes ago was growing on the wall of our house without any protection whatever ; it is the wall of the kitchen, and faces south. There are two more now out, and loads " (imagines a wagonload of *Maréchal*s going up Parnassus, drawn by thoroughbred horses, Pegasus leading, as an offering to the Muses) " to follow ! " I have only to add that I have never seen or heard of such a Rose as this now before me blooming out-of-doors in the first week of an English March.—S. REYNOLDS HOPE.

**Tropæolum Ball of Fire.**—This, in the form of good-sized plants, makes a very effective display at this time of year on the rafters of a greenhouse, where its side shoots should be allowed to hang down festoon fashion. Some good examples of it, trained in this manner, may now be seen at Hindlip Hall, Worcester, where they have quite a gay appearance.—T. W. S.

**Mr. Gordon's Herbarium.**—We understand that Mr. Gordon's herbarium is to be disposed of. It is very rich in Conifers and hardy trees and shrubs, and in many ways a most interesting collection. As the Hookarian herbarium was sold to the State for £5000, owners of good collections of dried plants may be pardoned for putting a high value on them, even from a pecuniary point of view.

**Varieties of Iris reticulata.**—We are indebted to Mr. Ware for blossoms of two forms of the violet-seeded, spring-blooming *Iris reticulata* (the ordinary form) and the variety *purpurea*. An *Iris* flowering in early spring, with colours rich beyond those of all early flowers, is a precious addition to our gardens, and the fact that it varies will make it all the more so.

**Narcissus aureus.**—I have now in bloom what I believe to be the true *Narcissus aureus*. It is a small, slender *Tazetta*, with flowers not much larger than *N. junifolius*, one to four on a stalk ; the corona is primrose-yellow, and the cup orange. I obtained the bulbs from a friend at Algiers. It has been grown in a pot in a cold frame.—H. HARPER CREWE, *Drayton-Beauchamp Rectory, Tring*.

**Hardy Flowers in Bloom at Pinner.**—This morning (March 2) I gathered the enclosed spring and winter flowers, just twenty different sorts, not including varieties. Amongst them will be found not only the lovely and most easily grown *Omphalodes verna*, but also *Anemone fulgens*, *Erythronium Dens canis*, *Scilla sibirica*, *Erica carnea*, *Lithospermum prostratum*, *Crocus vesicolor*, *Polyanthuses*, *Jonquils*, *Violets*, and others. Mine is a cold, non-congenial soil, and these plants might be grown in any garden. Crocuses, undisturbed for six years, are one solid mass of bloom.—A. K., *Eastcott Cottage, Pinner*.

WE understand that a legacy of £100 has been left to the Royal Horticultural Society under the will of the late Miss Parry, of Ham.

## NOTES FROM KEW.

Two species of *Prunus* are just now in fine bloom, and are really attractive objects. The first, *Prunus cerasifera*, is a remarkably neat-growing small tree, from the Levant; this specimen is yearly one sheet of bloom, but no fruit is ever produced, although apparently perfect pollen is very abundant. The other is the Chickasaw Plum, *P. chicensis*, of the South-eastern United States. This is not so graceful in habit as the last-named, but is yet worthy a place in any shrubbery. *Ribes speciosum*, a Californian shrub, is extremely handsome; it has small lobed leaves and long exserted stamens, which cause the crimson flowers to resemble in a marked degree some of the *Fuchsias*; indeed, *R. fuchsoides* is one of the synonyms of the plant. The British *Saxifraga oppositifolia*, and its variety *alba*, are very pretty rock plants; both are, however, much surpassed in vigour and beauty, and also apparently in precocity, by a variety which bears the name of *pyrenaica rubra*, and has flowers fully double the size of those of the type, and much deeper in colour. The well-known *S. ligulata* is flowering freely, as is also its near relation, *S. Stracheyi*, which has brighter-coloured flowers, and is altogether a more striking species. One of the most handsome of all the Alpine *Saxifragas* is *S. Buergeriana*, with its neat, mossy growth and large white flowers. A coloured figure of this was given with THE GARDEN of Sept. 15 of last year. *S. Rocheliana*, var. *coriophylla*, concludes our list of *Saxifragas*; it is a neat little plant, with pretty rosettes of small, roundish leaves, and short, leafy flower-stalks, bearing heads of white flowers. *Dondia*, or *Haecquetia Epipactis* (for it is known by both names), is a very peculiar as well as pretty little plant; it is a very dwarf Umbellifer, with dense heads of flowers, somewhat resembling those of *Astrantia*, but bright yellow in colour. One of the earliest of the true *Irises* is *Iris angulicaris*, a native of the hedges of Algeria, and a very beautiful and sweet-scented plant; it was figured in the "Botanical Magazine" as *I. stylosa*. The leaves are narrow, and from 1 ft. to 1½ ft. in length; the flowers are from 2 in. to 2½ in. in diameter, the recurved outer leaflets of these being pale violet, with a deep yellow central band, and mottled below the middle with pale yellow, while the inner ones are of a uniform pale violet colour. *Helleborus lividus* is a stately species with purple flowers; an unnamed variety, with greenish flowers and the vigour and habit of the type, is also in flower, and well worthy of notice. The finely-cut leaves and large, bright yellow flowers of the spring-flowering Pheasant's-eye (*Adonis vernalis*) are very beautiful; few members of the Crowfoot family are more easily cultivated or better worth growing than this pretty perennial herb. *Hepatica* (or as it is sometimes called *Anemone*) *angulica*, from Hungary, is most charming, with its large, blue flowers borne well above the fine foliage. *Solila sibirica* and *S. bifida* are too well known to need description; the colour of the latter is a most charming ultramarine blue. The purple flowers of the common Dog's-tooth Violet (*Erythronium Deus canis*) are now very conspicuous just above the beautifully-mottled leaves. The North-west American *Sisyrinchium grandiflorum* is represented by a good tuft of a variety bearing large, pure white flowers; these are borne singly on scapes rather longer than the narrow, Grass-like leaves. The early spring-flowering Vetch (*Lathyrus* (*Orobus*) *vernus*) is very gay just now, as well as a variety called *cyaneus*, which has flowers of a deeper blue. *L. daccidius*, which appears to be confined in a wild state to Austria, has narrower and more finely-cut leaves than *L. vernus*; the flowers are a much deeper red when young, and never assume the metallic blue colour of the first-named. *Pailostemon orientalis* has panicles of pendent, blue, Borage-like flowers, borne on short scapes, which, however, are long enough as yet to overtop the not fully-developed leaves. *Scopolia carniolica*, a native of the mountains of South-eastern Europe, is a pretty, dwarf, Solanaceous perennial, not often seen in cultivation; the light green, oval leaves are produced in pairs, and the dull purple, bell-shaped flowers are borne singly on rather long, pendulous stalks. Amongst Croci not previously noted the prettiest is *Crocus stellaris*, with its star-shaped, striped yellow flowers. This Mr. Baker supposes to be a garden hybrid between *C. massianus* and *C. ensifidus*.

The most noteworthy cool greenhouse plants are the following, all in the temperate house:—*Acacia verticillata* is a neat-habited, extremely floriferous Australian species, with Gorse-like growth and stalked spikes of bright yellow flowers. *A. Richeana* is confined to the southern parts of Tasmania, and is by far the most beautiful *Acacia* of that island; it grows like a Weeping Willow on the banks of some of the streams, and its long, whip-like, pendent branches are clothed with panicles of golden flowers. In cultivation it is eminently fitted for training up columns or along the rafters of the cool conservatory, and the length of time it remains in bloom renders it a most desirable acquisition. A large tree of *Acacia melanoxylon* is flowering freely; this, however, is not a species to be recommended for general cultivation, but is very interesting, as it shows so well the

development of the dilated leaf-stalk characteristic of the Australian *Acacias*. The lower leaves have a bipinnate blade, whilst the upper are reduced to the flattened leaf-stalk. This species is supposed to yield the "Miall" wood, a timber with a very sweet violet scent. The Sikkim *Rhododendron cilium* is one of the most useful and manageable of all the Indian *Rhododendrons*, on account of its small size, neat habit, and the freedom with which its nearly white flowers are produced. *Clematis Buchaniana* is a rampant Himalayan species with large, hairy leaves and branches, and short, bell-shaped, greenish flowers. The largest-flowering of all the *Camellias* is the net-veined *C. reticulata*, from Hong-kong; although the petals are not so well arranged as in the beautiful garden forms met with every day, a good plant, covered with its large, brightly-coloured, Peony-like blossoms, is a most brilliant object.

In the Palm house are several plants of more than ordinary interest. *Brauseola macrantha*, from tropical America, is the finest member of the genus in cultivation; the flowers are larger and deeper in colour than those of *B. eximia*, but in other respects these plants have much in common. The South Brazilian *Abutilon Darwinii* is a pretty bush, and is loaded with its very handsome, large, drooping, bell-shaped flowers, which are dark orange-red in colour, with blood-red veins. *Carissa acuminata* is a spiny shrub with opposite glossy leaves, and clusters of small, star-shaped, pure white flowers. *Acanthus montanus* is an African plant, with the spiny leaves possessed by all the genus, and woody stems, terminated by a spike of large rosy flowers.

Few fresh *Orchids* can be noted this week. *Trichopilia suavis*, from tropical America, is the most handsome of all; the sepals and petals of its large flowers are white suffused with rose, and the large, waved, and crisped lip is beautifully mottled with red and yellow. *Spathoglottis Lobbi* is a very lovely terrestrial *Orchid*, with a tall, erect, slender scape, bearing several large, bright-yellow flowers. The pretty little white-flowered *Dendrobium japonicum* is worth a place in any collection. *Brassavola cordata*, an epiphyte of the easiest cultivation, is perhaps more curious than pretty; it has long, fleshy, channelled leaves and racemes of whitish flowers. *Coleogyne falcata*, a native of Nepal, has long drooping racemes of rather disagreeably-scented flowers; the sepals and petals are white, the base of the three-lobed lip bears several crimson veins, and the middle lobe is yellow near the apex.—†

## LIFTING AND DIVIDING ANEMONE FULGENS.

"A. D." (see p. 144), having forgotten to divide his *Anemones* at the proper season, was, doubtless, quite justified in doing so after growth had commenced; of course, such a proceeding would not kill them. In my previous note on the subject I unfortunately overlooked the fact that some districts are drier than others. Here the inadequate term "wet" does not by any means describe the constant pluvial conditions under which, during a great part of the year we live; and if we leave this plant in the ground after it has gone to rest, when we look for it in the autumn we find it "missing." Why, even *A. palmata*, which is so fond of moisture when growing, rots with us when at rest; in fact, it is abundantly clear that this plant does not like a wet blanket to sleep in. I understand that in the case of most bulbous and tuberous-rooted plants "at home" the driest part of the year is that in which they rest. Where one has only one or two of any plant, *Anemone fulgens* to wit, it is usually easy enough to place them in specially favourable positions; and if these did not naturally exist, it would also be easy enough to place, as "A. D." suggests, a shovelful of coal-ashes over them, but when we have to count our bulbs by thousands even that becomes impossible. The time has come when this beautiful *Anemone* is being used for spring gardening, and, of course, under such circumstances, it must be lifted out of the way of the bedding plants, if for no other reason; and even if not necessary to make room for other plants, it is still the best plan to lift and place the bulbs in a secure position. Sand is a good medium in which to keep them, and not one of the least advantages of lifting is that one knows where they are. As to losing part of their weight being injurious, that is a pure illusion; indeed, I consider the loss of weight rather advantageous than otherwise. My first-planted bulbs, which were as dry as snuff, are now fine plants, nearly 1 ft. through, and bearing many beautiful flowers, and I am fully satisfied that under no circumstances could they be better. Besides, this plant is all the better for a change of soil, and so, I believe, are *Gladioli*. We have had spikes of the latter 7 ft. high on new ground from bulbs that had been lifted and kept in the usual way during winter. Some time ago I left a small bed of the latter alone just to watch the result. They were originally about 150, and last year—the third from planting—they were reduced to twenty-three; so much for natural conditions. But, on the other hand, those lifted and stored in the regular way are safe, as usual.—T. SMITH, Newry.

## NATURAL ROCKERIES.

STARTING on the assumption that the art of gardening is based on the study of Nature rather than on abstract geometry, the art of rock-gardening must be based on the study of natural rocks. In considering natural rocks from a point of view at once practical and artistic, we must discuss their material, their mode of occurrence, and their natural flora. Among the igneous and primitive rocks we have granite, basalt, and slate; and among more modern rocks we need only consider various sandstones, limestones, and chalk. The hard, older rocks largely modify the general surface of a country. Granite forms the spinal column of our mountain chains, rising in rugged peaks destitute of all vegetation, owing to their elevation and slope, or more often forming rounded hills with a scanty vegetation of Heath, amidst which rise piles of stones like gigantic ruins—the ruins, in fact, of once overlying granite. The Tors of Devon and Cornwall; the Logan Stone, near Castle Treryn, St. Leven, Cornwall; the Cheesewring, near Liskeard; Helmen and Rippon Tors on Dartmoor; and Hey Tor, near Bovey Tracey, are well known to

the tourist, and are well figured and described in Mackintosh's "Scenery of England and Wales." We do not want sham mountain chains in miniature in our gardens, and granite, when undecomposed, is too barren to be interesting to the gardener; yet structures similar to the Tors, and not of puny dimensions—made, moreover, of rocks, to be presently mentioned, more fertile in character—are what we do want in a rock garden which is to be natural and not a mere flinty and clinkery. Beautiful, too, in barren grandeur is the scenery of the Giant's Causeway; but if in our garden we roughly shape some hexagonal stone columns, they must not be basalt, and, being unbasaltic, they become unnatural. Few spots around our coasts are more sublime than Kynance Cove at the Lizard, where the serpentine rock, in all its richness of reds and greens, relieved by white veins of steatite or soapstone, is polished by the waves of the Atlantic, and where the botanist seeks among the white sands of the beach for the delicate green fronds of the Asparagus. But this scene, too, is not to be transferred, as it were, to the canvas of our gardens. The sublime depends largely on size; we had better confine our efforts to the beautiful. The exposures of rocky surfaces are modified by the "weathering" or "denuding" agents—frost splitting the rocks, snow and rain penetrating and producing landslips, the sun pulverising the surface with its heat, the waves of the sea or the quieter, but no less sure, action of a river current cutting back a cliff or deepening a ravine, the ice of a glacier polishing the rocky ground it traverses into domelets which now rise like sheep above the Grass of our Scotch hill-sides, and, lastly, the wind blowing sand round a corner in a natural blast. The texture and composition of the rocks has modified the influence of these agents, and so has the slope of their beds. A compact, homogeneous rock without fissures will be little affected by them. A limestone will be dissolved by the rain-water, and give rise to combs or dales, caves and ravines. A porous rock, with a clayey substratum, will give out springs at its base, and be liable, in wet seasons, to landslips. Only the hard grains of a sandy rock will be available for its own disintegration by wind. The influence of the slope of beds not only affects their water-bearing quali-

ties and liability to landslips, but also, as is well seen in railway cuttings, their "angle of repose," the necessary slope, that is, of their exposed surface. The sandstone known to geologists as the Upper Llandovery, in the Silurian system, is the first I will mention. A swift-flowing stream meandered over its pebbly bed, through a ravine some 2 ft. deep cut in its own "alluvium," overhung with Alders on the further side, with here and there a Willow just gilded with blossom when I saw the spot. I stood on a strip of meadow a few feet only in width, much of which was covered with the little golden Saxifrage, whilst behind me rose the sloping bank of the sandstone, on which all the flora of springtide luxuriated among the coppice of "Hazels tassel hung" and sapling Oaks. A perfect sheet of Daffodils first caught my eye; but soon I saw plenty of Primroses, Dog Violets, and Anemones, with here and there a budding Hyacinth or early Orchid. Our deep-rooted wild bulbs many of them rejoice in a loose sand. The slope of the coppice was steep, and it was lovely; but its summit gave it completeness. There for 3 ft. or 4 ft. the rough edges of the sandstone stood out of its perpendicular face, whilst over the top, amidst the gnarled roots of the king Oak of the glen, hung a luxuriant bunch of Polyopus. The whole of this might be reproduced—nay, improved upon—in many a garden. The next scene is on the old red sandstone in the Forest of Dean. In the background, a fine grassy hill, well covered with well-grown trees, from amongst which is a view unsurpassed of the winding Severn and the distant Cotswolds; a lower hill rises in front covered with many Oaks; between lies a steep-sided ravine. On its sides are a few Firs amongst a luxuriant growth of Bracken, Heather, Broom, and Furze; but all these do not hide the great rounded masses of red and yellow rock which have rolled down, some half way, some to the bottom. Here trickles a little stream which spreads in a wide pool at my feet. The scenery of the mountain limestone is well known. Dove Dale, Cheddar Cliffs, St. Vincent's Rocks, and Symond's Yat, by "Sylvan Wye, that wanderer through the woods," are magic charms to the mind of the appreciative tourist. The three first ravines are due to river action, possibly acting along a fissure. They may be compared to the ravine of the Blackwater, in the south of Ireland. They show that this rock will stand perpendicularly when the "dip" or slope of the beds is slight; but the north side of the Cheddar ravine, having a greater "dip," has been worn down to quite a gradual slope. The bluish-grey colour of this rock is warm and pleasant, even when bare; on its surface, and in crevices, it decomposes into a fine clay, and is well suited for trees. The Yew, White Beam (*Pyrus Aria* and *P. scandica*), Service (*P. torminalis*), Lime (*Tilia parvifolia*), Hawthorn, Hazel, Beech, Oak, Dogwood (*Cornus sanguinea*), Maple, Spindle tree (*Euonymus europaeus*), Crab Apple, Wych Elm, and Holly cover the heights of Symond's Yat and Leigh Woods, Bristol; whilst green Whortleberries and Mosses, Lichens grey, white, and umber, and clustering Heath vary the colouring of the declivities. Clematis, Columbine, and St. John's-worts abound. The Cheddar Pink and its allies, the rare *Veronica spicata* of St. Vincent's Rocks, and the *Arbutus*, *Toadflaxes*, and many other rarities are there naturalised, besides the Hart's-tongue, *Ceterach*, and *Asplenium Trichomanes*, which contrast their rich greens with

Water and Rocks with tuft of *Arundo conspicua*.

ties and liability to landslips, but also, as is well seen in railway cuttings, their "angle of repose," the necessary slope, that is, of their exposed surface. The sandstone known to geologists as the Upper Llandovery, in the Silurian system, is the first I will mention. But this scene, too, is not to be transferred, as it were, to the canvas of our gardens. The sublime depends largely on size; we had better confine our efforts to the beautiful. The exposures of rocky surfaces are modified by the "weathering" or "denuding" agents—frost splitting the rocks, snow and rain penetrating and producing landslips, the sun pulverising the surface with its heat, the waves of the sea or the quieter, but no less sure, action of a river current cutting back a cliff or deepening a ravine, the ice of a glacier polishing the rocky ground it traverses into domelets which now rise like sheep above the Grass of our Scotch hill-sides, and, lastly, the wind blowing sand round a corner in a natural blast. The texture and composition of the rocks has modified the influence of these agents, and so has the slope of their beds. A compact, homogeneous rock without fissures will be little affected by them. A limestone will be dissolved by the rain-water, and give rise to combs or dales, caves and ravines. A porous rock, with a clayey substratum, will give out springs at its base, and be liable, in wet seasons, to landslips. Only the hard grains of a sandy rock will be available for its own disintegration by wind. The influence of the slope of beds not only affects their water-bearing quali-

the blue rock where the air is moist enough, are sufficient recommendation of this stone where procurable. To be natural it should be built up in as large blocks as possible into an almost perpendicular cliff. Ivy grows freely on it, and they may be utilised for such a cave as that figured in THE GARDEN (vol. xii, p. 33). The coarse grit-stones of the millstone grit mostly form open, barren heaths; but where unequally hard are sometimes acted on by the atmosphere, forming grotesque "tors," such as the Idol and Pulpit Rocks at Brimham, near Harrogate. By a jump upward in the geological series, we have next to consider the beauties of the oolitic rockeries. There are two "horizons"—to use a technical term—in the series where springs are most frequent, viz., its junction with the clays of the upper Lias at its base, and the junction of the great or Bath oolite limestone with the underlying Fuller's earth. At the first of these we find, at the foot of a bare, breezy down, a wood of Oaks, in the midst of which gushes forth a crystal stream, which rushes down the steeply sloping escarpment, while its waters leave their traces behind them; for Hart's-tongue, Grass, and Chara remain "petrified," with a coating of carbonate of lime, and in time are compacted into a firm tufa. Here also landslips are frequent, and on the sloping sides of the lovely valleys down which these petrifying streams now run, now fall in cascades, are blocks of limestone of all sizes, weathered into fantastic hollows, swathed in Clematis or sheltering some of our rarest British Orchids. It is the Fuller's earth clay which throws out the parent springs of Father Thames himself and his many tributaries. Who that has ever seen it will forget the undulating hill-side, purple in spring with the silky cups of the Pasque flower, from whose abrupt, rocky base rush seven or eight separate streams, splashing downwards into the rush and Sedge-grown marsh, from which again they overflow into a river where the floating Pond-weeds relieve the sky-blue Forget-me-not, and on whose brink in September may be seen the perfect beauty of the Grass of Parnassus set in soft Moss of emerald brightness. But even where no water is near the oolite limestones often exhibit great beauty. A bank or quarry of the forest marble flag-stones, crowned with a group of noble Beech trees, over the brink of which hangs luxuriant Ivy and Clematis side by side, while the slope is gay with yellow Mullein, blue Bugloss, pink Minsk Mallow, and lilac Scabious, is suggestive of much improvement by the addition of rarer and foreign species.

The next group of scenes to be mentioned are the glens of Fairlight, Ecclesbourne, and Old Roar, Hastings, where streams have cut through the Wadhurst clay, and fall rapidly on reaching the underlying Ashdown sand. Very similar are the Chines of Luccombe and Shankin, in the Isle of Wight, though the sand here is of different age (Neocomian). Here a stream falls vertically over a cliff of sand and winds down to the sea through a ravine, clad with trees and Ferns, which it has cut for itself. Among our sand-loving plants suited to such a spot the Foxglove is pre-eminent. In a formation of intermediate age, the Tunbridge Wells sands, we get those remarkable "tors," for which the neighbourhood of the town, after which the sands are named, is celebrated. But, besides the well-known Harrison's Rocks, the Toad Rock on Russhall Common, and the beautiful High Rocks, where grow the Columbine, the climbing Corydalis, the Dentaria bulbifera, and the Orpine, and where once grew the Tunbridge Filmy Fern, besides the beautiful rocks where Art has helped Nature in the gardens of Mr. E. W. Cooke, at Groombridge—a model worthy of imitation—there are other less tourist-haunted spots. Who knows Great-upon-Little at West Hoathly, or Rock's Farm, Buxted? Here a natural sand blast has played upon the face of an escarpment; and amidst Broom and Furze, Foxglove and Ferns, riddled with martins' nests, stands a rocking stone more beautiful than any in Cornwall. Other beauties of these sandstone formations may be seen in the railway cuttings between Three Bridges and Lewes. I should be describing scenes almost identical with those on the Llandovey and Hastings sandstones did I speak of the beauties to be seen in natural rockeries of Neocomian or lower green-sand age. Nowhere have I ever seen the Foxglove more luxuriant, finer Hyacinths or Primroses than in woods on the Hythe beds, at Blechingley, and Tilburstow, in Surrey. In a shady wood at this latter place the bright little yellow Pimpernel covered the

ground. I know no more beautiful quarter of a mile than a Gorse-covered heath, with a disused Roman road—where the Wood Sorrel and Polypropy clung to the Mossy roots of the trees, which seemed ready to fall from the sandstone shelves—leading to an Alder-grown marsh gay with Ragged Robin and Forget-me-not, in this same neighbourhood.

Last, but not least, of the rocks to be mentioned is the chalk. Ugly from its glaring whiteness when bare, no rock better sets off bright greens and gay colours. It has the additional advantage of being almost equally effective either in large blocks or in an artificial quarry built up of the very smallest fragments. The bowtering Clematis clambering with the Bryony, the bushes of Sweet Brier, Yew, and Juniper, and the greensward blue with Milkwort, pink with Rest Harrow, or studded with nearly all our British Orchids, make many a nook in the North Downs dear to the botanist who looks for beauty. Clear springs rise at the base of the chalk, but become milky on running over it. This is to be avoided. Water is a great addition to the charms of the rock garden; but, unless we wish to make a feeble imitation of Iceland scenery, let us eschew cold-water geysers—so called fountains. G. S. BOULGER.

11, Burlington Road, Westbourne Park.

### THE SECATEUR.

THOUGH this useful instrument has been strongly recommended in the horticultural papers more than once since it was first introduced to notice, still it is by no means in common use in gardens. It is very seldom, indeed, one sees it, and few of the seedsman keep it for sale. Looking through the price list of garden implements in the seed catalogues of several eminent firms, I find everything mentioned but the secateur. When I tried to procure it at some of the seed shops in this district the shopman did not know it even by name, and I had to apply to Messrs. Stuart & Mein, of Kelso, who appear to be almost the only firm that have persevered in their attempt to introduce an instrument so superior to the common pruning-knife that one can but wonder it has not replaced the latter for most purposes long ago. I am aware that a certain prejudice exists against the secateur among some gardeners, who have stated that it crushes the wood in cutting, and does injury; but this is not so. I have used nothing else but the secateur for the last thirteen years for all outdoor pruning; and I can state, without hesitation, that it does no injury to the tree whatever, while a man can do three times as much work as he can with the knife. Gooseberries, for example, are, as a rule, troublesome subjects to prune with a knife; but with a secateur a lady may prune her bushes without much inconvenience, and prune them in a short time. Ladies and gentlemen who like to do a little pruning among their shrubberies will find the secateur invaluable, and they may cut anything with it that they have strength to cut. I can manage any branch up to 1 in. in diameter, with a secateur about 9 in. long, and we have sometimes severed a 1½-in. limb; but that tries the muscles. The smallest and second smallest sizes are, however, the best for light use, and they will cut anything up to the thickness of one's finger. Though it has been strongly condemned for pruning Vines, I have never used anything else, and it has never yet injured a bud. With a common knife one has to use both hands, and to be frequently putting an edge upon the blade, but with a handy-sized secateur we can run over a house of 100 ft. long in half an hour. I have also used it for cutting out thick branches in pruning Peach trees; but I prefer the knife for cutting the smaller shoots in their case, as it is important in the case of trees liable to gum that a clean cut be made. With very few exceptions, however, I use the secateur. It must not, however, be confounded with the common pruning-shears sold by the seedsman, and which are not unlike the secateur, but clumsier, and far less powerful in the cutting, the leverage being less. They are sometimes called by the same name, and I suppose many people do not know the one from the other. The only fault of the secateur is that the spring is apt to give way under constant work; but the blacksmith can repair this easily, J. S. W.

**Raising Seedlings in Bamboo Stems.**—In the last number of the "Indian Forester" Mr. Baden Powell describes a method of raising seedlings in Bamboo tubes, so that they can be transplanted when required without injury to the roots. Pieces of Bamboo stem are taken, 4 in. to 6 in. in length and about 1 in. to 1½ in. in diameter, and open at each end. These are placed close together on a sort of bed, well beaten down to prevent the roots entering it, and then filled with fine soil. In each tube two or three seeds are then placed, lightly covered over, and watered when necessary. When the seedlings have arrived at a few inches in height they are planted out, tubes and all, in the positions they are intended to occupy permanently.

## BEST PLANTS FOR MIDWINTER EFFECTS.

The plants which give life and interest to our out-of-doors garden in midwinter are worthy of note, and it is particularly, I think, desirable to give some account of them, as, according to circumstances and variety of situation, some plants seem to do well in one locality, while in other nearly similar situations they will not grow satisfactorily, although well cared for. The plants, therefore, which I noticed in my garden doing well and producing a pleasing effect in the beginning of last January, either from their flowers, foliage, or fruit, I will hereafter mention, with such observations concerning them as I think may be useful. Of plants in flower I shall only name those which were in good bloom, and not the remnants of last autumn's flowering. It may be well to premise before going into details that my garden, although within about 900 ft. of the seashore, is fairly well sheltered from the sea breezes, well open to the south and east, and has a soil consisting of good, rich loam. It also may be well to state that some sharp frosts had visited us a little before these notes were made. Of shrubs, none were more worthy of notice, being in full flower and very effective, than several varieties of *Veronica*. Their dark green, somewhat glossy leaves, which are produced in profusion, form a fine background to the flower-spikes, which throw themselves well out of the foliage. These varieties grow under south walls, and form rounded, dense bushes, some 3 ft. to 4 ft. high. They are all, I think, of hybrid origin, running somewhat away from the originally shrubby species as introduced into this country. They seem to have sprung from such species as *V. speciosa*, *salicifolia*, *parviflora*, and *decussata*. Some originated in my own garden, and others are, I believe, well-known hybrids. I find that they seed freely, and young plants are often found on the borders arising from self-sown seeds. With the *Veronicas*, but nailed to a south wall, *Medicago arborea* was flowering abundantly, and producing a very pleasing effect with its yellow blossoms, curious seed-pods, and rich, dark green foliage. In the same situation is *Daphne indica*, a charming plant, on account of its very fragrant flowers and persistent green leaves. The flowers with me are only produced sparingly in bunches at the ends of the branches. In a west situation, nailed against the wall of the house, the dull-flowered, but very odoriferous, *Chimonanthus fragrans* was in bloom. I find this plant will not do well except nailed to a warm wall. Against a south wall, which during winter is somewhat warmed by an internal fire, *Convolvulus Cneorum* grows well and flowers abundantly, and it is a great favourite of mine on account of its silvery leaves and white flowers rayed with red externally, which are constantly produced during the winter season. Like situated, *Grevillea rosmarinifolia* was giving its bunches of rose-coloured flowers, which show well against the dark green foliage.

In the open borders in my garden *Kniphofia* (*Tritoma*) *Rooperi* and *Burchelli* were in good flower, many spikes to each plant, and many more showing themselves. These *Kniphofias* are excellent for the winter garden, and should be more generally cultivated. Four species of *Helicoborus* have been in good flower, viz., *niger*, *lividus*, *maculatus*, *abchasicus*—the first, however, far the best for the amount and perfection of the flowers. It is a plant which should be in every garden where soil and situation would permit. On some warm rockwork under a south wall *Erodium hymenodes* has been in good flower, as well as three species of *Mesembryanthemum*, one of which, *inclaudens*, I set much store upon, as its flowers do not close when the sun ceases to shine upon them. I may mention here that on this sheltered piece of rockwork I grow many species of *Mesembryanthemum* and other succulents, and that they have stood the last three winters without any covering. They get a little nipped by the hard frosts, but shoot out again and form good bushy plants very full of flower during the summer months. I may also mention, while speaking of the *Mesembryanthemum*, that I make much use of the species as bedding plants and for wall decoration, growing many of the pendent species in flattened or wall pots, from which their branches hang down, and, flowering freely, produce a pleasing effect. That valuable bulb, *Schizostylis coccinea*, flowers and does well here, giving its beautiful flowers in the winter months. It seems to grow best with me in peat, but also flowers well

in loam. *Iberis gibraltarica* on rockwork is always in flower, and during the winter, although apparently a little checked by cold, gives its blossoms freely and in good condition.

Turning now to the effect produced by foliage alone in the dead winter, I may especially mention the *Hollies*, which, although so well known, cannot be too much praised. I have a large number of varieties, chiefly small bushy plants, but all seem to do well here, and produce fine foliage, variegated and green—shining and opaque, spined or smooth—almost endless in variety, but all pleasing. After the *Hollies* the varieties of *Euoonymus japonica* are the most attractive for their foliage. They are numerous, but one in particular, with dark green leaves broadly and pretty regularly margined with golden-yellow, produces a fine effect. They seem especially to love the vicinity of the sea, and are valuable, as they can be moved with safety, even very large bushes, at any season of the year. This vitality arises from the ball-like mass of whitish fibrous roots which the plants make, and which do not spread far from the stem of the plant. One of my most effective shrubs for foliage is a variety of *Veronica*, producing long, pinkish-white spikes of flowers and large, ovate-lanceolate leaves, green splashed with creamy-white. The leaves are 4 in. to 5 in. long and  $1\frac{1}{2}$  in. or a little more wide. It is a charming shrub, a hybrid, I suppose, and well worthy of cultivation. Several varieties of *Ivy* growing against a north wall should be mentioned for their winter foliage and the pretty, and I may say elegant, effect they produce. The Irish variety variegated is one of the most attractive from its large, dark green leaves with clear large patches of creamy colour. The Irish *Ivy* is a very fast-growing variety, but when not variegated is not so pleasing in effect as the common English *Ivy* of our woods, which is an admirable plant. Among smaller shrubs worthy of notice for pleasing foliage *Griselinia littoralis* must be noticed for its fine, glossy, bright green leaves. This, with *Osmanthus ilicifolius*, grown under a north wall in peat, do well, and are very effective. In bog borders exposed to the sun, *Pittosporum Maqui*, with its peculiar pale green, shining leaves, and *Pernetia macronata*, *Erica mediterranea* and *E. stricta*, with their numerous small green leaves, are pleasant objects for the eye to rest upon. Against a south wall I find *Eriobotrya japonica*, with its large, corrugated leaves, and *Photinia serrulata*, with its large, shining, dark green leaves, so beautiful when young, and some species of *Ceanothus*, are much admired for their winter foliage. I must not here omit to mention *Aralia Sieboldi* as a good plant during the winter, its large, fine, palmatifid leaves making a grand effect, and its bunches of cream-coloured flowers, produced quite late in the autumn, are very pleasing, and add much to the value of the plant. With me it appears to be quite hardy. Of low-growing plants the variegated *Vinca major* does well with me, and much enlivens the ground in shady places. The old *Farfugium grande* also is very effective, producing large masses of leaves so curiously spotted. Sharp frosts and high winds cause the foliage, however, to turn to a rusty colour at times. Very low on the ground grows with me in almost any situation the *Cyclamen hederifolium*, producing large patches of very beautifully variously-variegated leaves. I have tried this plant on rockwork, fully exposed to the sun, and under a north border, where the sun scarcely ever shines, as well as in various other situations, and I find the plant does fairly well in all, but more flowers are produced and finer foliage, I think, comes from a large plant close under a south wall, where the soil is loam. The tubers of this plant came originally from Corfu.

