*Semi-double Show Pelargoniums*.—The large-flowered semi-double *Pelargoniums*, such as Prince of Novelties and Queen Victoria, are of immense value for flowering early in spring. When well bloomed they are exceedingly attractive, and the flowers are most useful in a cut state. To have the plants in bloom thus early, a beginning must be made in propagating a stock at a very early period in the year previous. They must have plenty of time to acquire strength, the wood to become firm, and the roots to well fill the pots before the winter. Instead of waiting until the plants are out of bloom, and have ripened their wood before propagation is commenced, the cuttings should be struck about the time they are coming into bloom. The top of the young shoots will, if moderately firm, strike freely with the assistance of a brick bottom-heat. The usual routine of putting off, shifting on, and stopping must be carried out, and it must be borne in mind that they should receive the last shift about the first week in August, and the last stopping not later than the third week in that month. Pots of about 5 in. are the largest size that ought to be employed. The varieties that have been found to be the most desirable are album plenum, white; Beauty of Oxtou, maroon and crimson, with white margin; Captain Raikes, crimson marked with black; elegantissimum, vermillion, with white margin, the edges of the petals beautifully crisped; Madame Everard, crimson and maroon, in the way of Prince of Novelties, but better; Queen Victoria, vermillion and white; and Ville de Casen, dark crimson, with maroon markings, on the upper petals.—"Gardener's Magazine."

## PLATE CXIX.

## A GROUP OF CARNATIONS AND PICOTEEES.

Drawn by H. NOEL HUMPHREYS.

WITHIN these last few years Carnations, Picotees, and similar flowers have become such favourites, that growers of them for sale have had some difficulty in propagating sufficient stock to meet the demand. There is no doubt that this desirable state of things is to some extent owing to a return to the more refined taste of former years. The gaudiness of many modern flower gardens, with their panels and carpet bedding, is anything but pleasing to those who love flowers for their sweetness and beauty. The Carnation possesses both of these qualities, and it is also a plant of easy culture, succeeding well either planted out in beds or in the form of isolated specimens in the flower borders. Those who intend to cultivate Carnations out-of-doors should not trust entirely to the varieties which are exhibited at flower shows, inasmuch as some of the sorts that are valued for their shape and purity of colour are weakly in constitution, and do not succeed out-of-doors in winter. Raisers of seedling Carnations aim at obtaining well-marked flowers, the greatest favourites being scarlet bizzarres. In these there are two colours, viz., scarlet and maroon on a white ground. The petals should be broad and smooth, without serratures on the edges, and the markings should also be regular, and, if possible, there should be no spots on the whites. Next to the scarlet are the crimson bizzarres, then the pink and purple. There are also purple, scarlet, and rose flakes, classed in the order in which the names of these colours stand. In these the different colours are laid out in stripes, or, more properly speaking,

in flakes. Flowers with bright high colours are those most in request, and their ground colour should be pure and as near white as possible. Sells and flowers with fringed petals are disregarded. In large collections there is annually a certain percentage of what is termed run flowers; the white disappears entirely, and if this happens in a scarlet flake, there will be but one colour left, and that a scarlet self. Any other colour may also vary in the same way, leaving self-flowers the colour of the flakes. When this happens the plant becomes stronger and better able to withstand out-of-door culture. I have propagated many of these sports, and by some they are preferred to the marked flowers.

In order to grow the Carnation well out-of-doors, the ground should be prepared by being deeply trenched, and while this is being done, a good dressing of stable manure should be worked into it. I have planted Carnations and Picotees at different seasons, but perhaps November and February are the best months for doing so. If there be plenty of plants I would put them out in November, but in the case of scarce varieties I would much prefer keeping them in pots through the winter, so that the plants could have the shelter of a cold frame. Both the Carnations and Picotees like a soil with a considerable portion of clay in it, but it must at the same time be porous, and well

drained underneath. The tender fibrous roots seem to run into a mixture of leaf-mould and rotted stable manure mixed with the soil more than into any other material. I plant more closely together than many do. Carnations do not produce many flowers in proportion to the leaves, and one must leave room to layer the "Grass" round each plant. This can be done if the space between is about 1 ft. I generally provide neat flower-sticks to stand about from 2 ft. to 2½ ft. out of the ground. The most desirable are those made of double laths, and painted green. The sticks are placed to the plants when the flower-stalks have grown about 6 in. or 9 in., and after tying must be attended to, as the flowers are heavy, and Carnation flower-stalks snap very readily at the joints.

Layering should be done the first week in August. Strip the leaves off the base of the growth to be layered to about half its length; then, with a sharp knife, cut through a joint upwards; the layer is then fastened to the ground in an upright position with a peg. Some light sandy soil must be placed round the plant to facilitate the emission of roots. Half the plants may be removed to form another bed, or to plant out in the borders. If the others be allowed to remain where they are, and a surface-dressing be applied to the beds of light rich soil the following spring, the plants will grow freely and yield a rich harvest of beautiful blooms. Carnations are easily propagated by means of seeds, which may be sown in boxes set on a slight hobbed in March or April. When the seedlings are large enough to handle, they may be pricked out into boxes of the same size, placing them about 2 in. apart; when well established, plant them out 9 in. apart in prepared beds. They will flower the second year.

A few of the hardiest Carnations best adapted for border culture are:

*Scarlet Bizzarres*—Campanini (Turner), Guardsman (Turner), Lord Lewisham (Bunn), Mercury (Hexall), Sir J. Paxton (Ely); *Crimson Bizzarres*—Albion's Pride (Headly), Eccentric Jack (Wood), Gem (Headly), Graceless Tom (Wood), Marshal Ney (Headly), Rifleman (Wood); *Pink and Purple Bizzarres*—Falconbridge (May), James Taylor (Gibbons), Satisfaction (Rudd), Purity (Wood); *Purple Flakes*—Ajax (Hexall), Dr. Foster (Foster), Earl Stamford (Elliot), Juno (Baldon), Premier (Milwood), Squire Meynell (Brabbin); *Scarlet Flakes*—John Bayley (Dodwell), Sportsman (Hedderley), Superb (Ingram). The Scarlet Flakes are not free growers. *Rose Flakes* are very pretty, and by many persons of taste the most esteemed. The best sorts are—James Merryweather (Wood), John Keet (Whitehead), Mr. Hexall (Turner), Mrs. F. Burnaby (Turner), Sybil (Holmes), Samuel Newman (Hooper). *Sells* constitute a class much admired by the general public; some of the best are—Cremore (purple), Bride (white), Elysian Beauty (rose), Italian Clove (fine large crimson), King of Yellows, Mrs. Matthews (pure white, very sweet). To these may be added the true old crimson and purple clove-vented varieties.

Picotees are quite as well adapted for border culture as Carnations, and are divided into three classes. First in order is

Rock Walls, curtained with Ivy and Virginiaian Creeper, with Yuccas and rock shrubs in foreground.

CARNATIONS AND PICOTEES (A GROUP FROM SLOUGH)

the *Red-edged* class, the best of which are Forester (Taylor), J. B. Bryaut (Ingram), Mrs. Bower (Bower), Mrs. Horny (Turner); *Purple-edged*—the best in this class are—Admiral (Turner), Chanticleer (Fellowes), Ann Lord (Lord), Mary (Simonte), Picco (Jackson); *Rose and Scarlet-edged*—Edith Dombraim (Turner), Ethel (Fellowes), Fanny Helen (Niven), Mrs. Fordham (Turner), Miss Wood (Wood), Obadiah (Kirtland), Purity (Payne).

The above selection is made of sorts that succeed out-of-doors. A selection for exhibition purposes would be different. The accompanying coloured plate has been prepared from flowers of Carnations and Picoetes submitted to the artist just as they were cut from the plants; not having been subjected to the manipulations of the florist's tweezers. If this had been done the outlines of the flowers would have been more regular, and the small faulty petals would have been removed. It is certainly better that the public should see and judge of the flowers in a natural state than when art has been employed to assist Nature.

J. DOUGLAS.

## GARDEN BOTANY.

(Continued from p. 193.)

**QUICKNESS OF GERMINATION.**—Under the ordinary conditions of storing, seeds of various kinds retain their germinative force for one or more seasons, according to their nature; but after being kept beyond a certain time the energy of their vitality gradually diminishes until it is completely lost. The term for which seeds retain their germinating powers varies widely in different species; but in a general way it may be said that the younger they are the quicker they sprout under the same conditions, and the more vigorous the subsequent growth of the seedling. As seeds become older, the more feeble and uncertain their germination, and the longer the period that elapses before they show signs of active life. It is because they have begun to perish, and the store of

A Stone Garden Seat.

nutriment laid up for the use of the nascent embryo has been gradually wasting away; so that growth is necessarily retarded and rendered very slow until the seedling has had time to recover the loss, when it may proceed as rapidly as in a plant starting under more favourable conditions. Being, in a manner of speaking, invalids, old seeds require much more care and attention than fresh, and, like a half-starved man, must be cautiously fed at the outset. An excess of moisture, or a deficiency of warmth, soon proves fatal to a seed in this enfeebled state. A little higher temperature than is necessary for a vigorous seed of its species is recommended, and a very careful regulation of moisture. The safest method to prevent saturation and consequent decay is to manage so that the moisture reaches the seed in the form of vapour, and then the seed will gradually absorb it according to its wants. Age, then, other conditions being the same, has a great deal to do with the time occupied in germination, or, perhaps it would be better to say, to prepare the embryo for germination, because not only is the early growth of an old seed slower than that of a fresh one, but the first visible sign of life is much longer making its appearance. The lesson to be learnt from this warns us against mixing the seeds of different seasons and sowing them together. But, apart from age, there is a wonderful disparity in the vital energy of seeds, as displayed in their more or less rapid germination after they have been subjected to the proper conditions, and in the amount of growth the seedling makes in a given time. It should be fully under-

stood that the conditions must be congenial and suitable in each case, or the comparisons are worthless. Oftentimes we hear or read of certain seeds lying dormant in the ground a long time—a year or two, or three—after being sown, and then springing up; but in most cases the deferred germination may be ascribed to some unfavourable condition. On the other hand, no artificial preparation of the seed, beyond divesting it of its pericarp or taking it out of the fruit, is supposed, otherwise the chances are equalised to a certain extent. In describing the tests, the nature of this was pointed out as apparently limiting the period consumed in germination in some cases; in Acacia, for instance, in which it is so dense, that moisture is a long time permeating to the embryo. But there are others as many species of Gentian, Lily, &c., which are very slow to germinate, often as long as a twelvemonth after sowing. Others are remarkable for the short period that elapses before they begin to germinate. Many of the Cruciferae, Cabbage family, quickly germinate. Thus, fresh seed of the common Brassica, *Lepidium sativum*, in the most favourable temperature will begin to push forth the radicle in ten or twelve hours after being sowed and watered. Willow seed also germinates in a few hours. Some seeds do not germinate so evenly and vigorously the first season after collection as the second and two or three, or more, successive seasons. The seed of Corn Salad, *Linum grandiflorum rubrum*, and *Vinca rosea* exhibit this peculiarity. Possibly this may be accounted for by the fact

that the production of flowers extends over a considerable period, consequently the seeds of the earlier flowers are more perfectly matured than those of the later ones. The seed of the tuberous *Chervil* must be sown in September or October, and lies in the ground four or five months without showing any sign of life. This phenomenon is, of course, common in Nature, but the seed of *Chervil* loses its vitality if kept out of the ground. Seeds of the same age from the same tree, and even from the same seed-vessel, sometimes germinate very irregularly. M. Carrière records a very remarkable

instance. In 1854 he sowed some seeds of a Chinese Peach, and subjected them all to the same conditions. Two came up in 1855, two others in February and August, 1856, three in 1857, two in 1858, and the last in 1859. It is possible, of course, that although it was intended that the conditions should be the same, the seed were not all exposed to exactly the same influences. In some cases rapid germination seems to be a natural provision to ensure the perpetuation of the species under otherwise unfavourable conditions. One of the most singular on record is that of the germination of the seed of the "Rose of Jericho" (*Anastatica hierochuntica*), also a member of the Cruciferae. It is a dwarf, radiately-branched annual, which inhabits the sandy wastes of North Africa and Syria. As the seed approaches maturity and the leaves decay, the branches curve inward, forming a ball of the entire plant, which is soon detached from the soil, and blown hither and thither. The incurved branches prevent the seed from being scattered, where the next sand-drift might cover them too deeply; but as soon as rain comes the branches unfold and the seed-pods open. The germination of the seed follows very rapidly. Seeds of this plant taken from a specimen purchased at the last International Exhibition at Vienna, and sowed about five o'clock in the afternoon, had germinated by one o'clock the following day, and their rootlets pierced the soil. The seeds of this plant also retain their vitality for very many years, as I am informed by Mr. Nicholson, of Kew.

**DURATION OF THE VITALITY OF SEEDS.**—This depends upon

a variety of circumstances. Under exceptional conditions, such as being buried at a considerable depth in a moderately dry soil, some seeds will retain their germinating power for an almost indefinite period; but great doubt and uncertainty attach to all the accounts of the germination of very old seeds. This remark applies to the so-called Mummy Wheat, said to have been raised from grain taken from an ancient Egyptian sarcophagus, and some other instances of the same nature. It is, however, not impossible that some seeds may retain their germinative force under the exceptional conditions indicated for a much longer period than that for which we have unimpeachable evidence. A humid atmosphere is very destructive, but exposure to a moderately dry air acts beneficially. The degree of cold a dormant embryo will bear with impunity, providing it has not been saturated with liquid, seems to be practically unlimited. Mr. Darwin and others have made experiments on seeds by immersing them in salt water. Out of eighty-seven kinds sixty-four germinated after being in salt water for twenty-eight days, and a few after an immersion of 137 days. Instances are on record, too, of seeds of American plants which have been washed on the shores of Western Europe germinating after their long voyage across the Atlantic. Considering the question from a practical point of view, that is, how long different seeds will keep good under the usual conditions of storing, we may glean some useful information. For the substance of what follows on this point I am mainly indebted to the results obtained by the firm of Vilmorin & Co., of Paris, obligingly communicated to me through my friend, Mr. Hermann Stenger. The germination of unripe seed is the subject of another paragraph, the gist of which is that many unripe seeds will grow if sown directly they are collected. This fact furnishes the solution of another no less singular fact if taken by itself. It is this, that Carrot seed ripened in England will not retain its germinating power so long by at least one year as French-grown seed; and this peculiarity has been observed in Radish, Cabbage, and other seeds. This is, doubtless, due to climatal causes. In France the average number of sunny days in autumn greatly exceeds the number we enjoy in this country, consequently seeds are usually harvested in a better condition for keeping. Care should be taken, therefore, to harvest seeds as thoroughly as circumstances will permit. But perfectly ripened seeds of different species vary greatly in their germinative force; and the approximate duration of vitality of most common seeds when stored is known. Some seed, such as Angelica, Coffee, &c., must be sown soon after they are collected; others, like the China Aster, Alder, Birch, and Sycamore, will rarely germinate the second year, whilst others retain the power for an unknown period. Authenticated instances of seed, retaining their germinating powers for a considerable number of years are by no means numerous. Seeds of *Sida Abutilon*, which have been in Messrs. Vilmorin's warehouse for at least a quarter of a century, germinate as freely now as when first received. M. A. de Candolle, of Geneva, sowed in 1856 seeds of 385 species collected in 1831, 20 selected seeds of each sort being employed in the experiment. Only 17 species germinated, and of 15 of these only 1, 2, or 3 seeds, but 15 out of 20 of *Dolichos unguiculatus* and 6 of *Lavatera gred.* Radish seed has been known to grow freely when 17 years old, and it is also recorded that Kidney Beans 100, Rye 140, and *Mimosa pudica* 60 years old have germinated. Probably some of these records are due to unintentional errors in the experiments. So far as my practical experience goes, prolonged vitality seems to depend upon the nature of the pericarp, testa, or albumen, though there are some inexplicable exceptions. Thus Carrot seed will keep good four years, whereas Angelica and Parsnip, members of the same family, having more oily seeds, will only grow the first and second spring respectively after they are collected. The seeds of Australian Acacias, which have a very hard, dense testa, are long-lived, but the Kidney Bean, which belongs to the same family, rarely grows after the third season. Some seeds, for different reasons, are preferred two or three or more years old to quite fresh ones; in some instances because the older seed germinates more regularly as to time, as pointed out elsewhere. Old Balsam seed, other things being equal, has the reputation of yielding a larger proportion of double-flowered plants than new, because its vital force de-

creases with age. There are cultivators, too who think that old Cucumber seed gives better results than new. Probably there is some truth in this, but I have seen no record of the results of experiments conducted for the purpose of determining these points; and I am neither able to confirm nor refute them from my own experience. From what is said at the beginning of this paragraph on the duration of the vitality of seeds according to ripeness, it will be understood that any figures relating to the number of years different seeds will retain their germinative force must be regarded as approximations to the average duration of their vitality, under the ordinary conditions of storing, rather than as absolute and invariable periods. The following table embodies the results of the lengthened experience of the firm of Vilmorin and Co. It should be explained that some of those given as of one year's duration are only regarded as really fit for sowing the season following their collection. The terms for many species are under, rather than over, stated—Cucumber, for instance.

*Average duration of the germinative power of the seeds of some cultivated plants:—*

	Years.		Years.		Years.
Acacia . . . . .	many	Cervil . . . . .	2	Parsnip . . . . .	2
Alder . . . . .	1	Cervil, tuberosus . . . . .	1	Pea . . . . .	4 or 5
Amaranth . . . . .	5	Corn Salad . . . . .	1	Potato . . . . .	3
Angelica . . . . .	1	Cress . . . . .	5	Parslane . . . . .	8
Anise . . . . .	3	Cucumber . . . . .	5	Radish . . . . .	5
Artichoke . . . . .	5	Egg Plant . . . . .	7	Rampion . . . . .	5
Aster, China . . . . .	1	Eradive . . . . .	9	Rhubarb . . . . .	3
Balsam . . . . .	many	Leek . . . . .	2	Rocket . . . . .	2
Basil . . . . .	6	Lentil . . . . .	3	Rosemary . . . . .	4
Beans, Broad . . . . .	6	Lettuce . . . . .	5	Salsify . . . . .	2
Beans, Kidney . . . . .	3	Mais . . . . .	2	Samphire . . . . .	1
Beetroot . . . . .	5	Mallow . . . . .	5	Scorzenera . . . . .	2
Borage . . . . .	3	Marjoram . . . . .	2	Seakale . . . . .	2
Burnet . . . . .	2	Melon . . . . .	5	Sorrel . . . . .	2
Cabbage . . . . .	5	Mustard . . . . .	5	Spinach . . . . .	2
Capsicum . . . . .	4	Nasturtium . . . . .	5	Strawberry . . . . .	3
Caraway . . . . .	2	Onion . . . . .	2	Tomato . . . . .	5
Cardoon . . . . .	7	Parsley . . . . .	3	Turnip . . . . .	5
Carrot . . . . .	4				

An analysis of the above figures shows a general agreement in the constitution of the seeds of different plants of the same families, with exceptions which can be accounted for in the way already explained. The relation of albumen and duration of vitality are somewhat contradictory; but, confining our remarks to the plants here named, exalbuminous seeds and those with very little albumen retain their vegetative power longer than seeds with a minute embryo and a relatively large quantity of albumen. Taking a broader survey, the rule holds good that the more highly developed embryo, whether small in itself or large, will lie longer dormant without losing life than the large or small embryo of albuminous seeds. Sir Joseph Hooker somewhere states that seed of *Nelumbium speciosum* taken from a herbarium, known to be upwards of one hundred years old, germinated. This has an exceedingly dense testa.

**DURATION OF THE VITALITY OF SEEDS ON THE MOTHER PLANT.**—Most plants shed their seeds, or the seed-vessels fall off, the same season as they are produced. Many of the Proteaceæ (*Banksia*, *Hakea*, &c.) and Conifera (particularly some species of *Pinus*) bear the unopened seed-vessels or cones of numerous successive seasons. The first seed-vessels produced by some of the Proteaceæ do not open, if not detached from the plant, until the death of the plant, or under the influence of a very severe drought or forest fire. So long as they remain attached to the parent plant, the seed-vessels appear to absorb sufficient moisture to prevent them from opening; and so long as the seed-vessels do not open the seeds retain their vitality, assuming always that they have not been injured by insects or in any other way. It is the same with some Pines; and *P. maritima* may be named as a familiar instance. Or it should be said that the cones of several seasons may be seen on a tree and unopened at the same time. The cones of thirty successive seasons have been observed on some North American species. But the cones open when removed from the tree and exposed to drought, and then the seeds soon lose their germinative power. To prevent the cones from opening before it is desired, the Americans bore a hole up through the axis or centre and fill it with treacle, which they plug in. W. B. HEMSLEY.

## THE KITCHEN GARDEN.

### A VEGETABLE WASHING MACHINE.

In the Oneida Community large numbers of people are brought together to form one extensive family, and their kitchen operations are consequently on a correspondingly large scale. Many of the minor operations in domestic matters, which, when performed in an ordinary family, seem to require but little time and labour, when multiplied to meet the wants of a family as large as that of the Community in question become onerous and time-consuming. Washing Potatoes and other vegetables preparatory to cooking is one of these, and it is one in which, where much is to be done, the cook will gladly welcome any aid. Among the other labour-saving machines devised by some inventive member of the Community is a machine for washing Potatoes and other vegetables, of which the annexed is an engraving from a photograph. It consists of a slatted cylindrical grate, provided with a crank, and is so arranged that it may be revolved in water contained in a square tub, or it may be lifted quite out of the water by means of the handles of the frame in which it is hung, and carried over to discharge its contents into the wooden funnel, seen at the side of the tub, from which they fall into a basket or whatever may be placed beneath to receive them. The Potatoes or other vegetables are placed in the cylinder through a door not shown in the engraving; they are revolved in the water for about three minutes, when, by a single lift of the grate by the handles, they are dumped out perfectly clean. A similar machine is sometimes used in starch

A Vegetable Washing Machine.

factories. In large families, schools, or other institutions where cooking is done on a liberal scale, a machine of this kind will be found to save a great deal of unpleasant labour.—“American Agriculturist.”

### TREATMENT OF VEGETABLES FOR SEED SAVING.

It may justly be said that the saving of garden seeds, particularly of culinary vegetables, comes more within the scope of the professional seed grower than the practice of those engaged in ordinary gardening pursuits; but with some things of a special character there is no doubt that there are considerable advantages derivable from the cultivator saving his own seed. This applies not only to such subjects as are liable to deterioration through accidental fertilization by bees and similar agents, but also in the case of plants that are not susceptible or seldom become crossed in this way, yet to keep them up to their wonted excellence need careful selection. To this latter point it would be difficult to attach too much importance, so far as regards many of the most essential culinary vegetables. With such things as Peas, Broad Beans, Dwarf and Runner Beans, Celery, Onions, Tomatoes, Radishes, Parsnips, Lettuces, Leeks, Carrots, Beet, and others of like character, in which accidental crossing seldom takes place, it is certain that by attentive observation and careful selection of individual plants that evince a marked difference in their character, often as to more vigorous growth, as in the case of Beans and Peas, improved varieties may frequently be secured. With plants, the root portion of which is eaten, such as

Onions, Beet, Turnips, Carrots, and the like individual plants, may, in any garden, almost every year, be noticed that possess better-shaped roots, and that have altogether a distinctive character from the bulk of the crop. Where this selection for seed-bearing purposes of the most promising plants is not followed, deterioration is certain to take place, as in a few years may be seen by anyone who will take the trouble to work out an experiment on the subject. For instance, if a good strain of any variety of Turnip be sown, the greater portion of the bulbs will be well shaped, having thin tap roots, and free from thick necks, and coarse foliage, yet here and there, even from carefully selected stocks, there will almost invariably be a few found with coarser, thicker tap roots and tops, and worse-shaped bulbs containing more tough fibrous matter. If for seed purposes, any given number of roots be taken promiscuously from the crop, including a portion of inferior examples, such as the above, and this is continued for a few years, it will be found that the strain collectively becomes very indifferent, even to an extent that the comparatively few coarse bulbs at first overlooked would not have seemed to warrant; this can only be accounted for from the fact that the rough, ill-shaped roots generally appear to possess more than an ordinary share of fertility in seed-bearing, a circumstance which I have often noticed with many vegetables. With Carrots, this would appear to be the case more than with many plants. A rough, thick-necked root with a coarse big top will generally produce a larger head of fully-developed seeds than one better formed; at all events, so far as my own observation has gone in the matter, this conclusion has been borne out. With Celery, more than most things, an odd plant or two in a row may be often observed that without any advantages as to extra room, position, a greater abundance of manure, or, in fact, anything that could account for it, will show a decided superiority over the rest of the plantation. The same thing may be seen in Lettuces and similar vegetables, and with Endive to a greater extent than most plants; this can be accounted for by the fact that with plants, as with animals, there are some that, from the first stages of their existence, are endowed with more strength and vigour than others. It is by the judicious selection of these for seed purposes that the stocks of such vegetables as we cultivate can not only be kept to perpetuate the true character for which the variety is distinguished, but even improved. In respect to seed-growing of all such things as are particularly liable to get crossed or intermixed independent of the handiwork of the hybridist, and of which the Brassicas or Cabbage tribe may be taken as the principal representatives, most people with only limited experience in gardening matters are aware that these are so subject to get crossed through the agency of insects, that it is necessary to take considerable precautions with a view to keep them pure; otherwise any particular variety of such things as Cabbage or Broccoli is sure to become an interminable mixture, wherein the greater number of the produce will be found very dissimilar to the variety required, and in almost every case inferior to it. For example, it is a well-known fact that if a single plant, or any number of plants, of a given kind of such vegetables as those under consideration be in flower sufficiently near plants of another sort also in bloom, so that bees will visit both in their honey-gathering excursions, cross-fertilization is thus effected to an extent that will completely destroy the distinctive character of the plants produced from the seed. It will generally be noticed when a new variety of any such things as Cabbages, Cauliflowers, Broccoli, Kale, Brussels Sprouts, &c., first makes its appearance that the plants raised from seeds come true to their kind; yet, however desirable the sort when fully proved turns out to be, in a few years it often becomes a difficult matter to obtain it true; this can easily be accounted for. In the first instance, it was necessary on the part of the raiser, with a view to get a character to the variety in question, to use every care to keep the strain pure, and for the additional trouble and labour involved in this he was remunerated by the much higher price the kind, whilst new, commanded; but when this incentive no longer existed, through the sort becoming plentiful, proportionately less care was exercised by the seed-grower; hence the deterioration that ensues, and with which too often all the care and vigilance it is possible to use by those engaged in both the wholesale and retail of garden seeds is

insufficient to cope. It was through the disappointment I experienced in not getting some things of proved excellence true to their kind that induced me to set about saving a few of the most important of these myself, for to anyone who has to provide for a large family an uninterrupted succession of such things as Broccoli through the autumn, winter, and spring, it is something more than a disappointment to have a particular variety, upon which reliance has been put to come in at a given time when sown at its proper season, coming in either a couple of months earlier or later than it was expected, with a consequent gap in the supply.

Possibly the easiest way to make my practice in the matter understood will be to give a few brief details on the course I adopted. It is a well-known fact that the seeds of most of the Cabbage tribe retain their vitality for several years when stored under favourable conditions; acting upon this, I never attempted to save more than one variety of Cabbage, Broccoli, Cauliflower, or Brussels Sprouts that would be in flower at the same season. The Cabbages and Cauliflower I selected were always from such as had been sown—the former in the spring of the year preceding, and the Cauliflower in the autumn, being particularly careful to choose the best plants which most fully exemplified the distinctive form of the variety they represented, with plenty of strength and vigour, as it would be a great mistake to gather seed from a weakly plant; these were marked when sufficiently advanced to show their true character, and were allowed to remain to bloom during the spring and summer. With only having one kind in flower at a time there was nothing to fear by their getting crossed with other sorts, so far as being contiguous to anything from which this might result, but bees travel a considerable distance with the pollen of other flowers adhering to their legs and bodies. To guard against the intrusion of these, the plants were covered with fine hexagon netting, supported on Willows struck in the ground, with their heads bent together and tied over the plants. The woolly nature of the netting prevented anything getting through it; and to stop anything getting under it, it was brought right down to the ground and there secured, applying it directly the flowers began to open, and removing it as soon as the blooming was over. There is no necessity for this covering where there is a certainty that none of the same family of plants are in flower for a good distance, but I should not like to run the risk if any happened to be growing within say the distance of half a mile, as a few plants of curled greens, the stools of Brussels Sprouts, or anything similar negligently left to run up to flower, and exhaust the ground when they ought to have been dug in or removed to the refuse heap, would be ruinous to our work. If the heads of the Cauliflower be left entire and the weather come wet, I have found them liable to rot in the middle, consequently the centre portion before they began to run up was cut out. All that is further required is to use a net to protect the seeds from birds from the time they have grown to their full size, as long before ripe they are often attacked, and the whole cleared out so as to scarcely leave a seed. This is much more apt to occur where there is only a limited number of seed plants than where grown in large breadths. Broccoli, Brussels Sprouts, and Kale were treated in like manner from plants sown the spring previous; Lettuce and Endive alike from plants selected as the best of their respective varieties, both from seed sown the autumn before. With root crops, such as Turnips, Onions, Carrots, Beet, and Parsnips, it is essential to select the smoothest, best formed roots, giving preference to those over such as may be larger, yet coarser. They should be looked out at the present time from the stores of the above vegetables, and ought to be kept under cover in a place where they will be quite cool, to as far as possible retard their growth until they are planted out, which with all, except the Beet, may be done at the beginning or end of March, according to the weather and locality where they are to be grown. The Beet will not bear spring frosts like the others, consequently I deferred planting it out till the first or second week in May. With this vegetable colour is held quite as much in estimation as the texture; consequently it is necessary to be very particular to choose such as are the deepest in colour. Many varieties much extolled at the present day are more remarkable for the colour of their leaves than the required portion—the roots. Those that have roots of a reddish-crimson

shade are generally deficient in colour when cooked, whereas such as are almost black-crimson possess the wanted colour after boiling. In all cases choose an open situation on land rather poor than rich, as the object is not to promote luxuriant growth, and give plenty of space to all proportionate with the head-roots they require. Each stem of the Beet was supported by a single stick, to which it was tied, otherwise they are liable to get blown down. With the Onions I inserted some upright sticks in the row, tying others longitudinally across them, to which the tops were properly secured. With Radishes, I found it necessary to be particularly careful in selecting for seed those that were best shaped, or they more than most plants appear to have a disposition to degenerate. The excellent Olive-shaped variety, which, when true to its kind, for general purposes has no equal, is apt, unless where there is considerable care in selection of the seed plants, to result in a coarse produce, about half-intermediate betwixt it and the Turnip-rooted varieties. In the case of Tomatoes, there is nothing like growing one good kind alone, if seed is intended to be saved, selecting only from such plants as produce the most even, best shaped, highest coloured fruit. With Celery, the seeds of which will keep so as to vegetate freely for five or six years, it is well to look over the crop, in which will generally be found a few plants superior to the rest. Those should be selected that show the least disposition to produce suckers round the base, and that are not inclined to come too thick or club-shaped at the bottom, as when this occurs it causes a deal of the outer leaves to split at the base, which in wet seasons, with such as are intended to be kept till late in the spring, is liable to cause decay. One of the most important conditions is, that all plants retained for seed should be perfectly solid in their stems, with no inclination to become hollow, not even in the outer ones after being subjected to severe frost, a test which will prove the requisite solidity of Celery more than anything else. The plants of this vegetable intended for seed are best allowed to remain in the rows where grown through the autumn, but not fully earthed up, giving them protection with a little Fern or litter in hard weather. In the case of Peas, Broad Beans, and also Runners and Dwarfs, all that is necessary is to sow sufficiently early to allow the seed to get fully ripe before autumn, and thin enough, so that every plant will have a chance of developing its character; to go over the rows and pull out all plants that appear weak or inferior as soon as the pods are fairly set; and with Peas and Broad Beans, to so far as possible confine the seed saving to such plants as show a disposition to produce the greatest number of seeds in a pod. With Cucumbers and Melons, although for diversity growers are often tempted to cultivate a number of varieties, yet it is always better to be confined to one or two good kinds of each, in which case there is little difficulty in keeping them true. As to preserving seeds for any length of time, all extremes of heat or cold should be avoided, neither should the place in which they are kept be damp, or the opposite, too dry. There is no doubt that seeds keep better in the capsules in which they are grown than when shelled or thrashed out.

T. BAINES.

**A Useful Celery.**—Among a number of kinds, old and new (many of the latter cannot be distinguished from sorts we have known for years), none has been so serviceable as a true selection of Turner's Dwarf Incomparable saved from a stock in a private garden for many years. The seed was sown in an open border last April, and treated in the usual way; none has run to seed, and none has rotted in the ground. They are very dwarf, but almost to the outer stalks they are blanched, very crisp, and of first-rate flavour. The proportion of waste is less than that of any other kind; little earthing up is required, and the stems are of great thickness. Altogether, I consider Incomparable a Celery which cannot be surpassed by any other known kind. It is singular that this variety cannot be bought in the trade true to name. When this Celery is grown for a very late supply (say to June) it may be allowed to blanch itself. Planted in trenches four or five rows in each, very little earthing up is necessary, and loss from rotting is scarcely known.—M. TEMPLE.

**A Wild Onion.**—Dr. Regel is reported to have discovered in the Himalayas a variety of wild Onion, which he regards as the original source of our ordinary garden Onion. It is called *Allium Cepa sylvestre*.

## TREES AND SHRUBS.

## ABIES POLITA.

So confused has the nomenclature of the recently introduced species of this section of Pines become—several of them being distributed under three or four different names—that any incident calculated to clear up their synonymy is worthy of record. The confusion in question is partly owing to the close affinity existing between a few of the species; but as regards the one now under consideration, I must say that I never saw it cultivated under any other specific name than that of *polita*. It is so distinct in character from all its congeners, that once seen it is not likely to be ever confounded with any of them. Still the fact of a plant of it having produced cones here last year has enabled me to compare it with authentic specimens in the Herbarium at Kew, with which, I am happy

to say, it agrees in every particular; and as others may desire to so satisfy themselves, I herewith furnish an illustration of a cone and the parts of which it is composed—a leaf and a bud. When Professor Parlatore wrote the article *Coniferae* for the "Prodromus," he was in doubt as to the cone of this species being pendulous—he having to record one exception to the rule in this section, namely, *A. oborata*, which has erect cones—but I have found that it is decidedly pendulous. At first it is erect and pale green, but as it increases in size and weight, it becomes pendulous, and when mature, assumes a light chestnut-brown colour. This species inhabits the mountains of the provinces Dewa and Matsu, in North-eastern Nippon, Japan, where it forms, it is said, a handsome tree from 80 ft. to 100 ft. in height, with stout horizontal branches and long undivided drooping branchlets. I find that nearly all the Japanese

Spruces have very persistent leaves, and that they remain on the trees in a healthy state for from eight to ten years. This persistency of the foliage in the case of open-habited Conifers adds much to their beauty when employed as ornamental subjects, planted either singly or in groups on an extensive lawn or park. The leaves of our plant (which are long, stout, and spiny-pointed) are remarkably persistent, and, being of a glossy green, contrast well with the large reddish-brown buds. It is not fastidious as to either soil or position, being sufficiently rigid to withstand the keenest blast, and it seems as much at home in heavy as in light soils; but it is probable that, like the majority of Spruces, it may prefer a peaty soil to all others. It is in great demand for ornamental planting, its moderately slow growth debarring it from ever becoming a profitable timber tree in Britain; but, owing to the difficulty of obtaining seeds, plants of it are at present somewhat expensive. Fortunately, however, cuttings of the weaker shoots are easily rooted, after which they soon push adventitious leaders, and are then, I believe, as good as

seedlings. It may also be grafted on the Norway Spruce, with which it readily unites. It is very hardy in this country, being, even in its youngest state, very late in starting into growth in spring; indeed, all things considered, it is a most desirable ornamental tree. GEO. SYME.

*Borrowash.*

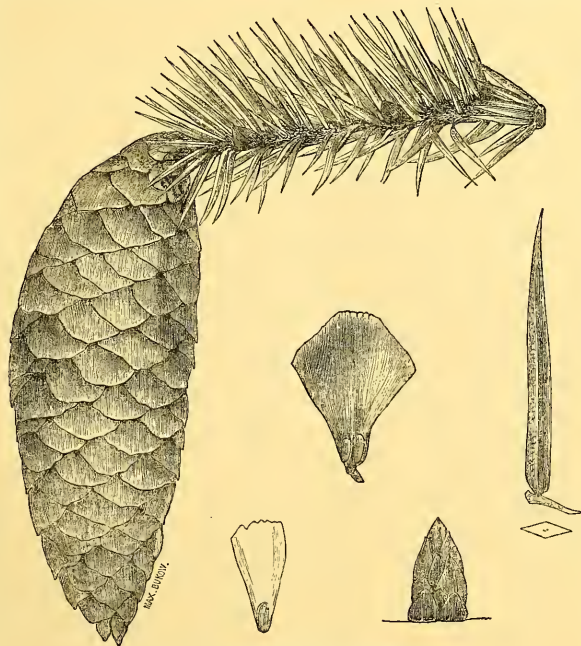

**The Rain Tree.**—The so-called "Rain Tree" of Mogobamba, South America, was made the subject of a brief communication by Mr. Thicketon Dyer at the Linnean Society's meeting on the 7th inst. This tree promises to excite as much interest amongst residents in hot dry countries as the supposed anti-malarious properties of the Fever Tree (*Eucalyptus globulus*) have done amongst the inhabitants of hot wet ones. From information obtained through Mr. Spruce, it seems probable that the Rain Tree is a species of *Pithecolobium*, and the so-called "rain" the fluid excreta of Cicadas, which feed on the juices of the foliage. Thus other trees might become "rain" trees. Indeed, the whole phenomenon, therefore, appears comparable to the production of honeydew from the Lime by the agency of aphides.—J. M.

**Planting Trees in Roads.**—The Honnello Local Board has recently been considering the desirability of planting trees in some of the broadest thoroughfares in the district; but the motion in favour of the proposed planting was lost on a division, there being seven for it and eight against it. Some of the objections were both original and ingenious. One speaker objected on the ground that the trees would grow up and shade the fruit trees grown in the market gardens; another stated that the roots would get into the drains and choke them, and that the leaves falling in autumn would be a nuisance; and a third remarked that the trees would injure the roads by keeping off the sun and wind. And so, in the end, this sort of wisdom prevailed. So much for the enlightenment of local Boards.—A. D.

**Camellias in the Open Air.**—I quite agree with the remarks of "A. D." on this subject (see p. 197).

Camellias grow luxuriantly and bloom freely out-of-doors in this part of Wales (near Swansea). Both red and double white blooms are open now (March 11) in exposed places. They never fail to flower yearly, but in some seasons they open in January and February; cold or frost does them no harm, but rain blemishes the blossoms. Our trees are not growing against walls or in sheltered positions, but as standards and bushes out on the lawn. The largest Camellia tree here is a double red variety; it has a stem about 2 ft. high, 3 ft. in circumference, and it branches into a fine round head which measures 21 ft. through the centre, and about the same in height. Are there any larger Camellias than this growing in the open air in this country? When the flowers are cut and put in water before the buds are fully expanded, they open as spotless as those grown under glass.—CAMBRIAN.

**Magnolia conspicua.**—Large specimens of this Magnolia in several London gardens have already burst their bloom-buds, and in a few days (if the weather be favourable) they will be a sheet of blossoms.

*Abies polita*, with bud, scales and leaf magnified.

## GARDENING FOR THE WEEK.

## Roses.

**Rose Insects.**—There is one difficultly inseparable from the cultivation of Roses, and that is their liability to insects; the three principal with which the grower has to contend are aphides, the Rose maggot, and red spider. After a mild winter like the present, some of the mature aphides, by secreting themselves on the leaves of any green vegetable form upon which they can exist near walls or other sheltered places, with the advent of the first sun's warmth begin to increase. Roses upon walls or in any sheltered position I find have already begun to be affected with them. Proportionate with the number of plants grown these insects are usually much worse to cope with in private gardens, which are generally more or less sheltered, than in the large open breaths cultivated by those who grow Roses for sale, and which are ordinarily in more exposed situations—a position in which they are freely open to the wind rendering them not nearly so susceptible to their inroads. As these, like all other insects, are much more easily kept down when attacked, as soon as their presence is detected no time should be lost in washing the trees. A good syringing with Quassia water will kill them, but for its effects in destroying both the mature insects and their eggs, and also in rendering the newly-expanded leaves distasteful to them, I have found none of the many remedies prescribed equal to Tobacco water to which has been added 2 oz. or 3 oz. to the gallon of Gishurst. The influence of this is such as to correct the oily nature of the Tobacco water in a way that makes it stick to the affected buds and leaves much better. From the insect-destroying properties of the Gishurst itself the Tobacco water, when used with it, may be employed much weaker than when applied alone. A dry day should be chosen for the work, which will enable the wash to adhere to the leaves better. A timely application of this sort I have found of considerable use in preserving Roses from the maggot, rendering the young leaves which are first preyed upon distasteful to the grub. The advantage of syringing and dipping the shoots of Roses affected in this way over dusting them with any powder disagreeable to the insects, is that it reaches all parts much more effectually with less waste. To those who are in the habit of never attempting the destruction of insects until they are swarming upon the plants, it may appear early in the season to speak of them, but if sought for even before many leaves are developed, the aphides will be found on the young expanded buds, and from experience I am satisfied that in this most essential operation of freeing the plants from insects remedies applied in time effect a great saving in both labour and the material used, as well as preserving the first blooms, which are the most acceptable, from coming malformed and useless, as Rose flowers, when arrived at maturity, are never worth much if in the bud state they have been preyed upon by insects.

**Mulching the surface of Rose beds with rotten manure** is of the greatest importance to secure a satisfactory crop of flowers during the current season, and equally necessary to the production of strong growth for the ensuing year's bloom. This is especially the case in dry situations, where the soil becomes parched during the summer season, and is much more effectual than the application of even an unlimited quantity of water alone, and this quite independent of the body of soil in which the plants are grown having been previously well enriched. The applying of manure in this way to standards, half-standards, and such as are grown bush fashion may be delayed for some weeks, but with those that are grown on their own roots to be pegged down the mulching should be put on directly the pruning is completed, before the shoots are pegged in the positions they are to occupy, or it cannot be conveniently done afterwards. Previous to this, as soon as pruned, the beds should be forked over, pointing in at the same time any manure that may be needed to incorporate with the soil.

## Orchids.

**Dendrobiums.**—The handsome, though old, autumn free-flowering *Dendrobium chrysanthum* will now be making active growth, and should be kept moderately warm, but not too hot. It is a native of the hilly district Nepal, and, like most plants from the same country, succeeds better in a medium than a high temperature. It needs plenty of moisture whilst growing. If this is wanting the bulbs stop short, never attaining their full length; the result of this is that the bloom is proportionately deficient. Another handsome species long known amongst Orchid growers, but still not very plentiful nor very often seen in good condition, is *D. Cambridgeanum*. This also is a hill region plant, from Khowsee, and, like the preceding, does not do well in a high temperature, succeeding far the best near the roof on a block. It will now be pushing up its fine yellow and purple-blotched lipped flowers. Care must be taken in the operation of watering not to wet the advancing buds much, or they are liable to damp off. One of the most useful of all *Dendrobies* for the production of flowers for bouquets, &c. is the Chinese *D. moniliforme*. There are two varieties—the large one much the best. It can be had in bloom without difficulty about Christmas, or soon after. It will now be commencing growth, and should have plenty of water at the root. Like all Orchids from the same country, it does better with more air and more light than it is advisable to admit to the generality of Orchids. Both this and the well-known, nearly allied species, *D. nobile*, with its many varieties—amongst the best of which are *D. nobile coccineum* and *D. nobile Wallichii*—can be better grown in the front shelf or close to the upright end glass of an earlyinery, where they are not exposed to work, than in an Orchid house, the drier atmosphere during a considerable portion of the day suiting them better. In such a structure I have

always found that this section of *Dendrobies* make shorter, stouter bulbs, with a much freer disposition to flower. So much is this the case, that in this way, these plants will frequently bloom from the preceding summer's pseudo-bulbs whilst yet the leaves are fresh and green upon them, a circumstance that rarely occurs when they are subject to ordinary treatment. Amongst the finest of all *Dendrobies*, as also ranking with the finest of all Orchids, is the white-flowered *D. formosum*; it requires more warmth to grow than such as the preceding. The different forms of this plant may be had in flower at various times in the year, but such as completed their growth late in the autumn and have since been at rest will shortly begin to grow, and must receive more warmth and moisture. The varieties of *D. Farmeri* intended to flower through May and June must still be kept dry at the roots, as also in a comparatively dry atmosphere. Even if the flowers are now showing, they may be kept back without suffering in any way, with only just as much moisture as will keep the bulbs from shrivelling too much, as if water is given liberally and they are kept tolerably warm, the flowers come on very fast; the same holds good with *D. densiflorum*, but the latter will bear a much lower temperature whilst at rest. In the tall, erect-growing section, *D. Dalhousieanum* and *D. fibrarium oculatum* are amongst the best. Where *D. Dalhousieanum* is required to flower late in May and June, it must still be kept quite dry at the roots, as if only a little moisture is given it will have the effect of pushing it off into growth. The Australian *D. speciosum*, one of the most magnificent species in existence, is often discarded by many, under the impression that it is difficult to flower. This is anything but correct if it is properly treated; if subjected to the moist, hot, close atmosphere of an ordinary Orchid house it will keep on growing year after year without producing the least surplus of the roots, and should find it more in its natural home, Kingiam, and *D. Johannis* will grow and flower as freely as any of the genus if grown in an ordinary warm greenhouse.

**Disa grandiflora**, a very beautiful Cape Orchid, when it commences growth, can scarcely be kept too moist; it should be syringed overhead at least twice a day. Anyone possessing an ordinary greenhouse should have no hesitation in growing it, placing it near the end of the house, where it will not be too much under the influence of a direct current of air from the front lights. It must have a damp medium to stand upon, as a current of dry air, such as is usually rising through an open stage or trellis is unsuitable for it. The most elegant *Dendrochilum*, *filiforme* and *glumaceum*, the former by far the most beautiful, will now be fast pushing up their flower-stems. Whilst in this stage, see that too much moisture from the syringe does not reach them overhead; but they must be well syringed at the roots, and should find it more in its natural home, as they do not like anything approaching a low temperature. *Epidendrum vitellinum* for many years was looked upon by the majority of Orchid growers as all but unmanageable, generally growing smaller every year from the time the plants were introduced until they ceased to exist; but now that its requirements are better understood, it deserves to be grown in quantity. From its comparatively small size, the little room it occupies, and the freedom with which its beautiful orange-red flowers are produced, it forms a most desirable contrast to the generality of other Orchids. It succeeds best in a temperature similar to that in which most *Odontoglossums* thrive.—T. B.

## Greenhouses.

Indoor plants have almost invariably started into growth; therefore such as require a shift must at once receive attention. Borders in which plants are growing should be lightly forked up, and if the soil is exhausted a dressing of loam, leaf-mould, rotten manure, or good peat may be added, according to requirements. Some plants need more water than others, and, in such cases, neatly-formed basins of soil should be made around them, so as to retain sufficient for their wants without overflowing. This is an excellent time for transferring plants from pots to conservatory borders, and, in doing so, disentangle and spread out the roots as much as possible. This may check growth for a time, but eventually, other circumstances being favorable, plants so treated will succeed better than such as are planted with the roots coiled up in a ball. Camellias, *Rhododendrons*, *Acacias*, &c., when grown in pots are more under control than such as are planted out; but the latter are generally the most satisfactory, both as regards growth and bloom. *Chanthus panicus*, if too thick, should have its shoots thinned out a little, so as to give sunlight light to the flowers. Passion-flowers should be pruned well in, and the soil in which they are growing should be thoroughly saturated with water, so as to induce them to start freely into growth. Cut in the branches of *Habrothamnuses*. Several of the free-growing *Fuchsias* are well suited for conservatory roof decoration or that of pillars, especially when planted out in borders. If trained to the rafters from the middle of April until they are completely denuded of side branches in the end of October or November, or for the purpose of resting them, and admitting light to the other inmates of the house, they form objects of interest, being richly laden during all that time with both flowers and foliage.

**Chrysanthemum** cuttings struck at the end of the year will by this time be well rooted and hardened off; they should be at once moved into 6-in. pots, using ordinary loam made rich with one-third rotten manure and leaf-mould in equal proportions, to which a little sand has been added. There is no grosser-feeding plant in cultivation than the *Chrysanthemum*. To grow it successfully the soil must be rich, and in its early stages it must never be allowed to become pot-bound, for if this occurs, no after treatment will ever impart to the plants their wonted vigour, as the stunted condition the roots get into when confined in little pots has the effect of prematurely hardening the shoots. It will be

necessary to decide upon the desired state of the plants. In most cases it is advisable to adopt two or three forms, but the flat, Mushroom-headed fashion should never be followed. The most generally useful for decorative purposes are plants with a dozen or more shoots, ultimately trained with just as many sticks as will support them. All plants intended to be grown thus should, at the time of potting, have the points pinched out to induce them to break several shoots. This shape will be found the most suitable for the Pompano, and also for the large kinds of *Chrysanthemums*, and also for the Pompano. Many of the large kinds that produce the finest individual blooms are not capable of being seen in their best form if many flowers be allowed to each plant; for ordinary purposes, six or eight will be enough on each; for growing in this way the plants must be also stopped now to cause them to form three or four shoots. Those who are disposed to attempt the production of a few of the finest flowers may do so by only allowing each plant in a 9-in. or 10-in. pot to carry from one to three flowers. These will be found very effective when in bloom if arranged in the greenhouse amongst the dwarfier flowers, relieving the even surface, which is justly held objectionable in a stage filled with *Chrysanthemums* of nearly the same height. To grow them in this way the young plants now potted should not be stopped at all, but simply trained to a single stem all through the season, allowing it to branch out in summer near the top to as many shoots as it is destined to carry flowers. *Chrysanthemums* are frequently seen but mere shadows of what they are capable of being produced; yet they are easily managed and well repay a little extra attention.

**Herbaceous Calceolarias** that have now filled their pots with roots and are pushing up their flower-stems will have their blooming capabilities much increased by the continuous use of liquid manure; these should be in a warmer place than the *Ciccerarias*, and a vigilant look-out kept to see that aphides do not get established upon either of them.

**Pelargoniums**.—The earliest-blooming, large-flowered, and fancy *Pelargoniums* will now be showing their flowers; and as the roots by this time will have taken full possession of the soil, they should be supplied with manure water once or twice a week. If attention in this matter be not paid to these plants, there is a difficulty in keeping the foliage of that dark green healthy hue which so much enhances their appearance when in flower.

#### Forcing Houses.

Keep these supplied with successions of *Lilacs*, *Spiræas*, *Deutzias*, and similar plants. Cuttings of *Coleus* struck early should be potted as they require it, pinched at the third joint, and the plants be kept near the light. Irregular form attractive summer objects in conservatories; therefore, treat them like *Coleuses*. The general stock of *Begonias* should now be potted and started into growth. *Caladiums* started in small pots should be shifted into larger ones before their roots become entangled. Continue to force *Lily of the Valley*; place the plants that have been forced under the stages of the greenhouse for a time, and after that plant them out, where, if they be well cared for, they will in two years make good plants for forcing again. Some plants of *Lilium auratum* should be introduced into this house for blooming in May. In making up baskets for suspending in the conservatory, keep them in a forcing house until they are in active growth, when they may be gradually hardened, so as to withstand the cooler temperature to which they are to be subjected. Keep up a young and healthy stock of *Fuchsias*, *Holotropes*, *Potunias*, and other plants for early blooming; those treated more hardily flower later.

#### Indoor Fruit Department.

**Pine-apples** that have not been already shifted should now be re-potted or transplanted into beds. Whether grown in pots or planted out in frames or pits, the heating material should be entirely or partially renewed. If fire-heat is used for protection, the greater care than would otherwise be necessary must be exercised in watering, as the bottom part of the soil frequently becomes dry when that on the surface is apparently quite moist. Now that the store plants are beginning to push, the atmosphere as well as the soil in which they grow must be kept moist. Ventilate a little during the heat of the day, and cover the frames with mats at night. Fig trees in pots will be swelling their fruits; therefore, some liquid manure given to them two or three times a week will be of great importance to the crop; mulchings of manure answer the same purpose. Those on walls or on front trellises should be started in succession, by closing up the house, syringing twice a day. Pot Vines, if liberally fed, will produce good crops; and, as they are frequently thrown away after bearing, as many bunches may be left on them as they can properly mature and colour. Thin Grapes in general, stop and rub off young shoots, encourage good foliage, and maintain a brisk, moist temperature, except in late Vinerias. All old Grapes yet on Vines should now be taken off and preserved. The dampness of the winter has been their productive of mouldiness amongst those kept in water-bottles. Regulate the growth of Peaches and Nectarines, and disturb and thin the shoots as necessary; thin out, also, all the smallest fruits, and syringe morning and evening. Keep Cherry houses well aired. Introduce successions of Strawberry plants, and place them on top shelves in Vinerias or Peach houses, or arrange them near the glass in pits or frames, when a little bottom-heat given by fermenting material is very beneficial to them. To plants whose fruit is colouring little or no water should be given, as it deteriorates the flavour. Sow the main crop of Melons and Cucumbers, and pot off those already up; such as are large enough may be transplanted permanently. Beds for the reception of the seedlings

should be formed completely of fresh soil, for from the plants raised now the greatest amount of fruit is commonly obtained.

#### Flower Garden.

**Auriculas**.—These are now making rapid growth—almost too fast for those intending to exhibit at the forthcoming show at the Crystal Palace. The trusses are showing up freely through the varied and beautifully powdered foliage. It is an anxious time, especially for the exhibitor, who has to get his flowers in perfection by a certain date, about the end of April, and unless he is well acquainted with the character of the different varieties, a mistake may easily be made. Not only do some varieties take much longer to perfect their trusses than others, but a great deal depends upon how the trusses come. Sometimes they can be seen deep in the centre of the plants in autumn. These take a long time to come to perfection; the flowers will probably not open until April. Another plant will have a large centre which will not show any signs of a truss until March, when, as if by magic, a leaf or two is unfolded, and lo! a fine truss is exposed to view, with the flowers almost expanded, and probably in advance of that formed in autumn. As a rule, the earliest-formed trusses produce the finest flowers. The plants must not now be allowed to suffer from want of water; but it must be applied without wetting the leaves; the fine, mealed foliage is easily injured, a shower of rain is most disastrous. The lights may be removed altogether in fine weather, but no rains or cold winds should have access to the plants. The small offsets potted in the autumn should now be shifted into a size larger pot; the little plants will make rapid growth, and form fine flowering plants by the next blooming time.

**Carnations and Picotees**.—I have shifted all our stock into their blooming pots, and placed the pots as far as possible under cover. If the present fine weather would continue it would be just as well to place the plants out-of-doors at once. I have done this and the plants have succeeded well, but if rain, snow, or sleet should come immediately after potting, or perhaps in the middle of it, the plants would be injured. The potting material, which is composed of turfy loam and leaf-mould, with a portion of rotting manure added to it, should be moderately dry, but not too dry; satisfactory potting cannot be done if the soil be either too dry or too wet. The size of the pots is a matter for consideration. I use 7-in. pots for single plants, 8-in. ones for a pair of weak plants, 9-in. ones for strong pairs, or three plants in a 10-in. pot. Probably these small pots would not answer for some growers, especially those who are absent from their plants all day long, as many of the most enthusiastic growers are. They would find larger pots answer better, containing, as they do, a large quantity of soil, which does not dry up so speedily. Growers for sale also find large pots best, because they are anxious to layer as many growths as they can, and sometimes the layers are uncomfortably crowded in a small pot. I am satisfied, however, that with care in watering one obtains the best blooms when the pots are of the size which I have named. Those who have not yet potted their stock should lose no time in doing so. The plants spindle for bloom in the south early in March, and the blooms will not be large or well marked if the plants be disturbed too late.

**Herbaceous Phloxes**.—These are cultivated in beds, borders, or in pots, for conservatory decoration. The Phlox is a gross feeder, and well manured; this ought to be done in the autumn, so that the frosts of winter may pulverise the soil, and it ought to be turned over two or three times. I have just now planted out a bed of plants that have been wintered in cold frames. Each plant is throwing up three or four strong shoots; the distance apart in the beds is 18 in. If all the cuttings have not yet been put in, see that they are inserted at once, as previously recommended. Cuttings put in early, and rooted in a gentle bottom-heat, are very useful for flowering in pots in the autumn. The plants must be potted on and carefully attended to, else they will not flower until the second year.

**Tulips**.—These are now above ground, and the mild weather is causing a strong, healthy growth; the surface of the beds has been covered over with some rotten frame-manure. Nearly all sorts of plants succeed well in soil when the surface of the ground is mulched; in that case water can be applied without causing a crust to form on the surface, and when water is applied it does not evaporate rapidly. Of course, it is not necessary to apply any water to the Tulip beds at present. I have not yet placed any covering over the beds. It used to be the practice of the old growers to cover their beds early in the spring, and it may be necessary to do so in cold, wet districts, but the plants do not sustain any injury from the weather in dry, well-drained districts south of the Trent.

**Pansies in Beds**.—The surface of the ground should now be stirred with a pointed stick, and all weeds should be carefully removed with the fingers. If there be sufficient space between the plants, it will be as well to run a Dutch hoe through amongst them. Mulch the surface of the beds with rotten manure.

**Pinks**.—These require treatment very similar to that given to Pansies. In our own beds perhaps a dozen plants have died during the winter, and the blank spaces will be filled in from a number of plants that have been saved in pots and wintered in a cold frame. There are a few varieties that will not die so well as the open ground during the winter, and if they should be scarce, it is better to save them all in pots, as in the case of Carnations.

**Gladioli**.—These should now be planted out for the main bloom. I

have generally succeeded best with those planted out about the middle of March or towards the end of that month. Directions for planting have already been given.

**Dahlias and Hollyhocks** that have been re-potted into 5-in. or 6-in. pots should be placed in frames and have plenty of ventilation, removing the lights altogether in fine weather. Hollyhocks will not suffer from frost, but the Dahlia is exceedingly susceptible to it. Dahlias are not often injured by insect pests, but thrips and red spider injure the Hollyhocks. Syringing and fumigating with Tobacco smoke is the best way to destroy them. Those who grow these useful autumnal flowers for exhibition will have by this time the ground in good condition ought to have been trenched and well manured in the autumn, and in fine weather the surface may be forked over to the depth of 3 in. or 4 in. Hollyhocks may be planted out in the course of a week or two. — J. DOUGLAS.

Sweep and roll lawns and walks as soon as the weather becomes favourable. Judiciously prune evergreen shrubs, such as Aucubas, Hollies, Bays, Box, Yews, Portugal and common Laurels, Junipers, Thujas, Cypresses, Ivies, &c., which may be out-growing the spaces allotted to them, keeping symmetry and gracefulness of form as much as possible in view. The knife is better than shears for such an operation, the latter being apt to mutilate the leaves.

**Herbaceous Borders.**—Most of the plants will be aboveground, and the mulching material put on early in the winter ought to be dug in. For this operation use a fork in preference to the spade. Should the Grass need edging it can be done at the same time, thereby imparting to the whole a neat appearance. Be very careful not to disturb the roots of any kind of Lilies, as they, more than most subjects, are impatient of any interference at this season. Summer and autumn-blooming herbaceous plants, such as Phloxes, Asters, or any flowers that exist in large masses when the season is considerably advanced, it will be well to divide at the present time, as by this means their roots will be placed within reach of fresh soil, which will strengthen them and enable them to bloom better. It is necessary to keep well back in the border all growing plants of this description; but, as far as possible, avoid planting them where the ground is occupied with the roots of deciduous trees, as herbaceous plants have but a very poor chance of success under these circumstances; yet, as in such situations it does not look well to have the ground bare, there is nothing better suited than the strongest tall-growing varieties of Michaelmas Daisies and Golden Rods, to assist which in such positions an extra liberal dressing of manure should be given every spring, digging the ground with the spade a full spit in depth, which will cut off the obtruding roots, and for a considerable portion of the summer spare the plants being affected by them. Any choice plants that are subject to the attacks of slugs will be benefited by 1 in. of coal-ashes being placed round the collar of the plants, which, though it will not altogether prevent the slugs from attacking them, will, in a great measure, hinder them from harbouring under the plants.

#### Kitchen Garden.

In this department a continuous supply of good vegetables through the season much depends upon the attention during the next few weeks in putting into the ground the numerous seeds that require it. The whole of the Potato planting should be brought to a close before the

end of the month. If the seed has been prepared as advised it will be in good order. In planting the general crop there are two courses to follow: either place the rows sufficiently far apart to admit the winter Broccoli, Cabbage, Brussels Sprouts, &c., being afterwards planted between the rows, or put the Potatoes for enough apart to ensure their well-being without anything else between them. In the former case the rows will require to be 3 ft. asunder; in the latter 2 ft. to 2 ft. 3 in. will be sufficient. I prefer the single-cropping system, as, when double-cropping is resorted to, the winter vegetables never do so well, and in many cases are too far apart when the Potatoes are removed. On the score of economising space, this double-cropping is evidently more loss than the gain.

**Sowing Seeds.**—Sowings should now also be made of Cocos-nut and Enfield market Cabbage, green Curled Savoy, Walcheren and Early Cauliflower, and Veitch's Autumn Giant Cauliflower. Prepare the seeds with red lead, to protect them from birds. Successional Broad Beans and Peas will now require putting in. Excepting where the vegetable ground is limited, and there is a difficulty in procuring Pea-sticks, there

is nothing to equal the tall Marrow kinds for furnishing a large and continuous supply, which does not come in altogether as the dwarf-growing varieties do. Where the tall sorts of Peas are grown, and the ground is rich and in good condition, they will require 5 ft. 6 in. space between the rows; this will be sufficient, and better than sowing farther apart with Broccoli or Celery between, as is sometimes done; such double cropping being here again no advantage, for the Celery, Broccoli, &c., so grown never has the necessary strength and vigour to withstand the winter that they have when grown by themselves. A row of Spinach can always be grown without any disadvantage between Peas so planted. Amongst winter vegetables there is nothing that is of more real use than Brussels Sprouts. To grow them well, the seed must be sown not later than the third week in March, so as to get the plants a good size early, planting them out where they are ultimately intended to grow as soon as they are large enough.

Celery sown in heat, as recommended some time since, will shortly be large enough for pricking out. Where it is required for use as early as obtainable, there should be prepared for it a slight hot bed, consisting of about 18 in. of fermenting manure and half-rotten leaves. On this place a two or three-light frame, with 10 in. of rich soil, into which put the plants 1 ft. apart each way, giving a little water, afterwards putting on the lights, which keep close for a few days, until the roots take hold of the soil; if the weather be sunny, shade in the middle of the day. As soon as growth has fairly commenced, give plenty of air, to prevent the plants drawing up weakly; and, if well attended to as regards water, they will progress rapidly. The lights should not be altogether dispensed with until all fear of frost is over; every alternate plant may then be removed with a good ball of earth and turned out into a well-prepared trench, leaving the remainder on the bed on which they have been grown, and when large enough earthing up with light soil brought in for the purpose. By this means those who want Celery very early can have it in good condition by midsummer, but, of course, not large. It will be succeeded by that which was planted out from the bed, which will be ready before the ground in the ordinary way. The principal portion of the plants from the same sowing should be pricked out 3 in. asunder in a frame, in which put 6 in. of good soil on a firm bottom composed of ashes well rammed, into which the roots will not penetrate far. For this purpose the soil should be of a

Vase of Roses by Mnisiat.

giving a little water, afterwards putting on the lights, which keep close for a few days, until the roots take hold of the soil; if the weather be sunny, shade in the middle of the day. As soon as growth has fairly commenced, give plenty of air, to prevent the plants drawing up weakly; and, if well attended to as regards water, they will progress rapidly. The lights should not be altogether dispensed with until all fear of frost is over; every alternate plant may then be removed with a good ball of earth and turned out into a well-prepared trench, leaving the remainder on the bed on which they have been grown, and when large enough earthing up with light soil brought in for the purpose. By this means those who want Celery very early can have it in good condition by midsummer, but, of course, not large. It will be succeeded by that which was planted out from the bed, which will be ready before the ground in the ordinary way. The principal portion of the plants from the same sowing should be pricked out 3 in. asunder in a frame, in which put 6 in. of good soil on a firm bottom composed of ashes well rammed, into which the roots will not penetrate far. For this purpose the soil should be of a

light sandy nature, to enable the plants, when moved for permanent planting, to be taken up with little breakage of the roots. Where Celery is desired late, say until April the following spring, a little seed should now be sown, as this will stand longer without running to seed than the earliest sowing.

#### Extracts from my Diary.

**March 18.**—Sowing Balsams, German and Ten-week Stocks. Putting in cuttings of Coleus, Fuchsias, and Verbenas. Potting off spring-struck Verbenas and Heliotropes. Levelling down Celery trenches, and getting the ground ready for Peas. Re-making Mint beds. Thinning out and cutting back Ivy on walls. Sticking early Peas, and giving them a little earthing up. Mending Box edgings.

**March 19.**—Sowing Long Pod and Windsor Broad Beans. Potting off Cucumbers and Melons. Putting in cuttings of Alternantheras and Mesembryanthemums. Watering forced Asparagus beds with warm manure water. Getting another batch of Strawberries into bottom-heat. Turning over manure for Celery, having previously mixed it with salt and soot. Giving the surface of the Carrot and Beet ground a dressing of soot, and preparing it for drilling.

**March 20.**—Sowing Snow's Winter White Broccoli, Brussels Sprouts, and Wallflowers. Shifting Tomatoes and Capsicums. Pricking out Celery and All the Year Round Lettuce. Planting the main crops of the following sorts of Potatoes: Snowflake, Carter's Breadfruit, Main Crop, Giant King, Model, Schoolmaster, Porter's Excelsior, Paterson's Victoria, King of Potatoes, and Perfection Kidney. Looking over Grapes in bottles, cutting out any bad berries, and filling up the bottles where required.

**March 21.**—Sowing Cucumbers and Melons; also Canadian Wonder French Beans in pots. Shifting a few stove plants. Planting out autumn-sown Cauliflower; also a few Brown Cos cabbages. Preparing ground for new Sea-kale beds, and also for Globe Artichokes. Earthing up Potatoes in frames. Looking over Pines and watering them. Forking over the ground amongst Cabbage plants.

**March 22.**—Thinning Grapes and tying down young shoots in early Vineries. Looking over Cucumbers. Getting netting and other coverings over Peach trees for protection. Looking over fruit room, and removing any fruits that are decaying. Tying in young shoots in Peach house. Renovating Limes round manure frames. Weeding Box edgings and gravel walks. Dividing and re-making herb beds. Getting a little more Chicory into the Mushroom house.

**March 23.**—Earthing up Beans in pots. Cleaning up the pleasure grounds, and rolling down all gravel walks that require it. Covering up Sea-kale beds. Looking over Pelargoniums; picking off all dead leaves and stopping the shoots where required. Clearing off borders, giving them a dressing of soot, and forking them up ready for seeds.

Dorsel.

W. G. P.

#### VASE OF ROSES BY MAISIAT.

It is a remarkable thing that with all the love which an Englishman has for the Rose, in the garden, or even when gathered and brought into the house, there are so few English artists who make the Rose a subject for a picture or an artistic study grouped with other flowers in a vase. Our walls in England are more commonly decorated with scenes from the hunting-field and racecourse than with refined groups such as these, which French artists paint so well. Perhaps there is something in the more genial climate of France which encourages a more abundant bloom, and causes the Roses to hang down over many a garden wall in festoons of flower, that suggests the overflowing abundance of floral beauty seen in the accompanying print. It is to be hoped that in time a taste for such subjects may grow up which will refine the too realistic and money-making spirit common in this and all ages.

E. W.

☞ **The Banksian Rose.**—If "J. G.'s" Banksian Rose (see p. 210) be a shy bloomer, he cannot have got the same variety which we have, unless it is planted on a very different aspect from the one we have, or is treated differently, as ours is exceedingly floriferous, so much so, indeed, as to be literally white with blossoms every year, unless, as was unfortunately the case last season, they get out off by frost. We spur it hard in as soon as the flowering is over, and then during the summer we cut out all the strong growth and thin that of medium size, so as to let in plenty of sun and air to thoroughly ripen it. The young shoots made under this treatment vary from 1 ft. to 1 ft. 6 in., and bloom at every bud, thus forming perfect wreaths of a length most serviceable for cutting. I ought to add that the plant referred to is on a south wall, where it covers a large space, and is now in a forward state. Anyone having these plants in similarly favoured situations may, by managing them in the same manner, have any quantity of flowers; and the same holds good with such Roses as *Maréchal Niel*, *Gloire de Dijon*, *Climbing Devonensis*, and most others of that class.—S. D.

#### KENSINGTON GARDENS.

LONDON has—perhaps it should rather be said had—the good fortune of possessing in Kensington Gardens a public park such as no foreign capital can show. The last few years have made this possession but the wreck of what it once was, and unless something can be done to arrest the decay the character of the place will soon be gone past restoration. It would be a strange misfortune if a garden which has given pleasure to so many generations of Londoners should be left to its fate in a time which professes—though, it must be admitted, without much success as regards practice—to care more for natural beauty than the generations that have gone before it. But this languid belief that we value a piece of ground for one reason is seldom strong enough to resist the precise convictions of those who know that they value it for another reason. Year after year something of the old aspect of Kensington Gardens goes, and by degrees there grow up new and mistaken conceptions of what their character should be. The first thing, therefore, to be done, if Kensington Gardens are to be saved for London, saved, that is, not merely as one among several open spaces—a Battersea Park without the sub-tropical plants, or a level Primrose Hill—is to realise clearly what this original aspect was. After that it will be easier to determine how far and why that original character has been departed from, and to what extent it is capable of restoration.

The essential charm of Kensington Gardens was its woodland scenery. It was like a piece cut out from Windsor Forest or Richmond Park and set down close to London. Indeed, the number of the trees in comparison with the space in which they stood, and the entire absence of underwood, gave singular importance to this feature. Scarcely anywhere was the effect of Grass and timber in conjunction more striking. There may still be some London-bred children who can remember that even a real forest seemed disappointing to expectations founded on recollections of Kensington Gardens. You passed at once from the bordering roads, or from Hyde Park, with its carriages and riders, into a sylvan solitude. No doubt it was necessary to manage your point of view a little, but with this precaution endless avenues of trees stretched away over indefinite distances of turf; and it was only here and there that a path recalled how near the boundary was, and to how many passers-by Kensington Gardens, at least on six days in the week, were nothing more than a convenient way home. Two things only went to make up this peculiar charm—trees and Grass. Deep shade and a green carpet underneath are precisely what the dweller in cities most wants and most seldom finds, and both were here to be found. These being the distinctive characteristics of Kensington Gardens, the principle on which they ought to have been managed was the maintenance of these distinctive characteristics. *Other purposes, such as the advantage of the neighbouring houses, or the provision of short cuts from one part of London to another, should have been kept strictly subordinate*—pursued, that is, when no injury to Kensington Gardens was involved, and left alone whenever any such injury was involved. Further than this, *all incongruous adornments, and all attempts to make Kensington Gardens more like other gardens, should have been carefully eschewed.* The convenience of those who are supposed to make use of the gardens has been consulted, in entire forgetfulness of the primary condition that the gardens should not be destroyed in the process of use. The causes which have made the Grass in Kensington Gardens the heart-breaking affair which a First Commissioner of Works once called it are three: unnecessary entrances, paths where they are not wanted, and the absence of paths where they are wanted. The objection to the multiplication of entrances is this, that from every new gate there spring not one but many new tracks across the turf; and the closer together the gates are the nearer to one another, and therefore the more conspicuous and disfiguring, these tracks become. There is a good instance of this in the south-west corner of the gardens. There is a gate at the bottom of the broad walk, and another a few yards further west. The consequence is that two tracks have been formed across the Grass to the gate at the corner of the palace; whereas, if there had been only one gate there would have been only one track. *The object of putting the second gate was the convenience of the dwellers in Prince of*

*Wales's Terrace.* That is to say, this part of the gardens has been injured in order to save a few nurserymaids the trouble of walking a stone's throw to the right or left before they can seclude themselves from the high road. The gate opposite Gloucester Road and the gate at the beginning of the Kensington High Street supply all the really needed means of entrance. This part of the gardens affords examples of the two other mistakes that have been mentioned. There is a great deal of passing to and fro between the gate at the bottom of the broad walk and the gate at the corner of Kensington Palace, but no path has been made to connect the two points. The result of this omission is seen in ugly footpaths across the Grass, which continually tend to become wider as those who use them take in more of the Grass in order to escape the central mud in rainy weather. It is not of the least use to assume that people will walk round two sides of a square when it is open to them to walk along the diagonal. If no path is made for them they will make one for themselves; and the path which they make for themselves will be much more injurious to the aspect of the turf than the path which is made for them. The edges of a gravel walk can be kept neat by railings or hurdles; and the colour of the gravel is not an unpleasant contrast with the colour of the Grass. In a foot-path along which many people walk the edges are always ragged, and the colour of the bare earth, especially in London, is neither in harmony nor in contrast with anything else. But, though there is no path from one of these gates to another, there are two close by which are of no use whatever: one running southward from the front of the palace and ending in nothing, the other running under the west wall of the gardens from the palace gate to the gate in the High Street. These paths are a survival from the old Dutch arrangement of the part of the gardens near the palace; and when this part was the quietest and the best cared for, and the avenue running southward from the palace was really an avenue and ended in that wonderful old summer-house which has now been removed to the head of the Serpentine, they were quite in place. Now, however, the object should be to have Grass where it has a chance of growing and paths where people are certain to walk. The chief sinner, however, in the way of unnecessary paths is the broad walk, which ran formerly in a straight, and now runs in a crooked, line from Lancaster Gate to the Albert Memorial. The walk was made long before the Albert Memorial existed, and was carried across what was then one of the most secluded parts of Kensington Gardens for no object apparently except to show that the Office of Works was not stingy of its gravel. No considerable number of persons ever want to pass between those two points. The entrance at each end is mainly used by the residents in the neighbouring houses, and they certainly do not need a walk as broad as the original broad walk at the Bayswater end of the gardens to enable them to visit one another. On the other hand, a path is really wanted between Porchester Gate and either the corner of the Rotten Row or the Serpentine Bridge; but it is left to the public to make one afresh every summer.

In the way of incongruous ornaments, the worst example, of course, is the hideous erection, like a section of a metropolitan railway station, and the equally hideous basins and water-spouts, which disfigure the head of the Serpentine. Probably something of the kind is necessary for the supply of water; but if so, the process should have been concealed instead of paraded. A reservoir might easily have been constructed on the other side of the road, and the Serpentine might at that end have been made to look like a lake, and not like a receptacle for the refuse water of some manufactory. As obelisks were not usually placed in woods, it is hard to see why Kensington Gardens should have been chosen as the site of the Speke monument; and even the Albert Memorial should have been allowed to appear over the trees, and not have had an avenue set awry in order to make it more conspicuous.

The practical deductions from all this fault-finding are simple enough. The management of the trees is, as has been said, a question for experts. Few probably of the older trees still standing can now be saved; but much may be done by give to future generations of Londoners the same kind if not the

same degree of pleasure which past generations have gained from Kensington Gardens as they have been. One portion after another should be selected for replanting; and though in the end the result might be that what is now open glade would be forest, and what is now forest would be open glade, yet the proportions of the two and the general character of the combination would be preserved. The Grass is a much easier matter. Here there can be no irreparable destruction. All that is needed is the breaking up of some useless paths, the addition of some new ones, and some attention to common sense in the details of their construction. Thus it is of very little avail to make a path in the full sun, if there is shade to be had on each side of it. In the winter a walker will keep to the gravel anyhow; but in summer he will only keep to it if it lies in shade. If it does not, there will be supplementary paths formed by the side of the gravel paths, and the object of making the gravel path will be lost. Nor should a path which runs along a line of trees be carried on one side only of them. As soon as the sun gets on the path, it is deserted for the Grass which is in shade. The path should be carried along both sides of the trees, as it now is on the north side of Rotten Row. Another point to be remembered is that there is a natural tendency in mankind to walk on the edges of a path, so as gradually to enlarge it. But this tendency, being instinctive rather than deliberate, can be checked by a low railing running along each side. Even though it is not too high to be stepped over, somehow it does not seem to be stepped over in practice. The only cure for incongruous ornaments is to take them away, and if the fountains at the end of the Serpentine could share the fate of the mounds which it was proposed to throw upon the northern bank, the Speke monument might bear an additional inscription to commemorate their removal, and might then be tolerated. The only other suggestion which need be made is that no part of Kensington Gardens ought to be treated as a nursery for young plants, whether those plants are to be used for the adornment of the gardens or for any other purpose. To the east of the Round Pond there is a hideous fence which apparently conceals some stunted promises of future timber; while near the corner of Rotten Row there is a plantation of stumpy Larrels which are so ugly where they are that it is only charitable to suppose that they are meant to be moved somewhere else. One of the few remnants of old Kensington is the brick ball-room to the west of the broad walk, and the gravelled terrace in front of this is now covered with gardener's frames, which suggest nothing but cuttings and bottom-heat. There can be no reason why all three excrescences should not be at once removed. The application of a little common sense to the problem how to make and keep Kensington Gardens as much like what they were a generation ago as change of circumstances will permit would still do much to remedy past blunders, and would ensure us against the commission of any new ones.—"Pall Mall Gazette."

[We italicise a few passages in the above article concerning matters to which we have at various times and in various ways called attention in THE GARDEN. Now that a general newspaper takes up the matter, perhaps more immediate good will come of it. The article is chiefly valuable for well pointing out the great folly of spoiling a noble park or garden by needless roads, walks, and entrances. The charms of the park would be greatly increased if entrances were only made at a few, and those the most essential points. Few people have the least idea of what harm is done to public gardens by the short-cut system.]

---

**Camphor Water a Revivifier of Seeds.**—In THE GARDEN of the 9th inst. (see p. 212), camphor water is spoken of as being powerful in revivifying seeds or causing them to germinate. When ordinary treatment fails, kindly tell us how to get camphor water, and of what strength to use it. The ordinary camphor of commerce is not soluble in water, or very little so. I have some very old seed that I should like to try.—J. NORTON. [Camphor dissolves in water in the proportion of twenty-five grains to the pint. The following is the best way of preparing camphor water: Take rather more of the gum than is required, pound it finely in a mortar, sprinkling it with a few drops of strong brandy or whisky from time to time to assist the pulverisation. When finely powdered throw it into a bottle containing the necessary quantity of water, and shake up now and then. The reduction of the camphor to a fine powder is a difficult operation, and cannot be performed without the aid of the spirit. The bottle should be kept closely corked.—C. W. QUIN.]

## THE FRUIT GARDEN.

### QUINCUNX PLANTING.

The planting originally known as quincunx consisted of four trees set in the form of a square, with the fifth one in the middle, thus:—

When this arrangement was extended, the rows of trees in the orchard stood as follows:—

The effect of this arrangement was that the trees were in squares running diagonally, and it possessed no particular advantage over common square planting. Any orchard planted with trees in rows running each way may be converted into quincunx by placing a fifth tree in the centre of each square, as shown in this diagram:—

The improved or modern quincunx, which is more properly termed the hexagonal form, has the centre tree surrounded by six other trees at equal distances from it, as represented by fig. 1. This arrange-

Fig. 1.

ment has a handsomer appearance, and it has the advantage that the orchard, if desired, may be cultivated in three different directions; it may also be adopted where small orchards are connected or form a part of the ornamental grounds, as in fig. 2. If a few symmetrical fruit trees are planted contiguously, they will serve to form a harmonising connection between the orchard and grounds. These

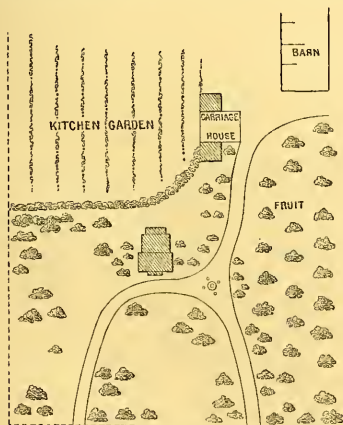

Fig. 2.

may consist of such vigorous growers as will succeed well when standing in Grass. Hexagonal planting would be oftener adopted if planters knew how to do it. True hexagonal planting consists of a series of equilateral triangles, six contiguous ones forming the hexagon.—“American Cultivator.”

dessert Apple with many varieties grown specially for that purpose, in this neighbourhood it forms a large tree, which does not suffer from canker, as in some localities. Its annual growth is tolerably strong, and although it can scarcely be called an abundant cropper, it bears a fair average crop in as many seasons as any other variety. And a most important fact in reference to it is this, that a small crop that will keep in good condition six months after gathering is of considerably more service than a heavy crop that must be used immediately to prevent its spoiling. I have never known a season when good sound London Pippins after Christmas were not worth a good price; for it frequently happens that the superabundance of Apples in autumn is confined exclusively to non-keeping kinds. This variety is familiar as the Five-crown Pippin, as the side ribs become very prominent at the crown.—“Field.”

### FRUIT TREES FROM AN ORNAMENTAL POINT OF VIEW.

In a letter addressed to the editor of the “Revue Horticole” by M. Charles Baltet, the claims of the Pear, the Apple, the Cherry, the Peach, the Plum, and their congeners to take a foremost place amongst ornamental trees are put forward with no common ability. The beauties of fruit trees in full bloom and in full bearing have been sung by poets and painted by artists in all ages, but, with few exceptions, these gifts of Nature have been hitherto strangely neglected by landscape gardeners. Even those which have been taken into favour seem to have been chosen because they do not bear fruit, as if a fruit-bearing tree ought to be looked upon as an intruder in an ornamental plantation. M. Baltet congratulates the editor of the “Revue Horticole” on his advocacy of the yellow-barked Peach (*Persica aurea*) as an ornamental tree, adding that fruit trees in general are too much neglected by landscape gardeners, or, as I regret to see, M. Baltet prefers to call them, “garden architects” (*architectes de jardins*). A little consideration and a visit to the Park Monceaux will, I think, show M. Baltet that it is the so-called “garden architects” who have done so much to make Nature ugly. I think the “garden architect” who placed that hideous pyramid in that otherwise pretty park would be horrified if M. Baltet were to propose to remove this erection and to replace it with a clump of Pear trees. But this by the way. Let us examine the Pear tree, says M. Baltet, and we shall find that its habit, its foliage, and its fruit leave nothing to be desired, no matter in what soil or climate it may be grown. It is true that a group of prolific, large-fruited varieties, such as Beurré de l’Assomption, Williams’ Bou Chrétien, Van Marum, and others, will always be a source of delight to the lover of fruit, but the artist will look for effect from the natural appearance of the trees. If he wishes for luxuriant growth, he will find it in the branches of the Pear known as the Curé, Louise Bonne d’Avranches, Conseiller de la Cour, and others. The Beurré Hardy, Vanquelin, and Duke de Nemours have long upright branches, while those of the Beurré d’Amanlis, Bon Chrétien, and Triomphe de Jodoigne spread out more or less horizontally, or even curve downwards. The latter tree is the type of hardness and vigour. *Arbre courbé*, *Nouvelle Fulvie*, and *Marie Louise* would not be out of place as drooping trees; while to rival the pyramidal varieties of the Robinia, the Oak, the Birch, and the Elm, we may admit a group of Pear trees which grow naturally in this shape, such as *Fondante du Panisel*, *Beurré de Nantes*, *Fondante de Noël*, *Beurré d’Angleterre*, and a number of others, including Charles Ernest, a new and excellent variety, which will be described and illustrated in the “Revue Horticole.” The “curious,” as they were called in the days of La Quintinie, have already borrowed from the domains of pomology such subjects as the Weeping Pear, the Mount Sinai Pear, the Sage, Willow, and Almond-leaved Pears, &c.; but their fruit is insignificant. The beautiful foliage of the *Sucrée* de Montluçon, *Delpierre*, *Triomphe de Jodoigne*, &c., is rivalled by that of the *Mikado* and *Daimyo* varieties, which are of Japanese origin, with large, thick, and somewhat cottony leaves. China furnishes us with two sorts, the thick, shuino, and ciliated leaves of which change to amaranth red in the autumn, like certain Maples and Sumachs. Amongst our own sorts we have the German *Kopertscher*, the Belgian *Délices de Jodoigne*, the American *Philadelphia*, and the French *Gil-ô-Gile*, which present the same character.