Of the plants producing berries or fruit which brighten up the winter garden, *Hollies*, as a matter of course, stand well forward; but I find the produce of berries very uncertain, some years very abundant, and then perhaps two or three or more years before a good crop will again appear. *Cotoneasters* seem to be more certain in their effect, and the variety or species called *Simmondsi* is very sure of being well covered with charming red berries every winter. A standard which I have was literally one mass of red berries about Christmas time, and could be seen all over the garden. The plant of all others which is the most attractive in my garden, on account of its berries, is *Solanum pseudo-capsicum*, generally, but little grown. I have a strong plant nailed

against a west wall, growing in loam, which for the last two winters has been very charming, from the quantity of large, orange-red, glossy spherical berries produced among lively green foliage. I have been able to cut many branches from the plant for my friends, who have used them for various decorative purposes. Until near the end of the year the large bunches of the red fruit of *Rosa ferox* were particularly attractive. The birds, however, and sharp frosts which came on, soon spoiled the beauty of the fruit. Another species of *Rose* (*Rosa sanguisorbifolia*) is quite as interesting in its fruit, which is of a bright glossy-red colour, produced in great quantities, and hangs on the plant in good condition until the spring, the birds and frost leaving it uninjured. Of low-growing plants, the seeds of *Iris foetidissima* produce a good winter effect, and are very showy. The pods of this *Iris* burst very late in the autumn, and then the seeds, which are about the size of a Pea, and bright orange in colour, expose themselves in glittering rows. Some care should be given to the plant to produce a good effect, and the flower-stalks should be carefully preserved and tied up, so that they may not be too much blown about. The plant will grow in any good situation, but it seems to like best an open, cool, rather shaded locality. The pods with their bright seeds come in well for Christmas decoration of our rooms and halls. *Skimmia fragrans*, grown in peat under a north wall, fruits well with me, and retains its red berries until the spring; and I have had the common *Aucuba japonica* show good and effective fruit, but this I find can only be done by distributing the pollen carefully over the pistil-bearing plant. I have a plant which was sent to me by Mr. James McRonald, Chichester, which was a perfect mass of red, shining berries, and I saw many others in this nursery equally well covered with fruit. I might mention many more plants which I grow, and which I think well worthy of cultivation for the mid-winter garden, but I have kept myself to those which seemed to put themselves most prominently forward.

W. W. S.

Raystead, Worthing.

### WINTER-FLOWERING PLANTS.

NOTWITHSTANDING that there is so little encouragement given to the cultivation of hard-wooded indoor plants, there are many very useful subjects amongst them, especially those which flower during the winter months. When a good selection is secured, liberally treated so that flowering wood is in profusion, the out flower basket may be well supplied with little difficulty; and we know how well New Holland plants and Heath's tell in a collection on the exhibition table. While forming a collection of plants a year and a half ago a number of specialities, chiefly hard woods were procured, and the abundance of flowers we have had from them during the past winter months, and the mass of flowers out and coming into bloom give much satisfaction as to selection. The small amount of labour and the minimum of expense incurred are not despicable items where employers are not inclined to become patrons of extensive plant culture. With the best of the kinds of *Azaleas*, *Camellias*, *Epacris*, *Heathes*, and *Correas*, a good addition for winter and spring decorative purposes are *Grevillea elegans*, growing naturally with shoots about 3 ft. long loaded with flowers. *Chorozoma Chandleri* elegans, not over trained, is fine during February; *Tremandra ericoides* with long shoots; *Genetyllis talipifera* and *fuchsoides* as free-growing pyramids; *Eriocaulon*, *Pimeleas*, *Boronia*, *Daphne hybrida*, *Aotus gracillima*, *Cyrtis racemosa elegans* as standards, and *C. Alceeanus* as a dwarf. These and all the *Acacias* may be had flowering profusely from January to the end of March or later. Their care as to keeping is very simple, and when well arranged, with the usual bulbs and soft-wooded plants, a display can be maintained in the cool greenhouse which would be difficult to surpass by any other class of plants. As climbers, *Plumbago aspenica*, *Lanargia rosea* and *Habrothamnus Auhleti* may be had in fall flower from November to April. The last named seems to be a perpetual flowering plant. On a back wall of a greenhouse planted out it has been a mass of flowers since last autumn, and when grown as small plants for tables and shelves it is invaluable.

M. TEMPLE.

ONE of the prettiest legends of Arabic literature attributes to Mahomet a saying that if a man finds himself with bread in both hands he should exchange one loaf for some flowers of the *Narcissus*, since that feeds the body indeed, but these the soul. Nothing could be more subtle than this ancient confession of the part that colour and perfume

and the eternal freshness of flowers take in the education of the heart. These marvellous flowers that spring in their clean lovely dresses out of the worn face of the dingy world, a miracle of beauty silently performed by Nature every year, bring more of poetic mystery with them than any other of the countless transformations of life that charm and perplex us. They are at once the most evanescent and the most lasting of things, and their rapid death only ensures their resurrection. In all religions they have taken a very intimate place in ceremonial, and no wonder; for, in their constantly reiterated disappearance and return, they are types of all that is most flattering to the anxious spirit of man, and most consoling in the bust of creeds. The simplicity and refinement of flowers gives a special distinction to almost every art that touches them.—*Examiner*."

**New Building in Hyde Park.**—The "Times" has received several indignant communications respecting the "nost villa residence" which has just been erected in Hyde Park. The building is three storeys high, appears to contain about a dozen rooms, and is, of course, abominably ugly. Its aesthetic merits are not, however, so much in question as the right of the Crown to appropriate any portion of the park for building purposes. In addition to the site, a considerable plot of ground has been levelled and fenced in around the building, and some alterations have been made in the neighbouring paths. Most ominous of all, there are indications that a hedge or belt of shrubs is about to be planted within the hurdle fencing. A short time back we showed what similar appropriations have achieved in Kensington Gardens by ringing the changes between hurdle fences and hedges. The process—which first moves one boundary forward, then the other—has gradually brought about the alienation from public purposes of all the superlatives between the front of Kensington Palace and the Broad Walk. In this instance there may have been some justification for the trespass in the necessity of securing a reasonable amount of privacy to the occupants of the palace. But if the same plea is advanced on behalf of the new villa, the public will be deprived of the most central portion of the finest open space at the West End. Without expressing any undue suspicions, we think the time has nearly come for putting an end to these enclosures.—*Examiner*."

**Paddington Flower Mission.**—We extract the following from the printed report of this Mission just received:—"In 1876 our gross number of supplies was 377; our bunches sent out, 13,024. In 1877 our supplies were 486; the number of bunches sent out, 17,297. During the season of 1877 our weekly average of supplies was over 16 peck weekly; our largest weekly supply of hampers, boxes, or parcels containing flowers, was 29, and our smallest 4. As usual, May stands by pre-eminence 'the flowery month,' by far our largest number of packages come from then. At the Christmas seasons of both 1876 and 1877, various baskets of Holly and evergreens were received, and distributed to the Paddington Workhouse, St. Mary's Hospital, and amongst one or two smaller institutions and private individuals. We wish the dwellers in the country could know the delight these gifts afford, especially in the workhouse, by the arrival, at that usually dark and dull season of the year, of 'real country' greens and red berries, so rarely seen by the inmates of such places. We have received many gratifying testimonies of the value put on the flowers by the recipients; one acknowledgment from a hospital, where anything cheering must be specially welcomed, is most encouraging. We shall re-open the Mission on April 4 next, and we would appeal to our country friends not to let us re-open without flowers. We do not press for garden flowers, but we feel sure we shall not ask in vain during the spring for wild flowers, these universal favourites whose 'gentle faces touch the heart.' Anyone willing to contribute is requested kindly to observe the following directions, and if possible, before beginning, to advise by post their contributions.—1. All parcels, paid or unpaid, to be addressed 'Paddington Flower Mission, 18, Conduit Place, Spring Street, London, W.' (Proper labels supplied on request.) 2. If from any distance out of London, to be sent off on Wednesday. 3. If box or hamper is to be returned, please say so. 4. In all cases please to send the name and address of the contributor. Any communications on the subject may be addressed to Miss A. L. Boyle, 10, Craven Hill Gardens, London, W., who will receive and acknowledge any contributions towards expenses, and who much regrets if, through inadvertence or address not having been sent, any contribution of flowers, &c., has been unacknowledged."

**Gardenia citriflora.**—This charming little evergreen shrub flowers in such abundance in quite a small state that it ought to be in every collection where sweet-scented decorative plants are in request. The blossoms, which are produced in bunches at the axils of the leaves, might readily be substituted for Orange blossoms. It grows freely in an intermediate house or pit, and should be included in even the most select collection of plants.—*JAMES GAOON, Henham.*

## TREES AND SHRUBS.

## THE LIQUIDAMBAR AT HOME.

This is one of our native trees, second to none for ornamental purposes, but which I have never seen in a city street or park, and in very few private gardens or lawns. Its flowers and seeds are inconspicuous, but it possesses striking beauty through the whole year, for when stripped of its leaves, its erect and symmetrical growth gives it a handsome outline. In its growth it is much like a young Poplar, or Tulip tree, but retains its lower limbs, and so never acquires the columnar style of trunk of the Poplar. The smaller branches have high ridges of corky bark, sometimes a branch 1 in. in diameter having two or three of these bark "fins" 1 in. wide. This peculiarity is quite noticeable, and the branches can be used with excellent effect in house adornment for a dozen purposes that could be suggested. Its leaves are thick, of a deep shining green, sometimes 7 in. or 8 in. across, deeply divided into five or seven lobes, which are notched on the edges and pointed at the tips. The children sometimes call them "star leaves." When crushed they give out a pleasant aromatic odour. In autumn they show a great quantity of beautiful colours, from palest gold to deepest crimson and purple-maroon. This tree is said to be found from Connecticut to Virginia, and southwards. It seems to like best moist places in woods and along the banks of small streams, though it grows vigorously when transplanted to well-drained uplands. The wood is of fine grain, but I have never heard of its being used for any special purpose. It rarely matures seed, but propagates rather readily by sprouts from the roots. One of the chief things to be kept in mind in making a selection of trees and shrubs for planting ought to be their autumn colourings of foliage and fruit. It seems to me quite as important as their flowering, but it appears to be a point almost wholly ignored or forgotten. Most city streets and parks, and private grounds as well, present in the autumn of the year aside from their gloomy evergreens, only a dreary expanse of naked branches or doleful brown leaves, whereas by a judicious choice of trees and shrubs, chiefly native, they ought to exhibit their greatest beauty just before the snows of winter. The citizen of Wash-

New hardy tree, *Cedrela sinensis*, in the Garden of Plants.

a fragrant odour, is imported under the name of Jamaica or Honduras Cedar. *C. Toona*, a native of Bengal and other parts of India, furnishes timber much like mahogany in appearance, but lighter. The flowers are used in some parts of India for producing a red dye. The red Cedar of Australia, *C. australis*, is now becoming scarce in that colony, the trees having been cut down for the sake of their timber, which was commonly used in the construction of houses. The species of which a figure is here given is a handsome hardy tree, of which there is a good specimen in the Garden of Plants at Paris. It was drawn from a photograph taken towards the end of last summer. It appears to be perfectly hardy. We hope it will soon be introduced and distributed.

## UNACCOUNTABLE DEATH OF YOUNG TREES.

I HAVE just read with greater interest than usual the very clear account of Mr. George (see p. 172) as to the depredations of the caterpillar of the goat moth. I did so for these reasons. A little before Christmas it was fine, open, planting weather, and I went to inspect a long strip

of wood, which, being anxious to get up as soon as possible, I had planted thickly with young trees, from 3 ft. to 5 ft. high, chiefly Poplars, Scotch Elms, and many other sorts. To my vexation, every one which had been in full leaf in early autumn seemed dead and blasted. The man with me thought that they had been injured by hares or rabbits (a rustic's solution for the failure of every sort of crop). This could not be the case, as the trees were not barked above the level of the Grass, which was 2 ft. high. I was very ill at the time, and could not make so minute an inspection as I would have done. I then thought of white-bellied field mice, about whose depredations we have often read. On baring the stem by parting the Grass, I found, in the apparently dead trees, a narrow round ring going through the bark, but not like what a mouse or rodent would have made. Since then I mentioned this to Mr. Burns, of Cockermonth, who supplied me with the trees, and he told me that he had lately been called to view several young plantations which had perished suddenly in a similar manner; and that the man in charge of them said he had found a beetle devouring them. He might have seen a beetle, no doubt; but that was probably

not the primary cause. No doubt it was done by an insect of some sort. The trees are springing again from the root, which shows they have not been blasted by lightning.

J. GILLBANKS.

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

Varieties of the Hemlock Spruce.—The queen of all evergreens is the Weeping Hemlock. Its graceful sprays have a permanent beauty that we only see equalled, in a fleeting way, by some stray form of common Hemlock. Not less striking, in its way, is the Broad-leaved Hemlock, the dark, massive foliage of which contrasts finely with the golden *Retinospora*.—S. PARSONS, in "Rural New Yorker."

A Wild Cherry Tree (*Prunus avium*).—As some notice has lately been taken of the size of this tree, allow me to mention one at present existing within a field of my farm, which presents the following proportions:—2 ft. from the ground, 21 ft. in circumference; 3 ft. from the ground, 15 ft. in circumference; 6 ft. from the ground, 21 ft. in circumference, 10 ft. from the ground, 19 1/2 ft. in circumference. 12 ft. up to the bifurcation of the branches. This grand tree was first shown me by my friend, Mr. E. Lees, when it was in fruit. Since then the hurricane of October 14 has swept away its principal arm.—J. B. Bradford Abbas, in "Science Gossip."

*Cedrela sinensis*.—This is the *Ailantus glaucescens* of Carrière. It is nearly related to the *Melias*, and forms a hardy tree in the north of China, but it is found all over the world. The *Cedrelas* are much valued for their fine appearance and for their timber. The trunk of *C. odorata*, a West Indian tree, is sufficiently large to be hewn out into canoes; this, which is of a brown colour, and has

## THE KITCHEN GARDEN.

### CULTURE OF THE AUTUMN GIANT CAULIFLOWER.

This Cauliflower is not only large in size, but good in quality, and very accommodating, coming into use, as it does, as those sown in autumn are finished. A succession of excellent heads may be had from the middle of September to the end of October by sowing a box at once, and placing it close to the glass in a late Vinery or greenhouse, admitting sufficient air to prevent weak growth. As soon as the young seedlings can be fairly handled, plant them out in a cold frame prepared as follows:—Fill the frame firm with any material that may be at hand to within 10 in. of the glass; on this place a layer of fresh soil and good rotten manure, well mixed together, and trodden quite solid to the depth of 3 in. Put in the plants 6 in. apart, supplying water freely whenever required. Give ample ventilation, increasing it gradually according to the state of the weather, till the frame may be lifted off altogether. Owing to the heavy rainfall during the autumn and mild winter, heavy soils are not only unworkable, but full of slugs and other insects. In preparing the soil for the plants, a steel digging-fork, with four prongs, is much better than a spade; it is easier to work and breaks up the soil better, rendering it more permeable to air and water—an important point as regards the growth of good vegetables. If the ground has not been trenched and ridged up in the autumn, it should be dug up two spits deep, and plenty of good rotten manure and a few handfuls of fresh slaked lime, should be mixed with it; the latter not only acts as a manure, but keeps slugs in check. About a week or so before planting out, take an old table-knife and run it down the centre between each row both ways, cutting the roots of the depth of the layer, and give a good watering from a roset can. This produces a sturdy growth, without which fine heads cannot be obtained. Every plant may be lifted with a spade, placed on the hand-barrow in a solid square, carried to its destination, and planted out, without the plant receiving any check. In keeping down weeds, a cultivator with two prongs, 2 in. apart, 6 in. long,  $\frac{3}{4}$  in. wide, and  $\frac{1}{2}$  in. thick, with a good stout handle, is much better than a flat hoe working amongst vegetables. It opens the surface, and allows air and water to penetrate freely. A second sowing about the third week in April will come in about the middle of October, and continue till the middle of December, according to the state of the weather.

Waterdale.

JAMES SMITH.

### CHEAP COLLECTIONS OF SEEDS AND PLANTS.

KNOWING that at this season many are undecided where to procure their annual supply of seeds, &c., from the legion of advertisements which present themselves, all claiming the merit of supplying the most liberal collection, a few remarks may not be out of place to show that these so-called "cheap" collections are "dear." Last year I was at some trouble in ascertaining what weight the 21 packets of seeds contained, and on carefully balancing up the results I found that many of them were sold at a higher rate than that which I paid for the same article in the leading retail houses of the metropolis, to say nothing about quality, which was in many instances very inferior, and it is on this point that I would caution amateurs who are not thoroughly conversant with the requirements of a garden to go to a respectable seedsman and state their case, when they may depend on being well served. Perhaps at the time the onlay may be considered to be large, but if the good results be taken into account they will doubly compensate for the first outlay. What is more galling than the disappointment arising from seeds failing to germinate? I must confess that seedsman's catalogues are most bewildering, and in this cause I attribute the mania for these collections. Why cannot seedsman use their utmost endeavours to simplify them? They may assert that without a fine catalogue their business would probably decline. Let me urge upon seedsman the necessity of doing away with synonyms, and let me also recommend them not to sell Early Six Weeks Turnip out of a bag of Snowball. The same may be said of white Spanish Onion; out of the same drawer come Nuneham Park, &c. Having had a slight insight into the retail trade in a London house, I am not giving these examples as imaginary, but as realities, which I could multiply if needed. Last season I bought a collection of herbaceous plants which individually averaged 4s., and they were guaranteed true to name. Well, I thought, there is a prospect at last of my getting these good old-fashioned flowers at a reasonable price; but, to my surprise, they were only miserable pieces roughly separated from a clump in a border; and the nomenclature was anything but good, a Narcissus being sent to me as Daphne Cneorum; and, in fact, the whole collection showed similar carelessness. What I want to point out, too, is the high rate charged for these pieces. Fancy an old-established clump

of Michaelmas Daisy divided into these fourpenny plants! The snub thus realised would astonish the uninitiated, and when the pieces in question are planted in borders a very large per-centage of them die. My advice is, that in whatever direction fancy takes us, I would recommend amateurs to go to the firm on whom they can depend for their seeds and plants, pay a fair equivalent, and never be allured away through cheap collections.

A. HOSSACK.

Ragley.

### WHERE TO PLANT POTATOES.

THE advice given by Mr. Groom (see p. 153) is excellent, so far as it goes, only, unfortunately, it does not carry the question much farther than it was left by Nicol and others who have written on Potato culture since his time. To say plant on such and such soils will not help those to secure a crop who do not possess the kind of land recommended; perhaps I shall be told they ought not to grow Potatoes at all, but that is rather evading the difficult points of the question than helping to solve them, as there are many gardens (indeed, the majority of small gardens) in which the choice of land is so limited as to have no practical influence whatever. The kinds of Potatoes recommended by Mr. Groom are excellent on suitable soils; indeed there are none better, but on heavier, moister land they are altogether so dependent on the weather, and in eight years out of ten are so much diseased, as to be valueless. I think the varieties of Potatoes, like some of our fruits, may be so selected as to suit the soil and climate of a place or district, and I have no doubt many cultivators are directing their attention to this subject; at least, I know our crops have been better in quality and far more in quantity during the last few years than they were formerly, when a sort of haphazard system was adopted. I am not now speaking of field culture, although if I had 20 acres of adhesive land to plant with Potatoes this spring, I should adopt the same course, and that is, plant approved, early, and second early kinds only. I have Snowflakes as firm and good now as they were four months ago, and by keeping them cool and away from the air, they will remain in good condition for some time longer. I am only giving this as one single instance. There are places I have heard where the kind I have named is badly diseased, but that only adds force to my argument that we should select our kinds of Potatoes to suit our soil. Where we cannot select land to suit the Potatoes, and on heavy retentive land, we must, if we are to have a crop of good quality, plant early-ripening kinds that can be lifted before the rains set in. The largest growers in this neighbourhood, and those who are making money by it, are now mostly growing Myatt's Prolific, Early Rose, and Snowflake, and the land produces more, and the crop is altogether more valuable than when later kinds were grown. In growing Potatoes for home consumption, it is always better to grow the kinds that can be relied on to produce a good crop, as it is a very easy matter to dispose of a part and purchase a like quantity of later kinds with the proceeds, if it be desirable. I feel convinced from my own experience that if we could persuade small growers to give up growing the old late kinds where they so often prove a failure, and grow others of more recent date—earlier ripening kinds—a much greater quantity of food would be produced than we now obtain.

E. HORDAY.

—No doubt there is much truth in Mr. Groom's article on this subject. Fresh soil, and probably also soil of moderate richness, with little or no manure, is the most suitable for producing a sound crop of Potatoes. The difficulty in most gardens is to find such soil; hence I have long contended that the place for the main supply of Potatoes is the farm, not the garden. The constant cropping and manuring that produces the finest results in Cauliflowers, Celery, Broccoli, Peas, Onions, &c., is not the most suitable preparation for a sound Potato crop; and, besides, the majority of gardens are Potato-sick. Hence only the earliest crops should be grown inside, and the main and late crops on the farm. Here they would come in on the four, six, or eight course system, and thus new soil, as it were, would always be available for the Potatoes. This freshness of soil is probably of far more moment than its quality. The Fir wood referred to by Mr. Groom probably furnished special antiseptic properties, as well as maiden land for the Potatoes. But, of course, such a site can seldom be commanded. It is a curious fact, in reference to the disease, that the roots or shade of the trees seem a partial or complete antidote to the malady. Seldom have many diseased tubers been found in young plantations, from which Potatoes are frequently taken as a nursing crop. Recently cleared timber land—whether it might have borne crops of Fir, Oak, Ash, or Beech—has shown a similar immunity. The effects of Oak leaves were likely to be partially deterrent to disease. Their large per-centage of tannin would probably prove as much or more fatal to the Potato fungus than Mr. Smith's "Salus." But be all this as it may, I think Mr. Groom

probably over-estimates the deterrent power of light soil as a preventive of the Potato disease. Last year especially the disease seemed impartial and indifferent as to soil. Light and heavy, medium and mixed, all seemed hit with equal virulence. Neither is it always the lightest soils that grow the cleanest samples, nor Potatoes of the highest quality. There is no vital or mechanical correlation between dryness in the soil and meanness in the Potato; on the contrary, it is often found that the cleanest samples and the best boilers are raised from the heaviest lands. With proper cultivation these often produce the most satisfactory results. Not, however, that heavy loams or clays are to be selected if lighter or more mixed lands are available, but that too much importance is attached to the mere lightness of the soil. It is a pleasure to be able heartily to endorse Mr. Groom's remarks on the importance of early thorough autumnal cultivation for the Potato. If the ground be poor, it may safely be manured; but it should be applied in the autumn to the land, and not direct to the seed in the spring. Deeply ploughed or dug in the autumn, left as rough as possible for the winter, and thrown up into ridges as soon in the new year as the weather permits, the entire mass of the earth would be aerated, mellowed, and enriched. The sets could be planted in these weathered furrows, and the ridges, with their thick layer of sweetened, warmed, fine soil split over them for a covering. The tubers would thus start with every earth influence in their favour, and it would be found—is, in fact, found, as measured by results—that the wares to plant is of less moment than the how. Fortunately, too, for Potato growers and eaters, the latter is within reach of all, while light soils or old woods are within reach of comparatively few. In regard to varieties the practice of West Suffolk seems to vary widely from that of East. Here such sorts as the Rough Red, Flukes, and Regents are almost driven out of cultivation by the Early Rose, Climax, and Red-skinned Flour-ball. In hundreds of gardens and allotments the Rose only is grown, and, for better or worse, it seems destined for a time to drive out most other varieties. Fortunately, too, it improves every year, and is far better in quality than when first introduced. As a cropper it can hardly be excelled, and it generally gets through the disease as well as most others, though not so well as the Red-skinned Flour-ball. The Potato that suffered most with disease about here last year was the Early Vermont. We hardly managed to save the seed of it, and others are in the same predicament. For lack of space we are compelled to grow our main crops of Peas at wide intervals among our Potatoes. I have never, however, found that either the partial shade of the tops or the impoverishing action of the roots of the Peas have had any good effect in preventing the attacks or moderating the virulence of the Potato disease. D. T. FISH.

*Hardwicke House, Wry St. Edmunds.*

## NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Paris Early Market Lettuce.**—We grow a large quantity of this new Lettuce last season; but, although it grows quickly and comes early into use, it soon runs to seed, and in this and other respects it is inferior to Wheelers' Tom Thumb, which I consider to be the best summer Cabbage Lettuce in cultivation.—CAMBRIDGE.

**Paraffin and Mice.**—Trusting to a recommendation in *THE GARDEN* last autumn, I planted two round beds and a long border with Crocuses, on which the mice have been feasting every night to that extent that I have just dug up the two beds, after taking the very few remaining to help to fill up the long gaps in the border. The smell of paraffin was quite strong on turning up the beds; besides this, several traps of poison have been taken, and I have caught three or four mice in steel traps. I am afraid the case is hopeless.—G. T., *Mells*.

**A New Mode of Cultivation of the Potato,** recommended by M. Calloigne, consists in placing on soil, deeply dug or tilled, halves of ordinary sized Potatoes at certain intervals apart, or, better, entire Potatoes at greater distances asunder, and in regular lines. The Potato (which is not placed in a furrow) is covered with a light layer of earth. In such good conditions of ventilation it is not long in penetrating the layer of mould, and after a few days it is repeatedly earthed up, to accelerate the growth. This method of planting is said to give very much better results than the common method of planting in furrows, and the Potato acquires its maturity before disease is declared. The Potato, coming originally from Peru, a country much hotter than ours, requires (says M. Calloigne) that the soil should be kept in a support, a medium round which as much air and heat should be made to circulate as possible. To put it in a cold trench, compact and moist, is to hinder its growth and reduce its production considerably, also to subject it voluntarily to the most troublesome influences of disease. [This is a good plan, but not new; it is the mode of planting usually adopted in Ireland.]

## THE INDOOR GARDEN.

### CULTURE OF ERIOSTEMONS.

ERIOSTEMONS are plants by no means difficult to cultivate. They are very suitable for conservatory decoration, and will bloom freely even in 4-in. pots, although they may be grown into large bushes. To be successful in their culture, vigorous bushy young plants must be procured, well-established in small pots. If they can be had in 3-in. pots it will be an advantage, as plants of that size are pretty well sure to be free and healthy at the root, and unless that is the case future progress will not be satisfactory. It is mere waste of time to attempt the formation of good specimens from plants which may have stood two years or so in the same pot, as they then become stunted, and can never be again made to acquire that free, healthy growth which is one of their characteristics when generously treated. They should be potted in turfy peat, broken small, to which should be added enough silver sand to keep it sweet and open. It is also very important to ensure perfect drainage, as although the Eriostemons enjoy abundance of water when in full growth, yet stagnation of moisture at the root is fatal to their well-being. They should be shifted in March, potting firmly, but not ramming the soil down, and placed where they may be kept close for a time, and occasionally syringed, until they come fairly into growth, when they should receive as much air as possible. They will thus be induced to form stout, short-jointed wood, which, when spring arrives, will be studded with little star-like blooms. By the second season they will have become established in 6-in. pots, when they must receive a little attention in the way of training. This will simply consist in placing one neat stake in the centre, to which the main stem is to be firmly attached, and four others at regular intervals near the edge of the pot. By means of these latter the plant is brought into shape, so regulating the branches that each one has room to grow and develop itself. The lower branchlets should be brought down as near to the edge of the pot as possible, as one of the objects of early training is to induce the formation of a good spread of bottom foliage. In a well-grown and trained specimen the stem and stakes will be almost hidden by the lower shoots. As the plants increase in size, more and larger stakes will be found necessary, the aim of the grower being to render efficient support, inducing symmetry of form without running too much into formality and regularity. If grown on into large specimens, this observation will especially apply, as many a good and handsome plant is spoiled through over-training. The Eriostemons are propagated by grafting them on *Correa alba* and ferruginea. The proper time to effect this operation is in August. Two-year-old stocks should be chosen, and the grafts should be placed as in the ordinary manner of side grafting. They should then be put into close frames in a propagating house and given air daily until struck, when they must be gradually hardened off. *E. buxifolium*, *intermedium*, *pulchellum*, and *seabrum* rank amongst the prettiest of the genus, all the species of which are very floriferous and distinct. JOHN CORNHILL.

*Byfleet.*

### LARGE-FLOWERING PELARGONIUMS.

As Pelargoniums, and especially the delicate fancy varieties, are susceptible of cold, a little fire-heat is absolutely required in frosty and, indeed, in dull, clammy weather. The plants can scarcely be said to cease growing at any time during the winter, and now, while the weather is mild they make a decided headway. Now is the time to lay the foundation of specimens in the case of young plants that have not yet been trained. A piece of strong bast should be tied round the pot just below the rim. A fine, but sufficiently strong, thread of the same material should be placed round the lowermost branches, which should be thersly gently brought down to the rim of the pot, taking care to apply the necessary force in such a manner that they do not snap off. The advantage of this method is that the hearts or centres of the plants, which otherwise would be much crowded, are thrown open, the surface of the specimen is broadened, the area of bloom is increased, without any necessary assumption of that severely formal mode of training seen at the large London flower shows. By judicious stopping, a good level framework of a plant can be had, but the shoots should be a little longer in

the centre than towards the edges. Anyone having a warm house can manage to have a long succession of *Pelargoniums* in flower. If some that are well established in pots have a little fire-heat given them in the evening, keeping them at about 50°, their growth will be accelerated without drawing if ventilation be afforded when necessary. Then the heads of bloom can be prolonged into late summer by keeping some of the later-flowering varieties at a moderately low, but safe, temperature. Cuttings taken in August, and put singly into small 3-in. pots, make capital plants for flowering late if they be stopped, low down in October, and then shifted in early spring as soon as they push into growth. They should be shifted into  $\frac{1}{2}$ -in. pots, and again into 6-in. pots, in which to flower. They do not make large specimens, but they grow into capital blooming plants. Greenly in troublesome now, and no pains should be spared to keep the plants clear. D.

### NEW HYBRID FUCHSIAS.

At a late meeting of the French Société Centrale d'Horticulture a letter was read from M. Lemoine, of Nancy, on some new hybrid Fuchsias obtained by him. Fuchsias, says M. Lemoine, are crossed with the greatest difficulty. Notwithstanding this, I obtained a hybrid variety last year which I unfortunately lost through not knowing the proper conditions of cultivation. This year I am in the same position. I hope, however, on this occasion to arrive at a better result. I have succeeded in crossing *Fuchsia boliviana*, which has the general habit of *F. corymbiflora*, although distinct from it in many of its characteristics, with a species which I received from the well-known traveller, M. B. Roehl, and which I have called *Fuchsia izarea*. The last-named Fuchsia has more interest for the botanist than for the horticulturist; nevertheless, its flowers, which are very small, with a thin tube, are remarkable for their colour, which has all the brilliancy of that of *Pelargonium zonale*. It was with the pollen of *Fuchsia izarea* that I fertilised *Fuchsia boliviana*. By this means I obtained a hybrid having the general appearance of *F. boliviana*, with the same bunches of flowers, but they have the divisions of the corolla turned outwards like those of the *F. izarea*, but with all its brilliancy of colour. Cuttings of this hybrid may be struck with the greatest ease, but if they are kept too warm they all die. It is only since I transferred them to a comparatively cool Orangerie that they have thriven. At the present moment they are showing buds on their extremities. Like the *F. izarea*, this hybrid must be kept in the most complete shade during the summer. C. W. QUIX.