**London Pippin Apple.**—This is one of the justly popular fruits that still maintains its ground against all-comers. It is of great service as a Kitchen Apple during the first three months of the year; and at the present time, when fully ripe, it bears favourable comparison as a

The observer who takes notice of the particular characters of each variety will know that Marie Guisse, Monseigneur des Hons, and Royale d'Hiver are the first to show their buds in the spring, while Martin sec, Madame Loriot de Barny, and Herbin seem sorry to shed their leafy clothing in the autumn. Bonne d'Ézée and Doynenné d'Alençon are the earliest to flower, and Alexandrine Douillard, Sylvange, and Nouvelle Fulvie protect their clusters of flowers with a sheltering rosette of leaves as soon as they open. If we wish for Pear trees with double flowers, we may gratify our desire with Comte Lelieur and Beurré de Nagain, with their regular corolla, or the double-flowered Bergamotte and Calebasse Oberdeck, with their drooping petals, will satisfy us. Without being able to compete with the coloured barks of the Birch, the Golden Ash, the scarlet Dogberry, or the veined Maple, we may content ourselves for the present with the Ash-coloured bark of the Bési Dubost, the ochrey Passe Colmar, the violet Beurré Giffard, the purple Doynenné Flon aigle, the dark brown Bon Chrétien de Bruxelles, the bright-barked Fondante Thririot, the sombre Rousselet, and the yellow-green and pretty-veined and variegated varieties Beurré d'Hardenpont and d'Amanlis, Verte longue, Saint Germain, &c. Amongst our ornamental shrubs we have examples which have their bark curiously split, crannied, and galled, but we can match them with Van Mons, Deux-Scours, Angélique Leclerc, Beurré Lebrun, and others, the latter having a vigorous stem, which looks as if it had been sprinkled with carmine. Wildings will furnish us with prickly varieties, and the study of local fruit has provided us with the Poirier de Posse, which, in the department of the Aube, is as large and tall as an Oak. Finally, the dwarf Pear is not a myth, and growers are endeavouring to form it into a new series. Thus we have everything—the grand and the stunted, the beautiful and the ugly, the agreeable and the absurd. A plantation of Louise Bonne d'Avranches in a park or English garden would give as much pleasure as an isolated Plane or a clump of Pteleas. If we push our arguments as far as the neighbouring genera, for instance, the Apple, the Pear, the Peach, the Apricot, the Plum, without forgetting the Sweet Chestnut, the Walnut, the Almond, the Orange, the Fig, and the Kaki, we shall be convinced that the title of this paper is not so paradoxical as it appears to be.

C. W. QUIN.

**Pear Blossoms.**—In the general abundance of fruit-buds the Pear here forms an exception, and I also see, by notes from other localities, that the same rule holds good elsewhere. Wall trees with us are blooming more irregularly than espaliers or pyramids, which, for the most part, are fairly well covered; but on walls, where one tree has an abundance of fruit-buds, others as favourably situated have none. This cannot be attributed to the weight of crop last season, as those that had the best crops are, as a rule, the most promising.—JAMES GROOM, *Henham*.

**Newtown Pippins.**—I ordered a barrel of Newtown Pippins from Liverpool last year, and found them much undersized, and not of so rich and juicy a flavour as usual. Some of the fruit were very highly coloured, but had dark brownish specks in the flesh; and they had been loosely packed in the barrels, for more than one-fourth of them were bruised and had begun to rot. In opening barrels of Newtown Pippins in former years I always found the fruit bruised in some places, but they never rotted like those in 1877. The season must therefore have been bad for them in America last year, for there is no more delicious Apple grown than the Newtown Pippin when the season is favourable for it.—WILLIAM TILLEY, *Welbeck*.

**Winter Nells Pears not Ripening** (see p. 189).—What is the aspect? Winter Nells ought to ripen well in the neighbourhood of Cork, if the aspect be either south or west. On a north or east aspect it cannot be expected to ripen, or any other kind of Pear of the same season. If the tree is cut down and the wall faces either south or west, graft on it *Josephine de Malines*—W.

**Early Bloom on Apricots.**—In answer to "A. D.," (see p. 213) who wishes to know when the first blooms expanded on Apricots in different localities, allow me to say that on a south-west aspect a quantity were open on March 1. We have since experienced cold winds for a few days, but vegetation is very forward, which makes one feel anxious for our forthcoming crops.—N. FULLER, *Downton Castle, Ludlow*.

## THE LIBRARY.

### THE CORN AND CATTLE PRODUCING DISTRICTS OF FRANCE.\*

This is the only book on French farming which has appeared in English since Arthur Young's famous work on the subject, which was published as far back as 1789. Although treating mainly of farming proper and cattle breeding, the fruit and vegetable grower will find much to interest him. The accounts given by Mr. Gibson of this branch of cultivation are full of interest, the only fault to be found with them being that they are too short. The last returns with respect to French market gardening were made in 1873, and show that no less than 1,250,000 acres were devoted to the growth of green vegetable crops alone. Thoméry Grapes, Roscoff Broccoli, Argentanil Asparagus, Vancluse Melons, and all kinds of green and preserved fruits and vegetables from *La belle Touraine*, are to be found in every good greengrocer's shop in Western Europe at one season or another. According to the statistics given by Mr. Gibson there are over 6000 men, women, and children engaged in growing early Asparagus, Lettuces, Carrots, &c. in and around Paris. The rent of the land varies from £36 to £48 per acre, according to situation and irrigation plant. These market gardens are of comparatively small dimensions, and vary from 2½ acres to 1½ acres. Taking the smaller size, the plant necessary to carry on business costs nearly £500, including large and small cloches, straw mats, glazed lights, frames, tools, baskets, horse, cart, and harness and other necessary materials. The regular workmen, it is said, earn an average wage of 1s. 7d. per day with board and lodging all the year round. Extra men gain 3s. d. per hour, women 2s. d. Most of the men come from the Nivernais and Burgundy, not so much for the sake of the wages, which are low for France, but in order to learn a business which they can turn to profitable account when they return to their homes after two or three years' service.

Amiens claims to be one of the oldest market gardening towns in France, vegetables having been grown there in the twelfth century—hundreds of years before a Cabbage was grown in England. There are at present about 250 acres under cultivation, the yearly produce of which is estimated at about £130 per acre. The Cabbages often weigh from 40 lb. to 50 lb.; Beetroots, 20 lb. to 25 lb.; Black Radishes from 12 lb. to 20 lb., and the Turnips from 12 lb. to 15 lb. The business, both here and elsewhere, suffers greatly from the short-sighted policy of the French railway companies, who refuse to further lower their charges for perishable goods sent by express train, although the Rhensish railways charge only ordinary goods train rates. The minimum quantity which can claim a reduction on the French lines—half a ton—is too large. A reduction of 50 per cent. on the present rates for quantities of say 1 cwt. and upwards, and a proper provision for returning empties by goods train would enable French growers to supply all the towns from the Rhine to the Baltic with early vegetables. The traffic, too, is much too slow. Paris is nearer to Cologne than Cologne is to Berlin, yet the smaller distance takes five days to accomplish, the larger only two; the consequence of all this being that by the time a dozen Cauliflowers arrive at Berlin the exposures have doubled their Paris price, while at Königsberg they become trebled. Still the trade done with Northern Germany is by no means unimportant, although Italy is competing successfully with France in this respect. Mr. Gibson gives one interesting fact—that no less than 6,000,000 bunches of Violets, worth £25,000, are sold annually in Paris. The climate of parts of the coast of Brittany rivals that of Italy in mildness. Frost is scarcely known; the Fig, and even the Pomegranate, ripen their fruit out-of-doors, and the Camellias are in full bloom in February. A stretch of about 15 miles of the north coast, near Roscoff, is celebrated for its early Artichokes, Broccoli, Onions, Asparagus, and Potatoes. England takes every year about 500 tons of early vegetables and 2000 tons of Onions, being about one-third of the whole production; 4000 souls make a comfortable living, and even grow rich on the produce of some 2000 acres of land. Touraine would seem to be the Paradise of the fruit grower. With a climate which allows the culture of the Vine, but is not hot enough for the Orange—"the finest climate in the world," according to Arthur Young—a fertile soil, a steady, thrifty, industrious, and not overcrowded population, and with an excellent and cheap railway system, it would be surprising if Touraine and the neighbouring provinces of Maine and Anjou were not increasing daily in prosperity. The account of the multifarious vegetable productions of this favoured district will be read with pleasure by all interested in vegetable and fruit growing. Poitou, the neighbouring province, has given its

\* "The Corn and Cattle Producing Districts of France." By George Gibson Richardson. Illustrated. Cassell, Pottet, & Galpin, 1878.

name to a gigantic Cabbage much grown in Western France, and largely used for cattle feeding. The leaves are carefully picked off in the autumn and at the end of winter, the plants being cut down in the spring. Gathered in this way, the Poitou Cabbage will yield from 14 to 17 tons per acre. C. W. QUIN.

**Uncle Charlie's Illustrated Game of Botany.\***—This is one of those well-meant contrivances for teaching science to children which, from being conceived and carried out on a wrong principle, must necessarily end in failure. The game consists of sixty-six cards, one-half of which bear the drawings of the leaves of a particular plant, the other half the description of those plants. For instance, the cards being all dealt out, the first player says, "I have an exogen with petiolate, ex-stipulate, radiate-veined leaves which are palmately divided, parted, cleft and lobed, and dentate." The player, who is supposed to recognise the *Anemone japonica* in this description, puts down his illustrated card, takes up that of the first player, and counts a trick. Surely this is not the way to teach young children botany. No doubt at the end of a certain time they would have their heads crammed with a mass of such words as macronate, obovate, crenulate, spatulate, and so on, and possibly have a glimpse of their meaning, but they would know nothing of botany. The only way of teaching botany to children, and to grown-up people too, for that matter, is from the actual plants themselves, leading them by judicious questions and suggestions to find out as much as they can for themselves. Give a child 100 mixed seeds, such as Peas, Onions, Radishes, Horse Beans, Wheat, Oats, Maize, &c., and let him sow them in ordinary garden mould. Let him be made to pull them up from time to time, and describe in his own language the changes which take place in them from the bursting of the seed until the plant produces its fruit, and he will know more of the real meaning of the little word "plant" than if he could describe by rote the specific differences that exist between the members of the whole order of Cruciferae in the Græco-Latin jargon of the schools. It is nothing but "cramming" to teach a child to say acute for sharp, apex for point, dentate for toothed, and petlate for round. Mr. Seelys tells us that he intends to publish a similar set of games for flowers and fruit, the present game only relating to leaves. For the sake of our young American cousins, we sincerely hope that he will break his word.—C. W. QUIN.

**The Home Naturalist.\***—This is one of the plentiful crop of manuals of practical natural history which do so much to spread the love of Nature amongst the rising generation. It makes no claim to be original, but is allowed to be founded on a German work by Otto Klasing, a well-known German naturalist. The directions for forming a herbarium are excellent, and the manipulations are quite within the reach of every boy or girl who can spin a top or crochet a collar. The same remarks apply to the directions for the formation of a collection of woods in longitudinal and transverse sections, a profitable amusement, which we do not remember to have seen described in any similar manual.

**The Vegetist's Dietary and Manual of Vegetable Cookery.\***—Although designed as a guide to vegetists as to what they should eat, drink, and avoid, this little book contains a large number of receipts for cooking vegetables that will be found valuable to meat-eaters as well. The author seems to be a rather liberal vegetist, as she allows the use of butter, milk, cream, and cheese, but evidently somewhat against the grain. Tomato salad is omitted in the list of salads, and this now common fruit, which may be dressed in a hundred different ways, receives but scanty notice. Beet and Vegetable Marrow sandwiches are good ideas, which might be extended to numerous other fruits and vegetables. There are also several excellent receipts for preparing Indian Corn in various shapes. The list of fruits and vegetables in season in each month will be found useful.

**Grammaire Française.\***—This is a capital example of what a grammar for the juvenile population of the agricultural districts should be. Instead of pasturing the children by giving them moral maxims as examples of the application of the different rules of grammar, they are given sentences containing words and ideas with which their every day pursuits have already made them familiar. For instance, in the conjugation of the verbs, instead of the hackneyed words "love," "speak," &c., we have "cultivate"

"plough," "reap," and so on; and in the first rule of syntax we have an example which teaches something—"Oats and Beans are sown at the same season." At the end is a vocabulary of all the more common words used in agriculture. Such an excellent idea is surely worthy of being tried for the benefit of our own rural population, whose ideas of grammar are, as a rule, of the rudest possible order. An excellent companion to this little work has been issued in the form of a reading book, the subjects treated of being entirely agricultural or horticultural.

**Illustrations of Ferns for Amateurs.\***—This useful little work on Ferns, the first part of which is before us, is to be published by subscription, and cannot be carried on, the author asserts, unless he obtains sufficient orders to meet the expenses. This, let us hope, he may get, for it promises to become a valuable book. It is full of small woodcuts, that show the habit of the plants which they illustrate, and enlarged pinns are also given, by means of which living specimens may be more easily identified. The letterpress is brief but to the point.

**Anemone blanda and other Windflowers.**—I noticed in last week's GARDEN that Mr. Barr has two distinct varieties of this Anemone. I also have two varieties, one much earlier and larger than the other, the smaller one being darker in colour. My climate is very cold and ungenial, consequently I never get *A. blanda* in perfection. I also notice that it is much less vigorous than *A. apennina*. This is almost a weed with me and blooms splendidly, whilst *A. blanda*, a few feet away, either dies or does not increase. The snails also play sad havoc with it. I am very fond of the white variety of *A. apennina*; it is so delicately beautiful. *A. ranunculoides* is very pretty, but does not seem to take kindly to my garden. *A. trifoliata* is very far behind *A. nemorosa*. The so-called double red variety of the latter is an imposition; it is not double, and it is not red. When fading it has a red discolouration. The pale blue variety of *nemorosa* is very lovely.—JAY AYE.

**Sending Cocoa Seeds to the Fiji Islands.**—A friend has asked me to forward to you a small boxful of good Cocoa seed, to be sent on to New Zealand. In getting this from one of my friends, a Cocoa planter of some experience, I have been informed that it would be of no use to send the seed simply dried in the usual way, as it would either start into growth long before it reached England, or the germ in it would be destroyed altogether; and as he recommended as the best way to send the Cocoa pods unbroken, and has furnished me with a few of the best description of Cocoa, I have had them done up in a box well perforated with holes to admit air, and I hope, therefore, they will reach you in good order. This box I send by the Royal Mail cargo steamer "Essequibo," which leaves here (Trinidad, Feb. 5) to-day, and should arrive in Southampton in about twenty days. My friend told me that he would recommend that the pods should be broken in England, and the seeds taken out and put in earth in a Wardian case, in which they should be sent to New Zealand, the probability being that they would start on the way, and reach there as young plants ready to be put into the ground. I think, however, I would be inclined myself to send on the box just as it is, if it is to be forwarded by steamer to its destination, and let it take its chance; or which would, perhaps, be better, break and plant one half and send the other on in pod. I now find that these seeds are to go to the Fiji Islands via Sydney, and not to New Zealand. How can they best be sent there?—C. J. A. H. [Clean the pulp away from the seeds and sow them (in England) in Wardian cases in well-prepared soil, not too wet. Carefully batten down, so as to keep soil without moving and yet allow space for the quickly-germinating seeds to push up their stems between the battens. If anything like care has been bestowed on this operation and luck attends them, a good per-centage should arrive in excellent order in Fiji. After arrival there, however, some attention would be required before the seedlings could be fit to put out in the open ground; this should not be done before they had been gradually inured for some days to fuller light, air, &c. Examine the seeds well before sowing them, for if the pods have not been properly packed the chances are that not a single seed is alive. The pods should be sent to England by quickest route, packed in boxes with perforated sides. To prevent fermentation as much as possible do not allow them to touch each other, and use packing material that will not obstruct a current of air. Sawdust and charcoal, &c., of which West Indians are somewhat fond, are very bad media.]

**Alpine Plants.**—When should these be divided?—H. R., *Louthborough*. [Usually in the autumn or spring months, but those accustomed to these plants may divide them at almost any season.]

## NOTES FROM GLASNEVIN.

The noble specimen of *Arbutus hybrida* which stands on the Grass lawn in front of the director's house is just now a beautiful object, every spray being terminated by a pendulous panicle of pale, waxy flowers. *Rhododendron præcox*, too, is a mass of flowers. The Tree Heath (*Erica arborea*) is also garlanded with pearly bells, and the lovely *E. carnea* and its white variety are in full flower. More interesting than any of these, perhaps, are bushes of Dr. Moore's remarkable *Erica* variety of *E. mediterranea*, which have been for weeks and weeks past in full bloom and exhaling an agreeable fragrance, whilst even now the typical form is far from being in flower. In the way of bulbous plants, besides the abounding white and gold of the "first pale blossom of the unripened year," and the yellow Crocus, the kindred, but far prettier, Snowflakes, of which we were gratified to see numerous patches in the borders, and the lovely *Iris reticulata*, are very attractive. Some of the Heliconias are still in good condition, notably *H. purpurascens* and the stately *H. orientalis*. White and purple patches of *Iberis*, *Arabia*, and *Aubrietia*, yellow bosses of *Alyssum olympicum*, and rosy-flowered cushions of *Saxifraga oppositifolia* serve to brighten up the herbaceous quarters. Leaving the outside ground, and turning into the cool conservatory which flanks the Palm house, we ("Irish Farmer's Gazette") found several Himalayan *Rhododendrons* in flower, notably two well-marked varieties of *R. argenteum*, the branches of which were crowned with heads of huge creamy white flowers; associated with these were the white-flowered variety of *R. arboreum* and *R. barbatum*, with flower-heads so remarkable for their compactness as for their dazzling brilliancy. In the Palm house the gigantic specimens which crowd its floor, and promise soon to force their way through its lofty and hideously ugly roof, have been retubed. In the Orchid house numerous plants were in flower, and a cool greenhouse, which forms the eastern division of the great curtilage range, was particularly gay with Epacris, *Ericas*, and other hard-wooded plants, associated with *Cyclamen*, a good strain of Chinese *Primulas*, and forced bulbs. The crimson fascicles of *Ilabrothamnus elegans* hung in profusion from roof and pillar, notwithstanding that it was cut in hard very late after flowering last year. In the stove conservatory that grand old plant *Astrapea Wallichii* had just done blooming, and its many pendant tassels, though no longer gleaming with colour, told that the bloom had been rather unusually profuse. We were much gratified here at meeting with a specimen of that fine myrtaceous tree, *Syzygium Moorei*, which, according to the director of the Melbourne Botanic Garden, affords when in full bloom "one of the most gorgeous spectacles imaginable, its every branch and even part of the stem being clothed with one mass of royal purple blossoms, having the appearance of rich pale velvet." This lovely tree is specifically named in honour of Mr. Charles Moore, director of the Botanic Garden, Sydney, from whom the specimen at Glasnevin was received. Dr. Moore has also got a supply of seeds of another beautiful myrtaceous tree, *Eucalyptus ficifolia*, of whose floral charm the Melbourne director, in his report for 1876, speaks in still more glowing terms.

**The Secateur.**—I agree with all that "J. S. W." says (see p. 202) respecting this useful French pruner, which I have used for several years. Last season I had occasion to lower two old Thorn hedges, which had been shorn for more than forty years. I fixed up a number of stakes, stretched a line at the required height, and employed a good workman to cut off the top in an even manner with the Secateur, lowering it 18 in. in order to bring a beautiful landscape into view. The work was done in a very even way, and in less than half the time the shears and saw would have taken, the stems being the size of a man's thumb. When such are bent by the hand the cut is then made much more easily, by one edge chiefly. I find the Secateur most useful for all kinds of shrub pruning. I have three in use, two of the largest 9 in. long, which I find the most useful, and which cost 4s. 6d. I have never found the spring of the large size to get out of order; the rivet should be kept oiled, and then the shears readily spring open. They can be had of the different seedmen in Exeter, and are illustrated in their catalogues. —JOHN GARLAND, Killerton, Exeter.

**The Phylloxera in Victoria.**—Owing to the appearance of the Phylloxera in the Vineyards in the colony of Victoria, the South Australian Government has prohibited the importation of Vines.

**Royal Botanic Garden, Edinburgh.**—The Regius keeper states that since last report the arrangements between Her Majesty's Government, the Estates trustees, and the Town Council of Edinburgh, with reference to the Arboretum, have been completed, and that the fencing of the ground has been commenced. He has still to complain of the want of funds for carrying on the ordinary work of the garden. The total sum allowed annually for this purpose is £1400. By the utmost economy, by dismissing efficient men during part of the winter months,

and by not giving an allowance to the curator to enable him to visit other gardens in order to procure plants, the expenditure has this year been kept with difficulty within the limit of the Government grant. An extra sum of at least £300 annually is required for the ordinary working expenses of the garden. There is no botanical garden of the same area, and used to the same extent for teaching purposes, which is kept up at such a small outlay. The accommodation for the students who attend the lectures on botany is still in the same insufficient state as it has been for some years. The class-room can only at the utmost accommodate 230, and last summer the number attending the class was 389. A plan has been transmitted to the Office of Works for a new class-room and a laboratory-room, which will fulfil all the conditions required for the accommodation of the students. It may be observed that additions to the plants in the garden are only effected by voluntary contributions. No funds are allowed by Government for the purchase of plants, or for the curatorship of the Museum, Herbarium, and Library. The Regius Keeper has therefore been compelled to beg for pecuniary assistance from other sources, and to expend part of his own garden salary, which is only £120 per annum. Government has determined to take away this small salary when the house for the Regius keeper is completed. In place of withdrawing this sum, the Government might add to it the allowance for the garden, more especially for payment of a Curator of the Herbarium and Library. The garden, as formerly reported, stands in need of an Aquarium and a Fern house, in order to complete its means of teaching. The garden continues to supply fresh specimens for the Government School of Design. The Arboretum Society of Scotland has been allowed to hold its annual meeting in, and the Botanical Society uses it for its monthly summer meetings. The Cryptogamic Society of Scotland will also hold its meeting in the garden next October. The number of visitors during the year 1877 amounted to 79,703.

## NOTES AND QUESTIONS—VARIOUS.

**Daphne Mezereum in Masses.**—The beauty of this *Daphne* is lost when planted singly, while when seen in masses it is most effective. I am led to make these remarks through observing a bed consisting of about 100 fine plants of it in flower in the grounds of Mr. Herridge, florist, in the Fulham Road, Hammersmith, the other day. The plants are about 4 ft. high, and being well backed up by evergreen shrubs, have a most charming effect.—J. CAOROSA, Sudbury House, Hammersmith.

**Sisyrinchium striatum.**—This little grown, and far from showy old plant I grow for the sake of its odour mainly. It deserves a nook in a fringe of dwarf American shrubs.—P. BAN.

**Grass for Game Cover.**—What is the best Grass for sowing in young plantations as a covert for game?—S. H. R. [Tufted Hair Grass (*Aira caespitosa*), in damp, marshy soils, makes a thick covert in a very short time, and in dry soils does tolerably well; it is the best of all the Grasses for coverts.—W.]

**Lilium auratum.**—For the information of "Amateur" (see p. 197) I write to say that from the first appearance of the flower buds, I watered my *Lilium auratum* almost daily until the flowers expanded, with liquid manure made from horse-droppings soaked in water, and afterwards with pure water only. W. J. T.

**The Gilbert Cultivator.**—Will some one be so kind as to tell me where I can purchase the Gilbert Cultivator, and the probable cost of it?—L. C. J.

**United Horticultural Benefit and Provident Society.**—At the monthly meeting of this society, held at the Caledonian Hotel, Robert Street, Adelphi, on Monday evening, March 11, the chairman of the meeting, on behalf of the committee and members, presented Mr. J. F. McElroy with a handsome silver watch and chain in recognition of his past services as honorary secretary.—R. H. B.

**Mushrooms in March.**—Is it not very unusual to gather Mushrooms in the open air at this time of the year? Yesterday I found eight good-sized ones on the Fernery, and this morning they were highly approved of at breakfast.—H. R., Tunbridge Wells.

**The Paris Exhibition.**—On the occasion of the visit of the Prince of Wales to the British section of the Paris Exhibition, His Royal Highness examined two workmen's cottages formed of concrete slabs, now being erected in the grounds of the Exhibition by Mr. Lascelles, the well-known horticultural builder, who explained to the Prince the advantages of this system both as respects price and construction.

**Procuring Trees and Shrubs.**—I shall feel grateful if you will say at what nursery we are most likely to procure the following:—*Ficus Banksiana*, P. Boursieri, P. Mugus vel. Pumblo, *Juniperus prostrata*, *Juniperus sabinoides*, *Philæa busifolia* (Witch & Son), *Pieris japonica* (rare, probably only as yet in Continental gardens), *Pieris formosa*, *Andromeda floribunda* (in any nursery), *A. polifolia*, *A. pulvulenta*, *Sambucus Ebulus* (a British plant, ought to be in every botanic garden); also the various *Hypericum* which have been so highly recommended of late in THE GARDEN (through the growers of herbaceous plants). I have failed at more than one of our nurseries in finding most of these plants.—L. C. J. [You should consult the catalogues of the more important nurseries growing good collections of trees, shrubs, and herbaceous plants; also our advertisement columns. It is impossible for us to recommend particular firms, except in cases where the stock of a plant is in the hands of one house.]

No. 331.] SATURDAY, MARCH 23, 1878. [Vol. XIII.]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## A GARDEN IN SOUTHERN FRANCE.

At Mentone, on the borders of France and Italy, there is a garden particularly interesting to the many visitors who frequent that favoured winter resort, for there, in the open air, may be seen growing, and flourishing too, many plants which in Britain are only to be found in conservatories, and even stoves. By the kindness of the owner, Dr. Bennet, visitors are admitted until one o'clock each week-day. On approaching it one can have no idea of the treat in store for the horticulturist, or imagine that such a wealth of beauty could be assembled on a few terraces of an Olive grove. The situation, with the blue Mediterranean lying far beneath, and an amphitheatre of magnificent mountains surrounding it, is one of striking beauty, commanding one of the finest views on the celebrated Corniche Road. There can be seen here, besides many species of Palms, the stately Wigandia, assuming the proportions of a large shrub, and producing its huge terminal heads of pale violet blooms in profusion. Some specimens of this may be seen in Mentone 15 ft. in height, and considerably more in diameter. There is also here the *Araucaria excelsa*, with its symmetrical but graceful growth, rapidly growing upwards; likewise the *Musa Busseti*, spreading its massive tropical foliage in all directions, forming a marked feature in the scene; and the *Ficus elastica*, so well known as a window plant in London. One of the most striking plants here is the *Bougainvillea spectabilis*, which under the powerful sunlight of Mentone produces its floral bracts of a depth and brilliancy of colour unknown in our gardens. A variety of *Bignonia* (*Tecoma*), almost hiding a False Pepper Tree which supports it, and now covered with its pendulous masses of small whitish purple-throated blooms, is an object of great beauty. Several varieties of that graceful twining shrub *Kennedyia* (*Hardenbergia*) are laden with their delicate Pea-shaped blooms of various tints. *Abutilons* of different varieties, but chiefly the *A. Darwini*, are remarkable for the size and richness of tint of their blooms. *Linum trigynum*, here laden with rich golden blooms, quite surpasses all our ideas of it as a pot plant. *Justicia arborea* also attains a large size and blooms abundantly. An extensive collection of *Agaves*, *Aloes*, and various succulents may also be found here, where the climate seems especially suited for such plants. *Pelargoniums*, *Primulas*, *Hyaecinth*s, *Salvias* of most brilliant colours, *Narcissi*, and many other plants too numerous to name abound in great numbers. A species of shrubby *Cineraria* named *platanifolia* attracts attention on account of its massive and imposing appearance. It has large handsome foliage, produces immense heads of pale yellow blooms, and its buds and stems are of a rich chocolate colour. Another shrub remarkable for its profuse, rich golden bloom is the *Osteospermum moniliferum*, a Composite, which I have never seen except along the Mediterranean coast. The purple-flowered *Polygala grandiflora* also assumes the form of a shrub, and grows to a considerable size. There are several small plant houses and pits, but it is the out-of-doors vegetation which is most striking in this charming spot where winter is unknown. I should have mentioned amongst plants remarkable for their fine foliage that the *Aralia papyrifera* rears its handsome spreading head in pleasant contrast with the growth around it. The above constitute only a small portion of the contents of this interesting garden. J. T. P.

Mentone, March 14.

**Christmas Roses.**—All varieties of *Hellebores*, it seems to me, are interesting and valuable. The specific names are, however, I confess, confused; our *Helleborus atro-rubens* we think much of, although your correspondent (see p. 160) despises a variety so named. Where is the semi-double Scotch variety *H. niger* to be met with? It is not known about Edinburgh, as far as I can make out.

In the last week of February we had eleven sorts of *Hellebores* in flower, and not one of these would we dream of casting away, although the flowers, or what are called the flowers, of some are slate-coloured, bright green, or greenish white. Even *H. foetidus* should have a place somewhere; its leaves are the only ones that are useful for cutting, and very good they are for many purposes. It is perhaps the only *Hellebore* that does not suffer from deprivation of leaves. The sharp weather which we have had has checked *H. colchicene*, but *H. guttatus* was in flower by March 2. Mr. Hooke's (of Bradford) bed of nearly fifty species and varieties of *Hellebore* will be a sight worth going any distance to see, and I have often thought what a charming bed for the end of February would be a centre group of *Rhododendron præcox* and *superbum*, surrounded with white *H. olympicus* or *orientalis*. The two make a most pleasing combination in our spring border, both in colour (ilac and white), height, and shape of foliage. *Narcissus obvallaris*, true, would brighten up the group and make it perfect, and it is sure to be in flower at the same time. One prizes that *Narcissus* most highly, as it is decidedly the earliest to flower. We got our stock of it from Mr. Harpur Crews and Mr. Fox, and we intend to increase it as much as we can. A bed is much easier protected than a line, or portions of a border, but the sudden frost which occurred in the early morning of March 8 made all protection useless for this season, as far as the *Rhododendron* flowers are concerned; the bushes were a mass of perfect bloom on the evening of the 7th, and the blossom was gone by the morning of the 8th. Spring borders are like skating and curling—highly prized, never to be depended on, and decidedly a slippery pursuit.—F. J. Hope, *Wardie Lodge, Edinburgh*.

**Daffodils on Grass.**—Conspicuous amongst hardy spring-blooming plants capable of defying the withering influence of an English March stand the Daffodils, the bright yellow flowers of which bend but do not break before the gales that sweep across our meadows. In this district the latter are just now quite yellow with them, large heads thus having been allowed to grow undisturbed for years, as, beyond some of the flowers being gathered for indoor decoration by those who have no means of procuring forced exotics for such purposes, the plants are allowed to mature their foliage, as neither cattle nor game ever molest them. Where it is desirable to naturalise Daffodils, good bulbs of them should be procured as early after their foliage has disappeared as possible, and planted in clumps on banks or in semi-wild portions of the grounds where the mowing machine is not an early visitor. Under such conditions they will give unflinching satisfaction; the only essential point needing attention in order to ensure success is that of allowing them to remain undisturbed for years.—JAMES GROOM, *Henham*.

**Polyanthuses and Primroses.**—These are more plentiful this season than usual. The common or wild one is now abundant in shrubberies and woodlands, where it is a welcome visitor at any time, whether early or late; the single white variety is also blooming well this season, and is useful in shrubby borders. One is surprised that these "harbingers of spring" have not been more cultivated than they are; now there is no excuse for not growing them, as a shilling packet of seeds will yield endless varieties, and furnish interesting employment for amateurs and cottage gardeners. Some twelve or fifteen years ago I began by planting Polyanthees, Primroses, and Cowslips together, and left them for the bees to fertilise. By saving seed from this mixture I obtained a great variety of colours, but principally Cowslips and a few very good Primroses. After a few years, however, I gave up the Cowslip tribe and kept to Polyanthees and Primroses, and by weeding out all the bad ones I soon got a good collection of both. I have now a good strain, and many varieties which do useful service in many capacities as cut flowers. Some of the plants have been gathered from continuously since before Christmas.—W. DIVERS, *Wierton, near Maidstone*.

**The Winter Heliotrope** (*Tussilago fragrans*).—We are making a new plantation of this. Can any of your correspondents tell me what portion of the roots is best to select, so as to ensure flowers next winter, this being a plant so erratic as regards blooming. The season does not seem to affect it, but one never knows where flowers will be produced. Sometimes they appear on the young runners, and again on what one would think were old hard crowns. We want to make certain of having a quantity of flowers; one spike in the little bunches of sweet green Thyme, Rosemary, Gum Cistus, &c., which we give weekly to the Blind Asylum would be a great delight in the months of January and February. We grow it in sundry situations, but never have sufficient flowers.—F. J. Hope, *Wardie Lodge, Edinburgh*.

**Linum trigynum.**—Everyone, I should think, who is acquainted with this *Linum* will allow it to be one of the most useful of winter and spring-flowering plants. Although of easy culture, it is not known so much as its merits deserve, for no better plant can be found

to brighten the winter months either early in the warm house or later on in the conservatory. Its blooms, of a rich golden tint and resembling a miniature *Allamanda*, are produced in the greatest abundance, and those who are not yet in the possession of it would do well to get it, and propagate it now for next winter's display in the conservatory or stove.—J. T. P.

### NOTES OF THE WEEK.

**The Soldanelias.**—It is quite refreshing to read from time to time in THE GARDEN the accounts of the various beautiful plants that are flowering in different parts of the country. Nothing can so much tend to create a love for such things as these notices cropping up, as they seem to do to the surface now and then, like strata charged with precious metals. Somebody in last week's issue gave a word or two of praise to the Soldanelias. It may not be exaggerating to say that they are the very rubies and diamonds of Alpine vegetation. There are about ten or twelve species and varieties of them, and they now and then manifest that tendency which most blue flowers possess of passing into the albino state. *S. Wheeleri* I consider to be the gem of the family. I have had some pots of it in a cold frame attractive enough to bring a man down on his knees. Their very look seems to have something of the glacial about them—something at once declaring them to be children of the mountains.—THOS. WILLIAMS, *Ormskirik*.

**The First Rose of the Year.**—I have had the pleasure, it seems, of plucking the first Rose of the year, or, at least, a Rose much nearer the beginning of the new year than the one which was sent to Canon Hole, of which you gave an account (see p. 199). I gathered some very good *Maréchal Niel* Roses the last week in January; one flower in particular was very fine, but pale in colour. They grew on the south end of a plant stove. I may add that we had Roses of different varieties up to Christmas, and, indeed, many unopened buds have been cut off in pruning since that time. We have never been without a Rose for a button-hole for many months; a few plants of *Madame Falcot* indoors have flowered all the winter with little or no heat. Roses generally are most forward here, most of them showing buds, on which I look with some anxiety. I have pruned very late this year; what I have done has been this week, and I have not yet nearly finished. Shoots with say a dozen healthy Rose buds on them are cut off with reluctance. To-night (March 15) we are having a sharp frost, the first for the last few weeks.—JOHN TAYLOR, *Hardwick Grange, Shrewsbury*.

**Rhododendron Nuttallii.**—I have forwarded for your inspection a truss of this fine *Rhododendron*, cut from a plant which is from 4 ft. to 5 ft. in height, and which has at the present time twelve fine heads of bloom in all, each consisting of from six to nine flowers. It bore fourteen heads, but two of them were, unfortunately, broken off. In order to flower this *Rhododendron* successfully, an early growth is indispensable; the plant which we have is brought on in an early Peach house until its growth is complete, when it is gradually introduced to a cooler place, and finally placed out of doors in June in rather a shaded situation. There it remains until the end of September, when it is again brought into the Peach house, where it remains until the house is started. Its buds then begin to expand in abundance.—R. OILEY, *gardener to R. Nicholl Byass, Esq., Daylesford House*. [The head of bloom sent was the finest of the kind which we have ever seen. It was 13½ in. in diameter; each bloom measured 6 in. across the mouth, 5½ in. long without the footstalk, and held as nearly as possible half a pint of water. The blossoms, too, are sweet scented, white, and of great substance. A plant with fourteen heads of such flowers as those just described must be a sight worth travelling miles to see.]

**Camellias at Waltham.**—There is just now a fine display of *Camellias* in Mr. Wm. Paul's nursery, at Waltham Cross. The plants, which are grown in pots, are arranged in a large span-roofed house over 100 ft. long, and form literally banks of flower. All the kinds worthy of culture are here represented, and ever since last October a good supply of blossom has been secured. Among the many fine kinds to be found here may be mentioned *Niuta Egeria*, a white variety, possessing a neat and compact habit of growth, glossy green leaves, and producing abundance of blossoms, equal in every respect (except in size) to those of the well-known *Double White*. Another good white kind is *Cap of Beauty*, the flowers of which are very large and the base of the petals of a rich cream colour. Among crimson kinds *imbricata*, which still ranks as one of the best, is here represented by large and healthy specimens. *Manara* is a good sort with well-formed, smooth-petalled flowers of a rich crimson. We also noted a kind with flowers of a slate colour. The plants are all grown in pots and subjected in every way to the same kind of treat-

ment; therefore the true habit of each variety can be seen as well as its flowers, and anyone desirous of gaining information as to culture or what to grow in the way of *Camellias* cannot do better than see this collection.

**Acacia lophantha in Windows.**—This plant may now be noticed here and there in London windows clad in its fresh green and graceful foliage, and looking like a beautiful Fern in the form of a bush. It is easily raised from seeds, and it is useful in the flower garden as well as in the house.

**Adiantum palmatum.**—When better known this *Adiantum* will doubtless be extensively grown on account of the long, elegant fronds which it produces. Its pinnae, which are larger than those of *A. Farloyense*, are palmate and gracefully set on slender, wire-like stalks, and for floral decorations will be found to be of the most useful description. Established plants of it in Mr. Williams' nursery, at Holloway, are producing fronds which will ultimately be at least 2 ft. in length.

**Scilla bifolia taurica.**—A good display of this fine form of *S. bifolia* may now be seen in Mr. Ware's nursery, at Tottenham. Its flowers, which are of a bright blue colour, are produced on stout stalks for many weeks in succession; and, either for borders or pot culture, this variety may be considered to be one of the best.

**Begonia Froebelii.**—Grown in pots in a greenhouse, this beautiful *Begonia* is now flowering freely in Messrs. Carter & Co.'s nursery, at Sydenham. The plants are furnished with large, *Cineraria*-like leaves, and their large, bright scarlet flowers form a striking contrast to blue or light-coloured *Cinerarias*, of which there is also here a good display.

**Rock Plants at Weybridge.**—Amongst plants now in good bloom in our rock garden are *Soldanella Wheeleri*, *Epigae repens*, *Polygala Chamæbuxus purpurea*, *Primula nivalis*, and *P. marginata*. The late severe frosts have done but little injury to flowers. *Rhododendron præcox asperum* in different aspects has, indeed, lost all its beauty, but *Primula denticulata* and its hybrid *P. concolor*, in several situations, and *Scilla sibirica* are unscathed; even *Hyacinths* look hardly the worse.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

**Seedling Irises and Squills.**—I have had some good seedling varieties of *Irises reticulata* in bloom; one, which I particularly admire, is all of a dark purple, except the orange marking on the falls. I have also a very pretty pale seedling *Scilla bifolia* quite distinct in colour from that of any of the kinds usually grown.—J. G. N.

**Lælia flava.**—A good plant of this charming *Lælia* is now in bloom in Messrs. Rollissons' nursery, at Tooting. Its flowers, which are of a bright golden colour, are produced on long, slender stalks; and the whole plant is so distinct from other *Lælias*, that it is almost indispensable in every good collection of Orchids.

**Allium neapolitanum.**—Cat blossoms of this, one of the most useful and beautiful of the *Alliums*, are now being used in quantity for bouquet making in Covent Garden market. The trusses of flowers are large and fresh, and last for a long time in a cut state. They are principally imported from the south of France, but in warm, sheltered places in England, under good culture, flowers of it might be had much earlier than is at present the case. They are devoid of all unpleasant smell unless they happen to get braised.

**Lælia Veitchii.**—This fine hybrid *Lælia*, raised by Mr. Dominy some years ago, is now beautifully in flower in Messrs. Veitch's nursery, at Chelsea. It is bearing two flower-spikes, one of which is furnished with seven massive blossoms, having long, delicate, violet sepals and petals, which are effectively set off by a lemon-coloured lip deeply tipped with rich velvety-purple. Altogether, this plant, on account of its clearly-defined, gorgeous blossoms, will hold a foremost place among large-flowered *Cattleyas* and *Lælias*.

**Tropical Plants at Naples.**—We are indebted to the Marquis Valle de Casanova for photographs showing the fine development of plants in Prince Sigliano-Colonna's well-stored garden, at Naples. He mentions the following as obtaining great perfection in the open air there, viz.: *Eugenia australis* (17 ft.), *Araucaria Cunninghamii glauca* (20 ft.), *Piconectitia tuberculata* (in flower), *Lantana horbonica* (beautiful specimen), *Corypha australis*, *Mahonia chilensis*, *Phoenix pumila*, *Strelitzia Augustæ*, *Musa sapientum* (ripening fruit in the open air), and *Alseophila australis*. Among the photographs one shows the *Faracorya gigantea* in flower measuring to the summit of the flowering stem 39 ft. 4 in.

**Primula denticulata.**—This is being grown at Gunnersbury Park for cutting from, and it is found most useful for the purpose. A well-established plant will throw up a number of flower-stems, and the delicate, silvery-lliac hue of the flowers makes them very accept-

able in vases, &c. The natural tenderness on the part of this plant subjects it to the chances of injury when grown in the open air without protection; and therefore, as it does remarkably well in the open ground during the summer and autumn, the plants should be so arranged that an ordinary garden frame can be placed over them to afford the protection needed. Strong plants can be lifted in November and potted, taking care to use a pot only sufficiently large to contain the roots; then put them into a cold frame to bloom. After the flowers are gathered the plants should be divided a little and returned to the open ground, planting them in deeply-dug, well-manured soil, top-dressing with manure and leaf-mould during the summer, and watering freely in dry weather.—D.

**Tea Roses at Lord Rosebery's Wedding.**—Mr. Wills used nearly 3000 Tea Roses in the floral decorations on this occasion; the wedding presents were surrounded by Roses. There was some difficulty in getting so many blooms, nearly all the Rose growers and many private cultivators contributing. There were also many beautiful Phalenopsis and Odontoglossums.

**Hardy Plants in Bloom at Edinburgh.**—At the meeting of the Botanical Society of Edinburgh, held on the 14th inst., Mr. McNab laid on the table flowering specimens of 118 species and varieties of hardy herbaceous and Alpine plants, all picked in the open air that day—a larger number than ever was yet in perfection at the same date during former years.

**Two good Chinese Primulas.**—Among single-flowered Chinese Primulas we have seen none so good as two now in flower in Messrs. Carters' nursery, at Sydenham. One has scarlet flowers with a rich yellow eye, and is called Carters' Scarlet, the other, named marginata, bears flowers of a bright mauve colour. The foliage of both plants is remarkably compact.—S.

**Polyanthuses.**—Mr. Caudwell, of Wantage, has shown us blooms of named Polyanthuses, including George IV., William IV., and other handsome laeod kinds, the colours of which are rich and varied. The plants which produced them were grown in bog soil in an open situation, thus showing that neither cold frames nor shady borders are absolutely necessary for the perfect culture of even the best kinds of Polyanthuses. As conservatory plants, many of them if grown well in pots would be very handsome.

**Tuberous-rooted Begonias.**—Greatly as these have been improved of late years, new kinds continue to be raised in abundance. Mr. Laing, of Forest Hill, who has devoted much attention to such work, has this season thousands of seedlings raised from seed obtained from crosses of the best known kinds. These plants are now being grown on for flowering in summer, when they will doubtless make a fine display, and out of so many, some good new sorts may reasonably be expected.

**Laurels in Ireland** (see p. 225).—These generally bloom well here, but I have never seen them so loaded with blossom as they are this year; some of them are over 30 ft. high. When living in the West Riding of Yorkshire, twelve years ago, I remember *Lærole* being killed by frost. I cannot recollect ever seeing one in flower there, and I had no idea that they grew to such an immense size as they do until I came to Ireland. No one who has not seen them in perfection can imagine how beautiful they are.—JOHN CLARKE, *Cork*.

**Bertolonia Van Houttei.**—Few of the Bertolonias are more justly prized than this, its hairy, attractive, pink-veined leaves rendering it one of the most desirable of stove plants. Though generally found growing under bell-glasses, these are not absolutely necessary for its successful culture, for some of the healthiest plants of it we have lately seen are now to be found in Messrs. Laing & Co.'s nursery, at Forest Hill, without bell-glasses. They are grown in 4-in. and 5-in. pots in sandy peat, and the pots are placed on Cocoa-nut fibre. They are kept well syringed and watered, and under such conditions they develop large and perfect leaves very rapidly.

**The Spring Snowflake.**—I fully concur in the opinion expressed (see p. 225) concerning this plant, viz., that it is only not more grown because it is generally seen in a weak state, for its beauty far surpasses that of even the delicately-formed single Snowdrop; and if its culture were as easy, I am sure it would in time take its place. Those who venture to try it must not be easily discouraged, as I find it requires to be perfectly established before it blooms freely. In the autumn of 1875 I planted several patches of it in my borders, which in the following spring were scarcely visible, leading me to suppose that the clay soil and cold situation of my garden did not suit them; but I was wrong in my conjecture, as time has proved, for a fortnight since those same plants were full of bloom, several of their stems producing, as at Hoatherbank, two flowers.—E. F., *Swaffham*.

## NOTES FROM KEW.

**Outdoor Plants.**—Severe frosty nights and cutting winds have, for the last week or so, much retarded many spring flowers, and have totally ruined the blossoms of several specimens of *Rhododendron Thomsoni* (in the pleasure grounds), which were one sheet of brilliant crimson-scarlet. It is much to be regretted that this magnificent Himalayan *Rhododendron* is so very subject to have its flowers and young growth cut off by the inclement weather of early spring. Few fresh hardy flowers are to be seen this week, the following being all that are deserving of more than passing mention: The Alpine Barrenwort (*Epidemium alpinum*) attracts attention on account of its panicles of dull reddish, drooping flowers. *E. pinnatum* var. *olegans*, from Persia, is a very handsome plant, with bold leaves and upright racemes of large, bright yellow blooms; the pinnate, ever-green leaves consist of three or more long-stalked, heart-shaped, dark green, leathery leaflets; the plant altogether much surpasses its European relation in beauty and effect. The rose-coloured Rock Cress (*Arabis rosea*), from Calabria, is a pretty little rock plant, with glossy leaves and panicles of showy flowers. The handsomest of all the perennial *Candytufts* is the South European *Iberis semperforens*; this makes a good pot plant, and, if allowed the shelter of a cool frame during winter, comes in really useful for greenhouse decoration in spring. *Iberis Garrochiana*, from Piedmont, and *I. collina*, from France, are species of similar habit to, but with much less conspicuous flowers and smaller foliage than, *I. semperforens*. *Polygala Chamæbuxus*—a coloured plate of a purple variety of which was issued with THE GARDEN for January 12 of the present year—is very charming, with its neat, glossy, box-like leaves, and its numerous, somewhat Pea-shaped, large, yellow flowers. A white variety of *Orubus veronis* is well worth a place in any flower border; indeed, all the varieties of this beautiful dwarf Vetch are well worth growing. *Psoschinia ecilloides*, a bulbous, liliaceous plant, has charming, blue, Scilla-like flowers. A white variety of this is also a decided acquisition. Next come two varieties of the beautiful *Scilla bifolia*, the one with reddish or rose-coloured flowers, the other with white flowers; both varieties are of the same size, and exactly resemble the type in everything except colour.

**Stove Plants.**—In No. 1 House there is at present in flower a most brilliant stove tree from Caracas, Brownea grandiceps. The fine, pinnate leaves and very large *Rhododendron*-like heads of scarlet flowers make a very attractive combination. The other stove plants worthy of notice are all to be seen in the New Range, with the exception of the last two, which we saw in the Palm House. *Siphocampylus Humboldtii*, from tropical America, is a low shrub with dark green leaves and bright scarlet, tubular flowers. *Sociodaclyx digitaliflora* is a remarkable Gesneriad, with long-stalked flowers borne in couples; the swollen, hairy tube is red and the limb is greenish spotted with maroon. *Marica Northiana* is a very beautiful, free-flowering Irid from Brazil; the flowers, which are very fragrant, have white outer leaflets, whilst in the inner blue, brown, and yellow are represented. *Macleania speciosissima*, from New Granada, is a showy Vacciniaceous shrub, with long, tubular, red, wax-like flowers. *Nidularium fulgens* is not remarkable for a showy inflorescence, but the bright colouration of the leaves lining the nest-like centre of the dense rosette, which contains the very shortly-stalked head of flowers, makes up for any deficiency in these latter, and renders this *Bromeliad* a very desirable stove plant. The Rose Apple (*Jambosa vulgaris*), from the East Indies, has good-sized flowers with four whitish petals; the brush-like mass of stamens, the filaments of which are very long, cause the plant to be very conspicuous. It flowers freely in a tolerably small state. Of the tropical American *Thyracanthus Schomburgkianus*, Lindley wrote just twenty-three years ago that it should be in every collection, as it really is one of the handsomest plants that has been introduced for years. It produces great quantities of brilliant crimson, tubular flowers, attached near the ends of long, branched, drooping flower-stems, which, when tied out a little, so as to fully expose the blossoms to view, render the plant very effective. The flowers also remain a long time in perfection, a desirable property at all times, and especially at this time of the year.

**Greenhouse Plants.**—Amongst these there are few to note, but the following in interest and beauty make up for lack of number.—*Senecio Ghiesbreghtii*, about 2 ft. high, has a stout stem with noble leaves and a large, Canthiower-like head of small, golden-yellow blossoms; this is a very striking and handsome plant. *Rhododendron virgatum*, one of the interesting discoveries of the present Director of Kew, is a neat-habited little bush, with small leaves and Azalea-like flowers—white with a faint suspicion of rose. In a wild state it skirts the Pine forests in the ravines of the Lachen Valley, in Sikkim-Himalaya, at elevations of from 8000 ft. to 9000 ft. *Thibaidia palmifera* is an evergreen shrub which will do well planted out in any

cool house; the veined and chequered red flowers, about 1 in. in length, are produced in clusters along one side only of the old wood.

**Succulent House.**—Some of the Cacti will soon be making a fine show. At present the best is *Cereus McDonaldii*, from Honduras. A large plant of this species, trained along one of the iron girders of the roof of the Succulent House, is producing its large and handsome flowers. According to the light in which these are seen, they seem glowing purplish-crimson, flaming scarlet, or an indescribable mixture of several colours. *C. flagelliformis*, from Peru, is also very showy, its pendulous stems being covered with bright pink flowers. This is of interest, too, on account of its being one of the very first of the Cacti introduced into this country. *Sempervivum aureum*, from the Canary Islands, has a dense rosette of glaucous, Echeveria-like leaves, and a short, bracteate peduncle, bearing a head of star-like, golden-yellow flowers.

**Orchids.**—*Spiranthes grandiflora*, a magnified edition of the Lady's-tresses of our English pastures, has a stout scape, bearing several creamy-white flowers, for the delicious fragrance of which the plant is well worth cultivating. *S. Smithi*, a companion terrestrial Orchid, has yellow and green flowers similar in size to those of the last-named, but lacking the perfume which renders them so pleasing. *Lycaste aromatica*, a Mexican Epiphyte, has numerous, orange-yellow flowers, which exhale a very pleasing, aromatic odour. *Oncidium Harrisonianum*, from Brazil, has a short scape, bearing a short, branched panicle of small, very pretty, yellow flowers, spotted with brown. *Vanda coerulescens* has charming blue flowers, the lip being two shades darker than the other dorsal organs. *Dendrobium luteolum* has long, spurred, whitish flowers, the lip being tinged with yellow at the base, and faintly lined with red. *Isochilus linearis* is a Trinidad species, with short, slender stems, bearing little, Grass-like leaves, and short terminal spikes of small, rose-coloured flowers.—†

### LILIES AND THEIR REPRODUCTION.

I QUITE agree with "Amateur" that my "only object is to increase our knowledge of such matters," and I also agree with him that "the main questions to be decided are, whether or not the bulb after flowering decays; and secondly, whence springs the flower-stem or stems of the succeeding year." But I cannot agree with him that in departing from the study of the organization of the Lily bulbs themselves, and arguing on the faith of certain appearances in bulbs and combs of other plants (the "speculation" to which I alluded in my paper (see p. 185), and which he now again indulges in), he can enlighten us with respect to the organic structure of the Lily. Nor can I admit that, by the pot-growing experiment which he describes and proposes to carry out, "he will settle," as he says, "the question beyond dispute." He further tells us that he has *Lilium giganteum* "now shooting up from the precise centre of the bulb, as previously." Now, the initiated might be content with this as a proof that it is the same bulb that shoots up year after year. But surely "Amateur" can hardly expect an experimenter, who examines the interior of the bulb every month during the year, to be content with such a theory. If he will look at the woodcut on page 143 he will see that, originally, the new flower-stem B sprang up from the very side of the stem A that bloomed last summer, and quite as close to that stem as the young seed-bud C is now springing up by the side of the new flower-stem B. This being so, we may ask what appearance had these bulbs before the scales were picked off so as to expose the interior? I answer, they were exactly as "Amateur" describes the outward appearance of his bulbs; for when I lifted them out of the ground on January 1 the young stems were shooting up about 4 in. above the precise centre of each bulb, and I might add in "Amateur's" own words, "as previously"; but I must also add, in my own words, "not from the same identical bulb." Thus it will be seen that if we desire to ascertain the nature and organization of Lily bulbs, it is not by merely examining the outside alone, but by lifting and dissecting several bulbs, month by month, during a period of two years, and by carefully and minutely examining the interior of each bulb as soon as they are lifted out of the ground. If "Amateur" had done this, I venture to think that his present remarks would have been very much modified. I have to thank him, however, for his kind offer to show me, in October or November, the results of his experiments with different bulbs; but I may mention, possibly for his information, that in those months with different bulbs, though the germ or seed-bud is actually in existence, it cannot be discerned by the naked eye, so that a proper examination would be incomplete.

Assizes, Western Circuit.

DUNEDIN.

— In the few remarks which I made on transplanting Lilies (see p. 83) I avoided the question concerning the reproduction of Lilies, so ably advocated by "Dunedin," and confined myself to cultural observations that I have proved to yield satisfactory results

years before this question was brought under discussion. The only point to which I took exception was that of cutting down the flower-stems before the leaves had faded. "Dunedin" will himself see that there is a wide difference between cutting the stems down in full and fresh bloom and waiting until ten days after the bloom has fallen to perform that operation. I cannot, however, understand in what way a Lily bulb is so totally distinct from all other bulbs as to be able to dispense with the services of the leaves, even if we take for granted that the connection existing between them and the new bulb is not direct, as "Dunedin" would imply. Under such circumstances the new bulb must perfect itself solely by the aid of its own roots. If "Dunedin" will illustrate the totally distinct character of Lily bulbs in such a manner as to prove that neither "directly nor indirectly" is the succeeding year's flower-stem affected by cutting down the leaves while they are yet green, he will confer a boon on many cultivators who up to the present time have attached great importance to retaining the foliage in health as long as possible. Bulbs of all kinds are generally treated well up to the period at which they flower, but the lack of attention to perfecting the foliage afterwards often leads to wholesale destruction. Those in pots are, as a rule, from want of space, thrust into out-of-the-way corners; while those in beds are lifted and laid in by the heels to ripen off as best they can. Anyone who has treated bulbs after flowering equally well as in their early stage can need no confirmation of the value of leaves in perfecting the succeeding year's flower-spikes. JAMES GROOM.

— I have followed with much interest the discussion about Lily growth, but for various reasons I have not taken part in that discussion. As, however, my name has been mentioned in relation to L. Thomsonianum, I am obliged to come forward in order to avoid misunderstanding. Lilies of various sorts form their bulbs very differently; therefore no general theory can be applied to every species. As to L. Thomsonianum, now classed amongst Fritillarias, I have already said that the old bulb annually dies, and this is certainly the case, as I know from having carefully experimented upon it; on the other hand, allow me to state that L. Thomsonianum has no side bud at all, but merely a central one. The leaves growing from that central bud form each a scale of the newly-forming bulb; the scales outside are of a very watery consistence, and, decaying, help to nourish the newly forming bulb. As to L. giganteum and cordifolium, I must openly say that I have made no dissections in regard to them, but from studying these plants in the shape of hundreds of bulbs, as far as growth is visible, it seems obvious to me that these species do not produce annually a new bulb from a side bud, but that the old bulb is enlarged annually by the scales growing larger through the growth accumulating from a central bud; and that during summer, when vegetation is active, another central bud is developed to grow next year. This goes on during five or six years, when the bulb arrives at mature age; it then flowers and "clearly dies," as Mr. Wilson rightly states, the entire bulb being exhausted by the flower-stem which it has formed. In the meantime the growth of the first and second year's existence of the bulb has decayed, either through pressure from the stronger scales of succeeding year's growth, or through general weakness. The year before flowering one or more offsets make their appearance, which apparently spring from the root stool, and not from side buds in the interior base of the old bulb. If "Dunedin" has a correspondent in California, and can have sent to him a large bulb of L. Washingtonianum carefully taken out, he will observe that his theory cannot be applied to that species, for he will find inserted in one long sideward-growing bulb the accumulated growth of eight or ten years. As to the majority, or perhaps as to all Lilies of the old world, "Dunedin's" theory seems to apply exactly as far as the formation of the next year's bulb from side buds is concerned, but not in relation to the entire decay of the old bulb. Every year some scales decay; not those of last year's growth, but those of three or four years of age. I am of opinion that "Amateur" (see p. 198) is right in his views, and that he will certainly be able to prove that the old bulb does not decay every year. I cannot now, from want of careful investigation, say much about the mode of vegetation of the rhizomatous group, but I may state that even among these a different mode of vegetation takes place.

MAX LEICHTLIN, Baden-Baden.

— I did not see "Amateur's" remarks on L. auratum in time to reply in last week's GARDEN. I have always believed it to be an acknowledged fact that when L. giganteum flowered its bulb decayed, leaving a circle of root-buds to carry on the race. With all these Lilies which we have bloomed both in and out-of-doors this has been the case. If "Amateur" can flower L. giganteum twice from the same bulb, he is a fortunate man. One objection to the experiment suggested by him of growing Lily bulbs close to the surface is, that some Lilies grown naturally root so freely from the base of the stem, that they have almost as much root above the bulb as below it.

GEORGE F. WILSON, Heatherbank, Weybridge Heath.

## THE FRUIT GARDEN.

### BLEEDING IN VINES.

MORE Vines are ruined through bleeding than growers suspect, and I have little doubt that many of those who so often complain about their Vines breaking and growing weakly would find, on stricter investigation, that bleeding was the cause. Experienced cultivators realise fully the disastrous consequences of bleeding when it goes on for any length of time; but there are hundreds of amateurs and others who would never suspect that anything was going wrong when, in fact, their Vines were perhaps bleeding almost to death, for the bleeding itself is hardly observable, and would scarcely attract the notice of any but those who know when and where to look for it. Hence the evil is not observed till the mischief is done and the Vine shows it by its feeble growth, by which time bleeding has ceased.

Whenever drops of water are observed hanging at the points of the Vine shoots where they have been pruned, and before the buds begin to swell, or contemporaneously with their swelling, bleeding is going on, and means should at once be taken to arrest it. If the Vine be watched, the moisture will be seen dropping at intervals from the wound, or running down the bark, not in great quantity, perhaps, but still sufficient to partially ruin the Vine if allowed to continue. I remember an experiment being made upon a very vigorous Vine in the way of bleeding. When the sap began to ascend naturally about the month of April an incision was made in the leading shoot, from which the sap at once began to flow copiously—not

actually running, of course, but dropping steadily at the rate of about a teacupful in twenty-four hours. The Vines were started at the same time, and the bleeding continued for a considerable period—about a fortnight, so far as I can recollect—till the Vines came into leaf, which they do not take very long to do late in the season. The effect upon the Vine was disastrous. It broke very feebly, made shoots like straws, with small leaves, and but little growth generally during the season, compared with the others. The bunches which it showed never spread out freely, and were cut away to relieve the Vine for that year. The following season it made a stronger but still weak growth, and during the next few years it gradually recovered; but the effects of the bleeding were distinctly visible for four years, the wood being weaker and the bunches smaller than in the case of the other Vines. Bleeding is always sure to occur in Vines that are started within a month from the time of pruning, and some-

times after a considerably longer period, much depending upon the maturity of the wood. Ill-ripened Vines are most liable to bleed, and *vice versa*. Though many preventives of bleeding have been suggested, it is well known that it cannot be effectually stopped, when once it has fairly commenced, by the application of styptics, unless the flow of sap can be completely arrested and the wounds allowed to become dry, when styptics will adhere; and if they have time to harden before the sap flows again, styptics like Thomson's or Joiner's Patent Knotting will stop bleeding. I have also seen collodion tried with good effect, but the two first named are most trustworthy. The only way of stopping the sap is by lowering the temperature to as near the freezing point as possible, and this is generally a difficult thing to do in a Vinery in March or April. Early in the season it can be done by simply throwing the house open. On one occasion I had a quantity of pot Vines that began to bleed badly after they had been subjected about

a fortnight to a moderate temperature in order to start them. The wounds had not been painted with styptic, as they had been pruned six weeks before starting; so our only alternative was to carry the Vines out of the house into a cold, dry shed where the pots were protected by litter and the canes left exposed. The sap very soon ceased to rise, the cuts were wiped with a cloth, and when quite dry painted well with styptic, and when thus hardened the Vines were moved back into the Vinery again, and no more bleeding resulted. This is the only plan I can suggest in such cases; those who have Vines bleeding at this season should open their Vineries to the utmost, and use the styptic at the earliest moment, applying it twice, first going over the

cuts and rubbing it into the pores of the wood with the point of the finger right up to the outer edge of the bark, and then going over again and putting another coating on each wound by way of a finish.

J. S. W.

Peach Tree with 20 vertical branches (Candelabrum form) in full bearing; variety, Chevreuse-Tardive; 10 years of age, 33 ft. long, 10 ft. high; average crop, 400 Peaches of the first quality and size.

**Peach Tree.**—The noble Peach tree here figured is from M. Jamin's garden at Bourg-la-Reine, where it grows on the outer side of the garden wall—a model of health and perfect training. There is no better evidence of intelligent culture than a fine Peach tree on a wall in a northern country. Trees in the most favoured parts of California or the south of Europe could not produce a better result than is here attained in spite of a less favoured climate.

**Baking Pears.**—I want a good baking Pear; will you kindly recommend me one?—A. [There is no baking Pear that can surpass the Catillac; it should be cultivated as a bush on the Quince stock. In spring, its flowers are very ornamental; and in autumn, the beauty of its fruit is equally remarkable.—R.]

## FRUIT TREE PROTECTION.

To glass copings, both permanent and removable, I have a decided objection, as I consider they do more harm than good. The annexed illustration shows a cheap glass coping that was in permanent use here several years previous to my coming to the place, and I believe the results were satisfactory for a few years, so far as fruit was concerned, but not as regards the growth and health of the trees. The coping was of rough plate glass, in pieces 3 ft. long by 18 in. The two ends rested on the brackets, and the glass was kept in its place in front by a hook attached to the bracket, and at the back by means of small wedges of wood inserted between the upper side of the glass and the under side of the coping. The brackets any ordinary blacksmith can make, and any joiner can put them up at the proper distances apart. The glass is placed in position by beginning at the one end, each piece being pushed through the hook on the bracket as the work proceeds. From the front of this coping was hung a kind of cotton or elastic netting about 3-16ths-in. mesh. This is a very excellent shading, but it does not keep off more than 6° or 8° of frost; therefore it is of little value against 10° or 20° of frost, as I have experienced. It may now be asked what are my objections to glass copings; they are these. From their being fitted close to the wall there are no means of ventilation. Some may be amused when I speak of ventilation in connection with a glass coping, but during bright sunshine the heat accumulates under the glass to a far greater degree than is generally imagined; in fact, its roasting effects may be plainly seen on the tops of the trees, from 4 ft. to 5 ft. down the wall.

In the case of permanent copings they keep off both the winter and summer rains to a very considerable extent, which is a great mistake as regards the health of the trees. Those here have barely escaped with their lives from the roasting process to which they have been subjected. Apricots have suffered most, and are so weak, that no crops have been gathered from them for the last three years. Temporary copings of wood, straw mats, or Spruce branches would not have the same evil effects as glass has, being more non-conductors of heat, and they have not the effect of keeping the tops of the trees in one temperature and their bottoms in another at the same time. I have used a coping of Spruce branches, as proposed by Mr. Knight (see p. 213), in Ross-shire with satisfactory results, and I have also fastened Spruce branches all over the face of the trees with equally good effects. If, however, I were to choose my own protecting materials for fruit trees, other than being wholly protected by glass, I would use cotton or elastic netting already referred to, and let it remain in position until all danger from frost is over. It equalises the temperature and guards against both cold winds and very bright sunshine. We often have in the months of March and April sudden transitions of temperature, which are in themselves a great evil to fruit trees that are

exposed to them; therefore I should let the netting remain in position night and day. It does not exclude too much light, air, and warmth for the securing of a good "set" of fruit as some may suppose, as I have tested over and over again, but, as I said before, it will not exclude beyond 6° or 8° of frost, unless everything be very dry. Therefore I would use along with the netting at night a thick kind of cloth that is made of wool and hair, an excellent protecting medium from frost; of course it could be used during the day as well, if required. Some may say that this might prove an expensive mode of protection, which perhaps it may be, but the material will last for years if taken care of, and if regular crops be secured by its use should not be a consideration. Of course there might be the loss of a crop now and then, as much depends upon well-ripened wood in the autumn, a condition in our uncertain climate not

always obtainable, without an entire covering of glass, a want greatly felt by all cultivators of tender fruits.

*Halston.*

JAMES FAIRWEATHER.

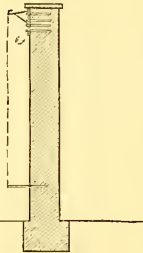

— As late and as little as possible should be the rule in regard to protecting fruit tree blossoms. Nothing suffers so much from coddling as wall trees; it not only enfeebles, but renders them liable to attacks from insects. There seems some hidden law that links insects on to weakness. Allow a plant to fall into ill health and insect pests gather around it. Now nearly all protectors, not even excluding glass, tend to weaken trees. They keep out more than cold—dews, rains, air, and light are reduced in volume or weakened in energy by our protectors, which, in so far as they conserve warmth, in a sense weaken. Heat is far from being in all times and places an advantage to plants; on the contrary, much of the heat of our springs is a direct injury to wall trees. It brings the buds out before their proper time, quickens the sap into dangerous precocity, and what may be termed killing energy. Glass protectors, admirable in most respects, collect, conserve, and thus add to the measure of this spring-tide heat, and, as far as they do so, endanger the safety of the trees. But opaque protectors, while useful in reducing rather than adding to the local wall temperature, weaken the trees by reducing the light. Light rather than warmth is the very basis of strength, and we cannot afford to lose any of it on our walls. It is too often forgotten that of necessity, perhaps, fully a fourth of the wood of our wall trees is deprived of light. Backed against opaque bricks, the wood and bark are in semi-darkness; consequently there is the greater need to fully expose Peaches and Nectarines to all the light possible consistent with their safety from spring frosts. A good way of limiting the time during which protection is necessary is to remove these trees from the wall and tie them to stakes 3 ft. or so in front of it as soon as the leaves drop in the autumn; the trees are thus fully exposed to atmospheric and solar influences all the winter. Trees thus treated lose that green and delicate look so common to Peach trees on walls and get browned all round. The cool quarters in front of the wall also keep the trees much later than they otherwise would be, so that they need not be placed in position till the middle or end of March. The change being so great, and the air more genial, the trees rapidly pass through their flowering and setting periods, and the season of danger, when protection is needful, is thus reduced to the shortest duration. Of course the labour is considerable, but few horticultural operations pay better. The annual removal of the trees affords rare facilities for cleaning the wall. The weather may be said to clean as well as harden the trees, and more, and best of all, this mode of retarding the blooming period and shortening it mostly results in the securing of a crop of fruit.

D. T. FISHER.

## POMOLOGICAL DICTIONARY.\*

THE student of Nature and the lover of Art united (as they often are) in the person of the man of science, may be congratulated in living in an age when nothing is suffered to stand still. "Many run to and fro, and knowledge is increased." In the science of horticulture especially great progress is being made. In a former paper I said that I believe the art to be yet in its infancy: this childhood, however, is strong and vigorous, and gives promise of a glorious maturity. A great future lies before us, and we English horticulturists ought thankfully to stretch out our hands to our fellow-workers on the Continent, receiving from them the fruits of their patient study, and making them, in our turn, partakers of our intellectual gains. The good which accrues to mankind from the triumphs of war is, at the best, doubtful. Victories which appeared important and splendid in the eyes of one generation are often almost forgotten in the next, or remembered but as some tale of an outlived past, while difficulties vanquished in the pursuit of knowledge, and victories achieved in the great Kingdom of Nature, are distinct benefits to the race; they depart not with the "passed time," but remain a stable pos-

\* "Pomological Dictionary." Containing the History, Description, and Outlines of Ancient and Modern Fruit most generally known and Cultivated. By André Leroy, Angers, France. [Published by the Author.]

session, the inheritance of people yet unborn. And here (if I may be allowed a short digression) I would urge on the attention of the gardening public the great necessity for an improved system of education for gardeners. Taking them as a class, they are doubtless much better instructed than the generality of persons in their own rank of life, but this is not enough. They are too often taken away from school when mere boys, and placed in large establishments to begin at the lowest round of the ladder of their profession. True, they acquire in time a competent knowledge of its practical branches, but unless they are very industrious, and resolutely devote their leisure hours to self-culture and patient study, they may even attain the rank of head gardeners without having become possessed of that theoretical and scientific knowledge which every day's experience shows to be imperatively necessary. I do not think we shall do much in the way of forwarding this "consummation devoutly to be wished" until we have schools and colleges instituted expressly for gardeners, in which the science shall be properly and systematically taught by competent professors. None of these, as far as I know, exist in England. We must not forget to mention with honour the pains bestowed on the training of gardeners at Kew. I am likewise informed that an attempt was made at Messrs. Veitch's nursery to carry on lectures on botany, but I am not aware if these are continued. Nurserymen whose establishments are on a large scale, like those of Messrs. Veitch and others, would do much to raise the tone of their profession if they devoted some time and thought to this matter. These, however, are isolated cases. I plead for a proper system, and one which shall embrace the whole of this country. The schools and colleges I advocate should be founded in every large town. The courses should include (among other important matters) botany and at least the elements of Latin and French. The expense should be moderate, so as to place these advantages within the reach of the many. Examinations should take place and degrees be conferred. I point to the establishment of the late M. Louis Van Houtte, at Ghent, as an example of a great gardening school. This is partly upheld by the government, and the education acquired there is (as I know) most thorough. If schools like this were founded in this country and well supported, we might hope that a dead level of mediocrity would not any longer be the rule among our working gardeners. Their standard would be greatly raised, and their attention having been awakened and their ambition excited, we might expect our efforts to be rewarded by fresh discoveries in the region of horticultural science. This matter should be taken in hand by the Government. We have a Chamber of Agriculture, why not a Chamber of Horticulture, with ministers for each of these departments? I may have another opportunity of referring to this subject. These thoughts were uppermost in my mind as I read the introduction to M. André Leroy's "Pomological Dictionary." The appearance of this remarkable work may be said to mark an epoch in the history of fruits, as we know that even in this day of increased interest in their culture the diffusion of accurate technical knowledge on the subject is very far behind the requirements of the age. The existing Manuals, that of Dr. Hogg, with Scott's excellent "Orchardist" (the former the product of scientific observation, the latter the result of practical experience), together with the nurserymen's catalogues, have hitherto been the only modern text-books. Our neighbours across the Atlantic are fortunate in possessing Downing's valuable treatise on the "Fruits and Fruit Trees of America," as, though in many respects incomplete and disappointing, this book may be regarded (from a pomological point of view) as the herald of a brighter day. Leroy's scholarly and exhaustive work was then greatly needed. Nothing at all resembling it in its thorough and masterly treatment of the subject has ever appeared before. To it the author has devoted by far the greater part of his life, for he says that he began to conceive the plan of his book in 1830 (the first volume was published in 1867), and during the thirty-seven years which elapsed before it was given to the world, he devoted all his time on the one hand to practical experiments in his fruit school, and on the other to the patient study of ancient and modern works on the subject; not, of course, confining his reading to those in his own language, but causing

to be translated into French all the principal writings on Pomology in Latin, German, English, Italian, and Dutch which have appeared since the introduction of printing, besides causing to be made, under his direction, the most careful and minute researches in Paris among rare books and manuscripts. Leroy describes himself as impelled to this laborious undertaking partly by his love for his profession, which he follows under the most favourable circumstances at the head of large and extensive nurseries situated in the garden of France, the fair province of Anjou, and partly by his wish to render a tribute of affection to the memory of his ancestors, who have been gardeners for more than 150 years. He dedicates the dictionary to the memory of his old master, André Thouin, formerly Professor of Culture in the Museum of Natural History in Paris; and also to his friend and co-labourer, Oscar Leclerc Thouin, formerly Professor of Agriculture in the Conservatory of Arts and Manufactures in Paris.

Leroy opens his introduction by dividing his argument (so to speak) into three parts. 1. The necessity for a more extensive and less costly Pomology. 2. Examination of the principal existing Pomological treatises. 3. Explanation of the plan of the dictionary.

2. "All our fruit trees are but the product of human invention, and as such unworthy the attention of the botanist," was the arbitrary dictum of Linnaeus; but he would probably have modified it could he have lived until our day, and have witnessed the publication of numerous treatises, as well as the formation of learned societies for the study of fruit. For some years, says Leroy, the want has been felt for a more complete work on this interesting subject, for many new varieties of Apples, Pears, and Grapes are not to be found at all in existing Manuals, and perhaps more exact and scientific knowledge would help to do away with the plague of synonyms—often the result of ignorance or error, and not unfrequently of tricks of trade.

2. M. Leroy gives under this head a short account of the principal French works on Fruit Culture, beginning with that of Jean Merlet, 1687, and going down through a succession of writers to Antoine Poiteau, whose valuable and elaborate book appeared in 1846. He regrets that this painstaking writer should have deferred its publication until he had entered on his seventy-ninth year. The work shows marks of the sort of intellectual paralysis, which is caused by the frosts of age. Though a treatise of great merit, and, by reason of its beautifully-coloured plates, occupying a distinguished rank among the artistic publications of this century, yet is it in some places provokingly incomplete. Many modern varieties of fruits are omitted, and the high price of the work (600 francs) places it quite beyond the reach of persons of moderate means. Most of the Pomological books cited by M. Leroy are more interesting to the French than to the English reader. Few, if any of them, have been translated into our language: I will, therefore, content myself with this brief mention, and pass to the third head—the plan of the Dictionary. Vols. i. and ii. describe Pears, vols. iii. and iv. treat of Apples, and vol. v. of stone fruits. The volume which is to describe Grapes has not yet appeared. The different species comprised in each volume are classed alphabetically, and the description of each forms a chapter to itself, where the varieties and its synonyms are also classed alphabetically. This classification explains the title "Dictionary." As to the prefix "Pomological," we must allow that our author never transgresses the limits comprised in this word. Here are to be found no principles, no rules of gardening, and but little advice on the management of orchards. These subjects are properly handled in treatises on other branches of horticulture. But with regard to fruits nothing has been neglected; every variety has been accurately described; even those confessedly inferior have not been overlooked. The reason for not omitting these is that a number of fruits which are quite unsuited to one locality succeed well under different conditions of soil, climate, and treatment, a fact not always sufficiently considered. Each description is divided into six heads:—(1) Name generally adopted; (2) Synonyms; (3) Description of the tree; (4) Figure and description of the fruit; (5) History; (6) Observations. It will only be necessary for me to touch upon one or two of these

heads. First, then, let me mention the "Description of the tree." This has been, for the most part, left out of Pomological catalogues. Leroy says if you wish to become acquainted with the true physiognomy of a tree in its primitive and natural form, you must select from a nursery a plant which has been grafted for two or three years. It has not, then, undergone the transformations at the hand of the pruner which are the products of caprice, fashion, or necessity. All the descriptions of trees given in his book have been taken from examples in his nurseries, and from specimens of two or three years old. He touches but lightly on their culture, as his work is not a Gardening Manual; it is a Pomology. He speaks of their fertility from records of his own experience, and not from those of others. Not wishing to make this treatise too expensive to be generally useful, he has resisted the temptation to adorn it with coloured plates, contenting himself with very exact outlines from drawings the size of life. All these drawings have been carefully prepared from examples taken from his fruit school, with the exception of varieties which have not hitherto fruited there. The remarks on the period of their maturity, as well as on their good qualities and defects, are likewise the result of observations made in his nurseries. Thanks to the exertions of the horticultural societies, the nationality of most of the fruits cultivated in France since the Revolution is pretty well known. There remains, however, a good deal to clear up on this important subject; among other things the origin of the ancient fruits is, for the most part, unknown. It would be interesting if we could answer these questions about every fruit tree. Is it indigenous, or foreign? Did it grow spontaneously, or from seeds? When was it produced? By whom? Where? How did it obtain its name? M. Leroy has anxiously striven to satisfy himself on these points, and in most cases with success. He has given great attention to four points. (1) The false synonyms attributed to any given variety. (2) The names which are likely to be confounded from their greater or less similarity with other of their species. (3) The merits, the defects, the exceptional habits of each variety, and also the imperfect or inadequate descriptions which have been applied to it. (4) Advice as to the best methods of cultivation, so as to bring out the finest qualities of fruits, and to prolong the duration of their maturity. It will be seen that the author has spared no pains in the preparation of his book. It not only deserves a place in every horticultural library, but the information it affords is communicated in so agreeable and intelligent a manner, that it may furnish a pleasant hour's amusement to the ordinary reader. I will give three examples which will fully illustrate the author's manner of dealing with his subject. I have to this end selected his description of the Pear Olivier de Serres, and the Apples Calville blanche d'Hiver and Reinette de Caux. I have been guided in my selection of the Apples by the fact that the Calvilles and Reinettes form each a distinct type, including many varieties. There are 90 Calvilles and 120 Reinettes.

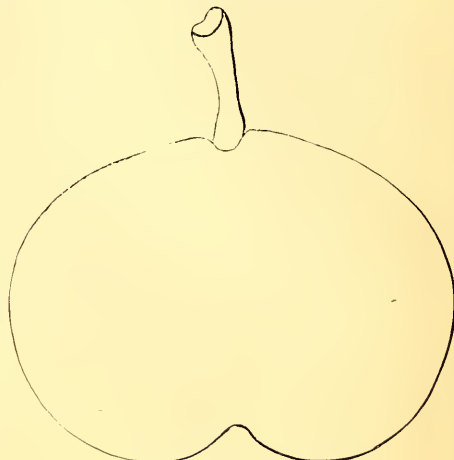

#### Pear.—Olivier de Serres.

**DESCRIPTION OF THE TREE.**—Wood, strong; branches, very numerous, almost erect, large, not very long, jointed, a light brownish-green, finely and abundantly dotted with marked bosses; eyes, voluminous, ovoid, pointed, well separated from the wood, the scales well apart; leaves, oval, or elongated oval, middle-sized, flat or slightly arched, deeply out, attached to a long and stout stalk. Culture: Its vigour is perfect either on a Pear or Quince stock; it grows splendidly in pyramids.

**DESCRIPTION OF THE FRUIT.**—Size, ordinary; form, spherical, flattened at the extremities, and often much bossed on the surface; stalk, short, curved, thick in the middle, enlarged at the extremities, inserted in a cavity whose depth varies, the sides of which are mostly ribbed; eye, large, regular, seldom open, not very deeply set; skin fine, of an olive-yellow, covered with fawn-coloured spots, coloured with the same at the top, and slightly reddened on the side exposed to the sun; flesh, whitish, melting, rather fine, and sweet scented, somewhat gritty at the core; juice, abundant, sugary, rather acid, and perfumed; maturity, from the beginning of February to the end of March; quality, the first.

**HISTORY.**—It was in 1861, and not in 1859 (as has been incorrectly stated), that stock of this variety, the product of Pippins of Fontaine d'Angers, produced its first fruits at Ronen, in the nurseries of M. Boisbunel, its grower. Offered for the inspection of the Horticultural

Society of Paris Feb. 27 and March 13, 1862, the Pear Olivier de Serres was justly pronounced a very good keeping fruit. In 1867 it received the medal (see the journal of the Society, vol. viii., p. 293, and vol. i of the 2nd series, p. 166). M. Boisbunel has wisely named his Pear after the illustrious man who well merits the surname of the "Father of Agriculture" in France, Olivier de Serres,

Olivier de Serres.

who died in 1619. He was a native of Ardèche, and the inhabitants of that Department have raised a statue to him at Villeneuve-de-Berg, the town where he was born in 1539.

#### Calville blanche d'Hiver (White Winter Calville).\*

The synonyms are very numerous, viz., White Zurich, Great Zurich, Admirable White, &c., besides twenty-seven others.

**DESCRIPTION OF THE TREE.**—Wood, moderately strong; branches, somewhat numerous, spreading, large and long, jointed, thinly covered with down, brownish-grey, spotted with red; lenticelles, large, thinly spread, more or less rounded; bosses, not prominent; eyes, small, egg-shaped, flattened, very downy, and strongly attached to the bark; leaves, large, tough, elongated oval, bright green above, a greyish-brown below, with a tapering point, and deeply indented edges; petiole (foot-stalk) long, thick, reddish, with the groove well marked; stipules short and thick; fertility, abundant.

**CULTURE.**—The prolific nature of this Apple renders it a good subject for either Paradise or Denon stock; it is suitable for pyramids, espaliers, cordons, or bushes. If it be grown as a standard, it must be grafted at the top. This sometimes causes the branches to become cankered, and the loss of the trees is then certain.

**DESCRIPTION OF THE FRUIT.**—Size, very large; form, irregular, sometimes conically bossed, sometimes conically elongated, the sides more or less unequal. This crookedness occasionally causes the fruit to become triangular, or even quadrangular. Peduncle, short, or of middle size, slender, generally deeply sunk in a hollow or cavity of variable dimensions; eye, large, half or entirely closed, with a very irregular cavity, large, and often deep and wrinkled; skin, unctuous, fine, glossy, of a straw-coloured yellow, streaked with greyish-white, and spotted with dark red, very scaly in the peduncular cavity, sometimes covered (particularly at the base) with a light downy coating of milky white—sometimes also shaded or striped with pale rose on the side exposed to the sun; flesh, yellowish, fine, and firm; juice, abundant, very sugary, with a pleasant acidity, and a most delicate perfume; maturity, December to May; quality, the first.

**HISTORY.**—Four conflicting assertions have been published with regard to the origin of the White Winter Calville. We will proceed to examine them before giving our own opinion; and this shall be done with great care, as this variety occupies among Apples the same position as the Bon Chrétien among Pears.

1. As is the case with the oldest fruits, it is said that the Romans

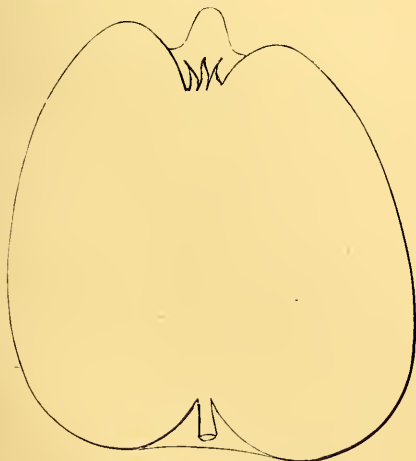

\* The price of this Apple a month ago in Coven Garden was 30s. a dozen, or 2s. 6d. each.

(Pliny among others) knew this Apple, and that this author called it Calvatium. To this I reply that Pliny never mentioned an Apple by the name Calvatium. I refer the disputants to the historical chapter at the beginning of this volume. They will find, under the heading "Varieties cultivated among the Romans," the authentic and com-

White Winter Calville—First Type.

plete nomenclature of all the Apples mentioned in the "Historia Naturalis" of this celebrated savant. 2. Dr. Jacques Daléchamp, who published in 1856 a voluminous history of plants in Latin, assures us that the Apples called Taponnes, then well known, are identical with the Orthomastia, whose name Pliny has transmitted to us. Now as these Taponnes have been identified by various esteemed

White Winter Calville—Second Type.

Pomologists with our White Calville, it remains then to demonstrate that the Orthomastia cannot be assimilated with them, or else this variety, by means of the synonym, must be carried back to the age of Pliny. Since the time of Daléchamp, then, what has become of the Taponnes? They had already disappeared in the seventeenth century, as Le Lectier and Claude St. Etienne (1670) alone mention them.