**Solanum Berries and Mice.**—Where *Solanum* berries are used for winter decoration, care must be taken to keep mice from them, as I find them invariably the most troublesome little depredators which spoil a good collection of plants in a short time. They climb up the branches and gather the berries as readily as a squirrel. Their presence may be detected by the remnants of the berries left on the surface of the pots. For catching mice I find the old-fashioned figure 4 trap very effective; any ordinarily handy labourer can make and set it, and at this season of the year I find it a good practice to keep a few set in various parts of the gardens, so that Peas and other seeds may not be molested.—J. GROOM, *Henham*.

**Tulips for Dinner-table Decoration.**—These are highly effective, as their brilliant colours show themselves off to great advantage under artificial light. We grow quantities of them specially for that purpose in 3-in. pots, three bulbs in a pot, and just as they are expanding they are at their best. Vermilion Brilliant is a striking variety, being a true vermilion with stout foliage; Pottebakkers, white and yellow, are exquisite; and the Duc Van Thol is also exceedingly effective, being dwarf and a good forcer for early work. Amongst double Tulips we find the best to be Tournesol, red and yellow; Duc Van Thol, scarlet; La Candeur, white; and Imperator rubrorum, crimson. In beds of fresh green Moss or Lyco pod, or mixed with dwarf *Adiantums* or *Pterises*, these kinds are extremely useful. The same, or perhaps even a better, effect may be produced with Hyacinths, but when they are used in quantity their perfume is considered by many to be too powerful, except when ample ventilation can be given.—J. GROOM, *Henham*.

**Hyacinths a Second Year.**—What is the best way of saving Hyacinth bulbs that have flowered in glasses and pots?—*Sir*. [As a rule, Hyacinths which have been forced in pots or glasses do not succeed well the second year, but you might try them treated as follows:—Cut off the flower-stems as soon as the blooms have withered, and plant the bulbs, without removing the soil from their roots, in the sunniest part of the garden in good moist sandy soil, or plunge them as they are in the pots. In September take up the bulbs, shake the soil from them, and re-pot them in rich turfy loam and sand.—*S*.]

### PLATE CXVIII.

#### TUBEROUS-ROOTED BEGONIAS.

Drawn by Miss DUFFIELD.

THESE beautiful, free-blooming, and easily cultivated flowers are rapidly becoming great favourites; and the more widely they become known, the more will they commend themselves to the notice of horticulturists, as undoubtedly the best value they can possibly obtain for their money—in the first instance, during the months of June, July, August, and September as ornaments of the summer bedding garden; and, secondly, as soon as there is any danger of frost at night, as ornaments of the conservatory for another month or six weeks by lifting them into pots from the beds, which can be done without the slightest check, as they invariably lift with capital balls and masses of fibrous roots closely and compactly surrounding the tuber. They thus afford from five to five and a half months of continuous and unintermittent bloom, which is more than any other plant with which we are acquainted will do. All that they require to make them thrive and grow luxuriantly and quickly into large, freely-branching tufts, which soon completely cover the beds, is a light rich soil, and copious waterings while making their growth if the summer be at all hot or rain abstain from falling for any length of time. The beds should also not be planted too thickly, as if the tubers be at all strong and of good size they make such vigorous and abundant growth, that if put too close to one another, the plants will soon crowd and interfere with their neighbours; but when this inadvertently happens, every second one may with perfect safety be taken up even in the middle of summer and removed to another bed, where, after a good watering, it will next day appear as if it had never been transplanted at all, and the room afforded by its removal will be most welcome and serviceable to those left in the bed, allowing them fully to develop themselves, by means of which growth they will soon cover and fill up the gaps made by the removals in question. All that they require is a sheltered situation, well and fully exposed to the sun, as the only thing to which they object is exposure to high winds, which are apt to break off the soft succulent stems at their junction with the tuber. No amount of heavy rain does them the slightest injury; the blooms are not knocked off by it, and though the heads droop somewhat and bend under it, they rise again absolutely uninjured as soon as the sun shines out after the shower. Those who wish to increase their stock of these lovely plants (as most who once begin their cultivation will desire to do) should begin in good time to take off their cuttings, just as they would those of a Zonal *Pelargonium*, about the middle of July, and these cuttings will root freely in silver sand and water in from a fortnight to three weeks, and before the end of the season make good-sized tubers, which often give a little bloom towards the end of autumn, and flower abundantly in the open ground the following year. Indeed, young tubers in about their second year often yield individually finer blooms than older and larger ones, which, as soon as they commence to start and show the eyes from whence the shoots spring, may be cut up just like a Potato.

The accompanying plate gives a faithful and accurate representation of three of the finest hybrids of British origin that have yet been obtained. The white one, named Queen of the Whites, is not yet in commerce, but it will be distributed by the Messrs. Veitch, of Chelsea, as soon as they can get up sufficient stock of it. The free-blooming, though smaller-flowered, species named Davisi, after Messrs. Veitch's collector, Mr. Davis, who sent tubers of it to them from Peru, is also not yet in commerce. The name of the lighter-shaded variety under Davisi is Emperor, sent out in 1877; and that of the fine, darker-shaded variety at the bottom of the plate is Acme, sent out the previous year, and which is certainly one of the finest and most free-blooming of all varieties. The Queen of the Whites, obtained as a chance-comer among a lot of seedlings of *rosiflora*, seems also to be an exceedingly free bloomer—a pan of small plants, all of them finely in bloom, being sent by Messrs. Veitch to the great show at Carlisle last autumn, where they presented an exceedingly pretty appearance, the shade of white resembling that of *Cypripedium niveum*.

W. E. G.

## THE FLOWER GARDEN.

### BEDDING PLANTS FROM SEED.

It is not everyone who has the space or means to provide and winter a large number of Pelargoniums and other tender bedding plants. No matter how favourably one may be situated, the keeping of a large stock of such plants involves a good deal of trouble, and takes up space that might be more profitably occupied. Moreover, it is quite practicable to make a garden very gay in summer and autumn—I will say nothing now about winter or spring—with seedlings alone, without keeping or purchasing a single plant; and a comparatively small amount will buy the seeds required. There will, of course, in some cases be a difference in habit and some variation in colour, as in those particulars a certain natural freedom, involving some departure from the normal type, is nearly always perceptible in seedlings, and must be expected; but to many people this will not be an objection. There are, however, a few plants which come true from seed through many generations; one of these we have in *Verbena venosa*, one of the best and most pleasing hardy bedding or border plants. I have raised many thousands of this *Verbena* from seed, and never saw any variation in them. It would be a great help to flower gardeners if other shades of colour of this useful old plant could be obtained. Another plant that comes true from seed is the *Salvia patens*; but both this and the preceding should be sown in a hotbed early in spring, in order to get them into flower early. This *Salvia*, as is well known, has tuberous roots, which can be taken up and stored in dry sand safe from frost. It is one of the most brilliant blue summer-flowering plants in existence, and was used more freely many years ago than now. Lobelias of the speciosa section come fairly true from seed; there may be some variation in strength and compactness of habit, but this feature can be subdued and regulated by cutting or pinching back any plants that seem disposed to outgrow their neighbours. Can anything, again, as a mixed bed be more showy than a mass of seedling *Petunias*? The colours are not harsh and irritating like the scarlet *Geranium*, but soft and pleasing; the soil need not be rich—in fact, they flower best in a rather poor soil—and in the driest summers they do not require artificial watering. There is, however, I suppose, some drawback to every earthly thing, and towards the autumn, especially if the weather be damp, they have a tendency to over-luxuriate, and to droop over the edges of the beds. The best way to keep them within bounds is, instead of pegging them down, to form a sort of rough trellis-work 6 in. or 8 in. above the soil, and train the shoots over it, not waiting, of course, till the shoots are too long before this is done, or the difficulty in putting matters right will be increased a hundred-fold. Treated in this way, the beds have a neat and tidy appearance, and I think also this training tends to check growth and keeps the plant more compact. Seedling *Verbenas* make a handsome bed, little inferior to the *Petunia*; and for a large bed, where the soil is good and deep, few things are superior to the double *Zinnias*, which can be had in various colours, separately if desired. Balsams, again, are not half so much used for open-air decoration as they deserve to be. Those who have only seen them starving in small pots cannot form an idea how beautiful they are when planted out in good soil in an open situation away from trees. Among yellow-flowering plants, the small single form of *Tagetes signata pumila* is useful, but it is not equal to the double variety, which really makes a very handsome bed. Both of these, however, no matter how carefully saved and selected, are all the better for having their growth regulated a bit till the beds are filled.

Those plants that take the lead should be pinched back when necessary, and this can be done without encouraging too much severe formality. However much we may be in love with Nature, there is an incongruous appearance about a group of plants that seem to have no natural resemblance to each other. Nature never groups plants in that way, and the pinching of a robust shoot when necessary adds to the plant's blooming capacity. For large beds or back positions in borders, the lemon and orange varieties of the African *Marigold* are very lasting and showy. The dwarf kinds of *Ageratum*, if selected and saved with care, may be raised in a gentle heat with but little trouble, and, with a little management, in summer very effective masses may easily be had. The tuberous *Begonias* will some day be a prime feature in sheltered positions; they will grow in all the colours of the *Pelargonium* without their liability to be washed out by rain, or exhausted by attempts at seed-bearing during periods of drought, and they require no expensive preparation to keep them through the winter. I have no doubt in a well-drained site they may be kept as easily as *Cannas* under a covering of litter. They may be raised from seeds in a hotbed, and if sown early and well attended to, most of the plants will flower the same season. The seeds are very small, and must be only lightly covered, just the merest

sprinkle of sand. Much more might be said upon this subject, and many other names of suitable plants given, not only of flowering plants, but also of plants of stately or pleasing habit of growth, all of which may be raised from seed, and will continue in most cases to improve in appearance during the summer and autumn till cut off by frost. I have said nothing either about the large number of perfectly hardy plants well suited for massing, and that cost nothing to keep. Take, for instance the large family of *Violas*, in almost all shades of purple, yellow, and white, and even a black may be had if desired. In a limited space one can only touch upon a subject so large in a very superficial manner, little more, indeed, than just to act as a reminder; and in doing so I do not wish it to be inferred that I am recommending those who have plenty of conveniences for wintering their stock of plants and cuttings, and who care little about winter or spring flowers, to give up doing so. I am only anxious to point out that by curtailing the winter stock, and making up with seedlings raised in spring, the space under glass perhaps might be more profitably occupied. Most of the plants I have named, and others of a similar character that might be added to the list, such, for instance, as the various varieties of *Phlox Drummondii*, which in good soil are exceedingly attractive and lasting in character, require a hotbed to start them in spring.

The best time to begin operations is about the end of February or beginning of March. Some anxious people start earlier, but it is better to wait for sunshine and full daylight, so as to keep a steady, well-sustained growth. The size of the hotbed must of course depend upon the number of plants required; but an ordinary two-light frame will hold seed-pans or pots sufficient to raise many thousands of plants in their young, undeveloped state. A second hotbed of a moderate temperature will be required later on—say about the middle or end of March—as by that time many of the young seedlings will require to be pricked off, as gardeners term it, an inch or so apart, into other pans; or boxes will do admirably. And early in April a cold frame or pit should be available to harden them off, beginning with the hardiest kinds. In this way an economical and efficient plant manufactory will be established, that will give far less trouble than striking the same number of cuttings, for which a stock of plants must be kept through the winter. There are one or two other matters of detail that might be referred to with advantage. The pots or pans should be clean and well drained. The soil should be used in a moderately dry state; this can be insured by placing a sufficient quantity in a shed a fortnight previous. Sandy loam and leaf-mould in about equal proportions will be suitable, and it can be passed through an  $\frac{1}{2}$ -in. sieve, and the rough reserved to place over the crotches in the bottom of the pots. The soil should be pressed in moderately firm, and be watered with a fine-roset pot, especially for all small seeds, as in a great measure this obviates the necessity for future waterings till the seeds have germinated. The covering of soil over the seeds should be about equal to the diameter of the seeds, or a little more. A sprinkle of sand will be the best covering for very small seeds. A bottom-heat of about 80° will be ample, and a few inches of sawdust or Cocoa-nut fibre forms a very good bed to plunge the pots in. When the pots are all arranged in the bed, mark it up for a week, night and day; the seeds will vegetate best in the dark; the light only helps to evaporate the moisture. At the end of the week look into the bed and see if any of the young plants are showing themselves; if they are, gradually increase the light, matting up every night, as before. The second hotbeds must be prepared in time, before overcrowding does injury.

E. HOBDAY.

### THE HOLLYHOCK AND ITS CULTURE.

NOTWITHSTANDING the damp character of the summer of 1877, the Hollyhock disease proved most destructive. It, together with the wet late season, so much affected the plants, that seed of a good strain of Hollyhocks is exceedingly scarce and difficult to be procured. For this season, at least, we shall have to depend mainly on seed imported from the Continent. At the autumn exhibitions in the north of England, where Hollyhocks are generally shown extensively and well, they were in September last not only sparingly represented, but the flowers were small and sadly disfigured. Such a season as that of 1877 may not, however, occur again for another ten years. In growing Hollyhocks, especially for exhibition purposes, much care is required in the selection of varieties, and particularly in reference to their culture. The first consideration ought to be a proper situation and soil in which to grow and bloom the plants. Probably the best site for a plantation of Hollyhocks is one open to the east and south, but sheltered on the west and south-west. The gales from these parts prove very destructive, and it is a great disappointment to have some of the most promising flower-stems snapped off just when a fine spike of flowers was anticipated. As the Hollyhock is a strong and fast-growing plant, a good depth of rich soil is absolutely necessary to the production of fine blossoms. It is best to prepare the ground in

autumn, and then during the winter to fork in once or twice a good dressing of well decomposed manure. This operation not only mixes the manure more thoroughly with the soil, but the movement of the soil necessitated by the operation becomes a means of exposing a greater quantity of the newly turned up soil to the action of the weather, thereby pulverising and sweetening it for the reception of the plants. Autumn planting is sometimes followed, but it is a risky process. If the plants do well and pass through the winter in safety, they get a rare start in early spring; but if they fail, the loss is great. If I were growing a collection of Hollyhocks, and it was advisable to plant in autumn, I should hold over one of each variety, keeping the plants in pots all the winter. Hollyhocks, if young and vigorous plants, do well during the winter in pots in a cold frame; and they should have a shift into a larger pot in early spring, so as to encourage them to grow. From plants so treated as fine blooms can be had as from those planted out in autumn. Growers of Hollyhocks who plant out in October adopt the practice of mulching the plants with manure and rotten leaves, and this serves as an excellent protection from frost. Spring planting may be done at any time during March and April. If the plants are weak, they will be best kept in pots till May. They are greatly helped at planting time by placing some fine rich soil about the roots to give them a quick start. It is advantageous to give the plants a slight watering as soon as planted if the weather be drying, and when dry weather sets in to water freely, and give some weak liquid manure water occasionally. This causes the plants to throw up a most vigorous stem, and this needs to be properly secured to a stake as it advances in height. Those who grow for exhibition allow but one spike to a plant, but those needed only for decorative purposes may be allowed to carry two or more. If fine individual blossoms are required, the buds must be thinned out to nearly one-half of their number, for anyone having a slight knowledge of the Hollyhock must be aware that many more buds are formed than there is space to expand. But a Hollyhock cultivator does not do this disbudbing at once, but commences with a few of the smaller buds, leaving the strongest, and so gradually thinning out till there remains the number required. If blooms are wanted for the exhibition table, some shading must be employed, or the sun, wind, and rain will impair their delicate beauty. Mulch well with good manure once or twice during the summer, water freely as required, and, if the dread disease should put in an appearance, dress the leaves with a mixture of soft soap and Gishurst Compound in a liquid state, and continue to apply it till there is an abatement of the ravages of this pest. D.

### PROPAGATING BEDDING PLANTS.

THE modern propagating house is yet but a stranger in most private gardens, the two or three-light frame resting on a prepared bed of fermenting material being the most commonly used, for reasons which must be obvious. This, together with pots or pans and soil proper for the purpose, must now be got ready where bedding plants have to be propagated on a large scale. The stock of Lobelias, Verbenas, Heliotropes, and other occupants of our flower gardens should be put into heat a fortnight at least before cuttings are taken off them, as the young soft growths made under such circumstances take root and grow more vigorously than the hard growth that was ripened off last autumn to withstand the winter. Early propagation is often a failure from want of a little system as regards arrangement; for instance, cuttings taken from plants out of a warm house and removed to a cold shed, where everything is cold, from the crocks upwards, cannot be expected to succeed as well as if there had been some little care taken to have all the material in readiness beforehand, and of an equal temperature. This becomes a matter of importance when the cuttings are rooted and are being transferred either to pots or boxes, where they are to remain till planting time. Verbenas and similar plants I find to succeed best transplanted into boxes, which should be crocked and filled with rich soil, such as the remains of a Cucumber bed. Both boxes of soil should be put into a warm house, and the cutting pots or pans should be taken thither to be shaken out and planted into the boxes. Those who prefer putting this class of plants in pots instead of boxes can take the same precaution by moving a portable bench into a warm Vinery or other forcing house "at work." It is generally at this stage that young plants receive a check, and instead of steady growth progressing with the season, the attacks of disease become in a measure unmanageable. Verbena disease is clearly propagated in this way; it is the result of checks and a saturated atmosphere, and is an infectious and dangerous enemy. The best remedy for it is not to start propagating too early, and to avoid checks keeping the plants in a growing atmosphere till the weather becomes naturally warm enough to admit of their being hardened off gradually, and ultimately turned out of doors. Where the stock of bedding Calceolarias has, by one cause or another,

turned out unsatisfactory, this defect can be filled up by making a bed of litter to the depth of about 2 ft. or so, just enough to create as much warmth as will expedite root action. On this bed place a frame of the size that is required, and fill it up to within a foot of the glass with the siftings of leaf-mould, a layer of fine mould being used for the top, then put a layer of sand over this, and insert the cuttings thinly, keeping the frame close and moist till they show signs of active growth, when air should be admitted freely. The stock thus raised may be planted out finally from this frame without further trouble. W. HINDS.

*Otterspool.*

### ATHYRIUM FILIX-FEMINA ELWORTHII.

THIS Fern, of which the annexed is a representation, was raised from spores by me, with many other tasselled varieties, from the true grandiceps, which I found myself—not the plant that the late Mr.

*Athyrium Filix-femina Elworthii.*

Ivery sent out under that name, which is properly macrocephalum, also raised by me, and called by Mr. Lowe scopiforme. Since then I have raised a great many very beautiful forms which are as yet unnamed, and also some that are named. C. ELWORTHY.

*Nettlecombe, Taunton.*

**Polyanthuses and Primroses.**—A writer in one of your contemporaries assumes that these are one and the same. I do not agree with him. He appears to regard the Gold-laced Polyanthuses as really representative of the Polyanthuses, but all others that are termed "Fancy" Polyanthuses, to distinguish them from the Gold-laced types, are but advanced forms of Primroses. If he grow the true Primroses and the Fancy Polyanthuses, he would soon find marked and even specific differences between them. A clergyman, writing to me from Kent, states, "I find it hard to save Primrose seed, but can get any amount from Polyanthus." Herein is one great difference. Another is that the seed of the former is smaller, and of a paler colour. Others might be named, for they become familiar to those who cultivate varieties of the two sections; but they would not be understood by those who are not growers of these flowers.—D.

**Leucothoe Davisiae.**—This beautiful little evergreen shrub is closely allied to Cassiope, from which it seems to differ chiefly in the corolla being more contracted at the mouth, and in having larger, petioled leaves. It grows from 3 ft. to 5 ft. high, bearing bright green, leathery, oblong, blunt foliage, 1 in. or 2 in. long, with spiny-toothed margins. The flowers are pendulous, on slender erect terminal and axillary racemes, which are produced in abundance; the corolla is pure white, about  $\frac{1}{2}$  in. long, and of a cylindrical or ovate form, with contracted mouth and five short spreading teeth. It is a native of the Sierra Nevada, California, and will probably prove quite hardy in this country, with the culture of other North American Ericaceae. The seeds, being very small, must not be covered with soil, but simply with a layer of damp Moss, and a cold frame with a northerly aspect will be the most available place for raising them.—W. THOMPSON, Ipswich.

**Banksian Roses.**—Is the white Banksian Rose a free bloomer? If it is, we have not got the true one. The yellow or lemon-coloured variety on the same wall is annually laden with flowers.—J. G.

GARDEN BOTANY.

(Continued from p. 193.)

TEMPERATURES AT WHICH DIFFERENT SEEDS WILL GERMINATE.—Numerous experiments have been carried out to ascertain the lowest and highest temperatures at which different seeds will germinate, and the temperatures most favourable to the growth of diverse plants. Some of the results obtained by the most trustworthy observers are so interesting, as to deserve citing, especially as they chiefly relate to plants in general cultivation. In all cases the figures have been reduced to Fahrenheit's scale. Any figure over 5 in the second decimal place in the conversion is raised to 1 in the first place. Leaving the microscopic organisms of the vegetable kingdom out of the question, the inferior limit of active growth is about 32° and the superior limit 120°, though few plants reach either of these extremes. Professor Julius Sachs obtained the following results from observations made to determine the temperature at which germination would take place, at what temperature it proceeded most rapidly, and the highest temperature at which the seeds would germinate at all:—

	Inferior limit.	Most rapid growth.	Superior limit.
Wheat . . . . .	41° Fahr.	53° 7 Fahr.	108° 5 Fahr.
Barley . . . . .	41	53 7	108 5
Pumpkin . . . . .	56 7	92 7	115 2
Kidney Bean . . . . .	49 1	92 7	115 2
Maize . . . . .	49 1	92 7	115 2

The foregoing figures can only be considered as approximations to the truth, but they may be accepted as sufficiently exact for all practical purposes. It is, of course, exceedingly difficult to obtain those relating to the extreme limits, and the observations of different persons do not absolutely agree. Indeed, it is not at all likely that they would be identical in all cases, independently of the difficulties attending the experiments, because the vital energy of the same kind of seed would not invariably be the same. According to this table, Wheat will not germinate below 41° Fahr., nor above 108° 5; but another observer, Köppen, obtained 45° 5 as the lower limit at which it would germinate, and 85° 5 as the temperature at which its growth was most rapid. The figures relating to Maize by both observers are almost identical. De Vries obtained the following results from experiments instituted to ascertain the most favourable temperature for the growth of the plants in question, and the upper limit of temperature at which growth ceased:—

	Most rapid growth.	Superior limit.
Kidney Bean . . . . .	88° 7 Fahr.	above 108° 5 Fahr.
Sunflower . . . . .	88 7	below 108 5
Cabbage . . . . .	88 7	108 5
Hemp . . . . .	88 7	above 108 5
Melon . . . . .	99 5	99 0
Mustard . . . . .	81 3	below 99 0
Cress . . . . .	81 3	below 99 0
Flax . . . . .	81 3	above 99 0

There is no doubt that the temperatures given in the last table refer simply to germination or to subsequent growth for short periods only; and those given for the most rapid growth are probably all too high for the healthy development of the plants. The temperature given in the next table, from observations made by A. de Candolle, seem to be more in harmony, generally speaking, with the results of practical experience, though Sachs characterises them as "moderately trustworthy, as far as relates to the inferior limit, but hardly so much so with respect to the superior limit and the temperature of most rapid growth," as, he adds, "may be concluded by comparing with the results of other observers." It is evident that different observers have not conducted their experiments on precisely the same basis, and therefore they have not the same value from a practical point of view.

	Inferior limit.	Most rapid growth.	Superior limit.
Mustard . . . . .	32° Fahr.	69° 3 Fahr.	32° 4 Fahr.
Cress . . . . .	35 2	69 3	32 4
Flax . . . . .	35 2	69 3	32 4
Collomia . . . . .	41 0	62 6	about 82 4
Nigella . . . . .	42 3	above 69 3 (?)	82 4
Candytuft . . . . .	42 3		
White Clover . . . . .	42 3	69 3—77 0	below 32 4
Maize . . . . .	43 2	69 3—82 4	about 95 0
Sesamum . . . . .	55 5	77 0—82 4	below 113 0

ROOT-GROWTH AT DIFFERENT TEMPERATURES.—This part may be concluded with some figures of the lengths attained by roots in the same number of hours at different temperatures, giving the lower and upper limits of the growth of the roots of seedlings. The figures relate to Maize, and were obtained by Sachs during periods of 48 hours. In the original the measurements are given in millimetres and tenths, but to one unfamiliar with the French metric system these figures convey no definite idea of the actual lengths, and therefore they have been converted into parts of an inch. These are, however, not absolutely correct, because, in order to simplify the calculations, a millimetre is taken as 0·04 of an inch, and 0·4 of a line or tenth of an inch.

Temperature.	Length attained by the root, Millimetres.	Lines.
62° 3	2 5	1 0
79 2	24 5	9 8
91 8	39 0	15 6
93 2	55 0	22 0
100 8	25 2	10 1
108 5	5 9	2 4

It will be seen that there was a rapid increase in the growth of the roots of Maize for each increment of temperature up to a certain point, above which, subjected to successively higher temperatures for periods of forty-eight hours, there was a marked decrease. Sachs does not state whether he continued his experiments in successively higher temperatures until growth was quite arrested. The difficulties attending experiments of this kind are so great, that it would be necessary to have the mean growth, at given temperatures, deduced from many series of observations, all conducted on the same plan, before we could act upon the results in practice. The following tables are interesting, as showing the discrepancies and agreements in the results of different observers, and the most favourable temperatures for the root-development of various plants. Throughout the figures relate to growth during periods of forty-eight hours. The first table embodies results obtained by Köppen:—

Temperature.	Lupin.		Pea.		Maize.	
	Millimetres.	Lines.	Millimetres.	Lines.	Millimetres.	Lines.
57° 4	9° 1	3° 6	5° 0	2° 0	0° 0	0° 0
64 4	11 6	4 6	8 3	3 3	1 1	0 4
74 3	31 0	12 4	30 0	12 0	10 8	4 3
79 9	54 1	21 6	53 9	21 6	20 6	11 8
83 3	50 1	20 0	40 4	16 2	36 5	14 8
86 4	42 8	17 5	35 5	15 4	64 6	25 8
92 3	14 2	5 7	25 0	9 2	69 5	27 8
97 7	12 6	5 0	8 7	3 4	20 7	8 3

Among the most noteworthy features of the above table are the temperatures at which each of the plants exhibited the greatest energy of root growth, and the actual lengths which the roots attained in periods of forty-eight hours. Both the Lupin and Pea made the longest growth at a temperature, in round numbers, of 80°, and in both instances the actual length attained, about 2 in., was the same. Maize roots grew most rapidly at a temperature of 92°, reaching nearly 3 in. in forty-eight hours. This agrees very well with the results obtained by Sachs, his greatest growth of Maize roots being at 93°, namely, 2·2 in., which was reduced nearly half on raising the temperature to 100°. The next table is the result of experiments conducted by De Vries:—

Tempera- ture, metres.	Melon.		Mustard.		Cress.		Flax.	
	Milli- metres.	Lines.	Milli- metres.	Lines.	Milli- metres.	Lines.	Milli- metres.	Lines.
59° 2	0° 0	0° 0	3° 8	1° 5	5° 9	2° 4	1° 1	0° 4
70 9	0 0	0 0	24 0	10 0	38 9	15 6	20 5	8 2
81 3	13 2	7 3	52 0	20 8	71 9	28 8	44 8	17 9
87 1	27 1	10 8	44 1	17 6	44 6	17 8	39 9	16 0
93 0	38 6	15 4	30 2	12 1	26 9	10 8	28 1	11 2
99 0	7 3	28 1	10 0	4 0	0 0	0 0	9 2	3 7

Generally speaking, the figures of this table accord with the results of practical experience, and they give a good idea of the diversities in the constitutions of plants. One point especially deserving of attention is the fact that plants native of temperate climates attain their maximum energy of growth at a temperature at which a tropical plant, like the Melon, commences growth, or grows very feebly; and the temperature most favourable to the development of the Melon was highly detrimental to the health of the others, and completely arrested growth of Cress. Köppen, who has conducted a vast number

of experiments bearing upon the effects of heat on the growth of plants, found that the more constant the temperature, the greater the increase of growth for the same amount of heat, and the greater the fluctuations the less the growth in proportion to the mean temperature for a given period. To give an example, a seed of *Pisum sativum*, common Pea, which had germinated and grown during 144 hours at a constant temperature of  $59^{\circ}2$  the roots had attained a length of about  $4\frac{1}{2}$  in.; when the mean temperature for the same period was  $60^{\circ}8$ , oscillating between  $65^{\circ}$  and  $59^{\circ}$  twice, the growth amounted to only  $3\frac{1}{2}$  in.; and when the temperature varied between  $59^{\circ}$  and  $80^{\circ}$ , the mean being  $64^{\circ}4$ , the length attained by the roots was only  $2\frac{1}{2}$  in. This seems to be all that is necessary to say here on this subject, but the relation of humidity, heat, &c., to the growth is more fully examined in the section on growth of plants.

**THE ACTION OF AIR ON GERMINATION.**—Healthy germination can only take place when seeds are within reach of the influence of the air. By this it is not intended to say that seeds must be fully exposed to the atmosphere, but it has been proved experimentally that the soil or water in which the seed is placed must contain some of the oxygen of the air, or the vital force of the embryo will not be quickened. Left to itself, the penetration of air into the soil is a slow process, but frequent digging and stirring effects the object quickly, and renews the supply of this element, besides benefitting the growing plants in other ways. Every practical gardener is aware of the almost marvellous effects of repeated hoeing among crops, especially the Cabbage tribe.

**ACTION OF LIGHT ON GERMINATION.**—It is assumed by many persons that light is prejudicial to germination and darkness essential to it; but most seeds appear to germinate equally as well when exposed to light as when covered up, providing always that they are kept sufficiently moist. In a natural way the only covering seeds get is a more or less thick layer of leaves, as the seeds usually fall before the leaves. Nestled among the leaves, the seed does not dry up, as it would on the bare ground, and we only imitate Nature, substituting soil for leaves usually. As a rule, it is the object of the cultivator to make the condition such that nearly all the seed germinates, and this in a general way is more easily done by burying the seed in a small depth of soil. But there are some seeds, especially small ones, that germinate more freely on the surface of the ground protected by dwarf herbage.

**STIMULATING AGENTS IN GERMINATION.**—Allusion has already been made to different means of hastening the germination of seeds, such as breaking the shells, soaking in very hot water, or even boiling for a short time. There are some substances which appear to exercise a stimulating effect in the germination of seeds and the future growth of the seedlings. Camphor, a vegetable product itself, appears to possess this property in an extraordinary degree. Indeed, it has been averred that camphor has the power of revivifying seeds, or at least of causing them to germinate when ordinary treatment failed. Benjamin Smith Barton was the first to point out its action upon plants at the end of the last century; and a few years ago a Mr. Vogel, of Munich, carried out a number of experiments with camphor on old seeds. Controlling experiments were conducted simultaneously, ordinary water being employed instead of camphor water. Seed of Cress three or four years old, treated with ordinary water, germinated very imperfectly and long after sowing, while that moistened with camphor water germinated quickly; that four years old in twenty-four hours, and that three years old in seven hours. Radish seed, which is usually regarded as useless after it is three or four years old, was tried seven years old, and it germinated in four days, or in a much shorter period than good fresh seed under ordinary favourable conditions. Seed of the Pea eight years old germinated in forty hours, and many other old seeds treated with camphor water exhibited equally rapid germination. Some that would not germinate at all under ordinary treatment had their germinative force revived by camphor. Other seeds, Clover, for instance, appeared to derive no benefit from the solution of camphor; but where it acts its influence is not limited to germination, but is extended to the subsequent growth. Humboldt discovered that chlorine accelerates germination, and acts as a restorer

where the vital force is almost exhausted or quite lost, so far as the usual method of treatment is concerned. This must be used in a highly diluted form; about two drops of an aqueous solution of chlorine in 2 oz. of water. Iodine and bromine are said to possess similar qualities. Acid and ammonia salts in very small quantities in the water have been found to hasten germination, but they have not the power of reviving seeds.

**OTHER MEANS OF FACILITATING GERMINATION.**—Under this head all the various modes of preparing different seeds for sowing would have to be considered were this a treatise on raising plants from seed. As it is, it is not out of place to direct attention to the fact that the seeds of many plants undergo, according to their nature, some process before being committed to the soil. It is, in most cases, a process of removing the pericarp or pulp from the seed by maceration, by crushing, or gradually softening by storing away in moist sand. Thus the fleshy fruits of the Hawthorn are collected in autumn, and as each fruit contains from one to three "stones," enclosing one or rarely two seeds each, it is desirable to separate and soften the stones before sowing, otherwise the seedlings would come up very unevenly and very irregularly as to time. To effect this, the fruits are mixed up with moist sand and stored away in pits or turf-covered heaps until spring, when the "stones" readily separate from each other and open. By a similar process Teak seed, which, if sown without preparation, is usually from one to two years before it comes up, may be made to germinate, as we learn from Amery's "Notes on Forestry," in three or four weeks. W. B. HEMSLEY.