After their time I lose all trace of them on our soil; they must have been either re-named or entirely abandoned. You meet with the name only of this variety by consulting the German authors Mayer and Manger, who insert them as synonyms in their "Pomologies" in 1776 and 1780. They are not, however, agreed, as Manger, after having (p. 68) appeared to share the opinion of Mayer (vol. iii., p. 76), who identifies the Taponne with the White Calville declares further on (p. 24) that this Apple is the same as the "Gause" (Goose-apple), or with the "Maiden zizchen" (Maiden's breast). This last name would seem to harmonize with the idea of Daléchamp, who thinks he sees in the "Taponne" the "Orthomastia" of the Romans, if Pliny had given us any other possible point of resemblance than these three words, "Mammaram Effigie Orthomastia," Orthomastia resembling the breast. It is, therefore, impossible to compare the species. As to the opinion of the German Pomologists that "Taponne" is the synonym of the "White Winter Calville," I accept the dictum without contradiction, but remark that this name of Calville appeared for the first time in 1628 (see pp. 166-167, in the article

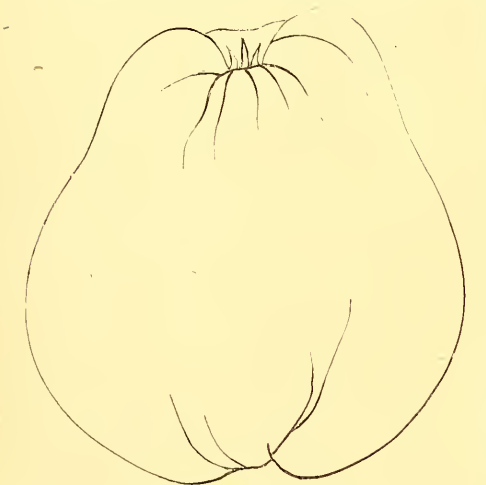

Admirable White—First Type.

where I establish this), and is, therefore, less ancient than the name "Taponne." This last, well known (as we have said) at the time of Daléchamp, 1510-1587, became a century later the "Taponnelle," or "Taponnelle" of Le Lectier and of Claude St. Etienne, who quote this Apple concurrently with the White Winter Calville. At any rate we must not conclude that these fruits are unlike, as our ancient Pomologists (the proofs are legion) register these names without a previous examination of the identity of the varieties. 3. In 1862, M. Eugene Forney, Professor of Arboriculture in Paris, thinking he had discovered the origin of the White Calville, announced it thus in the "Jardinier Fruitier," which he was then publishing. "We have," he says, "long sought for the origin of this Apple. It was Boyceau de la Baranderie, the director of the Tuilleries Gardens under Henry IV., who first made it known in his 'Traite des Jardins.'" He does not say where he found it, but this was probably in his garden of the Tuilleries, which was then a vast orchard. After reading the passage in which Boyceau de la Baranderie speaks of having discovered a new Apple, I am bound to reject the opinion expressed above; there is nothing, as far as I can see, relating in this passage to the Calville any more than to any other variety. The author, in treating of seeds, only calls attention to a fact in vegetable physiology which he considers absolute, and in support of which he says that certain seeds of the Red Calville produced a shoot which bore white Apples, then some seeds of "Pavie" jaune, which bore fruits with the skin and flesh white. Here is the text of La Baranderie:—"If you sow pippins or kernels of a fruit which has been grafted on a wild stock, the fruit which will be produced from this seed will partly resemble the wild

stock and partly the other parent. In this manner I have seen a pippin of a Calville Apple, which is red within and without, produce a plant which has borne before being grafted and transplanted. The form of the fruit was that of the Calville, long, wrinkled at the head, but white within and without, having only a few spots on its shining skin. In taste and smell, and in the nature and in the quality of its flesh, it partly resembled the Calville and partly the Reinette, which is a white Apple. The pippin possessed the qualities of both of these. I have seen a kernel of 'Pavie,' the fruit of which is yellow with the kernel red, produce a tree which bore without being grafted, in its third and fourth years, a fruit white within and without" ("Traité du Jardinage," 1638, pp. 39-40). Now for those who persist in discovering in this passage the account of the origin of the White Winter Calville we will add a decisive fact. Boyceau de la Barauderie died in 1635 or 1636; and this Calville was growing at Orleans, in Le Lectier's garden, in 1600, as we find on p. 230 of the Fruit Catalogue of this author, printed Dec. 20, 1628. Besides this, I can prove that this Apple has been cultivated in Franche-Comté, in Switzerland, and in Wurtemberg, ever since the middle of the sixteenth century, nearly 100 years before La Barauderie was born.

One last assertion—that of Louis du Bois—remains to be noticed. This learned writer, who was thoroughly acquainted with the fruit trees of his native province of Normandy, says that "the Calvilles,

Admirable White—Second Type.

white as well as red, take their name from the village Calville, Department of Eure." He makes this statement in his translation on the works of the Roman agriculturalist Columella, vol. ii., p. 461. It is generally believed in Normandy, where these two varieties have been grown from time immemorial, particularly in the departments of Eure and Calvados, but if I search further into the origin of the generic name of these Apples, I cannot admit that they are derived from the village Calville. Nobody before the time of Le Lectier (1628) had distinguished between the different kinds of Calvilles, red, white, and yellow; Olivier de Serres (1600) did not know them, nor did Dalschamp (1586). It is, then, evident that the date of the appearance in the nomenclature of this word Calville was the middle of the 16th century, at the very earliest; nevertheless the White Calville had long been grown (under another appellation) in Switzerland, Germany, and Franche-Comté; and that the Red Calville was equally well known in France, as I shall prove in my article on this Apple. The naturalist, Jean Bauhin, the author of the first illustrated Pomology, furnishes us with the proof that the White Calville derives nothing from the village of Calville but its name. He has described it twice. In 1598, in his "Historia fontis et Cateci Admirabilis" (p. 83); then about the year 1600, in a "Historia Plantarum Universalis," which was not published until 1650, thirty-seven years after Bauhin's

death. This work, being more complete, more exact, and fuller in details than the other, besides being adorned with exact outlines of the types represented, we will, therefore, borrow his historical and descriptive account of the subject. The Apple Admirable White, or large White Apple (says this naturalist), comes originally from the Fountain Admirable in the Duchy of Wurtemberg. Its form is uncertain; I have therefore caused to be outlined two types to prove this variability. It is an irregular fruit, rounded or turbinate, of a whitish colour, the flesh acidulated, and the sides very pronounced. It is a good keeper, and is identical with the Back Apfel (cooking Apple), so called because it is delicious when roasted. It is cultivated at Zell, from whence I have received two large specimens, whose skin is of a yellowish-white covered with milky spots. The height of each Apple exceeded 3 in.; its breadth was about 3 in. There exist, no doubt, much finer examples. I could easily have kept it sound and good until the middle of May. I cultivated this variety at Montbéliard (in the Grand-Ducal garden, at the head of which Bauhin was placed by the Prince of Wurtemberg—Montbéliard—whose doctor he was. Vol. i., pp. 12 and 13).

This demonstration, in my opinion, could hardly be more convincing. Here is our White Winter Calville, and Bauhin described it, we must remember, in 1598 for the first time. It is, however, impossible to indicate with certainty the exact origin of this Apple, because it appears at the same period under different names in Wurtemberg, then at Montbéliard (Doubs), as well as at Zell, a Swiss town in the Canton of Zurich. I must also add that Bauhin—p. 15 in a small treatise which followed the one I transplanted above—states that the "White Apple of Zurich" is identical with the "Admirable White" of the Wurtembergers. After this, it is difficult to contest the following conclusions:—

1. The White Calville appears to have been cultivated very early in Normandy, especially in the environs of Erreux, at Calville, from whence in 1600 it took its name.

2. Well-known even before 1598, under different local denominations in the Duchy of Wurtemberg, and at Montbéliard, then belonging to the Duchy, and also at Zell, near Zurich. This variety has originated in one or other of these territories. Wurtemberg on some grounds, may claim the honour of its birth, as Bauhin, says that the "Admirable White" comes from that country, which has always been celebrated for the number and excellence of its Apples.

3. With regard to the importation into France of this exquisite fruit, it is easy to imagine that from the district of Montbéliard, which is partly included in Franche-Comté, the "Great White Apple" of the Wurtembergers might easily have been brought into Normandy.

OBSERVATIONS.—Noisette in 1839 pretends in his "Jardinier Frutier," p. 181, that the "White Winter Calville" has been called "Blandureau d'Anvergne." I am ignorant of the source from whence he derived this synonym, which is mentioned by no other Pomologist. The "Blandureau" (I have described it p. 134) is certainly one of the most ancient Apples; but it resembles the "White Calville" in no one single point, and no one has ever heard of another "Blandureau" said to be of Anvergne. "Paris's Apple" is not identical with this variety, as may be easily seen by consulting my description of it under the heading p. The name Strawberry figures among the synonyms of the White Calville; it is therefore needful to state that this bears no resemblance to the "Winter Strawberry Apple" grown in England, but little cultivated by our nurserymen. The Germans possess a "White Winter Italian Calville" which is unknown to us, but their Pomologists declare it is quite different to ours. We are careful to state this, as it is very easy to make a mistake here. In Germany the true "White Calville" bears in some provinces the name of "Quince Apple." It is necessary to remember that this must not be confused with the "Winter Quince Apple," which I shall describe p. 228. I close this long article by recommending to epicures the compute of the White Calville, the most excellent compute that can be eaten. La Varenne (1655) mentions it in his "Cuisinier Française" (p. 350).

#### Reinette de Caux.

The name Reinette has been derived, according to some etymologists, from Rana (a frog), on account of the green spots which mark the fruit, and which are supposed to resemble those on the body of a frog; others suppose that this name was given to the Apple on account of its goodness (La Reine des Pommes)—hence, Reinette. Charles Etienne was the first French writer on horticulture who mentioned it in the Latin work which he published in 1540. There were but three varieties in 1667, there are now at least 150 sorts known in France, though of these eighty-four are alone described in M. Leroy's work; these are the best kinds. We will confine ourselves to his excellent description of the Reinette de Caux:—

SYNONYMS.—1. Grosse Reinette Rouge Tiqueté; 2. Dutch Mig-nonne; 3. De Laak; 4. Paternoster; 5. Copmantorpe Crab;

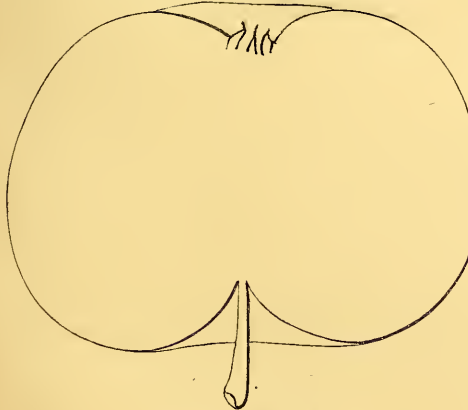

6. Stettin Pippin; 7. Vermilion d'Andalusée; 8. Dentoch Mignonne; 9. Reinette Impératrice.

DESCRIPTION OF THE TREE.—Wood, strong; branches, numerous, erect or slightly extended, large, long, very much knotted, downy, of a dark reddish-brown; lenticles, large, rounded, and very abundant, bosses prominent; eyes, middle-sized, rounded, and egg-shaped, attached to the wood, and very downy; leaves, middle-sized, rounded,

Reinette de Caux—First Type.

pale green on the outside, a greenish-white inside, generally pointed, flat, with indented edges; petiole, long, very large, grooved; stipules, middle-sized; fertility, remarkable. Culture: This variety is as valuable for its beauty as a tree as for its fertility. In order to obtain a fine-shaped tree M. Leroy recommends its being grafted at the top. It is equally suitable for cordons, pyramids, standards, and espaliers, particularly when grown on Paradise stock.

Reinette de Caux—Second Type.

DESCRIPTION OF THE FRUIT.—Size, large, sometimes remarkably so; form, uncertain, most often, however, rounded, sides globular, but flattened at the poles; peduncle, middle size, sometimes long, thick at the point where it is attached to the tree, straight, sometimes curved, deeply inserted in a cavity of variable size; eye, large, open or half closed, with long and large sepals, cavity large, with the edges sometimes slightly undulated; skin, glossy, of a golden yellow, washed or streaked here and there with carmine more or less dark, spotted with russet near the stalk, dotted with pale grey or

brown; flesh, fine, firm, and crisp; juice, abundant, sugary, pleasantly acidulated and perfumed; maturity, October to April; quality, the first.

HISTORY.—For a long time (says Leroy) I shared the belief of our principal Pomologists that the Reinette de Caux, Seine-Inférieure, was a French variety, but I must now acknowledge that I am convinced that it has positively no right to its present name, having been produced in Holland more than a century ago. "Dutch Mignonne" is (if not its primitive denomination) at any rate the most ancient one that we know, and as such I have frequently procured it from different parts, and then, in common with many of my contemporaries, multiplied it and sold it without suspecting its identity with the Reinette de Caux. Now, indeed, our principal nurserymen, instructed by Pomological collections, are aware that one of these appellations is synonymous with the other. This Apple was brought from Holland to Norwich in 1771 by an Englishman. The botanist, George Lindley, stated this fact on the 4th of January, 1820, before the Horticultural Society of London, of which he was then a corresponding member. "The 'Dutch Mignonne,'" says he, "comes originally from Holland, having been carried to the village of Catton, near Norwich, by a person now dead; but the Dutch name is forgotten in England." ("Transactions of the Horticultural Society of London.") Eleven years later, in 1831, Lindley, referring to this fact in his remarkable "Pomology," adds new details. "The Catton Pear," he writes, "comes from Holland. The late Thomas Harvey imported it, together with the Apple Dutch Mignonne, sixty years ago at least, and planted them both in his garden at Catton, near Norwich." ("Guide to the Orchard and Kitchen Garden.")

The name Reinette de Caux, which originated with us, made its first appearance in the "Jardinier Fruitier" of Louis Noisette, not, however, accompanied by any description. However, at that date our horticulturists had already known it for some time. I was induced to verify it at the request of some Englishmen. This passage occurs in the "Proceedings of the London Horticultural Society," with the signature of W. Hooker. "Reinette de Caux, the Grosse Reinette, spotted red, of Poiteau and Turpin, is called Reinette de Caux by many gardeners. Although the outline which these two authors give us is much larger than any of the so-called Reinette, I believe it to be the same variety."—Transactions of the Horticultural Society of London. This Grosse Reinette, with red spots, which is entirely identical with the Reinette du Caux, was described and outlined by Turpin and Poiteau in a work entitled "Traité des Arbres Fruitières de Duhamel, Augmente d'un Grand Nombre de Nouvelles Espèces," a magnificent publication in folio, the first volume of which appeared in 1807, and the sixth, and last, in 1835.

OBSERVATIONS.—The Grosse Reinette de Cassel, the Reinette de Caux, and the Reinette Dorée (Golden Reinette), have been often mistaken for each other, but if anyone will compare the description of these different Apples in this dictionary, with regard to both tree and fruit, they will see in how many respects they differ. It appears there exists a Reinette Grise de Caux, which the Pomological Congress of 1869 declared not worth cultivation. Not being acquainted with this variety, I mention this fact in order to show that it has nothing in common with its Dutch relation, the old Dutch Mignonne. In 1831 George Lindley (before mentioned in this article) thought he was able to identify the Dutch Mignonne or the Reinette de Caux with the Reinette Dorée of Mayer, which is also that of Duhamel. He was deceived, as we shall see later on in the article on this fruit. In 1848, and also 1860, two Apples were sent to me, accompanied by grafts, the first bearing the name Vermillon d'Andalusée, the second entitled Reinette Impératrice. I propagated them both, and admired their great beauty; but later on, being certain they were identical with the Reinette de Caux, I omitted them in my catalogues.

These examples will give some idea of the manner in which our author has treated his subject. It was impossible for me (within the limits of a short article) to do more than glance at so exhaustive a work, but I shall be satisfied if I have induced some of the readers of THE GARDEN to study the "Pomological Dictionary" for themselves. They will find it full of most interesting information. It contains an admirable description of a fruit house, with excellent advice for the gathering, storing, and keeping of fruit, a subject sadly too little understood, but one which is, nevertheless, of great importance. W. NEWTON.

Hillside, Newark-on-Trent.

Cherry Plum.—A fine specimen of this has for some time been in flower in Messrs. Osborn's nursery at Fulham—the home of old trees. This Plum, recommended by Mr. Ewing, of Norwich, in THE GARDEN (see p. 100) as a hedge plant, is also of great value as an early spring-flowering tree.—F.

## PLATE CXX.

## THE DWARF FLAXES.

(WITH A COLOURED FIGURE OF THE WHITE ROCK FLAX.)

Drawn by H. HYDE.

One predominant character which the genus *Linum* presents is a lightness and elegance of contour, to which the usually narrow leaves, slender stems, and delicate peduncles which support the individual flowers, all tend to contribute. This speciality is equally patent to those who are familiar with our commercial Flax (*Linum usitatissimum*), whose cultivation extends over large fields in some parts of the country, and where, when in full blossom, such fields can be compared to nothing more appropriate than an azure sea, varied only in its lights and shades as it is gently rippled by the summer's breeze, or in the condition with which most people are familiar, as cultivated in its perennial or Siberian form (*L. perenne* and *L. sibiricum*) as a border plant, possessing with neatness of

habit a long continued blooming season, and when that is over still retaining sufficient elegance of appearance to justify its retention as an occupant of the border till the November frosts decide the necessity of a clearance for the winter. Amongst our herbaceous Flaxes few will be found to rival the one here illustrated. *Linum salsoloides* obtains its specific title from some little resemblance there is between it and the Salt-wort (*Salsola Kali*) in its peculiar procumbent and irregularly branching habit of growth. With the general aspect however, the similarity ends, as on close examination all the parts of the plant are

found to possess a slenderness and delicacy of character, as well as beauty of blossom, to which its seaside sponsor cannot lay claim. Although we have called it an herbaceous plant, the term is scarcely correct, as it is really semi-shrubby—a character which applies equally to many other plants belonging to the genus—and all the trimming required is to cut away the flowering twigs of the preceding summer, leaving all the undergrowth, as the floral basis of the next summer's beauty.

The **White Rock Flax**, as we have already said, and as, indeed, is simply exemplified in the accompanying illustration, is a plant of essentially procumbent habit; its branches, freely crossing and intercrossing one another, are clothed with a dense arrangement of linear lanceolate leaves, of a greyish-green—the colour not arising, as is usually the case, from a cuticular exudation, but from a roughness in the epidermal cells, and more especially from the acariose margins of the leaves themselves. Its flowers are white, with a purplish eye in the centre, and are produced in short, cymose corymba. When abundant, as presented in the figure, the plant reminds one of some of our creeping white Phloxes. It is essentially a rock plant, being found on the mountains of Provence and Gascony,

and, indeed, it occurs pretty abundantly throughout the mountain districts of the south of France and north of Spain. I have, however, seen it thrive well in a border on the chalk; but that is exceptional, my own experience being against its adaptability to ordinary border culture. On the rockery, however, in a well-exposed sunny nook, it is perfectly hardy, and will trail freely over the surface of adjacent stones—conditions under which it will flower abundantly. It produces seeds but rarely, so that increase must be obtained by cuttings of the short shoots taken off with a heel about midsummer, just as they are hardening off; at that time they will be found to strike freely, and to make vigorous plants when potted off the following spring. It is considered by some to be a mere variety of *L. tenuifolium*, to which it is, indeed, closely related, but from which my experience leads me to consider it as a simply distinct. Another close ally is the *L. viscosum*, but in it the entire plant is more or less hairy, those on the stem and cauline leaves being of a glandulose, exstary character—hence originates the sticky nature to which it owes its specific title; its flowers are purplish, and the whole plant is considerably more erect in habit than the White Rock Flax. Although tolerably plentiful in South Europe, I have only once met with it in cultivation.

A Small Garden Landscape with fringe from the banks of Streamlet in foreground, and Group of Fine-leaved Plants in the distance.

Southern Europe, and grows freely as a rock plant, but we do not often meet with it true.

The **Mountain Flax** (*L. montanum*) is described by some authors as a distinct species, but we suspect it to be little more than a variation of the foregoing of somewhat stronger growth. Its flowers are a shade deeper tinted with blue, taking in point of fact an intermediate position between the Alpines and Perennial Flaxes.

The **Dotted-leaved Flax** (*L. punctatum*) is an exceedingly slender-growing plant, in aspect and habit like *L. perenne*. Its branches are more erect, and its flowers of a lovely blue not gracefully on their delicate foot stalks. Its specific title originates in the abundance of pellucid dots with which its small leaves are suffused. It blossoms in June, July, and August, and, seeding freely, may thus be easily increased. As a border plant, it possesses good lasting properties; but, like all the Flaxes, its beauty is always most appreciable in the forenoon, when its flowers are fully expanded.

The **Narbonne Flax** (*L. narbonnense*), one of the most distinct and well-defined species belonging to this section of the genus possesses a more decidedly herbaceous character than any of the foregoing. Its leaves are long, lanceolate, sharply acuminate, and sparsely arranged along the stems. The flowers are remarkable for the length of the

The **Dwarf Alpine Flax** (*L. alpinum*), while bearing some resemblance to our more common perennial plant, is a much more compact grower, rarely attaining a height of over 6 in. or 8 in. The stems, branching horizontally from the neck of the plant, are clothed with a dense arrangement of small leaves, the lower ones having a markedly deflexed character. The flowers are a very light delicate blue, usually solitary or in threes, and produced somewhat spasmodically through the summer. There is a tendency in this species to increase by adventitious buds from any portion of the roots that have become exposed, and in this way a ready increase may be obtained. It is a native of the mountainous regions of

THE WHITE ROCK FLAX (LINUM VISCOSUM. L.)

sepals, whose mucronate points form collectively a sort of beak like process to the flower-bud. The flowers are twice the size of any others of the blue species, of a darker colour suffused with a slightly slaty tint; they are erect, and when expanded fully each petal reflexes backwards in such a way that the defined marginal outline is almost lost. This is certainly one of the most desirable species for border culture; it is perfectly hardy, and although it does not seed abundantly, a sufficient number may always be collected, whereby increase may be obtained. In light soils it also produces offsets from root buds, as before explained. It is a native of Southern and Central Europe, and flowers in June and July.

*L. candidissimum* and *L. monogynum* may well be bracketed together under the title of white-flowering corymbose Flaxes, though claiming widely distant homes, the former being a South European, the latter a New Zealand plant; they are so closely related that for all cultural purposes we may consider them alike. In habit their growth is erect, about 12 in. high, the stems and foliage being of a light green colour; the flowers are distinctly corymbose, large, and pure white, and produced not only in June and July, but supplemented by a second set of flowering stems in the autumn. Both the species seed freely, and are remarkable for the size of their capsules; neither are dependable as absolutely hardy plants, although occasionally they may be found to stand two or three consecutive winters. It is always advisable to have some young plants reserved in a cold frame, in case of any exceptional severity.

**The Shrubby Yellow Flax** (*L. arborescens*).—This and the two following species belong to a very distinct section of the genus, wherein the slender leaves and graceful habit disappear, and a somewhat rigid and shrubby character of growth takes their place. The present species is remarkable for its blunt-pointed, broadly cuneate leaves, suffused with a greyish glaucous hue, from amongst which its large, bright, canary-coloured flowers are produced in great abundance from early summer to autumn; rarely is the plant, which in dry, sheltered localities assumes quite an arborescent character, devoid of blossom. We have seen it even in Yorkshire planted on the top of a snick fence, forming bushes upwards of 2 ft. high and fully 3 ft. across, perfectly golden with blossoms, but in ordinary border culture, especially on a damp subsoil, its hardness is something more than questionable. This will be readily understood when we say that it is a native of Crete, the extreme south of Italy and Sicily, where it is generally found in proximity to the seacoast.

**The Taurian Yellow Flax** (*L. flavum*).—For many years the previous plant was known by this specific name, and so generally had the misnomer become established, that even at the present day the mistake is frequently perpetuated; nevertheless, the two plants are amply distinct. This species is an herbaceous plant in the strictest sense of the word, dying down annually to a short, woody, subterranean rootstock, from which year by year arise several erect-flowering stems, sharply angled and clothed with dark, olive-green foliage, broad, ovate, slightly cordate at the base and gradually narrowing upwards; each stem is terminated with a somewhat dense dichotomous inflorescence; and the flowers, which are produced in August, are of a rich golden-yellow. It is perfectly hardy, and forms a handsome and long-lived herbaceous plant, and should certainly receive a larger meed of attention than it has hitherto done. By some authors it is named *L. tauricum*, being abundant in the Taurian mountains, and, in fact, is generally met with in the upland meadows in Eastern Europe.

**The Bell-shaped Yellow Flax** (*L. campanulatum*) occupies an intermediate position between the two previous species, not on the one hand so decidedly shrubby as the former, nor on the other so decidedly herbaceous as the latter; it nevertheless possesses a distinct individuality of its own. Dwarf and compact, not exceeding 8 in. or 9 in. in height, it may be botanically distinguished by its horny narrow sepals, which much exceed the ovary in length, and its olive-green broadly obovate spatulate leaves. Culturally speaking, by its dense habit of growth, for, when well established on the rockery, and enlivened, as it is, through the greater part of the summer by a succession of golden blossoms, it forms a most desirable plant, almost as hardy as the Taurian species. It is a native of Mount Gargaous and the Pyrenean range.

In the foregoing I have enumerated those species which possess the greatest cultural value; were I to add such as are of purely botanical interest the list might be trebled. I cannot, however, bring this brief article on the Flaxes to a close without a passing allusion to the annual species. *L. grandiflorum*, a native of North Africa, and which has now for years taken its place amongst the most showy of our much-neglected annuals; the colour produced by it, grown *en masse*, in its full

expanded mid-day beauty, is such as few flowers possess, and to my mind it appears to embody a happy blending of chocolate, claret, and crimson, in such proportions as to make its colour specially its own and distinct from that of any other flower that I can call to mind. Nor must we omit mention of the East Indian *L. trigynum*—when properly treated one of our gayest winter flowering plants, alike adapted for the stove and the warm conservatory, and remarkable for the large deep yellow blossoms which it produces freely at the duldest season of the year. As its cultural treatment has been several times detailed in the columns of *THE GARDEN*, I will content myself with giving it its due recognition amongst the valuable cultural species of the genus *Linum*. [Our figure of the White Rock Flax was prepared from a plant furnished by Messrs. Backhouse, of York.]

## GARDEN BOTANY.

(Continued from p. 236.)

**PRESERVATION OF THE GERMINATIVE FORCE.**—The proper storage of valuable seeds, in order to preserve their vitality for one or more seasons, is a question of no little importance. Even those seeds most tenacious of life quickly lose it if subjected to unfavourable conditions. The first precaution to take is thorough harvesting, and the next is to avoid dampness. A humid atmosphere promotes decay and favours the ravages of insects, and will ultimately destroy the vitality of seeds having the best natural protection in the form of testa or pericarp. In a climate like our own the air usually holds a considerable amount of aqueous vapour in suspension, and a sudden lowering of the temperature causes a certain portion, sometimes a relatively large quantity, to be precipitated. The evil of this may be counteracted by efficient ventilation, for under any circumstances stagnant air, like stagnant water, soon becomes impure, because it favours the growth and propagation of microscopic animal and vegetable organisms, which prey upon organic matter in a state of incipient decay, and hasten it forward to complete destruction. Seed thoroughly cleaned will keep better than when stored without separating it from the rubbish, because the latter more readily absorbs moisture from the atmosphere. These indispensable conditions in seed-storing are not difficult of attainment in most parts of this country, but there are other countries in which the atmosphere is much more heavily laden with moisture, and where it is almost impossible to keep seeds for a few months without constant attention. As a protection against the moisture practically air-tight tin boxes and canisters are used; but they act as a preservative in one sense only, because even thoroughly ripe dry seeds gradually vitiate the air. The best way to preserve seeds in transit from distant countries and passing through dissimilar climates is to pack them in close, nearly dry, earth, and for such seeds as quickly lose their germinative force, the additional precaution should be taken of soldering them down in the cases, filled to the brim.

**GERMINATION ON THE PLANT.**—The seeds of plants growing in very moist climates occasionally germinate in the fruit whilst this is still on the plant; and sometimes an unusually wet season will cause it to happen on a large scale. The seeds, too, of many plants with pulpy or fleshy fruits occasionally germinate in the fruit, but there is nothing particularly remarkable in this fact. There are few grown-up people who cannot remember a year or two during which it was difficult to obtain Wheaten flour from which good bread or pastry could be made; but comparatively few know what has deteriorated its quality. Continuous rain after the grain is ripe stimulates the germination of the embryo, and sprouts, from 1 in. to 6 in. in length for every grain in an ear, are not rare in such seasons. Grown or sprouted Wheat, as it is called, is bad in quality in proportion to the extent of the sprouting; and, be the sprouting ever so slight, it spoils the flour, because the contents of the grain have begun to undergo a chemical change incidental to germination. Fig. 75 represents a seed-vessel of a Lily with two protruding radicles at the base. The seeds of the "Sâl" (*Shorea robusta*), a valuable Indian timber tree, germinate normally while on the tree, and therefore require sowing

as soon as they are collected. And there is a small family of trees called Mangroves, which inhabit the muddy sea-shores of tropical countries, characterised by the seeds invariably germinating before falling to the ground. Only one seed comes to maturity, and the radicle of this grows out at the apex of the

Fig. 75.—Seed-vessel of a Lily, with the radicles of two seeds protruding at the base.

Fig. 76.—Fruit of Brugneria, with the club-shaped radicle projecting from its apex. The whole of the part above the calyx is radicle.

fruit, as in fig. 76. This radicle grows stout and heavy, causing the fruit to become pendulous, with the radicle downwards. In some species, *Rhizophora Mangle*, for example, the radicle often continues lengthening until it reaches the ground before the fruit is detached from the tree, attaining 3 ft. or more in length; or if it falls to the ground, its own weight causes it to penetrate the soft mud, and thus often secures itself from being carried away by the tide. As soon as it reaches the ground the plumule begins to grow, and throws off the pericarp. There is also one familiar native plant, the Mistletoe, whose seeds often germinate in the viscous fruit. Germination in the fruit is also said to be normal in *Secchium edule*, a cucurbitaceous plant, commonly cultivated in the West Indies, which has a one-seeded fruit.

**GERMINATION OF UNRIPE SEEDS.**—It has already been shown that some seeds must be sown almost directly after they are ripe, or they lose their germinative force, whilst others, without any special protection, retain it for years, though it gradually decreases in energy. Seeds that are to be kept, even for a short time, before sowing must be perfectly mature or ripe, but it is not necessary, in many instances, at least, that seeds should be absolutely ripe in order to be able to germinate. Many instances have been put on record by different observers of unripe seeds germinating, and several botanists have conducted extensive series of experiments in raising plants from seeds in different stages of development. At first it seems somewhat surprising that an imperfectly-formed embryo should grow into as vigorous a plant as a mature one; but, when we understand the general plan of growth in plants, this phenomenon is intelligible. Thus, Ferns actually develop from a single detached cell. This property of premature germination may be taken advantage of in practice in propagating plants that do not fully ripen their seeds in our climate. It is recorded that *Sophora japonica* does not ripen seeds at Breslau, in Germany, but they are so far formed that if taken and sown at once they grow. A rather longer period elapses before unripe seeds actually germinate, but frequently the progeny is equal to the best from mature seed. Indeed, it is stated that

the Brazilians always employ unripe seeds to propagate *Hancornia speciosa*, a valuable fruit tree, believing that the fruit borne by trees raised from immature seeds is of a superior quality. Formerly it was supposed that only exalbuminous seeds, or such in which the embryo fills the greater part of the seed, would germinate when unripe, but M. Sagot, a Frenchman, succeeded in germinating green grain of Wheat in which the albumen was soft, semi-liquid, and milky, and several other experimentalists have raised different cereals from grain collected a fortnight to three weeks before the crops from which it was taken were ripe. The gentleman named also records having raised Peas from seeds weighing one-half, one-fifth, and even one-twelfth of their normal weight. The half-weight seeds germinated rapidly, and produced plants hardly different as seedlings and afterwards from those sprung from fully ripe seeds. Those one-fifth of the normal weight germinated less quickly, and the seedlings were slender, and grew slowly at first; but in course of time they acquired strength, and produced flowers and fruit. Of the seeds sown when only one-twelfth of their normal weight, many did not germinate, and some died after the commencement of their development; and those which survived were very feeble, and grew very slowly. Although the practice of sowing unripe seeds is not likely to become general, and would not be profitable under ordinary circumstances, it might be useful to know, in the case of a rare plant suddenly dying before its seeds were mature, that there was a possibility of their germinating, and thus preventing the loss of, may be, a valuable plant.

**GERMINATION OF THE SPORES OF FERNS.**—In another paragraph the spore is described, and some phases of its development into a plant briefly examined. Being a microscopic

Fig. 77.—A seedling of *Salisburia aliantifolia*, showing the mode of germination, cotyledons remaining within the testa.

body, and its germination presenting no visible modifications, except of an anatomical character, there is little more to be said on this point. The spores of some Ferns possess the remarkable property of retaining their vitality or power of vegetating for a considerable number of years if kept dry,

several species having been raised from spores taken from dried specimens which had long been lying in herbaria. This is all the more wonderful when we consider that they are exceedingly minute, one-celled bodies; and furnishes us with a striking illustration of what an occult thing the principle of life must be. Most spores lie several weeks before germinating, and some of them for months, but those of *Osmunda* begin to grow in a few days after they are shed or sown; and the spores of the Hymenophyllum should be sown when collected, or they are likely to fail, though failure may possibly often be due to unisexual prothallia.

GERMINATION OF CONIFERS AND CYCADS.—Conifers have albuminous seeds, and the straight embryo lies in the axis of copious, usually oily, albumen. The seeds vary much in size and form. The cone-shaped seeds of *Araucaria Bidwilli* are from 2 in. to 2½ in. in length, and 1 in. to 1½ in. in their greatest diameter; whilst those of the *Cypresses* are small and nearly spherical, many of them not larger than quite small shot-corns. The Pines have flattened seeds, often with an oblique appendage at one end. In *Abies* alba the seeds themselves are not more than one-sixteenth of an inch long, and the delicate membranous appendage about three-sixteenths. The number of cotyledons varies from two to fifteen, the true Pines always having more than two. *Salisburia adiantifolia* (fig. 77) has two opposite cotyledons. By studying the germination of this species one may obtain an idea of the general plan. On

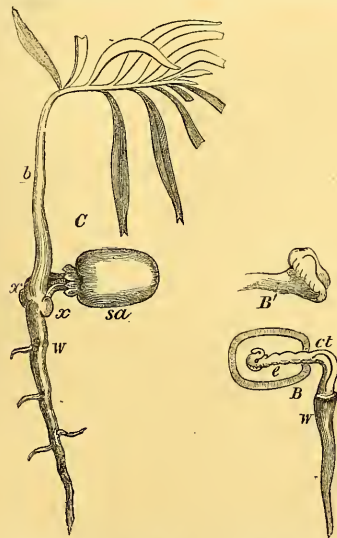

Fig. 78.—Germination of *Zamia spiralis*. B, commencement of germination; ct, the cotyledons cohering above their elongated base, one of them being at its apex a lobed (magnified as B) expansion indicating the pinnate leaves which follow; c, seedling, six months old; ca, seed; w, primary root; d, the first pinnate leaf; x, x, rudiments of adventitious roots which afterwards grow out. (After Sachs, reduced.)

the absorption of moisture the testa splits open at one end, whence the radicle emerges, as well as the lower part of the cotyledons. The radicle grows rapidly downwards, and soon the plumule appears between the bases of the cotyledons, the upper part of the cotyledons remaining within the testa until the albumen is absorbed. In *Salisburia* the cotyledons are never withdrawn from the testa, but the cotyledons of Pines, &c., eventually appear above ground and change green, often bearing the testa, which they ultimately cast off. Cycads present a similar kind of germination to that of *Salisburia* (see fig. 78). The radicle first emerges, and afterwards, from interstitial growth, the bases of the two cotyledons are pushed forth. The cotyledons are unequal in size, and coherent by their faces in the upper part, the larger one exhibiting some

indication of the future pinnate leaves (fig. 78, B'). They remain in the testa, gradually developing a spongy tissue, which acts as an absorbent of the albumen until the whole of it, or as much as the seedling requires, has been conveyed through the bases of the cotyledons into the growing plantlet. When the albumen is exhausted, or as soon as the seedling is able to assimilate food for itself, the cotyledons decay and detach themselves from the plant. The beginning of the germination of *Zamia spiralis* will be understood on reference to the section of a seed (fig. 78, B).

GERMINATION OF MONOCOTYLEDONOUS SEEDS.—The different families belonging to the class of plants whose seeds have only one cotyledon offer several very distinct types of germination. The individual seeds of some of the Orchids are almost invisible to the naked eye, whilst the seed of the double Cocoa-nut (*Lodoicea sechellarum*) is upwards of 1 ft. in diameter. Albuminous and exalbuminous seeds occur, but the latter are usually small. Two or three of the principal types may be described here. There is no universal plan of germination of monocotyledonous embryos as distinguished from dicotyledonous embryos, but the radicle or radicular end of the monocotyledonous embryo perhaps never forms a permanent tap root. But it is very misleading to state, as it does in some text-books, that the posterior or lower extremity of the axis of monocotyledonous embryos is never developed, as we shall presently see. There is, however, a very common mode of germination in monocotyledons, though not peculiar to them. The radicle, or primary root, instead of being a direct prolongation of the posterior end of the embryo, arises within a sheath or integument, which it bursts and protrudes through in germination. W. B. HEMSLEY.

Gum Ladanum-Gathering in Cyprus and Crete.—Gum ladanum, or labdanum, formerly largely used for incense and plasters, has become a very rare product in the East. A very small quantity is gathered in Crete and Cyprus from the twigs of the *Cistus roseus*, *C. villosus*, *C. salvifolius*, *C. creticus*, and *C. ladaniferus*. It is collected by means of a curious instrument, called by the natives of these islands a "lavhanostirion." It consists of a long handle surmounted by a hemisphere of wood, to which a number of leather thongs are attached. The instrument is drawn backwards and forwards amongst the bushes, and the thongs become speedily covered with the gum, which is scraped off from time to time. It has been figured by Joseph Detrich in his work on this subject. The so-called Gum ladanum, which is at present used in pharmacy and perfumery, is a fœtitious compound of mastic, olibanum, and styrax. The real gum is collected by allowing a herd of goats to graze amongst the *Cistus* bushes for a certain time. Their heads and tufts on their tails are then cut off and the gum melted out. The monks on these islands are in the habit of lending their herds of goats to the ladanum gatherers on condition of receiving a percentage of their profits.—X. LANDREER.

*Grevillea filicifolia*.—The habit and general appearance of this *Grevillea* are greatly superior to those of the well-known *G. robusta*. Its leaves, which are light green, are finely cut, and are produced in a gracefully drooping manner, rendering the plant either for table or greenhouse decoration one of the most desirable which we possess.—S.

*Vriesea tessellata*.—For furnishing vases in rooms this plant is well worth attention. It succeeds well under ordinary warm greenhouse culture, and the yellow and green tessellated markings of its leaves have at all times a pleasing appearance, and when in spring the plants begin to make new growth the delicate yellow leaves produced from their hearts, slightly veined with green, render them equal in appearance to the best of the *Pandanus*.—C. S.

*Festuca ovina curulea*.—This beautiful hardy plant, commonly called the Blue Grass, has a charming appearance when grown in small pots in the plant stove during winter. It contrasts well with *Isolepis gracilis*, and requires exactly the same treatment. I find, too, that in strong heat its colour becomes brighter than it otherwise would be. For mixing in bouquets and table decorations it is invaluable, giving them, as it does, such a light appearance. I have often been surprised that it is not more used for such purposes.—H. HARRIS, *Denne Park, Larkham*.

*Dracena Rothiana*.—Amongst the thousands of decorative plants grown by Mr. Wills, of South Kensington, this forms one of the most important. It is a plant of free vigorous growth, and its broad, gracefully-drooping, deep green leaves, associated with flowering plants under gas-light, are strikingly effective. For room and window decoration it forms a good companion to *D. terminalis*, both of which are easily cleared of dust, and they will last for a long time in good condition without much attention.—C. S.

## THE LIBRARY.

## THE "CHALLENGER" EXPEDITION.\*

ALTHOUGH put forward as being only a preliminary account of the work done by H.M.S. "Challenger" in the Atlantic in 1873 and part of 1876, this is a truly splendid work, and does honour to all concerned in its production. There is much in it that will interest the botanist and horticulturist, although the lion's share of the writer's attention has been given to the zoological departments of natural history. It may serve as a specimen of the entertaining style in which the book is written if we give an extract from Sir Wyville Thomson's account of the Monastery at Belem, near Lisbon:—"The interior of the church is even more pleasing than the exterior. Here there is no

excess of ornament, but simple, delicate shafts of pale grey marble support, with all the airiness of effect of Moorish architecture, a wonderfully carved and fretted Gothic roof. Service was going on when we were there. The church was cool and dim, and the clear sweet voices of the choristers rose and fell along the aisle, and seemed to linger in the roof among the sculptured Palm leaves. The high altar, with its lighted candles and vases of flowers, and the rich robes of the officiating priests, formed a warm patch of colour strongly in contrast with the cold simplicity of the grey marble. A small flock of worshippers, whose strongly-marked olive faces and picturesque attire had, to us, all the interest of novelty, made up for their small number by the apparent earnestness of their devotion. The whole scene struck us as being wonderfully harmonious and pleasant. The Monastery of Santa Maria of Belem, commonly called the Monastery of St. Jeronymo, from its having been occupied by monks of that order, is in connection with the church, and, with it, was founded in 1499 by King Manoel the Fortunate in commemoration of the discovery of the Indies, on the spot where Vasco da Gama embarked on his first eastern voyage. The monastery is now used as a State asylum for upwards of a thousand poor children. Visitors are ad-

mitted to the cloisters at three o'clock; and as that hour had not arrived, we were turning away from the door, when a servant opened it and invited us to enter. We passed through an archway into a large quadrangle with the sun shining brightly into it. Flower-beds occupied the centre of the square, cut out in various shapes, and separated by neat, trimly-kept gravel walks. The beds were planted with Oranges and Bananas, and clumps of Aloes, with their rich crimson spikes, alternated with the cool, white cups of the Calla; while Heliotrope and Jasmine, and many aromatic flowering shrubs and herbs sent up an almost oppressive fragrance into the warm

still air. While we were there several beautiful hawk-moths were hovering over the flowers, and dipping their long trunks into their bells."

The description of a Spanish Cork forest is very interesting. The trees are planted at some distance apart, with the green turf beneath and between, like the Oaks in an English park. The foliage of the Cork tree is dark and grey, and somewhat scanty, but the sombre-coloured trunks and branches were beautifully relieved here and there by the furry tawny rhizomes and bright green fronds of a Davallia growing in the clefts of the branches or the deep grooves of the split Cork. The account of the wonderful profusion of flowers in Madeira almost makes a person dissatisfied with one's own home. Even in the town of Funchal itself green flowering creepers hang across the streets in festoons and garlands, and clothe the walls and

trellises with gorgeous masses of colour. The climate of the suburbs of Funchal seems to be particularly favourable to the Bougainvillea, which is found everywhere in every shade of colour, from brick-red through crimson and violet, to delicate mauve. From its brilliancy, depending on its bracts and not on the flower, it lasts a long time, changing its appearance but little from early December to the middle of August. The *Bignonia*s, too, are singularly luxuriant in the capital of this favoured island. *B. venusta* runs into long wreaths, clustering round every projection, and throwing out countless trusses of orange bells. An interesting account is given of the preparation of true Bermuda arrowroot—the starch of the *Maranta arundinacea*. The superstition that arrowroot must necessarily be better than any other kind of fecula seems to be dying out, for Sir Wyville Thomson tells us that the quantity produced has been steadily decreasing for the last few years. West India arrowroot, which is cheaper and just as good, has nearly driven it out of the market, and the Bermudans are now turning their attention to growing the easily-cultivated and profitable Potato instead of the troublesome Maranta. Bermudans were formerly celebrated for its Oranges, but in 1854 a *Coccus* suddenly made its appearance, and destroyed the whole of the cultivated trees. Wild, self-sown Oranges, Lemons, and Limes still continue to perfume the air in the thickets of the island, but the cultivated varieties had disappeared from the gardens. Two of the best woodcuts in the book—and that is saying a great deal, for they are all super-excellent—are the natural swamp vegetation, Bermudas, and the Papaw trees in a garden in the same island. An *Altingia excelsa* and a *Cryptomeria* in the garden of M. do Canto at St. Michaels, in the Azores, are also beautifully drawn and engraved. A most interesting account is given of the culture of the Orange in St. Michaels. The mode of manuring the Orange gardens is a singular one, said to have been introduced by the Romans into our own island in the old days. Lupines, which grow rapidly and luxuriantly, and produce a large quantity of highly nitrogenous seed, are sown thickly in the hard soil, and when full grown are dug into the

Papaw trees (*Carica papaya*) in the Garden at Clarence Hill. From a Photograph.

\* "The Voyage of the 'Challenger.' The Atlantic: a preliminary account of the general results of the exploring voyage of H.M.S. 'Challenger,' &c. By Sir C. Wyville Thomson, Knt. In two volumes. London: Macmillan & Co., 1877.

ground—roots, stem, leaves, pods, and seeds. No other manure seems necessary. There is a beautiful little cut of the Orange groves near Ponta Delgado, St. Michael's, which reminds one strongly of the glorious Concha O'bro outside Palermo. The comic element is not neglected. The cut of the penguins at home in a bower of reeds is irresistibly ludicrous. It is rarely that we have the privilege of reviewing a book in which everything is executed in so perfect a manner—matter, cuts, and index, printing, paper, and binding—as Sir Wyville Thomson's delightful volumes.

"The Voyage of the 'Challenger'" will doubtless shortly appear in a French dress, but in this instance the publisher will have no need to have the illustrations re-engraved, as has been the case with too many of our recent illustrated books of travel or research.

C. W. QUIN.

**Carbolic Soap v. Mice.**—If your correspondent (see p. 207) who has failed in saving his Crocuses from the deprivations of mice will try carbolic soap, I think he will be more successful, as all vermin

## GARDENING FOR THE WEEK.

### Indoor Plant Department.

**Orchids that require exceptional treatment.**—In any considerable collection of Orchids there will necessarily be some found that are not naturally so free in flowering as others; and some still further, that, although they grow well, can rarely be induced to flower at all. In the latter case it will generally be found that there are some conditions under which they grow naturally, so far absent in the cultivated state they exist under as to prevent their flowering altogether. At one time there was an idea prevalent amongst Orchid growers, and by those of limited experience is even yet entertained, that if plants which make free growth are subjected to an extreme drying process, carried on for a length of time after growth is complete, they may be what I may term forced to flower; but wherever a flowering condition is brought about by such treatment as this it is generally of the most meagre and unsatisfactory description, usually causing a loss of leaf and permanent injury to the plants, such as is indifferently compensated for by the insufficient character of the bloom. I have long observed that the requisite disposition in Orchids to produce flowers freely is much more dependent upon the course of treatment to

Group of Gru-gru Palms on the Croquet lawn, Mount Langton.

have a decidedly strong objection to its taste. In this district it is in great favour with farmers for dressing seed corn, and so well does it answer the purpose in the case of Wheat and Barley, as to render the aid of a boy to keep off rooks unnecessary. This is an immense saving, as these birds do a large amount of damage in a short time, and it is a well-known fact that the work of scaring them off is often badly performed, and causes much anxiety to those most interested. Although an effectual safeguard when applied to the above-named grain, it is not found to be so in the case of Beans and Peas, which, as they begin to germinate, cast their skins readily, and of this the rooks take advantage by devouring the middle and leaving the husks with the carbolic soap adhering to them. For garden seeds, such as Radishes and all the Brassica tribe, it will be found most valuable, as in most gardens finches and linnets are so troublesome that it is impossible, except under close netting, to keep them off, and it often occurs that a whole bed is destroyed in a few hours. This is a great loss, as there is not only the seed gone, but the crop is thrown behind in such a way as to interfere with a regular supply being kept up—S. D.

which they are subjected, particularly to light, air, and a more or less moist condition of the atmosphere through the whole period of their growth, than to any long-continued drying ordeal they may be subjected to when at rest. Moisture more or less in the atmosphere is an indispensable essential to far the greater number of Orchids, consequent upon the presence of such in their natural habitats; but although they will not thrive without it, still there can be no question that more should never be used than is found necessary to insure a fairly free development. In a collection of Orchids where more atmospheric moisture is kept up continuously during the growing season than the plants absolutely require growth is generally rapid, the plants have a luxuriant green appearance with large foliage very taking to the eye, yet not bearing close examination, as it is invariably weak and watery; and, despite all the severe punishing treatment by excessive drying up to which the plants are subjected when at rest, they will never flower satisfactorily, and the leaves produced under these over-moist conditions are short-lived. To illustrate what I have said in reference to the conditions under which growth is made, having such an influence on the flowering, it is only necessary to point to newly-imported plants of such things as Vandas, Saccolabiums, and Aerides; with these it will almost invariably be found on examination that they have produced

bloom-stems at every leaf, which I have no doubt it is natural for them to do, and which it is possible to get in cultivated plants, evidence of which I have frequently had; but in every case it has been where the plants had been grown without more atmospheric moisture than was absolutely requisite.

**Renanthera coccoinea.**—There are some fine varieties of Orchids that rarely flower under ordinary Orchid house treatment. Take, for instance, the Chinese *Renanthera coccoinea*, one of the finest and most distinct plants in both form and colour of flower that we possess, producing, as it does, when treated as it requires, immense branching sprays of reddish-scarlet flowers, that have few equals in their persistency, as when kept, whilst in flower, under favourable conditions, they will last from eight to ten weeks. Anyone who has a couple of Vineries, one started about the beginning of the year, another some three weeks later, wherein the first Vines are pushed on freely with fire-heat, and the second with as much artificial warmth and a system of early sifting in the afternoons, so as to run the temperature up high by closing with plenty of solar heat, hastening the crop to maturity in a way that is practised by many good Grape growers, will find this just the situation in which to grow the *Renanthera*, moving it from the first to the second Vinery as soon as the crop in the first, from approaching maturity, needs the atmosphere keeping dry. By the time the second house wants a like reduction in atmospheric moisture the *Renanthera* will have made sufficient growth, and may be then kept dry and in a temperature of about 45° at the time, after which, if put into a warmer and moderately moist atmosphere, it will flower. During the whole time, both when making growth and at rest, the plant should be kept as near the light as possible. Close to the upright glass at the end of the house is the best position, as here the shade from the Vines overhead will not keep it too dark. The reason that this, one of the finest and most desirable of Orchids, will succeed under such treatment is, that in a position like this it receives the requisite amount of heat with a much drier condition of the atmosphere, consequent upon more air being given, than it could have amongst the majority of other Orchids without their being treated in a way that would injure them.

**Schomburgkias and Senticarias.**—Amongst other plants that require less moisture than the majority of Orchids are *Schomburgkias* and *Senticarias*. The *Demarcia* species of the latter (S. Steell), when well grown, makes its perfectly round, whip-like-shaped leaves from 3 ft. to 4 ft. long, and produces large, thick, leathery, yellow-spotted flowers. I have found this to succeed much better under such treatment as the above during the growing season than that necessary for the generality of Orchids. The plants just named are remarkable for their distinct, handsome habit, and on this account alone deserve a place in all good collections.—T. B.

**Hybrid Perpetual Roses,** started in heat some time back, will now be progressing, but under no consideration should they be hurried, for, if subjected to too much heat, not only will the flowers be deficient in size and substance, but some of the weaker sorts will likely not bloom at all. In the case of such plants as have been annually forced for some years, they will be much benefited by the application of liquid stimulants. This will not only be of assistance to the flowers at present in course of formation, but it will materially increase the strength of the plants—a matter of equal importance, for the object in view in cultivating pot Roses should not merely be to secure the present season's crop of bloom, but to treat the plants in such a way that instead of deteriorating they may go on improving. For this class of plants I have found nothing better than about this time giving them a dressing of Standen's Manure, using about a table-spoonful to each plant occupying a 10-in or 12-in. pot. This, repeated twice through the season, will be found to produce a marked effect. The increasing sun's power will render it necessary now to give more air to prevent the temperature from rising too high. The pipes should have little heat in them from early morning, when the weather promises to be sunny. Give plenty of air in the roof of the house by opening the lights sufficiently, but be very cautious about its admission at the sides, for the sake of a few plants the young growth of which is more tender than that of the forced Roses, and is extremely liable to be checked if cold external air comes in direct contact with it, even on a bright sunny day. Syringe freely in the afternoons, and by that means endeavour to keep down aphides; but should these make their appearance, I have found it better to syringe with, or dip the affected shoots in, Tobacco or Quassia water than to resort to fumigating thus early in the season, for unless it be done very slightly, injury is almost certain to occur.

**Tea Roses.**—Strong plants of these that have already produced flowers will go on pushing up strong growths that in turn will bloom; and to still further assist them, give manure water once a week, and an occasional dressing of "Standen" similar to that recommended for the Hybrid Perpetuals. Do not allow the plants to get too much crowded. When a house is first devoted to Rose culture a large number of small plants are generally prepared to fill it, and then go on requiring more space, unless such is at command, or the numbers grown are proportionately reduced, they become crowded to an extent that does not admit of their getting sufficient light, a condition that with Roses more than most things is fatal to their well-being. Should worms be found to exist in the soil (which Roses in pots, by being set or plunged out in the summer time, are more subject to than most plants), means should at once be taken to remove them, for not only is their presence fatal to an efficient position of the roots, but they also reduce the whole body of the soil to a dusty state unsuitable for the roots; so much so, that wherever the earth in the pot is found containing worms there will always be a

deficiency of feeding root-fibres. I have found nothing better to expel them than water in which soil to the extent of two or three handfuls to a gallon has been added, and kept stirred for two or three days, and then applied in a clear state.—T. B.

**Stove.**—The temperature of the stove should now be raised, keeping it 70° in the night, with a corresponding rise by day; but in the mornings of apparent sunny days, reduce the fire-heat sufficiently early, so as to avoid the necessity of admitting much of the cold cutting air we get at this time of the year. Shade such plants as require it when the sun shines clear, as its effects on the young tender foliage is at this season calculated to do more harm than later on, when the leaves are more fully developed. Supply all the free-rooting, quick-growing subjects here with a sufficiency of water at the root. Syringe the plants with tepid water early every afternoon, to keep down thrips and red spider, which the higher temperature will cause to increase apace, if not kept in check by this means. In general, however, more water will be required, especially with soft-wooded plants. Here, also, do not admit side air except in small quantities, when the winds are cold and piercing; but ventilate freely at the root during the middle of the day. Pot Lilies of all kinds, the moment they show above the soil, should be brought into a light, airy situation; keeping them even a very short time after they appear above ground in a dark or only partially lighted place appears to have two effects—it draws the shoots in a way that spoils their appearance, and seems also to curtail the root-forming capabilities of the plants; these weaknesses I have sometimes better noticed in surface roots than in the roots from the stems above the bulbs, which these plants, when well grown, throw out in quantity.

**Conservatories.**—These should now be gay with *Camellias*, *Heaths*, *Azaleas*, *Acacias*, *Cytisus*, *Daphnes*, *Euphrasias*, *Hya-cinthus*, and other bulbs, *Cyclamens*, *Primulas*, *Mignonettes*, *Cinerarias*, *Violets*, *Callas*, *Bouvardias*, and many other things, the whole being intermixed with fine-foliated plants, which serve to set those in flower off to good advantage. The temperature of these structures may be kept at 45° or 50° at night, allowing a rise of 10° by sun-heat. To plants started into growth give more liberal supplies of water, and keep the atmosphere moist by sprinkling from the syringe. Introduce flowering plants from the forcing pit to take the place of those done flowering. Give air plentifully in the morning, slanting up early in the afternoon. Such as intend to exhibit their plants must now be busy training, accelerating, or retarding them. Shade a little from bright sunshine *Azaleas* and *Camellias* that are in flower, and such as have done lowering place in an intermediate temperature, and encourage them to make growth.

**Greenhouses.**—From these and other houses it may now be necessary to remove *Pelargoniums* into frames, in which they will keep perfectly well until bedding-out time. By keeping them in warm quarters, however, better supplies of cuttings are obtained. Proceed with the propagation of different subjects from seeds, cuttings, or divisions as speedily as possible, for the stronger the plants are before they are planted out the better will they flower. Prick off from the seed-pans into other pans or boxes *Camellias*, *Wiganellas*, *Petunias*, *Golden Everlets*, *French and African Marigolds*, *Amarantuses*, *Begonias*, *Chrysantheums*, *Antennaria*, *Un-cloaked Beet*, for flower garden purposes, in a very gentle heat or close pit. Pot off cuttings of all sorts as they become rooted, and after they have yielded up their tops for cuttings they may be placed in a position a little cooler than the propagating pit, unless a further supply is required. Re-pot autumn-propagated *Pelargoniums*, and place them in a close pit or frame for a time. Give them plenty of water, but do not allow them to be saturated so much as to generate damp. Prick into boxes of light soil seedlings and leaf-cuttings of succulents, and keep them in a position near the glass. Put into frames 6 in. or 8 in. in depth of light soil, pack it firmly, and into it transplant the autumn cuttings of *Verbenas*, *Ageratum*, *Lobelias*, *Calceolarias*, *Salvias*, &c.; from such a position they transplant with excellent roots. Similar frames are also extremely useful for *Dahlias*, for the roots, after being divided, may be planted in them 6 in. apart, or the roots may be started in a propagating pit or frame and transplanted to these cold frames. Sweet Peas sown in pots and boxes should be removed to cold frames after they have germinated. Stocks, *Asters*, *Argemones*, &c., may be sown in very gentle beds that are ventilated a little day and night and shaded from the sun, for after the plants have appeared they are extremely susceptible of damp. When large enough for being pricked out singly prepare another frame in the same way for them, prick them thereon, shade well for a few days, and eventually completely expose them, but replace the sashes in showery weather or at night, when they may be tilted up. Instead of transplanting the Stocks and *Asters* in frames, a wall border with a south aspect will do equally well if a few sprigs of Broom or evergreen branches are stuck in front of them; indeed, seeds of these plants may be sown out-of-doors in April with satisfactory results.

**Pits and Frames.**—In such as are heated, give no more fire-heat than is absolutely necessary to expel the frost, and give the air as early in the morning as the state of the atmosphere will admit. Towards the middle of the month the stock of bedding plants should be looked over; and soft-wooded plants, of which there is a scarcity, should at once be placed in a growing temperature to produce cuttings for propagation. The *Heliotrope* is well deserving of extended cultivation, and is very desirable in mixed arrangements. The finest varieties for bedding are *Etoile de Marseille*—a star, indeed—*Surprise*, and *Jersey Beauty*, the last very dwarf, and one of the best for bedding. As regards *Geraniums*, boxes and sashes, a portion of the variegated sorts may be placed in boxes when cuttings are required, but we would warn the inexperienced not to

be in undue haste, as the loss of a week or two is often more than regained by the superiority of the cuttings put in later. Water carefully but effectually, so as to thoroughly moisten the ball. Cold frames containing comparatively hardy plants, such as Gazanias, Centaureas, Echeverias, and Veronicas, &c., must be attended to as regards covering when the weather is frosty.

### Flower Garden.

By means of neatness and order endeavour to render all ornamental grounds as enjoyable as possible. Walks and Grass must be frequently rolled when there is no frost, and no greater improvement could be desired than to have the verges and lawns perfectly level. We do not mean like a billiard-table or croquet-ground, but where the ground naturally slopes, the fall should be uniform and regular. Where verges are irregular it is easy to turn back the turf and to make the ground quite level, and then re-turf, beating firmly with iron rammers; but do not give the edges the final trimming until such time as the Grass has taken root, and all danger from hard frost is over. Smoothness, we need scarcely remark, is one of the main constituents of beauty; therefore, a lawn that is not tolerably smooth can never please. Turn up vacant flower-beds, and renew the soil in such a way as may require that being done, and lay Box edgings. Frequently examine half-hardy plants protected during severe weather, and endeavour to render their covering efficient by giving additional protection when necessary; also protect bulbs during severe frost. Stir the soil occasionally amongst spring-blooming plants, and if slugs are troublesome scatter some air-slaked lime around the outsides of the beds in which they are growing. Edgings of *Stachys lanata*, *Cerastium*, variegated *Thyme*, *Gnaphalium lanatum*, variegated *Arabis*, variegated *Queen of the Meadow*, *Antennaria*, *leaved Daisies*, crimson-leaved *Ajuga*, the dwarf *Pampasius*, *Scabellaria*, and a few other compact-growing plants, may now be lifted, divided, and transplanted. Two-year-old edgings are generally better than one, so that, unless they exceed that age, they are better left undisturbed. The variegated *Polemonium œruleum* makes one of our finest hardy edgings; the best way of treating it is to lift the roots and pot them in October or November, to keep them during the winter in a frame or cool Peach house, and to transplant them in spring when they begin to grow. Transplant from frames, greenhouses, or pits into beds in the flower garden *Pinks* and *Carnations* wintered in pots, or autumn layers planted in light soil in frames in winter. Bulbs of *Iliza* yet in stock should be planted as speedily as possible. *Pansies* and other spring blooming plants may yet be transplanted as occasion requires; indeed, few plants are more useful at any season than *Pansies*. *Gladioli* for blooming in beds or shrubbery borders may be planted at once 3 in. or 4 in. deep, and a sprinkling of sand should be strewed under and over the bulbs. It is a prevalent idea that *Gladioli* should not be transplanted till April for fear of spring frosts; but that is too late, unless the plants are required for late flowering. Sow *Mignonette* where it is required to bloom, and hardy annuals not sown last September here and there in beds or borders for transplanting. Sow also a good stock of *Sweet Peas*, *Nasturtiums*, *Tropæolums*, and *Scarlet Runners*, either where they are to bloom or in sheltered beds or corners for transplanting hereafter to their permanent quarters. Autumn-saved roots of *Scarlet Runners* throw up shoots freely, and bloom earlier than seedlings; the roots require treatment similar to that usually given to *Dahlia*s. Divide and transplant roots of herbaceous plants of various sorts.

**Shrubberies.**—The pruning of evergreens should be finished at once, if not already done. Shrubbery borders should be lightly pointed over, taking care not to injure the roots in the operation, or to disturb any bulbous plants that may be growing amongst the shrubs. Isolated specimens of newly-planted trees, especially if large, are much benefited by a few shrubs being planted around them for a year or two, to act as a protection from wind, frost, and drought; after the trees get established the shrubs may be removed. Prune, where necessary, *Vines* on walls, and fasten any in danger of falling away from them. Uncover *Myrtles*, *Magnolias*, *Fremontias*, *Stauptonias*, *Clematises*, and other half-hardy plants on walls, and otherwise put them in order for the summer. Plant and re-arrange flowering deciduous shrubs, keeping in view ultimate effect, and so dispose of the stronger-growing varieties as not to overgrow the more delicate kinds. Even *Hawthorns*, beautiful and desirable though they be, frequently occupy the wrong rank of mixed shrubberies when they would have been better placed further back, or in groups; but all the stronger-growing kinds are in better keeping as park ornaments. The best for dress grounds are the different varieties of *Crætagus Oxyacantha*, as, for example, *Paul's New Double Scarlet*. This is a splendid variety that merits extensive cultivation. *C. O. multiplex* (the best double white), *C. O. punicea* (the finest single scarlet), and *C. O. rosea superba* may be accepted as fair types of the kinds that will give most satisfaction. The double varieties just named are splendid subjects for pot culture. If not already done, much of newly-planted trees with leaf-soil dung, or spent tan; top-dress *Hollies*, *Rhododendrons*, and such plants as may require stimulating with rotten manure and soil.

### Indoor Fruits.

**Vineries.**—As soon as the shoots are sufficiently advanced to show which are the best placed, and which are likely to produce fruit, remove such others as are unnecessary. As they advance, mark the best of the wires in the places which they ought to occupy, bringing them into their exact positions by degrees, for if bent too much at once they are liable to break. Close the house early every afternoon, and syringe overhead freely with tepid water. See that inside *Vine* borders are sufficiently moist all the way down; through inattention to this, *Vines* suffer more frequently

and seriously than from any other cause. The appearance of the surface of the soil through daily syringing is very deceptive, as the top will often seem wet enough when below it is much too dry. Naturally there is a disinclination to disturb the soil in which the roots ought to be thickly interspersed by using a fork or other implement to examine what is the actual condition of the bottom portion of the border, but it is very easy to ascertain the exact state as to moisture from the surface down to the drainage by the use of the little implement which I have before mentioned. It consists of a hollow tube of thin iron open at both ends, in diameter something like an ordinary gun barrel; this, thrust down as far as the drainage, of course comes out charged with the soil, when, by pushing it out with a stick something like that used in the case of a boy's pegging, the condition of the soil may be seen at a glance. By using the implement in different parts of the border, the state of the whole can be ascertained with the slightest possible injury to the roots; it will involve little cost and equally little labour, and is much better than remaining in doubt as to the condition of the soil.

**Peaches** under glass, in houses closed a short time ago, will now be in full bloom; go over them daily, and strike the trellis to which they are trained with the hand; the vibration thus produced, if done in the middle of the day when the pollen is dry, will help to disperse it and assist the setting of the fruit. Always examine the soil to see that it is sufficiently moist right through the border as far as the roots penetrate; the Peach is a water-loving plant, and will not succeed if the soil be at all dry. Give air more or less every day, according to the state of the weather, but avoid cold draughts coming in contact with the young and tender foliage. Be careful not to allow anything like overheating, as *Peaches* cannot bear, especially in their early stages, being buried; a temperature of 46° or 45° is quite enough at night, and it should not be allowed, even on sunny mornings, to rise more than 16° above that without giving air.

### Hardy Fruits.

**Peaches and Nectarines.**—All Peach walls should be furnished with movable copings, the best of which undoubtedly are the permanent iron brackets with movable sheets of glass, the only objection to this being its first cost. A very efficient and inexpensive coping may be made of  $\frac{1}{2}$ -in. Spruce boards; the brackets to support these should be flat wrought iron, 1 1/2 in. wide by  $\frac{3}{4}$ -in. thick; these should pass immediately under the stone coping of the wall, and, to render them more secure, ought to be bent down 2 in., so as to clip the bricks at the back of the wall. Supposing that the permanent stone coping overlies the front of the wall 3 in., these iron brackets should extend 1 1/2 in. from the wall, and be turned up at their outer extremity  $\frac{1}{2}$ -in., that is, the thickness of the boards. In the middle of this turned-up there ought to be a hole that will admit a small screw, which must be screwed into the front edge of the board to secure it there. The brackets should be bent from the wall at an angle of 35°; the boards used should be 1 1/2 in. in width, which will allow of their slipping under the stone coping to a distance of 1 in., the angle to which the brackets are bent leaving room for this. The light or heavy character of the shading material used will determine the distance apart of the brackets. In moderately high-lying dry localities, where, in addition to the boards, a light material will be sufficient, the brackets may be 3 ft. or 10 ft. apart. In situations of this description, old fishing-nets, which can be had in most parts of the country at 1d. or 1 1/2 p. per yard, and which, further on in the season, are very useful in protecting *Strawberries*, *Cherries*, &c., from birds, will be ample. These should be tacked to the front edge of the boards sufficiently close to leave no openings, and to prevent the wind blowing them against the trees, which would only do serious harm. They must be secured at the bottom; this can be done by inserting in the ground, 6 ft. apart, stakes of the strength of a broom-handle, to which the nets are tied. This protection may, without injury to the trees, remain on from the first opening of the bloom until the fruit is fully set. For situations that are not exceptionally low, damp, and under the influence of more than an ordinary amount of spring frost, it will be found all that is requisite. I have had under such covering a full crop of *Peaches* and *Nectarines* during a season when we had 16° of frost whilst the trees were in bloom, the atmosphere and the trees being quite dry at the time. There are some places so unfavourably situated as to require thicker protecting material than the above, such as stout canvas. When this is necessary should be made in lengths of 25 ft. or 30 ft., fastened with strong tacks to the front of the coping boards, and securely tied to stout stakes driven in the ground at the bottom. A thick covering of this sort, of course, must be removed in the daytime. This can be done by folding it up from the bottom, and laying it on the top of the coping board, where it must be secured by cords, at intervals of 8 ft. or 10 ft., passing round the boards, to which they are nailed back and front; with these cords the canvas must be tied, to prevent its blowing about. A handy man, with a light ladder will, in a short time, cover and uncover in this way a wall of considerable length. Heavy coverings of this sort are frequently fixed with rings on wires, top and bottom, to slide as curtains, the objection to which is that, however tight the wires are fixed, even when in short lengths, the weight of the curtains causes them to dip at the top, leaving an opening, through which the wind rushes on to the trees. Heavy coverings of this description will necessitate the supporting brackets being nearer together.

### Kitchen Garden.

**Asparagus.**—Established beds of *Asparagus* should now have a portion of the surface-soil removed into the alleys, where it should be dug in, while the surface of the beds themselves should have fresh soil, a dressing which should be followed by a liberal application of salt. Besides being a suitable manure for *Asparagus*, salt also, to some extent,

prevents the growth of weeds, and destroys or drives away slugs and other depredators. Where fresh plantations of this esculent are intended to be made, the beds for the reception of the roots should by this time have been duly prepared, and the planting should be done as soon as the plants have commenced to grow, or when they have made shoots of about 1 in. in length. Plants one year old are generally found to be best for this purpose, and one-year-old plants of the variety known as Conover's Colossal will be found to be in all respects equal to two two-year-old plants of the common kind. Some prefer sowing seeds upon the prepared beds at once, and afterwards thinning out the plants to the proper distances apart, which should be 18 in. Remove the littery matter which may have been placed around the stools of Globe Artichokes for protection, and thin out the offsets, or suckers, which may be used, if required, to form fresh plantations.

**Peas** now in turves or boxes should now be planted out; give them a sheltered situation in the driest part of the garden, and choose a day when the soil is tolerably dry. Where it is so moist as to become compressed by treading upon, boards should be used. The little extra labour thereby involved will be well repaid by the better condition in which the ground will be left, as when trodden solid through this and the following month, and dry weather ensues, it becomes so hard and impervious to the roots that even the strongest-growing plants fail to succeed in it, if they otherwise would do. As soon as the Peas are planted draw a little soil to them, and at once stake them with small sticks, placing outside these a few branches of evergreens to protect them from cold winds. Keep a daily look-out that sparrows do not molest them. I have seen these birds attack early Peas even up to the time that the flowers were formed, nipping out the extreme points, after which the plants make but slight progress, for although they make an attempt to break out lower down, yet the produce of the early sowings that have suffered is never more than half a crop. Except in very light soils, ground that was dug and ridged up in the autumn from the excessive wet and absence of frost to pulverise it will this season require more stirring before cropping than the ridges being levelled in the usual way, as where the soil is heavy it has become as close and solid as it would be in ordinary seasons if not dug at all, and it will be necessary to re-dig it, after which, so far as possible, let it remain for a short time before cropping. In all cases the fork will be a better implement than the spade for this work. Leave the surface as light and open as possible, thoroughly breaking up pieces all hard lumps of soil. Hoing the surface on fine days will do much to dry the soil and thereby benefit the crop.

#### Extracts from my Diary.

**March 25.**—Sowing Veitch's autumn Giant Cauliflower; also Veitch's autumn self-protecting Broccoli (the last-named I consider a great boon to cultivators; we had it in use from the middle of August to the end of February). Putting in cuttings of *Santolina* under hand-lights. Potting on young *Fuchsias* in 6-in. pots. Dividing and re-earthing. Thinning out the autumn-sown Lettuce, and forking over the ground amongst the plants.

**March 26.**—Sowing two rows each of the following sorts of Peas:—James's Prolific Marrow, G. F. Wilson, Carter's Commander-in-Chief, and Giant Emerald Marrow; also Cucumbers and Melons. Putting in cuttings of *Coleus* and *Alternantheras*. Cutting back some old Apple and Pear trees, and grafting them with better sorts. Renovating the living round frames. Getting Green Gage and other Plum trees covered with double netting for protection.

**March 27.**—Sowing Carter's Dwarf Crimson Celery, Sweet Basil, and Sweet and Pot Marjoram. Pricking off *Petunias* and *Lobelias*.

Looking over all the Strawberries that have set their fruit, and removing all that are deformed; also late flowers. Raking down the Asparagus beds, forking over the surface of them, and giving them a light top dressing of salt. Breaking up and turning over gravel walks to give them a fresh appearance.

**March 28.**—Sowing Canadian Wonder French Beans in pots; also Mustard and Cress. Putting in cuttings of herbs of sorts; also *Iresine*, *Dahlia*, and *Mesembryanthemums*. Potting off *Tomatoes* and Sweet Basil. Planting out autumn-sown Red Cabbage plants. Digging up the alleys between Asparagus beds and planting them with Cauliflower plants. Looking over *Battles* in bottles, cutting out any berries that are bad, and filling up the bottles where required.

**March 29.**—Sowing the main crop of Parsley, Early Savoys, Brussels Sprouts, and Snow's Early White Winter Broccoli. Potting off *Iresine*, *Coleus*, and *Alternantheras*. Getting all Broccoli into the store shed as fast as it becomes fit for use. Planting Globe Artichoke suckers and Sea-kale plants in well prepared ground. Clearing off Savoy stumps. Manuring the ground and getting it dug up.

**March 30.**—Pricking out Celery and Brussels Sprouts; also Veitch's Autumn Giant Cauliflower (sown in January). Thinning out *Mignonette* in pots. Lifting some large clumps of *Lily of the Valley* and putting them into gentle heat. Looking over the Pines and giving them water where required. Lifting up *Petunias* in frames. Thinning Grapes, and tying down the young shoots in early Vinery. Tying in young shoots in early Peach house. Cleaning up the pleasure grounds and rolling down all gravel and turf that require it. Fruit in use for dessert:—Pines, Grapes, Peas, and Apples.—W. G. P., Dorset.

A Weeping *Gleditsia*.

*Spiraea palmata* elegant.—This new *Spiraea* is a grand acquisition for our collections of hardy plants. Its inflorescence is light and elegant, the crimson stamens contrasting well with the white petals. M. E. Pynaert, of Ghent, believes that there is a great future before this plant, which is described as a hybrid between two parents, which both occupy an eminent position in the horticultural world, namely, *Spiraea palmata* and *Astibe japonica*; and that it will be propagated and cultivated extensively for the ornamentation of greenhouses and apartments as a forced plant. From this point of view the new *Spiraea* is superior to the original *S. palmata*, since it is said to bear a high temperature better than this latter, whose flowering sometimes miscarries when it is urged on too rapidly.

Whether or not this novelty is really a hybrid, as is supposed, or only a seedling variation of *S. palmata*, as seems possible, it will be recognised as a hardy herbaceous plant of great and delicate beauty, and one which is likely to be freely grown for market and for decorative purposes. *S. p.* elegans most nearly resembles *palmata* in its foliage, but its inflorescence is of an intermediate character, and more branched than that of its female parent, which is terminal. The individual flowers have pure white petals, and in their centre a tuft of red stamens, which by-and-by spread out over the petals, these flowers being crowded upon the branches of the panicles. A peculiar and distinctive character is found in the increased number of leaflets in the foliage, which are twice as many as those of *S. palmata* itself. It is a vigorous plant, attains 2 ft. or more in height, and is perfectly hardy, growing freely in any good garden soil and eligible situation, and propagating easily, so that it may be expected, says M. Pynaert, "promptly to make the tour of the world." It is certainly a very fine subject for decoration, and a welcome addition to our hardy flower gardens.—"Florist."

**A Weeping *Gleditsia* (*G. Bojoti*).**—Among the various Weeping Trees now in the gardens of Europe we know of none more graceful than this, which is supposed to be a variety of that fine tree *G. triacanthos*. We have noticed several good specimens of it in

Paris gardens of late years. The trees "weep" in a picturesque manner, though not perpendicularly, and the form of the tree is broken and graceful in outline, the leaves elegant, and the shadow as light as that of a Grass. There is a good specimen in the Garden of Plants, but the best we have seen is in Baroness Rothschild's gardens, at Boulogne. We fear this tree is as yet rare in our nurseries, though it is deserving of general culture.

OPEN AIR VEGETATION IN FEBRUARY, 1878.\*

FEBRUARY, upon the whole, has been a very enjoyable month; there was little wind, and the sun was frequently seen. East wind was only experienced for two successive days; there was also very little rain and no snow fell. During the month vegetation made rapid progress, but in most instances not very robust. With the exception of *Rhododendron atrovirens*, *R. dahuricum*, and *R. præcox superbum*, which were particularly fine this season, the buds of the early scarlet *Rhododendrons* are very scarce, and far from strong. The forcing of many of the plants of the *Rhododendron Noëleanum* has been very precarious, when compared with the forcing of the same kinds whose buds were ripened during former years and after a fine summer. The same remark holds good this year with the forcing of many plants of *Deutzia gracilis*, *D. crenata*, *Astilbe japonica*, *Lilacæ*, &c. Fruit trees were far advanced during February, particularly *Jargonelle* Pears on walls, the buds of many being expanded. Buds are also far advanced on standard Apples, Pears, and Gooseberry bushes. The Scotch or Witch Elm is in flower, and leaves are also forward on many deciduous trees, such as *Thorus*, *Lilacæ*, *Ribes sanguineum*, *Nuttallia cerasiformis*, *Willows*, *Elder*, &c., and even the Larch trees have a greenish tinge over their branches. Numerous herbaceous plants have already made growth several inches long; of these may be mentioned the *Crown Imperial*, 10 in.; *Papaver orientale*, 8 in.; *Symphytum tauricum* and *caucasicum*, each 18 in.; *Hemerocallis fulva*, 12 in.; *Orobis elegans*, 6 in.; *Verbascum longifolium*, 10 in.; *Ferulas*, 12 in.; and the *Bunch Grass* (*Elymus condensatus*), 14 in. Many of the *Brassicæ* or *Cabbage* tribe are rapidly running to flower, kinds which ought now to be useful for culinary purposes; *Grass lawns* are very beautiful and green, as well as the foliage of all evergreen trees and shrubs. The *Biota elegantissima* and *B. aurea* have already assumed their green or spring phase, the brown or winter hue having entirely disappeared.

The dryness of the ground without frost, along with the comparative mild weather which we have had recently, has been the means of causing many herbaceous plants to flower, a larger number being in that condition this year than is usually observed during the month of February. Many kinds of bulbous plants were in flower during the month, while others were later, in consequence of the bulbs having been injured, and some having rotted in the ground, from previous excess of moisture.

Of the forty-two plants whose time of flowering has been recorded for these last twenty-eight years, the following twenty-one flowered during February:—

	1878.	1877.
<i>Eranthis hymalis</i> . . . . .	Feb. 2	Jan. 26
<i>Galanthus nivalis</i> . . . . .	" 4	" 16
<i>Crocus susianus</i> . . . . .	" 6	" 20
<i>Galanthus plicatus</i> . . . . .	" 7	" 26
<i>Leucjum vernum</i> . . . . .	" 8	" 18
<i>Rhododendron atrovirens</i> . . . . .	" 8	" 25
<i>Dondia Epipactis</i> . . . . .	" 9	Feb. 11
<i>Tussilago fragrans</i> . . . . .	" 9	Jan. 3
<i>Corylus Avellana</i> . . . . .	" 10	" 1
<i>Sisyrinchium grandiflorum album</i> . . . . .	" 10	Feb. 17
<i>Aubrietia grandiflora</i> . . . . .	" 13	Jan. 17
<i>Nordmannia cordifolia</i> . . . . .	" 15	Feb. 16
<i>Tussilago alba</i> . . . . .	" 15	Mar. 8
<i>Crocus vernus</i> , and varieties . . . . .	" 17	Jan. 28
<i>Scilla sibirica</i> . . . . .	" 18	Feb. 20
<i>Sisyrinchium grandiflorum</i> . . . . .	" 19	" 20
<i>Draba aizoides</i> . . . . .	" 19	Mar. 11
<i>Daphne Mezereum</i> . . . . .	" 22	Jan. 26
<i>Scilla præcox</i> . . . . .	" 22	Feb. 16
<i>Scilla bifolia</i> . . . . .	" 28	" 24
<i>Tussilago nivea</i> . . . . .	" 28	Mar. 18

On Feb. 26 the first open flower was seen on *Aponogeton distachyon* in the pond. In the rock garden the most interesting plants in bloom during February were *Hepaticas* of different sorts, which were particularly fine and flowering profusely between the crevices of the rockwork stones having a northern aspect. In similar situations we have also numerous plants of *Primula vulgaris rubra*, now in exquisite beauty, where they have been flowering since November last.

*Primula denticulata*, *P. purpurea*, *Rhododendron præcox superbum*, *Daphne Mezereum*, *Erica carnea alba*, and *Andromeda forficuuda* are also flowering freely. Besides these we have specimens in bloom in larger and smaller quantities of *Crocus Imperati*, *C. Etruscæ*, *C. nivalis*, *C. biflorus*, *C. annulatus*, and *C. suaveolens*, *Leucjum vernum*, *Galanthus nivalis*, *G. plicatus*, *G. Elwesi*, *Sisyrinchium grandiflorum album*, *Dondia epipactis*, *Helleborus colchicus*, and several other varieties, also *Aubrietia grandiflora*, *Veronica rupestris*, and *Lithospermum fruticosum*, &c. In no instance up to this time (Feb. 28) has open air vegetation suffered from frost, and in consequence slugs and other vermin are beginning to make their appearance.

The thermometer during February was eight times at or below the freezing point, indicating collectively 35°. The lowest markings being on the mornings of the 2nd, 3rd, 9th, 11th, 12th, and 13th, indicating 23°, 25°, 27°, 28°, 27°, and 25°, while the six highest morning temperatures were on the 16th, 17th, 20th, 21st, 22nd, and 28th, indicating 41°, 44°, 42°, 41°, 45°, and 42°. For the last twenty-four years the united frosts during the months of February amounted to 1517°. I have already stated that 35° were experienced during February this year, 36° being observed during Feb., 1577, 113° during Feb., 1876, 123° during Feb., 1878, 165° during Feb., 1864, 125° during Feb., 1860, and 220° during Feb., 1855; while the lowest February markings were during 1869, when 6° only were recorded, but in that year much damage was done to vegetation by frost before the end of March.

**Primroses in Kent.**—There is a wonderful wealth of these charming flowers in hedgerows in Kent. In the neighbourhood of the Romney Marshes the roadsides, woods, and dells abound with them; the plants are generally robust in growth, and the flowers very large. In the cottage gardens there are some pretty coloured varieties; and, indeed, the cottagers in the particular district in Kent to which reference has been made vie with each other in setting forth pretty spring displays in their forecourt gardens. I saw some pretty white, red, and lilac Primroses, and in one garden an old lady was so conservative of a bright maroon-coloured variety as to be insensible to any entreaties of mine to purchase a root. It was a possession, apparently, belonging only to herself, and probably that was the reason why she so stoutly stood by it. Where the common Primroses were finest I looked carefully for a double form of the wild Primrose, but could not find one. I have heard that they have been occasionally met with, but no one to whom I applied for information had observed it. I secured one plant having a large flower containing two pistils; it was perhaps a fasciated blossom, but I will save the seed from it, and see what it produces. Another peculiarity was noticeable, that of the absence of a scape; but the Primroses were only coming into flower, and a scape would probably appear with the latest blossoms.—D.

**Dividing Irises.**—We have had to break up many old clumps of *Iris germanica* this spring that have grown out of all bounds, and formed a ring around a bare island of soil. I want to re-plant portions of them that are certain to produce flowers—no chance work. Good strong pieces do not always flower, although that is the only answer one gets to such an inquiry as this. As we grow these Irises in groups of three colours it is mortifying when anyone fails, thus spoiling the effect intended to be produced. *Iris tuberosa* has not flowered for several years; plenty of Grass comes up. What should we do? Leaving it alone, the best plan with *Iris reticulata*, does not seem to suit *I. tuberosa*.—F. J. Hope, *Wardie Lodge, Edinburgh*.

**Myosotis rupeola.**—This is said to be "the most glorious blue of all the Forget-me-nots, and quite a gem for pot culture." Where can seed of it be obtained? I have applied to various firms for it in vain.—C. F. [Try some of the large dealers in herbaceous plants.]

**A Turk's-cap Cactus.**—I have sent you a singular specimen belonging to a friend of mine who is very desirous to learn to what family it belongs and what treatment is best suited to it. My friend grows it in a shaft in a window of his house, and all the nourishment which it gets is from the atmosphere.—M. CUMBERSON, *Rothesay*. [The plant, or part of one, is the cephalum of *Melocactus communis*, a native of the island of St. Thomas. It grows best in sandy soil in a brick heat without much moisture.—J. C.]

**Golden-leaved Dead-Nettles.**—I have a hybrid *Lamium*, the seed parent of which was *L. purpureum*, planted near *L. maculatum aureum*. A number of seedlings made their appearance all having golden leaves, but one, which I call *L. purpureum hybridum*, has bright golden foliage. It is a compact-growing plant, and flowers a month earlier than *L. maculatum aureum*. We shall use it largely this year for bedding purposes. Its colour late in spring and summer is a clear tawny-yellow, sobering down to a greenish-yellow in winter, during which time it is best propagated in a cold frame.—WILLIAM ELLIOTT, *Stapleford Hall, Notts*.

\*Read by Mr. McNab before the Botanical Society of Edinburgh, March 14, 1878.

## THE KITCHEN GARDEN.

## EARLY TURNIPS.

With a gentle bottom-heat, from a couple of feet or so in depth of stable manure and tree leaves, and a few old lights fixed temporarily over the bed, Turnips may be brought forward as easily, and in much the same way, as Carrots, Potatoes, Radishes, or any other vegetables that are commonly forced. Let a trench be opened at the foot of a south wall (or, failing that, a temporary screen of boards or reeds could be fixed); in the bottom put 18 in. or 2 ft. in depth of warm manure lightly trampled down, and on that 8 in. or 10 in. of light rich soil made moderately firm, and we have a bed that will in due course, if rightly managed, produce not only early Turnips, but all other kinds of early vegetables. The Turnips should be sown in drills 8 in. apart, as the roots are fit for use when young, and they need not be severely thinned, as by drawing the largest first the later plants will have space to grow. If, when the seeds are sown, a little superphosphate mixed with wood-ashes be sown in the drills, the young plants will grow with greater rapidity, and come in quicker. About 2 lb. to the rod of land will be sufficient, and if mixed with ashes or any other substance the mixing must be done thoroughly, so as to have it equally distributed. The quickest-growing Turnip is the Strap-leaved Stone, and, as it makes but little top, it is well adapted for early work. The early white Dutch Stone is also good, and it has a rather less tendency to run to seed if by any chance a check should be given, either through early drought or any other cause. Weak soot-water, in which a handful of salt to six gallons of water has been dissolved, will be very beneficial as the season advances if dry weather set in. Turnips, like Radishes, unless quickly and freely grown, are not of much use; hence the importance of keeping the soil regularly moist, especially when the roots are forming. If we had the making of a new garden, we should reserve a snug corner, with a full southern exposure, for the purpose of forming beds for early vegetables. It should be warmly fenced in, and laid out in beds 8 ft. or 10 ft. wide, with a good slope to the south. Each bed should have a temporary backing of straw or reeds, neatly woven between laths. We should not, of course, object to anything of a more permanent character. For instance, we have seen very good fences made by splitting Larch poles through the centre, keeping the flat surfaces to one face. Where Larch was plentiful and cheap, a boarded fence would not be a very expensive one; and fences of this kind might be used for training cordon fruit trees on. A temporary coping fixed to the top, and one or two thicknesses of ordinary fishing-net stretched from the coping to the front of the border, at an angle of 45° or so, would forward the early crops of vegetables immensely, and at the same time protect the blossoms on the trees. None but those who have had experience in such matters can form an idea of the amount of shelter that can be had from a single covering of netting; and the larger the space it incloses, the less is the danger of injury to the crops inclosed. The beds in a sheltered spot of this kind should never be idle. What opportunities would be furnished for Tomato culture, or Capsicums, New Zealand Spinach, or anything else that required a sunny spot in summer; and what a scope there would be for the production of autumn and winter salads!—"Field."