## THE FRUIT GARDEN.

### DROWNING ROOT FUNGI.

I CAN fully confirm Mr. Hobday's remarks on this subject (see p. 172). I have seen many trees greatly injured by root fungi in the south of England, especially where the soil is light and shallow, resting on a subsoil of chalk. In such localities fungi are particularly destructive, evergreen trees, such as Conifers, being exceptionally liable to their attacks. When I first came to Henham I found the trees in two fine Peach houses, that had been built and planted on the most approved principle, almost destroyed by root fungi. Indeed, to such an extent was the fungus established in the borders, that the soil looked quite white and mouldy with it, and the effect was, that when the trees started into growth the young leaves turned white, curled up, and dropped off, and if rubbed between the fingers the outer skin would peel off. Many of the branches died outright; and although later in the season the trees grew away strongly, it was too late for the wood to ripen satisfactorily. In our attempts to fork out the fungus it was evident that the parts of the border most affected were those at the front near the hot-water pipes, where the roots were most abundant; while at the back of the house, where the drip from some shelves had kept the border continually wet, no fungus was to be found. We therefore resolved to try the water cure, by giving abundant supplies of rain water with the chill taken off it, weakly diluted with soot and manure water, adding a mulching on the surface to prevent evaporation. The following season only a few branches were attacked, and by cutting these back as far as they appeared affected, and training in young wood from the base, we soon had the trellises thoroughly furnished with bearing wood. The third season we had to enlarge the trellises considerably, and ever since we have annually had fine crops of both Peaches and Nectarines. I have no doubt that in this instance the fungus was introduced to the border by mixing manure with the turfy loam, of which it was principally composed. The soil being rather light in texture, and the drainage perfect, a great quantity of water would be needed by way of compensation for the evaporation from so large a surface of foliage, and also for the wants of a crop of fruit. The watering of borders that have become dry to any depth should be done thoroughly to be effective, and the surface, too, if hard, should be loosened, in order to allow the water to penetrate equally all over the border, and the watering should be repeated at short intervals; mere surface waterings are

worse than useless. No manure should be used that is at all suspected of containing any substance likely to encourage fungus growth. If the staple soil be good, fresh manure would not be required in a new border for several years, when it can be added as top-dressing or in a liquid form during the growing season.

JAMES GROOM.

**Fruit Tree Protection** (see p. 176).—Straw mat copings are used in France by many cultivators. They are fixed on the top of the walls with nails, and are supported from below by a wooden bracket fastened to the trellises with which the walls are usually covered in that country, and to which the trees are trained. However, wooden copings are also used, but these are fixtures. We are going to try this spring Spruce branches hung from a narrow coping, and we expect the result will be satisfactory. Select branches that have a curved feather-like bend, and fasten them firmly on the top of the coping. These branches will curve naturally over, and, if neatly done, this green coping will look not at all unsightly. Many may suggest other modes of fastening them on the top of the wall, but I think that two studs thus  $\square$  would be sufficient to secure each branch. Where expense is no object, glass copings, no doubt, are the best.—HENRY KNIGHT, Floors.

**Winged Pyramid.**—This handsome form of tree is figured from

A Winged Pyramid Fruit Tree.

a photograph taken in M. Jamin's very instructive garden at Bourg-la-Reine, near Paris. The Winged Pyramid form is not adopted for its appearance only, as it has advantages in the preservation of the fruit from destruction by wind, and in the perfect exposure of both fruit and wood to the sun.

**Utilising the Air-roots of Vines.**—One of the best crops of Grapes grown in pots which I have seen this year is growing in the gardens at Syon House. The pots are plunged in a small bed, in which there is a slight heat, and are mulched with soil and manure. All shoots from the base of which air-roots are produced are bent slightly down, so that these roots may be layered in soil placed in large drain pipes, which are placed in an upright position on the bed. Down these pipes the roots soon descend into the bed below, and the Vines are thus so much benefited, that where shoots would otherwise only be allowed to carry one bunch, they are in this case permitted to carry two. The most forward of the bunches have just been finally thinned, and some of them when ripe will be very large for pot Vines. To form a succession to these, Vines, instead of being potted, are planted out in a narrow bed in front of the house; and, although it is generally thought that young Vines forced early and fruited the

first year are of no use for forcing another season, Mr. Woodbridge finds that by leaving strong shoots which failed to produce fruit their whole length, or nearly so, instead of spurring them in, as good and probably a better crop can be produced the second year than the first, for the obvious reason that there are more roots, and that the second season they do not require to be forced nearly so rapidly, as they naturally come earlier.—C. S.

**Grafting Apples and Pears.**—Where trees of these are found to be unfruitful year after year, either from the varieties being unsuited to the locality, over-luxuriance, or other causes, the best way of converting them quickly into fruitful trees is to cut the entire head off, not too closely, and to graft it all over with some trustworthy sort. By this means a healthy head of bearing wood is speedily developed, small branches healing much more rapidly than large limbs that are liable to decay, and so cause the destruction of the entire tree. Double-grafted trees, as a rule, bloom more abundantly than single-grafted ones, as, owing to over-luxuriance being checked, the energies of the tree appear to be more directed towards forming blossom than wood buds.—J. G.

**Cure for American Blight.**—The remedies which have been recommended for the destruction of this are innumerable. M. H. Lusseau, a landscape gardener of Bourg-la-Reine, has just published a small pamphlet on the subject, in which he recommends oxalic acid as the best cure for this destructive insect. M. Lusseau was first led to try this powerful poison by observing the effects produced on the aphides by rubbing the trees attacked by them with the fresh leaves of the Sorrel, which contains a large quantity of oxalate of potash. M. Lusseau speaks of his specially prepared oxalic acid as being superior to any other, but this is an assertion which we must beg leave to doubt. Good oxalic acid bought from any respectable chemist, at about eighteen pence per lb., will be as efficacious as M. Lusseau's. The acid should be dissolved in the water in the proportion of one ounce to seven pints, and the solution well scrubbed into every nook and cranny of the tree. Ten days afterwards the operation should be repeated, as it frequently happens that a few of the aphides will escape the first application. M. Lusseau has tried this remedy with great success for more than twelve years. At any rate the remedy is a cheap one, and is easily tested. It is as well to repeat that oxalic acid is a virulent poison.—C. W. QUIN.

**Figs Fruiting.**—Some of the stronger-growing kinds are made to fruit with great difficulty, especially the Castle Kennedy, Carrington, and Brunswick. If the current year's wood be notched at nearly every joint as the trees grow, and placed to the wall (if in such a position), they will throw out short stiff shoots like spurs, which will form fruit the same season. But to have the trees in fruitful condition for the following year, lift a few roots at one side of the tree in August and lay them over a layer of lime rubbish, bones, and soil rammed firmly, replace the earth, give water, and the roots will make some growth, but not the branches. Should they continue to grow, the roots on the other side of the tree may also be lifted in September (not too late to cause premature shedding of the leaves), treated as the others, and the following season abundance of fruit may be expected. We have adopted this practice for many years with Figs without failure; also with Peaches. A number of trees planted last year, which grew with great vigour, were treated as the Figs, and the gross wood became grown as a Nut, and is setting well. The flower-buds are in clusters of sixes and sevens. We consider it important to have the roots healed and growing before the leaves fall.—M. TEMPLE.

**Mulching in Winter.**—It often happens that mulching in winter, applied even as late as January, answers an excellent purpose. More plants are injured or destroyed during the freezing and thawing of the last half of winter, connected with the bright sun, which is more frequent at that time, than during the earlier portion. On a moderate scale, and when additional fertilising is not required, we find evergreen branches to answer an excellent purpose, as we have had occasion to remark heretofore, especially when the rotting of green leaves may be feared from too dense or impervious a cover. But when such danger does not exist when mice are not feared, and a vigorous start to the plants is desired in spring, nothing is better than coarse stable manure with plenty of litter. The richer portions are washed out and carried down into the soil, and the straw remains on the surface to protect from sharp winds, freezing, thawing, and the effects of the sun's rays on the frozen plants.—"Albany Country Gentleman."

**Apricot Bloom.**—The blooms on both Hemskerk and Moorpark Apricot trees fully expanded for the first time this morning (March 3rd) in the bright warm sunshine. It would be interesting to learn from other directions the date on which the first blooms of the Apricot expanded this spring, as it would afford valuable proof of the divergences as regards the advancement of vegetation in various localities. Of course I allude only to trees on the open wall. My own are on a warm south aspect, and on a cottage with a projecting eave of some 18 in. in width.—A. D.

## GARDENING FOR THE WEEK.

## Roses.

**Pruning.**—Many who grow Roses for exhibition prune at different times. This effects a double object. We are all pruned at once early, and the weather was to be of such a character as during the present season, for instance, most kinds would immediately commence pushing the shoots required for bloom; and when, as so often occurs after an unusually mild winter, we experience keen spring frosts, the growth would be either completely cut off, or so far injured as to seriously interfere with the display of bloom; and if the pruning were altogether delayed until danger from the above cause was not likely to be incurred, the blooming of all would be so much later as to considerably shorten the flowering season; whereas by pruning a portion, say early in March, another portion a fortnight later, and the remainder at the beginning of April, the danger of the whole being injured is avoided, and there is the chance, should the weather not be such as to injure them, of getting a portion so much earlier, and under any circumstances a better succession will be afforded, and this succession will not only be confined to the first flowering of the plants, for as a matter of course amongst the Hybrid Perpetuals those that bloom the earliest are correspondingly enabled to push the second growth necessary to secure a second crop of flowers. Those who grow Roses for ordinary decorative purposes will find it to their advantage to follow this course. This more particularly applies to standards and half-standards; dwarf grafted plants, or such as are on their own roots; of these also a portion may be pruned where grown bush fashion, but where they are intended to be pegged down it would be well to defer their pruning for a week or ten days later, as where grown in this way from the position in which the shoots are trained horizontally or, as more usual, with their tips a little lower than the base, it causes the plants to break almost simultaneously over the whole length, which is the great advantage, taking all in all, that the system presents; yet if the growth made be not kept back until all danger from severe frost is over, their capability to flower satisfactorily will be endangered. It is the more necessary to consider this, as the shoots when thus pegged down are just placed at the dew point, that is, a few inches above the surface, where the cold is always the most severe. As will be understood, these remarks are intended to apply to non-exceptional parts of the country, in the extreme southern counties, or in the western coast. Rose pruning, as other operations, can be carried out without the danger here indicated; and in the damp inland districts further north it is always well to defer the pruning a little later, as, by dear-bought experience, I have been convinced it is better to wait a little longer for the flowers than to run the chance of having the first, which are invariably the best, blooms cut off; and it is well to bear in mind that in open winters the pruning should always be deferred later than after severe ones, although the growth which, from the commencement of February, they make when there is an absence of protracted frost having to be cut away weakens them, and often tempts the grower to prune before it is safe.

**Attention to which Roses require Pruning.**—This not only varies considerably in the case of different kinds, but also as regards the object the cultivator has in view. Those who grow for exhibition prune comparatively close, so as to concentrate the strength of the plants into a few shoots, which, from their limited number, are necessarily strong, and may be expected to bear a few large flowers. For ordinary purposes it is better to prune less severely, as numbers of flowers are generally more acceptable than a few exceptionally large ones. It is difficult to convey in writing the exact method advisable to follow, as even among individual varieties require to be somewhat differently treated to others; but it may be taken as a safe rule that the stronger the natural growth of the variety, and the more vigorous the state of the individual plant, the less pruning needed, for the obvious reason that a plant in this condition is calculated to support a greater number of shoots with a proportionately larger crop of bloom than one that is weaker, either by accident or the less vigorous habit of the sort. In all cases it is advisable to remove completely out from their base the whole of the weak, thin wood the produce of last or previous seasons, and which has not sufficient substance to push shoots strong enough to flower; for the presence of these uselessly taxes the energies of the plants, drawing support which is better concentrated in the stout, blooming wood. These weak growths also tend to crowd the plants, keeping out both sun and air. With Roses that are naturally weak growers it is necessary to prune to fewer eyes than in the case of the strong ones, otherwise, if left too full, the flow of sap directed to the formation and support of a vast number of shoots than are ever strong enough to bear flowers, to the manifest detriment of those which are. As I have before stated, to the Tea varieties must be pruned very cautiously, leaving their strong growths without further interference than being somewhat shortened; but with these, likewise, it is advisable to thin out all the weak shoots. With the weakest growers of the Teas also leave the strongest shoots a considerable length, but reduce the number proportionate to the natural strength of the variety, and the more or less vigorous condition the plant happens to be in.

## Orchids.

**Potting.**—The general potting should now be pushed on; by this I mean such plants as are best potted in the spring, but where a large and varied collection of these plants are grown during every month of the year some or other of the species will need this operation. In this matter a good deal of discrimination is required, as nothing can be so injurious to the current season's growth than the disturbance of their

roots consequent upon removal whilst growth is being made. Any mutilation of the roots, such as is unavoidable in re-potting, is far more adverse in its consequences upon Orchids than with any other plants. From the persistent manner in which their roots cling to any surface with which they come in contact, it requires little reflection to see that removal must necessarily effect a check such as is not consequent upon the potting of plants in general, neither do they possess the recuperative powers, after being thus disturbed, that most other plants do. Acting upon this, it will be obvious that no Orchid should ever be potted until it absolutely requires it; at the same time where there are any doubts of the soil in which they are grown having been reduced to a close, adhesive condition, there should be no hesitation in moving them to fresh. Even if it should be found that the material is got into this state when the growth of the plant is right in the midst of formation, there ought to be no delay in shifting it, for, though the moving may result in the current season's pseudo-bulbs not attaining more than half their wonted size, yet this had better occur than the roots remain in the unhealthy mass, where they will most probably perish as fast as they enter it. I mention this for the guidance of young hands in Orchid growing, for the reason that they often make mistakes in the condition of the soil, which may appear sufficiently fresh and fibrous on the surface when it has become by age wet and adhesive underneath. This not unfrequently occurs where plants have been repeatedly potted, and it is not necessary to state that this is not a good reason for the well-being of the plants, as also for their appearance, but it never should be resorted to if there are any doubts about the material lower down in the pots being in an unsatisfactory state. All plants of any genus or species that form pseudo-bulbs and produce flowers from the current season's growth at or near the time of its completion before going to rest, and that have now rested and are about to commence growth, should at once be potted if they require it. In the case of plants that rest after growing, before producing their flowers, such as the majority of Dendrobies and others of similar habit, it is not well to pot them if it can be avoided until after they have bloomed, as the unavoidable breakage of their roots is certain to limit the extent of their flowering. This is all the more likely to occur when the plants are in a stout, healthy condition, with an abundance of roots adhering firmly to the pots or baskets in which they are grown, and where the object in re-potting is more with an intention of giving them additional root-room than through the material in which they grow having got into an unsuitable state. With such Orchids, and there are many, that grow and flower almost simultaneously after having rested for a period, after the completion of the preceding year's growth, there is no choice but to pot when required, either before the growing and blooming commences, or after the flowering, when growth is in full progress. In the case of such plants as these I should prefer potting previous to the flower-buds beginning to push, for although, as I have already stated, it will more or less interfere with the flowering, yet it will be generally found more expedient to do this than to pot at the later period, when the plants are in the full bloom of their season, and the growth of the young of peat, which forms so important and considerable an element of the soil in which the majority of Orchids are grown, I recently pointed out the necessity for using that containing the greatest possible amount of fibre, for on this depends its capabilities to last in a condition suitable for the roots. For Dendrobies, Colognyes, Epidendrums, and Chysis, I have found the proportions best suited to consist of two parts peat to one of Sphagnum, and one of broken crocks and charcoal, with a little sand. In all cases for plants that are to be grown in pots or baskets suspended from the roof I should prefer charcoal, on account of its being so much lighter, as where a large number are hung up in this way, it is a matter of importance to reduce the weight as far as possible. For Cattleyas, Lælia, Odontoglossums, Oncidium, Miltonia, Trichopilia, and Masdevallias, three parts peat to two of Sphagnum and one of crocks and sand will answer. Anguloa, Brassavola, Brassia, and Lycaste, three parts peat to one of Sphagnum, with a good sprinkling of crocks and sand. Cypripediums, except the insigne section, succeed better with a little larger proportion of peat to the Sphagnum than plenty of crocks or charcoal. Strong growers Zygopetalum, of the Mackay and orbifolium section and Limnæodes I have found succeed better in good fibrous peat, with crocks and sand, without any Sphagnum intermixed. The strong-growing Phaius and Cypripediums of the insigne section appear to like loam better than peat.—T. B.

## Conservatories.

Pots containing three or four Tulips, bordered with Club Moss, and set off in the centre with such Ferns as *Pteris serrulata*, have a beautiful effect in conservatories, and the same arrangement may with advantage be carried out in the case of Hyacinths. Forced shrubs are now particularly attractive and should be mixed harmoniously with such plants as are not in flower; amongst them are Lilac white and purple, Weigela, Roses, Frumsee, Thorns white and scarlet, Spiræa, Daphnia, Acacia, &c. Chærisia, Cyclamen, Zonal Pelargonium, Chinese Primula, Epacris, Heath, and Fuchsia are also now in great beauty. Plants in general are making fresh growth, and consequently require more water. Prune and tie all that require such attention. Any that are in a backward condition in borders should be moved, and have others put in their places. In planting from pots, loosen the ball of soil and spread out the roots, for, although this may occasion a little check for a time, the plants thrive better afterwards. All hard-wooded plants requiring re-potting should be attended to at once, and the soil for a few days after closely covered with a conservatory. They should not be watered for some days after being potted, but the atmosphere should, if possible, be some-

what damp. Climbers of various sorts should be thinned and tied, taking care in thinning to provide for a free display of flowers rather than a gross production of wood.

**Retarding Plants for Late Blooming.**—The materials for keeping up an effective display in conservatories will now have become more plentiful than during winter, and one of the most important considerations is, to see that portions of such plants as will bear retarding without injury are at once placed under conditions to ensure their being made available later in the season. Where, indeed, anything like a continuous supply of blooming plants is required, it is quite necessary to have at command a house so placed that the sun will have little influence upon it, except for an hour or two morning and evening. A lean-to with a north aspect is best. Many imagine that such houses are only required by those who retard plants for purposes of exhibition; this is a mistake. By selecting a portion of the stock of *Camellias*, *Azaleas*, *Epicurises*, *Geraniums*, *Oenotheras*, *Cyclamens*—in fact, any of the numerous greenhouse plants that are used for conservatory decoration, the blooming season may be prolonged to almost double its usual length, especially if judgment be used in selecting varieties that are naturally late in flowering. *Camellias*—*candidissima*, fine white; *Beali*, red; *Lavinia Maggi*, striped. *Azal* as—*Brilliant* and *Juliana*, both red; *Extrani* and *oronata*, both bright rose; *Gleditsi* *formosa*, white striped. *Epicurises*—*Eclipse*, *grandiflora*, *rubra*, and *minuta splendens*. These and others, which the careful observer cannot fail to note, can be retarded without injury, so as to come in at a time when they will be found of great use. And it is not only during spring that such a house will be found of the greatest value; it will also be an excellent place in which to harden the stock of *Ghent Azaleas*, double-flowering *Plums*, *Lilacs*, *Spiræas*, &c., that have been forced, and which frequently, from want of a suitable place, are subjected to treatment ill calculated to render them of use the following season. Later in the season, too, it will suit *Camellias* well that have set their bloom, and which, from want of proper accommodation, are turned out-of-doors. Still further on in the season, late-flowering *Chrysanthemums* may be kept safely in such a house until the middle of January, at which time they will be found most useful.

**Renovating Old Camellias.**—Large *Camellias*, which have got leggy from want of judicious pruning when young or through overcropping, may be improved in the following manner:—Take, at once, a couple of healthy young plants in 6-in. pots of any approved kind, place these on the surface of the ball of the plant to be operated upon; then march the heads of each of the young plants as low down as they can be got on the opposite sides of the large plant. These will become firmly united during the summer, when they may be severed from their original stems, and, in the following season, before growth commences, the head of the stock may be cut away just above where the young plants have been inhaled, when they will commence to grow apices, and in a little time make handsome plants. Movable shading of this material should be got ready, as bright sunshine on a hot day makes short work of many things in flower. Pinch out the points of a portion of the stock of *Pelargoniums*. These will be useful in July after the early ones are over. Start another batch of *Achimenes*, *Gloxinias*, and *Tydasas* for summer decoration. See that *Lilies* breaking through the soil are not left where they have an insufficiency of light, otherwise they make weak growth, which no care afterwards will put right.

### Stoves.

Gradually increase atmospheric humidity and temperature in these structures, and apply water rather more liberally to the roots of the plants. Almost all stove plants will now require repotting or top-dressing, and insects, if any, must be destroyed. For should they be spared the next month they will reward such kindness by committing unlimited mischief. Plants of all kinds should, therefore, be thoroughly cleaned before they are repotted. No stove plant should be shifted into cold soil. Shift *Palms*, using for the purpose a compost consisting of fibrous peat two parts, turfy loam one part, and some sand and finely broken crocks, an open compost and plenty of water being requisite for such plants. Shake out plants of *Impatiens* and re-pot them in a mixture of loam, leaf-mould, well-decomposed manure, and some sifted sand. Five *Gardenias* a compost of loam and peat in equal proportions, mixed with sand; the same compost, with a little more loam mixed with it, will also suit *Brownias*. *Dalechampsias* should have leaf, loam, and peat in about equal proportions; *Stephanotis* fibrous loam, peat, and some well-decayed manure; *Sauzechias* and *Rondeletias* peat, loam, a little leaf-mould, and sand; and *Legerstromias* peat and loam. Indeed, most hard-wooded plants grow freely in good peat and loam, with some silver sand added, and but few of them will object to the addition of a little leaf-mould. Gross-growing and soft-wooded plants, however, such as *Muscas*, *Ornams*, *Eranthemums*, *Tonias*, *Fuyas*, *Pentas*, *caras*, *Gesneras*, *Lasinidras*, *Coccyphylans*, *Carcumas*, &c., are very fond of some thoroughly decayed manure mixed in the soil in which they are potted; leaf-mould, Mushroom manure, spent hot-bed manure, &c., may be so used.

### Ferns.

The general potting of these should have been done last month, but if the operation has been delayed until now it ought to be at once accomplished. If the plants have begun to grow they will be more liable to suffer from shifting than they otherwise would be, but with careful attention in the way of shading, maintaining an equable but gradually increasing temperature, and supplying a moderate amount of moisture both to root and top, little danger need be apprehended. Ferns whose

fronds spring directly from the soil require a richer compost than such sorts as *Davallia canariensis*, whose rhizomes grow above ground. To the former give a mixture of equal parts of good fibrous peat and loam, with the addition of some leaf-mould, plenty of silver sand, and some small chips of fine sandstone. If the plants be required, however, for furnishing purposes, a little more loam and a little less peat will induce a hardier growth, and one better adapted for house work than the luxuriant growth promoted by the first-named soil. Those with rhizomes above ground may be potted in fibrous peat and a little leaf-mould, pegging the rhizomes down on the soil. Some of the *Davallias*, *Polypodioms*, *Plymatodes*, *Pleopeltis* and others grow well on old stumps of Trees Ferns affixing themselves thereto like *Orchids*. If the stumps are in the vicinity of other Ferns, spores of different species are sure to vegetate in their crevices, more particularly those of *Adiantums*, *Gymnogrammas*, *Aspleniums*, and *Pterises*. Syringing Ferns is an operation requiring skill and care, for although some genera are partial to such treatment, others are particularly averse to it, more especially the *Adiantums*, *Gymnogrammas*, *Cheilanthes*, and other delicate and farinose kinds. Finny Ferns are best grown in glass cases, or under hand-lights or bell-glasses, or a division of the *Ferney* may be specially set apart for their culture. Most of the small delicate species thrive well on blocks of decaying wood, pieces of the Tree Fern stumps, or in pots; whilst for strong-growing kinds, like the *Todeas*, pot culture is the best and most convenient. For pot culture fibrous peat, chopped Sphagnum, and some fine sandstone chips make a good compost, and for *Todeas* the surface may be mulched with live Sphagnum. The smaller kinds of Ferns thrive well on little mounds composed of fibrous peat and sandstone chips, or on a block of wood embedded in a turfy peat from which they take their nourishment out of the wood. These ferns like a steady moist atmosphere, but too much artificial heat is detrimental to them; in fact, a greenhouse temperature is almost sufficient for the whole of them. In watering let the water fall lightly upon the fronds, but in addition to these slight sprinklings water must also be given to the roots, more especially during the growing season. Hanging-baskets should now be replenished with Ferns and *Selaginellas*, and *Wardian* cases should be examined and refilled if necessary.

### Lawns and Walks.

The present winter has unmistakably exposed any defects that exist in the drainage, and where these are apparent means should immediately be taken to remedy them; and if the work be at once completed, the soil thoroughly well rammed down, and the turf carefully laid, the Grass will commence to grow directly, and the disarrangement in a few weeks will scarcely be perceptible. A wet lawn should never be tolerated, as after wet weather, even in summer, it is frequently for days unfit to walk upon with any degree of comfort. In draining a lawn the work should be so done as to insure the water quickly percolating from the surface down to the pipes; this is best effected by filling over them broken bricks, rubble, clinkers, ballast, or any similar open material to within 8 in. or 10 in. of the top. The whole surface should then be well swept, in order to remove all worsted leaves, or broken twigs, and rolled so as to present a neat appearance. Those who take a pleasure in having their gardens orderly usually each spring surface their walks with a thin sprinkling of fine gravel, independent of the general gravelling that is from time to time required; to effect this in a satisfactory manner, it is not necessary to pick up the old material to the same depth as when a considerable quantity of new gravel is laid on, still the surface should be loosened about 1 in. or so after a shower with an ordinary iron rake; but if the weather be dry, there is no necessity to wait, as the required softening of the old gravel can be easily done with a watering-pot. In the choice of material for this surface-dressing, it is necessary to study the nature of the gravel obtainable in any particular locality. Where the soil is of a loamy, adhesive character, with little or no sand intermixed, the gravel should not be so fine, that is, a larger-meshed sieve ought to be employed in riddling it, for, although the very fine gravel looks well when smooth and set after being rolled in a moist state, yet, from its adhesive nature, directly it is wet it becomes sticky and disagreeable to the feet. No well-made gravel walk will ever become soft, no matter what amount of rain has fallen, except during a time of excessive frost, when, as a matter of course, even the best gravel walks become loosened. In parts of the country where gravel is of a sticky, soft nature, it is best to pass it through a riddle with 1-in. or 1-in. mesh, afterwards using a fine sieve to screen out all the earthy portion, retaining nothing but the small stones; if this be sprinkled on the top so as to just cover the surface, and well rolled in whilst damp, it will make a walk clean, smooth, and pleasant to tread upon even in the wettest weather.

### Flower Garden.

Spring flowers are now daily becoming so plentiful that herbaceous and shrubby borders are getting quite attractive; on lawns, too, are tufts of *Crocuses*, *Snowdrops*, *Dog's-tooth Violets*, and other favourite bulbous plants that are beginning up and up, and are their beauty, when once planted in such positions. Under the wide-spreading canopy of large deciduous trees a spring carpet of white, yellow, and blue, furnished by early-blooming bulbs, is most desirable and pleasing, and in such a situation they thrive where not a vestige of Grass will grow. Only the commoner kinds, however, should be used in that manner, for the finer ones, if so treated, are apt to degenerate; hence the necessity of a good position for them, where they can retain their foliage until the bulbs are properly matured, when the foliage may be cut over, and the surface of the ground covered with a mulch of other kinds of rooting plants. Lawns should be swept, rolled, and, if necessary, mowed. Where they

are covered with Moss it should be raked off, a top-dressing of finely-sifted soil applied, and some Grass and White Clover seeds sown at the same time. The top-dressing should be equally spread, raked smoothly and level, and then well rolled. Should the lawn be thinly covered with Grass, although free from Moss, a top-dressing of good soil, with some guano mixed with it, and also a sprinkling of Grass and Clover seed, will greatly renovate the turf. Before applying it, however, go over the surface with an iron-toothed rake, so that the old and new soils may be more readily unite; siccot, salt, or guano applied alone in rainy weather is also productive of excellent results. If the edges of lawns or Grass walks be well rolled before trimming them, that operation can be more neatly and accurately done. Turfing of lawns may still be performed, but the sooner one works in this line, now the better will the Grass stand in the summer's drought. In the absence of turf, seeds may be used, but in that case a long time elapses before a thick, close carpet can be formed, and continuous attention in the way of mowing is requisite. Alterations in the flower garden or pleasure grounds may still be proceeded with. The planting of deciduous trees cannot, however, be too speedily finished now for a season; evergreens may be transplanted later. Coniferous trees, as a rule, transplant very well in the spring time. In planting, preserve the roots as entire as possible, and do not bury them more deeply than is necessary; stake such as require support. Instead of roughly filling in the soil, it should be well and carefully worked in amongst the roots with the hand, and a good soaking of water at planting time has also an excellent effect in setting the soil about the roots.

**Bedding Plants.**—Hotbeds should now be put up for the propagation of these where hot-water heated structures are not available for that purpose. Such beds may either be raised above the ground or sunk, and in extensive places some of both kinds will be found serviceable. A little extra warmth may be communicated to ordinary frames by means of a lining of fermenting material applied to their sides; this additional heat will induce the plants to start into growth and to soon begin to yield material for cuttings. Propagation of *Verbenas*, *Heliotropes*, *Ageratums*, and other soft-wooded plants should now be commenced, and places heated slightly should be prepared for the reception of the young plants when they are rooted and boxed or potted off. Apply a brisk heat to *Ferdinandas*, *Abutilons*, *Wigandias*, and other strong-growing, sub-tropical plants that were starved in pots last summer for producing stock, and pinch out their tops so as to induce the formation of side shoots for propagating purposes. Seeds of various kinds of plants for summer gardening may now be sown, such as those of *Aecia lophantha*, *Cineraria acanthifolia* and *maritima*, *Acanthus latifolius*, *Centaureas*, *Cannas*, *Pyrethrums*, *Lobelias*, &c. *Perillas*, *Mari-golds*, *Stocks*, *Asters*, and similar plants are best left undisturbed until next month.

#### Kitchen Garden.

Make another sowing of Peas. Where suitable sticks are plentiful, tall kinds are the best to sow at this period of the year, as they bear longer than dwarf sorts, or such as are of medium height. Where tall varieties are grown, always give plenty of room; there should be not less than 5 ft. between the rows, as to crowd them is the reverse of any gain, for without sufficient air and light the pods never fill as they ought. Directly the earliest sowings are sown, a line of Spinach should be sown between the rows. This will be ready for use and the ground cleared before the Peas are fit to gather, and it will in no way interfere with their growth.

**Onions.**—The main crop should be sown as soon as the land is sufficiently dry, but on no account if it be so wet as to adhere to either the tools or the feet, as should the seed be sown when the soil is at all sticky, subsequent dry weather will be sure to bake it so hard as to prevent its working well through the ensuing season. In pointing in the surface-dressing of manure spread over the ground, do not let it be too deep, or the young plants will be too long in getting their roots into it. Many of the north country Onion growers put the greater portion of the manure they use on the surface, allowing it to remain until it is well sweetened by the action of the air, sowing the seeds in it, and covering the whole with 1 in. of soil from the alleys. With this, as with almost all other vegetables, the system of growing in rows should be recommended. It must be admitted that it is not a considerable saving in sowing than the broadcast plan, but it affords such great facilities for thinning the crops, for the use of the hoe in destroying weeds, and for keeping the surface stirred (by which the ground is aerated and made open for the descent of rains, and the

loss of moisture by evaporation in dry weather is prevented), that the first trouble is amply compensated for by the succeeding results. The use of soil should not be omitted, especially in old gardens where the land is at all light, for in these the ravages of the Onion grub are most felt; the soil not only acts as a powerful manure, but the soil retains the smell through the season in a way that is so objectionable to the fly as to have a considerable influence in preventing it depositing its eggs on a sowing where the land has been dressed with it. After the ground has been levelled, tread the whole quite solid. The lighter the land is naturally, the more solid it ought to be made. Then mark out the rows 1 ft. apart and 3 in. deep. After sowing, draw the soil over the seeds with the back of the rake. Again tread the ground thoroughly, and finish by rolling.

**Broad Beans.**—In dry districts where Broad Beans were sown about the beginning of the year they will be now above the ground, and a second sowing should be made; this crop also likes heavy soil. Sow more Radishes, raking in the seed, it not being necessary now to cover it with litter. See that the litter is removed altogether from the second sowings as soon as you, for after this time the frost is not likely to be sufficiently severe to injure them. Sow a little Mustard and Cress every fortnight in well-manured ground; to have this young and tender, it is necessary to sow often. Lettuce should also be sown on the richest piece of ground available—a little of the Cabbage variety (Tom Thumb) as well as Cos—the former will be sooner fit for use and precede the erect-growing kinds.