**Principal Vegetable Products of Greece.**—The following are the principal vegetable products of Greece and their annual value:—Quercus Ægilops, the Oak which yields the Vallones Acorn largely used as a tanning material, from 3 to 4 million drachmas (£120,000 to £160,000). Olea europæa, which produces oil of the annual value of from 80 to 100 million drachmas (£3,200,000 to £4,000,000). Ficus Carica (Figs, green and dry), 80 to 100 million drachmas (£3,200,000 to £4,000,000). Grapes and Raisins, 50 million drachmas (£2,000,000). Wine, consumed at home and exported, 100 million drachmas, £4,000,000. Rabia tinctorum (Madder-root), 500,000 drachmas (£20,000). Rhus Coriaria and Rhamnus infectoria (Yellow Berries), 50,000 drachmas (£2,000). Turpentine, Spirits of Turpentine and Resin, 250,000 drachmas (£10,000). By good management this branch of industry might be increased tenfold.—X. LAN-DENER.

**Turnips and Salsify as Salads.**—A writer in the "Nord-Est" mentions a vegetable as salad, which, as such, is little known. This is the young leaves of the Turnip. In Italy and France they cultivate them in a special way for the purpose. The Turnips, after cutting off the leaves, are placed in sand close together in dark cellars, and occasionally watered. As soon as the leaves develop themselves they are out. Of course, this will take place all the sooner if there be a little warmth in the cellar. The leaves are white, or of a pale yellowish colour, and very tender. Either mixed

with Beetroot or alone, as a salad they form a vegetable when little is obtainable from the garden. The herbaceous parts of the shoots of Scorzonera and Salsify, which are often of no use, make a very good salad when blanched, which can be done without injuring the roots. The shoots must be covered with fine earth or leaf-mould to about 6 in. deep. A fortnight after, in taking up the roots, the blanched tops are cut off, to be served with Corn Salad, Celery, Red Cabbage or Beetroot, constituting a salad greatly appreciated by many.

**Ventilating Pits.**—At this season of the year, when Radishes, Potatoes, and similar vegetables are being grown in pits, it is often impossible to give them as much air as they require, owing to the fierce March winds blowing off the lights when propped up or pushed down. In order to get over this difficulty Mr. Woodbridge, of Syon, has constructed at the back and front of his pits a row of narrow wooden shutters which can be opened or shut in an instant; a free current of air can thus be allowed to circulate through the pit, if necessary, and at the same time the lights can be pegged down without any fear of danger from wind or rain.—C. S.

## CRIMPED DANDELION.

This, according to M. Vilmorin, is a valuable variety. It forms very full rosettes, and is distinguished by short, close foliage, curiously

crimped and having a tendency to become white. Like all other varieties, this Dandelion is perfectly hardy, and is fit for use during the greater part of the year.

**Mice Eating Peas, &c.**—Some of your correspondents complain that mice eat their Peas. My advice is, catch and kill them, and the best way to do this is as follows: Procure a few common bricks and a few bits of galvanised wire 2 in. long. On each bit of wire put a Pea about  $\frac{1}{2}$  in. from the bottom end. Two bricks are required for each trap and one piece of wire. The accompanying diagrams show how

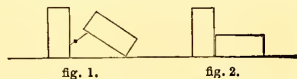

fig. 1.

fig. 2.

the trap is set, fig. 1 being set, fig. 2 the trap down and the victim dead underneath it. "G. T." (see p. 207) says he has caught three or four in steel traps. I have caught hundreds by the plan just described. In spring I have often caught five or six every morning, and as many sparrows during the day. It is an old plan, but one that never fails. It costs next to nothing, lasts a lifetime, and will work equally well in all weathers. When set on loose ground a firm bottom must be made for it, or a piece of slate or board placed underneath it. When set inside buildings one brick only is required for each trap, this being placed alongside the wall. I have caught numbers in that way. If "G. T." will try this plan, I will guarantee that he will find it to answer his purpose; and a little experience will soon enable him to set it to the best advantage.—H. HARRIS.

**Transplanting Onions.**—If not already done, no time should be lost in getting a good breadth of Onions planted in good rich soil, 1 ft. apart each way, for summer and autumn consumption. In lifting the plants, care must be taken to get the roots up as perfect as possible by loosening the soil with a fork as deep as their extremities, and holes also should be made deep enough to drop them into full length. Thus treated, they will start at once into active growth from the feeding rootlets being secured against the withering influence of parching winds, and at this early date applications of water to outdoor crops are more liable to check than encourage root action. The most popular sorts for autumn sowing are the Giant Rocca and Globe and Flat Tripoli, but the mild flavour for which they are esteemed depends very much on their culture. The rapid growth and succulence that render them so liable to decay rapidly is one of their chief merits.—JAMES GROOM, *Henham*.

## OPENING KEW GARDENS.

THE plea set up by the Kew authorities for keeping the garden closed until the afternoon on the allegation that its uses for scientific purposes would be interfered with may have weight with those who have not discrimination enough to see through such a flimsy pretext, but it only serves to exhibit the shifts to which those who object to earlier opening are put. The reasons for and against the opening, when fairly stated, are easily got at. Kew is kept up by means of the public money; the first object in doing so is to maintain it as an educational establishment, not alone for the use of those who are studying in the schools of medicine, but for those possessing more or less botanical knowledge, and who are desirous for an opportunity of seeing and observing living examples of the plants in which they are interested, and of which Kew has so many not to be found elsewhere. To the above must be added another and far more numerous, although possibly it may be said less important, class of individuals: these are the thousands connected with horticulture throughout the length and breadth of the land, and who visit Kew with a view to learn something of the immense number of plants that elsewhere are inaccessible. Plant cultivators who periodically visit London, and as regularly visit Kew, suffer more inconvenience through the garden being closed than all others put together. It is all very well to say that such visitors can gain access in the morning by complying with the requisite regulations in proof of their being *bonâ fide* botanists or horticulturists; but people do not care to have to establish proofs of their identity in this way, and it is monstrous to ask for them. It is persistently urged that earlier opening of the gardens would necessitate an increased expenditure. Those who urge this calculate upon the sensibility of the British taxpayer when any allusion is made about touching his pocket. But anyone who has visited Kew as often as I have done, and is as well acquainted with the routine work connected with a garden, can see the utter hollowness of such a pretext. No one wants, or needs, to walk on the exact spot where mowing, sweeping, rolling, or watering is going on—and these comprise nearly the whole of the operations that are carried on in the gardens in summer. As to the houses, the watering in all well-regulated establishments is finished before breakfast-time. Any attempt to make it appear that the staff engaged in the cultivation of the plants would (in the event of the gardens being opened say by nine o'clock) have more work thrown upon them, is as complete a fabrication as it is to say that those who visit the gardens either receive or require looking after by the gardeners employed on the place. The insinuation that those residing in the immediate neighbourhood want the gardens opened merely as a place of recreation to satisfy their own requirements is on a par with many other statements that have been made with regard to this matter. There is unlimited space in the neighbourhood accessible—Richmond Park in particular—where those who only want to lounge about can do so without the restrictions under which they must be put in any garden; and of these restrictions the class in question are fully aware, and act in accordance by betaking themselves where they can be without restraint. For twenty years, when living 200 miles from London, I scarcely ever missed a season in which I did not visit Kew; and if during my short stay in town I could, as opportunity presented itself, have run down when I had a few hours to spare morning or afternoon, it would have been of the greatest convenience; and I scarcely ever visited the place without meeting with others, similarly engaged as myself, who expressed themselves to be alike incommoded by the restrictions as to admission. This is a view of the subject that the residents in and about London, in this as in some other matters of a similar nature, appear to forget—that there are any other people in the world besides themselves. The fact that other establishments of a similar character existing here and elsewhere are open morning and afternoon, and which are kept up more for local use than Kew, which should be regulated to meet as far as possible the convenience of everyone far and near, is sufficient evidence of the necessity for its being open, as they are, at all times of the day.

*Southgate.*

THOMAS BAINES.

We reprint here a portion of the memorial lately published in THE GARDEN—a memorial of which the aim is to prevent

the opening of the Royal Gardens at Kew throughout the day:—

We venture, moreover, to point out that if the general public be admitted at an earlier hour than at present, the means now afforded by the unrivalled collections at Kew of meeting the wants of teachers, &c., which they supply to them, will be rendered practically nugatory; for neither in the open ground, nor in the museums and plant houses can instruction be given when these are thronged by visitors of all classes from a great metropolis. On the other hand, the TEACHER AND HIS PUPILS WILL IMPROBE THE PASSAGE OF THE PUBLIC; while of the visitors themselves, some from curiosity, others from a desire to be informed, would mix with the students, when oral instruction on the teacher's part would be difficult, and the reception of it by the pupils impossible; nor could examinations of any sort be conducted under such circumstances.

We question if anything lately seen in print will be more surprising to those who know Kew Gardens than the above passages. If all the botanical pupils and all the botanical teachers throughout the world were in the extensive gardens at Kew at the same time, it is probable that it would not "impede the passage" of a single being. It might be implied by the above passages that the gardens of Kew were crowded with students in the morning before the time of opening, whereas they are really deserted at those hours, except by the people employed about the place, and perhaps a few of those who take the trouble to get in by some back way. That the means now afforded at Kew of meeting the wants of teachers will be "rendered practically nugatory" by opening the gardens at such hours, as are the rule at all other important botanic gardens, that is to say, at such hours as the convenience of the horticultural and general public demands, is too amusing to require refutation; on the other hand, we have never yet seen the gardens at Kew on the most crowded occasions otherwise than in a condition when any number of men could 'study' to their heart's content. Anybody can verify this who goes on the most crowded days to the parts where the students most profitably work. As a matter of fact, the work that Kew actually does in teaching botany to students is much less in proportion to its means and extent than is done in many very small botanic gardens in cities. In these gardens, owing to their proximity to crowded streets, both the public and students are more numerous, and the grounds small as compared with those at Kew. The sketch of the visitors who from "curiosity" or a "desire to be informed" would mix with the students, making the reception of "oral instruction" "impossible," is so quaint in its way, that it would be interesting to know the author of it. We have all seen interesting sights at Kew, but few the professor and the class who would be incommoded in the above manner.

It is intolerable that the word "science" should be used in any way to justify such narrow-mindedness and such feeble attempts to justify a wrong to the public in a great establishment supported so liberally by the public purse. If this opposition to so just a demand be persevered in, we shall be compelled to enquire a little more closely into the management of the gardens, and the herbarium at Kew, with a view to proving whether the work therein carried out is of such kind and value that the public, in addition to paying for it, must also be shut out of the gardens during the best part of the day.

The "Journal of Horticulture," after having published recently a strongly-worded article against the opening of Kew Gardens, publishes in its number for March 14th reasons for opening them—such as every impartial person must believe to be just such as we have ourselves more than once expressed.

"We have ourselves," says the journal in question, "often found it hard when we required to visit the Botanic Garden, either for the purposes of investigation or to show them to a foreign visitor, that we were obliged to contrive some way of occupying the early part of the day till admission could be gained to Kew at one o'clock; and especially in the short days the inconvenience was aggravated, for before one gained admission at one o'clock there was not time to do what was to be done before the gates closed."

A correspondent of this journal also writes:—

"To country gardeners residing long distances from the metropolis it (Kew) is practically a closed book, because they have simply not time to visit the gardens and examine and investigate in any satisfactory manner without losing their night trains home. That, I submit, is not a sentimental, but a real grievance. I have more than

one hung about Kew Green waiting for the opening of the gates, and have thus wasted valuable time, simply because it could not be utilised sufficiently near for me to have entered the gardens at the moment the gates are opened.

The remedy which the "Journal" proposes is—

*That botanists, students of science, professional gardeners, and others wishing to make a legitimate use of the gardens might be furnished with tickets, available and renewable for six months, to be issued by the director upon application, certified by two householders that the applicant is a properly qualified person to receive the privilege.*

The "remedy" is so good a joke as to merit reprinting. "Hanging about Kew Green" does not appear to be very amusing to the correspondent of the "Journal" any more than to our own, but looking for the "two householders" does not brighten the prospect much.

The "Gardeners' Chronicle" wavers between what is just in the matter and that friendship to the director which makes it attempt to justify the present state of things, but in a half-hearted sort of way. It reasons thus—

"Ought we to consent to put Kew on the footing of High Park for instance, possibly to sacrifice its scientific utility, its charms of beauty and of quiet retirement, for the sake of pleasure-seekers pure and simple, or it may be of a band of "patriots," such as those who trampled down the flower-beds in the park on Sunday, rough-hewed the trees and playfully cast dead cats one at the other? Before unlimited right of entry be conceded there ought to be some assurance that this sort of desecration should not occur. It is unreasonable to ask for any concession which would be detrimental to the administration of the garden or the interests of students. We lay stress on the interests of students because we think it preposterous that local residents, who are the chief agitators in the matter, should bring their claims in preference to those of students. And let us not be misunderstood. Under students we include any person who can show that he has any bona fide business in the garden apart from pleasure-seeking.

In this it is assumed that the interest of the students are not identical with those of the public. But we who write entirely from the point of view of the student of horticulture complain because he cannot get into the gardens to study throughout the best hours of the day, while every other national garden of any importance is open throughout the day. We are told that he can get it by "applying to the director," "proving that he has business in the garden," &c., but we are mistaken if the system will be considered in any way satisfactory to those immediately concerned. As to the comparison with Hyde Park, it is very far-fetched. The Americans have got over similar troubles by making a regular meeting place near their parks, and we might do the same with advantage.

The "Gardeners' Magazine" says:—

The rule of admitting those who apply and state reasons does not meet the demand that is made for the admission of the general public at an earlier hour. We cannot but believe a compromise might be affected between the requirements of the scientific and the requirements of the pleasure-seekers. The Royal Gardens are sufficiently extensive to afford agreeable promenades to all sorts and conditions of men without disturbance of the scientific work, provided suitable tracts were opened to the public at an early hour and certain of the houses and nurseries were rendered inaccessible until the hour of 1 p.m. It might be better to yield with grace and reserve with power than, under the compulsion of a strong tide of public opinion, to yield inelegantly and too completely for the right use of the gardens."

**Primroses and Polyanthuses.**—I have just gathered a Polyanthus-formed head of bloom off what I have always supposed to be a Primrose plant. My stock originated from one, and this is the first, though I have had them for several years, which has ever sent up a Polyanthus bloom. I make mention of this as I see there is some discussion as to whether Primroses and Polyanthuses are one and the same plant.—E. PARKER, *Petyardes Hall, Swaffham, Norfolk.*

**Berberis Aquifolium for Spring Beds.**—We find this to be a most useful plant with which to furnish the centres of large beds in winter and spring, and when edged with spring-flowering plants, margined with Centaureas, the effect is all that can be desired. At the present time even the smallest plants are producing fine heads of yellow flowers, and the check on their growth, induced by removal, has caused nearly all the leaves to assume a bright red colour.—J. G.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

MARCH 19.

AMONGST subjects shown at this meeting those which created most interest were the collections of Hyacinths and Tulips, furnished by several of the leading nurserymen, and a group of Amaryllids from Mr. B. S. Williams, of Holloway.

First-class Certificates were awarded as follows:—

**Odontoglossum pardium** (Mill).—Exhibited in flower on this occasion for the first time. It produces strong, branching spikes of bright golden-brown spotted blossoms, and forms a striking contrast to the light-flowered kinds.

**Magnolia Halleana** (Veitch).—A new, white-flowered, hardy Japanese species, flowering freely in a small state, and deliciously scented.

**Hyacinth Grand Master** (Cutbush).—A strong-growing, pale blue kind, with stout, compact flower-spikes.

**Hyacinth King of the Blacks** (Veitch).—A variety bearing symmetrical spikes of glossy black blossoms.

**Narcissus incomparabilis aureo tinctus Leedsii** (Barr & Suggden).—A sort remarkable for its perfectly formed flowers, which have pale yellow petals and crimson-edged cup.

**Bollea Palini** (Veitch).—A kind with large, waxy flowers, the petals being of a delicate mauve colour, conspicuously tipped with violet-purple.

A Botanical Certificate was awarded to *Dendrobium linguiforme*, from the Horticultural Society's gardens. It bears white, narrow-petalled flowers of a pleasing character.

**Hyacinths and Tulips.**—Extensive collections of these came from Messrs. Veitch, Carter, Cutbush, and Osborn. The flower-spikes, though not so large, as a rule, as could have been desired, were fairly good, and the colours excellent. In the collection of Hyacinths from Messrs. Veitch, the best were—**BLUES**—King of the Blues, Fineman, Baron Van Tuyl, and Princess Mary of Cambridge. **WHITE**—also superbissima, *Mit Blanc*, and *Les Grandesse*. **REDS**—Prince Albert Victor and Von Schiller. Many other colours were also well represented. Messrs. Cutbush and Sons had likewise well-grown plants of similar kinds. The Tulips from Messrs. Veitch embraced both single and double kinds of the brightest colours, and, being associated with Narcissi in pots, they made a good display.

**Amaryllids.**—Amongst Mr. Williams' group of these were large and well-formed flowers of *A. expansa*, the brilliant scarlet *A. mirabilis*, the white *A. virginialis*, *Prince Teck* (a rich crimson kind), and bicolor (crimson, striped with white). Messrs. Veitch & Sons also showed Amaryllids of an attractive description.

**Miscellaneous Subjects.**—Mr. Wills, South Kensington, furnished tastefully arranged groups of Palms, Ferns, Clnb Mosses, Orchids, and Lilies; also *Anthurium Scherzerianum*, *Phalenopsis*, and *Cyclamen*. Messrs. Cutbush & Sons showed an attractive collection of hard-wooded plants, including Indian and Ghent Azaleas, *Brietas*, and *Epaerices*. Amongst the *Erics* were noticeable profusely flowered plants of the beautiful white *E. colomans* and *E. gracilis vernalis*; several large pansful of *Lily of the Valley* also came from the same firm. Messrs. Laing & Co. exhibited three new *Caladiums*, one of which has delicate transparent leaves resembling white tissue paper, traversed with brown and green veins; it was named *La Perle de Brazil*. The other varieties, though not so distinct, were also well worth attention. Messrs. Veitch & Sons sent a basket of cut sprays of hardy plants, amongst which were *Daphne Mezereum* and its white variety, *Erica hercacea*, and *E. mediterranea alba*; also branches of *Azara microphylla*, the under sides of which were laden with yellow inflorescence. Mr. Williams sent a fine specimen of *Imantophyllum minimum* bearing nearly twenty trusses of blossoms; also good plants of *Sarracenia purpurea major*, *Draecenas*, and *Cycads*. Mr. Cannell, Swanley, contributed flowering plants of *Petalogonium Salmon Vesuvius*; also cut blooms of *New Life and White Vesuvius* all in excellent condition. Messrs. Garaway & Co., Clifton, sent a variety of their white-flowered *Mignonettes*, which was admired for its effective bloom and delicious fragrance. Messrs. Rollisson & Sons furnished a flowering specimen of *Azalea Rollissonii*, a Japanese kind, to which allusion was made last week (see p. 224). Mr. G. F. Wilson exhibited *Krythronium grandiflorum* in a pot, and Mr. Parker, Tooting, sent flowering plants of *Megacasa*, *Dog-footed Violets*, and *Iberis*. Messrs. Cutbush & Son sent a *Draecena* with long, narrow, graceful, bronze foliage, excellent for table decoration. Mr. R. Dean, Ealing, sent an interesting collection of hardy plants, consisting of *Primroses*, amongst which were *P. denticulata*, the pure white *P. rivalis*, and *P. amoena* (Pink Beauty); along with these also came *Myosotis*, *Cheiranthus mutabilis*, and was followed by *Polyanthuses*. A collection of cut flowers of *Polyanthuses*, including a finely-colored kind, also came from Mr. Candwell, Wantage, Berks. Messrs. Osborn & Sons showed a group of ornamental-leaved plants, consisting of *Palms*, *Yuccas*, *Crotons*, &c., intermixed with well-grown plants of *Imantophyllum minimum*. Mr. Aldous, South Kensington, sent a group of decorative plants, amongst which were beautifully-flowered examples of *Solomon's Seal*, *Mignonette*, *Lily of the Valley*, *Spiraea*, and similar plants. From the

Society's garden came a group of *Eucharis amazonica*, *Imantophyllum* Lady's slippers, and *Habenaria lauchiana*, the last a useful winter-flowering stove plant, not so much grown as it ought to be. Mr. Parr, The Gardens, Harrow Weald Park, sent well-grown plants of *Begonia glaucifolia* in baskets, a purpose for which it is admirably adapted. Mr. Mill, gardener to Lord Rendlesham, furnished out flowers of *Cattleya Skinneri* unusually well coloured. Mr. Iguldren, gardener to R. B. Wingfield Baker, Esq., Romford, contributed large trusses of flowers of *Spargannia africana*; also a dish of Tomatoes, which, considering the earliness of the season, were of first-rate quality.

**Manchester Horticultural Society.**—The first floral meeting for the year of the Royal Manchester Botanical and Horticultural Society was held on Wednesday last in the Town Hall, and, from every point of view, may be pronounced to have been a decided success. The principal flowering plants exhibited were Hyacinths, Primroses, Lilies of the Valley, Azaleas, and more especially a fine collection of Orchids. Chief amongst exhibitors was Mr. W. Leech, of Fallfield, who obtained the Society's gold medal for a miscellaneous collection of Orchids, in which a lovely specimen of *Dendrobium Wardianum* figured very conspicuously. The silver medal was awarded to Mr. J. Broome, of Didsbury, whose collection of decorative plants and Orchids attracted universal attention. Mr. B. S. Williams, of London, contributed a large and fine collection of Cyclamens (for which he received a special certificate) and a number of new and rare decorative plants, chiefly *Draconas* and Palms.

**IMPROVED FUMIGATING PAN.**

ALLOW me to direct attention to this fumigator, which has given me great satisfaction. I find that the saving of Tobacco which it effects more than pays its cost in a very short time. The Tobacco, too, is not so liable to break out into a flame as it does in some fumigators, which I have used, and it does not need the same amount of attention, as it keeps burning steadily till every particle is consumed. This fumigator I obtained from Messrs. James Dickson, of Chester, along with a sample of their Medicated Tobacco Paper, which I find to be far the best article I have yet met with for the destruction of thrips, greenfly, and other troublesome insects of a similar character. Indeed, both the paper and fumigator can thoroughly recommend. *Enville.* Geo. H. GREEN.

**Reed Mats for Protection.**—Mr. Barr uses these large and excellent mats for protecting his beds of seedling and half-hardy bulbs, and they seem to be the most efficient things in use for this purpose. They are made of the stems of the common Reed sewn together with strong tarred twine. They are between 7 ft. and 8 ft. wide and very strong. They must be very useful for throwing off hail or snow, being so strong, and they may also serve for shading. They are much in use in Holland, whence they were imported by Mr. Barr. They could of course be made in England from the same materials, which are abundant in many districts.—V.

**FLORA'S ANATHEMA.**

BLUFF March, may your Boreas bow cusses,  
 Confounding the legions of low cusses,  
 Who swarm in the Parks  
 For political larks,  
 And tread down my Tulips and Croucesses!  
 Rude Roughs! of respect have they got any?  
 Of patriot feeling they've not any,  
 Of taste they've no little,  
 And care just as little,  
 For Britain's true blessings as botany.  
 My turf they would ruin by stamping on,  
 My blossoms they glory in jumping on;  
 Each ead, coster, clown,  
 May Aquarius drown—  
 The brutes are fit only for pumping on!

Punch."

**HOW TO GET RID OF SLUGS.**

The long continuance of unusually mild weather has made slugs very active and destructive. I receive many enquiries from horticultural friends as to how they are to get rid of the slug pest, and could only advise the following our own practice of putting a collar of pierced zinc round especial favourites while in bloom, and spreading Cabbage leaves about, so as to present a powerful counter-attraction, and in the morning killing the slugs found still feeding. An old horticultural friend from Australia, while looking over my plants, described a plan followed by him with great success. It seemed so promising and desirable, that I asked him to give it me in writing, that it might be published for the benefit of the gardening world. I now send you his interesting letter, and should state that Mr. Carson was formerly President of the Horticultural Society of Victoria, and is a practical man, as well as an enthusiastic and successful horticulturist.

*Heatherbank, Weybridge Heath.* GEORGE F. WILSON.

The following is the letter alluded to:—  
*London, March 11th, 1878.*

To G. F. WILSON, Esq.

Dear Sir,—I have much pleasure in giving you the details of how we managed to overcome the slug pest. You can well imagine that when once introduced in the warm, moist autumn and winter of Victoria they became a plague that you can have nothing like in this climate. This, following on a perfect immunity from pests of all kinds, vegetable or animal (owing to our virgin soil), set many minds to work to try to overcome the new difficulties attending on horticultural pursuits. I well remember, when in the year 1849 a slug was brought to me in the house one evening, found in my small garden plot in town, that we were as pleased to see it as if it had been an old friend. It was carefully placed back at its feeding ground; but the following season matters had changed, and it was every night's work to pick them up in the house of Mr. Scott, nurseryman, found also of his garden, but whose nights were taken up with his duties in Parliament, offered his sons 3d. per dozen to gather and destroy them; he soon, however, reduced the price to that rate per hundred, but afterwards told me that it would ruin a bank to keep it going—so gave it up. Seedling plants of all sorts were eaten as soon as they appeared above ground; young trees round the collars, grafts at the junction, buds and young growths from them, especially of the Orange, were all eaten. This was the state of the slug nuisance, when, with a few others, I was engaged till far in a winter night in the house of Mr. Scott, nurseryman. He, without preparing a schedule for our spring show. Our work over and enjoying the hospitality of our friend, the slug question came in for discussion, when Mr. Scott said, "There is no difficulty in the matter; I soon dispose of them. Get some unslaked lime, let it slake by the air in a dry place, put a shovelful in a bag; take this in one hand and a stick in the other at nine to ten o'clock at night, walk round your garden paths, beating the bag, when the lime will come out and spread like a fine mist all over. A few nights of this work and you will not find many slugs, practice in a garden of 4 acres with complete success." In the Vine, fruit, and vegetable borders the ground was gone over twice the same evening, about half-an-hour apart, and used more freely than in the shrubbery and flower borders, a warm, moist night being preferred. In the beginning of the wet season the liming was done twice a week. Of course, care has to be taken not to make the cure worse than the disease. Tender plants, and those that dislike lime, must have none or only a homeopathic dose, and this is sufficient, as it is not the slug the length of the finger that is to be got rid of so much as the thousands only starting into existence. I have counted dozens on one leaf not one of them over 1 in. long. My mode of operation was to walk round before the men (who some nights buttoned old coats over themselves) with a good bright lantern, facing the wind. If we saw any large slugs on the path, the foot was put on them; and as they are great cannibals, if there were any more large ones near when we came round that night, or in the early morning after liming, numbers would be found unable to get away, or still eating their fallen companions. After a few operations of this kind, only the boundary and moist corners required an occasional dusting. An hour sufficed to get carefully over each acre. There should be no trace of lime seen in the morning, unless in places where it would not be objected to. I trust I have made the matter clear to you; the operation is simple, the results certain.

JOHN CARSON.

**Show Pelargoniums at Clapton.**—The thousands of Pelargoniums to be seen in Messrs. Low's nursery at Clapton, besides being interesting to look on, suggest many useful cultural hints. In many private establishments plants of what are termed show Pelargoniums struck from cuttings in summer are considered to be of little value as decorative subjects until late in the autumn of the following year, or in many cases until they have made two seasons growth. August-struck cuttings, grown on in the following March, make the handsome bushy specimens which may now be found here loaded with bloom-buds. The cuttings are struck in small pots, and when they have attained a height of 6 in. or so they are stopped, but not by merely nipping out the growing points; on the contrary, some 2 in. or more of the tops are cut off, which induces the plants to throw out three, four, and sometimes five strong and vigor-

ous shoots, which, as they grow, never fail to produce abundance of side branches, all of which yield clusters of blossom. After being stopped and again started into growth, they are potted into 5-in. or 6-in. pots, in which they are allowed to flower. The soil in which they are grown consists of ordinary turfy loam and manure, and stimulants in the way of liquid manure are applied. Their fine growth is, however, not so much due to these as to strict attention in giving them air, light, and water when most required. Grown in the way just described, Messrs. Low have thousands of plants of all varieties, dwarf and bushy, furnished with large green leaves, completely hiding the pots, and studded with plump clusters of bloom buds.—C. S.

**Caccinia glauca.**—This is a dwarf hardy perennial belonging to the Boraginaceae, from the highlands of Persia. It grows about 9 in. high, with sparingly branched, somewhat succulent stems clothed with ovate-oblong glaucous leaves, somewhat rough to the touch from stiff hairs, and bearing short terminal racemes of flowers, each about  $\frac{1}{2}$  in. in diameter with a rotate corolla, resembling in form that of *Borage*, pinkish when first expanding, but changing to blue. It is a neat border plant, which will interest the botanist and general lover of plants, but can hardly be termed a showy plant. The seeds, or to speak more correctly, the nuts are remarkable for their large size, being of flattened roundish form, nearly  $\frac{1}{2}$  in. across, and are studded at the margin with a double row of minute whitish tubercles.—W. THOMPSON, *Ipswich*.

**heasants Eating Yellow Crocuses.**—I can confirm what Mr. Haunbury states (see p. 228) respecting this matter from repeated observation. I made a new very long border of Crocuses, yellow, white, and blue. The yellow ones never progressed, and we thought that they were eaten by slugs. One day, however, we observed from the window one or two pheasants commence at one end of the "ribbon" and almost destroy the yellows, leaving the others untouched. What connection there is between colour and taste in such a case I know not, but there must be one, or the same thing would not take place season after season. Other birds are addicted to fruits and flowers of a certain colour, and abstain from all others.—JACKSON GILLBANKS.

— I see that one of your readers complains that pheasants destroy his Crocuses. The best way to preserve the roots is to plant them from 6 in. to 8 in. deep. This defies mice and pheasants, but the latter, besides taking the roots, eat off the flowers as fast as they appear above ground. This year the Crocuses were at first very beautiful in our wild garden, but when the pheasants discovered them they were very soon all eaten off. They seem to like yellow flowers best. For this evil there is no remedy but to net, and this is unightly and inconvenient, or to destroy or banish the birds from the place, and not allow them to breed near where the wild garden exists. Where pheasants are kept Dog's-tooth Violets also suffer. Any other flowers in the wild garden I am not yet aware they touch. Could they only be driven off by some one appointed to watch early in the mornings (for this is the time when most mischief is done) while the Crocuses last? I see no reason why pheasants should be banished from the wild garden, as I like to see them marching stately amongst the bushes and occasionally crossing one's path.—A. MACFARLANE, *Great Tew, Enstone*.

**Begonias as Basket Plants.**—At South Kensington, on Tuesday last, Mr. Parr, of Harrow Weald Park, Stanmore, showed a pair of handsome plants of *Begonia glaucifolia* grown in wire baskets. They were the produce of cuttings struck last spring, potted into 5-in. pots in peat and leaf-soil, and afterwards turned out of the pots into the baskets. The shoots were stopped several times to induce them to branch and grow closely, and being pegged round the baskets the young shoots took root, and being kept well supplied with water and occasional doses of Stauden's manure, they became balls of glossy green leaves, interspersed with a profusion of salmon-coloured blossoms. Thus grown, they are desirable objects for either room or conservatory decoration. Other kinds of Begonias might doubtless be used in a similar way with equally good results, and now there are so many fine kinds in cultivation, effective basket plants may easily be secured.—C. S.

**Camellias in the Open Air.**—I am obliged to "A. D." for his observations (see p. 197) on Camellias in the open air, but I think he must have misapprehended my meaning, which I fear was somewhat obscure. What I intended to convey was, that although the Camellia will, in all respects, thrive in the open air, yet our variable spring climate often so damages the bloom that it is only in an exceptionally fine season that the flowers are enabled to assume and retain that perfection which a glass roof insures them. There is hardly a flower so delicate in texture and so susceptible of injury as that of the Camellia, and, as "Cambrian" says (p. 239), "rain blanches the blossoms," a fact which exactly coincides with my experience. I have seen a large collection in full flower which in a

few hours were so bruised by a heavy shower, that not a single perfect flower remained. It is owing to this uncertainty that I have hitherto considered the Camellia to be an unsatisfactory flowering shrub for outdoor culture. I speak, however, only from my own experience, and should be sorry to damp the ardour of those who might like to experimentise thereon. If planted in sheltered situations, where they could be insured protection from high winds and driving rain during the flowering period (and all engaged in horticultural pursuits know how seldom we escape such visitations in the spring time), there would be a better prospect of preserving their blooms in perfection, but planting in open, exposed situations I consider a mistake.—J. CORNHILL, *Byfleet*.

**The Poet's Narcissus.**—The beautiful Pheasant's-eye Narcissus so sweetly scented and useful for bouquets, is now being used in quantities in Covent Garden market. They come chiefly from the Channel Islands. Few places in England would produce flowers so early out-of-doors, but if grown in large pots and placed in a cool house they would make charming plants for the conservatory, or a good supply of cut bloom might be had from bulbs planted in a frame. If light, rich, sandy soil be used for them, and they receive plenty of light and air, stout well-formed blossoms will be the result.

**Popularity of the Auricula.**—A short time since a sale by auction of the extensive collection of Auriculas belonging to the late Mr. Samuel Cooper took place in Manchester, and the prices realised were something remarkable. The large plants were put up in lots of sixes, and the smaller ones in lots of twelve, and those that contained a crack flower induced a vigorous competition. One lot, containing a plant of that fine and scarce, and yet imperfect green edge, Prince of Greens, imperfect because of the want of life in the tube, and five others of ordinary reputation, fetched £2 10s., so great was the desire to obtain this particular plant. The desire to obtain the finest flowers was manifested by young beginners as well as by veterans, thus showing that the desire to grow this fine flower is spreading. One result of the sale has been to induce a Manchester Auricula dealer to advance his prices "all along the line." Those who possess a few fine and scarce varieties can bear testimony to the fact that they are constantly receiving applications for them, applications which cannot be entertained for some time to come.—D.

## ANSWERS TO CORRESPONDENTS.

**Blight and Insects on Rose Trees.**—What is the best thing I can do in order to get rid of blight and insects on Rose trees under glass? I have tried Tobacco cloth burnt, but with poor results.—J. K. T. [Thorough fumigation with Tobacco paper is the most effectual remedy for aphides, which are the insects that generally attack Roses, they should be fumigated two or three nights in succession, as one dose only supplies them. We presume the blight you mention is mildew; if, indeed, flowers of sulphur sprinkled over the affected parts will arrest it; but if badly affected, dip them in a strong solution of soft-soap water and repeat the application if necessary.—W.]

**Weeds on Lawns.**—Can you recommend me any mode of killing Plantains on a lawn?—F. T. [By far the most effectual way of clearing lawns of Plantains is to uproot them with a sharp-pointed knife. An active boy will soon clear a large piece of ground. After that fill up the holes with soil in which lawn Grass seeds have been mixed. If the operation be done at once, a fine turf will be insured by the end of May. Sulphuric acid is also a good remedy; a drop applied to the crown of each plant soon withers them up; then fill up the holes with Grass seeds as just recommended.—H.]

**Heating Small Greenhouses.**—I have a small greenhouse, 14 ft. by 10 ft. 10 in., which I wish to keep just free from frost, and I would like to use a terra cotta stove, to burn paraffin oil, for this purpose. What sized stove would be best?—E. [One of Roberts' 50s. Terra-Cotta Stoves would furnish heat enough for your purpose.]

**Lichen-cover'd Apple Trees.**—I have just taken a house where the Apple and Pear trees are covered to the tips of the smallest branches with Lichen. Is there any new mode of treating them? or new dressing which will remove this pest? They are too bad for scraping.—B. A. F. [Try sulphur, softsoap, and quicklime all well mixed together and heated in a boiler. When cooled to a temperature to be handled, distribute it all over the trees and branches with a garden engine or syringe. This mixture keeps mildew on Peach and Nectarine trees on walls in check, and doubtless it would help to destroy Lichen on Pear and Apple trees. If newly elsked quicklime were likewise dusted over the trees before vegetation commenced, it might have some effect in destroying the Lichen.—W. T.]

**Moss on Lawns.**—What is the best way of clearing Moss from lawn tennis grounds? I have heard heavily manuring is a good plan, but have not tried it.—T. B. A. [With a sharp-pointed rake loosen the surface of the lawn, scratching out all the Moss that will come off without destroying the turf; then spread over the surface the following compost:—Two one cart-load of loam, or ordinary garden soil, add 3 bushels of soot, 6 bushels of wood-ashes, and  $\frac{1}{2}$  a bushel of bone-dust; mix with the whole about 4 lbs. of lawn Grass seeds, roll the lawn frequently and especially after rain; a fine turf without Moss will be the result.—W.]

No. 332.]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### AMONGST THE DISAS.

BEFORE leaving England I determined that one of the first things to be done on reaching Capetown was to see *Disa grandiflora* in its native habitat, and on arriving my desire was intensified by seeing a bunch of its blooms, thus showing that it was the season for seeing it in flower. I immediately made inquiries about the ascent of Table Mountain, but experienced some difficulty in finding a guide, and what with business preventing me some days, and the weather being unsuitable on others, as it is dangerous to go up when the cloud, called here the Tablecloth, is hanging on the mountain, nearly three weeks passed by before my wish was gratified. The party I had expected to go up with failed me, but I was fortunate enough to make the acquaintance of Mr. Charles Ayres, who used to be in the gardens at Cliveden, but who is now established here in the nursery business. When he heard my wishes he most kindly offered, although at considerable inconvenience to himself, to accompany me, an offer which I readily accepted. As the weather looked promising, one Friday night we arranged to go up the next day, and accordingly at four o'clock on the Saturday morning I was at his garden, when we soon had everything ready, not forgetting a supply of Grapes, and a few minutes before five found us on our way. We crossed the Kloof, which is a spur of the mountain, the ocean below us, dotted with fishing-boats, looking glorious in the early daylight, and ascended by Kastell Berg, passing on our way a large number of *Amaryllis Belladonna*, which were just throwing up their flower-spikes. About two hours and a quarter brought us to the plateau in rear of Table Mountain proper, and my aneroid barometer showed that we had attained an altitude of 2700 ft. We had not proceeded 300 ft. before we perceived the bright-red spikes of *Disa ferruginea*, and almost at the same moment that charming flower, *Herschelia celestis*, called here the Blue *Disa*, met our view. Less than a quarter of a mile brought us amongst quantities of *Disa grandiflora*, and well may Harvey term it "the pride of Table Mountain," for it would be difficult to find a handsomer or showier flower, and when you see a dozen or fifteen of its brilliant-coloured blooms clustered together it is a sight not readily to be forgotten. The intensity of colour exceeds that of any wild flower I have ever seen, the Snow Plant of California, with its rich colour contrasting with the spotless snow, excepted. *D. grandiflora* grows most plentifully on the sides of the narrow watercourses which intersect the plateau, the sides, as a rule, being nearly upright, although we saw numbers on the face of large rocks where water was trickling down. The soil it grows in is a sandy peat, and it may almost be said to grow in the water, the soil being so wet; and as this is the driest month here, it is clear that the roots are always in wet soil, and I believe they never rest, as examination showed that even now they were pushing forth new growth. *D. ferruginea* and *H. celestis* both like damp spots, but not so wet as *D. grandiflora*; these two species do not appear to grow in masses as *D. grandiflora* does. There were several other terrestrial Orchids in bloom, and also that parasitical plant, *Harveya capensis*, the bloom of which is both large and handsome. The showiest flower was *Crassula coccinea*, some of the blooms we gathered being of an immense size. *Watsonia humilis* was very plentiful, but the blooms had passed; indeed, the seed was ripe, but of a tall species some blooms were left. A fortnight ago they must have been well worth seeing, as the flower is very handsome, and it grows in great profusion. *Agapanthus minor* was plentiful, and I saw one root which must have been *A. umbellatus*. Heaths and Geraniums were not in season, although occasionally we came across a flower. Having decided to return down the front of the mountain by way of Table Poort, we struck across, ascending to 3450 ft., when we came on the Table, and found we had been fortu-

nate enough to steer exactly to the Poort, and Capetown and Table Bay were stretched out right below us. The descent was by a worse path than the one we had ascended by, being steeper, and there being much loose stones to go over; but a little over two hours took us down, and we reached the town a little after three o'clock, after a thoroughly enjoyable day. I had thought of going up without a guide, but with my present knowledge I would recommend no one to attempt it, for even if he was fortunate, as we were, and had no cloud come over (when you cannot see a yard before you, and sometimes the cloud remains for days), he would find it difficult to traverse that large, dreary wild with but little by which to get his bearings.

HENRY BUCKLEY.

*Capetown.*

### HOW TO GET RID OF SLUGS.

I HOPE the plan of destroying these, recommended by Mr. G. F. Wilson (see p. 273), will be fairly tried and found successful, but I very much doubt if it will in this country, as the following instance will show. The worst garden for slugs which I ever saw or heard of was Dramlanrig. It was hardly possible to get annuals and young crops through the ground for them, so destructive were they. I have seen several long beds of newly-planted Lettuces and such like nearly destroyed in one or two nights, in spite of liming. Liming was a great institution about that time, and they were provided with long gowns made of sackcloth (!) that buttoned up to their necks and came down to their heels, like a modern "Ulster." The lime was elaked in the way Mr. Wilson recommends, but was scattered by the hand, and it was distributed in sufficient quantity not only to produce "a fine mist all over," but to whiten the ground, and the work was done quite frequently throughout the summer, and sometimes every evening, and the practice had been continued for many years, but only with this result, that it checked the ravages of the slugs at the time, if persistently continued, and that was all. If a night or two was missed they were just as bad as ever. I am afraid to state how much lime was spent on that garden, but I know there was always a shed kept full for the purpose, and it was used annually. The fact of the matter is, the lime must reach the slug if it is to kill it, and this it cannot do, dust as you may, in a garden where there is a variety of crops under which the slugs can shelter from the lime. The least little bit of a clod or a leaf is quite sufficient to protect the enemy till the lime storm settles and the lime gets moistened by lying on the ground, and then the slugs tramp over it with impunity.

J. S. W.

— The first garden of which I took charge was an old one fairly overrun with slugs and worms; all kinds of green vegetables were so much eaten, as to be almost unfit for use, and Potatoes were full of worm holes. In order to get rid of such pests I proposed to turn in some young ducks, to which at first some objection was made, but afterwards that plan was tried. Early in February I procured some duck's eggs and three Cochon-China hens, and by the end of March I had some twenty young ducks. I at once turned them into the garden, with one hen to take care of them for the first week or so, after which the hen was dispensed with, and arrangements were made for the ducks to get into the garden as early as they thought fit to turn out. The result was that they soon cleared every corner from both slugs and worms, for as soon as the men began to dig, they watched every spadeful that was turned over for worms, and by the time the first Peas were ready for table the ducks were already ready, and not a slug was to be seen.

JAMES SMITH.

*Waterdale.*

— Mr. Wilson's recommendation in reference to destroying slugs reads wonderfully like a good joke. Take, for example, the four acres carefully gone over in an hour. Why, it takes a man and two horses a good working day to plough an acre of ground; and to have the slightest chance of puffing lime into the eyes, mouth, or on to the backs of slugs, large or small, when feeding it would be necessary to walk over the ground pretty closely, rendering four acres an hour utterly out of the question. But there are other practical objections to the lime-puff cure which will occur to those most familiar with such matters. Unfortunately, quicklime beaten through a bag with a stick has almost as strong a tendency to rise into the air as to fall to the ground, and the result of the ascent of fine lime dust into the mouth and nostrils would, to say the least of it, be unpleasant. The Victorian slugs must be much more thin-skinned than ours if they can be cleared off by any such easy and simple process as that described by Mr. Carson. Lime will undoubtedly kill slugs, but an hour for a square pole under crop is more like the true time needful than an hour for four acres. Several

applications are also needed; and though the lime, to be effective, can neither be too hot, too fine, nor too dry, and the mere quantity is of less moment than these qualities, yet something more than a fine mist is needed to deal death to British slugs, as I can testify after a thirty years' war against them, and the expensiveness of not a few childrens of the hottest lime upon them.

D. T. FISHER.

— Mr. Wilson's Australian friend's method of destroying slugs by shaking slaked lime on them through a bag is only a roundabout and less effectual way than that which I have practised for a very long time, details of which appeared in *THE GARDEN* some time ago in the series of papers I contributed upon the destruction of insect pests. My method simply consists of sowing by hand air-slaked lime broadcast over the ground and whatever crops are on it. I have resorted to the bag-beating plan, it would have occupied four times the amount of time—an operation which is by no means so pleasant as to lead anyone to wish to prolong it longer than could be avoided; and, unless the material of which the bag is made is so open as to let the lime through it too fast, it would require an immense amount of beating with the stick to distribute enough to kill the pests is question, as anyone trying it will soon discover, for if only a slight dusting reaches them, they will in two or three minutes throw off their slinky jackets slightly dusted. When I first set about the work I converted a large tin canister into a dredging-box by perforating it with small holes, but I very soon found that I could distribute the lime by hand much more effectually, and get over the ground four times as quickly with much more certainty of the remedy being thoroughly applied. One good dressing given at a well-chosen time will effect the destruction of more slugs than trapping and hand-picking daily for months. It is, however, necessary for those who try such work to be well acquainted with the habits of the slugs, and the kind of weather that brings them out in the greatest numbers. T. BAINES.

#### IRIS RETICULATA, KRELAGEI, AND HISTRIO.

ALLOW me to make a few remarks about these beautiful Irises, to which allusion has lately been made in *THE GARDEN*. Here in Holland was first known, under the name of *I. reticulata*, the form which is now registered as *I. Krelagei*. This Iris, being cultivated only on a small scale, was lost from collections; in later years small quantities of bulbs were re-introduced. This form was figured as *I. reticulata* in the "Botanical Cabinet," in Sweet's "British Flower Garden," in the "Journal of the Horticultural Society," and in the "Gartenflora," but it is quite different from the original *I. reticulata*, as described by Marschal von Bieberstein. This true form was grown in a few places in Europe from seed, and some years ago our firm got a large stock of it and sent many thousands of it to England. I drew Prof. Regel's attention to the difference between the two forms, and sent him plants of both for examination. Prof. Regel kept the name *I. reticulata* for the original form of Bieberstein, and had the courtesy to affix my name to the other form, erroneously described as *I. reticulata*. A third form was described by Prof. Regel as *I. reticulata cyanea*, which is the well-known *I. Histrio*. All these Irises are exceedingly ornamental. As to their time of flowering, however, with us, the first is *I. Histrio*, then *I. reticulata*, and lastly *Krelagei*. We cultivate all three forms in the open ground in a well-protected position, and in winter we cover them with leaves. M. Max Leichtlin, in the last number of *THE GARDEN*, describes *I. Krelagei* as being a fortnight earlier than the typical form. Here, where it is cultivated in abundance in our garden for several years, just the opposite is the case; but as there are different strains of *Krelagei* as well as of the typical form, and as with newly-introduced bulbs the time of flowering is influenced by their removal to a new country, the difference of time of flowering of *Krelagei* at Baden-Baden and Haarlem may be occasioned by such circumstances. Newly-introduced bulbs here usually flower earlier than those cultivated some years. *I. Histrio* blossomed in our garden for the first time on January 17, 1874, just when it was in bloom at Kew, but it never flowered again so early. In the present very early season it was only in flower at the latter end of January. *I. reticulata* at present is nearly over, while *I. Krelagei* is yet in full bloom. *I. Krelagei* grows much dwarfer than *reticulata*. *I. Histrio*, although with us not so tall as when first introduced, grows like the typical form of *reticulata*. If bulbs remain undisturbed in the ground their growth the second year may be taller and their flowering earlier than when they are taken up annually. For horticultural purposes the type and *I. Histrio* are the best. The type, with its fine blue colour and delicious scent, cannot fail to be valuable as a winter-flowering bulb for indoor decoration. *I. Histrio*, which has a very delicate scent, would be equally useful, but it is yet too scarce for ordinary purposes. If good bulbs be planted their growth in pots is not difficult, but to grow

them in masses in the garden seems not to be so easy; at least, several growers have lost in one year large stocks of it through disease. This must be considered the only reason that these plants are not more generally cultivated than they are. Among varieties of *Krelagei* there are several very fine ones, while in others there is less beauty; but of these the stock here, at least, is very limited. Sowing and re-sowing all the forms of *I. reticulata* would be highly desirable, as a greater number of varieties would be very acceptable. There is a striking difference in the form of the bulbs of the three sorts just adverted to.

J. H. KRELAGE.

Haarlem, Holland.

#### CAMPANULA MEDIUM AND ITS VARIETIES.

NOW is the best time to sow seed of this biennial if it be desired to secure large massive plants that will produce several spikes of flowers, and display the beauties of one of our finest hardy border plants to the best advantage. The seed is small, and may, if plentiful, be sown in a warm spot in the open ground, but it is much safer to sow it in shallow pans or boxes placed in a frame or on a shelf in the greenhouse, as in the latter case all the seed will probably germinate and an abundance of plants be secured. When these are large enough to handle conveniently, prick them out into some shady spot, and keep them watered until the plants are well rooted. From that time they may safely be left to take care of themselves until September, when they should be transplanted into their permanent places in the flower borders, and so treated will not only get well established before the winter arrives, but will also develop their blooming crowns for the next year. This constitutes nearly all that it is needful to say as to the raising of a seedling stock of these Campanulas, better known as Canterbury Bells. They may be classed into three sections—single flowers, as seen in the old-fashioned single Bells; doubles, as found in the stout massive flowers in which two, three, and even four bells seem to be compressed into the outer one; and duplex flowers, as seen in the calycanthems forms, in which one bell grows in the other, and the combined two resemble a cup standing in a saucer. The single varieties, as of old, are still to be had, but no one would care to be dependent upon these only who have once seen the beautiful products of a fine modern double and semi-double strain, and which will also produce some single flowers. Whilst the old single strains comprised only white and blue colours, the modern strains include nearly a score of hues, inclusive of white, lavender, mauve, several shades of purple, pink, rose, salmon, and also blue. The duplex strains have hitherto been chiefly confined to white and blue, but other colours are now being introduced. It is a curious fact in relation to this section that whilst the seed of the white form is of a pale hue and the seed of the blue form is of a dark tint, the seed of the double and semi-double forms of all colours is the same, viz., a glossy brown. The habit of the latter section is compact and good, the plants when in bloom ranging from 18 in. to 24 in. in height, forming perfect pyramids of flowers. From frequent experience I have found that these may be lifted and placed in pots even when in full bloom without injury, and as they invariably flower from the middle of June to the middle of July, according to place and season, it would be possible, in the shape of a large group of these in pots, to introduce to some of the midsummer shows a very novel and interesting feature. If so required, or if to be used for corridor, house, or conservatory decoration, it would be best to lift the plants and pot them into 6 in. pots early in May; this would enable them to get well established before the blooming period. The calycanthema section usually exhibits both a taller and a looser growth, and should be planted in borders behind the double and single kinds.

A. D.

**Myosotis rupicola.**—This is undoubtedly a gem on rockwork, but it must not be regarded as useful for spring bedding. It is deciduous, and, unless its place be carefully marked, it is in danger of being destroyed during the winter. It is hardy, but can hardly be termed robust. Its flower-stalks reach to an height of from 3 in. to 4 in.; its flowers are small, but of a deep rich blue. I have grown it here in pots, but cannot get it to winter well. *Myosotis distillifera* has been in flower in the open ground for the past three weeks; when raised from seed it is, without exception, the earliest and most effective of all the Forget-me-nots.—A. D., Bedford.

**Machine-made Seed Boxes.**—A machine for constructing boxes, made of strong paper, exhibited at the United States Centennial Exhibition, is estimated by the United States Commissioner of Agriculture as able to save from £1000 to £1400 a year in the cost of putting up seeds for distribution from his department.

## NOTES OF THE WEEK.

**A Dublin Square.**—We regret to learn that the plans for Stephen's Green include a "geometrical parterre," "fontaine," and "a sheet of water," all of which are wholly needless in such a position, and can only tend to make all simple and beautiful design impossible in the square—already very fine, and wanting no "design" of the kind above specified.

**New Arctic Saxifrage.**—The Whipcord Saxifrage (*S. flagellaris*), a native of Arctic America, is now in bloom at the York Nurseries. It forms dense rosettes, resembling those of *Draba cuspidata*, of obovate, glaucous leaves of thick texture, beautifully ciliated with spiny teeth, or strong, viscid, glandular hairs. The whole surface looks "frosted" to a larger or smaller extent. Flowers solitary at present (sp. bears one to five flowers on the stalk), rather large, bright yellow, spotted at the base of the petals with orange, in the style of *S. Hirculus*. From the axils of the leaves slender stolons, 1½ in. to 2½ in. long, are emitted in all directions, which root again at the extremities and produce fresh rosettes. An interesting addition to our Alpine rarities.—J. BACKHOUSE, York.

**Puschkinias.**—These very beautiful hardy bulbs flower in February and March. *P. scilloides* is the earliest, being generally in bloom before the others show themselves above ground. It is much weaker in its style of growth than *P. libanotica* and *P. libanotica compacta*, and produces fewer flowers on a spike. *P. libanotica* is the next to bloom, and is a very pretty plant; but the most showy is *P. libanotica compacta*, which, when plentiful enough, will be in every garden; it is, I think, the most fascinating of all the spring bulbs. They all seed pretty freely, and arrive at blooming size in about four years. Those who grow them should look carefully after the seeds, and sow them as soon as ripe, either in pots or in the open border.—J. G. N.

**Tropaeolum Screens.**—A very effective way of growing *Tropaeolum* is practised in Messrs. Henderson's nursery, at Pine-apple Place. The plants are grown in pots placed against iron pillars on each side of the pathway; two wires are fixed across the rafters behind the pillars close to the glass, and along these the plants are trained, their lateral shoots being allowed to droop down, and thus form curtains of greenery intermixed with brilliant scarlet blossoms. When these shoots get too long they are looped up to the wires, and are thus kept within bounds. Besides forming an effective feature during the winter months, such plants afford abundance of bloom for cutting. The plants must, however, be grown in pots (the roots being allowed to run through the bottom if desirable) or rank growth and few flowers will be the result. The kinds grown here are *T. Lobbianum* and *T. Lobbianum splendendum*. The latter is considered the best; its flowers are much brighter, and are produced, if possible, in greater profusion than those of *Lobbianum*.

**Anthuriums at Anserley.**—When grown in small pots the scarlet-flowered *Anthurium Scherzerianum* is much more useful for decorative purposes than in the shape of large plants. Grown in 4-in. pots, there are just now hundreds of plants in flower in Mr. Wills' nursery, at Anserley, where, arranged on the side stage of one of the houses, they form quite a bank of bright scarlet spathes. The flowers do not, of course, come so large on plants grown in small pots, but they are more useful and quite as effective. In order to get small plants to flower freely, they require to be kept in a moderately cool temperature, and rather dry at the roots in autumn; and when introduced into a brisk heat in winter, and well supplied with water, small plants, such as we find here, bear four, five, and sometimes six waxy, scarlet spathes. Soil of a very sandy character is used for them, and for decorative purposes they rank among the most important of small-flowering plants grown at this nursery.

**The International Exhibition at Ghent.**—This begins to-day (March 30), and will, it is expected, prove a very interesting exhibition, though of a type of which we have already had many examples. It is a great mistake to hold these international exhibitions at this inclement time of year, simply because a few families of pot *Azaleas* and other plants are in flower, and when neither kitchen garden, market garden, fruit or flower garden, park, or even the country itself, can be seen with profit. So far as this country is concerned, the weather at so early a date is always such as to deter private growers from contributing in such a way (if at all) as to reflect the horticultural capabilities of this country. Such is not, however, the case with nurserymen, whose enterprise prompts them, even in such pinching cold as we are now having, to subject the most rare and valuable plants to the uncertainty of a long journey. Mr. Bull is sending a fine collection of his newest introductions, many of which have attained a size sufficient to exemplify their natural beauties. Mr. Williams also furnishes a miscellaneous collection, comprising his six new *Dracaenas*, shortly to be offered to the public,

including the very handsome *D. Bausei*; half-a-dozen new *Crotons*; numerous scarce new *Palms* and *Cycads*; numbers of *Orchids* in flower, consisting of *Odontoglossums*—amongst which is the beautiful *O. cirrhosum*, bearing six spikes—numerous *Dendrobiums* (comprising the lovely *D. crassinode* and *D. Wardianum*), *Cypripediums*, and *Masdevallias*. Along with these are also the exquisite blue-flowered *Tillandsia Lindeni*, and 100 beautifully-bloomed plants of *Cyclamen giganteum*, than which nothing, we predict, in the whole exhibition will have a more chaste or effective appearance.—B.

**Cinerarias at Dulwich.**—The *Cinerarias*, of which there is a large collection in Messrs. F. & A. Smith's nursery, at Dulwich, are now at their best. In size and form the flowers are perfect, and while some are self-coloured, varying from rich purple to the most delicate lavender or violet, others have dark centres encircled with white, and beautifully edged with purple, magenta, or rose. Such results are only obtained through careful annual selection of the best kinds for seed and hybridization.

**Cereus MacDonaldis.**—Last week we called attention to a fine crimson-flowered *Cereus* at Kew under the above name. That, however, is not correct, for *C. MacDonaldis* is a night-flowering species, with very large white flowers. The red one is the plant known in gardens under the name of *C. Mallisoni*.

**The Green Park.**—A considerable depth of soil is now being heaped over a portion of the Green Park where there are many trees. As a good many trees died in the Regent's Park some time ago from a similar deposit of soil, this is, perhaps, a doubtful practice. From a landscape point of view, it is also very doubtful if it be well to interfere with such natural and not unpleasing undulations as occur in the Green Park near Piccadilly.

**Dracena Mrs. Wills.**—For decorative purposes generally this is one of the best of the many *Dracaenas* which have been raised during the last few years. It is dwarf and graceful in habit, its leaves are green, elegantly striped with creamy-yellow, and, in point of hardiness, it is unequalled. As a companion to it *Elizabethi* may be used with advantage; its habit is similar, and its leaves are bronze and scarlet or crimson.

**Cycas circinalis glauca.**—This is one of the best of the *Cycads* for conservatory decoration. It has upright, glaucous fronds, which are easily kept free from insects, and at all times of the year, either in large or small plants, possess a lively and ornamental appearance. We saw specimens of it in Mr. Ley's nursery, at Croydon, furnished with fronds from 8 ft. to 9 ft. long.

**Dendrobium Ainsworthianum.**—This, one of the rarest and most beautiful of the family to which it belongs, is now in flower in Mr. Bull's nursery, at Chelsea. Its blossoms, which are borne on well-matured pseudo-bulbs, have petals and sepals of the purest white, forming a striking contrast to the lively purple lip, which has a distinct margin of soft cream colour.

**Aletis fragrans.**—The value of this plant for purposes of decoration is well understood by Mr. Wills, who grows as many plants of it as can be secured. Its broad, soft green leaves, which have a gracefully drooping habit, render it one of the best plants which can be used for room or dinner-table decoration. When in flower its value is increased, for the small, white blossoms, which are produced in whorls on stiff stalks, possess a strong scent, one small plant being sufficient in the evening to scent a large house. The flowers open in succession, and its period of blooming is thereby considerably prolonged.

**Orchids at Chelsea.**—There is just now a good display of *Orchids* in flower in Mr. Bull's nursery, at Chelsea. Conspicuous among them are well-flowered plants of the hardy *Lady's-slipper* (*Cypripedium spectabile* and *C. aculeatum*). When grown in heat the former variety bears flowers with snow-white petals, and the lip is much more delicate in colour than in the case of flowers produced in the open air. Associated with these are finely-flowered examples of *Dendrobium Devonianum*, *D. nobile Wallichi*, some fine varieties of *D. Wardianum* and *D. crassinode Barberianum*. The beautiful *Cattleya citrina* bears large, drooping, sweetly-scented, golden blossoms, which form an effective contrast to the showy flowers of *C. Trianae splendens*, *Odontoglossum Roezli* and its white variety. A plant of the curious chocolate-coloured *Masdevallia trochilus* is also in flower here, likewise a brilliant purple-flowered *Masdevallia* named *Harryana caruleascens*. *Oncidium sarodes* bears branching spikes of showy, crimson-golden edged blossoms, and *Ada aurantiaca* is furnished with graceful racemes of orange-scarlet, wax-like flowers.

**The Blue Polyanthus.**—Mr. Ambrose Balfie sends us a good specimen of this interesting plant from Dublin. It occurs, he says, in Irish gardens occasionally, but is far from common. "The 'blue,'" like that of other flowers to which the term is applied "by courtesy," is not quite true, but yet almost enough so to justify the name.

## NOTES FROM KEW.

**Hardy Shrubs and Herbaceous Plants.**—Foremost in beauty amongst trees and shrubs in the open air is the Yulan, *Magnolia conspicua*, which is covered with its large white flowers. Although rarely deserving to be called a tree in this country, in its native one—China—it attains a height of from 40 ft. to 50 ft. *Prunus (Amygdalopsis) triloba*, from Japan, makes a very handsome wall plant and produces flowers much more abundantly, larger, and richer in colour than when treated as a bush in the ordinary shrubbery; the buds are deep red, the fully expanded flowers rose coloured. If the wood be well ripened this forces well. A Chinese Quince, *Cydonia sinensis*, has fine large pink flowers, which are, however, not produced in sufficient numbers to warrant a recommendation of the species for general cultivation. *Discaria longispina* is a very remarkable and peculiar Rhamnaceous bush from Monte Video. The leaves (when present) are small and inconspicuous; the opposite, secondary branches are abortive and reduced to smooth, strong spines about 2 in. in length; the small, white tubular flowers, which present no special attraction, are produced in short racemes. *Xiphon caucasicum*, from the Caucasus and Northern Persia, is a pretty dwarf Iris with yellow flowers. A relation of this, more curious, perhaps, than pretty, but still worth a place in any flower border, is the Snake's-head Iris, *Hemodactylus tuberosus*, or, as it is sometimes called, *Iris tuberosa*, from Southern Europe; the long, four-angled, somewhat glaucous leaves considerably overtop the flowering stems with their strange black and green velvety flowers. *Mossari Heldreichi*, from Greece, is one of the most beautiful of the Grape Hyacinths; just the tips of its short, bell-shaped flowers are white, the remaining portions being a most brilliant blue. *Primula viscosa*, a very handsome Auricula-like Primrose, has purplish-red flowers and green—not nearly—leaves. A variety of the European *Corydalis tuberosa*, with its prettily-cut leaves and bold white flowers, is very striking; this has long been an inmate of our English gardens, as it is recorded to have been introduced in 1596. *Hypoxis orientalis*, from the Caucasus, is a very desirable perennial Herbaceous, with short stems and lilac-purple flowers. *Physoclaina physaloides*, a native of Siberia, is a near ally of the last-named, which it much resembles. Both are well worth growing because of their flowering so early in the season. *Leucium pulchellum* is a pretty Snowflake, with long, dark green, shining leaves and tall scapes, bearing couples of fine Snowdrop-like flowers. *Fritillaria tenella*, from Eastern Europe, has graceful, narrow, glaucous leaves and drooping flowers, purplish-red on the outer surface, veined and splashed with green and yellow on the inner. *F. glaucescens* has broader leaves and dull flowers, somewhat similar to those of the preceding species. *Anemone apennina* is one of the best of the Windflowers for general cultivation, as it seems to thrive and freely produce its charming blue flowers in any soil or situation. *Puschkinia scicula* is larger in all its parts than the pretty little *P. scilloides* mentioned in last week's "Notes from Kew"; the flowers are borne in racemes and are white, faintly veined with blue. With the exception of the common Daffodil—*Narcissus pseudo-Narcissus*—and some species which have been previously noted, the only *Narcissi* at present in flower in the Kew collection are *N. odorus* and its variety *latus* from Southern Europe.

**Greenhouse Plants.**—*Acacia pubescens* is a very graceful Australian species with light green bi-pinnate leaves and panicles of light yellow flowers. *Babianna stricta*, a bulbous Irid from the Cape of Good Hope, is a charming little plant with lavender-blue flowers, the basal portion of the six floral leaflets forming an eye which is two or three shades deeper than the blue of the other parts of the flower. *Eutaxia myrtifolia*, from Australia, is a very pleasing member of the Pea family; its slender stems are thickly covered with its orange-yellow flowers. *Gnidia pinifolia* makes a very pretty bush with its slight stems clothed with small Pine-like leaves and terminal heads of yellowish-white, fragrant flowers. *Adenandra fragrans* makes a very neat pot plant; its flowers are somewhat smaller than those of *A. umbellata* noted in THE GARDEN a week or two ago, but their beautiful rosy-pink colour more than makes up for lack of size.

**Stove Plants.**—*Rudges macrophylla*, a native of the neighbourhood of Rio de Janeiro, is a magnificent Rubiaceoens shrub with large, leathery, glossy leaves, and dense, nearly globular, heads of large, wax-like, white flowers; it deserves to be grown in every collection of choice stove plants. One of the most desirable of stove twiners is *Petraea volubilis*, from Vera Cruz; the large flowers of a peculiar purple colour are borne on long graceful racemes. For a coloured plate of this handsome shrub, and for full cultural details, see THE GARDEN for July 14, 1877. *Cyclonema myricoides* is a pretty bush from Abyssinia; its blue and white flowers are produced in abundance, but the disagreeable odour exhaled by the foliage—

very similar to the fetid smell given off by the bruised leaves of the Hedge Woundwort (*Stachys sylvatica*) of our own woods and copses—tends to confine this Verbenaceous purple to the botanic garden. A very lovely climber is *Bignonia purpurea*, from Tropical America; the upper part of the throat of the large trumpet-shaped flowers is white, the other portion, and all the limb, being suffused with rose, veined and striped with reddish-violet. *Burchellia capensis*, from South Africa, is a neat-habited little bush belonging to the same family as the first-named of this week's stove plants; the handsome scarlet flowers are borne in clusters at the ends of the short branches. An East Indian herbaceous perennial, *Monolophus elegans*, has large showy white and purple flowers borne on short stalks; the leaves develop some weeks after the flowers have withered. It is a member of the Ginger family, and an uncommon-looking and pretty plant.

**Orchids.**—There are but few noteworthy Orchids this week that *Cypripedium spectabile*, a hardy species from North America, forces well is evident from the fine pan now in flower at Kew; the light green leaves set off splendidly the large white and rose-coloured flowers. *Dendrobium Jenkensi* is a most charming Orchid; the creeping stems and short one-leaved pseudo-bulbs closely embrace the piece of wood on which it grows; the large yellow flowers are borne in panicles on rather long drooping stalks. It is a native of the East Indies. *D. litiflorum* belongs to the same section as *D. nobile*, and differs from it in its decided somewhat trumpet-shaped lip; the coloration of both is very similar.—†.

## RAISING CINERARIAS.

CINERARIAS are now in full flower. The new strains originated by Messrs. Standish & Co., James, and others possess one or two good qualities, viz., a dwarf, close, robust habit, and fine, symmetrical heads of bloom; the flowers also are large, bold, and striking in colour. Plenty of air is now necessary, except when the wind is cold; then it must not be allowed to play directly on the plants. If it be in the south or south-west, air may be given abundantly. The great disadvantage of growing *Cinerarias* in a close atmosphere is, that they become drawn and infested with green fly; and if the latter be allowed to make headway, the plants suffer materially. Shading from the midday sun is also necessary. The plants may be said to delight in shade when they are in flower. Water must be freely given in drying weather, and a little weak liquid manure is of great advantage to them.

Though named *Cinerarias* are still offered in catalogues, their culture is the exception rather than the rule. Seed of good strains is now so generally sold that the necessity for growing named varieties, in order to have flowers of good quality, is practically obviated. By careful seeding a batch of good flowers can always be secured. Therefore, the grower should select a few of the best varieties for seed-bearing purposes, and in doing this choose plants having the following points, viz., good form and substance, robust, close growth, and brilliant colours. The best plan is to isolate such plants, and, if possible, cover them with a netting, to cut them off from bees and other insects, which often spoil a strain; some netting does not exclude light and air, and it does not cost much. Then when some really good flowers are produced by seedling plants a few can be propagated by means of cuttings. The plan adopted is a simple one. When the seed is gathered the plants should be set out in a cool, shady place on a north aspect, kept watered during sunshine, and top-dressed with some good soil. In July and August shoots will be thrown up round the base of the flowering-stems, and from these cuttings can be made, struck in a slight bottom-heat, and then grown on through the autumn and winter to bloom in spring. Sometimes cuttings are taken in spring, as soon as young growths appear at the bottom of the stems; and if these be struck at once, and grown on during the summer, so as not to become pot-bound, the plants will flower in the autumn.

Some *Cineraris* seed may now be sown for a batch of early-flowering plants, potting off and growing on into size to bloom in October. D.

**Harrison's New Musk.**—This is a decided improvement on the old variety, and its scent is equally strong. It makes an excellent vase or basket plant, and at this season may be readily increased by division of the roots, or by means of cuttings.—J. GROOM.

**A New Mouse Trap.**—Permit me to thank Mr. H. Harris for his description and illustration (see p.270) of what he terms "an old plan of catching mice." It is, however, new to me, though I thought I knew most of the best methods of dealing with these most troublesome pests. We have never been so pestered with them as this winter, and though no end of figure 4 and other traps have been at work for months, and mice have been caught by the score, more and yet more seem to come. We shall therefore double brink the place over until an end is made of them.—D. T. FRAZ.

## TASMANIAN VEGETATION.

WHAT a happy provision of Nature it is that attractions of all kinds are seldom or never combined in any one place! Take, for instance, the world-famed shores of the Mediterranean, with its Palms, Orange gardens, terraced Lemon grounds, and acres of Violets, Roses, Tuberoses, and Jasmine; its mountains capped with snow, its blue waters, and, above all, its never-dying historical and actual interest. If to all this were added

the wealth and gigantic stature of forest trees, Ferns, and flowering shrubs that Mount Wellington in particular, and Tasmania in general, affords, how poor and tame, how wanting in interest, would any other part of the globe seem! A feeling akin to what has just been expressed certainly comes uppermost in the mind when visiting this far-off island, where a century ago the white man had not yet set foot, whose history is but a record of butchery of, or by, the aborigines, or a chronicle of details of brutalised convict life in the past; where now people and towns are few and far between; where, instead of hanging terraced gardens, the still burning ashes of a primal forest, set on fire to clear the ground, may be found; where no snowy peaks reflect the blue waters of an inland sea, but, for all that, a place where present people and prospects are as happy and prosperous as can well be found; where an artist can find never-ending beauty for his pencil; and where the botanist and gardener will find on the mountain sides, densely clad in virgin forest, that slope down to the stormy Antarctic seas, such trees, Ferns, and vegetation as were never imagined in the Old World. The accompanying engraving, from a sketch made

on the spot, may serve in some measure to indicate the majestic growth of the Tree Fern (*Dicksonia antarctica*) when in its native forest, but it does not attempt to show the countless numbers of similar or finer specimens that crowd the sides of each mountain valley, where some clear stream leaps down, buried perhaps 30 ft. deep by prostrate trunks of mighty trees fallen long ago, and now affording foothold for Tree Ferns, Ferns, and Filmy Ferns of a growth that astonishes anyone who has hitherto seen nothing more than

the puny attempts we can make under glass in England to reproduce their beauty. In such a valley Eucalyptus trees reach commonly 200 ft. in height, and sometimes attain 350 ft., with a girth of only from 30 ft. to 40 ft., their smooth columnar trunks, French grey or pale apricot in colour, towering up like pillars full 100 ft. to the first branch. Under the partial shade and shelter of such trees comes next the deep green *Sassafras* tree (*Atherosperma moschata*), which just reaches the lowest branches of the Eucalyptus with its topmost spray. This is a most noble pyramidal evergreen tree, with small dark-green leaves, and pretty white flowers, said to be confined to this part of the world, as it will not succeed, except under similar circumstances, when transplanted. Among and between these trees comes next a dense growth of evergreen bushes, such as the native Myrtle, with its shining leaves and upright growth, or the beautiful *Prostanthera lasianthus*, with aromatic-smelling panicles of white and lavender flowers; or again the native Laurel (*Anopterus glandulosa*), now well known in English greenhouses, with its pinky-white blossom (not in bloom at this time) and large leaves. All these give such a dressed appearance to the roadside as to remind a spectator of a well-kept gentleman's pleasure ground, more particularly as there are no familiar weeds to destroy the illusion. Where the shade is deepest and the moisture greatest, the *Dicksonias* actually arch over the highroad itself, as will be easily understood when told that the fronds vary in fine specimens from 8 ft. to 9 ft. in length; but what is most surprising is the quantity and substance of the fronds, numbering

often as many as from forty to fifty on one head, and all green and rich in colour. The trunks seldom reach more than 15 ft. in height before the fronds begin to make the head, and they are clothed with various *Hymenophyllums* and climbing Ferns, notably the ubiquitous *Polypodium rugulosum*. Feathery *Clematisses* hang in festoons from trunk to trunk, and *Lomaria proserpa*, with its bold, dark fronds and bright red young growths, carpets the ground, in company with a *Davallia* and many other Ferns, till conviction

Tree Ferns and Forests; Trees in Tasmania. (From a Sketch by E. H. Woodall.)

seizes the mind that no beauty is so great as that shown by Nature, unassisted by any art but that of the road-maker (for without that art it would be impossible to penetrate more than a few hundred yards without being utterly lost), as, once in the forest, vegetation prevents all view. A turn in the road brings us out into the bright sunshine as we round a shoulder of the mountain from whence a view of the sea is gained, which runs far inland, up creeks which bear some analogy to a Norwegian fiord on a small scale. Here an entirely fresh type of vegetation greets the eye, almost sated with shades of green, but rarely relieved by colour, and startles the most unobservant. An open, heathy space, covered with scarlet, pink, salmon, and pure white *Epacris* in fullest beauty, starred over with the delicate green paravols of *Geichenia dicarpa*, a Fern that delights in the fullest sunshine even on a dry hillside, is a sight no lover of flowers can ever forget, and which Tasmania boasts can be seen to greater beauty on her shores than elsewhere. Here also one of the *Leptospermums* (Tea trees or May Bough, as they are generally called) is in great beauty, its graceful drooping sprays of white flowers and brown-red berries contrasting with the stiff and sturdy *Epacris*. How strange it seems that so few of the beautiful shrubs and trees from this cool island will bear our English climate even in the most genial spots! Perhaps it is that our summers are at times as much too hot for them as our winters are too cold, and the additional evil of a changeable and cold spring is the last straw that crushes the spark of life out of many a beautiful shrub or plant that should ere this have been abundant in our gardens had conditions been more favourable. It is easy to see how sensitive on this point much of the vegetation is here. Tree Ferns, for instance, do not begin to grow until an altitude of 700 ft. is reached, and at 1200 ft. they reach their fullest development; below this elevation summer heat and drought are too great for them, above it becomes too cold; shrubs follow the same line, as in summer at an elevation of 3000 ft. the mountain is enveloped in cloud and mist when the prevailing S.W. wind blows, and but few can stand the cold and moisture that here prevails. *Eucalyptus Gunnii*, a Gum tree that reaches a height of 70 ft., grows under these conditions, and at a still greater elevation is replaced by *Eucalyptus coriacea*, a very distinct small tree, so these two species should be able to withstand anything but the damp cold of low-lying sites in England. It seems a pity that so much praise has been lavished on *Eucalyptus globulus*, which can never make a fine tree in our climate. It grows here in warm and sheltered valleys where the soil is rich and the rainfall very small; it also makes much of its growth in the rainy winter season, a fact that explains its unsatisfactoriness with us. On the summit of the mountain grows the *Waratah* (*Telopea truncata*), whose flower is so prized by Tasmanian belles that it is disappearing somewhat rapidly. A straggling shrub, it nestles among the great boulders that cover the "Col" leading to the highest point, and flowers at Christmas, when it is sought after by all. Too late to see it in flower myself, report says it is far superior to the *Telopea speciosissima* of the Blue Mountains; and if ever successfully introduced into this country would well repay any efforts made to establish it on rockwork. So much attention has been given to the China-Japan flora, that many beautiful plants may still be in store for us from our own colonies. E. H. WOODALL.

## THE FRUIT GARDEN.

### APPLE TREES FROM CUTTINGS.

This mode of propagation is never likely to supersede the one now commonly practised of grafting on a vigorous, free-growing stock when large, fully-developed trees are required; but the plan might be usefully employed for producing free-bearing trees of a limited size for small gardens. Its chief merit consists in the wonderfully dense, fibrous root growth which stout cuttings of well-ripened branches produce. I have lately lifted a number of little fruit-bearing trees, raised from cuttings about four or five years ago, and the thick, mop-like tufts of roots close to the surface fully explain their early and free-bearing habit, as well as the comparatively small amount of annual growth which they make. Some kinds of Apples, especially the Codlins, may be increased from cuttings with the greatest certainty; and, as these varieties are known to be good bearers everywhere, and have a hardy, vigorous constitution, my impression is that they will make excellent stocks on which to graft. Of course this grafting upon stocks raised from cuttings will have a dwarfing effect, but such trees will be useful for planting on bad fruit-growing soils. Anyone who has a large overgrown tree or two of the Codlin varieties—I have rooted other kinds, but the Codlins are the best for the purpose I have suggested—may spare any number of cuttings without doing much injury to the tree. The best branches for this purpose are those about  $\frac{1}{2}$  in. or a little more in diameter, and they should be cut off just under a joint. Larger pieces will root equally well, but they are hardly so well adapted for stocks, although they soon make little fruitful trees. Autumn is the best time to take off the cuttings, as during the winter the wound undergoes the necessary healing and callusing, and is ready in spring to push forth roots before the increased temperature starts the buds into growth. If the cuttings be not taken off till spring the only chance of rooting them is to plant them in a shady, moist border. H.

### PERFECT FERTILISATION NEEDED IN FORCING STRAWBERRIES.

It has been stated that a high temperature so acts upon the fructifying organs of the Strawberry as to render them powerless for their allotted task, and that, consequently, though to all appearance the flowers are right enough, they produce nothing in the way of fruit—only mere "tufts of abortions." This explanation, of course, means that, if we are to have crops of Strawberries, we must practise low temperatures while the flowers are setting; and the figure usually recommended by writers is from 50° or from 55° to 60° day and night respectively, till the fruit is set and swelling, and after that, according to Mr. Thompson, who bases his instructions upon Lindley's "Theory," it may be raised to 65° towards the ripening period, and occasionally to 75° by sun-heat. Now, as a matter of fact, Strawberries could not be ripened in anything like a reasonable time by such slow treatment, though we admit that, if these temperatures were much exceeded, the results as regards the setting of the fruit would be simply "tufts of abortions," unless artificial fertilisation was resorted to. Provided the flowers are gone over with a camel's-hair pencil about twice a week, the Strawberry may safely be subjected to a night temperature of from 60° to 75° or 80° by day when in flower, with every prospect of a good crop of fruit. I have, indeed, set the fruit of every successive batch in a position where the night temperature was as often above 60° as below it, and the day temperature proportionately high. It was under such circumstances that I first satisfied myself that artificial fertilisation is a necessity, when the plants were subjected to an unusually high temperature, by actual experiment. On different occasions part of a shelf of plants was left unfertilised, and they, as a rule, produced no fruit, or if they did, they were but few, and always deformed. It must not be forgotten that the Strawberry does not, properly speaking, consist of one fruit, but many. Every perfect pip of a Strawberry contains a seed, and must be fertilised separately. If this be not done, the pip, like the pip of a Pine-apple, goes blind, and the result is a small deformed fruit, just according to the number of pips that have missed fertilisation. The camel's-hair pencil, if used intelligently, insures the fertilisation of the whole ball, and an even, large, and well-swelled fruit is the result. As has already been said, the flowers should be gone over two or three times a week, particularly in dull weather when the ventilation is reduced. The work should be done early in the afternoon, when the pollen is dry. The brush should have a

**Road Making.**—Herr Weber, of Himmels-Redeck, near Lübben (Prussia), is reported to have constructed a simple machine for levelling roads, which for working requires only two horses, a driver, and a labourer, and renders it possible to make such improvements in a road in a short time as could otherwise be accomplished only by fifty or sixty workmen. The machine works equally well upon gravel or clay soil, and its cost is only forty-five marks (shillings). The whole machine works much in the same way as an ordinary carpenter's plane does upon wood.

**A Relic of the Temple.**—Archæologists have much deplored the disappearance of the venerable tree which for ages occupied a prominent place in the garden of the Middle Temple, and about which there are many interesting traditions. Among these is one that the tree was a favourite tryst of Henry VIII. and Anne Boleyn. We are informed that its timbers have been used in the construction of a cabinet of antique pattern, which is a valuable addition to the art treasures in the corridor of the Middle Temple Hall. The old tree was removed at the time when the ground was cleared for the continuation of Plowden Buildings, facing the Embankment.

broad point, and each fresh flower should get a touch with it over the yellow ball of stamens. The brush soon gathers abundance of pollen, and if kept dry will do its work well; and going over a hundred or two of plants is the work of only a few minutes, so that the labour is nothing to speak of. We have never omitted the practice once for many years, and have never missed a good crop of fruit, though we have always subjected our plants to a temperature 10° or more higher than is recommended at the setting period. At the present time we have some three hundred plants all set and swelling fine even fruit, among which not a sterile plant has been found that produced flowers.—"Field."

### LATE PEARS.

FEW English-grown Pears are fit for dessert longer than the month of March, though there are several varieties which keep well, and are

Fig. 1.—Prince Albert.

excellent for culinary purposes till quite the end of May. Amongst them, Prince Albert (fig. 1) is a good late kind for this purpose. After a very hot autumn, I have known it passable as a dessert fruit;

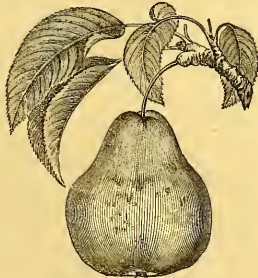

Fig. 2.—Bon Chrétien d'Hiver.

but it should not be planted with this view, as the flesh, though juicy, is coarse. It is a handsome-looking fruit, and will keep well till May. The tree is a free grower, and unusually fruitful. Bon

Fig. 3.—Beurré Bretonnean.

Chrétien d'Hiver (fig. 2) is one of the few late Pears that are good either for dessert or for culinary purposes; it is equally prolific as the preceding, and will keep in good condition till April. To do it justice it should be grown on a south or west wall, and may then be

depended on as a late dessert fruit of good quality, with size and fine appearance combined. Usually the fruit is more perfectly pyriform, and sometimes more uneven than is shown in the illustration. Beurré Bretonnean (fig. 3) is one of the latest of all late Pears, keeping sometimes till midautumn, and generally till May; when it ripens well, which is only after a hot summer and autumn, it is first-rate for table, but it is so uncertain that it should only be grown in the largest collections, as when it does not ripen it is hard and woody, and not even fit for stewing. The following are also amongst the best late Pears, viz., Best Mai, March Bergamotte, and Marie Guiseo. W. W. H.