Rows for the latter should be 15 in. apart; the others will do a third less. In sowing, the best method is to drop the seeds, half-a-dozen together in patches as required to be grown; afterward thin them out to a single plant. If the weather be mild, a portion of those that have been wintered in frames should be planted out in sunny, sheltered position, but do not risk the whole, as I have known the weather after this time to be so severe as to seriously affect them, especially after a winter like the present, when every kind of vegetation has been kept so long so soft and growing. Take them up carefully with a trowel, so as to preserve the roots as far as possible from injury; give some water as soon as planted, and if the days be sunny or the nights cold, place a small flower-pot over each plant for a few days, but not pressed down so closely as to exclude the light.

#### Extracts from my Diary.

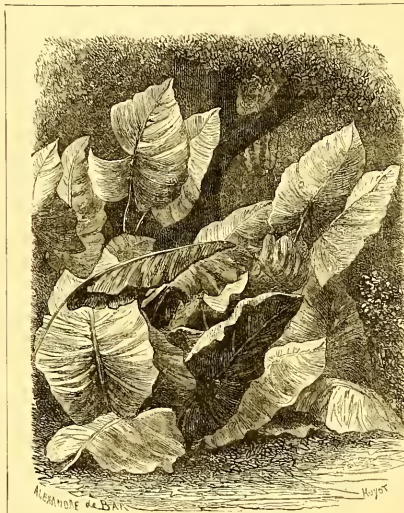

**March 11.**—Sowing the main crop of the following sorts of Onions, viz. Early White Naples, Improver White Spanish, Bedfordshire Champion, Danvers Yellow, and James's Keeping. Putting in cuttings of Tomatoes. Potting old smooth-leaved Cayenne Pine stools for suckers. Planting out Potatoes in frames previously brought forward in pots. Planting Selected White Spanish Onions for seed; also a few Beet and Early Nantes Cut com.

**March 12.**—Sowing Mustard and Cress; also Parsley and Early Frame Radish. Putting in cuttings of Alternantheras, Coleus, Mesembryanthemums, and Salvia. Potting off Melons, Heliotropes, Petunias, and Verbenas. Transplanting autumn-sown Onions and Red Cabbage plants. Lifting some large crowns of Victoria Rhubarb for making a new plantation. Renovating the linings round manure frames. Looking over the Strawberries in bloom. Removing all weak plants and cutting out all the weak flowers.

**March 13.**—Putting in cuttings of scented Verbenas, Pelargoniums, Gardenias, and Fuchsias. Potting off *Iresine* and *Ageratum*. Planting out Brown Cos Lettuce plants from the autumn-sown bed; also a few Cauliflower plants. Giving Cucumbers a little earthing. Looking over the Grapes in bottles, cutting out bad berries, and filling up the bottles where required.

**March 14.**—Sowing the following sorts of Peas, viz., William I., James's Prolific Marrow, G. F. Wilkes, Fortyfold, Carter's Commander-in-Chief, and Suttou's Giant Emerald Marrow. Potting off Alternantheras, Coleus, and Lobelias. Taking up Chamomile roots, dividing them and making a new plantation. Finished the pruning and nailing of Peach trees on open walls. Getting the wire guards put over the Peas and Broad Beans to protect them from jackdaws and sparrows.

**March 15.**—Sowing Mignonette in pots. Pricking off Celery in boxes and putting them back into warm frames, so as to keep it growing. Clearing out an old worn-out forced Asparagus bed, and put in another. Earthing up Potatoes in frames. Thinning out Carrots and Radishes in frames. Trimming out Pea sticks. Getting soil into manure frames ready for Melons. Getting netting and other covering over Apricot trees for protection.

*Caladium esculentum* after a Storm.

March 16.—Thinning Grapes, and tying down the shoots where required. Manuring and digging Rose borders. Earthing up Beans in pots. Cutting back and thinning out dwarf Laurel clumps. Tying in some of most forward shoots in early Peach house. Tying up Cos Lettuce, and covering up Endive to blanch. Manuring and digging the ground previously occupied by Brussels Sprouts. Covering up Sea-kale, and planting Potatoes. Fruit in use for dessert:—Pines, Grapes, Apples, and Peas. W. G. P.

Dorset.

### THE CULTIVATION OF ASPARAGUS WITH THE PLOUGH.

We take the following details concerning the cultivation of Asparagus with the plough from a pamphlet by M. Godefroy-Lebeuf, of Argenteuil. With the exception of the west, there is hardly a single locality throughout the length and breadth of France in which a large portion of the ground given up to market gardening is not devoted to the cultivation of this favourite esculent. It seems somewhat strange that the cultivation of Asparagus should make so little progress in the western districts of France, seeing that lands on the borders of the ocean are essentially favourable for the purpose. The sandy downs of those districts, which now produce nothing but Reeds, and here and there a scanty crop of small Potatoes, would, if devoted to the cultivation of Asparagus, yield a hundredfold of what they do under the present system. This apathy is all the more surprising, seeing that land is so cheap in these localities; besides which, it is easy to cultivate, manure, and above all, seaweed being plentiful. Other crops, too, yielding a good profit might be grown at the same time. The so-called green Asparagus has been gradually neglected, and has been replaced by the market or white Asparagus. The grower need have but little fear of not being able to get rid of his crop. As in the case of all good vegetables, he will find plenty of commission agents in all parts of the country who will buy his produce on the spot, and send it off to market. Last March whole cargoes of French Asparagus were selling in the London market before it made its appearance in the Paris Halls. M. Godefroy-Lebeuf does not hesitate to advise the Vineyard proprietors, who have felt the sharp mandibles of the Phylloxera, or the Beetroot growers, who are half ruined by taxes, to grow Asparagus. The method of growing Asparagus described here is not new. It was first devised by M. Parent some twelve years ago, since which time he has carried it on with thorough success. M. Parent has succeeded in growing Asparagus at a merely nominal cost. The following details of M. Parent's method of growing this vegetable will show that profitable crops may be obtained at a very small expenditure of time, money, and labour:—

**DESCRIPTION OF THE PLOUGH.**—The experience of the Asparagus growers at Argenteuil show that deep ploughing is not merely useless, but hurtful. The plough to be used for this purpose should not therefore enter the ground to a greater depth than about 3 in. The plough is a light one, and made entirely of iron. It will be readily understood that as such a plough has to work in the midst of plants with fleshy and far-spreading roots, it must necessarily be so constructed that it moves along with the greatest ease. These conditions have been completely fulfilled in the case of the Asparagus plough, or, as it perhaps ought to be called after its inventor, the Parent plough.

**PLANTING.**—We must begin by laying it down as a maxim that Asparagus must be grown in a firm soil. The ground must be ploughed to the depth of 8 in. Care must be taken to clear the land of roots and stones, alleys being provided for their convenient removal. This part of the work must be done during the autumn. In southern districts planting takes place immediately after ploughing. It has, however, been objected that as the Asparagus is, to a certain extent, a plant with tubercled roots, it ought to have a period of rest, and that the proper time for this rest being during the autumn, Asparagus planted at this time would be likely to suffer much more from damp than if it were planted during the spring. In the southern districts, however, M. Lebeuf maintains that autumnal planting is preferable. Everybody knows that the majority of Lilies, Amaryllises, and plants with bulbs, tubercles, or fleshy roots begin their yearly life in the autumn.

If they are dug up on the approach of winter, and the roots examined, it will be noticed that they are in a perfect state of development. If the Asparagus in the latitude of Argenteuil begins to grow a little later, it is because it does not meet with the climatic conditions necessary for its proper development; but if it is planted in the south, where the rays of the sun have more power, the young roots will begin to develop themselves a short time after they are planted. In speaking of the south of France, M. Lebeuf does not include the mountainous parts of that district under that head. Elevated plateaux ought to be classified according to their mean temperature and dampness. Autumn planting cannot be carried out with profit in districts which are too cold and moist. It is for the grower to determine under which category his land is to be placed, and to adopt one system of planting or the other, according to circumstances. In the central and northern districts a period between March and May should be chosen, according to the latitude, the mean temperature, and the condition of the ground. In any case, care must be taken not to plant immediately after severe rain, and never in heavy ground at any time. If the young plants are received at a time when the soil is too wet, there is no harm in keeping them in a cool, dry place, spreading them out so as to give them plenty of air, and avoid all chance of mouldiness. Under these conditions the young plants may remain out of the ground for a full month. With good soil, well-ordered cultivation, and a proper selection of plants, there is no difficulty in succeeding thoroughly in the cultivation of Asparagus by means of the plough. In the year 1874, after ten years' experience, the commission of the Société d'Horticulture appointed to report on the matter, acknowledged that the Parent system was a great success, although the ground upon which M. Parent's crops were grown was not of the most favourable nature. The ground having once been ploughed, must not be manured during the first two years. It must be carefully cleared of all weeds, large stones, &c., and divided into squares, each square containing twelve rows. The rows should be made at a distance of about 4 ft. apart, measuring from the middle of one row to the middle of another. Each square should be separated from its neighbour by a pathway at least 10 ft. wide, which will serve as a passage for manure as well as for the gathered crops. When no longer necessary, this pathway may be sown with some fast-growing crops such as Oats or Rye. The ends of each row are marked with a stake. At the time of planting, an operation which ought to be performed on a fine day, a trench is to be made from one stake to the other. The trench, once made to the proper depth, according to the quality of the ground, a labourer makes with a hoe a number of holes about 6 in. deep in the middle of each trench. In each hole he places an Asparagus plant, taking care to spread the roots out quite flat. Growers have given up the idea of making a little mound for the plant to rest upon, as they found that it was apt to become broken up by the frost, and to fall during drought, so as to expose the roots of the plant. The roots of the plant must be covered over with light earth to the depth of about 2 in. This completes the work of the first autumn in the south, or of the first spring in the north. During the course of the summer the beds must be hoed, and if the season is very dry, the young plants may be earthed up lightly. This hoeing ought to be repeated frequently, taking care to clear the ground of weeds, and stirring up the soil thoroughly, so as to destroy all eggs of insects. For the latter purpose it will be as well to hoe the whole surface of the ground every year during the month of June, this being the time that the cockchafer deposit their eggs, which only need to be exposed to the light and air to dry up and perish. The first two years hand-hoeing must be resorted to, for the harrow would disturb the young plants too much, but as soon as the Asparagus is sufficiently strong to bear the operation the harrow should be used, care being taken to harness the horse to the side. Let us suppose that the Asparagus has been planted for nearly two years, and that the young shoots have now gained sufficient strength to resist the attacks of all insects, with the exception of the cockchafer grub. We do not recommend manuring before the third year, when the land is moderately rich. The manure is deposited by the cart in rows of little heaps, which are afterwards distributed evenly all over the beds, as in manuring corn-fields. The report drawn up by M. Victor Bart

tells us that one of the members of the commission objected to this method of manuring, and recommended that the manure should be deposited round the base of the plant itself. M. Lebeuf does not understand the wisdom of this proceeding, for the member of the commission who made the objection, and the other members who sided with him, ought to know that in every Asparagus bed the roots of the plants extend in all directions; and that whenever manuring proves useless, it is because the manure is placed on the top of the stool, which becomes gradually stripped, and, especially in old Asparagus beds, ceases to develop any fresh buds and new roots wherewith to nourish them, instead of towards the extremity of their tubercles and ramifications.

The question of manure is a very important one. M. Parent advises the Asparagus grower to use sheep's manure, but this manure is very scarce, not only in France, but in most parts of Europe. It is to be wished that the Russians, instead of defiling the Black Sea and Sea of Azoff by throwing into them the enormous accumulations of sheep manure, many feet in height, which are constantly being formed in the Crimea, and at Taganrog, would send this valuable Asparagus-growing material to this side of Europe. We should, however, only recommend sheep manure to be used where the land is poor, and even then in moderate proportions. Fish manure and road scrapings form excellent fertilizing agents for Asparagus; it is, in fact, the manure that is used at Argenteuil. For light lauds cow or horse manure would grow excellent Asparagus. If we manure the second year, the material must be lightly ploughed into the ground at the end of autumn. The plough must be passed lightly over the whole surface of the plantation, always taking care to harness the horse in such a manner that the heads of Asparagus shall not be trampled down.

**EARTHING UP.**—The operation of earthing up, which consists in covering the stools about three weeks before gathering the crop with a certain quantity of soil, varying in amount according to the age of the plantation, has for its object the blanching of the heads of the Asparagus, without which their market value would be depreciated. Let us suppose that the Asparagus has reached its third year of growth. Up to this time we have done little more than keep the beds neat and clean, and lightly earth up the first year's heads, if the weather be very dry, or, at any rate, earth them up a little on the approach of winter, in order to avoid the destruction of the plants by frost. The approach of the first year for gathering renders earthing up a necessary step. The operation is best performed with the plough. The horse is harnessed in such a way that he cannot trample on the stools. The share of the plough the first time takes a portion off the top of the ridge, which is deposited on the stools. The second time a fresh portion of earth is taken off and turned over on to the stools, so as to form a heap of mould 8 in. or 10 in. in height. The earth is taken from the left side of the ridge the first time, and from the right the second.

#### Gathering.—Interlinear Cultivation.

The operation of earthing up having been completed, no carts need enter the plantation until gathering time comes. The pathways may therefore be sown, taking care only to leave just room enough for a man to pass. The ridges, too, may be utilised, only one being necessary for gathering two lines; the other may be used for growing vegetables of different kinds, such as Potatoes, dwarf Peas, Haricot Beans, Strawberries, &c. During the years which precede the gathering, the intervals which separate the rows of Asparagus, which may be utilised for pathways, are utterly useless as long as no gathering is going on. The Asparagus is cut by means of a knife or chisel of a particular form made expressly for the purpose. When only small crops are to be gathered, it is not necessary to use this special appliance; but when the vegetable is grown on a large scale, where neat cutting and expedition are necessary, it is of great advantage. It consists of a gouge, flattened at the top, the lower edge being toothed like a saw. M. Parent, who is the inventor, soon saw that the gouge in use at Argenteuil, which is saw-toothed at one side, split the Asparagus too much, making a jagged cut. He consequently tried a gouge with a plain edge, but it slipped on the stalk and

did not cut it cleanly. M. Parent perfected the instrument by putting teeth on one edge, as has already been described. The Parent Asparagus cutter divides the stalk at  $1\frac{1}{2}$  in. or so from the top of the stump, the pressure being exerted from the exterior of the clump to the interior. This operation must be performed with the greatest care. In all establishments where Asparagus is grown on a large scale, movable sheds are constructed, so as to afford the Asparagus gatherers shelter from the weather. The cutting takes several hours, and the Asparagus, if not rapidly protected from the effects of the open air, will speedily become withered and unfit for market. M. Parent has done away with sticks for tying up the Asparagus stalks, so as to prevent them from being broken by the wind. He has effected this saving by simply cutting the extremities of the stalks. This operation is performed three weeks after gathering by means of a "sécateur." The cut should be made above the twentieth branch for the male plants, and above the twenty-fifth for female plants; but this must be regulated according to the general strength of the plants. The female plants are generally less vigorous than the male; but, as I have just said, it all depends on the health of the plantation, taking care, however, never to cut below the twentieth branch in any case. Besides the saving effected by doing away with training sticks, this kind of pruning strengthens the plant generally. If the heads are cut back too much, the stalks will be developed at the expense of the next crop.

**UNEARTHING.**—In the autumn following the first harvest the operation of unearthing must be performed. It is, of course, the converse of that of earthing up already described. The labourer, passing along the beds the first time, takes off the top layer of the bed, throwing it aside. Passing along a second time, he takes away the exact quantity necessary to bare the stool. In winter, in fact,  $1\frac{1}{2}$  in. or 2 in. of earth is sufficient to protect the stump without preventing it being warmed beneficially by the early rays of the spring sun. As the Asparagus has been cut at  $1\frac{1}{2}$  in. or 2 in. from the base of the stool, it follows that the share of the plough will slide over these stumps without disturbing them.

In cultivating Asparagus by the plough, we plant nearly on a level with the soil. It will be easily seen that on account of the property possessed by the Asparagus roots of rising higher every year, the beds will soon present an aspect which will be directly contrary of that which they showed at the time they were made, that is to say, the trenches will become mounds, and *vice versa*. The Asparagus will thus be growing on the top of the mound, and this mound will gradually become higher as the plantation becomes older. The space, too, between the mounds will become deeper as more soil is taken out of it.

#### The Varieties to Choose.

In the case of shallow, cold, and badly-exposed soils, the late variety ought to be used. This variety grows but slowly, which renders it specially fit for cultivation in soils of no great depth. By choosing an unfavourable aspect we may cut late, and the crop will last a long time. In deep, warm, well-exposed districts, we must use the early variety. In southern districts we should, by preference, choose this kind. The great thing is to send Asparagus to market as soon as possible; the late kind, therefore, in spite of its other good qualities, is clearly unfitted for this purpose.

The grower will easily understand, from what has gone before, how economical this method of culture must necessarily be. We shall soon find that we save time in all the following operations. First of all in the tilling of the soil, next in planting, again in earthing up, which may be done at the rate of  $1\frac{1}{2}$  acre per diem, and in unearthing, which may be carried on at the same rate. In gathering, making into bundles, and in doing away with sticks for tying up the shoots, we economise both time and money. Again, by being able to cultivate the alleys and the beds themselves, we may almost pay the rent of the land. We do not mean to say that this system of Asparagus growing is perfect, but we must allow that it is a very important step in advance. We do not, it is true, obtain such excellent results as if we pursued the old-fashioned plan adopted at Argenteuil, but the crops are, nevertheless, good and profitable.

**THE FIG TREE AS AN OPEN-AIR STANDARD.**

COL. TREVOR CLARKE read a paper on this subject at South Kensington last Wednesday. He stated that, although it was known that the Fig was cultivated successfully in this way on the southern coast, and in some of the maritime districts of the north, yet its culture as a standard in the midland districts had been and was still to many somewhat doubtful. He had for some time past been making experiments in this direction in his own garden, the locality of which is, as near as possible, in the centre of England, and, from the results which he had obtained, he thought that the culture of the Fig near London as a standard was well worth consideration. The White Marseilles was reported to succeed best, but the Brown Turkey had also done fairly well. In favourable seasons standard trees had ripened their fruit better than those on walls, whilst in unfavourable seasons they had been neither better nor worse. Standard trees had the full benefit of the sun and wind on all sides, the latter playing not the least important part in ripening the wood, whilst only one side of trees on the wall were subjected to their influence. As regards pruning, in whatever way the Fig is grown, if the terminal shoots be allowed to grow untouched, the weight of the leaves soon brings them into an horizontal or sometimes even a drooping position, thus rendering the wood more fruitful; therefore it was best to keep the wood thin and uniform. Mr. Clarke's garden, in which these experiments have been carried on, is somewhat sheltered by a boundary wall, but has otherwise no climatal advantages. The soil is a strong red loam, sometimes clay, and in this good results have been obtained, the success being chiefly attributed to the steady growth of the trees and thorough maturation of their wood. The greatest drawback to the White Marseilles variety of Fig is that in a wet season it is said to be very liable to drop its fruit.

C. S.

**A RAT GUARD.**

To keep rats away from anything that is hung up the following simple method may be used: Procure the bottoms of some old fruit

cans by melting the solder which holds them upon a hot stove. Bore holes in the centre of these discs, and string a few of them upon the cord, wire, or rope upon which the articles are hung. When a rat or mouse attempts to pass upon the rope by climbing over the tin discs, they turn and throw the animal upon the floor. This plan, shown in the illustration, will be found very effective.—“American Agriculturist.” [Pasteboard or thin wooden discs are just as effective. The great thing is that they should hang quite loose, so as to afford no foothold to the rat.]

**TAR-PAVING v. WEEDS ON WALKS.**

The subject of weeds on walks, and the best methods of eradicating them, has been brought forward on many occasions, but no really good remedy has yet been suggested, except the old-fashioned one of hand picking. No one can, of course, deny that salt and strong acids, such as nitric or sulphuric acid, will kill weeds, but these cannot be generally used in consequence of the walks being bordered by Box, Grass, or other live edgings, near which the greater portion of the weeds grow; moreover, the acids, if used sufficiently strong to be thoroughly efficacious, are very destructive to watering-pots and the clothes of the operator. Indeed, so far as my experience has gone, I may say that acids and salt have neither been satisfactory in regard to cost nor effect. I am of opinion that if walks and roads were only formed where they were really necessary, and of suitable width, the traffic and a moderate expenditure would be sufficient to keep them free from weeds. Walks through woods

and plantations with trees overhanging them will, as a matter of course, always be troublesome in consequence of damp, but frequent sweepings and rollings would keep them in fairly good condition. Tar-paving is an effectual remedy for weeds of all kinds; but it is often badly made, and thought by many to be unsightly. If, however, crushed spar were used in the first instance, or if the walks were occasionally sprinkled with finely broken cockle shells, they would have an agreeable appearance. Walks of this description dry rapidly after rain, are perfectly free from mud and dirt, and weeds are never seen upon them. Before laying down tar-paving the foundation must be of the most solid description, and the drainage perfect; battens or ornamental tiles should be fixed at the sides of the walks, an operation which should be done very neatly and at the proper level, allowing for 3 in. in thickness of tar-paving. For all purposes two kinds of paving are sufficient; one coarse the other fine. Two in. of the former should be spread evenly over the walk, and thoroughly rolled. The ordinary garden roller is not so suitable for this purpose as a heavy stone roller. The success of the work very much depends upon its solidity. When the first layer has been sufficiently rolled, the fine layer must be laid on evenly to a depth of 1 in., care being taken to level this properly, or the walks will present a wavy appearance, and the surface-water will not run off rapidly. I cannot too strongly impress upon those about to make tar paths the necessity of heavy rolling—solidity preventing the absorption of moisture, which destroys the tar and is a frequent cause of failure. It must also be borne in mind that tar-paving, to be really good and durable, must be composed of clean stones—i.e., stones free from dirt—burnt and mixed while hot with gas tar, which should also be heated. If crushed spar be used it should be sprinkled uniformly over the surface of the walk and well rolled while the paving is in a soft state; on the contrary, if cockle shells or similar material be employed, the surface, after being well rolled, should be allowed to harden for a few days, when the paths must be painted over with boiling tar and covered directly with finely-crushed shells or the dust which has been sifted out of the burnt stones. The roller may then be passed over the surface a few times and the work is done. Walks made as just described are most suitable for the kitchen garden, and may in many instances be extended to the pleasure grounds. The odour of the tar passes off in a few days, and if the paving be properly made, it is unaffected by solar heat, and will bear any reasonable traffic, with even a horse and cart. The maintenance of such walks and roads consists in painting the surface periodically with tar, say once in three, four, or five years, and putting on shells, as in the first instance. The cost of this is very trifling. I am confident that, properly made, tar paths cannot fail to give satisfaction, and, although at first they may be somewhat more expensive than ordinary gravel walks, I will venture to state that if their durability, cleanliness, elasticity, and, above all, their entire freedom from weeds be taken into consideration, the balance will be greatly in their favour.

CHARLES DENNIS.

Southwark Park.

**Soldier Gardeners.**—General Sherman, according to the “New York Tribune,” lately received from Major Brisbane, Montana, reports of soldier gardeners for the year just ended. They state that the troops have been for two years constantly in the field during all the summer or growing months, yet both seasons they have had excellent gardens. All the vegetables used are of the best quality. So far as living is considered, Fort Ellis is one of the best stations for cavalry in the country, and the cheapest to supply. There have been no desertions for a long time, and the commander attributes this in a large measure to the manner in which the soldiers are fed and cared for. The reports above alluded to give the amount of Potatoes, Onions, Turnips, Carrots, Beets, Parsnips, Salsify, and Cabbages, raised on 26½ acres by companies F, G, H, and L of the 2nd, and company G of the 7th Cavalry. The commander says the value of the several articles, if bought there, would be about as follows:—

Potatoes .....	3865	dols.	Beets .....	315	dols.
Onions .....	2352	“	Parsnips .....	225	“
Turnips .....	785	“	Salsify .....	9	“
Carrots .....	206	“	Cabbages .....	1250	“

9007 dols.

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

MARCH 5.

THIS meeting took place on this occasion in the conservatory, which is itself just now gay with Rhododendrons, forced bulbs, and other flowering plants.

**First-class Certificates.**—These were awarded as follows:—

**Azalea William Carmichael** (Williams).—A hybrid, the result of a cross between *A. amœna* and a large-flowered kind. It flowers freely whilst in a very small state, and its blossoms, which are of a rosy-purple colour, are larger than those of *A. amœna*.

**Amaryllis Mrs. Rawson** (Williams).—A strong-growing kind, bearing large flowers with petals of a bright maroon-crimson conspicuously edged with white.

**Primrose Ootoroon** (Dean).—A dwarf-growing, Auricula-flowered kind, bearing a profusion of dark velvety crimson blossoms.

**Primrose Ealing Crimson** (Dean).—A kind with purple or magenta-coloured blossoms of unusual brightness.

**Primrose Scott Wilson** (G. F. Wilson).—A new and distinct kind, bearing bluish-purple flowers, and one likely, as regards colour, to be the forerunner of an entirely new race of Primroses.

A botanical commendation was awarded to Messrs. Veitch & Sons for *Epidendrum Wallisi*, a kind bearing unique little flowers, which have bright yellow sepals and petals, and a whitish purple striped lip; altogether a pleasing variety, and one well worth a place in good collections of Orchids.

Medals were awarded to Sir Trevor Lawrence, for a group of Orchids; to Messrs. Veitch & Sons, for a collection of Amaryllises; to Mr. John Wills, Mr. B. S. Williams, and Messrs. Osborn & Sons, for collections of plants; and to Mr. Ford, gardener to E. Hubbard, Esq., for a collection of Apples and Pears.

**Orchids.**—These were well shown by Sir Trevor Lawrence, Mr. B. S. Williams, and Mr. John Wills. In the collection from the first exhibitor was probably the finest plant of *Dendrobium Wardianum* that has ever been exhibited. It was growing on a flat piece of wood, and was furnished with nearly twenty stout pseudo-bulbs, eight of which were in flower, and numerous strong young growths were starting from the base, the flowering-bulbs representing complete wreaths of richly-coloured blossoms, of which the plant bore no fewer than 130. The plant was fastened to a naked stem of one of the *Araucarias* growing in a tub in the conservatory, where it could be seen to the best advantage. Above it was an exceedingly fine plant of *D. luteiflorum*, and the soil in the tub was hidden by well-flowered plants of *Odontoglossum Alexandræ*, *O. Rossi majus*, Ferns, &c., the whole effect being greatly enhanced by a central plant of *Sophranitis grandiflora* growing on a round stick of wood, and bearing sixteen brilliant scarlet, waxy blossoms. The contrast of colour produced by this group was the admiration of everyone present, and the Floral Committee awarded to the exhibitor the highest medal in their power. In Mr. Williams' group were well-flowered plants of *Dendrobium glumaceum*, *Cœlogyne cristata*, *Odontoglossum triumphans*, and the beautifully-scented *Pilumna fragrans*, from Columbia. A pair of well-flowered plants of *Odontoglossum cirrhosum* were shown by Mr. H. G. Elliot, Clapton. Each bore three or four branching spikes of flowers, which, though rather small, were beautifully spotted and perfumed. A cultural commendation was awarded them.

**Amaryllises.**—Good collections of these were exhibited by Messrs. Veitch & Sons, of Chelsea, and Mr. B. S. Williams, of Holloway. In the first group the best kinds were *Chelsoni*, a large, well-shaped flower of a dark crimson colour. *Fair Maid of Perth*, a free-flowering kind with medium-sized white blossoms, the upper petals of which are effectively striped with purple. An unnamed seedling was the best scarlet kind in that collection. A very effectively striped variety was one named *Wallenstein*. Mr. Williams' group contained a scarlet-flowered kind named *Prince Arthur*, and one named *Aurora* bore flowers of exquisite shape, and of a rich velvety maroon-crimson colour. Mr. Little, Uxbridge, also sent several Amaryllises of a meritorious character. In competition for prizes, offered by an amateur deeply interested in the improvement of the Amaryllis, for the best dark and light seedlings, Mr. Williams was awarded the first prize in both cases. The dark kinds consisted of a bright maroon-crimson named *Prince Teck*, and a dark scarlet kind named *Fairster*. The light varieties consisted of *Mrs. Rawson* and *Dr. Masters*, two very distinct kinds well worth extensive culture.

**Cyclamens.**—These were not nearly so numerous as on the last occasion, only one group being shown, and that by Mr. H. Little, Wellington Place, Uxbridge. The plants throughout were well-flowered, and the colours exquisite, varying from the purest white to the deepest magenta and purple.

**Cut Flowers.**—Colonel Trevor Clarke sent cut blooms of an Amaryllis raised in 1821, and when contrasted with seedlings of the same class of the present day, it was found that little or no improvement had been made since that date. A good collection of cut blooms of *Camellias* was shown by Messrs. W. Paul & Sons, including boxfuls of the white *fimbriata*, the rosy-scarlet *imbricata*, the bright single-flowered *corallina*, and the striped *Adamo*. Mr. Charles Turner, Slough, sent cut flowers of an attractive new Tree Carnation named *Alegitiere*, which will, on account

of its bright scarlet, well-formed blossoms, prove to be a valuable kind for market and general decorative purposes. The largest flowers of *Aponogeton distachyon* gathered from the open air which we have yet seen were shown by Mr. Parker, Tooting. Mr. G. F. Wilson, Weybridge, sent excellent flowers of *Rhododendron præcox superbum*, cut from plants in the open border. Messrs. G. Paul & Son furnished examples of the green-flowered Rose (*Rosa uniflora*). Mr. B. Hook, Reading, showed cut blooms of *Helleborus* and cut sprays of *Lonicera fragrantissima*, bearing white, waxy flowers, were sent from the Society's gardens at Chiswick.

**Miscellaneous Plants.**—An effective group of plants came from Mr. Wills, Onslow Crescent, South Kensington. It consisted of *Odontoglossum*, *Phalænopsis*, *Indian Azaleas*, and *Dendrobes*, intermixed with Mosses, Ferns, &c., and overlung with Palms, Pandanads, and *Dracænas*. Messrs. Veitch & Sons contributed a group of plants, consisting of *Rhododendron Early Gem*, surrounded by well-flowered plants of the beautiful white Japanese *Spiræa Thunbergi*, which is so easily grown, and so effective for conservatory decoration; also a pretty little Australian Fern, named *Doodia aspera multifida*. Mr. Parker also showed a pretty little Fern, named *Asplenium resectum*. Mr. B. S. Williams sent flowering plants of new hybrid varieties of *Indian Azaleas*, the results of crossing *A. amœna* with the large-flowered kinds, which, on account of their flowering whilst in a very small state, as well as being easily forced, they are likely to become popular; also a panful of plants of *Anemone fulgens*, *Primula denticulata*, and *Triteleia uniflora*. Mr. Aldous, South Kensington, contributed a neat group of plants, consisting of *Lily of the Valley*, forced bulbs, *Azaleas*, *Palms*, and *Ferns*. From the Society's gardens at Chiswick came flowering plants of *Imantophyllum miniatum* and *L. superbum*, the latter being, when seen side by side with the old variety, greatly superior to it in every respect. Messrs. Ivery & Son sent a seedling *Kennedy* named *K. Iveryana*, bearing a profusion of pretty blue, Pea-shaped flowers. For the decoration of the conservatory this is a first-class plant, of easy culture, and one which may be grown successfully either in pots or planted out; for furnishing flowers for cutting it will be found invaluable. A well-grown collection of *Palms*, *Yuccas*, *Crotons*, *Aralias*, and *Ferns* came from Messrs. Osborn & Sons, Fulham. Mr. W. Paul again exhibited plants of *Camellia Ninfa Egeria*, a white-flowered kind, remarkable for its compact habit of growth, deep glossy green foliage, and free flowering qualities.

**Primroses.**—Mr. R. Dean sent several pots of Primroses of a meritorious description, as did also Mr. Harrison Weir, Staplehurst. Colonel Trevor Clarke showed a neat little plant of *Ornithogalum narbonneense*, well furnished with stout trusses of some fifteen or sixteen white blossoms and buds.

**Fruit and Vegetables.**—A fine collection of Apples and Pears came from Mr. Ford, gardener to W. E. Hubbard, Esq., Leonard's Lee, Horsham. It consisted of twenty-one dishes of Apples and four of Pears, all of which were plump and sound, and excellent as regards colour and quality. Among the best Apples were *Winter Quoining*, *Court Pendu Plat*, *Alfriston Yellow*, *Newtown Pippin*, and *Cellini*. The Pears consisted of *Easter Beurré*, *Beurré Rance*, *Beurré Berckmans*, and *Uvedale's St. Germain*. A good dish of *Bedfordshire Foundling* and several other kinds of Apples also came from Mr. Lewis A. Kellick, Maidstone. Excellent bunches of *Black Alicante Grapes* were shown by Mr. Atkins, gardener to Colonel Loyd-Lindsay, and Mr. Mowbray, gardener to the Earl of Leven. Mr. Ford sent a good collection of Potatoes, including clean examples of *Carters' Main Crop*, *Bresée's Prolific*, *Veitch's Improved Ashleaf*, and *Myatt's Prolific*. Mr. Wilson showed fruit of *Theobroma Cacao*, from which the *Cocoa* of commerce is produced.

**Scottish Horticultural Association.**—The annual meeting of this Association was held at 5, St. Andrew Square, Edinburgh, on Tuesday last, Mr. Dunn, Dalkeith Gardens, in the chair. There was a large attendance of members. Mr. John Methven, the secretary, read the report, which showed that since the institution of the society, on March 20, 1877, twelve meetings had been held, with an attendance of between eighty and one hundred at each. The members at present on the roll of the Association were stated to be 241. The treasurer's report, submitted by Mr. Laird, showed that the total income had been £25 5s., the expenditure £14 18s. 11d., and the balance in hand at the disposal of the society, £10 6s. 1d. After the re-election of office-bearers, the constitution and bye-laws of the Association were submitted *seriatim*, and, after some discussion, approved of. The chairman proposed that Sir William Gibson-Craig, Bart., of Riccarton, should be elected hon. president for the ensuing year. It was announced that the first prize for a flower garden plan had been gained by Mr. William K. McLeod, Dalkeith Gardens; second, William Martin, Linton Park; third, William Garrett, Linton Park; and fourth, George McKinlay, Dalkeith. Sixteen plans were sent in for competition, all of them being of considerable merit. The judges were Messrs. Gorrie, Trinity; McNab, Botanic Gardens; Thomson, Drumlanrig; and Webster, Gordon Castle. It was intimated that Mr. Downie had again placed £5 at the disposal of the Association, to be applied as they thought proper. Messrs. Downie & Laird, Royal Coates Winter Gardens, exhibited a truss of a new seedling Himalayan *Rhododendron*, which has been named *Princess Louise*. Its large flower-truss is dome-shaped, of large size, and leathery texture. The colour is cherry-rose, the stamens black, and the anthers white, producing a novel effect. The plant from which the truss was taken has over fifty flower-heads on it fully expanded.

## KEW GARDENS.

We learn with regret that Sir Joseph Hooker's brother-in-law and some of his friends are endeavouring to collect the signatures of scientific men, with a view to prevent the opening of the Royal Gardens at Kew to the public in the morning instead of in the afternoon, as hitherto. Notwithstanding this, however, we think we can assure Sir Joseph Hooker and any of his "scientific" friends weak enough to give their signatures for such a purpose, that they will not succeed. The following is the memorial, for which signatures are requested:—

*To the Right Honourable the First Commissioner of Her Majesty's Works and Public Buildings.*

Sir,—We, the undersigned professors, teachers, and students, cultivators of natural science, and examiners for the public services, beg respectfully to lay before you our view of the *urgent need there is of keeping the Royal Gardens at Kew closed, as hitherto, to the general public before 1 p.m.*

We are led to believe that amongst the most important objects which the Government has in view in maintaining the Royal Botanic Gardens of Kew as a scientific institution is the providing for the wants of teachers and students, and especially medical, by giving them such indispensable means of instruction in pure and applied botany, as is afforded by classified collections of living plants and by museums exhibiting their structure, uses, &c. In support of our belief, we beg to draw your attention to the following extract from the Recommendations of the Committee appointed by Her Majesty's Treasury, in 1840, to inquire into the management of the Royal Botanic Gardens of Kew as then conducted, which recommendations we assume to have been the basis upon which the establishment was placed on its present footing, and has ever since been supported by large grants of public money.

[Extract from the report upon the present condition of the Botanical Gardens at Kew, with recommendations for its future administration, 1840, p. 4.]

"If the Botanical Garden of Kew is relinquished by the Lord Steward, it should either be at once taken for public purposes, gradually made worthy of the country, and converted into a principal means of promoting national science, or it should be abandoned. It is little better than a waste of money to maintain it in its present state, if it fulfil no intelligible purpose, except that of sheltering a large quantity of rare and valuable plants.

"The importance of public botanical gardens has for centuries been recognised by the governments of civil states, and at this time there is no European nation without such an establishment, except England. The most wealthy and most civilised kingdom in Europe offers the only European example of the want of one of the first proofs of wealth and civilisation. France, Prussia, Austria, Bavaria, Russia, Hanover, Holland, not to mention smaller Governments, have all botanical gardens, liberally maintained with public funds; and, what is more curious, Dublin and Edinburgh have similar establishments to which grants of public money have been liberally furnished; but London has nothing, except a small garden at Chelsea, maintained by the funds of a private corporation. It has usually happened that botanical gardens have been established to meet the wants of universities; and so long as London was not the seat of a university, the necessity of establishing a public botanical garden was less pressing than it is at present. Now that a great number of students are annually collected in London for the purpose of study, it has become indispensable that such means of instruction as a botanical garden affords should be provided. It appears, from returns obtained from the Society of Apothecaries, that annually, on an average of the last three years, as many as 433 medical students have been registered as attending lectures on botany in London; they are compelled to attend these lectures, not only by the Apothecaries' Society and the College of Surgeons, but by the regulations of the Army and Navy; and yet this large number of young men studying the most important of professions is practically deprived of the advantages of referring to a botanical garden, without which it is impossible that their studies can be prosecuted efficiently. It is true that there is a botanical garden at Chelsea, belonging to the Apothecaries' Society; but it is not to be expected that the funds of such a corporation, however liberally disposed it may be, should suffice for the maintenance of such a botanical garden as the wants of students render necessary."

To carry out these suggestions has ever been the aim both of the late and present director. Their efforts have been continually directed for the last forty years to adapting the Gardens, on the one hand, to meet the requirements of the public; on the other, those of scientific men. We would invite attention to the excellent museums, unique in their scientific character and importance; to the houses especially devoted to economic plants; and the large and well-ordered herbarious department, the arboretum and fruticetum, as well as the garden of medical plants. These are visited and studied by scientific men, not only from London, but from all parts of the country, and by foreigners, to whom it is of the utmost consequence

that they should be able to pursue their studies uninterrupted by ordinary pleasure-seeking visitors.

We venture, moreover, to point out that if the general public be admitted at an earlier hour than at present, the means now afforded by the unrivalled collections at Kew, of meeting the wants of teachers, &c., which they supply to them, will be rendered *practically nugatory*; for neither in the open ground, nor in the museums and plant houses can instruction be given when these are thronged by visitors of all classes from a great metropolis. On the other hand, THE TEACHER AND HIS PUPILS WILL IMPEDE THE PASSAGE OF THE PUBLIC; while of the visitors themselves, some from curiosity, others from a desire to be informed, would mix with the students, when oral instruction on the teacher's part would be difficult, and the reception of it by the pupils impossible; nor could examinations of any sort conducted under such circumstances.

We would, indeed, venture to take this opportunity of requesting that further facilities might be advanced in setting aside some beds containing a selection of medical and other plants for the express use of certain recognised medical and other schools of the metropolis, as well as the cultivation of certain specialities for lecturing and examining purposes, to be obtained, under necessary regulations, from the authorities of Kew; this would greatly enhance the scientific value of the Gardens, and would be deeply appreciated by a large class of teachers and students.

We beg to subscribe ourselves

Your humble and obedient servants,

We italicise the portions of the above which will appear most strange to those acquainted with the management of the Royal Gardens at Kew. The above memorial is accompanied by the following circular:—

26, Alma Square, St. John's Wood, London, N.W.

Dear Sir,—May we ask the favour of your signature to the enclosed memorial, with the addition of any titles and scientific positions you may hold? We would also request your aid in obtaining the signatures of any of your scientific friends.

We need hardly point out that the forenoon opening of the gardens and grounds of Kew to pleasure parties from the metropolis (a proceeding the adoption of which is now being urged on Her Majesty's Government) would render the forenoon hours as unavailable for purposes of study as the afternoon hours now are; and would thus defeat the principal object for which the establishment was created.

We are, Sir,

Yours faithfully,

GEORGE HENSLOW,

Lecturer on Botany at St. Bartholomew's Hospital and at the Birkbeck Institute, and Examiner in Natural History for the College of Preceptors.

ROBERT BENTLEY,

Hon. F. and Prof. Botany at King's College. Prof. Mat. Med. and Bot. to the Pharmacoeut. Soc. of Great Britain. Prof. Bot. London Institute and Examiner on Bot. to the Royal College of Veterinary Surgeons.

Memorials are much used at Kew. The Hookerian Herbarium was bought by the help of one. The design of bringing the herbarium to London was put aside by one. And now the public are to be kept out of the gardens by means of one.

**Meetings in the Park.**—To my mind all meetings in Hyde Park are nuisances. They are generally promoted by obscure men who wish to become notorious. London parks are, in their nature, pleasure grounds, in which the inhabitants of the metropolis hope to find quiet and repose. To convert them into areas for political gatherings is, for many reasons, most objectionable; but to convert them into battle grounds, where rival sections may test the popularity of their several opinions by free fights, is as dangerous as it is objectionable, and the only persons who can eventually benefit by such a state of things are the roughs. Thanks to the foolish behaviour of the "City gentlemen," the right to hold a public meeting has now been raised. Thirty years ago political parties in New York used to wage a war of stones and pistol-shots against each other, much to the discomfort of the inhabitants of that city. The evil worked its own cure. At present one party never interferes with the "demonstration" of another party. Last time I was there I saw several thousand Democrats assemble round a scaffolding in Union Square to hear speeches, and then march down Broadway with flags and transparencies. The Republicans looked on. A few days later the Republicans had a similar "demonstration," and the Democrats looked on. Thus all riot and disturbance was avoided, and it seems to me that if we must relieve our feelings by demonstrations, we should do well to imitate the New Yorkers.—"Truth."

## THE LIBRARY.

## NOTES ON INJURIOUS INSECTS.\*

This pamphlet, which it is hoped may be the beginning of a series of observations for the prevention of insect ravages, gives some useful information with regard to certain kinds of garden pests. Some experiments on methods of getting rid of the Asparagus beetle and its larvæ, when present in such numbers as to be destroying the plants, have turned out quite successfully; and other notes are given of practical interest, concerning applications for the prevention of Onion fly at Bury, Lancashire; methods of treating the ground for wireworm in Essex; and other matters connected with the subject, including the method in which some of the insect pests which go through their pupal change in the ground, or are aided by artificial protection, are often encouraged. The notes are by various observers, both agricultural and entomological, mainly English, but a few from North Britain, who have followed the suggestions given in a pamphlet—"Notes for Observation of Injurious Insects"—issued last year, calling attention to the great yearly loss by unchecked insect ravages, and especially to what might be done by the effects of the remedies in different districts being recorded for a few years, so as to obtain a knowledge of their applicability under various circumstances of soil and weather. The subject has been taken up much more generally than could have been expected on a first trial; good practical observers have come forward, and observations are promised for the coming season, and it is to be hoped that, as the beginning has thus been made, which is usually the difficult point in a project of this nature, the work may be expanded into taking in all our really injurious insects, and mature into a record of observations which, being entirely devoted to the causes, remedies, and prevention of insect injury, would be of much practical value. For this, co-operation is needed and requested, with all necessary references and addresses, in the "Notes for Observation of Injurious Insects," forwarded gratuitously on application by the printer, Mr. T. P. Newman, 32, Botolph Lane, Eastcheap, E.C., who also furnishes similarly ruled sheets for entries and the report of observation.

**The Freedom of Science in the Modern State.**†—Those of our readers who have been somewhat bewildered by the wild speculations respecting the origin of plants and animals set afloat in England of late years may derive some satisfaction from an eloquent and able address read by Professor Virchow before the Munich Association for the Advancement of Science. Earnest inquirers who have felt it difficult, if not impossible, to accept the theories of Sir John Lubbock and others, according to which we owe the propagation and preservation of plants with strongly-scented and brilliantly-coloured flowers entirely to insects, will find some comfort in Professor Virchow's protests against our taking the problems of research for actual facts, and the opinions of scientific men, no matter how eminent they may be, as established truths. With a few exceptions, this protest has been accepted by German naturalists, who feel themselves set free from the fetters of scientific dogmatism. The immediate origin of Professor Virchow's energetic protest was a paper read at the same meeting by Professor Häckel, of Jena, in which he adopted the theories of Lamarck and Darwin with regard to evolution. The preface to the English edition of the discourse has been written specially for it by Professor Virchow. The translation is admirably done, the tone of grave *persiflage* adopted by Professor Virchow being effectively preserved throughout.

**Fruit and Bread a Scientific Diet.**‡—In this book the author who is one of the leading German dietic reformers of the age, seeks to prove that man is a purely frugivorous animal. How far he has proved this proposition we must leave physiologists to determine. We can, however, most thoroughly endorse all that Dr. Schlickeyen says in praise of fruit, especially of the Apple, which he places at the head of the list, as far as its dietic value goes. We have always held that too little fruit is eaten in this country, but, judging by the large increase in cheap fruiterers' shops which has taken place during the last few years, the old notion that raw fruit is unwholesome, a superstition which still obtains to a great extent amongst the lower classes of the community, seems to be dying out. We cannot agree with the author that all fruit, using the term in its popular sense, should be eaten raw. The learned doctor allows his enthusiasm on behalf of fruit to carry him a little too far sometimes.

\* "Notes of Observations of Injurious Insects: Report 1877." Printed by T. P. Newman, Botolph Lane, Eastcheap.

† "The Freedom of Science in the Modern State." A discourse delivered at the Association for the Advancement of Science, Munich, by Professor Adolph Virchow, of Berlin. London: John Murray.

‡ "Fruit and Bread a Scientific Diet." By Gustav Schlickeyen. Translated from the German by M. L. Holbrook, M.D., &c. New York: M. L. Holbrook Co.

**Hooper's Gardening Guide.**—This is profusely illustrated with woodcuts. It contains choice selections of hardy flowers, annuals, &c., with instructions for their successful culture. Seed sowing, flower garden arrangements, rockeries, Ferneries, and Alpine gardens all receive a share of attention; altogether, the book contains much more valuable information for the amateur gardener than many more pretentious works.

We have received a specimen copy of "Flora des Jardins" from M. Chabaud, curator of the Botanical Garden at St. Mandrier, near Toulon. It treats specially of the flora of the Mediterranean climate, and promises to be an interesting addition to works on garden botany. The plates are extremely well done. The annual subscription for the twelve monthly parts is £1 8s. 4d., or each part 2s. 1d. It is published by the author, M. B. Chabaud, St. Mandrier, near Toulon.

**Carte's Practical Gardener.**—This has reached an eighth edition, a pretty good indication that it is found useful, 40,000 of it having been, it is said, distributed. It is of a handy size, arranged in calendrical form, and the information given is as concise as it is practical.

**Spring Flowers in Dublin.**—The mild sunny days of February have had a wonderfully quickening effect on spring flowers. Just now a beautiful bunch could be cut out-of-doors from such flowers as Daphne, Hepaticas, Anemones, Violets, Narcissi, Primulas, Heaths, Saxifrages, and Squills, which are all in great beauty, and at least a fortnight earlier than usual. I had almost forgotten to mention the Hyacinths which, out-of-doors and unprotected, are now in perfection. Appended is a list of subjects which flowered in February, and the date of their opening:—Feb. 1st, Daphne Marum; 4th, Mandragora vernalis; 5th, Berberis Aquifolium; 8th, Anemone stellata; 11th, Arabis alpina; and Vinca major; 12th, Lonicera verum and Eranthis hyemalis; 13th, Narcissus longistylis, Palmaria grandiflora, and Polygala Chamœburns; 15th, Ficus grandiflora, Hepatica angulosa, and Primula rosea; 17th, Rhododendron præcox and Viola the Czar; 18th, Iris reticulata and Anemone versicolor; 19th, Lithospermum orientale and various Heaths; 20th, Arabis blepharophylla, the Almond, Saxifraga oppositifolia, Orobus vernus, and Draba aizoides; 21st, Borago orientalis, Symphytum caucasicum, and Saxifraga Sternbergi; 22nd, Doronicum caucasicum and Viola forbiana; 23rd, Primula marginata, P. Palmieri, and Cardamine rotundifolia; 25th, Scilla bifolia and Narcissus maximus; 26th, Nouna flavescens; 27th, Ribes sanguineum and Saxifraga coriophylla; 28th, Narcissus telamonius, Epimedium versicolor, Erythronium Daus-garden, and various Hyacinths.—H. W. MOORE, *College otaic Garden, Dublin.*

**Kensington Gardens.**—There is an article on these gardens in the "Pall Mall Gazette" of the 6th inst. displaying more correct knowledge in the matter than is usual in such articles. We may, when space permits, reprint a few passages which seem to us to merit consideration.

## NOTES AND QUESTIONS—VARIOUS.

**Winter Nells Pears Not Ripening.**—Is Mr. Martin's tree (see p. 196) in a good situation? If not, he should remove it and plant it against a south wall. No fruit tree better repays good culture than the Winter Nells, and no Pear surpasses it in excellence. Is your correspondent certain that he has the true sort? With me it never fails to ripen. My tree on the Ormeau stock on a south wall is covered with bloom buds.—JOHN GARLAND, *Killerton, Esex.*

**Galium Molluge variegatum.**—This pretty plant I found in Storsy Lane, leading to the archbishop's residence at Addington, near Shirley, Surrey. I have grown it for years, but never in quantity till last season. It is one of the best plants for rockwork with which I am acquainted. It is very striking during the winter months, and when in bloom, at a short distance off it seems like clouds of silver.—WM. ELLIOTT.

**Varieties of Sedum acre.**—I have discovered on Mickleham Downs, in Surrey, a golden variety of Sedum acre, which I propose to call S. acre aureum, and another S. acre pumilion variegatum. They are both pigmy forms of this charming Stonecrop. I have also a Sedum acre found on the rocks at Torquay, and on growing the Surrey and Torquay plants I find that they differ widely from one another. The Devonshire variety grows much faster than that from the Surrey hills. They will doubtless be good subjects for carpet bedding and rockwork.—WM. ELLIOTT, *Stapleford Hall, Notts.*

**Mushrooms in Cellars.**—You would oblige me very much if you would tell me whether Mushrooms can be grown in a cellar under the dwelling-house, the manure being first of all sweetened outside, or whether disagreeable fumes would rise into the house. The cellar is furnished with a ceiling.—G. S. M. [Mushrooms have been grown successfully in cellars in two or three places with which we are acquainted, and, as far as we know, without any unpleasant consequences.]

No. 330.]

"This is an art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## THE OPENING OF KEW GARDENS.

To the Editor of THE GARDEN.

SIR,—The memorial which you reprinted in last week's GARDEN must, I am sure, have surprised most of your readers. With regard to the use of Kew Gardens by medical students, I think it is extremely important that more definite information should be given upon that point; and this could, of course, be most satisfactorily obtained from the lecturers at the various medical schools. That the medical students of London can get the specimens necessary for their purpose without resorting to Kew Gardens, is certain; the gardens of the Royal Botanic Society in Regent's Park, and of the Apothecaries' Company at Chelsea, are, from their position, more readily accessible to the majority of students, and it is from these gardens that the specimens used in the lectures and demonstrations of several of the medical schools are supplied. It is not too much to say that, compared with the benefits unostentatiously conferred by these two gardens in these respects, those afforded by Kew have been insignificant.

With regard to the assertion that the Kew collections cannot be used for educational purposes during the time that they are open to the public, I can state, from my own knowledge, that such use has repeatedly been made of them, and that without the interference of the public with the students, or *vice versa*. As a matter of fact, the "herbaceous department" and "garden of medicinal plants" are by no means attractive to the general public; indeed, the herbaceous ground, from its position, escapes the notice of many casual visitors to the gardens, while others find the long rows of straight narrow beds far from interesting, and pass through them as rapidly as possible.

If it be really desirable that the gardens should remain closed to the public until one o'clock, it is essential that some substantial reasons for this course of action should be brought forward.

JAMES BRITTEN.

—The subscriptions towards meeting the expenses incurred in the attempt to attain the opening of Kew Gardens throughout the day will show that the matter is far from being (as the Kew authorities and their few supporters would have us to believe) of a purely local character. As a further proof we may add that the opposition shown to those desirous for the proposed reform by the Kew officials has been remarked and freely commented upon by foreigners. The late Sir W. J. Hooker has left on record this peculiarly gratifying fact that, contrary to the anticipations of many persons, the privilege of the free daily admission of the public to the gardens, grounds, plant houses, and museums has been rarely abused. This experience of the late director must apply with equal force now that Kew is under the directorship of his son, for if the yearly number of visitors is greater at the present time than it was then, so is the staff in like proportion. That the British public is tractable enough is abundantly proved by Sir W. Hooker's evidence, given in the last issue of the "Authorised edition of the Guide to the Royal Botanic Gardens," dated 1873.

In THE GARDEN Mr. Croucher effectually disposed of the theory that scientific work would be prevented by the earlier admission of the public, for, as he tersely remarks, none whatever is carried on, except in buildings to which the public have not access.

The statement that, if the gardens are opened earlier, the labourers will have to be care-takers during the morning as well as in the afternoon, and that another set of care-takers will be required to attend to cultivation, is, to say the least of it, absurdly exaggerated. Only on busy bank holidays do the labourers leave their ordinary work to look after or interfere

with the public in any way whatever. Except on the days just mentioned, and on Sundays, the labourers are care-takers in no active sense. They leave at 6 p.m. in summer, and from then until 8 p.m. the gardens are left in the sole charge of a few policemen, notwithstanding the large number of visitors. Assuming that no alteration for the better could be made in the present arrangements as regards the number and duties of the staff employed, it can easily be shown that very little extra money would be required to fully carry out the proposed reform. The constables and gatekeepers have to be on the place at 8 a.m., so no additional expense would be incurred in this item, as a few decent labourers could perform the duties of the gatekeepers (as is frequently the case now) during the hour allowed for dinner in the middle of the day. As regards policemen, the case is somewhat different, but the three extra hours daily for six or eight policemen during summer and half that number during winter could not amount to much, and, by a slight change, this amount might be obtained without the British taxpayer having to contribute an additional penny.

The movement is of such general interest and importance that, in concluding, I can only hope the end may be attained, as it need not involve much, if any, extra expense, and as scientific work would not be in any way retarded.—"A KEW MAN."

—It is satisfactory to find that THE GARDEN is using its influence to get Kew Gardens opened throughout the day. Many have doubtless been put to great inconvenience through their being kept shut in the morning. There is one class in particular who are prevented from visiting Kew, on this account—I mean horticulturists from the country to attend the London flower shows. Many gardeners who exhibit in London would often have gladly availed themselves of the opportunity of visiting Kew had they been able to get in at say eleven o'clock, after they had stazed their exhibits, and during the time when the shows are closed to all but the judges. It has, I think, been said that such people may gain admittance at an earlier hour if they apply to the authorities; but if it is just that people for whom Kew Gardens have most interest, and who, more than any other class, should be at all times admitted, should be obliged to ask as a favour what they are entitled to as a right? As to opening the houses in the morning, all gardeners know that if there be any time in the day when they would rather open their houses than another, it is in the morning, and not in the afternoon. Long before ten o'clock in the morning all watering could be done.—W. P.

—As the statements of the Kew authorities, regarding the supposed interference of the public with the ordinary work of the gardens, have been refuted, I may perhaps be allowed to give my testimony, so far as the Museums are concerned, against the statements in the Memorial printed in THE GARDEN last week. I have had twenty years' experience in the Museums, during which time I was on duty from six to six in summer and from dawn to dusk in winter, with the exception of an hour and a quarter in the middle of the day. I can vouch that seldom, if ever, has any "professor, teacher or cultivator of natural science" brought pupils into the Museum before public hours, and even during public hours I have but very seldom seen anything like lessons given. The only exception is the course of lectures given to the young gardeners by the Museum Curator from 8.45 to 9.15 during the summer mornings.—G. RICHARDS (20 years attendant in Museums at Kew).

Mr. Jean Sisley writes to us from Lyons saying that the excellent Botanic Garden there is open throughout the day without any reservation, except in the case of the houses when the men are at breakfast for one hour. We have already published paragraphs showing that the Paris, Edinburgh, and Dublin gardens are also open to the public early in the day.

As a type of the "arguments" used against the opening of the gardens at Kew, we reprint the following specimen from the "Journal of Horticulture" of last week:—

*Meetings have been held, and deputations have waited on the First Commissioner of Works; flowers of local oratory have been cultivated, and the "rights of the people" have been asserted, as they always are when a small section of the community wants to appropriate public property for their own benefit. The only argument we have heard in favour of this movement is that some speculating builders having formed a neighbourhood along the road between Kew and Richmond, the inhabitants who have become possessed of these houses are endeavouring to increase their value by adventitious means, and these are, to urge the Government to open the Royal Botanic Garden of Kew from morning till night, that these people and their domestics may disport themselves at the national expense. Such a proposition, even at first sight, seems*

monstrous, and when it comes to be investigated one cannot but be surprised at the presumption which these people are capable of. It is known by experience that grounds like those at Kew, beautiful as they are, have not yet had the soothing and humanising effect on the British rough that optimists think they have.

When Kew gardens, like other national botanic gardens, are open to the public throughout the day, the above may be interesting as a specimen of the gentle and logical "arguments" which some do not hesitate to print in connection with the opening of this national garden to a public who support it with a liberality wholly unparalleled. Words very fitting to support the insupportable!

**Iris reticulata and its variety Krelagei.**—Here, in Derbyshire, *Iris reticulata* is perfectly hardy, and I have never found the slightest difficulty in growing it. It succeeds well in almost any situation, although when grown in a warm and sheltered position its flowers are much finer than they otherwise would be. The bulbs increase rapidly if left in the ground undisturbed. I have now three large clumps of it in full beauty, containing sixteen, twelve, and nine blooms respectively. These were planted in the autumn of 1876, and have not been moved or disturbed since. A single bulb which I planted in 1874 has now made a clump which this spring has six blooms. The variety *Iris reticulata Krelagei* comes into bloom here about ten days earlier than *I. reticulata*, to which it is decidedly inferior, both in colour and size. The two varieties should never be planted in close proximity to each other, for the lovely deep violet of *I. reticulata* does not harmonise with the dull Plum-colour of *I. reticulata Krelagei*.—HUGO HARPUR CREWE, *Calke Abbey, Derby.*

—There are among *Iris reticulata* var. *Krelagei* different strains, some very inferior, others just as good or even better than the type *I. reticulata*. In a strain which I have raised from seed the flowers of the former are rather broader in all their parts, and the purple is just as bright, only of a reddish hue. Seedlings vary, and I have slightly different ones. To perpetuate this and to improve the produce, sowing and sowing again must be maintained. *I. reticulata Krelagei*, moreover, has the advantage of being fourteen days earlier than the typical form. If Mr. Millington will remind me in June next I shall have much pleasure in sending him some of my bulbs to prove my statement.—MAX LEICHTLIN, *Baden-Baden.*

**Hydrocotyle sibthorpioides.**—This is an interesting, little-known, hardy trailer, well adapted for brackets and small baskets. As its name implies, it somewhat resembles *Sibthorpia europæa*, but it is a hardier and a handsomer plant. The leaves are cretated and serrated; they lie flat on the ground, and are not, like those of the *Sibthorpia*, produced in a confused, dense manner. This sparseness of foliage adds to its beauty, as every one of its pretty leaves has an individuality which the *Sibthorpia* does not possess.—T. WILLIAMS, *Ormskirk.*

**Spring Bulbs in Rose Beds.**—For several seasons we have planted our bulbs out, after having flowered them in pots, in beds, and banks of Roses, and the two certainly appear to advantage together, as the bulbs give a bright cheerful appearance to beds, which at this season would be nearly bare. As the Roses are pegged down, only the strongest young wood of the preceding year's growth is retained at pruning time, and the Roses may be set at tolerably wide distances apart, which allows ample space for a few clumps of Hyacinths, Narcissus, or Tulips, while a good margin may be allowed for an edging of Crocuses, Snowdrops, or Squills. We annually top-dress, but never dig the beds, and the bulbs are nearly ripened off before the shade from the Roses becomes dense enough to injuriously affect them.—JAMES GROOM, *Henham.*

**Pampas Grass Plumes from California.**—The plumes of this stately Grass were sent from California last autumn in large number to New York and other eastern cities. Nothing can be finer in the way of ornamental Grasses than these spikes, about 3 ft. long, of a dense wavy mass of silken florets and hairs, of nearly pure white. This Grass (*Cymbidium argenteum*) is dioecious, the pistillate or female spikes being greatly inferior to the staminate in size and silkiness, so much so that some dealers supposed that another Grass had been sent to them. The Pampas Grass must be cultivated largely in California, probably expressly for these plumes, which appear as if they had been exposed to sulphur fumes, as they are much whiter than we have seen them elsewhere. This Grass is scarcely hardy at New York, though it may usually be kept through the winter by giving the roots a covering. A sack placed over the clump, filled with leaves, and covered with boards to throw off rain, makes a not very sightly, but an efficient covering.—"American Agriculturist." [Messrs. Hooper, of Covent Garden, have had some of these spikes of Californian Pampas Grass, and very fine they were.]

## NOTES OF THE WEEK.

**Tritomas and Geums in March.**—*Tritoma grandis*, which forms such a noble object in some gardens late in autumn, is now throwing up flower-spikes freely in the Exotic Nursery, Tooting. This is remarkable, considering the enormous strength which it throws into the flower-stems in autumn. It is a most valuable plant, and in various ways distinct from all other *Tritomas*. The hybrid scarlet *Geum*, semi-double and single, are also flowering freely in the same place. They are young plants, which always have a greater tendency to flower out of season than the old ones. Among the fine-foliaged hardy plants in the same nursery *Eryngium Scra*, with its large rosette of handsome leaves close to the ground, is now very interesting.

**Pultenaea rosea.**—In Messrs. Rollissons' nursery, at Tooting, there is just now a good display of this new and interesting hard-wooded greenhouse plant. It comes from the Grampians of Victoria, where it is found at an altitude of 5000 ft. Its flowers, which are borne in round clusters on short, Heath-like branches, are of a bright rosy-lilac, a colour altogether distinct among *Pultenæas*, most of which are yellow. As a greenhouse decorative plant this will, when better known, doubtless prove a general favourite, both on account of its dwarf, bushy, free-growing habit and its neat, Pea-shaped blossoms, which are produced in profusion for several months in succession.

**Iris stylosa.**—As delicate and refined as the choicest of Orchids are the flowers of this *Iris* at this season. We find them being borne freely on established plants in several London gardens, and nesting among thick tufts of Grass-like foliage, they remain partially secure from frost and cold entering winds. Though not an attractive plant, on account of its flowers being thus hidden, for furnishing cut blooms it should be grown in every garden, for when mixed with even the most delicate flowers of the stove or Orchid house, the silky, sky-blue flowers of this *Iris* possess a charm and softness unequalled by perhaps any other flower of the same colour.

**Coloured Primroses.**—We have received some lovely hybrid Primroses from Mr. Clapham, Ramsdale Bank, Scarborough. Some of them, with the exception of the yellow eye, are nearly black; others are crimson laced and flaked with white; and some, like the *Polyanthus*, are narrowly laced with yellow. They are, however, sent chiefly to show that Primroses with a circular outline are preferable to those that have deeply-lobed flowers. They are undoubtedly the forerunners of an improved race of Primroses.

**The Variegated Comfrey.**—This plant is now very handsome, on account of its bold and striking variegation. At present the leaves are all in rosettes close to the ground, and in this shape form a bright ribbon at Mr. Parker's nursery, at Tooting. By-and-by the stems and leaves will rise and form a larger plant as the spring advances, and afterwards there will be numerous drooping blue flowers over all. In short, the plant may be used with excellent effect in the garden of hardy flowers, although generally it is only seen in mixed collections of lardy variegated plants.

**Azalea Rollissonii.**—This new double-flowered *Azalea* is now finely in bloom in the nurseries of Messrs. Rollisson & Sons, who imported it from the mountains of Japan. It may probably prove to be hardy, in which case it will be a valuable acquisition for border or rockwork planting. It is of very dwarf and compact growth, having spreading branches and small, hairy leaves. The flowers are about 1½ in. across, of a light salmon-red colour, very freely produced, and have the appearance of a well-formed *Balsam*. It received a first-class certificate last summer when exhibited at the Royal Botanic Gardens for its value as a decorative or market plant, for which purpose it is, when well known, likely to find general favour.—C. W. S.

**Chionodoxa Forbesi.**—There is no question about this being quite hardy. It is now in bloom with me in a cold glazed pit, but I gave a few of the bulbs which Mr. Maw kindly sent me to my cousin, Miss Lovell, who planted them at once in the open border at Calke Abbey, near Derby, where they have bloomed freely during the last week.—W. HARPUR CREWE.

**Aponogeton distachyon at Tooting.**—About London, during the winter, there has been no more interesting sight than the profuse bloom of the fragrant Cape Aponogeton. In the open air, in Mr. Parker's nursery at Tooting, myriads of its handsome flowers, with a scent like that of the Hawthorn, float gracefully on the water, and long and most graceful fresh green leaves lie quite flat on its surface. In the midland and cold districts it is necessary, for the perfect culture of this plant in the open air, to grow it in spring or other water that does not freeze; but in mild districts and in the south of England this is not needed. In Mr. Parker's nursery

where it grows so freely, it is supplied with water from an Artesian well, conducted into the reservoir in which it is grown. Where natural springs keep a pond from freezing it will grow well in any part of the country, with, of course, a little care in starting it. In addition to its blooming throughout the winter in England in the open air, it may also be grown and flowered well as a pot plant; in suitable positions it may be had in bloom all the year round, and it may be well flowered in an inverted bell-glass in a room.