### THE CULTIVATION OF FRUIT TREES IN POTS.

M. FIRMIN CHAPPELLIER, of the Avenue Daumesnil, Paris, having at recent exhibitions shown some excellent specimens of the Doyenné d'Hiver Pear grown on an unwall'd piece of ground, the French Société Centrale d'Horticulture appointed a Commission to inquire into the method of culture adopted by him. The results of their labours are published in the December number of the journal of the Society, from which are extracted the following details:—The Commission visited M. Chappellier's establishment at various times from the beginning of December, 1876, to October, 1877. On their first visit the members of the Commission were struck with the peculiar appearance of M. Chappellier's garden. They looked in vain for Pear trees grown as espaliers, palmettes, pyramids, or spindles; in fact, all the ordinary forms of fruit trees were absent. The whole of the ground was divided into squares planted with trees trained in the spiral cordon form, some in the ground and others in pots. It was these latter to which the Commission more especially directed their attention. The trees planted in the ground were in lines 6 ft. 6 in. apart, and were uniformly 6 ft. 6 in. in height. Those in pots were no more than 3 ft. 3 in. high, but, on account of being trained spirally, their single central stem was 6 ft. 6 in. in length, those of the trees planted in the ground being 13 ft. in length. This low form has the advantage of facilitating every operation connected with the trees. They can also be more readily sheltered from the cold when it is found advisable. The Pear trees in pots were prepared for passing through the winter. Some of these were arranged in squares of twenty-five, the pots touching each other, and surrounded by boards forming a kind of box about 18 in. high, something like a garden frame, and filled with dead leaves, which entirely covered the pots, filling up all vacant spaces. At the angles of the box were four uprights, joined to each other by cross pieces, which rested on and were fastened to the iron wire spirals to which the trees were trained. This framework was shortly to be covered with straw mats or cloth, to act as a shelter during the winter and early spring. Others, again, had been taken out of their pots and arranged in squares, and their roots covered with earth. They would remain thus "laid in by the heels" until the end of the winter, when they would be re-potted. The whole of the trees had been pruned, and the raw surfaces covered with composition. Nearly the whole of the trees, which were three years old, had their bases covered with fruit buds. In the middle of April the Commission paid a second visit to M. Chappellier's garden, and found all the trees in pots in full bloom. The planks and leaves which had sheltered them during the winter had been removed, but the framework, which has already been described, still bore the necessary sheltering materials. On the top rested a light frame, on which was stretched a piece of calico, another piece, about 1½ ft. deep, hanging from the horizontal pieces of the framework, and entirely surrounding the square like the top valance of an old-fashioned four-post bedstead. These different coverings are very simple in character, and can be taken away or replaced with the greatest ease and celerity. The third visit took place on August 18, at which period the Pears had attained their full size. The trees in pots bore an average of seven Pears each, mostly of excellent quality. The whole of the fruit, especially the Doyenné d'Hiver, looked very healthy, and were without specks or other blemishes. Amongst trees in pots the varieties singled out for high approval were a Passe Colmar with 10 fruits; a Baronne de Mallo with 9; a Beurré Diel with 10, of excellent quality; and a group of 10 Doyenné d'Hiver, bearing altogether 72 fruits. The whole of the fruit of the trees grown in pots, as well as the trees themselves, were much finer than those grown in the open ground in the same garden, notwithstanding they had been grown under the same conditions and trained in the same spiral form. The fourth and last visit of the Commission was paid on the 6th of Oct., that they might see for themselves that the fruit which was ready for gathering was in perfectly good condition. For this mode of culture M. Chappellier uses pots of 16 in. in diameter, pierced with five holes at the bottom, and containing about 150 cubic in. of soil composed of good garden mould and rotten manure well sifted. Dur-

ing the summer the bases of the trees are surrounded by straw to keep them cool and damp. Two waterings of liquid-manure are given during the season, at the rate of about five pints to each pot, waterings with plain water being given as occasion may require. The liquid manure used by M. Chappellier is composed of one part of night soil mixed with four parts of water. The cost of the pots is 2s. in Paris, and the training wire are about 1s. a piece. The cost of the trees and the expense of attending to them is not mentioned. For tying the young trees to the wire cordons woolen list, torn in two, is used, so that the young shoots may take the spiral form. Later on the list is replaced by Willow bark in the usual way. The pots are not sunk in the ground, but simply placed on the surface of the soil of the garden, which should be properly prepared and manured in case the young rootlets should push through the holes in the bottom of the pots in search of additional nourishment. Every year after the fall of the leaf the trees are taken out of their pots, the ball of earth gently shaken, and the space which was occupied in the pot by the earth thus got rid of filled up with fresh mould prepared as above directed. The fruit grower must not wait until the stem has grown beyond the spiral cordon, but must cut back as soon as it is necessary. The Commission sums up by giving its opinion that the method of culture adopted by M. Chappellier is a good one, and has been intelligently carried out, but that the different operations of pruning, pinching back, &c., are performed with so much care, that a similar good result may be looked for at the end of the present and every other year. For growing fruit commercially, or for home use on a large scale, this mode of cultivation would of course be rejected in favour of the ordinary system of open ground orchards, but it ought to be of great use to a large number of amateurs, who are often prevented from growing fine kinds of Pears either through the ground at their disposal not being suited for the purpose, or through not having sufficient room to grow trees as espaliers. By following this system of culture in pots, it will be easy to grow fruit without any garden, as a flat roof or even a paved courtyard may be used.

C. W. QUIN.

**Scarcity of Pear Blossoms this Season.**—Is this general or only local? I should like to have the opinions of your correspondents on this point. Last year we had a good bloom cruelly wrecked. This season we have the thinnest bloom, especially on pyramids, that I have seen for many years. It is somewhat difficult to account for it; true, the summer was wet, but I have seen seasons equally wet, and perhaps colder, succeeded by a fair bloom, as regards Pears. Apples promise well, not, however, an extraordinary crop, but a good medium one, which is far more satisfactory, as little thinning will be needed, and the fruit is always finer on trees not over-burdened. However, this may seem somewhat like counting our chickens before they are hatched, for March, April, and May frosts may yet blight all our Apple prospects. They are, however, late, and have a good chance of escaping; but as for Pears, their fate is sealed already.—D. T. FISK.

**Espalier Apple Buds Killed on Galvanized Wire.**—I have had trained on galvanized wire espaliers for five years some good growing sorts of Apples; at least, they do very well indeed on a wooden espalier within ten paces of the galvanized wire, and the same sorts do equally well as standards. I have watched these trees very closely, and the selection was carefully made when purchased as regards healthy clean trees. They did well after being planted, but every spring since I have had whole branches to cut out, as their buds were all dead. I had them lifted in November, 1876, and replanted in good fresh loam, adding some ½ in. bones, but no improvement has been made. The buds all seem to die, and I have now come to the conclusion that the wire, being a condenser of lightning, has killed the buds. I should, however, like to have the experience of others on this point.—D. LAMOND, *Arthursstone, N.B.*

**The Mume of Japan (Prunus Mume).**—This, which is only to be found in a few botanical gardens, bears fruit in abundance and of excellent flavour. It is a species which ought to be valuable, not only on account of its fruit, but because of its ornamental appearance as a shrub. Its foliage is large and abundant, and is borne on long pendent branches, which flower profusely, besides which it has the additional recommendation of being very hardy. The Mume is generally eaten in a cooked state in the far East, where it is greatly relished. Its kernel closely resembles that of an Apricot; in fact, as a fruit, it is half-way between an Apricot and a Plum in most of its characteristics. In Siebold and Zuccarini's "Flora Japonica" we find a plate which represents Prunus Mume with a round, speckled fruit, closely resembling that of a Plum, with rose-coloured flowers in one variety, and white ones in another. Possibly the latter is a wild variety. M. Lavallée exhibited to the Horticultural Society of France, the other day, a good figure of it which had been drawn

from a specimen grown in his arboretum, which differed in many respects from the one in the "Flora Japonica." M. Hodiard mentioned that he often received consignments of Kaki Plum in connection with his business as a foreign fruit merchant, and that they were greatly sought after by Creoles residing in Paris.—C. W. QUIN.

**The Fight for Fruit.**—March has now (23rd) set in earnest. This morning the thermometer registered from 9° to 14° of frost, according to locality and altitude. The frost was accompanied by a biting north-west wind, that made the air more like December than the latter end of March. To-night the frost threatens to be still more severe, with the wind in the same quarter. Apricots on wall have been in full flower for a week, Peaches and Nectarines are more than half open, and a few Plums are wholly expanded. Apples and Cherries are quite closed, the buds having as yet moved but little. Pears, alike on walls and in the form of pyramids and standards, are in a dangerous condition, though no buds are open. In addition to portable glass and wooden copings, we have half smothered our walls with boughs, and also tied quantities of these over all our Pear blossoms. From the copings all the nets in the place have also been suspended, and should the cold increase every mat and yard of bunting will also be called into requisition. Still, should the cold continue long or increase a few degrees, the chances are terribly against the cultivator. March severities of late years are provokingly prone to run into and through May. I have known blankets taken off the bed to save a crop of Cucumbers. Possibly all our blankets could hardly insure a good crop of wall fruit this year. Those who were wholly unprepared for the frost of last night have already lost their Apricots, and have had their Peaches severely thinned. Neither of these crops will bear 10° of frost when in flower. Unless our winters and springs revert to their original character all our superior stone fruit will have to be grown under glass and our open walls devoted to Pears, and these will also need protection to carry them through the severities of spring frosts.—D. T. FISK, *Hardwicke House, Burg St. Edmunds.*

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Best Baking Pear.**—I cannot agree with the statement (see p. 253) that the *Cailliac* is the best baking Pear. *Uvedale's St. Germain* is by far the greater favourite. True, it needs a wall in most parts of the country to grow it to perfection, while the *Cailliac* succeeds well as a pyramid or a bush. But the size and quality of the *St. Germain* are unrivalled. The custom, however, of using the finer dessert Pears for stewing is so rapidly extending, that stewing Pears of any kind are less grown than they used to be.—D. T. FISK.

**Painting Fruit Trees.**—Many advocate the use of whitewash upon fruit trees. Several are convinced that it will prevent and even cure Pear blight, but many object to whitewashing trees because it renders them unsightly. This need not be. A certain quantity of lamp-black and red mineral paint-powder may be mixed with the whitewash, imparting the colour of the bark so closely that it is not apparent to the casual observer that the trees have been washed at all.—"Moore's Rural."

**Fruit Tree Protection.**—A correspondent of the "Gardeners' Record" recommends the following plan for protecting the bloom of Peach, Apricot, and Nectarine trees from spring frosts:—Procure some paling wire, cut it into lengths of 10 in., drive them into the wall beneath the coping 3 ft. apart, and 5 ft. lower down drive another row the same distance apart. Then procure a quantity of Spruce Fir branches of the required length, and well furnished with leaves. Hang them on the wires top down. They will lie close to the wall and effectually protect the bloom and young fruit from frost. They should be hung on every night when there is appearance of frost, and taken off in the morning, except the weather is severe, when they may remain on while the frost continues.

**The Best Peaches.**—The varieties of new Peaches of American and English origin have become so numerous, that amateurs and others who very much like to do well to add the fine early melting *A Bee* Peach to their stock. The tree is hardy, a good grower, very prolific, and one of the finest and best for forcing, as it ripens about a fortnight later than the *Early Grosse Mignonne*. Flowers large; fruit equal in size, colour, and quality to *Royal George*, which it resembles, except in point of earliness and freedom from mildew. I have grown it in an early house, also as a pot-tree, and on walls, since 1860, and although I have tested many of the new varieties of more recent introduction, I still look upon this fine Peach as one of the best, either for general use or exhibition. It will probably be useful to many fruit growers if I here add a list of eighteen of the very best early, mid-season, and late varieties.—*Early Grosse Mignonne*, *Halle's Early*, *A Bee*, *Dr. Hogg*, *Grosse Mignonne*, and *Crimson Galande*. Mid-season varieties.—*Alexandra Noblese*, *Dymond*, *Noblese*, *Royal George*, *Violette Hâtive*, and *Bellegrade*. Late varieties.—*Belle Baucé*, *Barrington*, *Prince of Wales*, *Stirling Castle*, *Nectarine Peach*, *Walburton Admirable*, *Crawford's Early* is large, handsome, fine for exhibition, and decidedly the best of the yellow-fleshed section.—W. COLEMAN, in "Florist."

## THE FLOWER GARDEN.

### FUCHSIAS ON OLD WALLS.

ALTHOUGH we have not such fine specimens of *Fuchsia Riccartoni* in this neighbourhood as the Knight of Kerry possesses in Ireland (see p. 327, Vol. X.), yet with us this variety of *Fuchsia* is perfectly at home as a deciduous shrub in the open air, and grows to a large size, frequently reaching 10 ft. high, with stems from 5 in. to 6 in. in diameter. The accompanying sketch shows a remarkable plant of this *Fuchsia* growing on the top of an old garden wall. It is in perfect health, and measures 6 ft. high and 10 ft. through. The wall, which is built of stone, is 2 ft. 6 in. thick, and 7 ft. 4 in. above the ground on one side, and 8 ft. 6 in. on the other. The plant has been growing in its present situation, uninjured by frost, for at least ten years. It is supposed to be a seedling, as no one is known to have planted it there. The modern

*Fuchsia* on an old wall.

racers of *Fuchsias* do not appear to be so hardy as *Riccartoni*, although many varieties with us make considerable wood, the tips only being liable to be cut back by frost.

Falmouth.

J. D. MITCHELL.

### ASTERS IN MASSES.

AMONG the many annuals now in cultivation *Asters* stand pre-eminent, and, when well grown and cared for, do more, at a small cost, in rendering a garden gay and effective during summer and autumn than any other plant with which I am acquainted. To see *Asters* in their full beauty, however, they must be grown in masses of mixed colours—a way in which they show themselves off to great advantage, and produce a most striking effect. This being the case, the best way is to grow them in beds, and as the season will soon have arrived for sowing and planting them out, it is high time these were being prepared. *Asters* like a deep, rich soil, and it is only under such conditions that really fine flowers can be obtained and the plants induced to hold out should dry weather set in. Planted in the ordinary way they are mere weeds compared with such as are well fed and can get their roots deep down in search of moisture; and when they can do this, the hotter the weather is the better it suits them. Confined to the top shallow crust of earth, they are soon dried up and the blooms starved, and this is why we so frequently see the poor, puny plants that are to be found in borders, where, instead of being able to grow and develop themselves, all they can do is to struggle on for existence. I find the best way to manage them is to dig and cast off the top spit to one side handy to be

returned to its place again, and then trench or break up the soil below, working in with it at the same time plenty of short, decomposed manure, which will have the double effect of attracting the roots and affording them ample assistance just as they most require it, when expanding and perfecting their bloom. Trenching, as usually done, brings the crude earth to the surface and buries that which has been exposed to the ameliorating influence of the atmosphere—a fact that should be borne in mind, as it takes years to get in the condition in which plants will lay hold of it and start away freely. In very light dry soils, a few barrowloads of clay chopped up finely and mixed well in has a capital and lasting effect on all future crops, and will do more in producing fine *Asters* than any other help that can be afforded. The thing to aim at is to keep the bottom cool and moist, and, this done, all else is clear sailing, as then, if the weather is anything like favourable, the plants will take care of themselves.

When grown in groups of three in a border, similar preparations are required, or the roots of other plants already in possession are sure to rob them and cut short their beauty long before the autumn sets in. *Asters*, like most other flowers, have been greatly improved of late both in size and general appearance, and are now so large and beautifully symmetrical as to leave nothing to be desired. A few years ago they much resembled the wild *Chrysanthemum leucanthemum*, or the common form of *Pyrethrum*, having only a single row of petals around the outer part of the flower, while those of the present day have layer on layer, and so perfectly arranged that they are faultless in shape, and of the most exquisite colours imaginable. The best of the many varieties now grown is the *Victoria*, which has large globular flowers borne on stout branching stems that are strong enough to stand with but slight extra support. Next to these in point of beauty, or quite equal to them in the eyes of many, are the French *Pæony*-flowered, which are almost as round as a ball, and have elegantly-reflexed petals that give them a richly finished appearance. No one can fail to be satisfied with the above two kinds, as they are far ahead of all others in every respect; but if plants of less height are required, there are the Dwarf Bouquet, which only grow to about 6 in. or so, and are very suitable for small beds or pot culture. The so-called German *Asters* are stiff and formal-looking, as the flowers appear as if clipped into shape; but for all this they are favourites with many, and are certainly very rich and varied in colour.

There is a general idea that *Asters* to be good must be raised from imported seed, but that is a mistake, for, if care be taken in selecting the best to save from, English-grown seed is in every respect equally good. Continental growers certainly have the advantage in point of climate, as it often occurs that wet spoils the whole in a few days, and to get well-ripened seed requires a fine autumn, unless the plants are raised and got out unusually early. Being so exceedingly useful for cut bloom and for greenhouse or other decorative purposes, it is a good plan to grow a few in large pots, as then they may have had much later after fogs and damp nights have destroyed those out-of-doors. When required for such uses, the end of April is quite time enough to sow, and this should be done under handlights, or in pans of light rich soil, and then covered with pieces of glass and stood in a cold frame in the shade till they germinate. To have fine masses they are best grown three in an 8-in. pot, in which they should be placed triangularly a little way from the sides. A rich compost, consisting principally of loam and old hotbed manure, is the proper thing for them, and in this they should be potted somewhat firmly and then plunged in coal-ashes or other material in an open sunny spot till they begin to show flower, when it will be time to remove them under cover of a cold pit or frame. Being gross feeders, they will take and enjoy plenty of manure water if properly diluted before it is used. For growing in beds, seed should be sown at once, and if it can be afforded a very gentle heat, it will germinate the more readily; but directly they are up they should be kept near the glass, with plenty of air, in order to get them strong and robust by planting-out time, which may take place the beginning of May if the weather is then sufficiently favourable. A distance of about 15 in. apart will afford ample room, unless the object is to get extra-sized flowers for exhibition, when, in that case,

more space will be necessary, and if the beds are mulched over and heavy waterings given occasionally the blooms will be all the finer for the attention bestowed. S. D.

#### GROWING PLANTS FOR SEED PRODUCING.

In the same way that those who grow their own seeds of some of the better kinds of vegetables usually possess the finest and purest strains, so also they who grow their own seeds of the more popular sorts of annuals and biennials will find it advantageous to do so, as well as derive a great deal of pleasure from the operation, inasmuch, as with many of these, it is not simply a question of retaining individual varieties in the exact form and colour that a good strain possesses when first purchased, but marked improvement in both the general habit of the plants and individual character of the flowers may usually be secured by a little observation and attention in selecting such plants as from time to time make their appearance, and that are something in advance of the rest.

**Asters.**—Take, for instance, the many and markedly distinct varieties of *Asters* that at the present day exist, distinct not alone in the form and general character of their flowers, but also in size and habit of the plants, these, in a great measure, resulting from careful selection. Speaking of *Asters*, many are under the impression that the seeds of these cannot be successfully grown and ripened in this country, than which there cannot be a greater mistake. My first essay with them was unsuccessful, for the simple reason that, although I raised the plants in the spring on a slight hotbed, and afterwards planted them out in the ordinary way, I found they were not early enough, the cold autumn weather being upon them before they had time to ripen. After that I sowed a little of the varieties I wished to seed about the middle of February in pans in a little warmth, and as soon as large enough, pricked them off singly into 3-in. pots, gradually injuring them to the temperature of an ordinary greenhouse, keeping them on a shelf over the path close to the roof. They were not allowed to remain in the pots, so as to let their roots get matted, but as soon as they had fairly taken possession of the soil they received a shift into others 4 in. or 5 in. in diameter, according to the weaker or stronger-growing habit of the variety. It is essential to mind this, as if the roots in the first stages of the plant's existence get cramped, it induces a hard, stunted condition of the plant, which prevents its ever after growing freely. From the time of shifting them into these pots until planted out, an ordinary garden frame will answer for them. The principal things to be observed are, at the time of planting out to see that they are perfectly free from aphides; if any trace of these exist, the whole should be dipped in Tobacco water. It is essential, also, that they be kept free from these insects afterwards, otherwise the leaves curl, and the plants quickly get so injured that they never recover. Plant in an open situation, and allow the seeds to get quite ripe before gathering. They are free seeders, and a few plants of a kind will produce sufficient for the requirements of an ordinary garden.

**Stocks.**—In the case of annual *Stocks*, when seed was to be saved, I have always retained a few of the plants from autumn sowings in pots, moving them, as soon as their flower-buds gave evidence of their being single, into others 6 in. or 7 in. in diameter, and keeping them in a frame or pit during the season of their blooming and until the seeds were ripe, always selecting plants from strains that were remarkable for habit, colour, and a disposition to produce a large per-centage of double flowers. With the biennial varieties the course followed was similar. In both cases it is well to retain more plants of the single kinds than are required, for amongst them will be found some that produce to each individual flower one or sometimes two petals more than the usual number—four; from these, if sufficient in quantity, it is better to save the seed required, as this inclination to increase the petals evinces their tendency to become double; and from such I have invariably found the produce to comprise a greater number of plants bearing double flowers. With *Stocks* again, as with *Asters*, a large number of plants of each kind are not needed for a private garden.

**Zinnias.**—With both the double and single *Zinnias*, especially the former, so effective either for cutting or border decoration, it is essential, as with *Asters*, to sow early, treating the plants in the same way, so as to get the seeds fully developed and matured before the cold weather sets in.

**Double Helichrysums.**—Except in the southern and more favoured parts of the kingdom, it is necessary to sow the seeds of these under glass, so as to have the plants somewhat advanced and ready to turn out as soon as danger from frost is over or the wet

autumn weather overtakes them before the seed is ripe. They should be sown at the beginning of March in a little warmth, or this failing, a cold frame. At the time of blooming I marked the best-formed flowers of most distinct and decided colours, keeping an eye also on a dwarf, bushy habit of the plant.

**Phlox Drummondii.**—Of these, than which it would be difficult to imagine anything more beautiful than the best strains of self-coloured as well as striped flowers, the seed should be sown about the beginning of March in a pit or greenhouse, and kept on growing, where they will not get drawn up weakly, until the time for planting out. These, like all the plants under consideration, should occupy a good open situation, where they will be fully exposed to the sun away from trees and walls, and not allowed to be too close to the ground, for upon the strength of the plants will depend their ability to mature seed freely. When in full bloom, the plants bearing the handsomest-striped and most decided self-coloured flowers should be marked.

**Dianthus einensis of the Heddeewigi Section.**—There is nothing more beautiful cultivated in gardens at the present day than the splendidly flaked and coloured lacinate-petalled forms of this flower, the character of which is such as to render them completely devoid of all formality in shape, an objection which often exists in flowers that have undergone a process of improvement under cultivation, according to the views entertained by florists. I feel persuaded, if these *Pinks* were more generally known, there are few people who have a garden but would grow them; but in their case, as with all plants so variable in the colours and markings of their flowers, to keep the strain up to the high standard which has been reached, it is necessary to select the best marked plants to gather seed from. They should be sown at the beginning of March in slight heat or a cold frame, turning the plants out singly 1 ft. apart, where they will be fully exposed to sun and air, which is requisite to produce good seeds.

**Marigolds (French and African).**—To preserve the form of the flowers of the former kind, it is necessary to grow them apart from the large-flowered, orange-yellow African variety, otherwise the offspring becomes a confused mass in both colour and form. I have found that to get the beautiful striped and edged flowers in quantity in the French variety, this can be best done by occasionally introducing a few plants of the African kind into the bed where the French are grown; but, except by doing this once in four or five years, as I have already said, unless the Africans are kept at some considerable distance from the French, they destroy the character of the latter. The seeds of these vegetate very quickly. Sow in a cold frame the beginning or middle of March, planting out in patches two or three together, 12 in. or 18 in. asunder, about the middle of May. As they come into flower all the plants that produce single or semi-double flowers, which will be the case with a considerable portion of the French variety, should be cut out, leaving nothing but the best double forms, from which alone save seed. The only objection to these beautifully-marked flowers is their small, which is disagreeable to some people; yet others do not dislike it. The African varieties usually produce a greater number of double flowers. In the case of both the most dwarf, compact-habited plants should be selected to gather seeds from. There are some strains of the French varieties now much dwarfier than others, but none of these that I have seen produce the beautifully-striped flowers of the taller-growing kinds so much grown in the north of England, more particularly Yorkshire.

**Larkspurs.**—The taller-branching *Larkspurs* are much more useful than the dwarf *Rocket* and *Hyacinth*-flowered kinds more generally grown. They are amongst the most beautiful and effective outdoor-grown flowers that can be used for cutting. Some of the blue and violet shades are unsurpassable; they last long in water, and harmonise with almost anything else with which they may be associated. Sow in pans on a slight hotbed or in a cold frame about the beginning of March, and plant out the middle of May, marking at the time of blooming the plants that produce the most distinct and best-coloured flowers.

**Wallflowers.**—The darkest self-coloured flowers are the most prized, for although some of the striped-petalled kinds are pretty enough, still my endeavours were always directed to a selection of the darkest coloured kinds possessing a dwarf, compact, branching habit. In even the best strains, such as the growers for the London flower market have, some will be found at the time of blooming with much higher colours than others. It is well to mark such plants and save seed from them only.

**Sweet Williams.**—The *Auricula*-eyed strains of this plant are well deserving of a little extra care in seed saving; they should be sown about the beginning or middle of June for blooming the year following, and as soon as large enough pricked off into nursery beds. If

allowed to remain in the seed bed, unless sown very thin, they usually become drawn up so weak, as to possess little of the character of a well-grown plant. When in flower, the dwarfest, most compact-habited plants with the best marked flowers, in all cases possessing the Auricula-coloured eyes with as much diversity of colour as can be got, otherwise these generally get too great a preponderance of the dark ones, should be marked, and the seeds gathered as soon as ripe, or they are apt to drop.

The above are only a very few out of the many out-door plants which will well repay a little trouble in the selection for seed growing; but by pursuing a similar course with the large numbers of out-door decorative subjects, improvement in both the habit of the plants and colour and form of the flowers may be gradually effected. Where the seeds of all these spring-sown plants are raised in a hot-bed, or in a house or pit supplied with heat, care must be taken that they are removed sufficiently early to prevent their being drawn up weak, otherwise they had better be confined altogether to cold frames. As I have already said, the number of plants in each case required to select for seeds purposes need not be large; a couple of two-light frames thus occupied for eight or ten weeks in the spring will, for most places, raise enough to be sufficient. The labour involved is little as compared with the satisfaction derivable from a knowledge that the plants of these things grown are not likely to disappoint; and there is a good deal of interest attached to the marked improvement that from time to time will show itself in the colours and forms of individual plants amongst those thus grown by careful selection, for, as will be easily understood by what I have said, this is simply a work of selection, and has nothing to do with the more complicated manipulation and advanced horticultural knowledge required by those who essay the raising of new and distinct forms by hybridisation.

There are also a few of the more generally grown plants for decoration under glass either of an annual character, or such that are the most satisfactorily managed by being annually or biennially raised from seed. Amongst these the Chinese *Primula* holds the first place.

**Primulas.**—Very great improvement has been effected in these of late years, yet anyone who obtains seeds of a good strain may, with a little care and attention, still further improve them. Plants to produce seed should not be sown too early, or at all events not be allowed to bloom early, that is, through the winter, as the flowers which open at this time will not seed near so freely as those produced later on, say in March, or April, neither will plants that have been allowed to become exhausted by blooming through the winter produce seeds freely from any flowers which they may throw up later on in the spring. Such plants as are intended to be grown for producing seed will be early enough if sown at the beginning of June, growing them on under conditions conducive to a sturdy robust stout habit, and pinching out any flower-spikes they may throw up during the autumn or early part of winter, always selecting those, and only those, that have the best shaped and best coloured flowers; in whites it is desirable to have them as pure as possible without any of the pink tinge, which makes them not so effective for greenhouse decoration, and still less so when used for cutting. In the dark-coloured flowers those possessing the deepest shade will generally be found preferable to those of lighter hue, but with these more than most plants, being, as they are, of a somewhat delicate nature, and liable to damp off through the winter if subject to treatment at all at variance with their requirements, it is essential to choose plants that evince a natural strong disposition. At the time of their flowering they should be stood as near the glass as possible, as plenty of light more than anything else tends to a fertile disposition. As the sun gets strong the plants will be better for occupying a position less exposed to it, but still where they will get plenty of light. I have found that weak liquid manure through the time of their flowering still further assists the production of seeds.

**Cinerarias.**—These, more than almost any other popular plant, if not carefully managed as to the selection of the varieties, and equal care bestowed upon them in keeping the different colours separate when flowering, are subject to deteriorate until the greater portion of the produce becomes such an indescribable jumble of shades and colours, many of them the reverse of attractive, as to make them useless. In this deservedly popular flower for general purposes there is nothing equal to the strains possessed by the best growers for Covent Garden market; they confine themselves principally to flowers that may be classed under three heads as to colour, the various shades of red, or deep crimson self; blues, also different shades; and the ringed, or tipped flowers, consisting of more or less of each petal being pure white, with broad or narrow tips well defined of red or crimson, in all cases with the disc of the flower

almost black, or as nearly so as it can be. The individual flowers should be slightly cupped, not disposed to recurve, and with all the petals as evenly arranged as possible. Flowers possessing the above character are found to be held by the generality of buyers in the greatest estimation, and seed from them can with the most certainty be relied upon, if, as already stated, sufficient care be taken with the plants at the time of flowering. The plants should likewise possess a naturally vigorous, dwarf, bushy habit, with a disposition to produce large, healthy foliage at the base, so as to almost cover the pots, and without which half their effect for decorative purposes is wanting. The seed-bearing plants of these also should not be sown early—the middle of June will be soon enough—keeping them dwarf and strong through cool treatment during the summer and autumn until danger from frost is over, when they should receive plenty of light, air, and moisture, without being exposed to the full influence of the sun, and kept clear from insects. Winter in a temperature a few degrees above freezing point and near the light, but away from dry currents of air, which would quickly injure the leaves, and proportionately reduce their seed-bearing capabilities. If the plants come into flower by the end of March and through April, they will be quite early enough. To accommodate them whilst in bloom, they will need three six light frames; these need not be large, as if each will hold six good-sized plants, they will be ample for a large private supply. As the plants begin to open their flowers, they should be frequently looked over, and the best of their respective colours named, chosen, and placed in each frame, the frames themselves standing as far apart in the garden as they can be got, as there is no flower more susceptible of crossing through the agency of bees. All the pips on each plant that have expanded before they were thus isolated should be pinched off. Where the precaution is not taken of keeping *Cinerarias* separate whilst flowering, the produce of the very best strain in existence will, in one or two years, become useless, the blues greatly preponderating, and these also losing their character so far, as a great portion being of almost every shade of lavender and a dirty plum colour, or intermediate between that and crimson. Gather the seed as soon as it is ripe, and store in paper bags, keeping each colour separate. The whole operation involves little trouble, and by following it scarcely an inferior coloured flower or indifferent habited plant will be found, even if thousands be grown.

**Cyclamens.**—Those who obtain a good strain of these long, continuous-flowering plants will find no difficulty in keeping them up to the requisite standard by each year selecting some of the strongest, best-flowered kinds for seed. They are best sown towards the end of summer, in a temperature slightly above that of an ordinary greenhouse, with plenty of light, but not much exposed to the full influence of the sun. Those intended to produce seed the spring following, some eighteen months after sown, or equally as well from older and larger plants, should be discouraged as much as possible from flowering through the autumn and winter, as they will produce little or no seed during this time; whereas no difficulty will be found in getting the flowers to set later on in the spring. With these, likewise, select plants that produce the largest flowers with broad petals in the most distinct colours, marking them and keeping them separate before the blooming is over, gathering the seed when ripe.

**Balsams.**—These favourite greenhouse annuals are very liable to deteriorate unless careful selection be carried out. The large double-flowered or, as they are often called, *Camellia*-flowered kinds, can only be kept up to their proper standard by selecting the best forms and colours to produce seed. With these, as with many other plants, the best forms seed very sparingly as compared with the single or inferior. Those intended to select from for seed should be sown about the beginning of March, that is, sufficiently early as to be under the influence of the full summer's sun when blooming, as upon this very much depends their fertility. The largest, best-shaped double flowers are usually produced from the main stem, from which little seed is got; it is the lowest part of the side branches, which generally bear flowers less double, that the seeds are to be got from. Care must be taken to gather them as soon as ripe, or the pods will open and they will fall out.

**Herbaceous Calceolarias.**—With these, when once a good strain is procured, I have found less difficulty in keeping it up to the mark than with some things. Plants sown at the usual time, in August, grown on through the autumn and winter, with enough pot-room to insure sufficient strength, and not in any way hurried on so as to bloom too early in the spring, will produce and ripen seed, simply selecting the best-shaped, best-marked flowers, with a dwarf bushy habit, and, above all, evincing a disposition to carry plenty of stout, healthy foliage, for, without this, however fine the individual flowers, the strain is useless; and I may here observe that many of the most perfectly formed and beautifully-marked individual flowers

ars produced by plants so weak as to be unattractive and worthless. The seed is very fine and produced in small quantities, and requires care in gathering and preserving.

These are the principal families of greenhouse plants that are annually raised from seeds, and, holding as they do, a position as the most esteemed soft-wooded subjects for general purposes, are well deserving a little care in keeping up their character by those desirous of possessing good flowers according to their kind; which, it may be observed, occupy no more room than the mixed inferior rubbish often met with.

T. BAINES.

**Ivies on Stakes.**—This fine free young plant of Algerian Ivy, so happy on its two rustic posts, suggests a very simple and effective way of arranging some of the many valuable kinds of Ivy now in our gardens. One can fancy nothing more beautiful than a group of distinct kinds of Ivy trained up stout pieces of branches and grouped in a quiet corner of the lawn or pleasure ground. Such training has various advantages over training on walls—the kinds, one to each

branch or stump, are more easily kept distinct; the Ivy seems to thrive and look better than on walls, and that the effect is much more picturesque may be judged from our illustration, which is from a photograph taken last summer.

White variety of *Viola hirta*.—I have a white-flowered variety of this seldom, which I found here last year; unlike all the white forms of *V. odorata*, it is without the slightest stain of purple either on the petals or spurs, the entire flower being of the purest white.—*J. M., Axminster.*

**Leopard's-bane.**—In "Notes from Kew" (see p. 226) this plant is mentioned as a desirable one for cultivation, but, according to "Pratt," it is very poisonous; and such plants can well be spared from the pleasure garden, where the Corn Marigold would prove a brighter and safer substitute.—*LONDON STONE.*

**Popularity of the Auricula.**—In reply to "D.'s" remarks under this heading (see p. 274), allow me to say that I hope Auricula dealers will not advance their prices because of the supposed great sums paid for plants at Mr. Cooper's sale. In my opinion the prices were low. I bought 210 plants at an average of 10d. each, and secured 97 sorts, and amongst them the very best, such as Smiling Beauty, A. Meiklejohn, Chas. Perry, Lancashire Hero, &c. It is seldom so good an opportunity offers, as was the case at this sale; and any beginners who have to seek out the plants will find it very difficult, indeed, to obtain a good collection of them; prices are high enough already.—*BLACK-TRUSS.*

## PLATE CXXI.

### THREE NEW PERPETUAL ROSES.

Drawn by J. N. FITCH, JUNR.

**MAY QUENNEL** is a very fine, deep-petalled Rose, producing in abundance till late in autumn its flowers of rosy-magenta. As an exhibition Rose it possesses to a high degree the necessary qualifications of large size, fullness, and substance of petal; whilst as a garden Rose its fragrance, vigour of growth, and freedom of flowering will ultimately bring it into wide repute. It was raised from seed by Mr. Postans, of Brentwood, already well known in the horticultural world by his numerous and beautiful additions to our variegated and other Geraniums. May Quennell will be, we believe, the first of Mr. Postans' seedling Roses introduced to the public, but, judging from its excellent qualities, we trust that there will be many more to follow from the same raiser. For the information of those who have not seen it exhibited we may state that it received a first-class certificate from the Royal Horticultural Society last summer.

**La Rosière** is one of two good Roses which reached this country in the autumn of 1874, having been distributed by M. Damaizin, of Lyons. By reason of its free-flowering and fairly vigorous habit, we look upon it as a valuable addition to our dark Roses, now happily increasing in number. It has every appearance of being a hardy Rose, and is very effective in the flower garden. Bearing these good qualities in mind, we can overlook any little deficiency in point of size; and, having as we believe the exhibitors with us on account of its rich velvety appearance, we think we may pronounce it one of the most desirable of recent introductions. The other variety, alluded to above as having emanated from the same establishment and at the same time as *La Rosière*, is *Villaret de Joyeuse*, a rose-coloured flower, probably a seedling from Victor Verdier.

It is to the establishment at Lyons, so long presided over by Mr. Joseph Schwartz, and now bearing his name, that we owe some of our best Roses, and amongst them *Duchesse de Vallombrosa* occupies a foremost place. It had already obtained a reputation more than local when sent out from Lyons in the autumn of 1875, and we have now proved that the changeable climate of this country adds to rather than detracts from its many charms; and the frequency with which it was found in the prize stands at the Rose shows of last year is a sure proof that its value is being recognised as an exhibition flower. M. Schwartz describes it as a seedling from Jules Margottin, and in colour it stands midway between Captain Christy and *Mdlle. Eugénie Verdier*. It would seem to belong to the class of robust rather than vigorous growers, but the foliage is abundant and handsome, and the habit of the plant upright and sturdy. The flower is large and full, with good petals and of elegant shape, in this respect being a desirable deviation from the too rigid and formal style of florist flower now coming into vogue with Rose growers. As a light-coloured forcing Rose, *Duchesse de Vallombrosa* is equal to any variety we possess.

*Waltham Cross.*

ARTHUR W. PAUL.

[For the blooms from which the annexed plate was prepared we were indebted to Messrs. Wilmex Paul & Son, of Waltham Cross.]

**Remedy for Mildew on Roses.**—The following method of destroying mildew on Roses is described by M. Eugène Verdier in the "Cultivateur de la Région Lyonnaise": "Take an iron pot or an earthen pipkin and put into it 1 lb. of flowers of sulphur and the same quantity of freshly-slaked lime. Pour on the mixture 6 pints of water, and, when well mixed, place the pot on the fire and boil for ten minutes, taking care to stir all the time. Allow the resulting liquor to cool down, and when settled pour off the clear liquid into bottles, which must be kept well corked and in a dark place. For use, a pint of this solution is mixed with 12 gallons of water, which immediately becomes milk, and the trees attacked are well syringed with it. The remedy may be applied early in the morning, but preferably late in the evening. The best time of the year is the spring, when the young shoots are about 2 in. long. The solution should be used before any signs of the malady appear. If, however, it has made its appearance, two or three syringings will be sufficient to get rid of it thoroughly. It may be used for any other plant attacked by mildew. Its efficacy is due to the compound formed by the lime and sulphur.—*C. W. QUIN.*

ROSES. MAY QUENNEL DUCHESSE DE VALLOMBROSA. AND LA ROSIÈRE.

GARDEN BOTANY.

(Continued from p. 263.)

**GERMINATION OF GRASSES.**—All Grasses have albuminous seeds, with a small, or often very minute, embryo lying on the outside of the albumen at the base. While still dormant there is a distinct plumule to the embryo, but botanists differ as to what part is the cotyledon. Some regard the first or outer sheath of the plumule as the cotyledon, whilst others, and perhaps more correctly, consider that part of the embryo which remains within the seed during germination as the true cotyledon. This will be better understood on reference to figs. 79 and 80. Fig. 79 is a very much enlarged representation of a germinating embryo of Oat, the dotted line indicating the seed from which it proceeds. Before germination it consists of the cotyledon (sometimes called scutellum) and the part lettered *col*. This encloses the plumule, which emerges through a chink at the top, and from the basal portion several rootlets protrude simultaneously; not a solitary rootlet, as from most embryos. This is the general plan of the germination of Grasses. The cotyledon, or scutellum, remains within the seed, and absorbs and conveys the albumen to the growing plantlet. As the young plant grows other

plumule, which only begin to develop when they reach favourable conditions, and the plumule eventually breaks through some point in the partially hollow petiole of the cotyledon.

**GERMINATION OF ORCHIDS.**—The seeds of most Orchids are very minute, having to the naked eye more the appearance of Fern spores than seeds, and they are invested in a loose netted skin or testa. In some species, as *Cyrtosia erythrorchis*, the seeds are larger, though still very small, and the testa is expanded into a relatively broad membranous circular wing surrounding the seed. The seeds are exalbuminous; the embryo therefore occupies the whole of the interior of the seed.

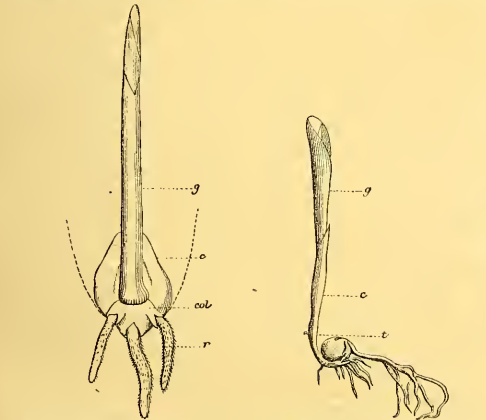

Fig. 79.—Germinating embryo of Oat. *g*, plumule; *c*, cotyledon; *col*, ligellus, or radicle; *r*, rootlets. The dotted line indicates the relative size of the seed from which it is springing. (Very much enlarged.)

Fig. 80.—Maize germinating. *g*, plumule; *c*, cotyledon or first sheathing leaf of the plumule; *t*, ligellus.

roots are produced above the original ones, and the result is the densely-tufted fibrous roots of Grasses. Fig. 80, representing germinating Maize, shows successive roots appearing above the first or primary root, which in this plant is very strongly developed for a short period, though it subsequently disappears. The first sheathing leaf is here marked as a cotyledon, but it is of the same nature as in the Oat, and there is also a similar shield-like body within the seed to absorb the albumen.

**GERMINATION OF ISMENE.**—The development of these bulbous plants from seed appears to be very singular. I am informed by Mr. Elwes that when the seed germinates in a pot it throws out a kind of descending shoot to the bottom of the pot, where a small bulb is formed the first season; and the following season a stem proceeds from this bulb.

**GERMINATION OF CRINUM.**—Many will be familiar with the large fleshy seeds of some species of Crinum. Respecting these seeds Robert Brown states that no visible formation of the embryo takes place until after the seed drops, and even not until after the seed is discharged from the pericarp. In germination the lower part of the cotyledon elongates very considerably, carrying with it out of the seed the radicle and

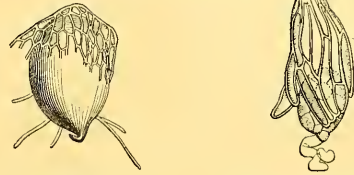

Fig. 81.—Germinating seed of *Miltaria*. Fig. 82.—Germinating seed of *Pleurothallis*. (Highly magnified.)

The embryo is not differentiated into radicle and plumule, &c., but it is a solid homogeneous mass of tissue. When germination begins the nucleus enlarges and throws off the loose testa, and emits rootlets from various parts of its body (fig. 81); and subsequently a plumule is formed at the apex. Fig. 82 is a more highly magnified figure in which the embryo has not quite cast its coat; a rootlet is emerging from the base.

**GERMINATION OF BLACK BRYONY.**—This plant has albuminous seeds with a small embryo, and the germination of this embryo

Fig. 83.—Germinating seed of Black Bryony (*Tamus communis*), the plumule comparatively undeveloped. (Enlarged.)

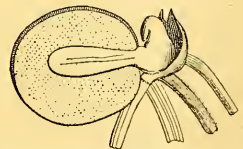

Fig. 84.—Section of a germinating seed of Black Bryony (*Tamus communis*), showing the enlarged apex of the cotyledon in the albumen.

commences by the intercalary growth of the basal part of the cotyledon, which pushes its axis outside of the seed, whilst the upper end of the cotyledon remains within the seed. From the lower part of the axis of the now exerted embryo a number of rootlets are quickly developed, growing to a considerable length before the plumule starts into growth. The upper end

of the cotyledon in the seed (fig. 84) gradually enlarges into a spongy kind of tissue, which absorbs the whole or a portion of the albumen, and ultimately fills its place.

**GERMINATION OF CALADIUMS.**—Respecting this Robert Brown says: "In these the nucleus of the seed is not properly a monocotyledonous embryo, but has an appearance and economy more nearly resembling those of the tuber of a root; for instead of being distinguishable into a cotyledon, plumule, and radicle, and of germinating in a determinate manner, and from a single point, it is composed of a mass whose internal structure is uniform, and on the surface of which frequently more than one germinating point is observable." It is probable that this is a case of polyembryony, that is, the existence of several embryos in the same seed.

**GERMINATION OF PALMS.**—The plan of germination in Palms

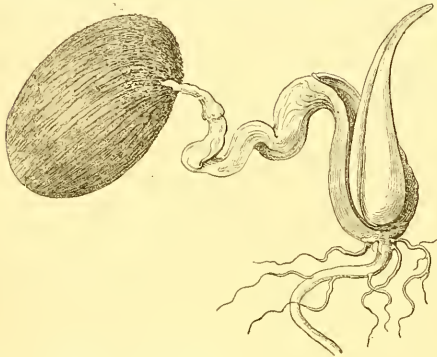

Fig. 65.—Germinating seed of *Borassus*, about a quarter natural size, all the parts very stout and fleshy.

is essentially the same as in Black Bryony, but there are many interesting modifications, especially in the subsequent development of the roots and stems. The seeds are usually large

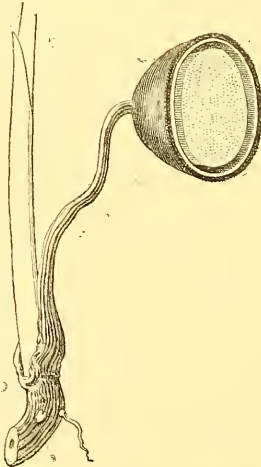

Fig. 66.—Portion of a seedling Palm, with a section of the seed showing the cavity nearly filled with the spongy tissue of the enlarged apex of the cotyledon.

sometimes very large, as the Cocoa-nut, and the embryo is comparatively very small, and situated somewhere near the surface of the usually very abundant and dense and sometimes excessively hard albumen. In some Palms the lower part of

the cotyledon is only just sufficiently elongated in germination to push the axis of the embryo outside of the seed, as in Bryony, whereas in others (figs. 85—88) it grows to a considerable length, varying apparently in this respect according to the nature of the soil upon which it may be lying, or in which it may be partially embedded. In the double Cocoa-

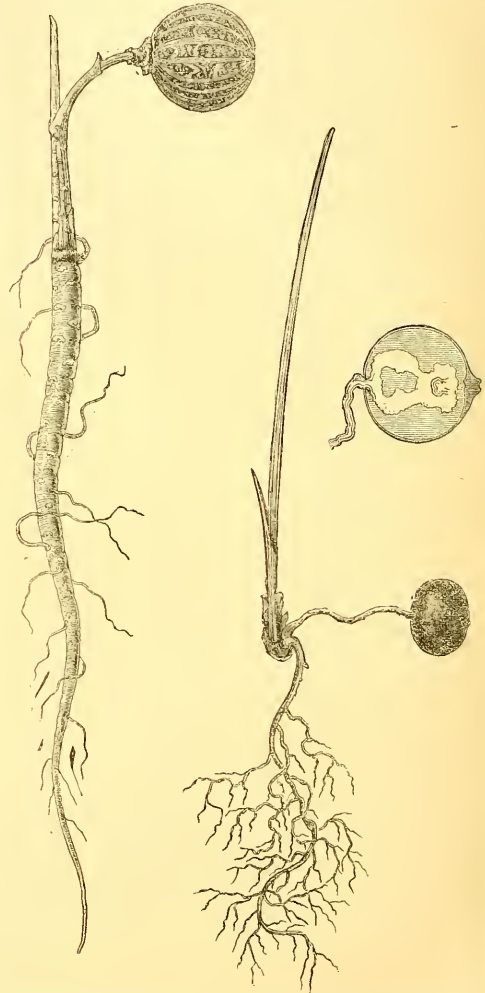

Fig. 68.—Germinating seed of *Corypha*, the root very strongly developed before the plumule hardly makes a start.

Fig. 67.—Seedling of *Sabal umbraculifera*, and section of the seed (enlarged) showing the spongy tissue of the upper end of the cotyledon, which enlarges and absorbs the albumen, and eventually fills the whole cavity of the seed.

nut it sometimes attains a length of 1 ft. or 1½ ft. Sometimes the root and plumule grow at a nearly equal pace, as in *Sabal* (fig. 87); in other cases the root is strongly developed, penetrating the soil to a great depth before the plumule starts, as in *Corypha* (fig. 88). The radicle or primary root is often very vigorous in seedlings, but it is stated that it is soon replaced

by succeeding roots which appear above its apex through the sheathing bases of the leaves. Whether this is invariably the case may be uncertain; that it often occurs there is no doubt. In *Borassus* (fig. 85), for example, although the primary root is very stout and strong at first, and if only the tip be broken off the plant will die, soon other roots pierce the sheathing bases of the leaves and the tap root gradually perishes. New roots are successively formed above the older ones, which, in their turn it would seem, cease to be the channels through which the plant obtains its nourishment. A very remarkable illustration of this kind of development is exhibited in the museum at Kew. It is a large, bowl-shaped, or hemispherical body pierced with numerous circular holes, which appear on the outside as tubular projections. This is what is found at the base of the trunk of the double Cocoa-nut (*Lodoicea sechellarum*), and it consists of the hardened bases of the leaves perforated by the roots, the less durable tissue of which has decayed, leaving the almost imperishable shell. Like some other Palms, this is many years—15 to 25, it is stated—before it begins to form a trunk, and the successive, closely-packed, sheathing bases of the leaves form this singular bowl, in which the lower part of the stem is said to be free. The bowl is of such a durable nature, that perfect specimens have been taken out of the ground sixty years after the trees were cut down. The double Cocoa-nut, it is stated, emits a number of roots in the first stage of germination. The primary root of *Sabal* (fig. 87) seems to differ from the others here described in not being a prolongation of the posterior end of the embryo, but a lateral production. In fig. 86 is a section of a seed of a *Corypha* from which all the albumen has disappeared, and is replaced by the enlarged spongy tissue of the upper end of the cotyledon, which perishes when it has performed its office. W. B. HEMSLEY.

**Vitality of Seeds.**—I observe that Mr. Hemsley in his interesting table showing the average vitality of seeds of various kinds gives Cabbage seed a period of five years. Probably that is a fair average of ordinary stocks, or if kept in bags, and thus exposed to the action of the atmosphere. Last summer I saw growing in the grounds of the Middlesex Industrial Schools, at Fulham, a large breadth of Cabbage raised from seed ten years old. It was originally carefully saved and preserved in a tin on the mantleshelf of a living room. The seed plant was a good one, as good as usually results from a sowing of new seed. No doubt the original sample was well ripened and harvested, and that the even dry temperature in which it was kept assisted in the retention of its germinating powers. No doubt many seeds suffer more from moisture—that is, from being preserved in a damp atmosphere—than from dryness. The Messrs. Sutton & Sons, who are among the largest exporters of garden seeds in this country, have a chamber heated with hot air in which all seeds to be sent over the seas are placed in tins made for the purpose, and subjected to a very high temperature, so as to thoroughly expel from them all superfluous moisture. They are then packed in air-tight canisters and hermetically sealed, and in this way retain their vitality after being subjected to the damps, changes, and vicissitudes of a voyage of several thousands of miles.—A. D.

**The Common Squill a Poison for Rats.**—The Squill (*Scilla maritima*) in a fresh state is prized by the modern Greeks as a poison for rats as well as for its medicinal qualities. Some years since the bulbs of the *Panacratium maritimum* were largely used to adulterate the Squill, and even as a substitute for it, thereby bringing Greek Squills into disrepute in the foreign markets. The Squill is found in large quantities on the shores of the natural harbour of Phalaris, the Gravensend of Athens, the islands of Egina and Salinus, and in many of those of the Greek Archipelago. It is also found on mountain plains, far away from the shore, and on the sides of high mountains, situated high above the level of the sea, although it is generally supposed to be a maritimus plant. It is much used in our gardens about Athens as an ornamental plant, its property of showing a plentiful crop of green leaves when everything else is burnt up making it valuable for this purpose. Whether it be true or not that Pythagoras prolonged his life to 135 years by the constant use of Squill vinegar, it is nevertheless a valuable diuretic and expectorant, and large quantities might now be exported from Greece had it not been for the adulteration which was formerly practised. The ancient Egyptians venerated this plant as the symbol of the god Typhon, and his temple at Pelusium, in Lower Egypt, is ornamented with representations of the Squill in marble.—X. LANDREER, *Athens*.

## THE INDOOR GARDEN.

### SPECIMEN BALSAMS.

TEN or a dozen years ago, Balsams, Fuchsias, and similar plants occupied a recognised position in gardens; but now they are elbowed into comparative obscurity by newer and more valuable subjects. Notwithstanding this, however, they will deserve a place in the greenhouse or conservatory. As regards colours, they comprise the most delicate tints of scarlet, salmon, maroon, rose, white, purple, &c., and the blooms rival in beauty, substance, and form some of the smaller species of *Camellia*. Of late years the blossoms of Balsams have deteriorated sadly, so that it becomes necessary in procuring seeds to see that they come from a trustworthy source.

The cultural details, though simple enough, must have attention at the proper time, or the foundation of a specimen plant cannot be laid. To have good specimens early in July, the seeds should be sown at once; if for late work, the sowing may be deferred till the middle of April; or if the plants be intended for front rows or small stages, and only intended to occupy 8-in. pots, a safe calculation may be eight weeks from the time of sowing till the plants are ready for decorative purposes. Specimen culture differs little from that of smaller plants, if the latter be well managed, except that a defective foundation will be more obvious in the former than in the latter case. In sowing the seeds it is necessary, in the first place, to make the usual preparation by having the requisite number of clean 3-in. pots crocked, and the soil ready to proceed with the operation of sowing. The different colours will be best kept by themselves and legibly named. The pots should be filled with mould about half-way up, and two seeds should be dropped into the centre of each (if both seeds germinate, one of the plants will, of course, be pulled out) with the name of the colour attached. If the pots be kept together on the bench, the seeds can be covered thinly through a fine sieve, and taken to a warm frame and plunged. I prefer beds where the heat is on the decline, as, for instance, one that has been used for propagating purposes till the heat had abated to a gentle warmth, so that something like natural time may be given for germination, and growth may not be unduly hastened. When the young seedlings appear above the rim of the pot, they should be earthed up, leaving the usual space for a supply of water. It may be necessary at the same time to raise the plants nearer the glass by a fresh addition of half-spent material to make up for the subsidence that took place during fermentation. At this stage especially it is of the utmost importance to have the young plants as near the glass as is consistent with safety from breakage when giving air or from scorching in case of changeable weather. Water through a moderate-sized rose, and ventilate on all favourable occasions, in order to secure short, stubby growth; better admit a little air, even if it be necessary to do so through a piece of fine canvas, if the weather should be unpropitious, than to give none. In a week or ten days the young plants will be ready for a shift into 5-in. pots, and will have made two shoots at the base of the perpendicular one on either side; those that do not behave in this way should be either potted for packing plants, *i.e.*, filling in between other pots, or thrown away, as they never make handsome specimens. A fine day should be chosen for removing them from the frame to the potting bench, and the material in which they are to be potted should be a rich compost of good soil, cow manure, and rough leaf-mould, well incorporated and warmed to the same temperature as that in which the plants have been growing. The pots should also be warmed by being placed in a warm house or shed for some time before they are crocked. In potting let the two bottom shoots hitherto mentioned be trained horizontally level with the rim of the pot. When the potting has been completed they should be returned to the frame and plunged, making allowance this time both as regards height and width for the rapid progress which they are sure to make under the conditions adverted to. The bottom heat at this stage will be about enough to accelerate fresh root action and impart tone and vigour to the plant. The frame should never be quite closed under any circumstances, and the

more air that can be safely given at all times the better. Another pair of shoots will soon be produced at the base a little higher up, and these must be pegged down as previously indicated. These four shoots form the foundation of the future specimen, and the upright stem will soon clothe itself with a number of shoots, which must be taken in hand in a similar manner. At the next shift the ultimate size of the plant must be determined. A 10-in. or 12-in. pot will be quite large enough for all practical purposes, and as the requisite conditions this time are identical with the last, it will be unnecessary to go over the same ground again. Up to the time at which the specimen is fully grown I would recommend a gentle warmth at the root. The plants should also be given plenty of room for a free circulation of air to play among them. When they have become re-established after their final shift they will require almost daily attention to training. A frame-work can be made of sticks painted green, with a piece of tar cord forming the extremity or outer line of the circle, and an inner circle might also be formed in the same way to facilitate the process of training. The leading shoot will, of course, be tied to an upright stake, and, as the plant furnishes itself, every shoot should be drawn in a downward direction by means of a piece of matting suspended from the outer extremity of the frame-work to the tip of the shoot. Each shoot pulled down in this way will break out at every point into a number of other shoots, and so on till the specimen attains the desired proportions.

The flowers should be picked off the earlier-formed growths as they make their appearance till the plant has become furnished and well proportioned from top to bottom, after which flowers may be encouraged, and, if necessary, the plants may be taken to any house in which there is plenty of light till such time as they are ready for the embellishment of the show house or conservatory. These plants require careful attention in watering, and will almost live on liquid manure throughout the whole growing season in case a rich compost is not at command.

W. HINDS.

#### CULTURE OF JAPAN LILIES.

I HAVE read with considerable interest the disquisitions on Lily culture which have appeared in recent numbers of THE GARDEN, and having been for several years a successful grower of Japan Lilies, I have ventured to furnish a few observations on the subject. When I commenced the cultivation of these Lilies, and was about to purchase some, a friend gave me this advice, "Do not consider any bulb a flowering bulb which does not measure  $1\frac{1}{2}$  in. in diameter, and one single bit of manure used at the time of planting will bother them." I used equal portions of sod mould and fibrous peat with some silver sand, and at first I flowered all my bulbs singly, planting them as deeply as I could in about 6-in. pots, giving little or no water for a few weeks after potting. When they had fairly started into growth I shifted them into blooming-pots of such size as the fleshy roots appeared to require, and sunk the bulb as much deeper as was practicable, leaving at least 2 in. at the top of the pot for top-dressing in summer. When all chance of frost was over I placed them out on a gravel walk, taking care to place slates or boards under the pots, as worms are very injurious to Lilies. I kept them well syringed during the summer months, and when they began to show the smallest appearance of a flower-bud I filled the pots up to the rim with some thoroughly decayed cow manure. The surface roots of these bulbs will bear manure, but the scaly bulb itself will not, and I attribute much of the degeneracy complained of (especially amongst imported bulbs) to the admixture of manure in the soil at planting time, for, coming in contact with the scales, it rots them, and the bulb grows smaller every year instead of larger.

I have gone into these details to show that the old bulb never dies, as your correspondent seems to think, inasmuch as I have grown these  $1\frac{1}{2}$ -in. bulbs in two years to the size of 4 in. across, and  $1\frac{1}{4}$  lb. in weight, so that annual death of the old and reproduction of a new bulb appears to have been impossible in my case; but when they had attained this size, the bulbs showed a tendency to propagate by dividing themselves naturally. By the simple mode of treatment I adopt, I have dark

shining foliage down to the rims of the pots, and from twenty-five to twenty-seven splendid blooms on single stems of about 5 ft. high. One great secret in growing these Lilies successfully is in making sure that the surface roots are well covered, for if exposed, the foliage will become discoloured and fall off. Of course, I always bloomed my plants under glass, for although these Japan Lilies are well known to be very hardy, if the weather should happen to be unfavourable at the time of blooming, I know of no flowers which suffer so much in appearance from exposure when we compare outdoor with indoor specimens.

I am of opinion that another cause of the degeneracy of Lily bulbs is consequent on encouraging them to make upward growth before they have made good root action, and with imported bulbs I think it an admirable plan to plunge them, like Hyacinths, in coal-ashes for a month or six weeks after planting, in order to induce them to fill the pots with roots before they are allowed to start into growth, for when once *L. auratum* appears above-ground it grows apace. The drying off after blooming should be merely allowing the sap of the stem to fall back to the bulb, when it ought to be shaken out and re-potted at once, taking every precaution to preserve the fleshy roots intact.

JOHN O. BEALE.

East Ferry, Co. Cork.

Will "Dunedin" allow me to suggest the possibility of dyeing a Lily bulb, and then tracing the fate of the coloured scales, supposing that it is possible to serve a bulb so, and yet not destroy its vitality. I would suggest madder as a dye, from the fact that it has already been used to colour the bones of living animals, and proved permanent, without any evil effects. Watering the growing plant with a solution of it might possibly lead to some interesting results if absorbed.—LONDON STONE.

#### FOUR FREE-FLOWERING CACTI.

**Cereus (Echinocereus) Roemerii.**—A small-growing plant, almost hardy, and quite so in the south-western districts. It should be classed with half-hardy Alpines. A full-sized plant of it is only 6 in. high, but the best of this section of the Cactus family is, that they produce such grand flowers. Those of the species under notice are purplish-red, shading off to pink. Its spines are meagre and pale yellow. For those who like the nobler sorts of Cacti, this is not a desirable plant, but amongst open-air sorts it will always keep its place. It comes from the northern parts of California, almost from the snow line.

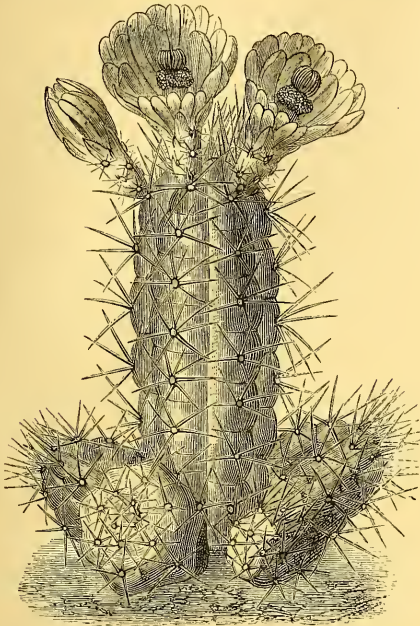

**Cereus Hayni.**—For a *Cereus* this is a small plant, and one which, when young and out of flower, might easily be mistaken for a *Mammillaria*. A plant 1 ft. high is old, and resembles a bottle-brush. The spines are brownish-white, rather soft, and very profuse. Its flowers, which are white, are not produced very freely, but this I attribute to our climate. The more sun the plant gets the better it blooms. It is nearly hardy, and, as is the case with all the more hardy kinds of Cacti, it is apt to be attacked by thrips and mealy bug, for which the best remedy is setting the plants out in the open air.

**Echinocereus pleiogonus.**—This is a plant of small stature, but one which certainly shows itself off to advantage. It is only a few inches in height, but it pushes up flowers larger than its stem. Its spines are stiff, yellow, and reflexed, from eight to twelve in a set. The flowers are purplish-red and very beautiful; but, unlike those of true *Cereus*, they only open during sunshine and last about three days. They shut up in the afternoon, and if there be no sun the next day they wait until there is. It is a very hardy little plant.

**Cereus nycitellus.**—This species is very similar to the old night-flowering Cactus (*C. grandiflorus*), but its stems are more robust and darker green. The flowers are orange-yellow, turning to white in the centre; they are quite as large as those of *C. grandiflorus*, and the plant requires the same treatment. It may be distinguished from *C. grandiflorus* by the quantity of white hairs that grow on the tube of the flowers. It opens about seven in the evening and closes about the same time in the morning. For those who want a night-flowering *Cereus*, and have only space for one, I should, however, recommend *C. MacDonaldiae*.

J. CROUCHER.

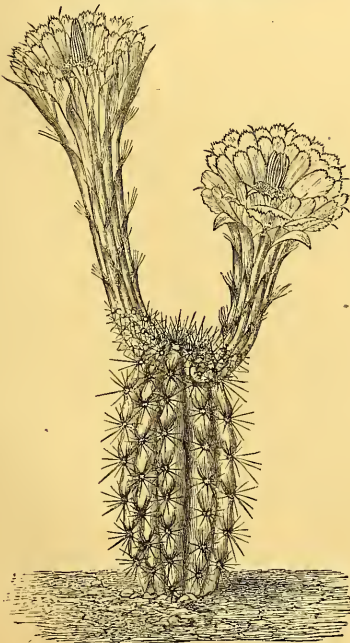

**Aphelexis macrantha.**—Amongst hard-wooded plants now in flower in nurseries few are more beautiful than *A. macrantha* and its varieties. In the shape of small, bushy plants, *Aphelexis* may be

*Cereus (Echinocereus) Ræméri.*

*Cereus Hayni.*

*Echionocereus pleiogonus.*

*Cereus nycitellus.*

used in a variety of ways, and their lively purple blossoms last, either on the plants or in a cut state, for months. In private establishments these Everlastings are seldom grown in quantity, on account of some imaginary difficulty attending their cultivation. They are, however, no more difficult to grow than many less beautiful plants. Cuttings, consisting of the flowerless shoots, should now be taken off and inserted in well-drained pots filled with equal parts of silver sand and sifted peat. Use a sharp knife for removing the cuttings, and avoid bruising them as much as possible. Make the soil round them firm when inserted, and place the pot containing them in a larger one, filling in the vacancy between the two with sand or fine soil. Plunge the whole in a gentle bottom-heat in a close frame or cucumber house. Careful watering is necessary. When well rooted pot the young plants in well-drained 4-in. pots, using peat, broken potsherds or broken bricks, and a little charcoal. When again established, move them into a cooler temperature, and when their pots are filled with roots, shift them into 6-in. pots, using the same soil as before. Abundance of air and water are necessary at all times. Large plants are not so useful as small ones, because they want training, which gives them a formal appearance; and by striking a potful of cuttings yearly, good, bushy plants, full of bloom for several months in the spring, may be obtainable. *A. macrantha purpurea* grows more upright than the type, and its flowers are superior to it in point of colour. *A. m. rosea* is also well worth culture.—C. S.

**Fairy Roses.**—Neat, bushy little plants of brightly-flowered Fairy Roses at all times meet with a ready demand in Covent Garden, where they may now be found in abundance. Considering their easy culture and their usefulness, they might with advantage be grown more largely than they are in private establishments. They are grown as follows:—Cuttings, consisting of the young tops, are inserted in pots of sandy soil in May or June, and placed in a warm house where they can be shaded from direct sunshine until they are fairly rooted. They are then potted singly into 4-in. pots, using sandy loam and leaf-mould. When these pots are filled with roots they are shifted into 5-in. or 6-in. pots, kept in a light, airy house, where they receive abundance of water at the roots, and by the following spring bushy plants, well furnished with deep green leaves and a profusion of buds and blossoms are the result. It is necessary to fumigate occasionally to keep down green fly, to which these little Roses are subject, and frequent syringings on fine days greatly improve their growth. In vases in rooms such plants last a long time in perfection, and they furnish sprays of green leafage and buds for bouquets and other floral arrangements.—C.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Todea superba** from Seed.—To get a good stock of plants of this Fern by means of spores is a rare occurrence. Mr. Laing, of Forest Hill, has, however, been fortunate in this respect, for spores ripened and sown in his nursery have produced thousands of young plants. This beautiful filmy Fern may therefore be expected ere long to be more commonly met with. Equally good success has also been obtained in the case of *Davallia Mooreana*, an old but comparatively scarce Fern.

**Cereus Macdonaldii.**—Surely your correspondent, writing about plants in flower at Kew (see p. 252), is wrong in his description of this species. Many years ago I received a small cutting of it from my friend, the late Sir W. J. Hooker, which grew rapidly, and a plant raised from it has long since reached the top of a small conservatory attached to my villa at Torquay. It has no aid from hot-water pipes or fire, the only assistance in the matter of heat being from the drawing-room chimney, against which it is trained. It produces its glorious flowers freely, which are pure white, except in the centre, which is a delicate lemon colour; the blossoms are sweet-scented. It would be desirable to know the name of the species your correspondent describes.—J. L.

**The Fuchsia as a Cool Greenhouse Climber.**—I have planted out here in a cool greenhouse some new varieties of Hybrid Fuchsias, raised by Mr. Lowe, Highfield House, near Nottingham, and find, by their rapid growth and free-flowering habits, that they will make excellent climbers when trained on pillars. I have in the same house a plant of the old Fuchsia Rose of Castle, 14 ft. in height, trained on a pillar, and during the summer months when in flower it affords one of the grandest floral sights which one can imagine in a Fuchsia. Mr. Lowe's seedlings are named Columbine, Sieva, Anatu, Adria, Concordia, Inez, Dragonina, Phoece, Violetta, Odin, and Robin Hood. Of the above sorts I have selected Odin, Adria, Violetta, and Columbine as being the strongest growers, and evidently having some of the strain of *F. fulgens* in them, from the shape and size of the flowers. To see the tender varieties of Fuchsias in all their beauty, we must train them as climbers, with plenty of room for them to get to a good size. When grown in pots for exhibition purposes, it is only a few cultivators that bring out collections of well-grown plants, owing to their rambling habits, unless, indeed, they are well stopped when young.—W. TILLERY, in "Florist."

#### GARDENING FOR THE WEEK.

##### Indoor Plant Department.

**Orchids, Insects, &c.**—To attain success in Orchid growing there is nothing more important than freedom from insects, to cope with which it is necessary to keep a continuous look-out. If the whole collection (as some weeks back was recommended) has been carefully gone over so as to exterminate all the adults perceptible, the work will be very much lighter now, but any that may escaped detection and the hidden larvae that lie undisturbed beneath the stem-stirrings of some, such as *Miltonias* of the spectabilis section, and the axils of the leaves of the East Indian varieties like *Vandas*, *Aerides*, and *Saccolabium*, will, by the increased warmth at this time rendered requisite by the growing season being at hand, quickly come to life. With that worst of all pests on Orchids, white scale, the grower should not be satisfied with anything less than extermination. This can only be effected by diligent and persistent examination of infested plants. The crowded condition that Orchid houses generally get into, necessitating the plants standing so close together that they touch each other in all directions, make this kind of the equally objectionable, but less injurious, brown scale, as also the third species which affects Orchids, the scale coverings of which are circular in shape like the white, with brown centre and white edge, more difficult to contend with, as it is only by actual contact that these insects spread from one plant to another, or in the case of a clean plant that stands immediately underneath one hung up or otherwise that is affected. To so far as possible prevent these insects spreading, I have found a considerable saving of labour effected by standing all the insects in a house together, frequent syringing over them until a complete riddance was made. The white and white-edged scale are easily seen, but beginners in Orchid culture do not always so readily detect the presence of the brown species on thick-leaved plants like *Vandas* and *Aerides*, for though it will live and increase apace on these, yet it never attains more than one-tenth of the size that it will grow to on thin-leaved species, like *Calanthes*, *Lycastes*, &c., and in this way I have seen the leaves of the former affected so as to seriously injure them before it was noticed. Orchids will not bear washing with any insecticide strong enough to kill the parasites, consequently there is little recourse except brushing and sponging, which, if persistently carried out, will effect a clearance of the insects; but it is necessary at all times, and especially now when growth has commenced and the plants are in a softer condition, to see that the cuticle of the leaf is not injured by the brush employed being too hard, or using it with too much force. I have frequently seen the pseudo-bulbs of *Lycaste Skinneri* and *Odontoglossum* turn rotten through the outer skin being injured in removing scale. Where the small yellow thrips, so difficult to eradicate, has existed, will not get to increase. It is particularly partial to some of the thin-leaved *Dendrobis*, such as *Devonianum*, are generally first attacked by it. It gets into the young, partially-developed leaves at the points of the shoots, and if left for only a short time unmolested causes the destruction of the leaves, which at once stops the further extension of the bulb. I never could grow this plant satisfactorily without daily syringing in a way so as to direct the water right into the points of the young shoots from the time that growth had fairly commenced, that is, after the flowering was over, until the autumn was completed. Before resorting to this the bulbs were invariably stopped short in their growth; this insidious little pest, unlike the larger black thrip, never appears to attack the leaves except in their first stages, and almost always confines itself to the thin, delicate-leaved species, such as *Dendrobium Devonianum*, *D. Falconeri*, *Odontoglossum*, *Lycastes*, and the fleshy, yet soft leaves of *Phalenopsis*, but it cannot endure a daily application of water, and where the plants are grown with sufficient light and air, and are not under the attenuating influences of too much heat and moisture in the atmosphere, they will bear syringing overhead daily, of course excepting the time when the tender flower-spikes are emerging from the base of the bulbs of those that throw up in this way, and whilst they are in bloom. I know there are many Orchid growers who syringe overhead very little, under an impression that it endangers the young growth; but of one thing we may rest assured, that where plants will not bear the application of water overhead in this, the natural way of their receiving it, there is something wrong in the conditions under which they grow rendering them too weak. The one thing necessary where daily syringing through the growing season is carried out is to perform it sufficiently early in the afternoon to admit of the plants getting all or in a great measure dry before darkness sets in. Of equal importance to the health of the plants is it to keep the leaves and stems perfectly free from any dirty sediment accumulating upon them. Many fine collections of Orchids are grown in the neighbourhood of towns where the soot-charged atmosphere is such as to render the frequent use of the sponge necessary to keep the pores of the leaves free and open; where this is neglected, especially in the case of *Aerides*, *Agnes-virgata*, *Saccolabium*, and *Cattleya*, the natural formation of which favours its lodging in the base, it accumulates to an extent that clogs up the pores, and causes the foliage to turn yellow and fall off long before its allotted time. In such places it is also necessary to repeatedly wash the glass both inside and out to enable the admission of full light, the unimpeded presence of which, except when the sun is actually shining upon the plants, is indispensable to their well-being. In any house devoted to Orchids that require either hot or cool treatment, or of an intermediate description, such as a stage of heat and cold, where there is space under the plants, or elsewhere, but not in one very three or four weeks a few barrow-loads of horse-droppings that will ferment; it will produce a marked effect upon the plants, both in appearance and reality, the collective growth being stronger under such condi-

tions, the leaves assuming a deeper shade of green, caused evidently by the presence of ammonia in the atmosphere given off from the manure. Several methods have been devised for thus charging the atmosphere of Orchid houses with ammonia, but nothing that I have tried was so simple and effective as this. Another advantage gained from the presence of stable droppings in an Orchid house is that woodlice and beetles hide themselves in them, and when removed, as they necessarily must be once a month or so to make room for fresh material, the insects are destroyed, or conveyed away with it.

**Heat and Air.**—The increased solar heat and advancing growth of many species will permit of the temperature both night and day being raised a few degrees. Give sufficient air by opening the roof ventilators for a few hours in the middle of every day, when the weather is such as to allow of this, so that the moisture in the house may get moderately dried up. I have found that the general character of growth in Orchids, resulting from the admission of a considerable amount of air for some time during the daytime, with a moderate charged atmosphere, when the house is closed and a few hours afterwards, is much superior to that which is produced by giving a small volume of air almost continuously, as frequently recommended. The sufficiently drying process to which the plants are subjected for a short time daily in this way has the effect of solidifying the growth during its progressive development in a manner that never takes place when they are kept in a more uniformly damp atmosphere during the whole of the twenty-four hours. Plants managed as above advised invariably make pseudo-bulbs and leaves of a more rigid and enduring character, with a greater disposition to flower, than when they are treated in a way that produces a softer kind of growth.

**Plants on Blocks.**—Now that more air is admitted, plants grown on blocks, such as *Dendrobium albo-sanguineum*, *D. Cambridgeanum*, *Phenacis*, *Phalaenopsis bilobum*, *Sophranopsis*, *Barkeri*, *Skinneri* and *epetabilis*, *Senticularis*, *Broughtonia sanguinea*, *Lullia superbiens*, *Cattleya citrina* and the Guiana species *C. superba*, and others that succeed best in this way will require daily attention with water; dipping in a pail is the most effectual method, but care must be taken that the advancing flowers, such as are being pushed by the first-named *Cattleya*, are not much wetted, otherwise they are liable to decay.

**Plants in Baskets** suspended and now making growth are also in a position for being quickly dried up, and, in addition to the water they get by syringing, should be closely examined once or twice a week, to see that they are sufficiently moist.

**Masdevallias** that are now throwing up their flowers will require abundance of water, but on no account should they be placed on an over-wet surface, where the pots keep sucking up the water until the whole material in which the roots are growing is wet to saturation. Though moisture-loving plants, growing naturally, as they do, with their roots in a wet medium, still, when confined in a pot, they do not usually succeed well when placed so that the water is continually sucked up in this way.

**Sobralias** that have been kept somewhat drier through the winter will now be forming their flowers, and must have sufficient moisture at the roots. These usually showy plants, although the individual blooms do not last long—rarely more than three or four days—are well worth more extended cultivation than they at present receive. They are amongst the most easily grown of Orchids, requiring a *Cattleya*-house temperature, and when they get strong they give a succession of flowers that compensates for the bloom individually being short-lived; and there is nothing in the whole family of Orchids that surpasses the combined size and splendid colours they possess. Their worst fault is, that in the macrantha section they often exhibit a disposition to grow too tall, but there are some varieties obtainable much dwarfer than others, and the great height they grow to is frequently, to some extent, attributable to their being subjected to too much heat and atmospheric moisture.

**Trichopillias.**—Such species as *T. crispata* and *T. tortilis*, now pushing up their flowers will need their roots moistening sufficiently after being dry through the winter. They are very impatient of water, and the young advancing flowers, which spring from the underside of the bulb in almost absolute contact with the soil. The best way to moisten the material in which the roots are placed is to plunge the pots in a bucket of tepid water; by this means the whole can be moistened enough without allowing the water to rise so as to touch the flower-spikes.

**Cypripedium caudatum** and **Uropedium Lindeni.**—These plants, somewhat similar in appearance, will now be pushing up their flowers; the latter especially is a water-loving subject, but care should at this time be taken that the water does not lodge to any considerable extent about the ascending flower-scape, which, from the formation of the plant, it is very apt to do, and, although anything but delicate subjects, the flower-stems, if thus continually in contact with moisture, will sometimes rot. The flowers of these plants are not surpassed in structural beauty and singularity by any Orchids, and no collection can be said to be complete without them.—T. B.

**Stoves.**—Put a few neat stakes amongst the leaves of the earliest-started *Caladiums* to keep them from getting broken. Keep the young stock of *Palms*, *Cycads*, *Dracenas*, *Ixoras*, *Crotons*, *Pavettas*, &c., in a warm, moist temperature, as in that case the plants start more freely into growth, and develop their foliage in greater perfection than they otherwise would do. Re-pot the stock of *Alocasias*. Plants belonging to the macrorrhiza section of that genus like a good substantial loamy compost; whereas those belonging to metallic delight in an open turfy soil.

They like plenty of water, both at the root and in the atmosphere; indeed, *A. metallicum* and *Marantaceae* would thrive set on inverted pots in an aquarium, &c. If the bases of the pots were just above the water. *Cyrtanthe*, *Phytolobos*, and *Medusa* also enjoy a similar position, and the large and magnificent foliage they produce under such circumstances amply repays any attention they may receive in that way. Put some *Tradescantias* of the discolor section in 4-in. and 6-in. pots, and keep them for a time in a brisk, moist temperature, when they will make excellent plants. Start *Clerodendrons* of the fallax, fragrans, and *Kämpferi* section, and give the climbing ones plenty of string to support their growing shoots. As soon as *Criminus* have done flowering, re-pot them in a good substantial loam mixed with some well-decomposed manure. The many *Phytolobos* and *Medusa* same pot for two or three years in succession if the specimens be large; but in that case manure water must be given them. *Centradenia* make useful plants, if propagated from cuttings now and well attended to. Keep *Brexiens* free from scale, and *Ixoras* from mealy bug. *Allamandas* must now be kept in active growth; *A. nobilis*, *grandiflora*, *Hendersoni*, *Cathartica*, *Schottii*, and *Aubleitii* are amongst the best. *Ficuses*, *Zeschynanthes*, and similar plants thrive admirably in baskets. Cut back plants of *Stentellaria Mocciana*, and pot and start them into growth. *Cissus discolor*, a plant which well deserves every encouragement, enjoys heat and moisture when grown, and is rather partial to a slightly shady nook. Cut back old plants of it close to the main shoots, and induce them to start afresh. Divisions of the cut-away shoots strike freely, and form striking little plants for suspended baskets or for pot trellises. *Torenia asiatica*, *Coccyzium discolor*, *Panicum variegatum*, *Hoyas*, *Selaginellas*, some *Ferns*, and *Dracenas* for centre-pieces are suitable for basket-work; but if a little extra shade can be afforded, many other plants, such as the beautifully-leaved *Philodendron Lindeni*, *Pothos argyrea*, different kinds of *Cissus* and *Pithecia* plants may be effectively employed for the same purpose.

**Green-houses.**—Hard-wooded green-house plants of all descriptions, except *Azaleas*, which are better moved later on, should immediately be potted. It is a very great mistake to defer this operation (as is frequently recommended) until further on in the season, as then the greater amount of solar heat necessitates air being given to an extent that the plants cannot well bear for two or three weeks after potting, the ill effects of which are further aggravated by the then drier condition of the atmosphere. Another great advantage in early potting plants of this description is, that whilst the weather is cool they do not require water being given so soon after; this also is a most important matter, as the more time that elapses before it is necessary to moisten the soil, the less chance is there of the roots suffering thereby, for despite the greatest care, there is always some mutilation in re-potting which renders them highly impatient of moisture. In all cases, see that the ball of every plant which has to be moved is thoroughly moistened beforehand; this should be attended to the day previous to potting, so as to give time for the water to drain off. Do not further disturb the roots than by the removal of the drainage crock from the bottom of each ball, and mix the new soil with the potting-stick until it is as close and solid as the ball of the plant, otherwise, when water is given afterwards, it will pass off through the new material, leaving the roots so dry that death or an unhealthy condition is sure to follow. In potting plants, avoid the error of placing them too high in the pots, the effects of which are more injurious upon hard than soft-wooded subjects, the result to all being that there is a difficulty in watering, through insufficient space betwixt the surface of the soil and the rim of the pot. All plants, large and small, should be placed sufficiently low in the pot for it to hold enough water at one application to moisten the soil, as where the watering of a plant has to be done by degrees in two or three applications (should this be omitted) the surface alone gets moistened. Some seed of *Colasia pyramidalis* should now be sown; it is well to sow it twice or thrice at intervals through the spring, by which means this useful decorative plant can be had in flower from the latter end of summer to the close of the year.

**Conservatories.**—Indoor plants now starting freely into growth must be encouraged. Deciduous shrubs and climbers still unpruned must now receive that attention in order to prevent unshapely growth, and all evergreen shrubs may yet be safely pruned. Stake plants in pots as requisite, bearing in mind, however, to use as few for that purpose as possible. As the young shoots lengthen they should be tied out at once to the principal supports. Wash all sashes requiring that attention, paint any other wood or iron-work that seems to need a coat of paint, and scrub off any coniferous or green slime that may collect on the sashes. No dirty water should be used in potting, and the pots in which plants not to be shifted this spring are growing should also be well washed, and if the surface-soil cleaned and, if necessary, a fresh dressing applied. Newly-potted plants should be kept in the warmest corner of the house for a time and excluded from cold draughts, but to plants in active growth plenty of air should be admitted and abundance of water given. Maintain the gayety of conservatories and other show houses by means of *Hoteias*, *Spiras*, various sorts of *Prunuses*, *Dentzias*, *Lilacs*, *Rhododendrons*, *Weigelas*, and *Roses*, brought from forcing houses. Keep up a good succession of *Hyacinths*, *Thilips*, *Narcisus*, and *Crocuses*, and for late bloom secure the latest of these to a cool house or pit with a north aspect. Introduce *Mignonettes* from frames, and, if necessary, sow a fresh supply in pots for summer blooming. *Rhodanthes* are charming plants both for summer and autumn decoration; therefore, sow some at once in 4-in. and 6-in. pots or in pans, and when ready prick the young plants out into pots, keeping them near the light and pinching them at the third joint.

### Indoor Fruit Department.

Pines are now being put in good condition; others are swelling, flowering, and coming on in succession. To those ripening fruit give but little water, whilst to those in a less advanced state supply it more liberally. For suckers maintain a temperature of 65° at night, and to those farther advanced allow 70° by day with a rise of 10° by means of sun heat. Keep the bottom heat at about 75° to 80°. Give weak manure water at the root, and also sprinkle the plunging material and paths with it. To late Vines give abundance of air, so as to keep their buds back. Vines that are just started should be kept close and freely syringed, thinning both bunches and shoots as they require it. The farthest advanced Figs should have a night temperature of 60°; these should now receive plenty of water overhead as well as at the root. The second house may now have the same temperature as the first; the third one kept at 55° at night, allowing a rise of 10° by sun-heat. Peaches, Nectarines, Apricots, and other fruits should be well syringed, except when in flower, and due attention should be paid to thinning the fruit as soon as it is tolerably well set, and again after stoning time.

### Flower Garden.

**Auriculas.**—It is a time of intense interest to the grower of these

spring flowers, especially at early dawn, to watch the development of the flower trusses and inhale the sweet perfume of the flowers. It is also a time of great watchfulness. The March winds and April showers that bring forth May flowers are not equally acceptable. The former must be guarded against, as they curl up the petals of the scarcely opened pips, and prevent some of the finer varieties from flattening out at all. The lights must always be tilted against the wind; and if this be not possible, some hexagon netting placed over the openings will moderate the force of cold winds. It is not necessary to place sticks to the flower-stalks if the plants are well managed; they ought to stand up stiff and erect. As a rule, the old growers have discarded those varieties that had weak stems. There are a few amongst the stage sorts, and more still amongst the Alpines, that will not hold their heads erect with the best management; notably *Petronella* (Heardly) and *Blackbird* (Spalding—both dark selfs). Then the pips are sometimes too numerous to develop themselves properly, and the badly-shaped ones must be removed with a pair of narrow-pointed scissors. There are frequently over a score of pips on a strong truss, and these may well be reduced to a dozen. The outside pips are often coarse, and those near the centre are small and the edges imperfect; great care must be taken not to damage the pips that remain. If the plants have to be taken to the exhibition, a stick must be placed to each truss, and some clean cotton string must be worked in amongst the flowers to prevent the pips from rubbing against each other. The usual way to remove the plants to the show in the north of England is to turn them out of the pots, and wrap the roots round firmly with some cloth or paper; they are then packed closely together in boxes in an upright position, and a large number of plants can be put into a small space. Empty pots are provided, into which the balls of roots still in their cloth or paper wrappings are placed, and the surface is nearly covered with green Moss. Other exhibitors prepare their plants at home, and take them to the place of meeting in vans.

**Carnations and Picotees.**—These were placed in their blooming pots a month ago, and have now taken hold of the new soil. Although the weather has been cold at nights for the last few weeks, the sun has had a stimulating effect by day, and many of the sorts are "spindling" for blooms. Our plants are all placed in frames under glass lights, and this permits us to shelter the plants if necessary, and also to fumigate them with tobacco smoke if it is necessary to do so to destroy greenfly. All decaying leaves must be removed with a pair of small scissors, and as the plants "spindle" for bloom the sticks must be placed to them to prevent accidents. Do not place the glass lights on unless the severity of the weather requires it.

**Herbaceous Phloxes.**—The cuttings put in some time ago are now rooted, and must be potted off. For want of room or time, we had to put in a number of cuttings in a 3-in. pot; these have been potted off singly, one in the same sized pot. A few Phloxes cultivated in pots are very useful, and make a distinct feature in the greenhouse or conservatory about the month of September. The plants for the pots will be potted, as soon as they are fairly established, in 6-in. pots; they will each produce one spike of bloom, and after this they should be placed out-of-doors. The plants in beds have made considerable growth, and it has been necessary to place the sticks to some of them. This must be done early, as the stalks snap off in a high wind close to the surface of the ground.