**Narcissus maximus.**—This is just now in fine condition in the College Botanic Garden, Dublin, large old clumps or masses of it making a fine show. It is indeed a noble plant, and deserves all the praise given it in THE GARDEN of last year. There is a good collection of Narcissus here, but this, to my taste, is the best of them all.—W. D. D.

**Scilla bifolia var. nivalis**, or *S. nivalis* (Boiss), is a rather showy little bulbous plant, just now in flower. Its numerous little balls of the purest white contrast beautifully with the corulean blue of *S. sibirica*.—MAX LEICHTLIN, *Baden-Baden*.

**Iberis semperflorens about London.**—This fine old plant, which is seldom seen in our gardens, is now in flower on the warm, light soil in Mr. Parker's nursery, at Tooting, and has been so for some time. It is common in Southern Europe, but scarce with us, no doubt on account of having perished in certain soils and localities. It ought to be in every garden in all mild districts, and also in warm soils on banks and rock gardens.

**Camellias at Chelsea.**—The large Camellia house in the Exotic Nursery is just now well worth a visit, the fine specimens which it contains being fully in bloom. All the best known sorts are here represented, and afford a good opportunity for selection. The central path through the house is gay on both sides with profusely-flowered plants of *Rhododendron Early Gem* and the white *Spiraea Thunbergi* placed alternately.

**Psychotria leucantha.**—This by no means common plant is well worth growing, for the sake of the clusters of snowy-white blossoms which it seldom fails to produce, even on small plants. A warm greenhouse temperature suits it perfectly, and the blossoms, which are produced from the axils of the leaves, last for a long time, and are sweetly scented. They might be used before they are fully expanded in place of Orange blossoms.

**Coptis orientalis.**—This rare little Japanese plant has been in flower here during the last fortnight. It is a small perennial, the flowers of which are never very showy nor conspicuous. Their interest consists in their singularity; they are of small size, white star-shaped, five or six in an umbel, of which each bush produces several. It flowers very early in spring, and on that account will be found useful.—MAX LEICHTLIN, *Baden-Baden*.

**Sarracenia Drummondii alba.**—A large specimen of this *Sarracenia* now forms an attractive feature in Mr. Williams' nursery, at Holloway. It is furnished with no fewer than fifteen large, dark, crimson flowers, which form a striking contrast to its delicate white, green-veined, trumpet-like pitchers.

**Monsieur Naudin.**—We have great pleasure in announcing that our friend, M. Naudin, one of the Garden of Plants, has been appointed to take charge of the most interesting garden at Antibes, lately given to the State. This was the celebrated garden of the late M. Thuret. It is now proposed to make it an experimental and botanical garden, which will be, so to say, a branch of the Jardin des Plantes under a southern sky.

**Dendrobium superbiens.**—The longevity of the flowers of this new *Dendrobium* is remarkable, blossoms which were opened on plants in Mr. Williams' nursery on Dec. 1 having only just decayed. It will therefore be seen that plants of it, if kept in a moderately cool dry temperature, would be attractive objects for at least three months in the year, and this during a season when good flowering plants are in most request.

**Medinilla magnifica.**—This well-known stove plant is seldom met with in really good condition, but it is well worth all the trouble it is necessary to bestow upon it in order to bring it to the highest state of perfection. Grown in a warm, moist temperature, and kept free from insects, large specimens of it in the Holloway nurseries, loaded with massive, pendent clusters of rose-coloured blossoms, rank among the most attractive objects of the stove.

**Orchids at Clapton.**—The Orchid houses in Messrs. Lows' nursery are just now very attractive, thousands of plants of the choicest kinds of Orchids being in full bloom. These include remarkably floriferous examples of *Dendrobium Wardianum*, *D. crassinode*, and the slender, free-flowering, delicate sulphur-coloured *D. luteolum*. A house devoted to the charming *Odontoglossum cirrhosum* contains many plants furnished with handsome spikes of sweet-scented, beautifully-spotted blossoms of that *Odontoglossum*;

whilst the *Phalenopsis* house, of which we made mention some weeks back, is now a grand feature. Thousands of plants of these attractive Orchids in full bloom represent a miniature meadow of waving, butterfly-like blossoms. The kinds now in bloom consist chiefly of *P. rosea*, *amabilis*, and *Schilleriana*. *P. grandiflora* is nearly over, but there still remain a few of its large, ivory-white blossoms to set off flowers consisting of other colours to advantage, and thus render the whole more interesting.

**Two New Roses.**—Mr. Henry Bennett, of the Manor Farm Nursery, near Salisbury (I cannot write the word without a very sad regret that we Rosarians shall see no more at our congresses a brother, whom we of us loved as a true florist and a good man—John Keynes), sends me two *Rosebuds*, which inspire me with hopeful admiration. The one is a new Hybrid Perpetual, called *Mabel Morrison*, in wood and foliage closely resembling the *Baroness Rothschild*, from which *Rosa* it is said to be a sport, but having flowers of a pure white, not showing until autumn the pink complexion of *mamma*. *Mabel Morrison* promises to be a precious acquisition in our present dearth of really white *Roses*, larger than *Madame LaCharme*, and more reliable and hardy than *Niphotes*. The *Rosa* was raised by a zealous florist, Mr. Joseph Broughton, of Leicester. The other *Rose* is from sunny France, bought by Mr. Bennett from *Madame Ducher*, of Lyons, and has that marvellous combination of colours only to be found in the Tea-scented class—a soft apricot-yellow flushed with rose. *Madame Welch* seems to me to have charms equal to those of *Catherine Mermet*; and “what can mortal wish for more?”—S. REYNOLDS HOLT.

**The Spring Snowflake.**—A dozen years ago it was a rarity to see a flower of this in the choicest private collection of hardy plants; now it begins to be somewhat plentiful, and it is very probable that it will some day be a greater favourite than the *Snowdrop*. It deserves to be so from its handsome rich green leaves, larger flowers, and freedom and vigour when established. It is one of the many fine hardy plants which are never valued, owing to being too frequently seen in a weak state. When well established in rich, free soil, as it now is in Mr. Wilson's garden at Weybridge, it is unsurpassed for beauty among the many spring flowers that now adorn our garden. At Heatherbank it is so vigorous, that the stems frequently bear two flowers each.—“Field.”

**Erica melanthera.**—Though this is one of the prettiest *Heaths* which we possess, yet, singular to say, it is not grown in such quantities as many other kinds. Either in the form of small plants or as specimens it never fails, under good culture, to produce a profusion of small, puce-coloured flowers with black anthers; the blossoms, too, last in perfection for a very long time both on the plants and in a out state, in which the long feathery sprays are effective when judiciously introduced amongst light-coloured flowers. Moreover, the outting of the flowers does not injure the plant in the least, but rather improves it by rendering it more bushy. A few good specimens of it may now be seen in several gardens round London.

**Laurels in Ireland.**—Everyone seems to me to write about *Quills* and *Primroses* being in flower, but no one has a word to say about *Laurels*. Mine are like forest trees, and this year, being so exceptionally mild, they have blossomed like the *Portugal Laurel*, and given us the glory of summer in the beginning of March. I can imagine nothing more beautiful than their creamy inflorescences, backed up by the large, shining leaves. The flowering of the *Laurel* does not, however, occur often with us—once in a dozen years, perhaps.—J. M. BARRY, *Mocullup Castle, Lismore*.

**Orchids at Chelsea.**—There is now a fine display of blossom in Messrs. Veitch's Orchid houses. Specimens of the attractive *Dendrobium Wardianum*, suspended from the roof, and furnished with pseudo-bulbs from 3 ft. to 4 ft. in length, beset with richly-tinted blossoms, make an effective feature; *D. crassinode*, grown in small baskets, is likewise furnished with short, stout, pseudo-bulbs, also laden with blossoms. There are, too, large plants of the beautiful *Odontoglossum cirrhosum*, bearing great branching spikes of sweetly-scented blossoms. Associated with them are well-flowered plants of *O. Andersonianum* and a very beautiful *Odontoglossum* named *Jennings*, which appears to be a variety of *O. gloriosum*. This has well-flowered blossoms with whitish sepals and petals spotted with rich brown. In addition to these, several specimens of the chocolate and golden-flowered *O. triumphans*, and the oblate, small, ivory-white-flowered *O. pulchellum* are also flowering abundantly. *Odontoglossum roseum* bears small, red, star-like blossoms, and *Masdevallia Chimera* is bearing numbers of its peculiar-looking blossoms.

**Species of Amaryllids.**—We understand that a premium will be offered by some Fellows of the Royal Horticultural Society for species of the Order *Amaryllidaceae*, of which due notice will be shortly given. It is very desirable that this beautiful and varied race of plants should be brought together if only for scientific purposes, as much confusion still exists amongst them.

## NOTES FROM KEW.

**Hardy Plants.**—*Erythronium giganteum*, a yellow Dog's-tooth Violet from Western America, which flowers a little later than its European congener, the common Dog's-tooth Violet, is a very showy and desirable plant, although its foliage is not so pretty as that of the European species. The earliest of the Tulips appears to be *Tulipa precox*, from the south of Europe; the flowers are very handsome, scarlet blotched with blackish-purple and yellow. *Anemone pavonina*, from the Mediterranean regions, is very attractive on account of its brilliant red flowers. Another Wind-flower, *A. Nuttalliana*, from North America, resembles the Pasque-flower, *A. Pulsatilla*, of the limestone pastures and chalk downs of England, but is rather more shaggy-looking than that species, and has flowers a trifle paler in colour. *Draba aizoides*, the British yellow-flowered Whitlow Grass, is a charming little rock plant, about 2 in. or 3 in. in height. A nearly-allied species, *D. Aizoon*, from Carinthia, has larger leaves, but is very similar in appearance to the last named. *Dentaria digitata* is another very handsome, dwarf, Cruciferous perennial, the large, rosy-purple flowers being rendered more conspicuous by the light green leaves. This is a North American plant, and is infinitely more beautiful than the common Coral-root, *D. bulbifera*, of the woods and copses of some of our southern counties. *Soldanella alpina* is a very charming Alpine; its small, firm, round leaves and numerous peduncles bearing each two or three drooping, beautifully-fringed, blue flowers, combine to render this one of the most elegant of rock plants. Amongst Primroses the prettiest are *P. nivalis*, with large, umbellate heads of white flowers; *P. marginata*, with mesly leaves, and flowers of a light purple colour; and *P. Dinyana*, with smaller, bright reddish-purple flowers. Three species of Leopard's-bane are worthy of special mention, on account of their beauty and of the ease with which they can be grown. The earliest of these European Composites is *Doronicum caucasicum*, the large, bright yellow flowers of which are very conspicuous. *D. Pardalianche* is a rather taller grower, and *D. austriacum*, which flowers next to *D. caucasicum*, is also rather larger than that species. All these will succeed in almost any soil or situation, and are admirably suited for the wild garden, as they flourish well under trees. Indeed, *D. Pardalianche* is thoroughly naturalised in several places in Britain. The smallest of all the Hoop-petticoot Narcissus is *N. nivalis*, which has been bearing its miniature yellow blossoms for a week or more past. *N. juncifolius* var. *rupicola* is a very rare plant in collections; it is also a small grower, and differs from the type in its lesser size, and also in the lobed, not truncated, corona. *Asphodelus acutis* is very pretty and uncommon. Its large, rose-coloured flowers are borne on a dense, umbellate, very shortly-stalked head, nestling in the tuft of rush-like leaves. *Daphne Blagayana*, a native of Carniola, is a most desirable rock plant. The good-sized flowers are produced in umbels, are deliciously fragrant, creamy-white in colour, and the anthers, reaching to the mouth of the tube, form a fine yellow eye, which adds to the beauty of the plant. The blue and white Grape Hyacinths (*Muscari botryoides* and *M. botryoides* alba) are too pretty to be passed over without mention. *Bolboodium venustum*, from Spain, is a beautiful little bulbous plant, with purple, Colchicum-like flowers. This, which seems to like a sandy loam and to object to strong, clayey soils, is worthy of careful cultivation. *Nonnea lutea* is a free-flowering little annual from South Russia; its yellow flowers are produced in great abundance, and the early period at which it blooms ought to secure it a place in the flower garden, where it will sow itself and hold its own without becoming a weed. *Cardamine trifolia*, a bitter Cress, with trifoliate leaves and upright racemes of pure white flowers, is well worth growing. The *Mandrake* has played too important a part in popular superstition for any species of *Mandragora* to be passed over. *M. vernalis* is now in flower; the entire, lance-shaped leaves spring from the summit of a very short stem, and the flower-stalks, springing from amongst the leaves, bear each a solitary flower, greenish, tinged with dull purple. Two *Fritillarias* conclude our list of hardy plants. *F. lilacea* has (at Kew) single-flowered stems, about 6 in. in height, and greenish-purple flowers; it came from California and Nevada. *F. crassifolia*, from the mountain regions of Armenia, is a still smaller species than the last, and has dull purplish-red flowers.

**Indoor Plants.**—The most interesting of the greenhouse plants are those mentioned below. The Jessamine-flowered *Rhododendron*, *R. jasminiflorum*, introduced many years ago to this country from Mount Ophir, in Malacca, by Messrs. Veitch, through their collector, Mr. T. Lobb, is a very elegant species, and one eminently adapted for greenhouse work, as it flowers freely in a young state. The pure white flowers, to which the anthers form a sort of red eye, are produced in large heads, and are remarkable for the long, straight tube and salver-shaped limb. The Snowball tree, the cultivated variety of the British *Viburnum opulus*, is an extremely pretty object when forced, and vies with many rarer and more

expensive plants which are used for similar purposes. *Pyrus Malus* var. *floribunda* also forces readily, and its beautiful red buds contrast well with the fully-opened white flowers. *Lonicera sempervirens* var. *minor* is a very attractive and desirable rather plant for the cool conservatory; its fine red flowers are very freely produced. *Adenandra umbellata*, a most charming Rutaceous shrub, from the Cape of Good Hope, has flowers nearly 1 in. in diameter, white, with the exception of a reddish line at the base of each of the five petals. *Xerotes longifolia*, a peculiar New Holland plant, has long, toothed, somewhat Grass-like leaves and panicles of orange-yellow flowers, which exhale a strong Vinous odour, similar to that of the yellow Water Lily; this Sedge-like herb ought to grow well in the open air in sheltered positions in most of our southern counties. *Bomarea Caldasii* is a very handsome Cape climber, with large umbels of orange-red flowers, minutely spotted with black. *Beschorneria Tonelli* is an Agave-like *Amaryllid* from Mexico, but its long tubular flowers, being greenish in colour, are not nearly so handsome as those of *B. yuccoides* or *B. tubiflora*. The preceding may be seen in the Succulent House (No. 5).

**Orchids.**—Of these the following are amongst the best not previously noted;—*Odontoglossum cirrhosum*, from Ecuador, is very beautiful; its lance-shaped sepals and petals are pure white spotted with brown and the lip is yellow. *O. Rosii* is a smaller species from Mexico; the whitish ground colour of the sepals is nearly hidden by large brown spots; the petals are white, except at the base; the base of the lip is yellow, the remainder being white; the column is of a purplish colour. *Notylia nuptialis* is a rare species from tropical America; it much resembles a small *Angraecum* in habit, and bears its little, whitish flowers in dense, pendulous racemes about 6 in. in length. *Dendrobium thrysiflorum*, introduced from Moulmein by Messrs. Veitch some years ago, is like *D. densiflorum* in habit, but is a stronger grower than that species; the lip is a rich golden-yellow, the remaining parts of the flower being white. *D. superbum*, generally known under its garden name *macranthum*, is a vigorous plant with large, showy, purplish flowers, which, however, emit a disagreeable scent. *D. Kingianum* is a small Australian species with rosy-purple flowers.—†

**Solanums and Mice.**—Mice have a particular fondness for the berries of the Solanum, but as soon as their depredations are discovered I have checked them in the case of standard plants by putting a collar made of cardboard half-way up the stem, beyond which they could not pass. In the case of bush plants the simple expedient of placing them upon inverted pots, so as to elevate them several inches above the pots of the surrounding plants, proved to be an effectual bar to their incursions. Of course traps were not neglected. The old figure 4 trap is one of the best in my experience, and it can be made in five minutes or so.—A. D.

**The New Zealand Flax for Tying.**—The leaves of *Phormium tenax* (the Flax Lily of New Zealand) constitute one of the best materials which we have for tying plants. It is superior to bast or Raffia Grass, and, being green, is not unsightly. The New Zealand Flax grows freely in any rich loam to the height of 5 ft. or 6 ft., and is perfectly hardy. The leaves should be cut as they are wanted for use. They split freely, as fine as thread and almost as strong. The plant is very ornamental, and some of its variegated forms are extremely beautiful; it is a matter of great convenience to have a plant growing in the herbaceous border from which a few leaves have only to be cut to supply oneself with a good tying material which costs nothing.—JAMES PINK.

**Dwarf Sedums.**—Mr. Elliott seems (see p. 222) to be unaware that there is already in existence a variety known as *S. acre aureum*. What is so generally grown as the golden-tipped Stonecrop is thus named in plant lists, and has been so for these past ten years. *Sedum acre elegans* has silver variegation, but with this variety the pale colour is not limited to the points of the shoots, but generally marks all the new growth. It is a very pretty kind, and is best in summer, the golden-tipped form being in great beauty in winter and spring. Curiously, although both of these kinds are assumed to be sports from *Sedum acre*, which blooms so freely, yet neither of these flower. *Sedum acre elegans*, silver variegated; glaucous, silvery glaucous; and *lydium*, deep green, are the best known kinds for carpet bedding, and are more useful than any tender plants.—A. D.

**Wild Cucumbers.**—M. Naudin, who, it is well known, has made a special study of the Cucurbitaceæ family, asks us to state that he will be very much obliged to any of our readers who, living in hot countries, happen to meet with any of the family growing in a wild state, if they would send him ripe seeds of the same. His address for the future will be Villa Thuret, Antibes, France. This climate for the growth of the Cucurbitaceæ will be all that can be desired.

## THE FLOWER GARDEN.

### CUTTING DOWN LILIES IN FULL BLOOM.

"I AM surprised that anyone should say that Lily bulbs do not suffer from being cut down in full bloom. We have found that the bulbs are injured or killed outright just in proportion to the time at which cutting down is performed." This is what Mr. C. M. Hovey, of Boston, Mass., says (see p. 196) with reference to my remarks of an opposite nature on the same subject. I am glad to see a communication from the New World, and hope they may continue, but Mr. Hovey's, at present, does not throw much light on this part of the subject. Some of the readers of THE GARDEN may recollect that in October last (see p. 375) I said: "On Saturday, the 30th of June, I lifted several clumps of *L. candidum* when they were in full bloom, having previously cut off the stems with the flowers. As I had to leave home on the following Monday for six or seven weeks, I placed them in a basket in my tool-house for further examination. On my return home, towards the latter end of August, I took the bulbs out of the basket and re-planted them, as I had noticed amongst them some interesting specimens. Considering that these bulbs had been taken up while the parent bulbs were in full bloom, and that they had been out of the ground more than six weeks, they were in very good condition; the parent bulbs were, however, very much decayed. This I expected, for as the parent bulbs had bloomed once—all that Nature requires—nothing remained for them but to decay and die. In about a fortnight after I had re-planted the new bulbs I was rewarded by seeing the green tufts shooting up above the ground. Allowing the specimens, which I had replanted separately, to grow for another fortnight, I again took them up, when I found them to be in as strong and healthy a condition as any other Lilies of the season. The other bulbs that I had lifted and re-planted at the same time were, when I left home a few days ago, growing as strongly, if not stronger, than those that had not been disturbed at all. In addition to what I have said on this subject, I may mention that a nurseryman, whose grounds are near London, is in the habit of growing thousands of Lilies for the sake of the flowers as a marketable commodity. After having cut off all the flowers, he lifts the bulbs, and after gathering all the offsets for stock, as he calls it, he re-plants the bulbs. This he does annually, and I have never seen a better show of bloom. Mr. Hovey says that he is surprised that anyone should say that Lily bulbs do not suffer from being cut down in full bloom. I hope he will look out for my next paper on another part of the subject, because I think his surprise will be somewhat increased, but not, I trust, in an unbelieving way.

Assizes, Western Circuit.

DUNEDIN.

Being "all curiosity" to know "Dunedin's" discovery with regard to Lily bulbs, which he promises to let us know shortly, I venture to suggest meanwhile (though I feel myself reminded that fools rush in where angels fear to tread) that, in default of a better word, the term, "rhizomatous bulb" might best explain the somewhat contradictory characteristics of what have hitherto simply been called Lily bulbs. Some Lilies, notably *L. pardalinum*, are so markedly rhizomatous, that, while the scales decay after one year, the root-stock and base of the decayed scales remain for at least three years (I have not observed this bulb for a greater length of time). In one instance the root-stock, growing horizontally, divided into two equal parts, the two ends clothed with scales being still joined by a fresh and succulent stem. This Lily, then, is neither a simple bulb, nor does it die and renew itself entirely every two years. On the other hand, only last week I found the young growth from a bulb of *L. testaceum* actually growing up inside the decayed flower-stalk of last year, and blanched in consequence. This points clearly to the upward and unbroken growth from the core of last year, which was so exactly under the flower-stem of last year as not to have

swerved in the least to one side or the other. In this hybrid the scales of more than one season's growth are visible in autumn very distinctly if a bulb be mutilated one year and examined the next autumn. In a third instance there appears to be a total change both of scales and core in a year's time. *L. Martagon dalmaticum*, therefore, seems to justify some of "Dunedin's" remarks, but I shall be curious to see if he can find a term that will satisfy both himself and his fellow searchers after truth. The different ways of reproduction in Lilies are so marked that alone it would afford subject matter for endless remarks and controversy. I will therefore content myself with offering a name that seems somewhat to express the true nature of what has hitherto been recognised by the name of Lily bulb.

E. H. W.

### HARDY PRIMULAS.

This is the most interesting period in the year as far as this charming family of hardy plants is concerned, as all the earlier kinds are now in bloom, and many others are following in close succession. We have here single and double Primroses, Polyanthuses in many forms, and *Auricula* single and double, all of which largely come under the head of florists' flowers, and are very different from the kinds that

have distinctive botanical appellations. The Japanese *Primula amœna* is one of the most beautiful of Primroses, both as regards flowers and foliage, and already this has proved the most fertile in the production of kinds from seed. In addition to the dozen sorts of seedling Primroses now being sent out, we have as many new and very charming kinds raised by an eminent amateur cultivator, Mr. James Allen, of Shepton Mallet, and I have further some forty seedlings that will flower for the first time this year, so that the *amœna* section promises to excel the Chinese species in the production of variety, and is at the same time much easier grown. Just as the Chinese *Primula* has done its winter's work the Japan form comes in and takes its place admirably as a greenhouse decorative plant. Earliest of all these hardy Primulas to flower are the Himalayan *P. denticulata* and *P. purpurea*, both beautiful forms for the greenhouse or the open ground, but one is reluctant to subject such very charming flowers to the uncertainties of our climate, except in some sheltered position. *P. purpurea* differs from *P. denticulata* in having leaves of a darker tint and with smoother edges, and in producing trusses of flowers of a rather deeper tint; but both are equally beautiful, and should certainly have a place in every garden.

Both under glass and in the open ground the beautiful snow-white *P. nivalis* is in full bloom, and a lovely gem it is. It is the earliest of all the *Auricula* section, and is one of the most distinctive. In order to have *P. nivalis* in all its beauty, several plants of it should be placed in a 12-in. pan and be dressed over with Moss; it then resembles balls of snow cushioned with green. *P. intermedia*, just expanding its flowers, is a desirable companion to *P. nivalis*; the contrast afforded by the deep rich purple hue of the flowers of the former is most striking. Perhaps one of the prettiest of all these *Auricula* Primulas is *P. marginata*, also just in bloom; the flowers resemble in shape an inverted bell of a pale purple hue; the foliage of this kind is singularly pleasing, the leaves being very farinose, and in some the edges are distinctly marked with white. *P. villosa* has small hairy leaves that have serrated edges, and the flowers are small and of a pale reddish-purple colour. This has just expanded, as have also the flowers of the Liliputian *P. minima*, a very charming kind that does not too freely flower, and should therefore be all the more cared for. *P. integrifolia*, a kind even more minute than *P. minima*, is about to flower this year for the first time; it has hitherto refused to blossom. I have also some unnamed seedling Alpine varieties just beginning to flower that promise to be very pretty, and a couple of named varieties of *P. intermedia*—*Portia* and *Minstrel*—sent out a few years ago. Of powdered kinds, the

Date Palms placed in the open air in summer, with Acanthus in the foreground.

pretty *P. farinosa* is just about to open its little trusses of bloom, and the stronger-growing *P. verticillata*, sometimes called *P. abyssinica*, will be in bloom in a few days. Some of the varieties of *P. amona* are in flower, and all will be so in a week or two; but April is the great month for these kinds. *P. Munroi* is just pushing up its leafage from the crowns that have been dormant through the winter; and a variety of stronger growth, that I anticipate will be identical with one recently figured as *P. nivalis turkestanica*, promises to succeed it. A. D.

**Daisies from Seed.**—We find these to be extremely useful for edgings, or as a front row in ribbon borders. I retain a vivid recollection of the beautiful effects obtained at Cliveden by means of these little hardy flowers. But hitherto I must confess that the results obtained from plants raised from seed have not been encouraging, so large a percentage of them having single flowers, although the seed has been procured from the best source. This, however, need not deter anyone from having Daisies, as they are cheap plants to buy, and may be readily increased by division. I would recommend that seedlings be proved in some trial ground before they are used for bedding purposes.—JAMES GROOM, *Henham*.

**Anemone fulgens Lifted and Unlifted.**—Mr. Smith's latest remarks (see p. 205) respecting this *Anemone* exhibit the futility of attempting to lay down strict rules as to the cultivation of any given hardy plant in many and various localities. In his case the soil and climate are moist, and the roots are in danger of rotting if left in the open ground. Here, where the rainfall is comparatively limited, and the atmosphere and soil are seldom excessively wet, the roots thrive well in the ground, and are far better there than if they were lifted and stored in the best possible way. Except where it is absolutely necessary to do so for business purposes, I should recommend that the roots be not lifted too often, or if necessary for bedding they should be taken up with good balls of soil, when the plants would suffer but little. Even scarlet garden varieties of the *Anemone* that have been untouched for twelve months are grandly in bloom in the open ground, but none of them are so gloriously coloured as *A. fulgens*.—A. D., *Bedfont*.

**Camassia Fraseri.**—*C. esculenta* is one of the best known and the most esteemed of our hardy Liliaceous bulbs. It is a safe prediction that the *C. Fraseri* will ere long become as popular. It is a native of the States east of the Mississippi. Its flowers are rather smaller than those of the western species, but when seen in perfection it is scarcely less attractive. It grows about 1½ ft. high, with from six to eight leaves rather shorter than the scape, the latter bearing a raceme of from ten to thirty pale blue flowers, each about 1 in. across when expanded. All the parts of the flowers are smaller than in *C. esculenta*; the style is scarcely declinate, and the segments of the perianth are marked externally by only three or four nerves, those of the western species having from five to eight nerves. It is well known that the bulbs of the *C. esculenta* furnish a not unimportant article of food to the Indians of Oregon and California under the name of Quamsh, and those of the present species are equally employed as food by the Indian tribes of the districts where it occurs.—W. THOMPSON, *Ipswich*.

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN:

**Crocuses and Pheasants.**—I have a border filled with various kinds of Crocuses. The pheasants have destroyed all the bulbs of the yellow varieties and left all others untouched. Can any of the readers of THE GARDEN account for this?—R. HANBURY, *Poles, Ware, Herts*.

**Iris reticulata.**—"J. S." (see p. 80) says that *Iris reticulata* is not the freest flowering variety of the *Iris* tribe. I have just counted 137 blooms on a single row 3 ft. long. That does not look like sparse blooming. What does "J. S." say as to the varieties of *I. Kœmpferi*?—A. R.

**Lithospermum fruticosum.**—As a perpetual flowering plant I do not know any that equals this *Lithospermum*; a plant of it here on rockwork has been in flower for considerably more than a year, without, I believe, a single day's intermission, though of course sometimes in winter there were but few flowers open on it.—C. M. OWEN, *Knockmullen, Gorey, Ireland*.

**Hybrid Primulas.**—I send you a flower-head (though much injured by the stem having been eaten away by slugs two or three days ago) of a hybrid *Primula*, between *P. denticulata* and *P. pulcherrima*, raised by Mr. Anderson-Henry, of Edinburgh, who gave me the plant. The calyx, when the flower is in bud, is almost black, the head of flower being a perfect ball. There are thirteen other smaller heads coming on, though the plant was a small one, consisting of one crown. It began to blossom here somewhat earlier than *P. denticulata*.—C. M. OWEN, *Knockmullen, Gorey, Ireland*. [The flower-head sent resembled that of *P. pulcherrima*, but the flowers were much paler, being blue with a yellow eye, and though somewhat bruised, evidently when in perfection very pretty.]

#### ORCHIDS AT STAMFORD HILL.

In Mr. Bockett's collection of Orchids I recently saw one of the most beautiful and distinct varieties of *Odontoglossum Alexandræ* (crispum) that I have yet met with; the variable character of this species is well known, but this is essentially different in its markings from any I have previously seen. The flowers individually are of medium size; both petals and sepals are broad and have plenty of substance, and the ground colour is the purest possible white. In the centre of each petal and sepal is a large circular blotch, almost regular in outline, blackish-brown when the flowers first expand, but growing slightly paler as they get older, these single large spots bringing out the pure ground colour to a remarkable extent. As most people will have observed, the marking on these *Odontoglossums* is not always of a persistent character, individual plants sometimes varying from year to year, but should the plant in question retain its present character it will rank as one of the very finest of these most lovely plants. Standing near it was a very fine example of *O. mulus*, bearing a grand spike of large primrose-coloured deep brown spotted flowers; also the rare and exquisite *O. Blandianum*, in form not unlike *O. gloriosum*, as in the latter variety the sepals and petals are slightly incurved at the point. The ground colour of the labellum is pure white with distinct purple spots; the petals and sepals are also white, but not so pure, spotted and lined with warm brown. In the same house was a fine example of *O. Andersonianum*, bearing a branching spike furnished with twenty-four flowers, and a good form of the variable *O. cirrhosum* with large, beautifully-marked blossoms; also several varieties of *O. triumphans*. On the various *Odontoglossums* in this house I counted some thirty-five spikes bearing open flowers, and 130 others in different stages of development. Intermixed with the chaste, light-coloured flowers of the *Odontoglossums* were a number of examples of the bright scarlet *Sophranitis grandiflora*, an association that was strikingly effective. In the adjoining house, which was principally filled with *Odontoglossums* and *Masdevallias*, were several other good plants in flower. In the other houses devoted to Orchids were half-a-dozen large masses of *Coleogyne cristata*, wreathed with their crisped white blossoms, than which few more useful flowers for winter exist. Associated with these were also the lovely *Lolia anceps Dawsoni*, and the highly-coloured *L. anceps grandiflora*, several examples of *Cypripedium villosum*, one bearing twenty-four flowers. *Cattleya Trianae delicata* is furnished with thirteen large, beautifully-tinted blooms, and I noticed half-a-dozen other forms, one of which deserves especial notice. The individual flowers are very large; they have broad sepals and petals of the most delicate pink, and a very large, intensely-coloured labellum, as deep in shade as that of *C. labiata*. In the same collection were *Dendrobium nobile cœrulescens*, and also *D. nobile pendulum*, the latter bearing 200 flowers. Of the numerous forms of *D. Wardianum*, one in particular, though not so deeply marked as some met with, is a most lovely plant, bearing 130 flowers, and forming a complete wreath of the most delicate colour. Associated with these were likewise *D. crassinode*, *D. Farmeri aureo-flavum*, numbers of *Phalenopsis*, including *P. grandiflora*, *P. amabilis*, and *P. Schilleriana*; *Coleogyne Lemoniana*, bearing thirty-five spikes of its large, white, lemon-shaded flowers; *Odontoglossum Roelzi*; *Spathoglottis pubescens*, bearing distinctly-formed yellow blooms, the lower petals streaked with purple; and the small-growing *Saccolabium violaceum*. There were also coming on a couple of finely-grown examples of the late-flowering *Angraecum sesquipedale*, each bearing two spikes, five flowers being on a spike. T. B.

**Mixed Collections of Orchids.**—Much has of late been written about the culture of cool Orchids and hot Orchids, and beyond all doubt such things as *Masdevallias*, *Dissas*, and some *Odontoglossums* must have cool quarters, but we are sometimes startled to hear that cool Orchids are grown in the same houses with *Vandas*, *Aerides*, and other hot subjects, as, for instance, at Clonfert, on the Tweed. I have seen lately the same practice successfully carried out at the College Botanic Garden, Dublin, where, for want of proper accommodation, all the Orchids are grouped in one house, the kinds requiring warmth being on the outer stage and rather elevated, the kinds requiring coolness being on the front and end stages. Here were

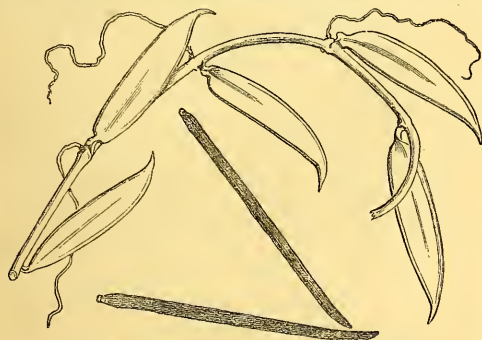

*Angrænum eburneum* in fair health with two fine spikes of bloom, *Odontoglossum grande* with fine large well-fed bulbs, *Coleogyne cristata*, *Peristeria elata* with fine large healthy bulbs, *Lycastea*, *Epidendrum*, *Cattleya crispata* with very fine growths, *Lælia superbiens*, and others, all bearing witness to the care bestowed on them last year, and promising grandly for the present season's growth. No one need despair of having a pretty large and varied mixed collection of Orchids in one house if the necessary attention be bestowed on them.—W. D. D.

### SCENT-YIELDING PLANTS.

By G. W. SEPTIMUS PIESSE, Ph.D., F.C.S.

#### *Vanilla planifolia*.

Of all Orchids this climbing Epiphytal one is the most valuable from a commercial point of view, on account of its scent-yielding fruit. There are several species of *Vanilla* which yield beans or pods more or less fragrant, and of these some five kinds are common in our English markets, the value of which varies from 10s. to 80s. per lb. The genus *Vanilla* is indigenous to Peru, Brazil, and Mexico, and some of the species have been successfully cultivated in the West Indian Islands, Ceylon, and the Mauritius. From the last-named wonderfully fine specimens were sent to our International Exhibition of 1862, for which the jurors awarded a gold medal. There is no

Stem, leaves, and pods of *Vanilla planifolia*.

reason why the culture of *Vanilla* should not be extended into some of our warmer colonies, such as Western Australia and Queensland. Its propagation is by no means difficult. *V. planifolia* climbs up the tallest trees, and its main stock becomes woody and hard as that of the Vine; the root sends up many offsets, which may be separated, and in that way the plant may be increased. Cuttings of the last growths, 2 ft. or 3 ft. in length, may also be made and rooted successfully. The *Vanilla* will produce saleable pods the third or fourth year after propagation, and they may then be gathered annually, in September, in increasing quantities for thirty or even forty years. Therefore, he who plants a *Vanilla* forest leaves his son a valuable heritage. Two good specimens of the plant may be seen in the Orchid house at Kew, and it is also grown plentifully at Syon.

When the pods are gathered, which should be done before they are quite ripe, it is most important that they be properly cured, otherwise they rapidly become mouldy and lose their scent. Parcels in this condition may often be found at the Mincing Lane drug auctions. The curing of the pods is best effected by drying them in a moderate heat, pressing them with the thumb and finger from end to end, and then brushing them over with an oil that does not itself become rancid, such as that of Cocoa or Cashew Nut. It is at the apex of the pod that the mouldy parasite first appears; the pods then quickly become soft and flabby or dry and chippy. On the other hand, when *Vanilla* pods are in good condition, they become covered with an efflorescence of needle-like crystals of Vanillic acid. The interior of the Bean is then soft, unctious, and balsamic.

In order to obtain the perfume or essence,  $\frac{1}{2}$  lb. of such pods are cut up small, and put into one gallon of pure alcohol, of a strength known as 60° over proof, giving the whole a shake up daily. The ingredients must remain together for say four weeks, at which time all that is worth extracting will be found in the spirit, which may then be strained off quite clear and bright. It is then suitable as a flavouring agent, or when blended with other scents it makes delicious perfumery. Those sold under the titles of *Clematis*, *Heliotrope*, *Wall-flower*, &c., mostly contain about one-half in bulk of *Vanilla* extract. About two centuries ago *Vanilla* may be said to have been unknown in this country; it is, however, stated that Morgan, an apothecary, showed to Queen Elizabeth a sample, but he knew nothing more about it than that "it was brought from abroad by some Spanish merchants." At the present time the total annual average crop of all the varieties of *Vanilla* from the several countries which produce it may be estimated at 80,000 lb., representing a value of not less than £150,000.

#### *Vetiver* (*Andropogon muricatus*).

The fibrous roots of this large Grass yield a most peculiar but pleasing perfume. If the scent of *Roses* may be termed sweet, then *Vetiver* has a bitter smell of the Myrrh kind. *Vetiver* Grass, which is also known under the name *Khus-Khus* Grass, grows extensively in Bengal and Southern India. It is there manufactured into awnings, blinds, and sunshades, but it is principally used for screens, which, during the hot season, are placed in doorways and windows, and are known as "tatties," which, when wetted, diffuse a peculiar and refreshing perfume, and the evaporation of the water at the same time cools the air. *Vetiver* is imported into England in bales of about 2 cwt. each, but the average annual quantity does not exceed 5 tons, and about the same quantity goes to France. When *Vetiver* is distilled and is good, it yields about 10 oz. of Otto for every cwt. Several perfumes, such as *Mousseline des Indes* and *Maréchal*, owe their speciality to a small addition of this material. Bundles of *Vetiver* are sold for perfuming linen, and when ground it is used as an anti-moth material.

#### Elder Flowers.

In Nichols's "Progress of Queen Elizabeth" he mentions that at Hawkstead, among the rooms on the ground-floor, was one called the still-room, an apartment where ladies of the Court much amused themselves in distilling fragrant waters. In the Northumberland "Household Book," a work so often quoted by historical writers, there appears the following list of plants, viz., "Roses, Borage, Fumitory, Parcelly, Balme, Walnut leaves, Sage, Elder flowers, &c., for the use of the still-room." The still-room maid to this day preserves her name, though not all her old avocation. The cymes of the Elder, after being plucked and placed in a heap, very quickly heat; the corollas then fall off and are separated, by sifting, from the stalks. During the season many tons of these are sold by Covent Garden herbalists. Of corollas 9 lb. are distilled with 4 gallons of water; the first 3 gallons that come over only are preserved for use under the title of Elder-flower water.

**The Saffron Plant in Greece.**—Although much used for dyeing and culinary purposes, the Saffron plant is not yet cultivated in Greece. It is found in large quantities growing wild on the slopes of the hills and on rocky plains, especially where the soil is of a dry, calcareous nature, as for instance on Mount Hymettus, about Delphi, and in the mountains of the Greek islands. Most of that which is wild is collected by the inhabitants of the islands of the Greek Archipelago, who take it to Smyra and dispose of it to the merchants, who in turn sell it to the small shepherders. In the Turkish portion of the Archipelago the gatherings are made by the women, particularly in the little island of Simi, and sold in the bazaars of Smyra and Salonica as Macedonian Saffron. The amount that is collected on the mainland of Greece and sent into the market would scarcely exceed 50 lb. in weight. If, however, this easily-cultivated plant were properly grown this figure might very soon be depleted, especially as it may be so readily propagated either by the division of its bulbs or by seed. The principal species of Crocus (which still retains its ancient name *Krokos*, bestowed on it by Theophrastus) growing wild in Greece are *Crocus sativus*, *C. vernus*, and *C. minimus*.—X. LANDERER, Athens.

## THE INDOOR GARDEN.

### LARGE PLANTS OF POINSETTIA.

Of late years large specimens of Poinsettias for winter flowering have almost disappeared, a matter difficult to account for, unless by the mere change of fashion, and that has latterly run in favour of small plants, rooted and flowered the same season. These are as useful for decorative purposes as they are beautiful in almost every imaginable position. The Poinsettia is also most accommodating in regard to size. It may be flowered at almost any height, from 4 in. to 4 ft.; but there is no reason why the beauty and usefulness of dwarf Poinsettias should drive the taller plants out of cultivation. The latter are invaluable for the centres of stages, the floors of lofty old-fashioned plant stoves, for halls, staircases, corridors, and backs, &c., of floral arrangements in lofty rooms. Every winter and spring, in most private gardens, quantities of fine Poinsettias are thrown away after flowering once that would flower even more profusely if kept another season. Poinsettias that have been liberally cultivated one season lay up, as it were, a reserve of strength at the base of their stems for a strong break and grander bracts the next year. They may be dried off in any out-of-the-way house with a temperature of 60° for a month or two, then cut back and started afresh, and they will break and do well under such rough treatment. They would, however, do better still could the leaves be fully exposed to the light for a time, and the wood be allowed to ripen gradually. The best place for this finishing process is on a stage near the glass, not under it—the place mostly chosen for the storing of Poinsettias where the old plants are kept over. Sufficient water should only be given to keep the leaves from flagging. A temperature ranging from 60° to 70°, with a rather dry atmosphere, are the best conditions for maturing the wood of Poinsettias. This care in ripening the wood is well bestowed, if only for the superiority of the young plants raised from it. They are far superior in habit, and produce finer bracts than those raised from immature, gross wood. As soon as the plants are sufficiently ripened off, they should be cut down to within 4 in. or 6 in. of the ground, and kept without water for a fortnight or so, until the wounds heal; the roots may then be watered, and the plants placed on a stage in the stove near the glass, or in a pit in bottom-heat to break. A temperature of 70° or so is the most suitable for the roots, the tops having from 5° to 6° less heat where the plants are broken in pits. Select from three to a dozen of shoots of equal strength as near as may be to form the future plant, and rub all the others off. It will be but seldom that there will be any excess of shoots, as Poinsettias are not given to produce large crops of branches. As soon as the shoots make an inch or so of growth, shake the plants out of the pot, remove as much of the old soil from them as possible without breaking or bruising the roots, and carefully repot. This requires to be done with care, as Poinsettia roots are numerous, are easily injured, and resent injury by bleeding at once. The roots should also be carefully distributed through the soil. The plants are by no means particular about soil. The orthodox mixture of half-peat, half-loam, a fourth sand and powdered charcoal answers well. Equal parts light loam and leaf-mould, or loam and well rotted manure with a dash of bone-dust, is perhaps better. Some of the finest plants ever seen by the writer were grown in spent tan, fortified with house sewage. After the first shift a close regimen and partial shade should be applied. The best place for carrying out these conditions is a close pit, with bottom-heat derived from manure, leaves, tan, or other fermenting material. These genial sources of warmth quicken the roots into prompt and vigorous action, and the pots are filled and the tops started in a very short time. As soon as the roots reach the sides of the pots, and before they become matted, the plants should receive their final shift into their flowering pots—3-in., 10-in., or 12-in. pots may be used according to the size of the plants. The latter will grow a magnificent plant with from eight to twelve stems—such specimens are seldom seen. As soon as the plants get a good hold of their flowering pots, a cooler system of treatment may be adopted. Bottom-heat should be dispensed with and more air given, and until towards the autumn, say

through August and September, the plants may be grown in cold pits, shut closely up, however, about four o'clock after a heavy overhead syringing. This will develop a sturdy habit with great size and substance of stems. The shoots should never be stopped. A good many cultivators recommend this. They say it makes the plants bushy and multiplies the number of shoots. As a rule, it does neither. The shoots stopped generally only break one bud; there is, therefore, no multiplication of the number of shoots. As the new shoot is apt to run further before showing a bract than the old one, there is, consequently, no shortening of its length. The stopping is, therefore, a waste of time and of growing force, as well as a sacrifice of beauty, for the bracts are hardly ever so fine on a pinched shoot as on an unstopped one. Sufficient shoots should be chosen at first to form the plant, and these should be kept in form, so that the finished plant should consist of so many shoots as near as may be uniform in strength and beauty. Neither should the Poinsettia be trained nor tied down. The plant is perfect with its shoots and leaves left the natural size and length; and where there are many shoots, it is very easy to regulate them so that each bract has room to display its full beauty without overshadowing the others. Towards the middle of September the first batch of Poinsettias should be placed in a temperature of 65°; a moist atmosphere is also important at this stage. If the tops of these fine shoots can be kept within a few inches of the glass, the bracts will not only be distinguished by a much higher brilliance, but even the upper leaves of the plants will be deeply stained with crimson or vermillion, as if the excessive colour of the crowns had run into and suffused the leaves at their bases. Another lot may be introduced into heat early in October; and, in fact, no Poinsettias will be safe in cold quarters after the beginning of that month. These remarks apply to all Poinsettias; but they are particularly applicable now that we have such a valuable addition to this invaluable tribe of plants. To anyone who meditates throwing away a single root-stock of Poinsettia plenissima, we hope our urgent "don't" for the foregoing reasons will be in time to prevent such a prodigal waste of beauty and of growing force.

D. T. FISHER.

### ACACIA RICEANA.

It is surprising, considering the readiness with which anything new is picked up, how long some really good plants are neglected, amongst which this *Acacia* is an example. We cannot state how long it is since it was introduced into this country, but from the apparent age of some plants with which we are acquainted, we should think it is perhaps thirty years or more. And yet it is comparatively little known. Hardly anyone who comes into our greenhouse here, where a fine plant of it is growing, knows its name or have seen it before. But the plant strikes everyone at the first glance, as it cannot fail to do, for it is one of the finest of the *Acacias*, and the list of greenhouse varieties is a long one. A number of years ago attention was directed to its merits, and there was a demand for it, but it became again neglected. It is now its flowering season, and we desire again to point out its value as a climber for the cool conservatory or greenhouse. The flowers are like those of all the *Acacias* in character, but more feathery, and are borne on long, pendulous, and perfectly supple shoots, that droop perpendicularly from the stem, making the plant appear to be quite laden with feathery spray. It is a fast-growing subject, too, when planted out and trained up the rafter. Only a few years ago a small seedling plant of it was put out in the bed of the greenhouse here, and it is now about 20 ft. high, and extending at the rate of 4 ft. or 5 ft. annually, besides producing quite a profusion of lateral shoots which droop 4 ft., or 5 ft. from the rafters, and flower their whole length. By gaslight the plant has quite a fairy-like appearance, and the long pendulous shoots may be out off and used for decorative purposes with nique effect; and, what is of much importance, they stand uncommonly well. Where a graceful drooping plant is needed for the roof of a conservatory or corridor, we can heartily recommend this *Acacia*. It is an evergreen, and the shoots themselves, without the flowers, are very pretty from their creeping habit; but it is at mid-winter that it is at its best, and it lasts in flower for a long period. Our plant began flowering at Christmas, and though a sheet of flower, it is hardly at its best yet. This *Acacia* is best propagated from seed, and we believe it is generally so propagated by the trade. It grows well in good loam, or loam and peat; and it is of little consequence whether the roots are in an

inside or outside border. An old tree here has all its roots outside in unprepared soil, and it is healthy and vigorous enough; but the younger plant which has been referred to has its roots confined to a pit inside the house. The branches need little training. Any number of leading shoots may be led off when covering space quickly is an object; these only need to be carried forward, horizontally or otherwise, the side shoots being allowed to hang down as they grow. Plants of it may, however, be grown as standards in roomy conservatories, in which case they would form handsome weeping trees.—“Field.”

#### CRESTED CELOSIAS.

THE annexed cut represents a finely variegated *Celosia* lately sent out by Messrs. Vilmorin, of Paris. The brilliant flower heads of these *Celosias*, and the length of time during which they may be had in bloom render them very desirable plants to cultivate either for the purpose of supplying cut flowers, or for greenhouse or conservatory decoration, where for effect they have few equals among soft-wooded plants. Unfortunately, they are very subject to red spider; and, unless kept well syringed while growing, and freely supplied with water at all times, they

*Celosia cristata variegata.*

become so much injured as to lose their foliage entirely long before the flowers become shabby. Valuable, too, as they are for summer, they are even more so for winter work, and, for that purpose they should be sown in May or June. The seeds soon germinate if placed in a shady position in the stove, or where they can be kept under a bell-glass or hand-light to prevent the soil drying, which, unless protected, it soon does in summer. When the young plants are up, pot them in light rich soil, and shift them on as they progress. Till the end of August or middle of September no place will suit them better than a close pit or frame, where they can be plunged in leaves, or something of that kind, syringing freely overhead both morning and evening to keep down red spider. M.

#### WINTER-FLOWERING GREENHOUSE PLANTS.

THE commonest plants in bloom during winter frequently command an amount of admiration equal to that so willingly accorded to the magnificent examples of cultural skill and painstaking which adorn the exhibition benches in summer. Comparatively few garden establishments are expected to furnish collections of stove and greenhouse plants for exhi-

bition purposes; but all, or almost all, are required to produce flowering plants throughout the winter as well as in summer. Let us begin with soft-wooded greenhouse plants, or such as will be likely with ordinary care to render a greenhouse or conservatory gay and cheerful throughout the winter and early spring months, and also furnish at the same time an abundant supply of cut flowers which in almost all establishments are more or less in demand. In the first place may be mentioned

#### The Chinese Primula,

(*P. sinensis*), which is certainly one of the best of our winter-flowering plants. It is generally, although not necessarily, treated as an annual, on account of young plants of it being found to succeed best. In order to have plants of it in flower by Christmas, the seed should be sown early in April in a seed pan or well-drained pot filled with light soil. The seed should be gently pressed into the soil with a smooth piece of wood or the bottom of a small flower-pot, and it should be only slightly covered with silver sand or fine soil. The pot or pan should be placed or plunged in a slight bottom-heat—say in a Cucumber frame or pit—or it may be set in an ordinary greenhouse, placing a piece of glass upon the surface of the pot or pan until the seeds have germinated, when the glass should be removed, and the young seedlings shaded during bright sunshine. When large enough to be handled, they should be pricked into pans of soil composed of say two parts light rich loam, and one part finely-sifted leaf-soil. The plants should not be placed too closely together, as they should be allowed to remain there until large enough to be potted off singly into pots some 3 in. in diameter. By the time the plants have become well established, the season will be somewhat advanced, and they may with safety be placed in a cold pit. As soon as they have well filled their pots with roots, they should be shifted into the pots in which they are to flower, and which need not exceed 5 in. in diameter. The soil used may be similar to what has been already recommended. The plants may be allowed to remain in this pit until about the middle of November, when they should be placed where they are intended to bloom, such as on the front shelf of a greenhouse or other suitable situation. All the varieties of the Chinese Primrose are essentially winter-flowering plants; therefore, if, from late sowing or other causes, their flowering is retarded until the spring is advanced, careful shading is then necessary during bright sunshine, and even with this precaution the display of spring bloom will be inferior to that of mid-winter. So many fine varieties of this beautiful winter-flowering plant now exist that it is difficult to make a selection. I will venture, however, to name the following distinct varieties, viz: *Magnum Bonum*, a vigorous growing kind, which produces large trusses of violet-crimson flowers of good substance, and elegantly fringed; *Sunset*, a beautiful sort, which bears large trusses of a distinct shade of colour, viz., a rich magenta or scarlet; *alba*, a kind with flowers of the purest white, and beautifully fringed. The above are three of the most distinct varieties with which I am acquainted. But there is also a distinct section of these plants known as the Fern-leaved varieties, which, in addition to fine flowers, possess foliage of a very ornamental character; of these, two of the best and most distinct are *filiicifolia* and *filiicifolia alba*; there is, too, another section of more recent introduction, and that is the double, or rather semi-double fimbriated sorts, all of which reproduce themselves true from seed, and are known as *rubra*, *magenta fl.-pl.*, *alba fl.-pl.*, and *Maiden Blush*. All the above semi-double varieties are essentially distinct from the well-known old double white and double red Chinese Primroses, which have for so many years been grown in the greenhouses of this country, and to which of late years many valuable additions have been made. They are sometimes considered as somewhat miffy or difficult to manage, but this can hardly with justice be said of them. I have always found them to succeed best when the minimum temperature of the structure containing them is not allowed to fall under 45°. As they do not usually produce seed they are necessarily increased by division or by means of cuttings which root freely when inserted in a mixture of silver sand and sifted leaf-soil, and placed upon a slight bottom-heat in a close propagating pit; they should be inserted not later than the beginning of March. As regards soil for Chinese Primulas

it should be a mixture of about two parts of rich turfy loam and one part of leaf-soil, with, if thought necessary, a small portion of silver sand. When the plants are placed in their flowering-pots (which need not exceed 5 in. or 6 in. in diameter) a few small lumps of charcoal may with advantage be inserted in the soil of each pot.

#### The Persian Cyclamen.

This is another very beautiful winter-flowering plant, and one which belongs to the same Order as the Primrose. It may be had in flower from the beginning of December until May. By crossing it with the more hardy and high-coloured European species, improved varieties have been secured, as well as increased hardiness in the constitution of the plants. Some of the varieties are also conspicuous on account of the beauty of their foliage. The treatment formerly accorded to Cyclamens has of late years undergone a beneficial change. Instead of allowing the soil in which they had grown to become quite dry as soon as the flowering season was over (by which practice the tubers were frequently injured), they are now allowed to go to rest gradually, water being only entirely withheld when the foliage has quite disappeared. Many growers, indeed, adopt the plan of turning the plants out of their pots into a bed of prepared soil in the open air as soon as they have ceased flowering, and from this bed they are potted early in autumn, or as soon as growth has commenced. This more natural system of treatment is generally attended with the best results. Cyclamens may be increased by offset from old tubers, but they are most readily raised from seed, which should be sown as soon as it is ripe, when it will generally vegetate quickly; whereas old seed will not unfrequently remain for months in the soil before it germinates. The seed should be sown in a pot or seed-pan of light soil (such as has been recommended for the Primrose), and the young plants should afterwards be pricked off into other seed-pans not too closely, as in these pans they may be wintered, and early in spring they should be potted singly into 3-in. pots, and from these, when large enough, they should be shifted into their flowering-pots, which should be some 5 in. in diameter. Soil suitable for them may consist of about two parts rich light turfy loam, and one part well decayed cow manure or leaf-mould, with a portion of sand. During the summer they should occupy a cold pit, where they can have plenty of air, and be slightly shaded during strong sunshine. Plants thus treated will generally bloom profusely during the ensuing winter and spring months; and unless it be in cases in which large specimens are desired, such plants are in some respects to be preferred to older ones. Varieties of Cyclamens are now very numerous, but the following six may be considered as a good selection, viz., the original *C. persicum*, white and crimson; *candidissimum*, pure white; *grandiflorum*, a large-flowered and fine variety; *rubrum*, bright crimson; *marginatum*, white margined with rose; and *roscum*, a beautiful kind shaded with rosy red.

#### Cinerarias.

These useful winter and early spring-flowering plants are easily increased either by means of cuttings or division, but the method mostly followed is that of raising the plants from seed. One section produces blooms of a somewhat irregular form, but this is compensated for by the richness of their colour, which is a deep blue. Another strain of more recent introduction has well-formed double flowers, which to a certain extent reproduce themselves from seed, or at least furnish a considerable percentage of plants with double flowers, and the best of these should be increased by means of cuttings. When it is desirable to have seedling Cinerarias in bloom by Christmas, or soon after that time, the seed should be sown early in April, and as this is exceedingly minute, care must be taken to prevent its being sown too deeply. A well-drained pot some 6 in. in diameter should be filled to nearly the rim with light soil, which should be made quite level, and watered with a fine-rosed watering-pot; the seed should be sown upon the moist surface and pressed gently into the soil, covering the pot with a piece of glass until germination has taken place. When the young plants have become large enough to handle, they should be pricked off into seed-pans, and afterwards potted singly into small pots, shifting them afterwards into large ones as they

appear to require it. It is of the greatest importance that they should sustain no check from either want of room or lack of water; on the contrary, they should be kept growing as quickly as possible. The best situation for them during summer is a cold pit, where the pots can be plunged in ashes and the plants kept near the glass, shading slightly during intense sunshine, and moving them into the greenhouse or other light structure soon after the middle of October. The soil for the final shift (which should not if possible be later than the middle of August) may consist of two parts rich turfy loam, and one part well-rotted cow or hotbed manure or leaf-mould. It may be added that the Cineraria is exceedingly liable to the attacks of aphides, which, if unchecked, will speedily disfigure if they do not entirely destroy the foliage. For such pests no remedy is equal to repeated fumigation with Tobacco smoke, and this, too, should be applied carefully, as an overdose might seriously injure the foliage.

#### Zonal Pelargoniums.

Of late years these have become greatly improved. They have always, correctly enough, been regarded as summer-flowering plants, but they may at the same time be induced to bloom in winter. One condition necessary as regards the plants specially intended for this purpose is that they should not be allowed to flower during the summer, and young plants in comparatively small pots are better suited to the purpose in view than older and larger specimens. Autumn-struck cuttings should be shifted in March or April into pots one size larger than those in which they have been wintered. They should be placed in a cold pit and kept near the glass, where they can have abundance of air. Early in summer they should be transferred to their flowering-pots, which need not exceed 8 in. in diameter. They may then be placed in the open air, and the pots should be plunged in ashes and well attended to with water, all trusses of bloom being removed as soon as they appear. Early in October they may be taken into the greenhouse, and may now be allowed to flower, which they will generally continue to do until the end of January; but in order to insure success, the minimum temperature of the structure should not be allowed to fall under 45°, and the atmosphere should be kept somewhat dry. Those sorts should be selected for blooming in winter whose flowers are naturally of good substance, and the trusses not too large.

#### Salvia splendens.

This is an old, but very effective winter-blooming plant, the terminal plumes of bright scarlet flowers, of which have a light appearance, and they remain in perfection from the beginning of November until at least the end of January. It is easily increased by means of cuttings, and young plants of it generally succeed best. The cuttings should be inserted as early in spring as they can be obtained, and, although less hardy than the Chrysanthemum, they may nevertheless during summer have in all respects similar treatment as regards soil, exposure, &c. But they cannot with safety be left in the open air later than the beginning of October. *S. gesneriflora*, a more recent introduction than *S. splendens*, is also an exceedingly showy winter or rather early spring-flowering plant which may be treated in all respects the same as that kind.

#### Coronilla glauca.

This is an exceedingly useful winter-flowering plant, which is moreover nearly hardy, and its flowers, which are bright yellow, remain long in perfection. When grown under glass its season for flowering is during the depth of winter. It is easily increased by means of cuttings formed of the young shoots, inserted in a mixture of sand and leaf-soil early in spring, and such cuttings will form small-flowering plants for the following winter. They will, however, be found to be more serviceable both for the production of cut flowers, and for general decorative purposes the second season. The same plants may, if desired, be grown for many years, but when old they are apt to become infested by a small white scale, which ultimately render them unhealthy. Any light, and not too rich, soil is suitable for their culture.

#### Cytisus racemosus.

This and several other species of the same genus make useful plants to flower during winter and early spring, and they

may be treated in the same manner as the Coronilla. When they have done flowering, their shoots should be more or less cut back, and they may then be made to assume any desired form, such as a standard or a pyramid. They should be grown in the open air in summer, and be placed again under glass early in October.

#### Acacias.

Most of these flower early in spring, though some of the species do not remain long in perfection. Among the most ornamental are *A. affinis*, *armata*, *Drummondii*, *grandis*, *pulchella*, and *vestita*. The last is one of the best, and it is well adapted for training on the back wall of a greenhouse, for clothing pillars in a conservatory, or for ordinary pot-culture. Its flower-buds begin to show themselves soon after Christmas, and give the plant an ornamental appearance long before the blooms are fully expanded, when they remain in beauty until about the end of March. All the species of Acacias are increased by means of seed or cuttings, although some difficulty is now and then experienced in increasing some of the species by the latter method. They are by no means particular as to soil; a mixture of turfy loam with a small portion of peat suits them perfectly.

#### Echeveria retusa.

This is a very beautiful winter-flowering plant, and one which only requires to be better known to be more extensively grown, if only for the purpose of furnishing cut flowers in winter. It is a Mexican plant, and belongs to the *Crassula* family. It succeeds well in an ordinary greenhouse, in which it will begin to throw up its large spikes of beautiful flowers about Christmas, and will generally continue in bloom until the middle or end of March. The flowers have the property of remaining long in good condition when cut and placed in water. They have a rich wax appearance, and their colour is orange-scarlet faintly striped with yellow. The plant itself is easily increased by means of cuttings, which may be inserted singly in 3-in. pots, filled with a mixture of sand and sifted leaf-soil, and placed upon a shelf in a propagating house, or in any other structure where a temperature not under 60° is maintained. Such cuttings will speedily form roots, and may be shifted into 5-in. or 6-in. pots. During summer they may occupy a cold pit, but they should be placed in the greenhouse early in October. Plants of this description will be in bloom soon after the middle of December. Any light and not over rich soil will suit them.

#### Libonia floribunda.

This is also a useful winter-flowering plant, and one which is easily increased by means of cuttings formed of the young shoots. It continues to bloom throughout January and February, and should occupy the warmest parts of the greenhouse, as a very low temperature is not unlikely to cause it to drop its leaves. It will succeed well in a soil composed of turfy loam, with a portion of peat or well decayed leaf-mould.

To the winter-flowering plants just named should, if possible, be added a collection of *Chrysanthemums* and a selection of *Camellias*, winter-flowering *Cape Heaths*, and *Eparcises*, together with such imported bulbs as the *Hyacinth*, the *Narcissus*, and early-flowering *Tulips*.

P. GREVE.

Culford Hall, Bury St. Edmunds.

#### DEUTZIA GRACILIS.

THIS charming little Japanese shrub which with propriety be called everybody's plant, as it will grow and flower under almost any sort of treatment, and it can be had in bloom from Christmas to midsummer. It is one of the most useful of plants for conservatory decoration and also for furnishing cut flowers, and the cultivator may always depend on being well rewarded for any extra care which he may bestow on its cultivation. It strikes freely from cuttings taken from the young growth and put in thumb-pots in sand and leaf-soil in an atmosphere of from 60° to 70°. As soon as they are rooted, they should be potted off into 3-in. pots and replaced in heat, and as soon as the roots have reached the sides of the pots, they should be shifted into 5-in. pots, using a strong, fibrous loam with a little clean coarse sand at each potting, making the soil firm. Keep the plants in a good moist heat till they have made their growth, when they require a drier atmosphere in which to ripen the young wood before they are

turned out-of-doors. If this be not attended to, plants of it started in November and December will be a failure, through the blooms going blind at a time when flowers are of most value. When the growth is finished and well ripened, harden the plants off by degrees and plunge the pots up to their rims in ashes in a sheltered situation well exposed to the sun. If any of the plants require a shift, do it before plunging them, as they force better than when it is left till they are taken into heat. Plants required to be in bloom at Christmas should be started in an atmosphere of from 55° to 60° about November 20, and a few should be introduced into heat once a fortnight where a succession is required. For late blooming set the plants behind a north wall until they are required. When they are in growth and the pots are full of roots, supply them freely with liquid manure, and when in bloom, keep them cool and shade them from the sun, in order to prolong the bloom. When the flowers have faded cut out all the old wood, allowing nothing to grow but the young shoots from the bottom, and as they advance in growth draw them towards the rim of the pot, so that when in bloom the flowers will hang gracefully over the side.

JAMES SMITH.

Waterdale.

*Clematis indivisa lobata*.—This attractive greenhouse species is just now coming into flower in a cool house. It is not a hybrid variety, but a species from New Zealand. The flowers are white and rather fragrant, but the stamens and pistils are of a purplish-red colour, affording a pretty contrast to the white petals. It is an easily-cultivated plant in a perfectly cool and airy greenhouse. Where it is restricted to limited space it is best grown in a pot, for it is a vigorous grower, and soon covers a large space. The flowers are produced in profusion from the axils of the leaves, and this must be taken into account in training the plant. One matured shoot, well exposed to the light, will produce quite a wreath of flowers. It may also be trained in the form of a balloon if confined to a 9-in. or 10-in. pot. One or two limbs only should be led away from the root and trained regularly round the balloon trellis spiral fashion, so as to cover all the space, but without crowding the shoots in any way. About this season they will break freely and produce a mass of blossom. Common loam principally, with a little leaf-mould or peat and sand, makes a good compost in which to grow it.—W.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

*Imantophyllum miniatum* as a Forcing Plant.—I agree with Mr. Hinds (see p. 180) as to the usefulness of this plant for decorative purposes. But Mr. Hinds appears only to have discovered half its merits. When treated the same as *Eucharis amsonica*, it can be had in bloom two or three—or even more—times in one year.—A. W.

*Amaryllis formosissima*.—This has dark scarlet or crimson blossoms, which are abundantly produced on established plants, and for decorative purposes, in a cut state, they are very valuable. It is largely grown by Mr. Woodbridge, at Syon House, C.-S.

Seedling *Cape Pelargoniums*.—I have sent you blooms of one of our *Echinatum* seedlings for inspection; the habit, &c., of the plant is exactly the same as that of the old *Echinatum*, and the colour of the flowers being the only point of difference.—CHAS. E. PARSONS, *Chilwell*. [The flowers in question were bright rosy-pink, approaching to crimson, with a white purple-streaked centre, and spotted on all the petals with maroon. Though individually small, they are produced in clusters of from fifteen to twenty, thus fully making amends for want of size, which with some might be considered a fault.]