**Pyrethrums.**—This is a class of hardy border plants that are not sufficiently known. The large flowers, in form like a double-headed Aster, are freely produced in June and July. They are also perfectly hardy, and are increased by division of the roots. If not seen to already, no time should be lost in doing so. Our plants were potted in the autumn and have been wintered in cold frames; they are now planted in beds in rich soil. Although the finely-divided leaves look tender and fragile from being under glass, they received no injury from 10° of frost, to which they were exposed a few days after being planted out.

**Tulips in beds** also look remarkably well. I find the leaves suffer but little from frost if they be dry and the ground is also dry around the plants. The surface of the beds has had a dressing of rotted manure placed over it; and this is, I believe, also a slight protection to the plants. Still, if the glass lights could be spared, I would place them over the beds, and this would be ample protection. We may yet have keen frosts, accompanied with rain or snow, and it would be better to shelter the beds from such a contingency as that. Nearly, if not quite, all the growers for exhibition place iron hoops over their beds, and throw canvas over them in rough weather and when it is frosty at night. Then there is the usual tent erected over the beds, high enough for a man to walk under and attend to his flowers. The canvas, of course, is movable, and is drawn up with pulleys when it is not used to shelter the flowers. In all cases it is desirable to keep mats and canvas coverings out of sight as much as possible. I have seen the mats and other coverings of frames thrown carelessly down close to the frames, and if it should rain, the water from the lights saturates them. Mats and canvas coverings ought to be quite dry when used to protect the plants from frost.—**J. DOUTLAS.**

**Lawns.**—Where new lawns have to be formed the preparation of the ground is of the greatest importance, and, except this is attended to in the first place, no after management is likely to be so thoroughly productive of that verdant, close, even, evergreen turf desirable. Unless good, firm turf can be secured, perfectly free from coarse Grasses and weeds of every description, it is best to sow with seeds adapted for the formation of a permanent lawn, being particular that the ground is made evenly solid. Lawns that were top-dressed early in winter, and such as are patchy, will be improved by being sown with Grass seeds and White Dutch Clover; afterwards rake and roll over the ground. Finish turning repairs and edge the margins of walks. This is a good time, before the ground becomes hard, to grub up Daisies, Dandelions, &c. Sweep and roll the turf; the rolling should be done the day previous to mowing, and lose no time in laying the Grass out with the machine, which will greatly improve the appearance and texture of the turf.

### Kitchen Garden.

**Cauliflower and Lettuce.**—Cauliflower plants from frames may now be planted out in well-dug, highly-manured ground—a planting trowel being used to remove them, in order that as much root as possible and a good ball of earth may be secured—planting them 2 ft. apart each way, which for this crop will be ample space. The Cauliflowers that have been wintered under glass—a portion of the plants must now be removed, some three of the strongest being left under each glass, and as

Entrance to great Stalactite Cave in Park Monceau, with Ivy, &c.

these undisturbed plants advance in growth raise the glasses on bricks, removing them in the daytime so as to give plenty of air, but keeping them over the plants at night. This not only protects them from any severe frost that may occur, but in mild weather brings them on quicker than would otherwise be the case. The plants that have been removed from the hand-lights will form a succession to those remaining. Should there be an indication of keen frost before these newly-turned-up plants get established, there is no better protection for them than 8-in. or 10-in. flower-pots placed over each. These pots effectively ward off the frost, and the labour of removing and replacing them is small compared with the benefits to be derived from their use. Lettuce from frames and under the protection of south walls should also now be planted out in well-prepared and richly-manured ground—the richer the better—in order that they may be grown large and crisp, and also to prevent their running early to seed. Plant them 15 in. asunder in the rows, with the same distance between the rows. In taking them up use the planting trowel so as to check them as little as possible—the barbarous system of tearing up plants intended for replanting, entailing, as it does, the certain destruction of their roots, should never be tolerated in a garden where there is any pretension to intelligent management. For this reason the fork or planting trowel should be used in taking up for re-planting even the commonest or least valuable vegetable; the little extra labour involved is nothing as compared with the gain. Lettuce or Cauliflower plants that have been sown in a little warmth must, as soon as large enough, be gradually hardened off and pricked out in frames, sufficient air being given them in mild weather to induce a sturdy growth.

**Rhubarb.**—This crop, from the great weight of its produce, quickly exhausts the soil; neither is it desirable to let it stand too long without removal, as plants that have been for some time undisturbed have a greater disposition to produce flowering shoots, which, even if cut out as soon as they appear, are prejudicial to the growth of the edible stalks; but it is not a good plan to disturb the whole plantation at once, as this stops the supply for a time. If some of the outside crowns be severed from strong established stools with a portion of root each, and planted now two or three together, and allowed to attain a maximum of strength, not gathering from them this summer, they will bear strong stalks next spring; or roots that have been forced through the winter planted now and permitted to regain strength through the summer, will succeed. As Rhubarb is a deep-rooting, gross-feeding plant, in all cases it should have rich soil, and if it be of a heavy retentive nature, some old, exhausted tan, leaf-mould, wood-ashes, or sandy road-drift, if such can be procured all mixed together, with 6 in. or 8 in. of good rotten manure, should be mixed with it, trenching the ground 2 ft. or 2 1/2 ft. deep, planting 6 ft. apart each way. A crop of Radishes, Spinach, or Lettuce may be had off the ground between the rows before the Rhubarb makes sufficient growth to interfere with them. Existing beds of Rhubarb will be much benefited by heavy dressings with strong manure water during the next two months.

The value of trenching and ridging ground in winter has been made fully apparent this spring, for, while plots that were dug only have been hardly workable, the ridged ground crumbled down like dust, even though there has been little frost; and, indeed, it is soon next ground we depend on for our Cauliflowers, Lettuce, Peas, Potatoes, &c. Sow a full crop of Savoy and Broccoli; sow, also, some seeds of Asparagus in lines 18 in. apart; likewise successional crops of Radishes, and occasionally some Lettuce, both Cabbage and Cos kinds. Finish transplanting Onions, and, if not already done, sow the summer crop at once. Sow Round Spinach between rows of Peas, or, in some other places, in quantity sufficient to meet the demand; sow also some of the New Zealand Spinach in heat for a summer and early autumn crop; this variety often affords fine succulent leaves when ordinary Spinach cannot be had. Of Carrots sow a full crop in deeply-trenched ground, which should get a good dressing of fresh air-slaked lime. Sow some small kinds of Turnip in lines 1 ft. apart, or in beds 4 ft. wide, on warm, light soil. Earth up and stick Peas as they advance in growth; any exposure to cutting winds should have the assistance of a few evergreen branches to break its force. The following are first-rate sorts for sowing about this time, viz., Champion of England, Laxton's Prolific and Quality, Veitch's Perfection, Dixon's Favorite, McLean's Best of All, Prince of Wales, Wonderful, Fairbairn's Surprise, Victoria Marrow, Knight's Tall Marrow, British Queen, and No Plugs Ultra. Transplant Cabbages as required.

**Herb Plantations.**—Herbs in many gardens frequently do not receive the attention which they require; they are often fondly neglected in some out-of-the-way corner, where they become almost wholly thrust; from this cause their product is but small, and their appearance very untidy; Mint especially, if it be allowed to occupy the same ground too long, exhausts the soil, which generally gets foul with weeds. Now is a good time to make a fresh plantation of herbs, fork up the underground creeping roots, prepare a piece of ground in size proportionate to the supply required by digging and putting in a fair amount of manure, forming it into a bed about 4 ft. or 5 ft. wide; then take an inch or two of the soil off the top, lay on the roots not too thickly, and cover them with the soil that was removed, leaving the surface tolerably smooth. Growth will soon commence, but the produce will not be so soon ready as from an established bed, consequently it will be well to leave a portion of the old plantation undisturbed until that from the new is ready for use. Camomile, Pennyroyal, and similar herbs, where required, should be planted in similar beds prepared in like manner, putting in rows 1 ft. apart in small pieces divided from the old plants. Sage is a green from cuttings struck in the latter part of summer, when they get freely; such as were struck at that time can now be planted in rows in a bed where

they are to remain permanently, as also Tarragon and Fennel; the latter, from its taller growth, must have considerably more space allotted to it. The principal thing necessary with the above, and any other herbs that may be required, is to keep the ground clear from weeds, and not to allow them to grow too long in one place. Chives.—Where these are held in estimation they may be fast increased by taking up and dividing the root clumps, re-planting in thin rows. The planting of all the above should not be delayed, otherwise the season's growth is much interfered with through their not getting established in their new quarters before dry weather sets in.

#### Extracts from my Diary.

**April 1.**—Sowing first lot of Spanish Cardoons, Green Curled Endive, and All the Year Round and Carrot's Giant White Cos Lettuce; also Long and Red and Early Turnip, Radishes, &c. Drawing drills for Carrots and Beet. Hand-weeding and Dutch-hoeing amongst autumn-sown Onions. Making new Mushroom bed under north wall for summer use. Earthing up Potatoes in frames; also French Beans in pots, and putting sticks to them.

**April 2.**—Sowing the main crop of the following sorts of Carrots, viz., Early Horn, Early Nantes, James' Intermediate, Long Surrey, and Altringham; also the following sorts of Beet: Eastwood Early Red, Osborn's Select Red, Nutting's Dwarf Red, Pine-apple Short Top, Veitch's Improved Black, and Spinach or Green. Potting spring-struck Petunias, Heliotropes, Salvia, and Verbenas. Renovating linings round frames. Dutch-hoeing amongst Strawberries.

**April 3.**—Sowing Aytton Castle, Giant, Carentan, Henry's Prize, and Large Rouen Leeks; also Vegetable Marrows and Ridge Cucumbers. Putting in cuttings of Dahlias and choice sorts of Pelargoniums for winter flowering. Pricking out Cery in boxes; also Golden Pyrethrum and Tagetes species. Clearing off Seakale beds and getting them forked up. Sicking Peas and earthing them up.

**April 4.**—Sowing the following sorts of Broccoli: Early Purple Cape-early White Cape, Watchtower, Snow's Winter White, Osborn's Winter White, A Jan's Early White, and Early Purple Sprouting; also dwarf Green Curled Savoy, Early Dwarf York Cabbage, Asparagus, and Green Curled Kale. Potting off late sown Tomatoes, Lobelias, and Melon Plants. Forking up the ground amongst the Cauliflower plants left in the frames to come in early, and giving them a top-dressing of rich manure.

**April 5.**—Sowing Dandelion for salads, Mustard and Cress, Balsams, Asters, and Cockscombs. Putting in cuttings of Coleus and Alternantheras. Washing all the Roses with Quassia Water to keep down green fly. Watering early Vineries and Peach houses with tepid water. Giving Broad Beans a little earthing. Watering Carrots, Asparagus, and Potatoes in frames. Clearing off Brussels Sprouts stumps, and getting the ground manured and dug. Looking over the Grapes and removing the bad berries, and filling up the hotches where required.

**April 6.**—Potting on Sweet-scented Verbenas, Fuchsias, the forward Tomatoes, and Sweet Basil. Planting out Melons in manure frames. Removing hedging plants from Vineries in cold pits to harden. Disbudding and tying down shoots in early Vineries, and thinning Grapes where required. Looking over Strawberries in bloom, and picking off all weak and late blooms; also getting another batch into warmer quarters. Mowing and cleaning up the pleasure grounds. Rolling down all gravel and turf that require it. Looking over Fines and watering them all through.

W. G. P., Dorset.

**Streamlet Issuing from Ivy-clad Rock.**—In this case (see opposite page) a pretty garden-streamlet is made to issue from an Ivy-clad rock. After coming from beneath the sheet of dark Ivy it is soon busy amongst Flags and other waterside plants and flowers. The idea is one which may be worked out with advantage where there is natural or good artificial rock within the reach of the designer.

**Effect of Sulphate of Iron on Plants.**—At p. 69 of Vol. XII. of THE GARDEN is a paragraph upon the injurious effect of sea water on land, partly "from the formation of sulphate of iron, which is known to exert a very prejudicial effect upon plant growth." Lately an account has been published of the beneficial results of using a solution of it, and in the face of these contradictory records how are we to arrive at the truth? Last summer, having a quantity of the double salt of sulphate of iron and ammonia on hand, I was giving a very weak solution of it to my plants, and I thought with beneficial results, possibly owing to the presence of the ammonia, but no reading the paragraph just alluded to I left off using it. Now I shall again employ it on some pot plants, and trust some authority will kindly publish his opinion on its use.—LONDON STONE.

**Sowing Sweet Peas.**—Everyone who has a garden should have a row or two of Sweet Peas. If sown at once (not too thickly) on deeply cultivated land, they will continue to furnish successive crops of bloom throughout the whole season, and the more the expanded flowers are gathered, the more the peg and satisfactory will be the results, as if allowed to mature seed-pods the plants become quickly exhausted. Sweet Peas may now be had in many distinct colours, but a good mixture will usually yield the best results. I generally drop a few seeds of Convolvulus major in the rows, and these late in autumn form beautiful objects.—J. GROOM, Henham.

## GARDENING AT FROGMORE.

The Royal Gardens at Frogmore are at all times well worth a visit, on account of the excellent manner in which they are kept, and the many cultural hints which they afford to anyone interested in horticulture. Every branch of gardening is carried out here in perfection, and although there are no pretensions made as regards effect, or grand displays of indoor plants, good and useful subjects well grown, can always be found here. All the plants cultivated here are for supplying cut flowers, or for room decoration. Large Camellias which are yearly divested of all their blossoms never fail to grow and flower freely; and of Tea-scented Roses, planted in an outside border and allowed to cover the roof of a large lean-to house, the best kind in bloom at the time of our visit was *Celine Forestier*, which grows well and yields abundance of golden-tinted flowers for many months in succession. In the same house was also a plant of the beautiful *Clematis indivisa lobata* loaded with snowy blossoms. Gardenias are grown here extensively; they are planted out in a narrow bed at the back of a half spau-roofed house, and being kept well pruned and tied in, form quite a thick hedge, which when in full bloom is a sight worth seeing. By keeping the plants thus close blossoms of a better description are obtained than when they are allowed more freedom, as in the latter case they are usually loose, and will not last long when cut. In the same house we also noted a very attractive plant of the old *Euphorbia splendens*, or by some called, and perhaps more properly, *E. spinosa*. It was planted out, the shoots being kept tied closely in so as to form a cone, and at the time of our visit was a mass of flower. Amongst other plants grown for furnishing cut blossoms and for indoor decoration may be named *Hebeclinium uthinum*, the great, feathery mauve-coloured flower-heads of which are very showy; cuttings of it struck last spring, and grown in the same way as those of *Poinsettias*, now make good plants in 6-in. pots. Older plants of it form large bushes, from which great quantities of cut flowers are obtained. *Begonia hydrocotylifolia* is also grown in considerable quantities. Cuttings of it struck every year in winter make handsome plants, with large stiff green leaves hiding the pots, and produce quite a thicket of stout flower-stalks laden with light and graceful white and rosy-tinted blossoms. *B. dracenaefolia* is also grown largely for decorative purposes, and of all plants which are used for room decoration by gaslight these rank amongst the most effective. The scarlet-flowered *Salvia Heeri* likewise plays an important part in house decoration; cuttings of it are struck in spring and planted out during the summer in good soil in the open air. In Sept. they are lifted and potted and placed in orchard houses, where they open their long racemes of brilliant scarlet blossoms in profusion; and some of the plants grown in this way attain a height of 3 ft. or more, and are as much through, and are more effective in rooms than many choicer subjects. The flowers just before opening are very useful for bouquet making. Fine pyramidal-shaped plants of the white *Eupatorium* are also great favourites here. In vases they look bright and elegant, and last good for a considerable period. Neat bushy plants of *Crotonas*, *Dracenas*, *Pandanas*, and similar subjects are likewise grown in large quantities for vase decoration, and many more old, but nevertheless useful, subjects are grown by hundreds for supplying cut blossoms.

## Fruit.

No one who has not seen Frogmore can form the least conception of what is done there in the way of fruit growing.

VINES are cultivated with the greatest success. The principal supply is needed during winter, and this is kept up by fruit of smooth *Cayennes*, weighing on an average  $8\frac{1}{2}$  lb. to 9 lb. each. The plants are grown in deep pits, bottom-heat being supplied by means of Oak leaves and other fermenting material. The soil is a rich sandy loam, and the plants are grown on ridges. When the fruit has been cleared from a pit, the plants are pulled up and divested of their suckers; and, after duly preparing the soil, &c., these are planted as before, and a never-failing succession of large, handsome, well-formed fruit is the result.

VINERIES.—From these nearly 2000 lb. of Grapes are obtained yearly; and it is satisfactory to find that, so far from the crops being on the decrease, owing to the age of the Vines

a much greater weight of fruit has been obtained during the past two or three years than was gathered even when the Vines might be considered at their best. These results have been brought about by supplying the roots with good soil and liquid food, and paying unremitting attention to other points connected with their culture. Some of the oldest and least productive of the Vines have been cleared away and replaced by younger ones, which have not yet come into bearing, but which appear likely to yield fine crops, judging by the growth which they have made since they were planted. Pot Vines are grown to perfection, no bottom-heat or plunging material whatever being used for them; the pots are placed on plain slate slabs, and the crops which they bear are surprising. The earliest permanent Vines are yielding a large crop, which has been thinned, and the berries have just done stoning, so that ripe Grapes may be expected early in May. Most of the Vine borders here are made both inside and outside, but a late house, planted with *Lady Downes* and *Black Alicante*, with a half-span roof, has its border entirely outside, and the wall plate is so constructed that the Vines, when cleared of their crops, can be brought through the front ventilators and tied to stakes outside, thus leaving the house ready for the culture of Strawberries in pots, French Beans, and other crops. This method ought to be more extensively practised than it is, for, in addition to the accommodation made with regard to house room, the Vines are greatly benefited by being exposed to the sun, wind, and weather for a few months whilst at rest. When started, Vines thus treated break strongly, are hardier, and, as a rule, produce better results in the way of fruit than are attained from Vines always confined indoors. The principal aim here in Grape growing is to keep the table well supplied with fruit every day throughout the year; and that this end is attained may be gleaned from the fact that there still remains some 300 lb. of sound, ripe, and well-coloured Grapes in the Grape room—a quantity sufficient to supply the table with from 4 lb. to 5 lb. of Grapes per day, irrespective of new fruit, until far into the month of May.

THE GRAPE ROOM.—No one need despair of keeping up a supply of Grapes until new fruit can be had in the spring if they will only adopt the plan in use here. There is no need to keep Grapes hanging on the Vines until growth again commences, and it becomes dangerous to prune from fear of bleeding, thus keeping the wood in a half-ripened state, instead of being dry, plump, and hard, ready to bear better crops in coming years. The Grape room in question is but a small one, but it is nevertheless capable of holding some hundreds of bunches. It is from 15 ft. to 20 ft. in length and about 7 ft. or 8 ft. wide. All round the walls are placed upright pieces of deal about 3 ft. apart. These are furnished with zinc troughs which slide into places made for them on wooden ledges fastened to each upright about 2 ft. apart. Along the centre of the room is a stand of similar construction, but which is supplied with wider troughs, in which are two sets of holes, so that Grapes may be hung on both sides. These troughs are simply pieces of zinc turned up, so as to form sides and bottom of box-like fashion, and the tops and ends are soldered on. In the bottom of the troughs inside is placed a little ridge of zinc, against which to rest the Vine stems bearing the Grapes. In the lid are bored holes about 6 in. apart in rows nearest the side farthest from the wall, but the troughs are supplied with two rows of holes, as before stated. There is a window in the front end of the room, and a ventilator in one corner at the back, so that a free circulation of dry air can be maintained. Small hot-water pipes, connected with one of the boilers generally in use through the winter, run round the room; on fine days a little heat is turned on, the ventilators are opened, and the Grapes thus get thoroughly dried. By this means any mould which may occur in any of the berries which have been injured or slightly affected with mildew is at once dried to a powder, and prevented from affecting the fruit which is in close proximity to them. They are kept regularly filled with water, and a few pieces of charcoal are added to keep it sweet. When a bunch of Grapes is cut the hole it occupied is corked up, thus preventing any dampness from arising. Early Grapes as well as late ones are kept in this room—a good plan, inasmuch as a house occupied with pot Vines can, when the fruit is cut, be used for other crops.

**STRAWBERRIES.**—Of early Strawberries in pots some 8000 or 10,000 are grown here yearly, and from these nearly 500 lb. of ripe fruit are obtained. The earliest plants, consisting of Keen's Seedling and La Grosse Sucrée, are now just ripening their fruit. These are grown on shelves in houses; others are being brought on to succeed them plunged in pits. For later supplies plants which were forced last year are planted out in pits, and bricks are placed between the rows in order to raise the plants as near the glass as possible and afford greater facilities for watering. To succeed these a quantity of plants are put out on a warm, sloping bank under a wall, and a thin canvas is placed over them when showing bloom. In like manner a quantity of plants is placed in rows under Cherry trees on the wall, from which good crops are secured just before Strawberries ripen naturally in the open ground. Thus a good supply is obtained from the end of March until late in autumn.

**CUCUMBERS** are, as a matter of course, grown here in quantity, and that, too, all the year round. The only variety used is Hedsor Prolific, a short-fruited kind, very green and excellent in flavour; the soil in which they grow is a rich, turfy, yellow loam. Whilst the plants are young saucers made for the purpose, which have two rims and a hole in the centre, are placed over them; these are kept filled with water, and by this means the stems of the plants are kept from the ravages of slugs, crickets, or other pests.

**CHERRIES.**—Some of those in houses are grown in pots, but others are planted out, a plan which it is intended to adopt throughout. The houses in which they are grown are span-roofed, and the trees are planted so as to be easily trained up the rafters; a pyramidal-shaped tree is planted between every other two. When we saw them the trees were loaded with blossom. The kinds found to succeed best for forcing are May Duke and Knight's Early Black. Newer sorts have been tried, but they did not prove so satisfactory as those just named. The beautiful fan-shaped trees on the walls were one sheet of blossom, being protected by a wide glass coping and supplied with canvas blinds on rollers, which can be let down whenever required. A famous crop may reasonably be expected.

**THE FRUIT ROOM.**—This, which is 110 ft. long and about 10 ft. wide, is a lean-to on a northern aspect. The floor, which is concreted, is sunk some 3 ft. or 4 ft. below the ground level; the walls are of brick, and about 1 ft. thick; the roof is slated, but under the slates are 4 in. or 5 in. in thickness of straw. There are several ventilators along the back and at the ends to let out the damp, and in front are small iron gratings, so that a free circulation of air can at all times be maintained. No heating apparatus of any kind is employed, but in case of severe frosts the iron gratings are stopped, and a never-varying temperature is thus always kept up. The shelves or stages on which the fruit is placed consist of lattice-work, on which no straw or other material is placed, and therefore no objectionable flavour is imparted to the fruit. There are still some good examples of Apples and Pears to be found in this fruit room, the flesh of which appears to be nearly as fresh and plump as on the day on which they were placed there, and early varieties are said to keep nearly as well as late ones.

#### *The Kitchen Garden.*

This has been much improved by doing away with unnecessary walks, grubbing out old fruit trees on the walls, and replacing them with young ones. Much is now being done in this way, for a great number of the wall trees bear fruit only on the ends of the branches; therefore, a piece at a time is cleared right away, the ground trenched, and young trees, previously grown and trained for the purpose, are planted. This is a much better method than introducing young trees between the old ones, as is often done, but which seldom proves satisfactory. Where Plums are done away with Pears are planted, and *vice versa*, so that a change of soil is secured. With early Pears a very good way has been adopted; the trees are trained with a shoot in an upright position, and the side branches, which are kept closely pruned in, are led downwards, which induces fruit-bearing spurs to be formed. These Pears are planted between Cherry trees on a south wall, where they occupy little more than 12 in. or 18 in. of space, and being protected like the Cherries, by means of glass copings and canvas blinds,

they set their blooms perfectly, and a supply of good early Pears is the result. Root-pruning is practised whenever the trees show signs of being over-luxuriant, and thus a large supply of excellent fruit is obtained. The Pear trees on low arches by the sides of the walks in the kitchen garden are being done away with. They were planted under the middle of the arch, over which the shoots were trained downwards to the ground, but the young trees which are planted to take their places are being trained horizontally, and the growth which they make is such as to show at once the superiority of the system over that just described. In this case, as in that of the walls, an old tree is not taken away and a young one planted in its place, but a piece is completely cleared and the soil is well prepared for the reception of the new tree. A piece of land lately added to the garden is being planted with Apple trees in such a manner as to admit of classification. All new kinds are procured as they appear, and Mr. Jones purposes to spare no pains in obtaining the true name of each variety planted.

#### OPENING KEW GARDENS.

WE are sure that the peculiar hardship of the gardens at Kew being kept shut in the morning is not known to the Chief Commissioner, or it would not be tolerated by him. In the museums, galleries, &c., where space is limited and every inch has to be cleaned every day, there is need for reserving certain hours for cleaning; but even in such vast and magnificent galleries as the Louvre this difficulty is arranged for at such hours as suit the public. In such great galleries and museums the sole reason why they are not opened for a longer time every day than is now the case is the impossibility of lighting them efficiently without danger to the structure or injury to its contents. In the case of a garden, but a small portion of the surface will undergo cleaning on any given day; and as for the lighting, that is done by the sun himself. It is therefore more than unreasonable that a noble garden like Kew should be closed to the public at the hours when such places as the National Gallery or the British Museum have their doors wide open. There is good reason why it should be opened hours before and hours after them, just as in other cities public gardens are opened early in the morning, while the adjacent museums may not be opened till after breakfast. The forenoon is so much the more agreeable time for the public to visit a garden, that if Kew must continue alone among the botanic gardens of the world open for about one-third of the time the flowers are open, it will be necessary to ask that these few hours should be the forenoon hours. It is pitiful to see the narrow-mindedness which persists in endeavouring to justify a state of things which would not be tolerated for an instant in any other city in Europe. It is astonishing to see the noble name of "science" used, and most frivolously so, in this vain attempt to keep the public out of their rights; for it cannot be that those most interested in the matter—that is to say, the horticulturists of the United Kingdom—and the general public will consent to be deliberately shut out of a place designed and kept up at an enormous cost for their instruction.

There is another aspect of the case which well merits consideration by the "powers that be," that is, the claim of some so-called "scientific" men who ask for exceptional privileges for themselves, and appear to consider the public as a kind of necessary evil, deserving no kind of consideration as compared with their scientific majesties, who, instead of being amiable public servants, act the uncomfortable part of the "wet blanket." No high nature or scientific man—using the term in its best sense—would claim exceptional privileges for himself or his work. On the contrary, he would, as Thackeray did in the case of "literary" men, disclaim any exceptional favours at all. This is a particularly disagreeable aspect of the question when we consider the liberal way in which the public pay for the garden, and that Sir Joseph Hooker, who opposes the opening asked for, is the paid servant of those against whom he shuts the gates. As to the "scientific work" question, that is easily disposed of. The Chief Commissioner or any person interested has merely to go to the garden in the morning, see the miles of walks and the acres of turf

and the flowers open, too truly "wasting their sweetness," for neither students nor public are there. Such "scientific work" as is really done, is, we presume, done in the working rooms of the Director and his assistants, in which we think the public of all shades are willing to leave them unmolested, no one having ever claimed that these able gentlemen, or even the men in the houses, should be disturbed at their labours.

— I feel sure that many gardeners, like myself, would be glad to know what the scientific and other work which Kew is supposed to be doing. That it does accomplish something in some directions, I would fain believe; but as far as horticulture is concerned in this country, its influence, hitherto, has been almost *nil*. The Garden of Plants in Paris, I understand, exercises a kind of central authority over a number of other and similar institutions scattered throughout the country, and distributes plants and seeds amongst them, which eventually find their way into the gardens and nurseries of the country; but does Kew do any good practical work of that kind? As far as I can learn, it is as often a recipient of favours as otherwise, and it is certainly looked upon by gardeners as having few interests in common with them or their profession. But the question is, what is Kew doing? On this point gardeners are almost profoundly ignorant. They do know something of the Royal Geographical Society, the Transactions of the British Association, and even the Royal Horticultural Society, and other learned associations and institutions, but the Chronicles of Kew are a sealed book. As regards the admission of gardeners and others, we are now told by the "Gardeners' Chronicle" that they could be admitted before public hours by applying at the curator's office, and much capital is made of a "photographer with his apparatus" who managed to get in; but we should like to know who has ever heard, in a general way, of that rule before. If the rule was in force, it has been a dead letter hitherto. If the fact had been intimated in the public papers, or placarded at Kew gates, it would have saved many a gardener a useless journey, paltry provision as it is; but now that the question of admission and other matters is fully opened, let us hope that it will be satisfactorily answered. J. S.

— The Jardin des Plantes at Paris is open all the year round without exception—in summer from six, in winter from seven a.m. until dusk. There the department containing the chief plants used in medicine and in the arts is crowded with visitors every day, chiefly in the morning. The strictly botanical department, including all the annual or perennial hardy herbaceous plants (the most complete in the world), is open at the same time in the morning, but closed at about ten, then opened again for a few hours in the afternoon; and I must say that quantities of students meet in the morning for the sake of conferring together, and that they are always surrounded by a great number of visitors, who at last get interested in botany; but people never think of going there in the afternoon, owing to the heat. This department is accessible to any visitor at any time by applying to the foreman. The greenhouses are never opened to the public, but admission is granted to anyone who wishes to inspect them. Now why should not Kew Gardens be opened from early in the morning until dusk, the houses only being closed during certain hours when absolutely necessary? The hardy herbaceous department will not require enclosure or a continual watch. It is also a great hardship to be made to keep to the footpaths; and I should like to know why taking notes in writing is not allowed there. A FRENCHMAN.

— Though the Kew authorities do not seem inclined to yield to the public, I cannot help thinking that the present struggle—in which decidedly the majority are in favour of the earlier opening of the gardens—has disposed them to make certain concessions. For example, only a fortnight ago, through the medium of the "Gardeners' Chronicle," it was made known to all whom it might concern that "any gardener or under gardener, any artist, any student of botany or other science, can be admitted for purposes of study before public hours, on application at the curator's office." This looks well, and may be perfectly correct, but the further statement, that this has always been the case since the present director came into office, is very far from being true. The "Richmond and Twickenham Times" of Saturday last says:—"As a matter of actual fact this statement is erroneous. Only last week we were in conversation with a Richmond resident, whose scientific tastes are well known,

who, on purely botanical grounds, made formal application for such a pass. In this instance a reasonable request was refused and no explanation given. And if, wholly unsuspecting, such a case comes under our notice, it is reasonable to suppose that in London and other parts of England there are hosts of other persons similarly aggrieved." I have heard of several instances, and can myself vouch for one, where permission to study during private hours was refused by the director, who is now announced as the friend of all students and artists. I have no doubt that numbers of similar cases could be quoted.—VERITAS.

— A gardener holding a good position writes to us as follows:—"The first time I went to Kew was on a Sunday, and I trusted to Mr. Donald McLeod, then orator's assistant there, to get me in in the forenoon, a little sooner than usual, as I had little time, and had come all the way from Edinburgh for a few days only, but he could not, although he went twice into the curator's house and explained how I was situated. I had, therefore, to hang about Kew Green till the gardens were opened. I have applied since at the gates before the time of opening, and could not get in, and was never told about the rule respecting earlier admission, though I explained all about myself."

— A correspondent of the "Chronicle" says—"Wishing a few years since to devote a day to study in the gardens, I met with only a gruff intimation that they would not be opened until one o'clock. But a harder fate befell a friend from one of the midland counties, who brought his gardener all the way for a day's rest at Kew, and found to his dismay that but a short interval would elapse from the time of admission until that of starting upon his return journey."

— A correspondent writes:—"Mr. Carruthers gave a demonstration in the public gallery at the British Museum on Saturday to more than fifty members of the Geologists' Association, and neither they nor the public were impeded." How then can the public be "impeded" by any lecture given in the wide gardens at Kew?

— There is one argument in favour of the Kew Gardens Public Rights Defence Association which has received but slight attention. Although the Gardens are opened at one o'clock, without great inconvenience to the visitors, the hour of actual opening to the public must be two or half-past. One o'clock means dinner or lunch time, and after Kew is reached, half-past two will have usually arrived. It is no just argument to reply that a number of visitors flock in the moment the gates are opened; this simply proves the eagerness of some of the public who are willing to forego the comforts of the usual meal so that they may secure the pleasures of Kew at the earliest hour available by the present clumsy and selfish arrangement.

The Kew Gardens Public Rights Defence Association are still moving with that persistent energy which befits so good and just a cause. They are organising a meeting for April 5 at Richmond, at which Sir Trevor Lawrence, M.P., will preside, and in which Mr. Cave and other members of Parliament will take part. On and after to-day petitions to Parliament praying for the early opening of the gardens will lie for public signature at Waterloo, Richmond, and Kew Gardens Railway Stations. Surely this fact need only be known to secure such an array of signatures as shall fully prove to official obstructives how thoroughly in earnest are the public in their persistent attempt to secure what is not only a boon, but an undoubted right. Such gardens only open a few hours daily, and those hours most inconvenient, would be dear to the nation at half their present yearly cost. If we are to pay annually over £20,000 for their maintenance, let us at least have some reasonable return for it. If not, let future grants be largely reduced, and obstructives thus brought to their senses through the tender medium of the breeches pocket.—"Richmond and Twickenham Times."

— There are a few points in the memorial published in THE GARDEN (see p. 221) respecting the early opening of Kew Gardens about which I should like to say a few words. When, let me ask, do the teachers go to the garden with their students? I never saw one lecturing there yet. But the point of most importance to scientific men, horticulturists, and the public generally, is the following statement, viz., "The means now afforded by the *unrivaled collections at Kew!*" Now, it is a well-known fact that the collections at Kew are inferior to many others. For instance, if we wish to see a good collection of Pitcher-plants, do we go to Kew? No; we must go to the nurseries of Messrs. Veitch & Sons, in the King's Road, Chelsea; and the same may be said in reference to Orchids. If we want to see a good collection of Alpine and herbaceous plants we must not go to Kew. If we want to find a good collection of economic plants we must go to the Royal Botanic Gardens, Regent's Park. If we want to see a good collection of Protocææ or Cape Heaths do we go

to Kew? No; they are represented there only by a few stragglers. If we want to see the best collection of Agaves, Cacti, and similar plants, it is useless to go to Kew, for there will only be found the older varieties. No; for a person who wishes to inspect the latest importations, or see rare species of living plants, Kew is not the place. There is, however, at Kew good collections of Palms, Ferns, and Aroidae; but if we want to examine the *Acanthodes* or *Melastomadae*, or even the great Order *Leguminosae*, we cannot find them arranged there with any kind of intelligence, though many plants belonging to these Orders may be found scattered about the place. If we want a good collection of Aquatics we must go to Oxford. The want of system in the arrangement of the plants in the houses at Kew is also a great drawback as far as students are concerned. The museums are well arranged and managed satisfactorily, and I know from experience that what is done in the museums can be done in the houses and grounds, and until this is done the words "scientific work" and "unrivaled collections" should be struck out of the Kew memorial. It may be said that Kew is the finest botanical establishment in the world. That I admit; but that does not prove it to be what it might and ought to be. How making it more popular can detract from its usefulness I am at a loss to guess; for let it be remembered that if science be not for the people, the people ought not to be called upon to support it.—J. CROUCHER.

## SOCIETIES AND EXHIBITIONS.

### ROYAL BOTANIC SOCIETY, REGENT'S PARK.

MARCH 27.

THIS, the first exhibition of this Society this year, was held in the long corridor adjoining the Conservatory, the latter structure being itself gay with forced bulbs, Acacias, Azaleas, and similar plants. The principal features were groups of pot Herbs, from Messrs. Veitch & Sons and Mr. Charles Turner, and large collections of Hyacinths and Tulips from some of the leading growers.

**New Plants.**—Messrs. Veitch & Sons sent a collection of new or rare plants, among which the following were named and certified of merit, viz., *Magnolia Halliana*, a new Japanese species, mention of which was made in THE GARDEN last week; *Cypripedium porphyreum*, a hybrid, the result of a cross between *C. rosei* and *C. Schlummi*. The flower-spike is branching, and the blossoms somewhat resemble those of *C. Sedeni*, but they are larger, and of better shape and substance. *Carnation Alogatiere*, a fine-flowering scarlet kind, which will be valuable for market purposes, and of which notice has before been made in THE GARDEN. *Hyacinth Queen of the Blues*, a kind bearing compact trusses of pale blue blossoms, forming a good companion for the dark King of the Blues; also *Hyacinths King of the Blacks* and *Grand Maître*; a beautifully-spotted variety of *Odontoglossum cirrhosum*, *Pavonia Wiota*, and *Microlepis hirta cristata*, which was also shown by Mr. Williams. It is an elegant Fern, with light green fronds resembling in appearance those of the well-known *Davallia Mooreana*. Mr. Williams also received a certificate for *Anemidictyon Phylliditis tessalata*, a Fern of considerable interest. Certificates were also given to Mr. Smith for *Polyanthus Duke of Wellington*, a beautiful velvety-black, and rich seedling variety, with yellow centre, and edged with gold; also to Mr. Clarke, Twickenham, for *Cyclamen Brilliant*, a miniature variety of compact growth, and having short-stalked marbled leaves, the flowers being of a rich velvety-magenta or crimson colour. Among *Cyclamens* this is, without exception, the greatest improvement in habit of plant and colour of flower which has been made of late years. Among other new plants were several seedling *Amaryllids* from Mr. B. S. Williams, several curious *Orchidaceous* plants from Messrs. Veitch, also a good plant of *Croton Macarthurii*, and *C. Hawkeri*, a species from the South Sea Islands, of dwarf habit, and having narrow, pointed leaves of a rich creamy colour edged with olive-green. Mr. James sent excellent cut blooms of *Cinerarias*, and Messrs. Cutbush & Son sent plants of a *Dracæna* (species) excellent for decorative purposes.

**Roses.**—Of these, considering the season, there was a good display. Messrs. Veitch & Sons had an extensive group of well-grown plants, among which were noticeable the delicate bluish *Madame Liebaud*, *Madame Lacharme*, the pure white *Cocquette de Blanches*, associating effectively with the brilliant *Monsieur Boncenne*, Dr. Andry, and well-flowered specimens of the crimson *Duke of Edinburgh* and the deep rosy-pink *Anne Alexieff*. In the class for six forced *Roses* Mr. Charles Turner, of Slough, was the only exhibitor. The plants consisted of well-grown specimens beautifully in flower; the kinds were *Madame Victor Verdier*, *La France*, *Madame Lacharme*, *Duke of Edinburgh*, *Edward Morse*, and a magnificently-flowered specimen of *Souvenir d'un Ami*. This was altogether an interesting collection, and showed which were the best kinds of *Roses* for early forcing.

**Stove and Greenhouse Plants.**—In the class for twelve stove and greenhouse plants Mr. G. Wheeler, gardener to S. F. H. Goldsmid, Bart., Regent's Park, had the best collection which consisted of neat,

shapely, and well-flowered plants of *Clorodendron Balfouri*, *Erica affinis*, *Eriostemon densiflorum* and *E. pulchellum*. These associated effectively with magnificent-flowered specimens of *Imantophyllum miniatum*, the brilliant-flowered *Azalea Stella*, *Anthurium Scherzerianum*, and several *Heaths*. Mr. Roberts, gardener to W. J. Perry, Esq., Fulham, had a group in which were finely-flowered plants of *Dendrobium nobile* and *Chorozema Chandleri elegans*.

**Orchids.**—Only one collection of these was shown, and this came from Mr. Heins, gardener to F. A. Philbrick, Esq., and to which an extra prize was awarded. Noticeable in this group was a large plant of *Cattleya citrina*, growing on virgin cork placed on the top of a stump of *Tree Fern* to a standard. It bore about a dozen large, golden, waxy blossoms, which, on account of their drooping character, were, grown in the way described, seen to the best advantage. A plant of *Dendrobium crassinode* bore six pseudo-bulbs clothed with richly-coloured blossoms. With these were associated well-flowered plants of *Dendrobium litiflorum*, D. Freemani, several good *Phalænopsis*, *Odontoglossum triumphantis*, O. Andersonianum, the curiously-spotted *O. maculatum superbum*, and a plant of *O. cirrhosum* bearing a profusion of sweetly-scented, beautifully-spotted blossoms, and a pair of *Sophranitis grandiflora*.

**Azaleas.**—Of these there was a good display, the best in the nurserymen's class coming from Mr. Charles Turner, who had small but profusely-flowered plants of *Queen Victoria*, a kind with large white flowers conspicuously striped with bright purple; *Juliette*, a semi-double flower of a brilliant rose-crimson colour; and the best of purple, *Duc de Nassau*, together with other good kinds. In the amateur's class the best plants came from Mr. Ratty, gardener to R. Thornton, Esq., who had standard and bush-trained specimens of well-known kinds. Mr. James, Isleworth, had also a group of well-flowered plants, the best white kind being *Ivryana*, and the best coloured kind *Duchesse Adelaide de Nassau*.

**Hyacinths and Tulips.**—These occupied a narrow stage the whole length of the corridor, and the blooms throughout being of fair average quality, they made a very attractive display. The best and most extensive collections of *Hyacinths* came from Messrs. Veitch & Sons, Messrs. Carter & Co., and Messrs. Cutbush & Son, and, although not shown in competition, an extra prize in all cases was awarded. In the first collection the best flowers were King of the Blues, Mont Blanc, Charles Dickens (blue and white), yellow Bird of Paradise, and a bright crimson kind named *Vuurbaak*. In Messrs. Carter's group were similar kinds; also, *Lord Derby*, lavender; H. M. Stanley, dark blue; *Lord Macaulay*, pink; and a large white-flowered kind, named *Lord Shaftesbury*. The best twelve plants in the amateur's class came from Mr. Douglas, who had well-grown plants, with symmetrical, well-coloured blossoms of the best kinds. Mr. Morman, gardener to the Misses Christy, Kingston-on-Thames, had also good plants furnished with dense heads of blossoms, among which were especially noticeable *La Grandesse*, purple white; *Grandour*, lavender; and *White Bird of Paradise*, rosy pink. In the class for plants with a number of flower-spikes, Mr. Douglas was again first with finely-flowered plants, and Mr. Morman was second. In the nurserymen's class, Messrs. Cutbush & Son had the best collections, the next best coming from Mr. Hill, Alfred Street, Bow, and Messrs. Osborn & Sons, Fulham. The best collection of *Tulips* came from Messrs. Cutbush & Son and Mr. Morman. Among the best kinds exhibited were the *White Pottshaker*, *Vermilion Brilliant*, *Yellow Prince*, and the purple *Van-deer-neer*. Well-flowered groups of *Narcissi* came from Mr. Douglas and Messrs. Osborn & Sons.

**Cinerarias.**—Extra prizes were awarded to collections of *Cinerarias* from Mr. James and Mr. Lovesley, Isleworth; also to Mr. Wiggins, Waverley Nursery, High Street, Tottenham. Mr. James' group consisted of dwarf, bushy plants, bearing large, self-coloured, and exquisitely-edged flowers. Mr. Lovesley's were small plants grown in 6-in. pots, and were not more than 6 in. high, and bearing large heads of small, but beautiful and variously-coloured blossoms. Mr. Wiggins' strain consisted of edged, named kinds, among which were some very good blooms, but others were very loose and ragged in the petals.

**Cyclamens.**—Of these, there were several good groups, all of which were of a meritorious description. The best twelve plants came from Mr. H. B. Smith, Ealing Dean Nursery, Ealing, who had well-grown plants furnished with large, glossy, green foliage, and masses of large, pure white, purple, rose, and tinted blossoms, many of them delicately perfumed. The second prize was awarded to Mr. Edmunds, Hayes Nursery, Hayes, whose plants were good, but had smaller flowers than the preceding group. The best six plants came from Mr. James, gardener to W. F. Wilson, Esq., Isleworth; they were dwarf, clean, and well-flowered. An extra prize was awarded to Mr. R. Clarke, Twickenham, for a group of *Cyclamen* of the most meritorious description; the flowers were large, well formed, and varied in colour, and the leafage was elegantly marbled and mottled; also to Mr. H. B. Smith, Ealing, and Mr. Lovesley, Isleworth.

**Forced Herbaceous Plants.**—The best collection of these came from Mr. Roberts, and comprised neat plants of the beautiful blue-flowered *Symphytum capenseum*, *Dielytra spectabilis*, *Spizæa*, and a well-flowered plant of *Primula cortusoides*. Mr. Wheeler sent plants of *Polygonatum multiflorum* furnished with long, graceful racemes, and a group of *Primulas* flowers, a good plant of *Amaryllis macrantha*, giant  *Lily of the Valley*, and *Gloxinias*. Six *Primulas* were shown by Mr. Roberts, the best kinds being the white *P. nivalis* and *P. acialis rubra*.

**Miscellaneous Plants.**—An extra prize was deservingly awarded to Mr. B. S. Williams, of Holloway, for a collection of *Amaryllids*. It

contained many of the newest and best kinds, embracing the most brilliant self-coloured and striped flowers. These were effectively associated with Palms, Dracænas, the light and elegant Casuarina samaritana, so useful for table decoration; also Cupania filicifolia and Baucaura recurvata. A similar award was also made to Mr. H. Little, Hallington Place, Usbridge, for a group of Amaryllids, also for a group of small plants of Indian Azaleas, which, on account of their bright and varied colours, were much admired. Excellent specimens of Dentzia gracilis came from Mr. J. Douglas, gardener to P. Whitbourne, Esq., Ilford. They were 3 ft. high and nearly as far through, and represented a profusion of graceful garlands of snowy-white blossoms. Mr. James had smaller but well-grown, profusely-flowered plants. An extra prize was awarded to Messrs. James Carter & Co. for dwarf, well-flowered plants of *Dielstra spectabilis*. Good potsful of Lily of the Valley came from Messrs. Cutbush & Sons, Mr. Douglas, and Mr. James. An extra prize was awarded to Mr. Ratty for a well-grown plant of *Imantophyllum minutum*, bearing six massive heads of brilliantly-coloured blossoms; also to Mr. Wm. Paul for a display of cut blooms of *Camellias*, including the best kinds, mention of which has been before made in THE GARDEN. Of Chinese Primulas there were three collections, the best coming from Mr. James, and consisted of kinds with well-coloured, imbricated blossoms. Mr. Edmunds had a group in which were plants bearing flowers of a bright scarlet colour, and double kinds of a delicate mauve, very valuable for bouquets. A good collection of hardy bulbous plants came from Mr. Roberts, consisting of *Scillas*, *Græpe Hyacinths*, *Dog's-tooth Violets*, *Lachenals*, and *Fritteleins*, and Messrs. Gelsom & Sons sent a group of *Crocuses* in pots, for which a second prize was awarded.

At a recent meeting of this Society a fine bunch of Plantain fruit, 50 lb. in weight, grown in the Society's garden, was exhibited, and also several interesting medicinal plants in flower. The secretary reported the receipt of several donations of plants and seeds, and of £100 from Earl Dudley to the Conservatory Building Fund.

### THE WEATHER AND THE FRUIT CROPS.

This year February failed to "fill the dyke either with rain or snow," and in this part of the kingdom the weather that month from beginning to end was of such a mild, sunny, pleasant, and, I may add, unseasonable character as has seldom occurred within the memory of most people. Yet wital, the majority of plants that usually begin to move under the influence of the first returning sun's warmth were more than ordinarily backward until the extreme end of the month. A few of the first days in the present month were so sunny and warm as to feel more like May than March, the effect of which on vegetation was almost magical. Many things advanced with a rapidity such as we seldom experience in this country. The bloom of Peaches and Nectarines on open walls made as much progress in one week as is usually observable in three. After this the wind veered round to the north, where, with little alteration, it has been ever since. We had then over a fortnight of cold, unless weather, the dust blowing almost daily in clouds, much more seasonable than agreeable, with frequent frosts. On the night of Thursday, 14th inst., we had 12° of frost; on the 15th, 9°; and during the night of the 16th, 13°. I cannot hear that on the south side of London, even in the valley of the Thames, there was more than 8° or 9° on any of the above dates. This is remarkable, for high and dry as we are here on the north side, when frost occurs we usually get 3° or 4° less than on the south. On the night of the 23rd there was 12°; the snow shower of the 24th inst. was followed by 13° in the night, and 8° the night after. Peaches and Nectarines on walls are in full bloom, and these, as well as Apricots, have the bloom injured more or less, but to what extent, especially with the former, it is impossible to say. The air and soil were so unusually dry, has, no doubt, to some extent saved them, or none might have been expected to escape. In most places that I have seen through the southern division of the kingdom there is a profusion of Apple, Pear, Plum, and Cherry bloom, which fortunately, with the exception of a very few varieties of Plums and Pears, has been kept back by the dull, cold weather that prevailed during the greater part of the month, and will not expand before near the middle of April. During the continuance of unseasonably mild weather, which prevails to the last fortnight we experienced, I noticed one unerring sign that winter was not over, viz., the presence of considerable numbers of fieldfares; these birds never make any mistake, and so long as they remain we have not done with hard weather. T. BARNES.

Southgate.

**Bleeding in Vines.**—"J. S. W.," in his excellent article on this subject (see p. 253), omits one specific which I have found most successful in stopping bleeding, viz., ordinary sealing-wax. We lately planted out six Vines in a small house; they were cut back at the time of planting. Unfortunately, as the house was also required for bedding plants, a certain amount of fire-heat had to be kept up, with the inevitable result of copious bleeding. A hot iron, knotting, pitch, and quick-drying varnish were all tried without avail. As

in every case the bleeding recommenced before the various applications had time to dry, as a last resource I tried sealing-wax, first drying the cut with a hot iron, and then applying the wax with a taper. This set at once, and we have not been troubled with bleeding since.—C. H. W.

**Effects of the Frost on Spring Flowers.**—The late severe frosts coming after so long a spell of mild weather have done less harm to spring flowers than might have been expected. With Primroses it has been shown that very little protection, such as that of an overhanging plant, has prevented all damage. Snug nooks in the rockwork have proved their value. Polyanthuses and Primroses of the altaica type have been most touched. A small collection of Mr. Barr's beautiful and rare species and varieties of *Daffodils* in the corner of our rock garden seemed to be cut hard, their heavy leaves and flower-stems being bent to the ground; they have, however, recovered. A large clump of *Aubrietia purpurea*, with its pretty flowers peeping out of the snow, made one realise the beauty of the early Alpine flowers. Two plants which have not before bloomed with us (*Saxifraga virginensis*, with its pretty little white flowers, and *Pulmonaria virginica*, with its blue buds) seem unhurt.—GEORGE F. WILSON, *Heatherbank, Weybridge*.

### ANSWERS TO CORRESPONDENTS.

**Ivy on Trees.**—Does Ivy injure timber trees either young or full grown? and is it advisable to destroy it to any and to what extent?—J. M. [Ivy is generally thought not to injure old trees. When their bark is thick they do not feel its embrace like young ones. It is worth encouraging on some trees for the picturesque effect which it produces, and if too luxuriant it can be kept under by pruning the leading shoots now and then. On young trees Ivy is injurious, as it keeps off the dampness and air required for the swelling of their bark, and in their case it ought, therefore, not to be encouraged to any extent.—W. T.]

**Raising Privet.**—I want to rear some common Privet to make a hedge. I have frequently tried cuttings put in in spring 5in, or 6in, deep, but very few of them have grown. At what time of the year should Privet be set?—H. O. G. [The best time for planting Privet cuttings in order to form a hedge is in September or October, even if the foliage be on them. The cuttings should be from 1 ft. to 15 in. in height, so as to give them when planted a good hold of the ground. Privet is not particular as to soil, although light ground suits it best. Cuttings might easily be obtained from places where Privet is grown in quantity.—W. T.]

**Green Damp on Stone Seats.**—By what means can this be removed from a stone seat under a Yew tree—washing is of little or no use?—G. S. [Try boiled linseed oil, which must be rubbed over the stone with a hard brush; after a coat or two of oil the green damp will, as a rule, disappear.—W. T.]

**Name of Plants.**—~~TERRERIN~~—The name of your fungus is *Peziza coccoinea*. It is not uncommon about, and upon sticks (especially Hazel), in some places at this time of the year.—W. G. S.—B. C.—The plant you send is a species of *Oxalis* with pretty canary yellow flowers, which grows very freely as a naturalised plant in warm countries. We fancy we have seen it abundant among the Grass in the Naples Botanic Garden. It is probably *O. cernua*.

**Celery for Exhibition in July.**—Can you inform me which is the best and quickest way of growing Celery for exhibition in July, and also the best manner to use as a stimulant, and the best variety to plant as regards size and earliness?—SUSANNE. [If you require your Celery in the forthcoming July you must sow at once in shallow pans of light rich soil, well drained, placed in a warm house or plunged in a manure frame; place a sheet of glass over the pan, and on the lay Moss or leaves to shade the soil and keep it moist. Always water with tepid water, and as soon as the plants show themselves remove the Moss and, a day or two after, also the glass. Gradually inure the plants to the light and air, and as soon as they are large enough to handle, prick them out carefully into other pans or boxes, 4 in. or 5 in. apart, or into a warm bed of light soil in a frame. When well established let them be as near the glass as possible, keep them well watered, and occasionally stir the soil between the plants and sprinkle a little soot on the surface, afterwards watering it in. A frame which has been used for early Potatoes or a similar purpose will answer well in which to finally put out the plants. Use turfy loam, as free from worms as possible, and with it mix plenty of manure, which should be prepared at once by adding to every barrowload about 1 lb. of salt and a shovelful of soot; turn frequently until wanted and then mix it thoroughly with the soil, which should be about 1 ft. in depth. The after treatment consists in giving plenty of water and air on fine days. Raise the frame when the plants get too near the glass, and in June it may be removed altogether. Earth up with dry soil free from manure, and syringe frequently overhead. The last earthing should be done about three weeks before the Celery is wanted for use. White Celery is the earliest, but smaller than the red; the chief point, however, to observe is to get solid, well-hatched heads rather than large woolly ones. Avoid checks, or the plants will run to seed. By strict attention you may obtain fairly good Celery in July, but the seed ought to have been sown in February.—S.]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

### FUCHSIAS ON WALLS.

MR. MITCHELL'S remarks, together with the striking illustration of a Fuchsia on a wall (see p. 283), suggest the question, Why Fuchsias on walls are so rare? All the older varieties, such as *Riccartoni*, *globosa*, *macrantha*, and others, were almost hardy on walls in Scotland some thirty years ago; they are not likely to have become less so, and several most useful sorts for open air culture among more modern varieties, such as *Corallina*, *Madame Cornelliessen*, and others, seem about as hardy as the old *Riccartoni*. Some of the finest specimens of Fuchsia in the open air which I have ever seen were on a wall at Bellwood House, the residence of Mr. Turnbull, of the Perth Nurseries. They were from 10 ft. to 15 ft. high, if I remember rightly, and were simply magnificent. The position was somewhat warm and sheltered, but hardly more so than thousands of sites that might be chosen for Fuchsias in numbers of gardens in different parts of the country. Then it is so easy in less favoured climates to afford Fuchsias on walls a little protection in winter when needful; a bunch of Wheat straw tied over them, the whole being enclosed under a common mat, would carry the majority of Fuchsias safely through our winters; being deciduous, this treatment would suit them well. When uncovered all that is needful would be the pruning off any superfluous or dead shoots. The mass of the plant would pass thus through most of our winters in safety, and make a free growth and bloom profusely the following season. Fuchsias live long on walls, and the longer they stand the more profusely, as a rule, they bloom, and this property renders them peculiarly well adapted for the clothing of walls. No plant, indeed, is more accommodating in its habits than the Fuchsia. It may be cut or trained into any shape or form; run up into a stately pillar, displayed over a panel, or, best of all, allowed to ramble freely over and densely clothe a wall as a huge bush or half-standard tree backed up against it. Planted in a well-drained border of medium rather than rich soil, the wood of many varieties of Fuchsias get sufficiently hardened before winter to bear a considerable amount of frost with impunity.

There is another capital mode of growing Fuchsias against rather than on walls. For this mode of culture the soil can hardly be too rich, nor the summer treatment too liberal. This method is admirably adapted for hiding low walls and fences with a rich screen of summer beauty. If Fuchsias be simply treated as *Pentstemons*, *Phloxes*, *Asters*, or other herbaceous plants, it is as well not to cut the shoots back till the spring; or if pruned back in autumn, a little Cocoa-nut fibre refuse, ashes, sawdust, or a mulching of rough manure should be spread over the stools to exclude the severe frosts of winter. Such plants break or grow with extraordinary vigour. The shoots may be either thinned and trained vertically up the wall or in any other direction required, or a sort of forest of Fuchsias may be tied back to it by a thick cord passing along in front of them. By the use of manure water and other means the annual shoots of Fuchsias treated thus may be made to grow from 3 ft. to 6 ft. or more in the summer months, and flower freely from base to summit. Few sights in a garden are equal in grace and beauty to a Fuchsia wall well and fully clothed.

Of late years, too, when so much has been said and written on the flat monotony of the much-abused bedding-out style of flower gardening, it is surprising that standard Fuchsias have not been more used than they have been. The Fuchsia is quite at home as a standard, and any variety may be grown into that form with a little care and skill in the formation and training of the plants. The flowers are never seen to such advantage as when they droop and weep down from a head considerably elevated from the ground. If half the care and labour bestowed in the growing and forming of standard *Pelargoniums* were devoted to Fuchsias, the effect

would be far more rich and congruous. Then there are some noble species of the Fuchsia, such as the *corymbiflora*, that must be grown as standards to have their beauty fully seen. The racemes of flowers and the flower-tubes themselves are so long that they only look their best when raised on clear stems of 4 ft., 6 ft., or more in length. This species, too, now so seldom seen, is one of the very best for outdoor culture. Thirty or more years ago I used to bed out Fuchsia *corymbiflora* and *fulgens* in East Suffolk, and found them both the most valuable of all flowers for the decoration of large silver epergnes and vases for the dinner-table. But, though the *corymbiflora* flowered freely in beds of poor soil, the corymbs of bloom were too long for the dwarf plants, as they used to whip the ground in windy weather, and so got soiled. The foliage alone of this and a few other species makes them fit to associate with so-called sub-tropical plants, whilst the noble flowers would add a peculiar richness and grace to groups of *Dracænas*, *Solanums*, *Cannas*, or *Beet*.

Standards of Fuchsia *corymbiflora* used to form striking features at Shrubland many years ago, when Mr. Donald Beaton was in the hey-day of his strength and success. A row of these plants flanked the walks in the looking-glass garden, and the effect was as pleasing as it was at that time unique. The walk terminated in a small summer house, the notable feature of which was a picture of a lovely landscape in the centre of the wall. In front, as the visitor advanced the illusion dissolved, and he found himself entranced before an open frame, commanding the richest parts of the garden, the park beyond, and the woods and fields in the far distance, with the river rippling, which becomes the Orwell, winding like a large silver thread through the verdant green meadows that it enriches and adorns. The looking-glass garden is, I believe, still at Shrubland, but I fear the noble specimens of the Fuchsia *corymbiflora* that used to form its richest embellishment have disappeared. If not, I have no doubt that Mr. Blair, the present gardener at Shrubland, will tell us something concerning them. Mr. Beaton, my first friend in East Anglia, and one of the truest and kindest that ever man had, was marvellously proud of those Fuchsias, and took pains to describe their origin and treatment to me, though just then his enthusiasm was at white heat in pursuit of a white, scarlet, and a blue *Pelargonium*. The finest specimens were in 12-in. pots. About October 1 the best of them were placed in the conservatory for winter flowering. The others, and those not in pots, were closely stowed away in a dark, Orangery sort of place, among huge *Camellias*, *Rhododendrons*, &c., for the winter. About April they were overhauled, pruned, if necessary, and started for a time in one of the houses, and reinstated in their quarters in the borders in the looking-glass garden about the end of May. For bedding out a similar course of winter storing was adopted. Old plants of these larger species flower more freely than cuttings, and in choosing cuttings rather weak shoots should be selected, and rooted early in the autumn. Fuchsia *fulgens*, being bulbous-rooted, may be taken annually, and stored and treated like *Marvel* of Peru, *Salvia patens*, or *Dahlias*. The hardy red Fuchsias in beds or borders, however, do not need lifting; they may be safely left in the open air for the winter with such protection as we have indicated, or without, if their tops are left on till the spring. It is rare, indeed, that winter frosts will destroy the wood of well-ripened plants of Fuchsia to the ground, and should it do so it is better, perhaps, for next year's crop of shoots, for the Fuchsia almost invariably breaks the strongest just at the ground line or around the collar. The whole of our greenhouse varieties, as far as I am aware, might be used for bedding out with less rather than more attention than is now bestowed on *Pelargoniums*. In many positions, as in raised beds, borders, baskets, and in vases, what a welcome change and freshness would be produced by the use of Fuchsias! To those who may doubt these thriving and flowering in the open air, I would add that they need have no fear on that head. We generally grow most of our late specimen Fuchsias in the open air from June to the middle or end of September, and find the foliage finer, the wood stronger and more short-jointed, and the flowers far more numerous as the result of this hardy treatment. Large spare plants, from 6 ft. to 8 ft. high, have also been frequently planted out in beds or borders, and have

done well. Therefore, to all in search of a new sensation or a more graceful form of beauty in their flower gardens, we would earnestly give the advice to try Fuchsias on their walls, in their beds and borders, as standards, and as dwarf single plants, or in masses.

D. T. FISK.

### THE FIGHT FOR FRUIT.

THIS continues, and becomes more severe. March indeed went out, like an angry lion, in a blinding snow-storm, succeeded by a tremendous frost, registered in such widely differing degrees as from 10° to 20°. Coming so suddenly on the heels of the snow probably added to its intensity. The ground this morning (April 1) was as iron, like what we find it in December. In low-lying situations the frost was so severe that I fear little or no fruit can have escaped. Even the hardest plants, such as Violets, have their leaves blackened, as if a current of fire or of hot water had passed over them. Dwarf Roses have every young shoot killed or browned. Standards have suffered much, though not quite so severely. Marshal Niel, showing Roses in the open air, has got so severely bitten that the myriad trusses of Banksian Roses droop, as if for support and warmth, on to the branches. Common *Dafodils* and *Narcissus* are lying all over the ground—a confused mixture of leaves and flowers. Common *Primroses*, and even the *Tusilage* fragrans, are also flattened or blackened; while the lovely *Myosotis disitiflora*, first blushed with a tinge of red colour, and then bent to the earth in sheer despair. Most of these will rise again with a change of weather; not so, however, the fruit blossoms—stabbed through the heart of their pistils and ovaries with the cruel black darts of the frost. These stabs in the cold and the dark are absolutely fatal. No refreshing dew or soft summer-like rain, nor bright warm sunshine can bring back the dead flowers to life. These but make the death more apparent; hence, I always contend for spring protection. Broadly stated, every unprotected Apricot, Peach, and Nectarine bloom has perished within the last ten days. It is equally certain that protection from without, or a very small consumption of fuel in heated walls, would have saved at least a crop out of all those myriads of blossoms frozen to death. I cannot find a single exposed bloom alive. Apricots are frozen worst before the flowers were even open, and closed Peach buds cannot resist such tremendous frosts and winds as these, so these, too, are gone. Many under copings, &c., look suspicious, but I still hope a crop is left on the trees best protected. Forward Pears also seem dead; the embryo fruit behind the unopened flowers are frozen through. Some of the Apples also look suspicious; it is too soon to be sure of them yet. Those protected with canopies of branches look sound and fresh, though they were the forwardest. Gooseberries on the summits of the branches are gone; but those, rather thick, on espaliers seem to have escaped better, the upper branches sheltering the under ones a great deal. Currants are less forward, and, so far, do not look black. Nuts seem much injured, as do forward Plums. Cherries seem safe, but appearances are very deceptive. Apricots, for example, turn black at once, and show that the fruits are destroyed. Not so Peaches; the petals look as pink and beautiful as ever, though the pistil and ovary are quite dead. A further and more minute examination to-day (April 2) shows very few blossoms, even under the threefold protection of wooden or glass copings, double nets, boughs, &c. The weather promises a change at last, but the greater part of the crops of wall fruits is ruined.

D. T. FISK.

— Tiffany I consider the cheapest, lightest, and most effective material for protecting wall trees. Have light wooden frames made strong enough to bear the stretching required; as to height, the tree must be the guide. The frames should be about 5 ft. in width. Stretch and nail the tiffany on them, and they are fit for use. Lean them against the wall, leaving room enough to walk behind them. Fasten them to the wall with cord and nails. They need not be removed until all danger is over, and they shade the trees just enough to prevent them getting too forward.—F. CANNELL, *Feltthorpe*.

**Fruit Prospects in Cleveland.**—After ten days of continued hard frost and snow, fruit trees and bushes present a very frost-bitten appearance, and we hardly expect the fruit crop to be better than last season. About Yarm—a fine, low-lying, sheltered spot—where fruit for market purposes has been grown from a very early date, the trees look seriously injured, Pears specially. At Great Ayton, where Apricots are cultivated on almost every house wall, the crop will this year be a failure. The latent buds of Gooseberries may yet produce a light crop, if the weather become favourable. This season will test the reputed hardness of the Gooseberry called *Industry*, which is so favourably spoken of about Newcastle. It would be doing useful service if growers of this variety would report on

this season, Gooseberries forming, as they do, the most important part of the fruit crop in the north of England.—C. M'D.

**Fruit Crops in Devonshire.**—Peaches and Nectarines have been in full bloom here for these three weeks past, and appear to be setting freely. The trees, too, are making healthy growth. Apricots are also well set. My plan is to protect with double ordinary fish netting, but in addition this year I have used large, flat branches of common Laurel, grown under the shade of trees, and the bloom seems quite uninjured. The trees were quite protected by the netting and branches from a heavy fall of snow which we had during the morning of March 29. The whole of the Peaches and Nectarines here are on an east wall, and some of our finest trees are fully forty years old. The netting and branches are supported on Larch poles, placed about 6 ft. apart, and tied together on three pieces of tar cord run the entire length, which keeps both netting and branches off the wall.—JOHN GARLAND, *Killerton, Exeter*.

**Limes in Montserrat.**—A pamphlet, entitled "The Island of Montserrat," just published, contains much interesting and valuable information respecting the cultivation of the Lime (*Citrus Limetta*). According to a Blue Book for 1875, the little island of Montserrat has been raised during the last fifteen years from a very low point of depression to a degree of substantial prosperity mainly through the efforts of Sturge's Montserrat Company. The Lime tree plantations owned by this company now cover about 600 acres, and contain 120,000 trees. These are generally planted about 15 ft. apart, and the highroad passes between them for a distance of two miles. We are told that no more beautiful sight can be seen than these orchards when the trees are laden with their bright fruit, and at the same time the air is pervaded by the luscious fragrance of the blossoms. The leaves, even, are so highly fragrant, that they are commonly used throughout the West Indies to perfume the water in the finger-glasses at dessert. About seven years elapse between the sowing of the seed and the tree arriving at full bearing. Regular pruning is required, and the plants must be kept clear of those mischievous parasites, *Mistletoe* and *Dodders*. The juice from the finest fruits—which are first sliced by water-power, and afterwards squeezed until all the juice is expressed—is sent to England, where it is used in the manufacture of various Lime-juice products; that from the inferior fruits is converted into citric acid. Graphic descriptions of the glorious scenery and vegetation are given, and some highly-coloured chromos help to convey a good idea of the beauty of the Lime orchards.

**Cucumber Growing.**—What is the best way of growing Cucumbers under glass, heated by hot-water pipes, beginning with directions for sowing the seed, heat required, soil, ventilation, watering, the cure or prevention of insect enemies, the room each plant should have, and the distance the trellis should be from the glass?—**QUEERIST**. [This is a good time to commence the cultivation of Cucumbers successfully, as every day we expect more sun-heat and light. The seed ought to be sown in pots or pans, and when of sufficient strength the young plants should be potted singly in small pots, and kept in a temperature of from 60° to 65°; the soil used for potting them off, and for the border when planting them out, should be of a light loamy character enriched with some well-rotted manure. When planting them out they may be about 2 ft. apart, and the trellis should be 15 in. from the glass, the plants being trained on the inside of the trellis. Sufficient ventilation must be given on warm sunny days, from 75° to 80° being the maximum, and if a slight shading of tiffany be put over the pit on very warm weather it will keep the plants from flagging. They must be syringed frequently to keep red spider in check; and if thrips make their appearance a little Tobacco water or soot water may be syringed over them with safety to keep them under. Some of the smaller varieties of Cucumber, where quantities are wanted, are the best for cooking or eating. Bollisson's Telegraph and Master's Prolific are excellent kinds. Where long show varieties are desired, Tender and True, Blue Gown, and Daniel's Duke of Edinburgh can be recommended.—W. T.

**Apricot Bloom.**—"A. D." (see p. 213) wishes to know the date on which the first Apricot blooms expanded. Our first blooms were open on March 6; the flowers seem unusually large and fine this spring. Our trees are on a south-east wall and unprotected; those on other positions are opening fast. On first Peach blossoms opened on the 12th, on an east wall without protection. Plums and Pears will soon be opening, and there seems no lack of bloom buds G. NOAKES, *Mountfield Court, Sussex*.

**Destroying Crickets.**—My Cucumber house and one of my orchard houses, both heated by hot-water pipes, are infested with crickets. Can you recommend an effectual means for destroying them? Last year they ruined a large number of my Peaches; and, as I have a promising crop for this year, I am anxious to know of some method by which this noisy and mischievous little enemy may be destroyed.—G. L. M. [Try Chase's Beech's Paste.—S.]

## NOTES OF THE WEEK.

**Violet Belle de Chatenay.**—Flowers of this fine new double Violet have been sent to us by Messrs. Lee, of Hammersmith, and very handsome they are. They are nearly as large as a very Daisy, white, here and there slightly tinted with violet, and very fragrant. A good woodcut illustration of this Violet is given at page 117 of the current year's volume.

**A New Pavnionia.**—The best Pavnionia which we have yet seen is now in bloom in Mr. Bull's nursery, at Chelsea. In habit it is much stronger than *P. Wiota*, and its flowers are considerably larger and brighter than those of that species. When better known it will doubtless be appreciated as a winter decorative plant.

**New Gardenia.**—A new Gardenia, named *G. Kalbreyeri* is described and figured in the last number of the "Journal of Botany" by Mr. Hiern. It has fragrant Lily-shaped, yellowish, flowers spotted with brown, and is stated to form a shrub some 12 ft. or 15 ft. in height. It was collected by Kalbreyer at Old Calabar.

**Blandfordia Cunninghamii.**—This, one of the best of the Blandfordias for greenhouse decoration, is named *G. Cunninghamii* after the London nurseries. It is of easy culture, and established plants of it never fail to produce stout flower-spikes surmounted by whorls of orange-scarlet, bell-shaped blossoms, which are exceedingly effective when associated with small Ferns, Grasses, or Palms.

**Clerodendron Balfourii** on Low Walls.—Although this beautiful stove climber always succeeds best in a light sunny position, it will do fairly well when trained along low walls, such as are frequently found in glass structures. For such purposes it is best grown in pots, and if the shoots be well pruned in every year they will produce an abundance of large green leaves and a fair amount of blossom. We lately saw some thus grown in a London garden blooming freely.

**Daffodils at Tooting.**—Mr. Barr's collection of these hardy spring flowers is just now in full bloom, and well worth a visit by anyone interested in this class of plants. All the known species and scores of varieties are represented, and many of them are almost as beautiful as some of the choicest Orchids. In spring gardening the smaller and better kinds of Daffodils should everywhere play an important part.

**Amantophyllum miniatum.**—The improvements both as regards the habit and flowers of this useful decorative plant which have been made lately are very satisfactory. A variety named *superbum*, now flowering in Mr. Parker's nursery, shows a decided advance on the type. The leaves are broad and glossy green, and the flowers, which are well formed and of a brilliant orange-scarlet colour, are produced in trusses of from fifteen to twenty. Another advantage is that the flower-heads are borne on longer stalks than those of the type, and are, therefore, more effective.

**Iris reticulata in Pots.**—During snowy or wet weather the beauty of this valuable Iris, when grown in the open border, is often, to some extent, lost. It therefore requires to be either covered with a hand-light or potted, in order to preserve its flowers. We lately saw some in pots and pans, in a nursery near London, which had been taken from the open ground whilst in full bloom. Placed in a cool house, it keeps in perfect condition for several weeks, and it fills the whole house, with its scent. Either for the conservatory, or for placing in vases in rooms, this Iris might be used extensively; and if grown in pots or pans, plunged in a bed of ashes or soil during summer, and taken indoors when cold weather sets in, beautiful plants of it in full flower might be had much earlier in the year than they could be obtained in the open air, and they would form fit associates for Cyclamens, Primulas, and similar decorative plants.

**Tree Peonies in the Conservatory.**—Plants of the Tree Peony forced into bloom now form attractive objects in the conservatory at Pine-apple Place. They consist chiefly of plants with a single stem 12 in. to 15 in. high, and surmounted by large heads of blossom. The variety grown is one named *P. arborea Elizabethae*; it bears very large heads of flowers, which are well-formed, very double, and of a bright rose-pink. In order to get Peonies to open their blossoms perfectly little heat must be given until the bloom-buds are visible, when they may be placed near the glass in a warm temperature with every prospect of success. On account of the attractive character and longevity of the blossoms of the Peony, they might be grown for conservatory decoration either in the shape of large or small plants to a much greater extent than is at present the case. Small plants, such as those just described, are among the best subjects for vases in rooms.

We are obliged to keep a considerable amount of correspondence concerning the opening of Kew Gardens until next week, owing to the report of the meeting at Ghent taking up so much space.

**Answers to Correspondents.**—Many of these we cannot insert till next week, owing to pressure of matter.

## NOTES FROM KEW.

**Hardy Herbaceous Plants.**—Owing to the unfavourable weather but few fresh outside flowers are to be seen. One of the prettiest of these is the Blood-root (*Sanguinaria canadensis*), from the United States and Canada; the white flowers are large and showy, and overtop the kidney-shaped leaves. The orange-coloured juice of the root-stock was formerly used by the American Indians to smear their bodies. A rare variety of the Hoop-petticoat *Narcissus* (*N. Bulbocodium Græzellei*), which, in a wild state, is confined to Spain, is also in flower. *N. moschatus* is another very charming Daffodil, with fine blossoms, the trumpet-shaped corona of which is primrose and the remaining portion white. *N. Tazetta* var. *Polyanthus* has a yellow corona, the rest of the flower being white. *N. poeticus* var. *radiiflorus* is an attractive variety of that beautiful section of the genus to which the name of Piesant's-eye is often given. *Fritillaria montana* is a dwarf Frilly from Algiers, having narrow, glaucous leaves and drooping, bell-shaped, dark purple, faintly-bell-shaped flowers; this rare species is, however, inferior in beauty to the Snake's-head (*F. Melegriæ*), of the moist meadows of some of our eastern and southern counties. *Corydalis solida* is a very pretty tuberous-rooted Fumitory, with glaucous leaves and purplish flowers this has naturalised itself in some localities in England.

**Greenhouse Plants.**—*Geranium anemoneifolium*, introduced nearly a century ago from Madeira, has long-stalked, deeply-lobed leaves and panicles of purplish flowers. *Palargonium ardens* var. *superbum* is a Cape species, with small, brilliantly-coloured flowers fiery-scarlet with black blotch. The orange-velvet flowers of *Imantophyllum miniatum* are exceedingly lovely; this beautiful Cape Amaryllid seems to succeed quite as well in the cool greenhouses as in the stove. *Acacia pulchella* is an Australian bush, with very small, pinnated leaves and globular heads of orange-yellow flowers, borne singly on stalks as long as, or even longer than, the leaves; this very desirable species is worthy of general cultivation. Another *Acacia*, *A. brachybotrya* var. *glaucophylla*, differs from the last-named almost as much as one species can differ from another of the same genus; it bears no true leaves; the flattened leaf-stalks which take their place are oval, very glaucous, and thickest on the branches; its blossoms are similar in colour to those of *A. pulchella*. *Brahysema melanopetalum* makes a rather straggling bush, but is remarkable for the colour of its petals, a genuine black being extremely rare in flowers. *Guodia lotoifolia* is a very pretty member of the Pea family from Australia, and one, moreover, of very easy cultivation; its neat, trefoil-like, light green leaves and racemes of conspicuous yellow flowers are very pleasing. *Coleonema album* is a handsome, dwarf, evergreen shrub from the Cape of Good Hope; its branches are closely set with small, linear, aromatic leaves and small, pure white, star-like flowers. *Diosma ericoideus* makes a charming pot plant, and is of very neat habit; the branches are thickly set with small, oiliated leaves, and terminated by umbellate heads of white blossoms. One of the very best and most showy of the Pimeleas is *P. spectabilis*, with large heads of creamy-white flowers. *Phytica gnidioides*, with flowers many times the size of those of *P. ericoideus* (mentioned in "Notes from Kew" some time ago) is well worth growing. *Amphicomme Emodi* is again in flower; it is a remarkably handsome *Bignoniaceae* plant, about 1 ft. in height, with pinnate leaves and racemes of large, pink, tubular flowers. *Rhododendron fulgens* has deep crimson flower-heads, and is one of the most striking and distinct of the Himalayan *Rhododendrons*.

**Stove Plants.**—A double variety of the West India *Amaryllis* *egnestria* has large, very beautiful, vermilion-scarlet flowers. This was introduced to English gardens at the commencement of the present century, but is rarely seen, in spite of its beauty. Genera *rosea* Raesi, one of Van Houtte's seedlings, is a most desirable kind of the Leopoldi type; it is of very dwarf habit, and its pink flowers are freely produced. *Soberberia mexicana* is another *Generad* with fine, showy, dark blue flowers. *Jonesia Asoca*, or *Saraca indica*, as it is also called, the *Ushoka* of the Bengalese, is commonly planted throughout India and the Mauritius for the beauty of its foliage and flowers; the latter are produced in great abundance, and bear a considerable resemblance, both in size and colour, to some of the scarlet *Ixoras*; the only drawback is that it requires more room than can generally be afforded it in any but large establishments. *Clavija macrophylla*, from tropical South America, has an upright, unbranched stem, crowned with a fine head of large, leathery, dark green leaves. From the old wood, for some distance below the crown, spring large numbers of racemes of orange-yellow flowers.

**Orchids.**—*Dendrobium crystallinum* is a handsome species from Burmah; it has narrow, white sepals, and broader, purplish-tipped petals; the apex of the large lip is also purplish, the whole of its base yellow. *D. superbum* var. *gigantum* is a free-flowering variety, bearing very large, disagreeably-scented flowers, the sepals and petals

of which are rosy-purple, and the base of the large, trumpet-shaped lip several shades deeper in colour. *D. Parisii* was introduced from Moulmein some fifteen or sixteen years ago by Messrs. Low. Although it bears a certain resemblance to *D. nobile*, it is quite distinct from that species. Flowers spring from nearly the whole length of the stiff, leafless branches; the sepals are a beautiful light rose colour; the petals are broader but of the same colour, while the nearly round, downy lip is richly marked with purple. *Odontoglossum roseum*, with its delicate, deep rose-coloured flowers, is a most charming little Orchid. *Restrepia elegans*, found in a wild state in Caracaca on the Mosay bark of trees, at elevations of from 5000 ft. to 6000 ft., is similar to *R. antennifera*; the general ground colour is yellow, thickly spotted with purple. *Oncidium Papilio* and *O. Kramerianum* are two nearly allied species, the first from Trinidad and Venezuela, the other from Peru; both have very singular flowers, borne singly on the ends of very long, slender stalks; the upper sepal and petals are long and narrow, the lateral sepals are shorter and much broader. From the appearance presented by these strange, yellow and reddish-brown flowers, the name of Butterfly plant has been applied to the two species.—†.

### HOW TO GET RID OF SLUGS.

THE discussion as to how to get rid of slugs has begun very well, and I hope it will be continued. The plan suggested (see p. 273) is Mr. Carson's; not mine. I have sent him a copy of THE GARDEN that he may answer any remarks made in it if he pleases. It shows well the good of free public discussion, that one great authority looks upon the plan as "wonderfully like a good joke," and is followed by a greater authority with still wider experience, who says that it is substantially what he has long adopted, recommended, and found efficacious. I hope the ball will be kept rolling. In some gardens, especially where the plants are not much disturbed, slugs are a most serious nuisance, the more so that, owing to some mysterious law of Nature, our favourites seem almost always to be theirs.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

— I am pleased to see the interest that is taken in my remarks in reference to the destruction of slugs. I must, however, disclaim all merit or originality in the matter; but, having tried many plans, I have found this to be one of the best. "J. S. W." says truly "that if a night or two be missed they are just as bad as ever. The lime must reach the slug if it is to kill it." Now we found in practice for at least fifteen years that no plan got the lime so thoroughly amongst the crops, and that without injury to them, as the fine dust carried like a mist by the wind into all parts. The plan of keeping young ducks, mentioned by Mr. J. Smith, is an excellent one, and was practised by us for several years; but we found that the ducks had to be turned out long before they were fit for the table, owing to their laying down and tramping on plants and borders, and also stuffing themselves with green Peas and Strawberries instead of Sage and Onions. Mr. D. T. Fish is disposed to be severely facetious, but I accept it all in good part for the help which he gives me when he says "the lime can neither be too hot, too fine, nor too dry, and the mere quantity is of less moment than these qualities." With regard to the time required for the operation, he cannot have read my letter carefully, as I mentioned that two men walked round the paths; yet he says "that the lime has almost as strong a tendency to rise into the air as to fall to the ground." This very tendency allows the wind to carry a portion of it, perhaps, across an acre. In practice we found in large gardens, with few walks, that about 20 ft. apart was enough; if the operation was repeated in these gardens, they were gone over so as to cross the previous tracks, so that the quantity a man can plough in a day is no criterion as to the time required for this kind of work. Again, I mentioned that in 1849 we had no slugs in Victoria, and therefore those there now are not likely to be thinner in their skins than their parents introduced from Britain.

Mr. T. Barnes concluded with some excellent remarks when he says that "one good dressing, given at a well chosen time, will effect the destruction of more slugs than trapping and hand-picking daily for months. It is, however, necessary for those who try such work to be well acquainted with the habits of the slugs and the kind of weather that brings them out in the greatest numbers." He, however, seems to have missed the idea that I wished to convey, but may have failed to put as clearly as I might have done, viz., that this dusting can be put in practice with good effect without disfiguring a garden or injuring delicate plants, and he fails to consider that when a slug throws off its slimy jacket and the lime on its back, it cannot move from the spot without coming in contact with a fresh supply of lime on its more tender and vital parts underneath, thus insuring its destruction. I have often tried his plan of heavy liming, having used as much as forty bushels of unslaked lime at one dressing, and, as far as slugs were concerned, found more benefit from five bushels

used through bags. Let me add that the lime must be hot and caustic, not long slaked, as I have found, on moving a bag of lime that had remained from a previous season, several large slugs snugly sheltered under it, and at least 6 in. of similar inert lime underneath them. I can thus understand a failure at Drumlanrig, where "there was always a shed kept full for the purpose." While fresh from the kiln, the smallest quantity will kill; yet when it comes in contact with damp ground, or wet by a shower, though spread an inch thick it will soon be harmless.

One general remark to my critics and I have done; we always worked, as a sailor would say, to windward, beginning at the lee side of the garden and walking away from the dust, and when there was a steady breeze, the men could dispense with any covering over their clothes, the filling one or two shovelfuls into the bag being for them the most trying part. Should the arms get tired beating when the lightest of the lime is on, the bag may be shaken up and down. I trust that some of your readers will give the plan a fair trial, as it is easily put in practice and entails no more trouble than many other operations in the garden, such as watering, hoeing, digging, &c.—JOHN CARSON, *Clapham.*

— One of the best plans for clearing a garden of slugs, and one which I have adopted for many years, is to place small handfuls of fresh brewers' grains about the garden on a mild, damp evening, about six o'clock, and then when it is quite dark, or between nine and ten, to go round with a bucket of fresh lime and dust each heap, thereby killing great quantities. I have seen fifteen or twenty on a handful of grains, and they come to them from all directions.—JOHN GARLAND, *Killerton, Exeter.*

— Is it a fact that ducks do eat slugs? For some years I have encouraged them in the garden, but on several occasions I have caught and given slugs to them, which they invariably fail to see, while at the same time they eat and devour with the utmost avidity the smallest or largest worm. The idea that ducks are fond of and devour slugs is, I fear a delusion, for, notwithstanding their constant presence, if there be a special plant or plants—unless other means are taken to secure them—the slugs are pretty sure to devour them. Fresh slaked lime, applied at a proper time, makes short work of them, and is, in fact, the only certain remedy. It is, however, only on special nights, known alone to those who have noted the habits of the slug family, that they all seem to come out with one accord, and then, if the opportunity be seized, old and young, big and little, suffer alike. The only drawback to the use of lime is that it makes the place look so unsightly afterwards. I have mixed soot with it to take off its glaring whiteness, but think that thus diluted it is less effectual. An atom of fresh lime will literally drill a hole into a slug, but it requires at least two doses of soot to settle him. Cultivators resort to many devices to entice slugs from pot plants; it would be well to make these known.—T. SMITH, *Newry.*

— I am sure that Mr. Smith's suggestion (see p. 275) concerning ducks, as a cure for an evil that many of us have to contend against at this season of the year, is a very good one. It was mentioned to me by a friend twelve months ago, and since that time I have never been without a few of these birds, to do that work which all human efforts had failed to accomplish. My garden, till 1872, had been for many years very much neglected, allowing slugs and worms to increase enormously; and although, by means of perforated zinc and pot protectors, Cabbage leaves, and Barley chaff, I avert for the last few years preserved the rarer flowers, I never could exert the great destruction caused by these horrid pests upon the larger kind of herbaceous plants, and as Mr. Smith says, many of the green vegetables have been almost unfit for use. I am quite certain that the number of slugs is greatly diminished this spring. The patches of *Iris pumila*, which last year were almost all eaten off, are now swelling for bloom; and the plants of *Delphinium Belladonna* (to all appearance their favorite food) are almost untouched, and if I may not attribute this to the ducks, I do not know where to look for the cause of so happy a result. Sea gulls, if they can be procured, are far prettier, and I believe more effective than ducks, but I have never been able to keep them long enough to do much good.—E. F., *Swaffham.*

**Propagating *Nertera depressa*.**—Anyone wishing to get up a stock of this can readily do so in the following manner, viz.: Take the old plants, divide them into small portions, and then pot them off. They should be placed in heat for a time until started into growth, when all the points of the young shoots should be taken off and inserted in pans filled with one part leaf-mould and the remainder sand. When watered, a large square of glass or a bell-glass should be placed over the pan. Thus treated, they will take root in a few days, when they should be potted off into thumb-pots and again placed in heat until established, when they should be removed to a shelf in the greenhouse until the fruit is set.—T. W. S.

## THE FLOWER GARDEN.

### ANDROPOGON HALEPENSIS.

THERE are so few large hardy ornamental Grasses in cultivation, that it is with pleasure we from time to time recommend anything useful in that way. M. E. André informs us that this plant is a native of Syria, and that it has been grown in Paris gardens since 1862. It is quite hardy, at least with a covering of leaves about the root, during winter. Its aspect is quite different from that of the Pampas Grass or the New Zealand Arundo, which now adorns so many of our gardens, but all the more valuable from being so distinct from them. Plants well grown in the public gardens of Paris attain a height of nearly 6 ft., spreading into large clumps, and the effect is very grace-

*Andropogon halepensis.*

ful when the plants are laden with flowers or seeds. To secure a good development of this plant it is necessary to plant it on rich and deep soil, well drained and well watered in summer.

**Aplopappus Fremonti.**—This is a comparatively dwarf species, growing from 6 in. to 12 in. high, with smooth erect stems branching corymbously upward, and oblong, or linear-oblong, half-clasping leaves, mat entire and pointed. The flower-heads are more than 1 in. across, terminating the leafy branches, both disk and ray florets being yellow, the latter being about  $\frac{1}{2}$  in. to  $\frac{3}{4}$  in. in length. It promises to be a desirable addition to hardy border Composites. It is a native of Colorado in the sub-Alpine districts, and requires only the treatment of other plants of its class.—W. THOMPSON, Ipswich.

**Duplex Polyanthus.**—The Duplex forms of the Polyanthus, or, as they are known in commerce, *Primula veris* duplex, possess, in addition to their decorative qualities, the curious property of having one flower growing out of the other. All of these Hose-in-Hose kinds are very early, which is an important matter, and they are also robust; either for the open border or in pots in the hardy plant house they are very beautiful. They comprise white, yellow, sulphur, buff, and crimson hues, some partaking of the form and habit of the Cowslip, and others Duplex kinds of the self and fancy Polyanthus. One of the yellow kinds throw up first golden-yellow flowers on Primrose stems in great abundance, and these are followed by scapes, so that the period of blooming is materially

lengthened. The older forms are pin-eyed, with the exception of the one just alluded to, but the newer kinds have size and form equal to that seen in the best Polyanthus flowers. I hope, during the present season, to secure seeds from many of these plants, but it is an undoubted fact that, owing to the extreme length of the floral tube, fertilisation of the pistil is very difficult; and, therefore, seed is by no means abundant.—A. D.

### NEAPOLITAN VIOLETS AFTER FLOWERING.

THE principal season of flowering as regards these, the most beautiful of Violets, being now nearly over under glass, preparation should at once be made for next year's supply. The earlier the young plants are out in their growing quarters the greater chance there will be of satisfactory results. The plan we adopt to have plants full of bloom from the first week in October until April is as follows:—As soon as the bloom is cleared off the plants, they are lifted and divided; all the stoutest young side growths, with single crowns, are selected for planting, all hard crowns and wiry, slender growths being thrown away as useless, as they never make good plants. Having chosen a favourable position, viz., a border shaded from the midday sun, and which has been deeply cultivated and well enriched with manure the preceding autumn, and the staple of which, if possible, consists of tolerably stiff loam, the surface is levelled with a rake, and the plants are firmly inserted in rows 1 ft. apart each way with a dibber. If the weather be mild and showery, little watering is needed for some time; but if very dry, sufficient water must be applied to keep the soil constantly moist until the plants begin to grow freely. Frequent surface stirrings with the Dutch hoe are highly beneficial to the plants at this stage, for it keeps down weeds and promotes root action by aerating the soil. As soon as side runners are observed, they are carefully cut closely off with a pair of Grape scissors; but the main leaves must not on any account be removed. By this operation all the strength of the plants will be concentrated in their crowns, exactly as Strawberries in pots are prepared for forcing. During the heat of summer, when growth is active, an abundance of moisture must be applied to the roots, weak liquid manure being alternately applied with clear water. A good heavy syringing after a bright day is a good antidote for red spider, which is sure to attack Violets of all kinds, especially the Neapolitan, when they lack soluble food, but when liberally treated they seldom suffer to any injurious extent. By the middle of September plants treated as described are covered with flower-buds; they are then carefully lifted with their roots intact and transferred to frames in sunny positions and raised well up at the back, so that every ray of sunlight during the winter months may be admitted to the plants. We fill the frames nearly full of leaves and litter, which, trodden firmly in, imparts a gentle and lasting warmth to the roots. When planted the leaves of the plants almost touch the glass. From a quantity of plants treated as described we have had an abundant daily supply of large fresh Violets for six months past. The surface of the soil in the frames after planting is covered with Cocoa-nut fibre, which keeps the blooms clean. The lights are kept entirely off in fine weather and tilted up during heavy rains; but on the first indication of frost a good covering of reed mats, supplemented, if required, with dry litter, is applied. Very little water is needed during the winter months, but in February and March a more liberal supply is necessary. Anyone not having hitherto grown this beautiful Violet should at once commence; the routine is simple, and the results certain. JAMES GROOM.

*Henham.*

### SPRING FLOWERS AT MENTONE.

THE charming and extensive grounds surrounding the residence of Mr. Hanbury, at the Palazzo Orongo, situated between the frontier towns of Mentone in France and Ventimiglia in Italy, form an object of great interest to the observer and cultivator of rare plants and shrubs. The plants enumerated in THE GARDEN of March 23, as growing in a garden in the same neighbourhood, may mostly, if not entirely, be found here also, while the greater extent of the grounds affords room for many specimens of shrubs and ornamental trees,

such as the *Greivillea* and *Schinus Molle*, *Pittosporums*, and *Daturas*. Perhaps, however, the most striking part is that which might be called the "wild garden," or if such a term seems unenited to any part of a highly-cultivated spot, the "natural garden;" the beauty and simplicity of this has a charm which makes one wonder that it is so seldom to be met with. Here, springing up through a green undulating sward, are large tufts of various species and varieties of *Anemones*, varying from pure white to deep violet and dazzling scarlet; *Narcissi*, white, pale yellow, and rich orange; *Crocuses*, *Hyacinths*, &c. These, with a varied surrounding of ornamental trees and plants remarkable for the beauty of their foliage, form a scene of unusual interest, having for a background the grey-green of the Olive with the *Pinus halepensis* on the hills above. Anyone who has space to devote to this simple mode of cultivating spring flowers may produce an effect, the beauty of which cannot be thoroughly realised till seen. Succulents, which abound in great quantities, form some fine and striking features, and seem quite at home here on the hot limestone soil. A variety of *Kennedy*, bearing deep violet flowers in the greatest profusion, is particularly beautiful. Then, of course, there are *Roses*—*Banksian*, *Tea*, *Climbers*, *Dwarfs*, and *Hybrid Perpetuale*, besides many other familiar plants. To enumerate all the contents of this very attractive garden would require more space than could be spared in the pages of THE GARDEN.

Montone.

J. T. P.

### RENOVATING GRASS LAWNS.

Now is the time for this work. Lawns that were not turfed in autumn may be done now, or any time during the month. There are three ways of forming a lawn—by turving, and thus covering the ground at once; by inoculation (where turf is scarce); and by seed. The two first methods are the best where good turf can be got, which is not always the case, as it is difficult to procure turf quite free from *Daisies*, *Dandelions*, and coarse Grasses. The best is usually to be procured from commons, and sometimes from roadsides, or places where there is a certain amount of traffic. Hereabouts it is not possible to procure good turf for lawns anywhere but on the roadsides, just at the edge of the roadway where people walk. This, when the authorities will allow it to be removed, if chopped up and scattered on good soil and well rolled, makes a good sward. For small plots, however, I would recommend fine lawn seeds. I saw last August, at Southport, the most perfect examples of a sward that ever came under my notice, and which, indeed, attracted the attention of even the non-professional eye at once. The ground appeared to have been laid down with the finest of lawn Grasses, and was scrupulously kept. Not a blade of coarse Grass or a single weed was to be seen, and the pile was like that of a carpet, the Grass being cut apparently about twice a week. No doubt the sea air helped to give greenness, but the keeping was simply perfect, and showed what could be done by a little timely forethought and attention. I have often seen lawns the produce of seed, but never any examples like those facing the beach at Southport, and it would no doubt be instructive to learn how they were made and managed. As regards the renovation of Grass lawns, the best plan, when it is not desirable to go to much expense in renewing them, is to harrow or scratch the turf well, to give it a good scarifying, and then to top-dress with fine soil, free from stones and mixed with soot and wood-ashes, and sow Grass seeds pretty thickly. This work may be done any time this month.

J. S. W.

**The Best Bedding Lobelias.**—I do not admire white *Lobelias*, they are so dingy; indeed, all the so-called white kinds are anything but white; these, therefore, will have no place in my list, nor will the purple or lilac varieties, as I consider them worthless, or, at the best, ineffective, either in masses or lines. Only the true blue varieties are really effective in the flower garden, and the best of these are the following:—*Blue Beauty*, a rich dark blue with a white eye, is always covered with flowers throughout the entire season, and rarely exceeds 6 in. in height; its growth is very dense, and, unlike the *pumila* section, it is not liable to damp off on account of its density (I have given up growing the *pumila* varieties because of that fault). *Blue King*, another good kind, is an exact counterpart of *Blue Beauty*, with the exception of the colour of its flowers, which are light blue. *Blue Stone* is the darkest flower I have yet seen, and, but for its disposition to produce nothing but flowers, would be in every way a most desirable variety; as it is, if planted very thickly to make up for its sparse growth, it is most satisfactory. *Ebor* is a near relative of *Blue Stone*, but, of the two, the better grower, and both are fine dwarf kinds. I am, however, by no means sure that both must not succumb to *St. Martin's Blue*. I saw a basket of this at the Carlisle show last September, exhibited by Messrs. Ireland & Thomson, of

Edinburgh, which, if as good for bedding as it was when shown in pots, will displace all other dark blue varieties; the flowers are of the richest dark blue imaginable, with the smallest white eye, whilst the foliage is distinct from that of all other *Lobelias* I know, being a real bronzy-purple with a sturdy habit of growth. I think so well of this kind that I propose using it largely this season. There are numerous other good varieties, but the above constitute the cream of the many kinds that have been grown here for trial.—W. WILDSMITH, *Heckfield*.

**Astragalus diphysus.**—The extensive genus *Astragalus* furnishes our gardens with several very desirable border or rock plants, among which *A. monosperulans*, *A. alpeocroicoides*, and *A. dasylotidis* are specially deserving of mention. Of the numerous American species few have at present been introduced. *A. diphysus* is a very distinct and desirable plant from New Mexico and Utah. It is of dwarf habit, not exceeding 1 ft. high, with numerous stems bearing pinnate foliage of from nine to eleven pairs of small oblong fleshy leaflets, and dense terminal heads of blue-purple flowers each about  $\frac{1}{2}$  in. long. The plant may be recommended as a desirable contribution to the ranks of dwarf hardy perennials. It is scarcely necessary to add that it is perfectly hardy, and is suitable either for the mixed border or the rockery.—W. THOMPSON, *Ipswich*.

**Polyanthus and Primrose.**—Your correspondent, Mr. Farrer (see p. 272), is not the only grower of these beautiful spring flowers who has been puzzled to understand where the characteristics of the *Primrose* end and those of the *Polyanthus* begin. Now it is desirable to understand that these flowers, although having distinct titles, have few arbitrary distinctions, and derive their titles more from the florist than from the botanist, the former finding it necessary to so classify them for his own convenience. The *Primrose* proper we all know, and whether of the most beautiful and richly coloured garden kinds, as recently figured, or whether of the most ragged outline and palest hues, they are exact counterparts in habit of the wild *Primrose*, dwarf, compact leafage, and flowers borne on single stems from the base of the plant. The *Polyanthus* proper, as recognised by the florist, produces its flowers in scapes or bunches on single, erect, stout stalks, and has no *Primrose* flowers. The truss should be even, compact, and rounded, and the individual flower-stems short and stiff, so that the flowers may be kept erect and in place. These are essential elements in the making of a good *Polyanthus*. Between these two distinct forms come a hybrid race that produce flowers in both ways, the *Primrose* blooms on single stalks always preceding those borne on the taller stalks, which come last. These are, as far as possible, classed as "Hybrid *Primroses*;" they are most useful and effective in the spring garden, flower early, and for a considerable period. Seed saved from either *Primrose* proper or *Polyanthus* proper will give some of this latter form in the seedlings. The whole of the family of these hardy spring flowers are very sportive, but on that account none the less beautiful.—A. D.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Ivies on Stakes.**—I am charmed with the illustration, and the idea of growing *Ivies* on stakes (see p. 288), and shall certainly adopt it. I can imagine how effective a trio of plants, viz., dark green, golden variegated, and silver variegated would look. The picture also reminds me of some plants of *Clematis* that are trained in a similar manner in the pleasure ground of Beerwood Park, Wokingham, and which when I saw them in June last were a sight to be remembered.—W. WILDSMITH, *Heckfield*.

**Primroses in Kent.**—The woods about Tonbridge are now gay with *Primroses*. Blooms of them have been procurable sparingly all through the winter from warm and sheltered situations. About a month ago a double flower was brought to me, having been found by a young friend in a wood between Sevenoaks and Tonbridge.—W. T. T.

**Stealing Snowdrops and its Punishment.**—Two men, named Sampson and Wells, were indicted for stealing *Snowdrops* and bulbs from the garden of Mr. Balguy, the Woolwich magistrate. Wells pleaded "Guilty," Sampson "Not Guilty." They had both been previously convicted of similar offences, and the remarkable feature in the case was that they appeared to be systematic depredators. It was proved by Mr. Balguy's gardener that he saw them pulling up *Snowdrops* and bulbs in his master's garden. On seeing him they ran away, but were pursued and taken. It was proved that Sampson had been convicted in 1876 at East Grinstead, in Sussex, of stealing *Pansies*. The jury found the prisoners guilty, and the learned judge, in passing sentence, said the prisoners had been convicted several times of like offences since 1869, and seemed to make their trade of such depredations. Sampson had already had eighteen months' imprisonment, and Wells three months, for similar offences, and it was of no use dealing leniently with them. He therefore sentenced them each to seven years' penal servitude.

## THE FRUIT GARDEN.

### POT STRAWBERRIES AND THE SEASONS.

It appears to me to be a matter of very little importance, as regards pot Strawberries, whether the season be wet or dry; but if I had my choice, I should prefer a pretty moist summer to a very dry one. Still, as I say, it is not of much importance, provided the plants are propagated early and from a fertile stock, and they should be kept in pots that they are sure to cram with roots by the end of September. Watering, soil, &c., are important, but secondary considerations to these, which are the main points in the culture of Strawberries for forcing. The late Mr. McEwen, of Chiswick, who was one of the most successful and enthusiastic of Strawberry growers, said that he liked to see the roots bursting the pots about, and then he was sure of a crop; and he was right. During the last twelve years our pot Strawberries have never missed a crop, and I must say that the plants that were grown in wet seasons have always done just as well as those grown in those that were dry. I believe the best ripened plants we ever had was our stock of 1868, when we were without rain from June till some time in October, but they were also the smallest plants, owing, no doubt, to the excessive sunlight and drought, though the plants were watered twice, and sometimes three times a day. Yet the crop from these was hardly so heavy as from our plants of 1872, when we registered 5 ft. of rain, and which fell, chiefly, during the summer and autumn. That year our plants grew amazingly, and had to receive more room than usual; the leaves were so large and fine, and the crop of fruit the spring following was excellent. Last season, again, was pretty moist, some 42 in. of rain having been registered here, a large proportion of which fell in September and early in November, about 9 in. altogether, all of which our Strawberries received, for they were not housed till later on, and after they had been subjected to a touch of frost. It was, in short, what may be described as a bad season for ripening Strawberries; yet I do not think we ever had a finer crop than we have this season. We have been gathering at the rate of a large dish every day since about the middle of March, and have a great quantity coming on. The flowers were unusually large and fine, and the fruit is well swelled. I saw it stated somewhere lately that Strawberries were inclined to make leaves more than flowers this season, in consequence of the plants being imperfectly matured last autumn; but I feel sure that this has very little to do with the matter. Premature leaf-growth is, in most cases, caused by too hard forcing and high night temperatures. We have not only our Strawberry house here crammed with plants, but the shelves of other houses as well; and we could, at the present time, show plants of the same batch and variety which manifest in one case a disposition to make leaves fast, and in the other to flower; but the former are in houses where they cannot be accommodated with a temperature to suit them exactly, being rather too high. However, by pinching the prematurely forward leaves—in some cases only the middle lobe off, and in others the whole leaf out by the socket—till the flower-scapes get well up, we always prevent injury, and, of course, the plants are moved forward to suitable quarters as soon as room can be found for them. Upon the whole, then, although I believe the seasons have much to do with the crops on permanent plantations, I do not think they influence pot plants in a sensible degree. I may state that this is one of the coldest situations in England. J. S. W.

### MAKING VINE BORDERS OF LIGHT LOAM.

In making Vine borders of light loam, is it a good or economical practice to chop the sods up in the usual way? From my own experience of light sandy loam, I have come to the conclusion that it is not, and that the organic or fibry portion of the sods decomposes much more rapidly than it otherwise would do, affording for a short time a glut of nutriment to the Vines, and ultimately leaving a comparatively poor border. On taking charge of the gardens here, about seventeen years ago, everything connected with them was old and dilapidated, and it was decided to remodel them all at one time. The heaviest loam to be had within reasonable distance was very light. It was chopped up in the usual way, and mixed with  $\frac{1}{2}$ -in.

bones, charcoal, and old lime rubbish. In turning this to mix all well together, the fibre appeared even then to have disappeared to a considerable extent. The Vines grew well in it, and for some years carried good crops. The Grapes generally finished well, and were of excellent flavour. These borders—made with great care, in the usual orthodox fashion as regards chopping and mixing—have not lasted so long in a condition favourable to the production of good Grapes as in other cases where the sods have not been chopped, but simply cut into pieces 6 in. or 7 in. square, and which, in forming the borders, have been packed closely together in layers with the Grass side down. The manure and bones used were strewn on each layer of sods, and a little fine soil was used to fill up any open spaces left in packing, my object being to get so solid and firm a mass as to exclude as much as possible the decomposing power of the atmosphere. Borders made in this manner remain in proper condition for a much longer time than when the turf is chopped fine. This has been very strikingly seen in the case of wall borders which were concreted and well drained, and the turf put into them as it was taken from the park, and packed closely; the carts passing over the border made the turf very firm, and these borders have retained their fibre longer than any about the place. Four years ago a Vinery was put up for late Grapes, and as soon as the fruit was above the ground level, the inside border was made. The sods were packed as closely as possible, and each layer was trodden and rolled. Bones and charcoal were all that were added, as lime-rubbish has a decomposing effect on the fibre. The carpenters, glaziers, and painters did all their work over the border, and it was as solid as it could be made. All the fine soil used was just enough to plant each Vine. The Vines I struck from eyes, and planted them in the end of June. They have done exceedingly well, and we are cutting some very fine Grapes from them now (January). In comparing these Vines planted in borders made as above described with others grown in chopped, loose turf, the former are not only equally strong, or more so, but the character of the wood is far better than that of the latter, it being harder, and has less pith. On examining the roots, they are found very different in character in each border. Those in the chopped, loose soil have produced comparatively few large roots, and but few fibry ones near the stems of the Vines. In the solid border they are just the reverse, there being a perfect network of roots up close to the collars of the Vines. From this experience, I would never, when working with light soil, chop a single turf, but use them as they came from the field, and make the whole as solid as possible. Neither should any description of lime be used, but instead some charcoal, and, of course, bones. Our subsoil being sand, and the rainfall light, copious waterings of manure water are given—and care has to be exercised that the borders be regularly attended to in this way. I feel certain that any who have to make borders of light soil will not regret trying the plan described.—A. H., in "Gardener."

### PERFECT FERTILISATION NEEDED IN FORCING STRAWBERRIES.

A WRITER on this subject (see p. 280) has found out, it appears, that in order to insure perfect fertilisation of Strawberry flowers, an artificial process affords the best means of securing that result. Under certain circumstances I quite concur with this view, and have no doubt that such a discovery would have been welcome news a century or so ago. In the present age, however, it is the every-day practice of most practical men, but on a somewhat different basis from that recommended in the remarks alluded to. It appears the author of the remarks referred to would recommend the general application of principles founded on his own notion of what a crop should be, or, at least, what he thinks people should be satisfied with, forgetting that those who write for the public only recommend what they know and have proved to be the best and safest plan of securing the best results. Besides, there are those who aim at securing quality in preference to number. An allusion is made to time as a justification of a high temperature. Now, I think anyone possessing ordinary powers of calculation, with a little practice, would overcome this difficulty by making natural allowance as to time at the beginning. Anyone accustomed to grow Strawberries "to time" will see at a glance how useless it is to raise difficulties for the self-gratification of overcoming them. There is one important point which the writer in question would seem to have altogether ignored, viz., the organic capacity of flowers for performing their natural functions of fructification. A strong heat would simply be the ruin of imperfectly ripened plants, of which there are not a few this season, inasmuch as they would yield submissively to the influence of a high temperature by throwing up leaves before the flower trusses; the latter would therefore be, in a degree, robbed by the former, owing to the premature application of a too high temperature, and the

flowers subjected to such debilitating influences would lack stamina to impart the vigour necessary for the development of fine fruit. The fact of a flower setting does not prove that its organs were not weakened, and the produce would necessarily take the same character. Give plenty of time till the fruit is set, and while that process is going on keep up a healthy circulation of warm air from 50° to 60°, going over the flowers once a day with a feather duster, and there need be little apprehension as to results, whether the temperature afterwards be high or low. W. HINDS.

Otterspool.

**Scarcity of Pear Blossoms.**—Allow me to say, in reference to Mr. Fieh's inquiry (see p. 282), that I rather think this is general this season; at all events in this garden and district such is the case, but for all that, the probability is that there will be a better crop of fruit; for I have noted that, as a rule, the thinner a tree is of fruit buds the better the fruit sets, so that with propitious weather (which at present is anything but that), I think the majority of trees possess flower-buds sufficient to produce an average crop, *i. e.*, if the severe frost of the past week has not frozen them, for although no blossoms are unfolded, I much doubt their being able to withstand from 7° to 12°, which we have registered nightly during the whole of the past week. Apricots have flowered and set well under thick canvas coverings, but where netting protection only was used, they are all destroyed. Peaches have not flowered so well for years as they have done this season, and at present, under thick canvas, they are uninjured. Apples are wonderfully well budded, and, I think, late enough to be as yet safe. Plums of all kinds are one mass of blossom. Cherries are the same, and as they are not yet expanded, I think they must be safe. Gooseberries are too forward, and all the upper parts of the trees will be fruitless. Currants are late, and therefore safe, but, as the saying is, "we are not yet out of the wood."—W. WILDSMITH, *Heckfield, Hants.*

**The Weather and the Fruit Crops.**—March has this season reversed the old adage—it came in like a lamb and went out like a lion. The weather during the last ten days has been exceedingly wintery, but culminated last night with a depression to 15° or 17° of frost. This is the lowest temperature experienced here since the last day of December, 1874, when it fell to 16°. It has of course blasted all hopes of securing crops of such fruits as the Apricot and the Peach, and has seriously imperilled that of the Pear and the Plum; and if Gooseberries and Currants be found to have escaped, which is doubtful, it may be attributed to their being well covered with snow. The trees upon the Apricot wall here are under a temporary roof formed of old lights, and this extends some 6 ft. from the face of the wall; the fruit which had set in abundance was as large as Peas, and up to last night did not appear to have greatly suffered from a nightly temperature ranging from 22° to 31°. But 17° of frost have proved too much from them. Some isolated Apricot trees upon a south aspect, the same as the others, were covered with branches of the Red Cedar, and a few trees were left unprotected, but in all cases the fruit has met with a similar fate.—P. GRIEVE, *Culford, Bury St. Edmunds.*

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Bleeding in Vines.**—When a youngster, and wishing to be orthodox in all my gardening operations, I, of course, practised all the remedies recommended to prevent bleeding, such as burning the ends with a hot iron, fixing Potatoes on the ends of the rods, sealing with wax, painting with painters' knotting, Thomson's Styptic, grafting wax, &c.; but some years ago now I gave up all these remedies, and now when a Vine manifests a disposition to bleed, I stir up the fire with a view of inducing a quicker motion of the sap; there is then soon an end to bleeding. My treatment is therefore just the opposite of that recorded by "J. S. W." (see p. 253), but I can vouch for its effectiveness.—W. H.

**The Jolly Beggar Apple.**—This excellent early kitchen Apple was sent to us some time since, with a very high character for its quality and good bearing properties, by Mr. Rivers, of Sawbridgeworth. It is a fruit of full medium size, roundish, and somewhat ribbed near the crown, pale yellow, with a tint of deeper yellow on the more exposed side. The eye is large and open, and set in a shallow basin formed by the ribs already alluded to. The stalk is inserted in a deepish hollow, and is  $\frac{3}{4}$  in. or more in length. The flesh is tender and juicy in texture, white, sweet, with a brisk, pleasant flavour. Dr. Hogg, in his "Fruit Manual," identifies it with a variety called Lord Grosvenor, and notes that it is a first-rate cooking Apple, in use from August till October (Mr. Rivers says, October to December). "The great merit of this variety," he remarks, "is its great fertility, the small bush bears producing an abundance of fine yellow fruit. The tree bears very early, and is one of the most useful for garden culture." Others speak of it as a prodigious bearer.—"Florist."

## ROSES ON STOCKS FROM BRIER CUTTINGS.

There are few matters connected with Rose-growing on which more diversity of opinion exists than on that of the kinds of stock on which Roses do best. Some are in favour of the seedling Brier and Manetti, others the common Brier, or on their own roots. The seedling Brier has much to recommend it, and I believe that it will be more extensively used as it becomes wider known; but it is not without its drawbacks, especially for standard Roses, because it takes several years from the time of sowing the seed until the stocks are large enough for budding, and in the case of many time is money. The old style of getting up standard Roses by digging up a number of old Briers with long stems from the hedgerows in autumn, and budding them the following season, is still very generally practised; indeed, it has been so long followed that few agree with anything that is said against it, but the system has many weak points that may be improved with advantage. I have often heard it remarked that standard Roses, as a rule, do not make such vigorous growth, produce such fine blooms, nor live so long as dwarfs on their own roots or on the Manetti. I know a good many Rose growers who object to grow standard Roses on the Brier altogether, because they are so liable to die off or decline in strength. It is not the least surprising that they should do this, and if people would only look at the roots of the Brier before planting it would not be difficult to imagine the cause of their decay in the generality of instances. The scarcity of standard Briers is acknowledged; consequently those who are in the habit of grubbing stocks from the hedgerows and elsewhere are compelled to take every Brier that is tall enough and sufficiently thick, no matter what age it is. Briers of this description never have many fibrous roots, and few of them are found without a large club at the end of the stem, which lifts as clear of roots as the head of a walking-stick. How stocks of this kind can support buds and growth until the plants are saleable I cannot imagine, but I can say this, that I have frequently received dozens of standard Roses with club roots as fireless as the palm of one's hand. Therefore, seeing that fibrous roots are so necessary in order to produce fine Roses and healthy bushes, what wonder that standard Briers should prove so unsatisfactory and die prematurely. Instead of lifting old Briers with rootless club heads, never disturb the roots at all, but secure all the straight shoots on the Brier bush that can be had, and put them in as cuttings. To insure their rooting they should not be cut, but pulled off with a heel of the old wood attached. When put in in November they are ready for "working" the following July or August. All buds, except two or three at the top, should be removed from each shoot. In putting them in, the rows should be about 2½ ft. asunder, with 6 in. or 8 in. between each in the row. The cutting should be inserted about 3 in. under ground, and the soil must be pressed very firmly around it. It is an advantage to mulch between the rows after the cuttings have all been put in. Treated in this way 90 per cent. of them will root. I am aware that this is not a new way of raising Brier stocks, but it is not practised anything like so extensively as its merits deserve. Stocks thus raised possess all the good qualities of the seedling Brier, as the fine fibrous roots freely produced by the cuttings are equal in every respect to the best produced from seed. And it has this important advantage, that good plants may be got up from cuttings in half the time which it takes to raise them from seed. The old way of procuring Briers will bear no comparison with the plan now suggested, so far as growth and culture are concerned; and where only one or two Briers could be got from a bush with suitable roots, dozens of suitable shoots can be often had from the same bush. Many grow Roses extensively, using only the cuttings of the Brier, and the plants are healthier and finer grown than any others of the same age. Those who have planted them in previous years are so satisfied with their superiority that they will have no others, and I am acquainted with one garden in which 800 of them have been planted this winter.

CAMBRIAN.

**Protecting Rose Cuttings.**—I find a slight covering of dry Fern to be an excellent protection for Rose cuttings and dwarf Roses when the buds are expanding, and until the young shoots get from 3 in. to 1 in. long. The frost comes and blackens them when unprotected, and in the case of cuttings they have not the vitality to start again.—R. GILBERT, *Burghley.*

## TREES AND SHRUBS.

JOINTED IRON COLUMNS AS SUPPORTS  
FOR TREES.

Those interested in street trees, avenues in parks, or trees planted singly have doubtless noticed their tendency to grow towards the east, or, from some cause, growing otherwise than in an upright position. I could point to many instances in London where the beauty of trees is completely spoiled by inattention to this matter. There is no reason why we should not, by judicious care, prevent this unnatural growth in trees. It is probably well known that light has a tendency to retard growth, a simple instance of which may be seen when plants are placed in a room near a window; these we can turn occasionally, but trees we cannot. I have no doubt, also, that trees are in a condition most conducive to growth in the early morning, when they are covered with dew, hence when the sun rises to warm the surrounding atmosphere the darkened side of the tree makes rapid progress, while that on the sunny side is retarded, causing the unnatural growth alluded to, and which may be exemplified by a very simple problem, *i.e.*, the inner curve is constantly shorter than the outer, and if continued would form a circle, or something nearly approaching to it. Since, therefore, no natural remedy exists to prevent this, we must devise an artificial one. A friend of mine suggested to me some time ago what appeared an extraordinary method of overcoming the difficulty; in fact, what he suggested was the paradoxical difficulty of making two wrongs one right, that is, he proposed to calculate with mathematical accuracy the amount of bias a tree would gain in a given time, and plant his trees so much out of an upright position in an opposite direction. I assume that this is impracticable, or, to say the least, a most undesirable method of procedure.

I am of opinion that trees should be planted perfectly perpendicular, and maintained in that position until they are capable of taking care of themselves. The only sure way with which I am at present acquainted of arriving at such a result is, for trees in streets, staking firmly with stakes long enough to go well up into the head of the tree. On lawns or similar places the same result may be arrived at by using three short stout stakes driven in triangularly round the tree at several feet from the stem, and tying with wire or other suitable material, to keep the tree in position. Much may also be done by judicious pruning, so far as the head is concerned, but it will never have the effect of keeping the stem perpendicular. Staking with wooden stakes, if properly done, is expensive work, in consequence of the frequency with which it is necessary to renew them. Light iron columns, say 20 ft. in height, would answer the purpose admirably, and would not require to be renewed. They could be removed for use elsewhere if required, as no difficulty would be experienced in drawing them from the ground with the aid of some mechanical contrivance. The length of time they would probably be required to remain in London to support trees would be from ten to twenty years. They would not be unsightly, and could be made in two or three lengths, so that they could be added to as desired and never appear above the tree. The tying would, of course, be done in the usual manner, and in as many places as necessary.

I really do think the adoption of the foregoing suggestions would insure straight trees in avenues and other conspicuous places. These columns would be lighter in appearance than wooden stakes and much cheaper in the end. Moreover, it is impossible to drive down large stakes without injury to the roots, which should at all times be avoided. With respect to the best method of making these jointed iron columns, they could either be made to screw into the ground or be pointed and driven in, if not fixed at the time of planting the trees, in which case they would probably be put in like an ordinary post and solidly rammed. The joints could be made to fit in sockets and riveted or pinned, or made to screw on. The advantages I claim for these columns are lightness of appearance, durability, rigidity, and cheapness. In cases where trees have been long neglected it would be necessary to open the ground round them and place them upright before the columns were fixed.

CHARLES DENNIS.

*Southwark Park.*

## THE POISONOUS PRINCIPLE OF THE YEW.

THE recent loss of a valuable herd of cattle, poisoned by eating the outtings of Yew trees has once more directed attention to the unsatisfactory state of our knowledge of the properties of common plants. The Yew has the reputation of being poisonous, but its

berries are eaten freely by children without inconvenience, and an infusion of the leaves (Yew Tea) is employed by country people for certain ailments, over which it undoubtedly exercises some effect. Its action resembles that of Digitalis, though its effects are scarcely so evident. So far as cattle are concerned, Yew is popularly supposed to be a dangerous tree to have within their reach, but it is certain that deer, and probably also cows and horses, eat it with impunity when in the fresh and growing state, while the latter, at all events, are fatally injured by devouring the half-dried cuttings. An exactly similar action is attributed to the common Laurel, cattle browsing

upon the living leaves apparently without any injurious results, but being poisoned when they consume the half-dry and partially decomposed trimmings. The fact that the cuttings of Yew trees exercise more powerful toxic effects than the fresh leaves is well known, but no explanation of the extraordinary difference when consumed by cattle has been forthcoming. There is of course the obvious explanation that in the fresh leaves the toxic principle is more largely diluted with water, while in the half-dry state of Yew trimmings the poison is of sufficient strength to produce disastrous results; but that explanation is not altogether satisfactory, and it would be of service if someone would determine whether cattle may be allowed to eat Yew leaves fresh from the tree, and explain why the half-dry cuttings exercise so fatal an influence upon them. Although a decoction of the leaves is used by country people, they are careful to administer only small doses; and even the children, who eat the fruit, are strictly enjoined to eject the stone or seed, because it has poisonous properties capable of producing serious results. Actions at law have been brought to recover damages for injury to horses through eating the young branches of unprotected Yew trees, and in some cases they have been successful; but now that Earl Lovelace has lost a valuable herd of cattle through eating Yew in his park, we may expect that an exhaustive investigation will be made.—“Echo.”

**Shrubs on Rock Gardens.**—It is not only for Alpine plants that rockwork, rock gardens, and rocky banks are desirable; there are numbers of mountain shrubs for which such offer the very best

Shrubs on Rock Gardens.

positions. Many elegant dwarf shrubs are lost or weakened in the struggle for life. Shrubberies well exposed to the sun on rocks or rocky banks would form objects as attractive as any seen at our flower shows. Apart, too, from shrubs there are numbers of graceful creeping, trailing, or recumbent plants which also demand such a home. As important as any of these plants, however, are the more beautiful hardy climbers, which are rarely seen in perfection in our gardens. The rampant and vigorous climbers may be trusted to take care of themselves in various positions, and some of them would, indeed, if placed in a rock garden, soon overrun it and destroy all plants but themselves in it. But there is a host of beautiful life among the not less hardy, not less free-flowering climbers, which are admirably suited to the larger type of rock garden, such as the more elegant Clematis which are seldom seen, Atragene, and various herbaceous climbers, such as the Jalop plant, which also does well in such positions.

### SPIRÆA THUNBERGI.

This beautiful Spiræa has not been generally known more than ten years, and may therefore be fairly termed new as well as choice. It is one of the acquisitions obtained from Japan, and named after Thunberg, the great botanical explorer of that portion of the globe. No weakness or imperfection of any importance prevents its general acceptance, and it has therefore gained favour with more than usual rapidity, so that now all well-assorted nursery collections must include it among their varieties. It is rather remarkable for excelling alike in foliage and flower. The leaves are quite small, which gives the plant a light, feathery aspect, and of a tender, greenish-drab, very peculiar and attractive. Thick and vigorous, the foliage in full growth assumes very graceful curves, suggesting, from a distance, some light-coloured weeping evergreen. It is one of the earliest plants to put forth in the spring, when its unusual green is very fine, relieved against the brilliant, early verdure of the Grass. Indeed, the appearance of this delicate little Spiræa is quite unique among hardy shrubs, and it is therefore invaluable for producing contrast and variety on the lawn. The flowers, likewise, are both striking and beautiful. Pure white, small, and wreathing the entire plant, it should have received the name of the Bridal-wreath Spiræa, had not the older variety *S. prunifolia* already, with less justice, secured that title. The end of April or the beginning of May nearly always finds this Spiræa in its full glory, and few objects appear more agreeably to the eye than these late wreaths of snow unfolding the bending branches. It is moreover remarkable that so delicate and feathery a shrub should be hardy under all circumstances, and so vigorously withal. Under the strain of transplanting it behaves equally well, although this need not astonish us in a Spiræa. Its size is neither large nor majestic, yet to the landscape gardener it is invaluable, because it doubly perfects a group of shrubs by its early white flowers as well as by its delicate and peculiar leaves. It is no less beautiful standing singly near a gateway, or by the steps and in the angles of houses. Indeed, if groups were to be constructed with the intention of deriving autumnal colour effects alone, this Spiræa would still be most useful; and certainly no finer masses could be formed than such groups. I am aware that my remarks may seem to claim overmuch favour for a shrub that has lost somewhat of its attraction by becoming very common on our lawns, but I feel that its intrinsic value fully supports my assertions, and that a rapidly acquired fame only confirms their accuracy. S. PARSONS, in "Country Gentleman."

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Hollies on an Elm.**—In going through a wood the other day I saw a Holly which had actually grafted itself in the fork of two suckers of an Elm tree, just as the *Mistletoe* does. This circumstance has been so unusual to me and those to whom I have mentioned it, that I determined to make a note of it, and ask if anyone is acquainted with a similar case.—*EBORACU.*

**The Catalpa at Home.**—It is stated by Prof. Burrill, of the Illinois Industrial University, that, from experiments performed at that institution, the Catalpa is one of the cheapest and easiest trees to grow, and one of the most rapidly growing of forest trees, native or introduced. Its growth has been surpassed only by the White Willow and Soft Maple among the various trees tested in the last eight years. It has outgrown the American Elm, White Ash, European Larch, Osage Orange, and Black Walnut on the same ground and under the same treatment. It is not attacked by any insect. Some statements are added showing the great durability of the timber.

OVER 200 species and varieties of the Willow family are said to be now in the Washington (U.S.) Botanical Garden.

## THE KITCHEN GARDEN.

### CARROTS AND THEIR CULTURE.

Of all garden esculents the one which gives the most trouble, or is the most difficult to grow in a clean, clear shape, is the Carrot, which in rich cultivated soils is generally grub-eaten or disfigured by wireworms, which have a special fondness for this root, as may be seen by the innumerable perforations they make in it. Nor does the injury end there; they cut off the tap root, which in the case of Carrots is the principal feeder, and once they lose that their downward course is stayed, and a profitable crop is then out of the question. Many who grow this useful vegetable are often puzzled why it is they flag so, little thinking there is an enemy busy at work below; and even when they escape wireworm, canker often sets in and quite spoils their appearance. This disease is brought about by a too free use of manure, which in some way affects the delicate skin, and more particularly is this the case if it happens to be of a rank, crude nature, and not thoroughly decomposed. Even in this state the less Carrots have of it the better and clearer will the crop be; and in growing them in gardens the best way is to so arrange that they are made to follow Celery, or some esculent of that kind, for which the land has been previously enriched and well aerated, as it is when dug out and thrown up into ridges for the purpose of blanching and protecting the plants. This exposure not only sweetens the soil, but is very destructive to insects, the larvæ and eggs of which during the winter are so vulnerable, as to be readily affected by frost. Besides this there are other advantages in a systematic rotation, not the least of which is the labour saved in trenching or digging, as by a little management one crop may be made to prepare the way for the other, much to the benefit of both. Premising, therefore, that the ground recently occupied by Celery is now at liberty, all that will be necessary is to level it down, and so work it about by means of a fork and rake as to get a thoroughly smooth and pulverised surface, which for all root crops is a matter of the greatest importance. Previous to doing this, however, a good dressing of soot should be given, as it is not only a most powerful fertiliser, but is very obnoxious to insects, and particularly such as affect Carrots. By its use I have had splendid crops in situations, where without it they would have been eaten up or so damaged, as to be comparatively worthless; and whether it kills the grub of the wireworm or not, I cannot say, but if not, these pests vacate the soil and betake themselves to fresh fields and pastures new. From my experience of soot, I am convinced it is not half enough used in gardens; as, were it more liberally applied, we should not have the bother we have with slugs and such like devouring the young plants the moment they make their appearance.

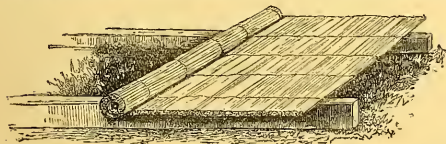

As Carrots are rather slow in germinating, the final preparation of the land should be deferred till the seed can be got in, as when allowed to lay undisturbed for a time, weeds are apt to get up before them and take possession of the ground before the rows can be seen. This makes cleaning a difficult matter, and if done ever so carefully, it causes such a disturbance that the crop is sure to be checked. To get ahead of the weeds and save this, I find it is a good plan to damp the seed and let it lay a couple or three days in a warm place, but when this is done it requires close watching, and there must be no delay in sowing directly it begins to sprout, or the young germs will be injured. The first or second week in April is the most suitable season for getting it in, but it is better to be a little late than to venture to sow when the weather is bad or the soil not in good order, as the condition of this has so much to do with success or failure, not only with Carrots, but with most other crops. When required to grow to full size, the proper distance for the rows is about 1 ft. apart, which affords ample room for the hoe to get well between them for the purpose of hoeing and cleaning. If there is a certainty of the seed being good, it is always advisable to sow thinly, but whether this is done or not the singling out should be set about early, or the young plants get soon drawn up and weakened. As young Carrots are always in great request, the best way is to leave them at about 3 in. apart, and then take out every other one when required for use. The hand-

somest and most serviceable Carrot for general purposes is James' Intermediate, which is of medium length, rich colour, and delicate flavour, and altogether a great favourite with most people. For use in a small state, however, there are none equal to the scarlet French Horn, which, when young, is delicious. These should be sown in rows about 6 in. apart in beds prepared specially for them in the following manner:—Select a sheltered border in a warm sunny spot, and if the soil be not naturally light, make it so by digging in some road scrapings, sand, or leaf-mould, mixing the same well up as the work proceeds. To have these really good during the summer and autumn, it is necessary to sow regularly at intervals of every three weeks or a month, so as to have a constant supply of young roots, which are far more tender and succulent than those that are allowed to stand till they get large before being used.

Anyone having a half-spent hotbed may, by putting on it 6 in. or 9 in. of light sandy soil and sowing at once, soon have Carrots fit to pull, which in May are looked upon as one of the choicest of early vegetables. In a frame the object is to make the most of the room, and therefore the best way is to sow broadcast evenly over the surface, and then thin out when large enough to be of use. In very unfavourable soils, or where Carrots are required very clean and good for show purposes, it is a good plan to dibble holes and fill them with prepared mould containing a good deal of sand, and then sow the seed in the centre of each. By so doing, very fine roots may be obtained free from spot or blemish of any kind, as they can easily run down and swell out without meeting with any obstruction. S. D.

#### REED MAT PROTECTORS.

The accompanying is a representation of these mats, to which allusion was made the other day (see p. 278). It gives a good idea both as

to how they are made and used. They consist of the stems of the common Reed, sewn together with strong tarred twine. They are between 7 ft. and 8 ft. wide and very strong. They must be very useful for throwing off hail or snow, and they may also serve for shading.

#### CELERIAC, OR TURNIP-ROOTED CELERY.

Or vegetables used in foreign countries large quantities are not worth growing in England, but the Celeriac is an exception. It may be found in a few large establishments in this country, but its culture ought to be extended to even the smallest gardens, on account of its fine flavour. It is by no means difficult to grow, and it is one of the most useful of winter vegetables, coming into use, as it does, when the kitchen garden is almost bare. On the Continent it is met with on every table, and is considered a welcome delicacy. It forms an irregular, globular, Turnip-like root or knob from 2 in. to 3 in. in diameter. It is brown on the outside, but the flesh is white, tender, and very pungent. Three varieties of it are in general cultivation.

1. **The Common Celeriac**, which has leaves about 1 ft. long, spreading, and dark green, stalks hollow, root irregular, globular, growing nearly entirely in the ground, gray-brown outside, top large, flesh white, tender, of first quality, medium precocity, requires protecting against severe weather. This variety is that most generally known.

2. **Erfurt Celeriac**.—This has leaves from 12 in. to 15 in. in height, erect, not so numerous as those of the common kind, dark green, stalks hollow, tinted with purple, root half above ground, more regular than that just alluded to, frequently angular, and conical in shape above ground, brown outside, flesh white, tender, sometimes woolly if the growth has been impeded; much earlier than the preceding, more delicate and not so hardy, but well worth attention.

3. **Curled Celeriac**.—The leaves of this are numerous, erect, and spreading, light green, and beautifully curled; root irregular, spherical in the ground, somewhat flattened, rough and nearly white outside, flesh white. This variety is interesting on account of its curled leaves. It is the latest of the three, and the hardiest; in fact, it only requires protecting against very severe weather.

As regards cultivation, a deep, well-prepared rich soil is necessary, the secret with respect to growing Celeriac to perfection being heat, manure, and water. It should be sown in February or March on a hotbed, or in pans under glass; the seed will come up in about sixteen days. Thin out, transplant in another genial bed as soon as the seedlings will bear handling, and plant them in the open ground in May 14 in. apart in rows 16 in. asunder. Frequent hoeings and a thick mulching are of great benefit to the plants, and during summer water must be abundantly supplied, as should they get dry, or suffer from any cause, the quality of the root would be deteriorated. When Celeriac can be irrigated during the heat of summer it produces a marvellous effect upon the growth and the size of the roots; frequently when the early months are cold the growth for several weeks has the appearance of being checked, but when hot summer days set in, it soon makes up for lost time. In warmer regions market gardeners sow Celeriac in March in the open ground, and as the seed is about twenty days in coming up, a crop of Radishes is grown and removed before the young seedlings are in any way injured by the Radishes. The roots of the Celeriac are ready for use by the beginning of October, and they may be kept in the open ground until the following April, if protection be given them, consisting of mats, straw, or any other kind; otherwise they must be removed to a cold cellar before severe weather sets in, or they may be put in a bed close together after part of the leaves has been cut off. Thus situated, they will be easily secured from frost. In February, however, they must be again removed, in order to check growth, which would destroy their quality. Treated in this way, Celeriac will be most serviceable during the winter, and will afford excellent dishes. It never requires earthing up—an advantage which it has over Celery.

As regards its use, cut off the leaves, remove all irregular knobs, give the root a hard crushing in clean water, and it will be ready for the cook. In a raw state, cut it into thin slices; it forms a good addition to winter salads. Cut in pieces  $\frac{1}{2}$  in. thick, and when boiled, fried with butter and served with sauce, is the general way in which it is put on French tables. Boiled as above and made into salad, with salt, pepper, oil, and vinegar, like Potatoes, is the chief way in which it is used in Germany.

Celeriac is also called large-rooted Celery; (French) Celeri rave, Celeri navet, Celeri boule, Celeri à grosse racine; (German) Sellerie Wurzel, Knoll Sellerie. D. GUIHENEUF.

#### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Broccoli**.—We are now cutting that prince of midseason Broccoli, *Watts' Excelsior*, some heads of which weigh 5 lb. each, the flowers being securely wrapped up in its own foliage. What is wanted in Broccoli is a late Excelsior, which will not come in until May or June. *Castleg's* is now among the best, but the flower is yellow.—R. GILBERT, *Burghley*.

**Large Stick of Horseradish**.—When in the neighborhood of Malvern Wells the other day I saw a stick of Horseradish taken from the railway embankment measuring 24 in. round the crown, or rather under the crown, and 18 in. in length. I thought it an extraordinary specimen.—JAMES PRESSING, in "Field."

**Cauliflowers Buttoning**.—The whole of my early London Cauliflowers have buttoned, but not the Walcheren, at least at present. I hear, too, this is also the case in many parts of the country. I have for years noted that after a cold, severe winter and a warm spring both Cauliflowers and Cabbages "bolt," but this season having been quite the reverse, I thought they might have escaped.—P. GILBERT, *Burghley*.

**Removing Potato Flowers**.—A Paris letter to the "New England Farmer" says that Dr. Boeghs has published the results of his experiments on the removal of the flower of the Potato. By this process he has found an increase in tubers of 25 per cent. in addition to their quality being improved; he succeeded best with the blue and the white varieties of the Potato. One woman can nip off an acre of flowers in a day.

## PLATE CXXII.

## IXORAS.

(WITH A COLOURED FIGURE OF I. DUFFI.)

Drawn by H. NOEL HUMPHREYS.

*IXORA DUFFI* is a distinct species from the South Sea Islands. In habit it is not unlike *I. Lobbi*. The leaves, which are of ample size, are of a beautiful deep green. Some of them measure as much as 10 in. in length. In colour the flowers are deep red, with a slight tinge of crimson as they get older; one truss of them on quite a small plant measured  $8\frac{1}{2}$  in. in diameter through the centre, not across the top. It is a fine addition to our evergreen stove shrubs, and is named in compliment to Mr. Duff, foreman in the Botanic Gardens, Sydney, New South Wales, by whom it was discovered.

If asked to point to a genus of plants inhabiting our stoves that combines the showiest of flowers with the finest evergreen foliage, I should have no hesitation in naming *Ixoras*; and the freedom with which their great trusses of flowers are produced, ranging in colour from deep red through all the shades of scarlet and orange to white, entitle them to the first place in any collection of stove plants where there is sufficient heat to grow them. This is indispensable, for, coming, as they do, collectively from the hottest parts of the world, they are essentially heat-requiring plants; in fact, they will bear as much heat as any plant in cultivation; and, although they may exist in a temperature not sufficiently high, yet where there is not the means of keeping them, not only in the summer but also in the winter, hot enough, I should not recommend their cultivation, for to arrive at the highest point of success they should be kept growing slowly even in winter, as if growth is ever completely stopped through insufficient heat, they are almost certain to get into a stunted condition, from which it takes a considerable portion of the spring to get them out. Another advantage, when enough warmth is used, is that some or other of the kinds may be had in flower almost all the year round. They strike freely from cuttings taken off at any time of the year when young, half-ripened wood can be obtained. I prefer the strongest cuttings that can be got, as they make plants much quicker than weaker ones. Take them off at the latter end of February or beginning of March, and insert them singly in small pots, drained, and filled with sandy peat, the remaining portion being pure sand; they may be placed in bottom-heat if the temperature of the house be not kept sufficiently high at night, otherwise it is not necessary. Keep them moist and covered with a bell-glass, and they will strike in a few weeks; then inure them to the air of the house. As soon as the little pots are fairly furnished with roots shift them into others 4 in. larger, using the best fibrous peat, with a moderate quantity of sand added, but no leaf-mould or manure, which for this and the majority of other plants of a similar character is a mistake, as both decompose too rapidly, getting into a pasty condition. Manurial elements can always be supplied in a liquid state during the period of active growth when the pots have got full of roots, at which time they are most wanted. As soon as growth has fairly commenced pinch out the points, to induce them to break back, and keep them near the light with little or no shade. The atmosphere should be kept moist, with never so much external air admitted as will make it too dry, not even in the hottest parts of the day; for this reason, it is well to keep these, along with a few of the most heat-requiring subjects, at the warmest end of the house, giving the greater portion of the air needed at the opposite end. The temperature from the beginning of May throughout the summer months should run from  $70^{\circ}$  to  $76^{\circ}$  at night, with  $5^{\circ}$  more by day in dull weather, and  $5^{\circ}$  or  $10^{\circ}$  above this when it is sunny will be rather an advantage than otherwise. For some time after the house is shut up in the afternoons during bright weather the temperature may rise to  $95^{\circ}$ , or even a few degrees more will do no harm, providing the plants are grown in a good light house, and kept near the glass. After root-growth fairly commences the plants must be always well supplied with water; never at any time, even during winter, should they be allowed to get so dry as some plants need to be. Continue to treat them as just directed, with a

liberal use of the syringe until the end of August. The treatment now must be based upon the temperature that can be maintained through the winter; where sufficient heat can be kept up, the plants may be at once moved into pots 6 in. larger than those they occupy, tying out the shoots, so as to give enough room to the young growths that in healthy, vigorous plants are always being pushed up from near the base. Syringe now more slightly, and, at the same time, a little more air, with a somewhat drier atmosphere, will be requisite for the general stock in the house; but the dry condition of the atmosphere that used to be at one time considered necessary through the autumn and winter for these and most other stove plants is simply wrong. As solar heat decreases reduce the temperature, but it should be kept up as near to  $70^{\circ}$  at night as possible, with a rise of  $5^{\circ}$  in the daytime. In this the plants will keep on growing slowly through the winter, and with the increased warmth of spring will commence to push away freely. Any shoots that appear to be taking an undue lead may be stopped back. By the end of March plants that were not potted in the autumn should receive a shift more or less in accordance with the plentiful or otherwise condition of the roots. By the beginning of May the autumn-moved plants will also need larger pots, using the soil, now in a rough, lumpy state and as full of fibre as it can be had, with a fair mixture of sand.

*Ixoras* are naturally such free flowerers that they will bloom whilst small, in which state they are very useful for the decoration of the stove; if they have been kept, as suggested, sufficiently warm through the winter, they will be in flower during the latter part of May and the beginning of June. As a matter of course, the temperature will have been raised, as in the preceding year, and other details of cultivation, as then recommended, carried out. There is no necessity to cease syringing whilst the flower-buds are advancing or when the plants are in bloom, provided the operation be carried out early enough in the afternoon to allow of the moisture to dry up before nightfall, otherwise it will sometimes cause the unexpanded bloom-buds to drop off. After flowering the shoots may be shortened back more or less as may seem to be necessary in order to preserve the symmetrical form of the plants, but if cut in considerably it will be late in the autumn before they flower again; whereas, if the decayed trusses of bloom be only just pinched out shoots will be emitted from the sources from which these spring that will make a short growth and then flower, after which any strong growths that require it may be shortened back. Winter the plants as before, and in the spring give additional pot-room as needed. The treatment from this point will be of a routine character as hitherto recommended. When the plants have grown as large as is required, they need not be potted oftener than once in two years. In potting remove as much of the soil from the upper portion of the balls as can be got away without too much disturbance of the roots, returning them to the same pots or larger ones if requisite. A large-sized specimen will require a pot 18 in. or 20 in. in diameter. To facilitate their blooming early in spring, say by the beginning of May, whatever potting has to be done it will now be better to carry out about the beginning or middle of September, which will give time for the roots to get established in the new soil before winter. About a month or so previous to potting any cutting in that may be required should be effected. They will bear a free use of the knife, even to the extent of reducing them one-half their size. This has the effect of promoting the growth of strong shoots, which produce the finest heads of flowers, and are much better than numbers of little blooms borne by plants allowed to get too large and to be full of weak growths. Managed as described, *Ixoras* will go on for almost an indefinite period. I have cultivated individual plants for twenty years, and have had them as strong and vigorous then as during the earlier portion of their existence.

*I. coccinea*, from Eastern India, is a magnificent species, and one which bears freely very large heads, when well managed, of scarlet flowers. Its foliage and habit are also unexceptionable.

*I. salicifolia*.—This comes from Borneo. Its flower trusses are large, but somewhat thinner than those of the preceding, and they are orange-scarlet in colour; the leaves, as its name implies, are of a long Willow-like shape. It generally succeeds better when grafted

than on its own roots, the best stock I have found for it being *I. javanica*.

**I. alba.**—A white-flowered species from India, handsome and distinct, but not so free a grower as the others.

**I. Griffithi.**—This is a large-leaved, erect-growing species from Singapore, with thick leathery leaves, and yellowish-red flowers.

**I. amboynensis.**—A very fine species introduced from Amboyna, a good grower and free bloomer, bearing a profusion of large orange-yellow heads. It is of a bushy, broad-spreading habit. Young specimens of this variety are preferable to old plants.

**I. javanica.**—This is the freest grower of any which I have cultivated, and it is equally free in flowering, bearing a profusion of orange yellow trusses that open almost simultaneously. It does not flower so freely for some time after being severely cut in as the other kinds.

The following, which I believe are all garden hybrids, are most beautiful, free-flowering kinds, viz. :—

**I. Williamsi.**—This has fine, dark green foliage, is a good grower and free flowerer, producing a profusion of blossoms of a dark orange-red colour.

**I. amabilis.**—A strong, compact grower, with dark green leaves and very large flower-heads, dark orange in colour and produced freely.

**I. Colei.**—This has dark green, somewhat ovate leaves, and produces large, dense heads of white flowers in profusion.

**I. Prince of Orange.**—Another free-growing, fine orange-red-flowered variety.

**I. Dixiana.**—This also is a vigorous-growing and free-flowering hybrid, the flowers of which are salmony-orange in colour.

There are several other species and varieties in cultivation, but the above are the best and sufficient for all ordinary purposes.

*Ixoras* are very liable to the attacks of brown scale and mealy bug, which, if not either completely eradicated or kept well in check, entail a great deal of labour from the rapid way in which they increase consequent upon the strong heat which the plants require, and a natural partiality of the insects for them. I may here say that to do full justice to them, and to preserve their flowers in full beauty, they must be kept completely free from bug, as when it gets up into the young flower-heads its removal can never be effected without injuring the bloom. Repeated and thorough washings, dippings, or syringings in strong insecticide through September and October, when the plants are making less growth, if persisted in, will free them from this pest, and also destroy scale. If the latter reappears, washing and sponging at intervals through the season will keep it down. The humid atmosphere and continuous syringing through the season of growth will be sufficient to keep down red spider, and will also check green fly and thrips, but, should these make their appearance, fumigation must be resorted to.

T. BAINES.

*Southgate.*

#### HOW TO IMPROVE THE CINERARIA.

Of all plants grown for general decorative purposes *Cinerarias* are unquestionably the most useful, and more particularly is this the case as regards amateur cultivators who have only a limited amount of house room, as the *Cineraria* is a plant that does exceedingly well in pits and frames. Indeed, if these be of that substantial character which they usually are when built with bricks, no better place can be had for growing them; and if a single hot-water pipe happens to run along the front wall for the purpose of drying the atmosphere when necessary and to keep out frost, the situation will be perfect, and it will exactly meet all their requirements. Anyone, therefore, having the convenience of such a structure, will have one of the most perfect, not only for growing *Cinerarias*, but also many other plants for keeping a greenhouse gay during the winter and early spring months, as the same temperature will just suit *Cyclamens*, *Lachenalias*, *Libonias*, *Eupatoriums*, and a host of such plants that come in about the same time, but which, until they get into bloom, are not easy to manage among others, where they have to stand far from the glass and are crowded for room.

Valuable as *Cinerarias* are at this season, they are doubly so at or soon after Christmas, at which time they may be easily had by sowing seed at once and growing the plants on during the summer in a cool, shady retreat, so as to keep them free from the attacks of red spider. The best way of raising them is to fill pans with light, rich soil, consisting principally of leaf-mould or peat finely sifted and pressed down level and smooth. Before sowing, however, this should be watered through a fine-rosed pot, and then allowed to stand and drain for a night or so to get rid of the surplus moisture. Seed of such a delicate nature as that of the *Cineraria* should never be watered till the young plants are found to be peeping through the soil, and the necessity for this may be obviated by covering the pans with a sheet of glass and laying a little Moss or a piece of brown paper over that, so as to shut out the light and sun; but, in all cases in which this is done, much watchfulness is needed to remove these coverings directly the young plants make their appearance, as a day's confinement in the dark will be sufficient to draw them up to that degree as to weaken them very considerably. In order to facilitate the banding and pricking off, as well as to prevent the plants from becoming etiolated from being too near each other, the seed should be sown thinly and slightly covered with silver sand and fine soil in about equal proportions, and if then placed where it can get a gentle moist heat, the young plants will soon be through, after which a shady place near the front of a hotbed or the back shelf of a forcing house is the best place till they are large enough to pot off singly, and when this is done they may be transferred to any cool frame where they can be kept close for a short time to give them a start. Although *Cinerarias* will grow in almost any kind of soil, they delight in that which is rich and light; and if a mixture of about equal parts of loam and leaf-mould, together with a little decomposed cow manure, be afforded them, they will be found to flower stronger and better than in anything else. A pinch of soot at the bottom of the pot, or a little mixed up in the soil, is a great help to keep them in health and add to the size and deep green colour of the foliage, besides which, being disagreeable to worms, it is desirable on that account. During summer we select a shady site for them near a building or where a large tree casts a shadow; on this spot we place a three-light box, and then put in 3 in. or 4 in. of coal-ashes to form a firm bottom for the pots to stand on. A situation of this kind is always better than a more open one, as the shade is natural to them, and they get more light than could be had if the sun's rays have to be screened by mats or other means, and it often occurs when these are used that they are not on when most wanted, or that they remain on long after they ought to have been removed, thus damaging the plants by causing the leaves to come thin and flimsy. In a naturally shady position there is no fear of this, and they may be grown much more successfully with far less labour and attention than they require anywhere else. The same remarks apply to Chinese *Primulas*, which, during the summer months, should be grown and treated in a similar manner. An important point with both is to surround them with an atmosphere saturated with moisture, and this may be secured by copious syringings overhead, or gentle watering through a fine-rosed pot every afternoon before closing. These repeated applications will saturate the ground under them, and keep it in that desirable condition throughout; and if this be done, the growth of the plants will be rapid, and there will be no difficulty in maintaining them in the most perfect health, provided they are shifted on from time to time as they require more pot room. This is one of the most important matters in the cultivation of *Cinerarias*, for if they be allowed to remain stunted from want of root room till the flowering period arrives, or suffer from an inadequate supply of water, they are never so fine or have anything like the sized leaves and quantity of bloom they otherwise would have. The great thing with these, as with all other so-called soft-wooded plants, is to keep them growing right on without a single check, so as to insure a full and free development of foliage, without which they can never be regarded with satisfaction.

Besides being subject to red spider, *Cinerarias* are likewise liable to attacks of mildew and green fly, the latter of which is frequently troublesome, and can only be destroyed by

repeated fumigations with Tobacco. This is a work that requires great care, as no plants are more easily injured by overdoses than Cinerarias, and therefore the fumigations should only be light at one time, but repeated again and again after a few hours' interval till the insects are dead. From want of caution, and not using it in this way, I have seen a whole year's labour and attention lost, and no doubt this has been the experience of many, both as regards Cinerarias or other plants, as few escape such mishaps at some time or other, especially if Tobacco paper be burned instead of the genuine article.

The sportive tendencies of Cinerarias are so great that there is sure to be a marked difference in the quality and size of the flowers of a batch of seedlings; and as most of last year's plants are now in bloom, it is a good plan to go over them and pick out any that show special merit, in order that they may be placed somewhere apart from the rest, as it is only by thus isolating them that they can be kept pure, or any improvement effected. In cases where it is desired to perpetuate any particular kind and increase the stock, it may easily be done by saving the plant, which after it has done flowering should be turned out of the pot and plunged in leaf-soil in a cold frame, where, if kept duly syringed and attended to, it will soon send up a quantity of suckers around the base. These form the future plants, and should be taken off as soon as they have made sufficient root to support themselves. They should be potted singly in 3-in. pots, and afterwards treated precisely the same as seedlings. Years ago few of the latter were grown, and even the named varieties of that time would now be thought little of, so great has been the improvement that has taken place in these popular flowers. It is no uncommon thing at the present day to see them with broad thick petals overlapping each other forming individual blooms larger than a two-shilling piece—a striking advance compared with what they used to be. The new race of doubles that caused such a stir have disappointed many; but, considering what has been done with Cinerarias during the last quarter of a century, there is reason to hope that we have not yet reached the limit to which they may be brought. All progress, however, must be made by seeding from the very best, and no other, and if this be done constantly we may look for still better results. S. D.

#### PERFECT DARKNESS NOT NECESSARY FOR PRODUCING WHITE LILAC.

I EXTRACT the following particulars respecting the production of the white variety of the coloured Lilac from an interesting article by M. A. Lavallée, Secretary-General of the Société Centrale d'Horticulture de France, published in a recent number of the Society's journal.—In December, 1876, M. Lavallée laid before the Society several branches of the Red Marly Lilac with perfectly white flowers, and at several subsequent meetings he exhibited similar specimens, all of them produced upon a system differing from that generally adopted. The most usual method of obtaining the artificial white Lilac is to grow the plants in a greenhouse from which every ray of light has been carefully excluded, but M. Lavallée has proved, by repeated experiments, that absolute darkness is not essential for producing the white flowers. The effect of darkness, perfect or partial, on the plants is due to the well-known principle of vegetable physiology, according to which the colouring matter of leaves known to chemists as chlorophyll—itsself, by the way, being a mixture of variously-coloured constituents—can only be perfectly developed under the influence of light. This principle has long received valuable application in the blanching of Seakale, Celery, Endive, Asparagus, &c., but it is only lately that it has been applied to the bleaching of flowers, and, as far as I know, in the case of the Lilac only. M. Lavallée goes on to point out the needlessness of growing the plants in perfect darkness, and observes that the mistake which horticulturists have made has arisen from the fact of their having confounded two distinct notions; the one being that leaves grown in darkness are pale in colour, the other the absence of colour in flowers in which the colouring principle has never been developed, and which therefore remain white. According to M. Lavallée, specimens of the artificial white Lilac were first exhibited to the Society by M. Laurent in 1860. These specimens excited a great deal of interest and surprise amongst the members of the Society at the time, and a commission was appointed to investigate the means by which M. Laurent succeeded in obtaining such beautiful results. M. Laurent's mode of procedure was found to be very simple. It consisted in

forcing the plants in a hothouse heated to 80° Fahr., and kept in a perfect state of darkness. M. Laurent, however, allowed that it was not impossible now and then to obtain white flowers on plants grown in broad daylight. At the same time the commission reported on the results obtained by another Paris gardener, M. Berthelot, who was also engaged in forcing Lilacs, who produced the same effect in the full light of day, using for the purpose a well-lighted house, heated to a high temperature. From this fact M. Duchastre, who acted as reporter to the commission, concluded that heat as well as absence of light was capable of preventing the formation of the colouring matter in the petals of the Lilac. M. Lavallée has thoroughly tested both these totally different methods of arriving at the same result, and has succeeded in obtaining perfectly white flowers in both cases. He is decidedly of opinion, however, that white Lilacs, grown in an ordinary well-lighted house, give thicker and larger bunches of flowers, and which last a longer time than when M. Laurent's method is employed, and that, finally, the open daylight mode of culture requires much less care and attention. Some 9 ft. or 10 ft. of a frame in a Dutch greenhouse were devoted by M. Lavallée to this experiment, the Lilac plants being planted perpendicularly, so that their buds were within from 8 in. to 1 ft. of the glass. They were then left to themselves for nearly three weeks, the house being kept at a temperature of from 68° to 72°. At the end of this time the Marly Lilac was in full bloom, while the Charles X. variety did not blossom until four or five days after. It has been stated that the last-named beautiful variety could not be forced, but M. Lavallée has proved this to be a mistake. It seems, however, that in the early part of the season it does not always come to perfection, the plants placed in the forcing house by M. Lavallée in November having failed to flower; but after the beginning of December it is the best variety for forcing. Two specimens of the Charles X. variety were shown by M. Lavallée, both of which were grown in the light, but under different conditions of temperature. The first one, which had pale lilac flowers, was placed in a house heated to a temperature of 68° Fahr. on December 23, 1876, to force its growth. At the end of four or five days the flower-buds began to make their appearance, and it was transferred to a cool house, the mean temperature of which was 40° Fahr. The flowers began to open about January 10, and were of a pale lilac. The shade of colour having been carefully noted, M. Lavallée replaced the plant in the forcing house, which was now at a temperature of 70° Fahr., in order to see if the heat would have the effect of destroying the small amount of colouring matter already formed; but not the slightest change took place, the flowers preserving exactly the same tint. The second specimen had perfectly white flowers, and was put in a well-lighted forcing house on December 30, where it remained until it was exhibited to the Society. Two specimens of the Marly Lilac, with equally white flowers, were also shown. They were grown in a well-lighted forcing house at a temperature of 72° Fahr. To vary the experiment, several plants which had produced pale lilac blossoms in a cool house were transferred to a perfectly dark forcing house, but without the slightest change taking place in their colour. From these experiments we may draw the following conclusion—that a prolonged heat of from 68° to 72° Fahr. prevents the formation of the colouring matter in the petals of the Lilac, but that when once it has been formed, this temperature is incapable of destroying it, and that a temperature of 40° Fahr. has no influence on the colouring matter of the flowers of these plants. M. Lavallée therefore supposes that it is on account of the rapidity of their growth in the forcing houses that these Lilacs produce colourless flowers, and that darkness has nothing whatever to do with the phenomenon; and that when the Lilac is forced into blossom in fourteen, fifteen, or even twenty days, the colouring principle has not sufficient time to develop itself. Whenever, therefore, we wish to obtain Lilacs with white flowers, all we have to do is to place the plants in a forcing house, the temperature of which is kept at 68° Fahr., without seeking the aid of the powers of darkness. This method of producing artificial white Lilacs is extensively practised by the country people in the neighbourhood of Antwerp. They simply plant the common Lilac in tubs at the proper season, and place them in their living rooms close by their stoves, which are never allowed to go out. The plants flower well, the flowers being always perfectly white. The same result is obtained by cutting off the flowering branches at an early stage, placing their extremities in a bottle of water, and keeping them in a forcing house or in a well-warmed room.

It has been said that when the Persian Lilac is grown in a forcing house it will not yield colourless flowers like its congeners, but M. Lavallée has obtained identical results with this species. He attributes the want of success which has hitherto been met with is due to the fact that this Lilac is of very rapid growth, and that a lower temperature, say from 60° to 64° Fahr., is sufficient to make it pro-

duce colourless flowers, which would not resist a greater degree of heat. These very philosophical conducted experiments have been repeated by several members of the Society, who have borne witness to the correctness of M. Lavallée's results. We may, therefore, conclude that a certain degree of heat by accelerating vegetation prevents the colouring matter from being formed in the petals. M. Lavallée's experiments open up a wide field for practical research in this direction. It would be interesting to know if other flowers submitted to similar treatment would yield colourless blossoms. Be this as it may, M. Lavallée's experiments are of the highest interest to the practical gardener, the scientific chemist, and the vegetable physiologist.

C. W. QUIN.

## RHIPSALIS FUNALIS.

This comes from Brazil and the West Indies, and therefore requires to be grown in a stove. It is naturally an epiphyte; consequently it makes a good basket plant; but the flowers are so small that it is not likely to receive much notice, except from amateurs, who might

Rhipsalis funalis.

like to grow it as a curiosity. Its flowers burst through the epidermis in all sorts of places, and its fruit bears considerable resemblance to that of the Mistletoe.

J. CROUCHER.

Sudbury House, Hammersmith.

## ADVANCES AMONG PRIMULAS.

THAT there is a marked improvement going forward in the Chinese Primrose will be evident to those who have seen the grand forms which have been exhibited of late years. The many superb double varieties, of which that which we recently figured is one, show a very decided advance; for useful as is the old double form, the newer ones far surpass it in quality. But this is not the only direction in which progress is to be observed. The single-flowered sorts have been perhaps even more improved in size, in substance, and in colouring. A batch of these has recently come before us, and in them we find these important qualities to be specially well marked. We refer to some choice forms which have been bred by Mr. Tomkins (Sparkhill

Nursery, Birmingham), and of which we propose to specially notice four, namely, two white-flowered and two bright red varieties. Of the white, the best known is that called Princess Louise, previously known as Marchioness of Lorne. This is a large pure white of remarkable substance and boldness of character, with a well-marked yellowish spot, and perfectly flat. It has foliage of the typical palmatifid type. A newer variety called Monarch is larger than this, but equally pure, equally stout, and considerably more frilled, so that it is scarcely so symmetrical, but is nevertheless a bold and striking flower of great endurance. This has a bold and yellowish eye  $\frac{2}{3}$  in. across, and differs essentially in having the more novel Fern-like foliage characteristic of some of the sports. Of the carmine-red sorts just referred to, both are far in advance of anything yet in general cultivation. In size the flowers vie with the largest, in substance they compare favourably with the stoutest, while in colour nothing approaches them for brilliancy of hue. They belong to the group which originated in kermesina, the colour of whose flowers may be described as carmine-rose. The brightest of these is Scarlet King, which has flowers of a particularly brilliant tint, with yellow eye, and associated with the old-fashioned palmatifid leaves, while Sunrise, which is a Fern-leaved sort, scarcely falls behind this in the delicacy of its rosy-salmon colouring. These grand varieties, it is said, come true from seed. Another near approach to scarlet has been raised at Chiswick, from seeds of M. Vilmorin's strain. The system of culture practised at the Sparkhill Nurseries has been thus described:—The compost used is a mixture of burnt earth, stiff loam, old mortar, charcoal, very rotten cow manure, and leaf-soil, well mixed together, the roots having a great liking for the pieces of mortar and charcoal; this compost does not necessitate much drainage, as it is sufficiently porous in itself. The crown of the plant is kept low down in the soil in potting, as from this part are thrown out many surface-roots, which add much to their vigour. Seeds are sown at intervals from March until May, so as to insure a succession, the earliest batch furnishing the earliest bloom. Cuttings of special sorts are struck in the spring in a gentle bottom-heat. The plants are grown in a low, span-roofed house, with ventilation at the sides as well as at the top, and in brilliant weather the light is subdued by a little shading, too much exposure being avoided. Careful watering is essential, and tepid water is always used, watering over the foliage until the plants begin to flower. Liquid manure is used most carefully, for the roots are so sensitive that mischief is soon done from an overdose; it is, however, used frequently, but in a very weak state, and always in a tepid condition.—"Florist."

## STRIKING CUTTINGS IN WATER.

M. E. BOURDEAUX, of Vandrenil (Eure), has lately laid before the French Société Centrale d'Horticulture an account of his method of striking cuttings of Crotons, Cissus, Gloxinias, Achimenes, Dracænas, Ficus, Begonias, and other hothouse plants in water. It has long been known that Vine cuttings might be struck in water, but it has remained for M. Bourdeaux to apply this method to the plants we have named. M. Bourdeaux chooses the months of July and August for the operation. The slips are placed in bell-glasses turned upside down and filled with water. The bell glasses should be sunk in a cool frame, the glass of which has been whitewashed, in order to moderate the intensity of the sun's heat. The slips are cut about the beginning of August, and will be found to have struck perfectly about the end of that month. The frame in which the bell-glasses are placed should be warm enough to maintain the water at a temperature of from 70° to 85° Fahr. It is of great importance that these cuttings should not be sunk deeper in the water than about  $\frac{3}{4}$  in., otherwise they are apt to become rotten. To keep them in their proper positions they must be loosely fixed in a round piece of thin board of nearly the same size as the bell-glass. A wooden frame may be used for the same purpose. Vine cuttings struck in this way may be transferred to pots, and within a month of the time they were first put into the water, that is to say, as soon as ever the rootlets are properly developed. They are then placed under a frame until they have become well established. They may be sent into the market a few weeks after. M. Marx, a horticulturist at Notre Dame de Vandrenil, who is a great admirer and grower of the best sorts of Vines, more especially those which are most suitable for the soil and climate of Normandy, possesses the collection made by Dr. Houdebine, M. Bourdeaux taught M. Marx his method of propagation, and M. Marx promises to deliver during the coming autumn specimens of the 200 varieties of the Vine which he possesses, perfectly well struck in 2-in. and 3-in. pots, on very low terms. This method of propagation has the additional advantage of causing the Vines grown by it to fruit much earlier. Crotons and Cissus which were struck from herbaceous cuttings gave the best results. Gloxinias, too, which were struck from leaves formed in the course of a month such strong tubercles, that they

could be potted off and sent into the market. The Achimenes also struck well and grew rapidly in the water. The ease with which Ficuses, Dracaenas, and Begonias are multiplied by this method confirms M. Bourdeaux in his idea that a large number of hothouse plants may be propagated by this means with the greatest certainty.

C. W. QUIN.

**"GEHENNA," A NEW INSECT DESTROYER.**

UNDER the above name I received a small bottle of mixture for destroying fly, thrips, spider, mealy bug, &c. After having tried it on various subjects, I feel convinced that it will, if carefully applied according to the directions, destroy any kind of insect without injury to the plants, although the fact of its requiring to be syringed off after the lapse of a certain period denotes that there is some risk of injury to tender subjects. This is rather the rule than the exception with most of the remedies already before the public for a similar purpose, and I feel little hesitation in affirming that no part of a cultivator's duties requires greater care than that of keeping down insect pests, for if even the best of existing remedies be not applied with discretion they may prove worse than the disease. While the fully-developed foliage of some plants will bear with impunity the maximum strength of the solution, the young tender leaves of even the same plant may be seriously injured by a diluted application of the same remedy. I may mention such subjects as Gesneras, Cinerarias, and most rough or woolly-leaved plants as being particularly liable to injury from the difficulty of thoroughly washing off the solution, while smooth-leaved plants, such as Crotons, Dracaenas, &c., will, if the foliage be pretty well matured, withstand a strong application, as, from the nature of the leaves, they are readily cleansed by syringing. These powerful solutions are of great service for the winter-dressing of Vines, Peach trees, and other deciduous plants at rest, as they may be applied to well-ripened wood in a state strong enough to destroy any kind of insect life. Plants of a hard-wooded nature that are much infested with thrips or scale may be cut into shapely specimens and thoroughly cleansed when divested of foliage, after which the young growth may be kept tolerably clean. It must not, however, be supposed that even the very best of remedies completely eradicate insect pests at the first application if they are at all numerous, for some will be almost certain to escape uninjured; and as their reproductive power is marvellously rapid, and the eggs of some kinds are not easily destroyed, a second or even third application may be necessary to entirely get rid of them. Perseverance is the only thing that will effectually overcome the most obstinate attacks; if only moderate success is to be attained in plant or fruit culture the plants must be kept clean, otherwise they will reflect little credit on anyone concerned in their culture. For fly of various descriptions fumingating is the most expeditious remedy in houses; but in small collections of plants in windows a remedy in a liquid form, which can be readily applied with a small syringe, will be of great value to amateurs.

Henham.

JAMES GROOM.

**Primula purpurea as a Table Plant at Night.**—A few evenings ago I introduced this beautiful hardy Primula to the table after the gas was lighted, and the effect was most striking, for the clear mauve-purple of the blossoms, so perceptible by day, appeared at night to be of a charming pink hue. A plant with the leaves pretty well developed, and having five or six flower-stems, is by no means an ungainly object on the table. There is a tendency now-a-days to make certain plants, such as Palms, Crotons, Ferns, Dracaenas, &c., the regulation plants for the table, and any departure from these is regarded as a breach of good taste. But there is no reason why any charming plant should not be utilised for the purpose, and I confidently commend to the notice of plant cultivators the subject that heads this paper.—D.

**NOTES AND QUESTIONS ON THE INDOOR GARDEN.**

**Salvia splendens compacta alba.**—This is an exact counterpart of *S. splendens compacta* in habit and foliage; the flowers are pure white, and when intermixed with the scarlet variety, have a charming effect. It is comparatively new, and as yet but little known.—R. H. B.

**Azalea imbricata.**—This may now be found in flower in several of the London nurseries. It is one of the most beautiful double kinds yet produced; the flowers are white, spotted with delicate bluish, and last a long time in perfection. This variety cannot fail to find a place in every collection of greenhouse plants.

**Anthurium variegatum.**—This plant is well worth growing for furnishing small vases or for conservatory decoration. It was introduced from the Cape of Good Hope. It is of a hardy character, and in variegation and habit closely resembles *Pandanus Veitchii*. It is, however, much more easily cultivated, and its foliage never fails to assume a bright grassy green colour, beautifully striped and margined with creamy white.

**GARDEN BOTANY.**

(Continued from p. 289.)

**GERMINATION OF DICOTYLEDONS.**—In dicotyledons the cotyledons or seed-leaves are usually so different, as to be easily distinguished from the leaves which follow (fig. 89), but they are not in all cases visible on the seedling plant growing in the ground. There are two essentially different kinds of germina-

Fig. 89.—Germinating seed of Bean, one cotyledon or seed-leaf removed, showing the first true leaves.

tion of dicotyledonous seeds connected, it is true, by intermediate nodes. In the one case the cotyledons remain enclosed within the seed, and the seed itself continues underground or close to the surface. This kind of germination is called hypogæus or underground germination, and is, perhaps, confined to

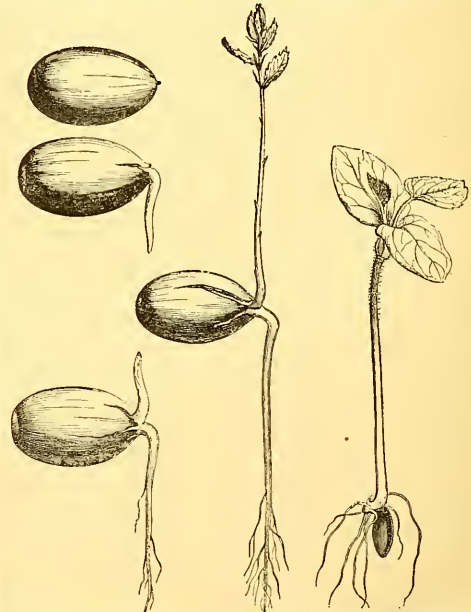

Fig. 90.—Acorns in various stages of germination. The cotyledons remain enclosed in the seed and pericarp; radicle strongly developed into a tap root.

Fig. 91.—Seedling of Melon in germination; radicle above ground; radicle shrivels and dies away early, and is replaced by a cluster of roots.

exalbuminous seeds with thick cotyledons, though some of this class of seeds are not hypogæus in germination. A good example of hypogæus germination is afforded by the Oak (fig. 90). At that end of the seed (here fruit) where the junction of the cotyledons is, the radicle first appears and takes a downward direction, and soon afterwards the plumule begins to grow. In the other kind of germination the cotyledons are

withdrawn from the seed, appear above ground, and usually change to green, as in the Cucumber, Melon (fig. 91), Cress, &c. This is termed epigeus or aboveground germination. In epigeus germination the testa may be left underground, as in the Melon, or it may be borne aloft and finally cast off by the cotyledons aboveground. In dicotyledons, as in monocotyledons, the radicle or primary root is often little developed, and soon replaced by numerous lateral rootlets. It has been explained that the embryo presents various modifications in its development. Sometimes the cotyledons are very large and the radicle very small, and more rarely the radicle is very large, and the cotyledons minute or altogether suppressed. In the *Guttifera* or *Clusiaceae* these two extreme modifications are characteristic of different tribes and genera. The seeds are exalbuminous, consequently the embryo fills the seed; and when the cotyledons are large, they usually cohere or grow together by their faces, so that in germination the plumule and radicle appear much as in the Oak (fig. 90). In the genus *Garcinia* (fig. 92) the embryo consists of a thick radicle, filling nearly the whole cavity of the seed, and surmounted by a

Fig. 92.—Seedling *Garcinia*. Radicle projecting from one end of the seed, and a plantlet, which has formed an adventitious root, is produced from the other.

rudimentary plumule without any trace of cotyledons. The exact nature of this embryo is easiest determined in germination, when the radicle emerges at one end of the seed, and at the opposite extremity the plumule appears. Then commences the most singular growth. The true radicle soon perishes; to replace which the plumule emits a root, or roots, at its base, whilst its apex elongates into a stem. In the place of cotyledons, the stem below the first pair of ordinary leaves is furnished with a number of scale-like appendages. Another curious kind of germination is that of *Nepenthes*. The seeds are very small, and the testa is relatively very much elongated into membranous tails, and the minute embryo lies in the midst of albumen. It is an almost universal rule that the radicle or primary root is the part to elongate and protrude first from the seed, but in *Nepenthes* it often happens that the plumule precedes the radicle, emerging on one side of the seed and unfolding one or two leaves besides the cotyledons before the radicle pierces the other side of the seed. Some dicotyledonous seeds germinate after the same plan as Palms; that is to say, the upper parts of the cotyledons remain within the seed, and they elongate at the base by intercalary growth into long stalks (petioles), carrying with them the entire axis of the embryo. Frequently the petiolar portions cohere along their margins, forming a slender tube sometimes 2 in. or 3 in. or more in length. Eventually, after the tube has ceased to elongate, the radicle begins to grow from the lower extremity,

and the tube itself is burst open near the base by the enlarging plumule. This kind of germination has been observed in several *Ranunculaceae*, amongst others in *Eranthis hiemalis*, *Delphinium nudicaule*, *Anemone alpina*, and *Aconitum Anthora*; also in some *Umbelliferae*, as *Charophyllum bulbosum* and *Smyrniolum perfoliatum*. According to Mr. Magnus, a German botanist, sometimes in germination of this kind a period of rest intervenes between the outgrowth of the cotyledons and the development of the plumule. The latter does not grow out until the second year, after the tubular portion of the cotyledons has decayed, and no longer present any obstacle to its elongation. This, he states, is the manner in which seeds of *Aconitum Anthora*, *Eranthis hiemalis*, and *Smyrniolum perfoliatum* germinate. Quite recently Dr. Asa Gray recorded a similar mode of germination of a *Curcubitaceae* plant, *Megarhiza californica*, formerly in gardens under the name of *Echinocystis fabacea*. This plant has large seeds, and therefore the different stages of germination are more easily seen than in most of the other plants named. Numerous other curiosities in germination might be described, but enough on this point has already been said, it is to be hoped, to excite the interest of cultivators in this phase of plant life. Comparatively little of what is known of this subject by practical men has been put on record, and doubtless much still remains unknown.

**SEEDS RIPENING UNDERGROUND, &c.**—Whilst the majority of seeds appear to require all the sunlight and air they can obtain to attain maturity, there are some which normally ripen underground. *Trifolium subterraneum*, an annual species of Clover not uncommon in some parts of England, is a plant that ripens its seeds underground. After flowering, the heads, containing the pods and enlarged calyxes of barren flowers, burrow in the earth, where the seeds ripen and in due time germinate. *Arachis hypogea*, another member of the Pea family, which is very generally cultivated in tropical countries for its seeds, exhibits the same peculiarity. Indeed, it is asserted that if the pods are accidentally unable to thrust themselves into the ground, the seed never comes to perfection. It is no ordinary obstacle that would prevent them, as they are able to pierce the firmest soil and avoid small stones. *Geococcus pusillus*, a small plant belonging to the *Cruciferae*, discovered in West Australia by Drummond, also buries its pods in the ground, and there are several other authenticated instances. The ripening process of the seeds of *Colchicum* and *Crocus* deserves mentioning by way of contrast to that just described. In these plants the seed-vessel is formed below the surface of the soil and immediately on top of the bulb, and long after the flower has withered the seed-vessel appears above ground supported on a stalk, which grows out after the flowering season. The *Colchicum* flowers in the autumn, and its seed-vessels remain under ground all the winter, appearing above ground in the spring to perfect the maturation of the seeds. *Vallisneria* ripens its seeds under water.

#### The Root.

**DEFINITION.**—Following the development of a germinating seed into a perfect plant, we usually find that the body or axis of the embryo grows in two opposite directions; the radicle, or root end, growing downwards, and the plumule growing upwards, one being the basis of the root system of the plant, and the other the basis of the stem system, which bears the leaves and flowers. In young seedling plants there is no difficulty in distinguishing root and stem, whether the embryo gives birth to a single primary root, as the seeds of the Oak (fig. 92), or whether several rootlets are emitted at the same time, as in some Grasses, &c.; but the subsequent growth of many plants is such as to render it impossible to give any general definition of a root. The rule is that roots pierce the soil and avoid light, whilst stems seek light and avoid darkness by growing in the direction of the greatest light, as is the case with plants in a window. But it is not always so easy to distinguish between root formations and stem formations, because some stem formations are produced underground in darkness, and because certain stem formations and root formations are in external appearance very much alike. Indeed, there is no absolute difference in the nature and capabilities of stem and root, though there is in function, &c.;

but their functions may be arrested and their characteristic growths reversed by altering the conditions or influences to which they are subjected. It has already been stated that plants differ materially from animals in their capability of reproducing their like from almost any part of themselves. Thus in practice we propagate plants not only from seeds, but also from fragments of leaves (*Begonia*), of stem (*Cordylina*), branches (*Verbena*); and in each case the plants thus obtained usually possess all the attributes, or at least all the capabilities, of seedling plants. By subjecting these parts of plants to certain conditions we obtain such results. But the parts of plants are even more the result of conditions than would appear from this, for it is possible, with some plants, as just stated, to actually reverse the nature of root and stem. Duhamel bent down and buried in the earth the head of a young growing Willow tree, and in course of time the branches emitted roots, so that there was a plant with roots at both ends. This being the case, he dug up the original root-end, and raised it erect. The exposed branches of the root soon gave birth to buds, which developed into leafy branches. It is important to note that the roots were not themselves transformed into branches, nor the latter into roots, and that the experiment proves that conditions determine the nature of the outgrowths. Once a root, always a root, and once a stem, always a stem, though the growths that proceed from them depend upon circumstances. Furthermore, the normal roots of the Willow

are many singular exceptions. Roots differ, too, from stems in their mode of growth, elongating only by growth near the tips, not throughout the whole length of each season's growth. This kind of growth is manifestly better adapted to the medium in which roots usually grow. The tips of roots are guarded by a cap of loose tissue overlying the growing point, and this cap is renewed by growth from within.

W. HEMSLEY.

## GARDENING FOR THE WEEK.

### Indoor Plant Department.

**Pleione.**—These beautiful little plants are amongst the brightest and most distinct of all Orchids, and producing, as they do, a complete sheet of flowers almost all open on a plant at the same time, and not over-balanced by an excess of foliage, they are most effective. They increase fast if treated in accordance with their requirements. Some growers put them in a mixture of fibrous peat and turfy loam, mixed with sand and coarse, others use peat and leaf-mould, or leaf-mould added to peat and loam, with sometimes dry, shaly, rotten manure, and I have seen them do well in each of these mixtures, and also in peat alone. The handsome *P. humilis* may be said to be a true epiphyte, and will succeed well on a block with fibrous peat and Sphagnum in quantity sufficient to retain enough moisture to keep the roots wet when growing, and they should never be very dry. In addition to *P. humilis*, the kinds most usually grown are *P. maculata*, *P. lagenaria*, and *P. Wallichiana*; these are all from the cool, moist hill regions of India, which is sufficient to point conclusively to their requiring somewhat cool treatment, plentifully supplying them with water combined with abundance of light. Most of the species will now be making active growth, and, if properly treated, the result will be a profusion of bloom after their season of rest, and a yearly increase of three or fourfold.

**Oncidium Lanceanum.**—Anyone having a good stock of the best variety of this beautiful old plant possesses one of the very finest late summer-flowering Orchids in existence. Now, when the young growths are in course of formation, more care must be taken than is requisite with most species that water does not lodge in the expanding leaves, as they are more liable to suffer from moisture hanging about them than many plants.—T. B.

**Conservatory.**—At no time of the year should conservatories be better furnished with flowering plants than at present; nor is there a time when they should be more interesting, on account of the numbers and diversity of plants that can be had in bloom during this month. In addition to the last batch of Hyacinths, Tulips, Narcissus, and other bulbs, there will be forced Hydrangeas, Roses, Deutzias, double-flowering Plums, Spiræas, Lilacs, Epacrisæ, Cytisus, Azaleas, Cyclamens, Cinerarias, and Primulas. These afford so much variety as to admit of the most effective grouping, if tastefully arranged along with such foliage plants as are indispensable, such as Agaves, Yuccas, Dasylirions, Cordylines, Rhopalas, and Tree Ferns. Without these, whatever numbers and variety of blooming plants may be at command, the general effect will be unsatisfactory. Never crowd, even if more plants are at hand than are required, as it has a most injurious effect. The object should be to grow every plant, even the commonest, so that it will bear looking at individually. Attend well to *Fuchsias*, *Geraniums*, and *Calceolarias*, as these will be required to play a conspicuous part when early spring plants are over. Keep *Fuchsias* well stopped in, and encouraged with manure water as soon as their pots are filled with roots. Be careful not to use too strong, however, as when that is the case it does more harm than good. In tying *Geraniums*, use just sufficient sticks to support them, and no more, as soon as their flowers are formed, give them weak manure water once or twice a week; yet be careful never to give *Geraniums* too much water at any time, as they cannot bear nearly so much as many things. When *Achimenes* have made 6 in. of growth, pinch out their points, to induce them to break and grow stocky, and tie them out sufficiently open to allow the light to act on their bottom leaves, otherwise these will turn yellow and drop off. It is time now to make provision for next autumn and winter's display, by making a sowing of *Primula* and *Cineraria* seed; also by striking a batch of *Euphorbia jaquinoides*, *Hydrangeas*, and *Poinsettias*. Some experience difficulty in striking this *Euphorbia*; if the young shoots are taken off with a heel when from 4 in. to 6 in. long, and inserted in silver sand, in a moderate heat, covered with a bell glass, very few will fail; but if the cuttings are made from a joint in the ordinary way, the greater number will not succeed. Give attention to such plants as *Deutzias*, *Spiræas*, and similar things that have been forced; for if neglected now they will not flower satisfactorily next winter. It is the best practice to cut all the old wood out of the *Deutzias*, depending on young shoots from the base of the plant for next year's bloom.

### Flower Garden.

**Rose Borders.**—One of the most effective means of arranging Roses so as to bring the largest number under the eye at once when in flower is to plant a broad border on each side of a walk with full-sized standards at the back, i.e., furthest from the walk, with rows of half-standards next, followed by dwarfs, and those nearest the margins of the walks should be pegged down. One of the finest effects I have ever seen produced by Roses was the result of planting in this way. It was in the case of a walk

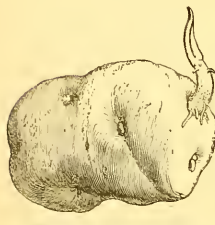

Fig. 93.—Tuber of Potato with one of the buds growing into a stem. The rootlets do not proceed from the tuber itself, but from the base of the stems which arise from it.

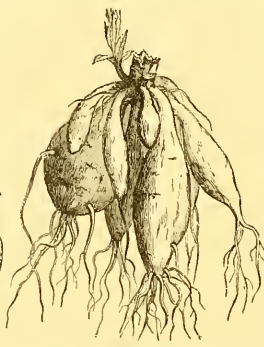

Fig. 94.—Tuberous root-stock of Dahlia, consisting of tubercles, which are tumefied roots, and the permanent base of the axis or stem from which the annual stems proceed.

and those proceeding from its buried branches are indistinguishable; and all roots, so long as they remain under suitable conditions, exhibit the same mode of growth and other characteristics. Thus root formations and underground stem formations may have some general resemblance, and bear the same popular name, as the tubers of the Potato and Dahlia (figs. 93 and 94); but a cursory examination will reveal important differences. Dahlia tubers are branches of a true root, termed a tuberous root, and known to be a root because buds appear only at the apex where the tubercles are connected, whereas buds are produced on no determinate part of the surface of a Potato tuber. There is the great difference between Dahlia tubercles and Potato tubers; the former are true roots held together by the perennial base of the stem, in which the buds of the annual stems originate; whilst the latter bear buds themselves, which, growing into stems, give birth to roots at their bases. In the one case we have tumefied or tuberised roots, and in the other tuberised stems. The distinctions are more fully described in the paragraphs on root stocks, tubers, and tubercles. True roots never produce buds unless brought under the influence of light, like the superficial roots of some trees and shrubs which throw up suckers. But not all roots form buds under the influence of light, nor will the shoots of all plants root if put into the ground. As a rule, the shoots of herbaceous and soft-wooded plants root much freer than hard-wooded shrubs and trees; but there

some 9 ft. or 10 ft. wide, and about 350 ft. in length, with 3-ft. Grass margins, flanked right and left by borders that admitted of five rows of plants in each. The front rows were planted 8 ft. from the Grass, and 3 ft. 6 in. asunder; the kinds used in these front rows consisted mostly of Teas, with some Noisettes and a few Moss varieties, all on their own roots, and they were kept pegged down close to the ground each spring when pruned. A space of 4 ft. intervened between these and the next row, which consisted one-half of Teas and Noisettes; the other half were Hybrid Perpetuals. These, also, were all on their own roots, and were allowed to grow in bush fashion sufficiently limited in size so as to rise gradually higher than the inner rows; in this second row the plants stood 4 ft. apart. The third row, which consisted of half-standards, were one-half Hybrid Perpetuals; the other half Noisettes and Bourbon Hybrids. The fourth row on each was composed of full-sized standards, mostly dark-coloured Hybrid Perpetuals, with some strong-growing, light-coloured Noisettes and a few Gloire de Dijon. These stood 5 ft. behind the preceding row, and the same distance apart in the row. At 6 ft. behind these was a row of pillar plants trained to strong iron supports 9 ft. high, with a stout wire attached to the top of each, and allowed to dip in the middle between the uprights in the usual festoon fashion. The kinds employed in this row were such as are generally used for similar purposes, and comprised the strongest-growing Hybrid Perpetuals with a striking habit, Noisettes, Bourbons, and Ayrals. These were not kept trained any closer than was necessary to prevent their being blown loose from the ironwork that upheld them. At a distance of some 9 ft. on the north side was a dense bank of shrubs sufficiently high to act as a background to the whole in a way that brought out the full effect of the blooms when in perfection, and served as a protection without too much confinement, a matter of such importance in the case of Roses that it should never be lost sight of. On the southern side at the back was a row of Hollies.

**Arrangement of Rose Borders.**—To avoid the too even formal descent from back to front in the case of the Roses that would otherwise have occurred, there were introduced into each of the three front rows on both sides at intervals a few taller plants that broke up the surface without any appreciable interference with a sight of the whole when in flower. The walk and borders slightly diverged from a direct line, which still further tended to prevent the formality inseparable from straight lines of plants running parallel with each other. The colours were so arranged as to secure much the greater proportion of light kinds in the front rows with a preponderance of darker shades at the back, but the rows furthest from the eye were sufficiently broken up by light kinds to do away with the objectionable effect often produced by continuous straight lines of any particular colour, as seen in ordinary modern formal arrangements. The walk was planned at each end by a light border and such of wire-work and trellis others of similar character were placed at intervals between these, covered with Roses, which still further helped to break up any appearance of formality. The whole arrangement was very much superior to that of the Rose gardens introduced in too much exposed places, where the plants on pillars and arches are too frequently seen struggling for existence against the adverse influences of wind, unbroken by any surrounding objects, yet, as is well known to all who have had only limited experience in Rose growing, they cannot bear to be much confined; still, on the other hand, they do not succeed when trained to any height if too much exposed. The season is now too far advanced to admit of an arrangement such as the above being carried out at present, but anyone purposing alterations in or additions to their Rose grounds, and possessing sufficient room and a suitable position will not be disappointed by adopting it, and more satisfactory results are generally arrived at by having sufficient time to consider the details. The advantages of such an arrangement are, that the bare stems of the standards and half-standards, never existing in appearance, and still less so when not in flower, are to a great extent hid by the plants gradually diminishing in height in front, with the increased breadth of foliage and flowers thus brought under the eye, without any sacrifice as regards the cultivation of the plants.

**Pruning Roses.**—In cold districts where Roses are yet unpruned the work should be completed at once. Those who have decided on the wise plan of deferring the pruning of a considerable portion of their plants until a later period than that chosen by the generality of growers will this season reap the advantage of their delay, in seeing their plants break right off into growth and bloom without check, whereas a good deal of the early pruned plants have their first shoots injured, or killed outright, and have to depend on a second effort which the plants will make, but which never results in flowers equal to those produced by the shoots that push first.

**Staking Roses.**—If not already done all standard and half-standard plants should be gone over, and where any broken or doubtful stakes exist they should be renewed. The whole stock ought to be retied every spring, and for this there is nothing better than good fair twine, and not low-priced inferior material that will give way before the wind as usual. The larger the heads the stouter the supports should be, and will be obvious from the greater hold the wind has on them.

**Labelling.**—Rose growers generally know most of the varieties which they grow by the wood and leaves even when not in flower; nevertheless, in every well-appointed garden each plant should be named, or half the pleasure derivable from seeing them when in flower is lost by those who are equally fond of Roses, but who do not know so much about them; consequently all that require it should have fresh labels attached to them. For ordinary cultivators I have found nothing better or neater in appearance than zinc labels written on with indelible ink.

**Shrubberies.**—In many gardens the shrubs are often met with in a most unsatisfactory state, in some instances never having been thinned out from the day they were first planted, and, where sufficient time has elapsed, it is no uncommon occurrence to find them all grown together in a thicket, instead of standing clear of each other, so as to allow every plant space to assume its natural habit of growth, and where they have not been allowed to encroach one on another; the equally objectionable practice of keeping them out in until the whole has much the appearance of a meadow covered with large haycocks. Now if, instead of this, there had been timely thinning carried out whilst the plants were not yet too large to move, the result would have been infinitely more satisfactory. If there is no use for the superfluous plants elsewhere, it is much better to destroy the least valuable. Where room shrubs, like the Holly, the Rhododendron, or the Aucuba are standing with a coarse-growing, common Laurel, the latter will encroach upon and shortly smother the whole. Hesitate not, therefore, to cut it out at once. It is better to have three good plants than four starvelings. Wherever the knife is required it should be used very sparingly, and only to reduce any straggling branches. Do not attempt any pruning that will destroy the natural habit of the plants, or at all tend to give them a formal appearance, for this is worse than allowing them to grow in what may be termed a wild state. Many varieties of shrubs that have been allowed to get into an unsightly condition by overcrowding may with advantage be headed down to within 2 ft. or so of the ground; common and Portugal Laurels especially will be much improved by this, and will soon form good heads.

**Ivy** on walls, covering arbours, or any similar structures should now be cut. This most useful of all plants for wall covering is very often neglected and allowed to grow from year to year until the accumulated weight of the shoots not actually attached to the wall is such that, with the force of the wind, the whole gets torn away, in which case there is very great difficulty afterwards in getting it to attach itself properly to the wall, which often necessitates the complete cutting away of the loosened portion, and until the denuded part of the wall gets clothed with fresh growth it has an unsightly appearance. Another advantage in yearly cutting the least valuable, which are not shrubs, is that they are all cleared away at once, and although the Ivy thus stripped of its leaves for a few weeks looks bare, still, when the work is done at this season just as growth is about to commence, it shortly becomes clothed with new foliage of the most beautiful green. The present is a good time for planting Ivy. It is sometimes thought that this most accommodating plant (which will grow in some way almost anywhere, except in situations where the soil is excessively wet) does not need the ground to be prepared for its reception, yet there is no plant that better repays liberal treatment with good soil and plenty of manure. If the soil be deficient add as much as will bring it up to 1 ft. in depth at least, to which dig 4 in. of good rotten manure. With suitable preparation Ivy will make more growth in a single season than it would in three seasons in poor, shallow soil. Where the space to be covered is limited in extent, I should recommend the use of plants that have been grown in pots, as those taken up from the open ground do not make nearly the progress the first season that those that have been kept in pots do; in which condition they are to be had in most nurseries often 6 ft. or 8 ft. in height, with several shoots each, and a fine display of foliage on over a considerable surface. When turned out of the pots disentangle the roots without breaking them more than is unavoidable, spread them out and cover with 3 in. or 4 in. of soil, treading it firm, at once nail the shoots into the position required. If the situation be inclined to be dry, as is often the case near walls, mulch the surface during the summer with 3 in. of rotten manure.

#### Indoor Fruit Department.

**Vineries.**—In early Vineries, where Grapes are beginning to colour, a good watering should be given to the border, if inside, mulching it over at the same time with some well decayed manure, so as to render additional watering unnecessary until the fruit is ripe. Continue the thinning of berries to the pinching of shoots, and the regulating of growth as occasion requires. Muscat Grapes in flower ought to have a temperature of 75° at night, and Hamburgs 5° less.

**Peach Houses.**—The earliest house of Peaches and Nectarines will now be nearly past the stoning process, when a rapid change takes place in the swelling of the fruit; but before this takes place it must be thinned if too thickly set, as no more will drop off. If the trees be in good health the fruit on them may be regulated from 8 in. to 10 in. apart at this last thinning. When it begins to colour air may be given freely, and the temperature may rise to 75° or 80° by sun-heat. Succession houses will want syringing daily, and attention must be paid to watering the inside border, for although the surface may look moist, underneath they may be as dry as dust. Tying down the shoots as they progress, and thinning them gradually where not wanted, keeping aphides and red spider in check will be routine work now for some time in the late houses.

**Figs.**—Keep these well watered and syringed daily. When the fruit begins to ripen watering must be gradually discontinued. Stop all shoots when 6 in. or 8 in. long, in order to encourage a second crop.

**Cherry House.**—The earliest forced Cherries will now bear a higher temperature, but plenty of air must be given in the daytime, to colour, and to give flavour to the fruit. The supply of water at the roots must likewise be lessened for that purpose.

**Cucumbers and Melons.**—Plenty of heat, together with light, air, and moisture, will now be required for Cucumbers and Melon plants, and the shoots must be regulated frequently, by stopping and pruning them, so as not to get too crowded. A steady bottom-heat must be

maintained to Melons till they flower, and after plenty of fruit is set liberal supplies of tepid water may be given to the roots. Sow good batches of seeds of both Cucumbers and Melons for a late supply of plants, and some of the ridge variety of Cucumber for planting out in the open air.

#### Hardy Fruit.

**Strawberries.**—These will now require attention. First go over them with the hoe, stirring the soil between the rows. If there be any small weeds it will destroy them, and if any of larger growth they must be removed. After this the Strawberries should at once receive their spring dressing of stable manure. That which has lain together a few weeks will be in the best order. This should be put on 2 in. thick, the whole of the ground between the plants being covered. The manurial portion will get washed in with the rains, the straw will be left quite clean, and in a condition for keeping the fruit from getting soiled with heavy rains. If applied at once, there is plenty of time for the straw to get thoroughly cleansed and sweetened by exposure to the weather. In this respect it will be just as good as the new straw that is sometimes

which is so essential to the maintenance of a healthy tilth. During mild showery weather slugs are sure to be troublesome, devouring, as they do, young vegetables, especially those in seed beds. To prevent their ravages, sprinkle with fresh air-slaked lime. The weather during the last three weeks or so has been favourable for cropping and seed-sowing; and now that "bright days have come again" these operations may be proceeded with. Should gaps appear amongst vegetable crops, they should be filled up from parts that are thickest, carefully preserving the roots and lifting with good balls, with a trowel. Most kinds of crops may be successfully transplanted when in a young state by using hand trowels; even tap-rooted plants, such as Parsnips, Beet, Parsley, &c., will withstand moving in this way whilst young, whilst pulling or taking up young plants, and dibbling them in with naked roots, will be found to be attended with little success.

**Sowing Broccoli, Lettuces, &c.**—A sowing should now be made of Broccoli for autumn and winter use; it is better to sow a little now, and again later on. It frequently happens that, in a very mild winter, the plants intended for late use come in earlier than they are wanted, leaving

River Scene: North-Western America.

placed on just before the fruit is ripe, and it has the advantage of acting as a mulch just at a time when it will benefit the crop and serve as a mulching, which prevents the undue evaporation from the soil of the moisture stored up during the winter, and of which these shallow surface-rooting plants stand so much in need whilst the crop is swelling. Nothing can be more unsuitable than the mulchings of Grass mowings sometimes used. These are naturally cold, in addition to which, whatever seeds are in them will germinate, filling the ground with Grass, which is much more difficult to deal with in a kitchen garden than annual weeds.

#### Kitchen Garden.

A golden rule to be kept in mind in reference to the kitchen garden is, to sow little, often, and thin. Thin out and otherwise attend to all growing crops. Trench every bit of ground as soon as it becomes vacant, casting it up rough with a strong steel fork. Where necessary, give it a good dressing with manure or other compost, thoroughly incorporating it with the soil, as the trenching progresses. Care must, however, be taken not to bring up too large a quantity of the subsoil to the surface; but it is of great importance to loosen it well every time at the bottom of the trenches. This allows water to run through it freely, and renders it pervious to air,

a blank which the second sowing will fill up. The following kinds will afford a succession—Backhouse's White, Snow's Winter White, and Williams' Alexandra; these, with Walcheren and Veitch's Autumn Giant Cauliflower, which two latter, with good management, will keep good till Christmas, will be found to last until late in the spring. Dress the seed, as previously advised, with red lead, to preserve them from birds, as a failure in this sowing of these important vegetables would cause a blank in the crop. A little more Lettuce should now be sown (Cos and Neapolitan Cabbage), as also small salads and Radishes; by sowing these successants a little at a time and often, a continuous supply may be relied upon, notwithstanding extreme dry or wet seasons, in a way that cannot be done where the sowings are made at longer intervals. Ground that has been occupied by Coleworts, &c., should, as it becomes vacant, be dug; if it requires trenching, bury the stalks and refuse leaves of the preceding crop in the bottom of the trench as the work proceeds. This is even better than removing it to the refuse heap, as it slowly decomposes in the ground, affording acceptable food for the roots of future crops. The dry cold weather we have had for some weeks has had the effect of bringing the soil into condition for cropping; where the land is heavy and retentive, that which was dug during the winter will be much benefited by

being again turned over with the digging fork previous to cropping; and the sun and air acting upon it, after being thus loosened up, will pulverise and render it much more suited to the requirements of the tender roots germinating seeds. When the land is thus brought into a fine tiller even the most hardy vegetable will progress in a way not possible when the soil is in a hard lumpy condition. Keep the hoe going in dry weather amongst existing crops of Cabbages, Winter Spinach, early Peas and Beans; the object ought to be not to allow a weed to get in, high, and they are destroyed with one-tenth the labour whilst thus small. Red Cabbage and autumn-sown Savoy should now be planted, and, as these are no better for being grown extra large, 18 in. apart in the rows, and 2 ft. asunder between the rows, will be sufficient space for them.

#### Extracts from my Diary.

April 8.—Sowing the following sorts of flower seeds, viz., Primulas, Cinerarias, Asters, Stocks, Mignonette, Heart's-ease, Polyanthus, and Nasturtium. Pottling Balsams, Petunias, and scented-leaved Pelargoniums. Removing bedding plants from Vineries to colder quarters. Cutting all the old flowering wood out of Deutzias so as to encourage the growth of young shoots. Planting a quantity of small Ashleaf Kidney Potatoes to produce seed for next year. Finished levelling down Celery trenches for Peas.

April 9.—Sowing Carters' Dwarf Crimson and Incomparable Dwarf White Celery in a frame for the main crop; also Spinach and Radishes. Pottling Caladiums, Achimenes, Chrysanthemums, and large Camellias. Putting in cuttings of Dahlias and Alternantheras. Planting out a four-light pit with Melons and three manure frames with Cucumbers, and earthing up those in a more forward state. Getting out trenches for two early rows of Scarlet Runner Beans. Clearing off Seakale beds and getting them forked up. Watering Mushroom beds with manure water.

April 10.—Sowing one row each of the following sorts of Peas, viz., Fortyfold, Giant Emerald Marrow, and Omega; also the following sorts of Broad Beans, viz., Johnson's Wonderful, Longpod, Seville Longpod, and Hardy's Pedigree Windsor. Putting Dragonas, Palms, and a few stove plants. Pricking off Perilla and Golden Prostrum. Clearing the litter from early Rhubarb, manuring the ground, and forking it in round the plants. Sending in the last Lady Downes and Mrs. Pince's Grapes.

April 11.—Sowing Canadian Wonder French Beans in pots; also in hot-water pits; also Osborn's Early Forcing French Beans under a south wall. Pottling off Alternantheras, Coleus, and Dahlias. Pricking out Celery in boxes; also from boxes into frames. Tying in shoots in the early Peach house, and thinning the fruit on trees where stoned. Giving early Vinery where the bunches are thinned a good soaking of guano water, and getting all vacant ground dug up.

April 12.—Vacant a collection of ornamental Grasses; also Mustard and Cress. Picking out Brussels Sprouts and Cauliflower plants in frames. Planting out spring-sown All the Year Round and Carters' Giant White Cos Lettuce. Getting all Broccoli into the store shed as fast as it becomes fit for use. Dutch-hoeing amongst Strawberries, Gooseberries, and Currants. Turning over gravel walks to give them a fresh appearance.

April 13.—Tying down young shoots in Vineries, and thinning the bunches where required. Cleaning off Broccoli stumps and other vegetable refuse, and getting manure on to the ground. Earthing up and sticking Peas. Getting nets put over Broccoli seeds to keep them from small birds. Mowing and cleaning up the pleasure grounds, and rolling down all gravel and turf that require it. Fruit in use for dessert: Pines, Grapes, Apples, and Strawberries. W. G. P., Dorset.

#### WATER MARGINS IN LANDSCAPE GARDENING.

Of the many weaknesses of landscape gardening in its efforts after natural effects there are few, as we have often pointed out in THE GARDEN, more evident and wholly unintelligible than the forming of the margins of artificial water. More than one landscape gardener of our acquaintance has complained to us of the difficulty of getting men to carry out this kind of work well. Admitting the truth of this, we nevertheless think that the real fault in this way is generally the want of observation and taste in the designers themselves, otherwise we should never see the outrageous examples which are formed in all countries where artificial water is designed. It is not for a moment admissible that the water margin, perfectly natural in play and gradation, may not be as attainable in a garden as the hard, stiff, and in all ways wrong margins we so often see. Good design would also arrange such work as conveniently for the wants of public or private gardens as could be desired. As regards opportunities for planting, the advantages are all on the side of the natural and the right way. In connection with this subject the annexed illustration may be studied with advantage for its beautiful fringes of river and islet banks. Although artificial water is generally puny in comparison with such beautiful natural scenes, these illustrate, as well as smaller scenes, the laws which regulate the gradation and fringing of water margins.

## SOCIETIES AND EXHIBITIONS.

### THE GREAT INTERNATIONAL HORTICULTURAL SHOW AT GHENT.

THIS was opened last Saturday, and, notwithstanding the worse than Arctic weather that occurred during the early days of its opening, it was a great success. As we have several times stated in THE GARDEN, the practice of holding these shows so early in the season is an unwise one, considered from a national or international point of view. The horticulture of a country like Belgium—we mean the general horticulture, the fruit gardens, market gardens, country seats, landscape gardening, parks (public and private), arboriculture, open-air nurseries, State schools of horticulture—none of these things can be seen to advantage at the time of the year at which these shows are held. The compensating advantage, if it be one, which determines the holding of these shows at such a time of the year is, that Azaleas, Camellias, and a few similar plants of the same type may be best seen in bloom at that particular time; but, considering the little difficulty one has in seeing these anywhere, it can scarcely justify a course so injurious to more important interests. No doubt the city of Ghent is so full of nurseries richly stored with hothouse plants, that it is desirable that the interests of these should be almost paramount at such a meeting, but we hold that the show of pot plants would be none the less interesting during the fine weather of summer, while many other phases of horticulture could be seen with advantage by all. So far as this country is concerned, moreover, it is certain that exhibitions of plants held in Belgium in March do not show so many English productions as they would if held at a more convenient season. Only the great nurserymen are represented, and even of these the consignments are often limited, or stopped altogether, as happened this time to our own knowledge; however, hoping that some day the authorities in Belgium will give us a summer or autumn show in that most interesting country to horticulturists, we are grateful to them for the excellent organization displayed in the late show, their ample hospitality, and pleased with their successful culture of many plants. The Azaleas of Belgian growers were the brilliant feature of the exhibition. Among these there were some pretty effects secured through grafting different kinds of Azaleas on the same plant, the colours being tastefully associated, and the lines of colour clearly defined, owing to successful grafting and the cultivation adapted to the end in view. English growers contributed very materially to the best features of the show. Mr. Bull exhibited new plants very largely, and was remarkably successful, beating some of the great Continental exhibitors in some of their specialities, such as Palms. Mr. Wills found time, from his many important floral decorations in London, to exhibit some very fine groups of plants, which excited the admiration of foreigners, and was unanimously awarded the highest prizes. Messrs. Veitch and Mr. Williams also contributed very extensive and valuable collections. Many of Messrs. Veitch's Orchids were, however, kept in England by stress of weather. As will be seen by our prize list, the old and well-known house of Messrs. Rollisson, of Tooting, exhibited in various most important classes, and were most successful, particularly in subjects for which they have long been famous, such as New Holland plants.

#### First and Extra Prizes.

Twelve plants newly introduced to Europe by the exhibitor (in or out of flower).—Mr. W. Bull, London, for

Encephalartos Hildebrandi	Dieffenbachia triumphans
Dracaena Goldieana	Carludovicia Drudei
Bowenia spectabilis serrulata	Catakidozamia Hopei
Croton Rex	Cibotium Menziesi
" picturatum	Dieffenbachia splendens
Lomaria discolor bipinnatifida	Aralia splendissima

Six plants newly introduced to Europe by the exhibitor (in or out of flower).—Mr. W. Bull, London, for

Sadleria cyathoides	Croton Disraeli
Dracaena Goldieana	Dieffenbachia Leopoldi
Bowenia spectabilis serrulata	Anthurium Veitchii

Twenty plants newly introduced into Europe by the exhibitor (in or out of flower), and not yet in commerce—Mr. W. Bull, for

Panax plumatum	Alocasia Johnstoni
Aralia venusta	Doodia aspera multifida
Dieffenbachia Shuttleworthii	Croton princeps
" regina	Pandanus princeps
" Leopoldi	Aisophia undulata
Dipteria Horsfieldii	Croton cornigerum

Six plants newly introduced into Europe by the exhibitor (in or out of flower), and not yet in commerce—Mr. W. Bull, for

Aralia concinna	Dendropanax argenteus
Davallia fijiensis	Anthurium insigne
Dieffenbachia Leopoldi	Zamia princeps

Twenty plants newly introduced into Europe (in or out of flower)—M. Louis Van Houtte, Gentbrugge, for

Dracæna speciosa	Croton Challenger
Dieffenbachia marmorata	" afro-maculatum
" brasiliensis	" Earl of Derby
" Parlatoresii	" Regina
Anthurium argenteo-marmoratum	Dracæna Goldieana
" Veitchii	Dracæna Neo-Caledonia
" Waroocuanum	Eranthemum atropurpureum
Aralia gracillima	Goodyera Rolliisoni
Araucaria excelsa elegans erecta	Kentia Van Houtteana
Caladium souvenir de Louis Van Houtte	Nephrolepis Duffii

Twenty plants of distinct kinds or varieties, introduced and put into commerce by Mr. W. Bull subsequently to 1873.—M. Massange de Louvrex, Liege, for

Aralia elegantissima	Dracæna Goldieana
Maranta bella	Tillandsia nuseica Massangei
Aralia hieifolia	Croton Disraeli
Dieffenbachia Cheloni	" majesticum
" amabilis	Curatæria Wallisii
Dracæna Robinsonii	Bilbergia chlorosticta

Plant in flower newly introduced into Europe—M. J. Linden, Ghent, for Anthurium Deohardi.

Plant not in flower newly introduced into Europe—M. J. Linden, Ghent, for Massangea Lindeni.

Plant in flower raised from seed, and never before exhibited at any of the Society's exhibitions—Mr. W. Bull, for Dendrobium Ainsworthii.

Twenty exotic Orchids in flower (amateurs)—M. Oscar Lamarche, Liege, for

Selenipedium caudatum roseum	Odontoglossum Alexandræ
Cypripedium Lowi	" Pescatorei
" Roezli	" novium
" Parishii	Huntleya melegris
Phalanopsis Ludemannii	Lælia superbiens
Epidendrum pseudo-epidendrum	Saccolabium ampullaceum
Ondontium thysiflorum	Acerides Foidlingii
Odontoglossum pulchellum majus	Vanda tricolor Wiotii
Oncidium ampliatum majus	" tricolor
" sarcoades	" Dennisoniana

Twenty exotic Orchids in flower (nurserymen)—Messrs. Rolliison & Son, Tooting.

Fifteen exotic Orchids in flower—Messrs. Rolliison & Son.

Ten Orchids (cool house) in flower—M. Massange de Louvrex, Liege.

Fifteen hardy Orchids in flower—M. Louis Van Houtte, for

Aceras anthropomorpha	Ophrys lutea
Calopogon plicifolius	" myodes
Cypripedium acule	" rosea
" arietinum	Orchis Lingua
" parviflorum	" longicornu
" pubescens	" Morio
" spectabile	" spectabilis

Ophrys apifera

Ten Sarraacenas, Cephalotus, Darlingtonia, Drosera, Dionæa—M. Van Geert, Ghent.

Ten Sonerilas and Bertolonias—M. Louis Van Houtte, for

Bertolonia guttata albo puncta.	Bertolonia hybrida semis
tissima	" maculata marmorata
" hybrida miranda	Sonerilla Hendersoni
" " smaragdina	" " marmorata
" " Van Houtteii	" margaritacea
" " semis	

Eight Nepenthes—Mr. J. Wills, South Kensington.

Aloes and Mesembryanthemums—Mr. C. Eggermont and Sister, Ghent.

Twenty-five Hothouse Plants of variegated, marbled, striated, or coloured leaves—M. L. Van Houtte, for

Abutilon Sellowianum variegatum	Dieffenbachia Bowmanni
Acalypha macrophylla	" Imperialis nobilis
Alocasia Lowi	Dracæna amabilis
" macrorrhiza fol. var.	" Regina
Anthurium crystallinum	" striatifolia
Bertolonia semis	Maranta fasciata
" "	" Makoyana
Caladium Meyerbeer	" rosea-picta
Croton fasciatum	" zebra
" Weismanni	Pandanus Veitchii
Curculigo recurvata fol. var.	Phyllotacium Lindeni
Curmeria picturata	Tillandsia tessellata
Dieffenbachia Bausei	

Fifteen Coleus—M. Jacques Coene, Ghent, for

Coleus Bambergi	Coleus Leopardi
" Frobeli	" M. Fries
" Prince Troubetzkoi	" Vicomte Aguado
" Mad. Boury	" Charles-Quint
" Princess Louise	" Jacob Makoy
" Verschaffelti	" multicolor
" " major	" Uranie

Six Musas—M. L. Van Houtte, for

Musa diecolor	Musa sapientum
" Cavendishi (sinensis)	" violacea
" Ensete	" vittata

Theophrata remarkable for its culture—M. L. Van Houtte, for Theophrata macrophylla vera.

Four Strelitzias in flower—M. Louis de Smet, Ghent, for

Strelitzia Regina	Strelitzia rutilans
" bunulis	" Regina longiflora

Four Imantophyllums in flower—M. Louis Van Houtte, for

Imantophyllum intermedium splen-	Imantophyllum semis
dens	" semis
" miniatum	

Imantophyllum miniatum, remarkable for good culture and profusion of flower—The Count de Kerchove de Denterghem, Ghent.

Anthurium Scherzerianum, remarkable for good culture and abundance of flower—M. Ad. d'Haene, Ghent.

Six stove and greenhouse plants of distinct kinds in flower, remarkable for their beauty and culture—M. L. Van Houtte, for

Acacia linifolia	Medinilla magnifica
Dendrobium nobile	Rhododendron virgatum candidissim.
Diosma capitata	mun
Erica arborea	

Specimen plant, not for special competition—M. L. Rosseels, Louvain, for Aletris capensis.

Specimen plant (not in flower), distinguished for good culture, not an object of special competition—M. Beaucarne, Benaeme, for Diosma purpurea.

Twenty-five Palms (amateurs)—M. de Ghellinck de Walle, for

Areca furfuracea	Livistona rotundifolia
Corypha australis	Phoenix reclinata
" cerifera	" tenuis
Chamædorea desmonceoides	" zeylanica
Chamærops Fortunei	Sabal glauca
" gracillima	" Adansoni
" arborea	" Moccini
Cocos Bonnetti	Rhapis flabelliformis
" Yurumagua	Seaforthia elegans
Jubæa spectabilis	Thrinax elegans
Kentia australis	" elegantissima
Lantana borbonica	Dekenia nobilis
" Verschaffelti	

Twenty-five Palms (nurserymen)—M. Ad. d'Haene, Ghent, for

Acanthorhiza etauracantha	Corypha cerifera
Acroecomia sclerocarpa	Euterpe edulis
Areca Baueri	Geonoma Spitziana
" madagascariensis	Kentia Balmoreana
" sapida	" Forsteriana
" Verschaffelti	Lantana borbonica
Caryota Chantini	Martinezia Lindeni
Cocos Weddelliana	Phoenix reclinata
" majestica	Rhapis flabelliformis
Chamædore speciosa	Thrinax elegans
" fragrans	" brasiliensis
Chamærops Fortunei	Verschaffeltia melanochætes
Corypha australis	

Forty Palms—M. de Ghellinck de Walle, Ghent, for  
 Areca Baueri Ptychosperma Alexandræ  
 " spida Livistona alissima  
 " Verschaffelti " sp. robusta  
 " lutescens Latania borbonica  
 Astrocarum mexicanum " rubra  
 Attalea compta Phoenix spinosa  
 Ceroxylon andicola " reclinata  
 Cocos australis Pritchardia pacifica  
 " Weddelliana " Martiana  
 Acanthopanax crinita Phytolophus macrocarpa  
 Ceroxylon viviparum Phoenicophorum Sechellarum  
 Chamærops elegans Scaevola elegans  
 " Fortunei Sabal Adansoni  
 " humilis " Blackburniana  
 " stauracantha " princeps  
 Brahea dulcis Thrinax Chucuo  
 Euterpe edulis " Martii  
 Geonoma Schottiana " elegans  
 Kentia Mooreana " graminea  
 " Balmoreana Verschaffeltia melanochætes  
 Livistona australis " excelsa

Twelve Palms, large specimens—M. J. Nuytens-Verschaffelt, Ghent, for

Chamærops Fortunei Corypha australis  
 Rhapis Sierotisk Phoenix reclinata  
 Jubæa spectabilis Kentia Balmoreana  
 Areca spida Chamærops melanocantha  
 Latania borbonica " excelsa  
 Areca Baueri Cocos Weddelliana

Eight Palms of recent introduction—M. W. Bull, for

Thrinax barbadensis Cypthokentia macrocarpa  
 Plectocoma himalayana Geonoma Bluntd  
 Kentia Wendlandi Desmonocia granatensis  
 Drymophloeus paradoxus Martineux Roezli

Twelve Coolhouse Palms—M. L. Spaë-Vandermeulen, Ghent, for

Areca spida Corypha filifera  
 Phoenix reclinata Chamærops humilis  
 Corypha australis Areca Baueri  
 Latania borbonica Kentia Forsteriana  
 Phoenix pumila Chamærops Fortunei  
 Latania robusta Jubæa spectabilis

Palm, remarkable for its beauty—M. Louis Hervivauz, Paris, for Cocos Weddelliana.

Palm, remarkable for fine development—J. B. de Saegher, Ghent, for Saribus olivæformis.

New Palm—M. Ad. d'Haens, Ghent, for Areca Verschaffeltii pendula.

Fifteen Cycads (amateurs)—M. de Ghellinck de Walle.

Fifteen Cycads (nurserymen)—M. J. Nuytens-Verschaffelt.

Six Cycads—M. Vanden Wouwer, Antwerp, for

Zamia horrida Dion edule  
 " cycadæfolia Encephalartos Lehmanni glauca  
 Cycas circinalis " villosa ampliata

Cycad, remarkable for its beauty—M. Louis Van Houtte.

Cycad remarkable for fine development—M. de Ghellinck de Walle.

New Cycad—M. Van Geert.

Fifteen Pandanads—M. Van Houtte, for

Pandanus amaryllidifolius Pandanus madagascariensis glauca  
 " caricosus " Pancheri  
 " elegantissimus " pygmaeus  
 " furcatus " reflexus  
 " gramineus " utilis  
 " javanicus " Veitohi  
 " madagascariensis " Van Houttei

Pandanad, remarkable for its beauty—M. Louis Van Houtte.

Pandanad, remarkable for fine development—M. Louis Van Houtte.

Twelve Tree Ferns—The Count Kerchove de Deutergem, for

Balanium antarcticum. Presl. Cyathea Dregei. Kze.  
 " Sellowianum. Presl. " Cunninghami. Hook. fil.  
 Dicksonia squarrosa. Sw. Chnoophora elegans. Hort.  
 " fibrosa. Cul. Alsophila australis. Rob. Br.  
 Cyathea princeps. Hort. Cibotium regale. Moore  
 " dealbata, Sw. Alsophila denticulata. Reich. fil.

Six Tree Ferns—M. Nuytens-Verschaffelt, for

Balanium antarcticum Alsophila Williamsi  
 Cyathea dealbata " capensis  
 " specios (Nouvelle " Williamsi  
 " Zélande)

Tree Fern, remarkable for beauty—M. Vanden Wouwer, Antwerp.  
 Tree Fern, remarkable for fine development—M. de Ghellinck de Walle.

Forty Tree and other Ferns—M. de Ghellinck de Walle, for

Alsophila australis Cyathea dealbata  
 " excelsa " medullaris  
 " contaminans Cibotium Barometz  
 " infesta " Clcitium  
 " Van Geerti " princeps  
 " australis var. " regale  
 Adiantum cuneatum " Schiedeii  
 " macrophyllum " spectabile  
 " Farleyense Davallia hemiptera  
 " concinnum letum Lomaria zamioides  
 " trapeziforme Angiopteris pruinosa  
 Aepidium odonites " maorophylla  
 " Fabianum Platycerium alciorme majus  
 " diversifolium Polystichum species  
 " Bellangeri Pteris prolifera  
 " Nidus avis " quadricolor  
 Aepidium spe. nov. " scaberula  
 Balantium antarcticum Gymnogramma Lautoheana  
 Dicksonia squarosa gigantea  
 Didymoglossum orinatum Polypodium aureum  
 Cyathea Beyrichiana

Forty Ferns (various)—The Count Kerchove de Deutergem.  
 Twenty Ferns (various)—Messrs. Wyckaert, Ghent.  
 Three new Ferns—Mr. W. Bull, for  
 Lastrea aristata variegata Pteris splendida.

Cyathea Imryana Adiantum—The Count de Kerchove de Deutergem.  
 Twelve Ferns with translucent leaves—M. Louis Desmet.  
 Fifty Hardy Ferns—M. Louis Desmet  
 Seventy-five bulbous plants in flower—M. Vauderlinden, Antwerp  
 Twelve Lilies in flower—M. Louis Van Houtte.  
 Six Lilium auratum in flower—M. J. Nuytens-Verschaffelt.  
 Six Tropæolums in flower—M. L. Desmet.  
 One Hundred and fifty Hyacinths in flower—M. L. Van Houtte.  
 One Hundred Hyacinths in flower—M. L. Van Houtte.  
 One Hundred Tulips in flower—Messrs. Schotzer & Son, Haa

Thirty Echeverias—M. Albert Vanden Wouwer, Antwerp, for

Echeveria agavoides Echeveria imbricatissima  
 " argentea (pulverulenta) " Funcki  
 " californica " securifera  
 " farinosa " candicans  
 " De Smetiana " carinata  
 " globosa cristata " gandavensis  
 " " extensa " hybrida  
 " mirabilis " blanda  
 " pachyphylloides " undulata  
 " rusciformis " agavoides rubella  
 " scaphylla " metallica grandis  
 " Scheideckeri " " superta  
 " costata " cristata  
 " spatulata " pumila  
 " imbricata " misteca

Twenty-five Euphorbia—M. Louis Desmet, Ghent, for

Euphorbia abyssinica Euphorbia havanensis cristata  
 " articulata " nereifolia cristata  
 " bulepirifolia " hystrix  
 " canariensis " " viridia  
 " Caput Medusæ " irregularis  
 " bulepirifolia femina " meloformis  
 " cereiformis " odorata  
 " cœrulescens " officinalis  
 " clubriana " Richardi  
 " Commelyni " stapyliformis  
 " erosa " Pescatorei  
 " globulifera major " splendens  
 " grandicornis

Twenty-five Cacti—M. Louis Desmet, for

Mamillaria cornifera Echinocactus ingens  
 " elongata " Leopoldi bicolor  
 " longimamma " tulensis  
 " nivea cristata " undulatus  
 " pycnantha Echinopsis formosa spinosa  
 " Schiedeana " Zuccariana cristata  
 " spinosissima Pilocereus Dautwitzii  
 " subulconata " Haageanus (lanatus)  
 Echinocactus concinnus " senilis  
 " corniger flavispinus Echinocereus pectinatus cristatus  
 " crispatus Cereus Dumortieri  
 " domatus Opuntia cylindrica cristata  
 " electracanthus

## Fifty Cacti—M. Louis Desmet, for

Mamillaria cirrhifera	Echinocactus gilvus
" Galeottiana	" gladiatus
" cirrhifera longispina	" hexedrophorus
" conopsea	" lancifer
" crucegera	" leucanthus
" elephantidens	" lophothele
" Hermentiana	" longhamatus
" hystrix	" mammulosus
" nivea	" Mirbeli
" Oleriana rufispina	" Leopoldi
" polyedra	" albispinus
" pycnantha	" bicolor
" Scyloimoides	Leuchtenbergia princeps
Melocactus coronatus	Echinopsis formosa spinosa
" pyramidalis	" Pentlandi longispina
Malacocarpus corynodes	" tricolor
Echinocactus acifer	Pilocereus fossilatus
" acutissimus	" Houlettianus glaucescens
" Cactetianna	" senilis
" corniger	Echinocereus acifer
" flavispinus	" candicans
" crispatus	Cereus corulescens
" denudatus	Echinocereus Kranssei
" electracanthus	Cereus peruvianus cristatus
" gibbosus	Echinocactus coptonogonus

## Twenty Aloecias, Amorphophallus, Colocessias, and Dieffenbachias—M. Louis Van Houtte, for

Alocasia gigantea	Colocasia esculenta
" Lowi	" heliohorifolia
" macrorrhiza fol. var.	" Mafala
" metallica	" violacea
" Sedeni	Dieffenbachia Baraquianiana
" Veitchi	" Bowmani
" zebraia	" Imperialis
Amorphophallus cornutus	" nobilis
" Rivieri	" latimaculata
" simlensis	" nobilis

## Thirty Caladiums—M. Louis Van Houtte, for

Caladium Ad. Adam	Caladium Marchandi
" Alfred Bleu	" Max Koll
" argyrites	" Meyerbeer
" Beethoven	" mirabile (bleu)
" Bellini	" M. Dombraun
" Brongniarti	" Paillet
" Chantini	" Pœcile
" Dr. Buisduval	" Prince Albert Edward
" Dr. Lindley	" quadricolor
" Due de Cleveland	" Reine Victoria
" Duchartre	" Ricci
" Houletti	" splendidum (bleu)
" Laingi	" triomphe de l'exposition
" Leplay	" Velleda
" Madame Alfred Mame	" Verschaffelti

## Twenty Caladiums—M. Louis Van Houtte, for

Caladium Adolphe Andrieux	Caladium Impératrice Eugénie
" Alfred Bleu	" Leopoldi
" Barra	" Madame Hannebelle
" Beethoven	" Meyerbeer
" Duc de Ratibor	" Prince Albert Edward
" E. G. Henderson	" quadricolor
" Eukei	" Rossini
" giganteum	" Rouillard
" Hérold	" splendidum
" Houletti	" Wighti

## Twenty-five Marantas—M. Louis Van Houtte, for

Maranta argyrea	Maranta Porteana
" corifolia	" roseo-picta
" fasciata	" smaragdina
" illustris	" staurantha amabilis
" Kummeriana	" Van Houttei (ornata)
" Lindeni	" picta)
" Luciani	" variegata
" Makoyana	" Veitchi
" Massangeana	" virginialis
" Mazeli	" major
" medio-picta "	" Wagneri
" Oppenheimiana	" Wallisi discolor
" porphyrocaulis	" zebraia

Maranta remarkable by its culture—M. A. Dallièrè, Ghent, for Maranta Massangeana.

## Ten Marantas—M. Florent Pauwels, Antwerp, for

Maranta virginialis	Maranta amabilis
" illustris	" Wallisi
" fasciata	" rosea picta
" zebraia	" splendida
" Porteana	" setosa
" ornata picta	" princeps
" Van den Heeki	" Baraquiana
" Makoyana	

## Twenty-five Bromeliads—M. A. Vanden Wonwer, Antwerp, for

Æchmea Marie-Regnia	Distiactanthus scarlatus
Ananas piangensis fol. var.	Guzmania fragrans
Encholirion corallinum	" grandis
" Saundersi	Tillandsia glaucophylla
" Joughi	" zaticiflora
Tillandsia argentea	" Zalini
" Lindeni	" juncea
" musica (Massangei)	" tessellata
" sanguinolenta	Hoplophytum giganteum
Anoplophytum Rollisoni	Vriesia Glaziouana (Regina)
Vriesia Malzinci	" Hillegeriana
Tillandsia streptophylla	Roubergia Morreniana
" guttata	

## Ten Bromeliads—M. A. Troffant, Versailles, for

Vriesia Glaziouana	Hechtia carnea
Æchmea densiflora	" pitcairniaefolia
Greigia sphaacelata	Æchmea spectabilis
Bromelia Binoti	Distiactanthus basilateralis
" Species of Paraguay	Bromelia latifolia

## Thirty Begonias—M. C. Mees, Ghent, for

Begonia laciniata bicolor	Begonia gandavensis
" diamant	" Annica
" Couste Alf. de Limminghe	" Helena
" alveata	" Secrétaire Kegelman
" Griffithi	" albo coccinea
" Queen Victoria	" Acté
" miranda	" Hildegarde
" Mad. Stuart	" Rex Leopardina
" Sarrazin	" Rex
" grandis	" Dedalea
" Fran Prof. Kock	" Fernand D'waus
" millia	" Dr. Regel
" Rex Leopardinus	" Princess Charlotte
" Blinsifolia	" Manoël de Silva Bruschy
" J. J. De Beucker	" Ad. Polak

## Fifteen Tuberous-rooted Begonias in flower—Messrs. Blauquaert &amp; C. Vermeire, Ghent, for

Begonia Adrian Benoit	Begonia Mad. Rodigas
" bella	" Minerva
" carminator	" miranda
" boliviosis	" Monsieur d'Offoy
" Comte de Flandre	" Pearcei
" étoile polaire	" rose d'amour
" Mad. de Beukelaere	" rubie
" Gerni	

## Twelve Crotonas—M. Ad. d'Haene, Ghent, for

Croton Andreaum	Croton interruptum
" acumbifolium	" irregulare
" fasciatum	" undulatum
" grande	" variegatum
" Hillianum	" Veitchi
" Hookeriaum	" Weismanni

## Eight Crotonas—M. Ad. d'Haene, for

Croton cornutum	Croton maximum
" fucatum	" undulatum
" Cooperi	" variegatum
" interruptum	" Veitchi

Croton remarkable by its culture—M. Ang. Van Geert, Ghent, for Croton angustifolium.

Seventy-five Amaryllids (amateurs) in flower—Coust de Kerchove de Deutergem.

Seventy-five Amaryllids (nurserymen) in flower—M. L. Van Houtte.

Forty Amaryllids (amateurs) in flower—M. G. d'Hooghe, Loochristi.

Amaryllis (a seedling) in flower, not exhibited before—M. Louis Van Houtte.

Azalea indica (a seedling), not shown before at the exhibitions of the Society—M. Louis Van Houtte.

New variety of grafted Azalea in flower—M. D. Vervaene, Ghent, for Azalea indica La Favorite.

Azalea, single specimen—M. Jean Vervaene, for Azalea indica Totteriana.

Forty Camellias (nurserymen) in flower—M. Jacques Van Eeckhaute, Leideberg, for

Camellia Auguste Delfosse	Camellia Rubens
" Lavinia Maggi	" Napoleon III.
" alba plena	" Madame de Strekaloff
" il 22 marzo	" Victoria magnosa rubescens
" Comte de Gomer	" Triomph di Loddi de la Reine
" Leeana superba	" do la Reine (bicolor)
" Valteverada	" tricolor nova
" Prince Albert	" Reine Marie Henriette
" Princess Clotilde	" Augustina anperba
" fimbriata	" Dyonisia Piotowski
" Polydore	" Marie Thérèse
" Mazuchelli	" Madame de Sôigné
" Leon Loguay	" General Drouot
" Reine des Belges	" maculata perfecta
" Madonna	" Comte de Paris
" Leopold I.	" Giardino Franchetti
" Countess of Orkney	" Lucullus
" Raffia	" Faustina
" bella Romana	
" Mathotiana alba	

New variety of grafted Camellia in flower—M. J. Linden, for Camellia Madame Linden.

Camellia, remarkable for good culture and abundance of bloom—M. L. Eeckhaute, Denis-Westrom, for Camellia Mrs. Abby Wilder.

Ten Himalayan Rhododendrons in flower—M. L. Desmet, for Rhododendron Gibaoni

Rhododendron Gibaoni	Rhododendron Sterotianum
" Edgworthi	" oiliatum
" Madoni	" calophyllum
" Countess of Had-dington	" Princess Alice javanicum
" multiflorum	

Fifty Rhododendrons (nurserymen) in flower—Madame Ve. Hellebuyk & Son, Gentbrugge, for

Rhod. concanum (Byle)	Rhod. Leopold II.
" Duc de Brabant (Vervaene)	" Madame Wagner
" Auguste Van Geort	" Bouquet Royal
" Prince Eugène	" Leopard
" Madame Cannart d'Hamale	" nigrescens
" Minnie	" Sir Thomas Sebright
" Alarie	" Mrs. Heneage
" John Waterer	" Caractacus
" Vesuvius	" Tamerlan
" Jago (Noble)	" Purity
" Bouquet de Flore	" Duc Adolphe de Nassau
" Stanfordianum	" The Warrior
" Prince Camille de Rohan	" Brayanium
" Everestianum	" Mrs. John Waterer
" pardoloton	" Mrs. John Clutton
" Joseph Whitworth	" George Cunningham
" Verschaffelti	" Michael Waterer
" album novum	" Oberon
" stella (Waterer)	" Joseph Vervaene
" Surprise (J. Waterer)	" roseum egregium
" Anilcar	" Gloire de Belle Vue
" Broughtoni	" Mrs. John Penn
" Lady Emily Peel	" The Queen
" The Maroon	" Evelyn
" Comte de Gomer	" William Downing

Twenty Rhododendrons, in flower (cut)—M. de Coninck, Ghent, for

Rhod. Archiduc Etienne	Rhod. Rienzi
" Gloire de Belle Vue	" Raphael
" Princesse Amélio	" Prince Camille de Rohan
" Everestianum	" Vesuvius
" Lady Armstrong	" Cyanoides
" Madame Wagner	" Cynthia
" Mistress R. S. Holford	" President Jules Hye
" The Warrior	" Minnie
" Leopold II.	" Jago
" John Waterer	" Joseph Whitworth

Six new Rhododendrons in flower—M. L. Van Houtte, for

Rhod. Annie Newett	Rhod. M. Joseph Shuttleworth
" Madame Gustave Guilmot	" parvifolium
" Mdlle. Bertha Frœbel	" William Austin

Rhododendron (seedling) not before exhibited at the Society's

exhibitions—M. Louis Van Houtte, for Rhododendron Comte de T'Serclaes.

Rhododendron, remarkable for good culture and profusion of bloom—M. Nuytens-Verschaffelt.

Twenty-five Lycopods—Comte de Kerchove de Denterghem.

Ten Glyceriums—M. Louis Desmet.

Thirty Analias and Rhopalas—M. Dom. Vervaene, sen.

Twenty specimen ornamental plants (nurserymen)—M. d'Haene. Ten specimen ornamental plants (nurserymen)—M. Ad. d'Haene.

Thirty Aroids—M. de Ghellinck de Walle.

Thirty Dracenas, remarkable for good culture, beauty, and novelty—Mr. Wills, South Kensington.

Six Dracenas, not yet in commerce—Mr. J. Wills.

Three Dracenas, remarkable for good culture and beauty—Mr. Wills.

Twenty-five greenhouse plants with variegated, marbled, striated or coloured foliage—M. L. Eeckhaute.

Hardy evergreen shrubs with variegated, marbled, striated, or coloured leaves—M. Louis Desmet.

Zonal Pelargoniums with variegated, marbled, striated, or coloured leaves—Messrs. Vandermeersch.

Twenty Acer palatum—M. Louis Desmet.

Fifty Azaleas in flower—M. de Ghellinck de Walle.

Forty Azalea (amateurs) in flower—M. de Ghellinck de Walle.

Forty Azaleas (nurserymen) in flower—M. Jean Vervaene.

Six new Azaleas in flower—M. Ed. Vandercruyssen, for Azalea indica Héros de Flandre

Azalea indica la Puelle de Gand

" Charles Turner " Comte de Chambord

" le Vengour " Jules Verne

Twenty-five Camellias (amateurs) in flower—M. Beaucarne, Eenaeme.

Twenty-five Camellias (nurserymen) in flower—M. J. De Coster, Melle.

Six new Camellias in flower—M. L. Van Houtte, for Camellia Andrea Spinola

Camellia Pallazo Tursi

" Capitolina Odero " Santa Maria dei Fiori

" Madame Aimé Van Lan- " Scherzo della Regina genovese

Twenty-five Euonymys—M. L. Desmet.

Eight climbing plants in flower—M. Nuytens-Verschaffelt.

Six Hydrangeas in flower—M. S. Desmet.

Thirty Cape and New Holland plants in flower—Messrs. Rollinson & Sons, Tooting.

Two variegated Yuccas, remarkable for good culture and fine development—Mr. Wills, South Kensington.

Twenty-five Cyclamens in flower—M. Spaë, Ghent.

Seventy-five plants in or out of flower—M. L. Van Houtte.

Fifty plants in flower, comprising at least twenty kinds—M. Desmet-Davivier.

Seventy-five plants in flower, comprising at least twelve kinds—Messrs. Wyckaert.

Twenty hardy Azaleas in flower, others than Azalea Mollis—M. L. Desmet.

Six climbing Roses in flower—M. Nuytens-Verschaffelt.

Forty Roses in flower—Messrs. Wyckaert, Ghent, for Alexandriini Bachemotoff

Aimée Vibert

La Reine Paxton

Baronne Prevost Gloire de Dijon

Louise Odier Maréchal Niel

Louis Bonaparte Reine des Violettes

Alcindor Frans Arago

Paul Neron Madame Guillot de Munt Forest

Hermosa General Jacqueminot

Jean Bart Eugène Appert

Jacques Lafitte Archimède

Enfant de France Jules Margotin

Pie IX. Alfred de Rougemont

Da Koi Madame Lacharme

Twenty Roses in flower—Messrs. Wyckaert, for Alexandriini Bachemotoff

General Barral

Baronne Prevost Paxton

Louise Odier Jacques Lafitte

General Jacqueminot Du Roi

Paul Neron Aimée Vibert

Jean Bart Reine des Violettes

Hermosa Nephtes

Gloire de Dijon Enfant de France

Extra prizes were awarded to Messrs. Veitch & Sons, for a miscellaneous collection of plants; to Mr. B. S. Williams, for a similar collection; to M. Verveane, sen., for a collection of Azaleas; to Messrs. Veitch & Sons, for Hyacinths and Cyclamens; to Mr. B. S. Williams, for Cyclamens; to M. Van Houtte, for new *Bertolonias*; to M. Banmann, for *Araucarias*; to M. Schwartz, Lyons, for a new Rose; to the School of Horticulture of Vilvorde, for various plants; to M. Vanderzwaln, for *Hepaticas*; to M. Van Hoecke-Peeters, for a grotto; to M. Spithoorn, for various objects; to M. Leopold Haeck, Destelbergen, for tressels for movable steps; and to M. Ferd. Rowan, for garden railing.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 2.

PLANTS were shown much more plentifully on this occasion than might have been expected, considering the severe weather which has lately prevailed, and that most of the London nurserymen have many of their newest and best plants at the Ghent Exhibition. The more prominent feature of the show were long banks of pot Roses and choice Orchids and *Amaryllids* from Messrs. Veitch & Sons, and fine-foliated plants, *Amaryllids*, and *Orchids* from Mr. B. S. Williams.

First-class Certificates were awarded as follows:—

**Amaryllis Crimson Banner** (Little).—A medium-sized flower of good form and substance, and of a rich crimson colour, scarcely any green being visible even at the base of the petals. Apparently one of the best seedling *Amaryllides* which has been raised for some time.

**Primrose Prince Charming** (Dean).—A large-flowered hybrid variety having a golden eye, the petals being systematically striped with white and magenta.

A botanical commendation was awarded to *Masdevallia radicea* (Williams), a curiously-flowered variety, somewhat resembling *M. Chimarra*, but much lighter in colour, and rather smaller.

**Orchids**.—These were well shown by Messrs. Veitch & Sons and Mr. Philbrick. The most noteworthy plants in the former collection were specimens of *Odontoglossum cirrhosum*, furnished with magnificent branching flower-spikes literally covered with beautifully-spotted, sweetly-scented blossoms; and *Dendrobium Devonianum*, bearing between twenty and thirty pseudo-bulbs, beset with delicately-coloured, imbricated flowers. Associated with these were also an unusually large-flowered variety of the golden *Oncidium Marshallianum*, beautifully-flowered plants of *Dendrobium Wardianum* and *D. crassinode Barberianum*, *Oncidium concolor* (conspicuous on account of its lemon-coloured blossoms), and a well-established specimen of *Dendrobium chrysothoxum* bore numerous fine, massive, drooping clusters of rich golden blossoms. *Odontoglossum Rozeii* and its white variety were also shown, and were much admired, on account of their abundance of bloom. *Cypripedium*, too, were well represented. This group, which was originally intended for Belgium, but kept back on account of the unfavourable weather, was one of the most effective which has been shown at South Kensington for some time past. It contained, in addition to those already mentioned, specimens of the following, viz., *Dendrobium Wardianum*, album, and *Cambridgeanum*; *Lycaste Skinneri*, and its white variety; *Masdevallia Lindeni*, *Veitchiana*, and *igneæ*; *Odontoglossum Rossi majus*, luteo purpureum, *prenitens*, *gloriosum*, *cordatum*, *Cervantesi*, *Halli*, *triumphans*, and *roseum*; *Stenia fimbriata*; *Lælia Pilcheriana*; *Ada aurantiaca*; *Oncidium Forbesi*, *sarcodeus*, *fuscatum*, and *leucociliolum*; *Vanda cristata*, *suavis*, *Melagris*, and *tricolor*; *Bollea Lindeni*; *Dendrobium macrophyllum giganteum*; *Aeridee Fieldingi*; *Cymbidium eburneum*; and *Phalaenopsis Schilleriana*. In Mr. Philbrick's group were well-flowered examples of *Odontoglossum Andersonianum*, *gloriosum*, *cirrhosum*, and *Pescatorei*. *O. Alexandræ* was remarkable for the wealth of crisp waxy blossoms which it bore, and an excellent plant of *Cattleya citrina*, bearing nearly a dozen large golden blossoms, rendered the group very attractive.

**Roses**.—These were represented by a large group of well-grown, healthy plants from Messrs. Veitch & Sons. The foliage was green and fresh, and the blossoms strikingly beautiful. Amongst the best varieties were noticeable the pure white *Coquette des Blancs*, the scarlet *Paul Verdier*, and an elegant plant of *Madame Lacharme*, bearing a profusion of partly expanded, delicate blossoms. Well-formed blooms of the bright crimson *Pierre Notting* and of *Richard Wallace* were also observable.

**Amaryllids**.—For the prizes offered by an amateur for seedling *Amaryllids*, light and dark varieties, there were several exhibitors. From light-coloured varieties the prizes were withheld, the kinds shown not being considered sufficiently in advance of sorts already in cultivation. The dark varieties were much better. Mr. Little,

Hillingdon Place, gained the first prize for a kind named *Crimson Banner*, already described. The second prize was awarded to Mr. B. S. Williams, for a very large scarlet-flowered variety named *Dr. Hogg*. Messrs. Veitch & Sons and Mr. B. S. Williams also showed attractive groups of *Amaryllids*. In the former collection the best kinds were—*Clio*, a large, crimson-flowered variety, with broad, recurved petals of great substance; *Sir Trevor Lawrence*, a well-formed, maroon-scarlet flower, well worth culture; *Mrs. Speed*, a free-flowering kind, with medium-sized blossoms, the ground colour of which is white, conspicuously striped with salmon-scarlet. In Mr. Williams' group were plants of the beautiful white-flowered *virginalis*, the elegantly-striped *A. Alexandra*, the dark maroon-purple *Ackermannii purpurea*, and other valuable kinds.

**Miscellaneous Subjects**.—Mr. B. S. Williams contributed a group of Palms, Ferns, and *Dracaenas*, intermixed with which were several finely-flowered *Orchids*, including a brightly-flowered variety of *Masdevallia Lindeni*; and a plant of *Crinum ornatum*, furnished with a stout flower-spike, was surmounted by nearly a dozen large, delicate flowers and buds. The same group likewise contained a healthy plant of *Illicium religiosum*, furnished with waxy flowers somewhat resembling those of *Chimonanthus fragrans*. Mr. Aldous, of South Kensington, again showed an effective group of decorative plants, consisting of dwarf bushy specimens of *Azaleas*, show *Pelargoniums*, *Hydrangeas*, *Lilies* of the Valley, and *Fuchsias*. Mr. James Lovesley, Spring Grove Lodge, Isleworth, sent a group of exceedingly dwarf *Cinerarias* with rich and variously-coloured blossoms. Where small plants are required for vases or for room decoration this strain of *Cinerarias* will be found to be invaluable. The same exhibitor also contributed a good group of *Cyclamens* and *Polyanthuses*. Messrs. Carter & Co. exhibited a collection of new *Hyacinths*, and Mr. Laing again showed an example of *Caladium La Perle du Brésil*. *Sir W. Strickland, Bart.*, sent a cut spike of *Crinum campanulatum*, sometimes called *C. riparium* or *C. aquatum*. Messrs. Osborn & Sons, Fullam, furnished an attractive group of Palms, Cycads, and *Aralias*, intermixed with *Azaleas*, *Lily* of the Valley, and other flowering plants. Mr. Cannell, Swanley, sent boxes of cut flowers of *Pelargoniums*, which attracted much attention. Amongst them were the salmon, white, and striped varieties of *Vesuvius*, and other brilliant and variously-coloured flowers. Amongst these the most attractive were *Circulator*, dark crimson suffused with rose; *Louisa*, a distinct rose-coloured kind; and *Anone*, one of the largest and brightest scarlets, measuring across the petals nearly 2½ in. Mr. R. Dean, Ealing, sent a panful of seedling *Alpine Primulas* of the intermediate section. The foliage resembled very closely that of the *Alpine Auriculas*, and the blossoms were rich and varied in colour. The same exhibitor also showed a self *Polyanthus*, bearing large trusses of yellow blossoms set on long, stout footstalks. Mr. William Chitty, Stamford Hill, contributed a basket of pot plants of *Narcissus juncifolius*; each pot (6 in.) contained nearly twenty blossoms, accompanied by an abundance of graceful leaves. Messrs. Barr & Sugden furnished a group of *Daffodils*, consisting of some thirty or forty varieties, among which were many choice and valuable kinds. Mr. C. Green, gardener to Sir G. Macleary, sent cut blooms of *Crinum pedunculatum*, large, white, and waxy, and conspicuously striped down the centre with rosy-purple.

**Fruit and Vegetables**.—A cultural commendation was awarded to Mr. McLean, The Gardens, Linton Park, Maidstone, for a collection of variegated *Kales*, the colours of which were rich and well varied. Mr. Joshua Atkins, gardener to Colonel Loyd-Lindsay, sent three bunches of Black Alicante Grapes in excellent condition; and examples of a white *Seakale* came from the Society's gardens, at Chiswick. A good dish of Apples was also shown.

## OBITUARY.

WE have to announce, with much regret, the death of Charles George Turner, the youngest surviving son of Mr. Chas. Turner, of Slough, and a youth of much promise. After an education at a good school, he selected medicine as his profession, and proceeded to the University of Edinburgh to graduate in the usual way. He passed his preliminary examination on every subject immediately on his presenting himself, and was preparing for his professional examinations when he was cut off at the early age of eighteen.

THOMAS JOHNSON, who had been gardener to Colonel Battersby, Conny Meath, for the long period of sixty years, died lately at the age of 106. He retained all his faculties to the last. Longevity in his case appears to have been hereditary, for his father, it is said, died at a still riper age, namely, 115 years.

The death is announced of Michel-Charles Durieu de Maisonneuve, on February 20, aged eighty-two. He was honorary director of the Gardens of Bordeaux. As member of the Scientific Commission of Algeria, he was known to botanists for his researches in the flora of that country.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### MY WILD GARDEN.

THIS being introduced, as it now is, in many places as a part or branch of gardening, I have thought that a few remarks in reference thereto might not be uninteresting to some of your readers. It is now some seven years since we commenced our wild garden here. Its size is 8 acres, and nearly in the form of a square. It was formerly full of underwood, but this was all grubbed up many years ago and planted with Laurels, large Yews, and other shrubs, which now have grown to such a size as to quite hide its square form. It contains some very fine old trees, such as Sycamore, Lime, and Silver Fir; one of the latter, mentioned by London, in his "Arboretum Britannicum," has been a landmark for many years. It also contains some Oaks, but these have been more recently planted. Such trees are very essential to give shade to such plants as require it. *Cryptomeria* and *Sequoia* are quite at home here, and beautifully clothed with branches from top to bottom; their heights are from 40 ft. to 50 ft. and upwards. The common Laurel, another fine object here, grows to a great height and size, and when singled out as specimens there are few evergreens that excel it; and as standards in the Orange tree style, it is particularly beautiful when in flower. The Laurel is a plant too often subjected to ill-usuage. After flowering it should be cut back with a knife, to encourage it to make flowering wood for the following year. The beauty of the wild garden is greatly enhanced by having flowering shrubs to skirt the Laurels, such as *Cotoneaster Simmondsi*. This should be cut back a little every year, where there are any gross-growing branches, in order to make it bushy, otherwise it gets naked and unsightly. The *Deutzias* also make good wild garden plants, and so do *Eunymus europæus*, with its red berries, and the varieties of *Ribes* and *Guedler Rose*. This last, when planted close to the Laurels, gets surrounded by them in a year or two in such a way as to just show the top with its beautiful white blossoms, set off to advantage over the green leaves of the Laurel. *Laburnums* should be treated in the same way, as should also *Lilacs* and some of the *Spiræas*. *S. ariæfolia* makes a good plant for the wild garden, as do also *Weigelas*, some of the newer sorts of which are very beautiful. The Double Bird Cherry should on no account be omitted, nor *Malus floribunda*, which is most attractive, and a shrub which one never tires of admiring. *Mahonias*, too, come in very well clustered together at the bottom of the Laurels. There are some new sorts of Laurels (*Jeffreyi* and *rotundifolia*, for instance) which have very beautiful leaves; indeed, from seed, many varieties, with different kinds of leaves, might be produced. About ten years ago we raised some from seed, and amongst the seedlings scarcely two are alike; some are much longer in the leaf than the common one. Again, the Traveller's Joy has a pretty effect, covering parts of bushes, and also the wild Honeysuckle; nothing can exceed the beauty of the latter when once established amongst rambling bushes, Briers, or Thorns.

Our wild garden is not in finely-rounded curves, circles, and squares, but quite the reverse. In making a wild garden the ground should be thoroughly trenched; we go two spits deep and then dig the bottom, getting all roots and weeds out. This we do two or three times over during six months, letting it lie a month or six weeks between each operation, and if any roots be left they will be making renewed efforts to grow, and are easily discovered. Of weeds in the wild garden I may as well state that those which we discard are the common sorts of Thistles, Nettles, Goutweed, Docks, and Dandelions. Such work will doubtless seem to many very expensive, and so it is; but it is afterwards well repaid, and it need not be all done at once. A piece or pieces may be operated on every year until all is done that requires it. Last year we dug about one-quarter of an acre, and in August, which is the

best time, sowed over it Forget-me-not, Foxglove, and other sorts of wild flower seeds. Now the ground is quite carpeted with plants from which we "expect great things" this season. On other places might be sown thinly dwarf Grasses—*Cynosurus cristatus*, *Festuca ovina*, and *Poa nemoralis* rank amongst the most useful—and in order to have flowering plants amongst the Grass, the Welsh Poppy, Columbines, Buttercups, Harbells, Lady's Bed-straw, *Linarias*, Meadow Sweet, and others may be used.

The wild garden season begins with the Winter Aconite and single Snowdrop. The latter I gathered this year on January 7. The Aconite seeds freely, but the seed should be looked after early, as it soon ripens, and very quickly sheds itself. The next bulbous plant is the Crocus, of which there is a great variety, and when distributed in large patches about the wild garden they are most interesting; a little preparation of the ground is, however, highly beneficial. We choose a piece of ground, say one, two, or more poles in extent, with an irregular outline, about September, dig off the top spit, and then lay it on the sides; we then dig up the bottom roughly to let the air and sun into it. At planting time (about six weeks afterwards) we fork the bottom over, levelling it; then we lay down a few  $\frac{1}{2}$ -in. boards to stand on when planting, as it is unadvisable to tread the ground unevenly; then set the bulbs irregularly all over the surface, some within 1 in. or so apart, others 6 in. to 9 in., and along with them may also be put some Lilies and single Tulips; then with the spade lay on the top spit gently, when the roots will have a covering of 7 in. or 8 in. of soil, and the result will be a prolonged season of flower. I hope to send you rambling notes of what we are doing from time to time in our wild garden, which has already proved a source of great beauty and interest. TEWENSIS.

### FUCHSIAS ON WALLS.

THE *Fuchsia Riccartoni*, described and illustrated in THE GARDEN (see p. 283) reminds me of two other instances of its remarkable talent for choosing its own place of abode: one, where a fine plant has located itself, at about 4 ft. from the ground, on the north side of an old stone wall. This is not a seedling, but must have pushed its way through some crevice in the wall, and eventually taken root there, from a large plant which formerly covered the sunny side of the wall, but which was removed a few years ago. This seems to prove its liking for shade, and certainly a more flourishing and flowery plant could not be than this self-made one. The other instance is of much older date, not much less than forty years ago, when, I believe, this fine old *Fuchsia* was, for the first time, brought to Ireland by one of our family, to whom it was given by the owner of Riccarton. It may have been the following summer that a seedling plant of it was discovered at the top of the village church tower, where it grew afterwards to a sufficient size to be plainly seen from our garden, which joined the churchyard. It is refreshing to see, from time to time, such "honourable mention" made of such valued old plants that few people now living have the good taste and discernment to preserve and cherish. Among old *Fuchsias* I should like to say a good word for *F. globosa*, so well suited, by its spreading growth and hardiness, for rockeries or rustic beds, and being so easily pruned into shape without disfiguring it, even when in full flower, which is not the case with some of the other *Fuchsias*. DELGANY.

**Baby Castle Wallflower.**—This is the best habited of all the Wallflowers, and to my mind, the best in colour, notwithstanding the prejudice (at least for market purposes) in favour of the dark varieties. It is nearly equal in colour to *Cheiranthus Marshalli*, and a few plants of it in early spring brightens up a place wonderfully. But I am desirous of pointing out its utility as a pot or decorative plant. Sown now (March or April), and when strong enough planted out to nurse in poor stiff soil, stout dwarf plants about 9 in. or 1 ft. high will be the result. These lifted late in autumn, wintered in a cold pit, and introduced early in spring to the conservatory, will yield a scent and give a mass of flower that will be very acceptable so early in the season. Everybody loves the scent of a Wallflower.—THOS. WILLIAMS, *Omskirck*.

## NOTES FROM CALIFORNIA.

THIS is a fine country for the Japan and South American plants. The winters are of Italian mildness, and many of our old greenhouse favourites remain in the open ground, and bloom profusely. Camellias, Chorozemas, and Azaleas are hardy shrubs where protected from the wind; even the *Cycas revoluta* succeeds in a warm situation, and *Phoenix dactylifera*, *Sabal Adansoni*, and *Brahea filamentosa* often form conspicuous features in the landscape. Still glass is a necessity here, as everywhere, I fancy, for propagation, and for the growth of soft-wooded plants, Orchids, winter flowers, &c. Conservatories are increasing amongst the classes who have leisure, and a conservatory is always a delightful mirror in which to study a man's character. The enraptured owner may choose to luxuriate in fruit out of due season, or to revel in masses of bloom, or to fairly despise colour, and hide himself in leaves, brilliant and shapely. Some unstable possessors of a few square feet of glass are everything by turns, and nothing long; but if there is, to the rightly-balanced mind, any pure delight, it is to slowly obtain those permanent plants which will grow better and better for a series of years, and which everybody does not have. I notice to-day that my seed-boxes are fairly awake. Possibly the most fascinating moment to the lover of flowers is when some little brown seed has set in order her curious underground palace, and got her forces and economies fairly under way, so that she can come delightfully up through the mould, and begin to breathe the upper air. I confess that I have a tender sympathy for every seedling, and love to imagine how the cells divided, and the germ increased, and to notice how early peculiarities of form reveal themselves. This month there is a whisper of hanging baskets, and I begin to arrange them at leisure. The variety of possible effects is most surprising. Your basket may be simple or profuse, modest or gorgeous, subdued or overwhelming. It is a good plan to select the plants one wants, take them to the potting-bench, and there group them until the general effect is satisfactory. It is not pleasant to mingle too many colours or styles of foliage in the same basket. Choose one plant to give the impression, and let the rest be subordinate. Now and then we find a basket in which art is hidden; it is a bit of Nature, full of simplicity. You may span it with your hand; yet there are cool depths in which the fancies wander beneath traceries of Fern and the plants which love shade. Someone planned it in a happy moment, and Nature seconded his efforts. This month the Cyclamens begin to show their delicate flowers, with their reflexing, tinted petals and rosy beak, shining above the cordate leaves. "Jest the old shootin' star," said an over-hasty country visitor once; she meant the American Cowslip (*Dodecatheon Meadia*), but arguments were futile. Still, it is often delightful to take people around. There is the busy merchant, who thinks flowers as a rule are foolishness, but show him that Bluebell yonder, and he is a boy again in the bonnie woods. Here, too, is the modest maiden, just tiptoeing in to see if she may have a rosebud and a sprig of Geranium. And now and then, on memorial days, some friend, who knows and loves plants in a cheerful, embracing fashion, drops in with an armful of bright ideas, questioning, criticising, praising. Someone asked me the other day what I considered the most accurate test of the inborn gardener. Now that is one of those questions which are somewhat puzzling, because the true gardener makes every plant personal, and real, and separate, even as every true nurseryman knows every tree over whole acres. I showed him a little box of Coffey plants. In that little box there might be seen infinite variety; here a crooked leaf, there a twisted one; yet again, one narrow and another wide; some dark, some light, and some spotted—the stems being of differing thickness, colour, angle of inclination, or even shape. Now the true gardener perceives this difference, enjoys it, and acts accordingly, in all his daily work.

Niles, California, U.S.A.

CHARLES H. SHINN.

Destroying Crickets.—I observe that "G. L. M.," who enquires about destroying crickets, is recommended (see p. 322) to use Chase's Beetle Paste. This paste is not near so effectual in the destruction of crickets as Hardman's Beetle Powder, which I have found very good, and it may be obtained of any chemist.—F. B.

## ORCHIDS AT WHITCHURCH RECTORY.

THE collection here even now well repays a visit, although there are not nearly so many species in bloom as there will be later in the season. The following were, however, the other day finely in flower. In the first house was *Odontoglossum Cervantesi*, *O. radiatum*, *O. Pescatorei* (one spike of which bore forty-five flowers), *O. luteo-purpureum*, and *O. triumphans*, the last one of the largest-flowered and finest-coloured forms of this species with which I have met. As to *O. hystrix*, the last bulb on a plant here is 6 in. long, and bears a couple of spikes 4 ft. in length; associated with it were also *O. Andersonianum*, *O. Prestans*, *O. Halli*, *O. gloriosum*, *O. roseum*, many forms of *O. Roezli*, and numbers of *O. cirrhosum*, on one spike of which I counted seventy flowers not yet open. In the same house were *Dendrobium Wardianum*, *D. crassicaule*, *D. Boxalli*, *D. primum*, *D. cucullatum*, *D. subriatum* oculatum, one plant in particular with very large flowers finely-blotched; *Lycaste Skinneri*, both white and other varieties; various forms of *Cattleya Trianae*, including the best that were in Mr. Marshall's and Mr. Russell's collections. One especially bears unusually large blossoms, the petals and sepals being pure white, with an intensely purple-coloured labellum. One specimen of *C. amethystina* bore seventeen flowers, and on *Oncidium sarcoodes* were spikes  $\frac{1}{2}$  ft. long. Of *O. Marshalli* one plant bore a seven-branched spike, and others were equally fine. In an adjoining house were numbers of *Odontoglossum cirrhosum* with not less than 100 spikes of flowers pushing up; *Cyclopogon conferta*, a seldom-seen, pretty, white and yellow, sweet-scented species; *C. Baccida*, scented like a *Narcissus*; *Helicia sanguinolenta*, a seldom-seen plant with a white labellum streaked with blood-red, and with petals yellow and crimson—these were all finely in flower, as well as many others. In an adjoining house I noticed a plant of the white *Anthurium Scherzerianum* bearing several flowers in an abnormal condition; from the spadix were issuing a number of small spathe clustered together in a curious way in its attempts to produce double flowers—not by the formation of two or more spathe at the base of the spadix, as may be frequently seen in the red variety, but absolutely from the spadix, the stamens assuming this spathe-like condition, which, in a flower so formal as the Aroids, to which this *Anthurium* belongs, gives it a most singular appearance. As to culture, Mr. Shields, who is an adept at Orchid growing, avoids the extremes of too much heat or the opposite of keeping them too cold, to both of which, especially the former, may be attributed the great losses that have been and that are still being continually experienced in connection with these costly plants. The atmosphere in the different houses is sufficiently moist, but an excess of humidity is carefully guarded against. The houses are constructed and so situated as to afford an abundance of light; less and thinner shading material is employed than many growers use, and the plants are kept well up to the glass—the only rational conditions under which Orchids can be grown with a view to the plants going on increasing in size and vigour individually for an indefinite time, and which, even in a cultivated state, they are capable of when subjected to treatment suited to their natural requirements.

B.

Tree Peonies and the Frost.—The effect of the recent frosts on the Tree Peony (*Paeonia Moutan*) has been here most disastrous. There must be many living who remember May 15, in the year 1838, when a frost not only destroyed in many places the opening bloom of the Peonies, but also seriously injured that of the Lilacs and Laburnums; but never before have I witnessed at this period of the year such damage as the late frosts have effected in the foliage and bloom-buds of the Tree Peony. A nipping of the most advanced shoots at this season is not of frequent occurrence; but the almost total destruction of four-fifths of the current year's produce is what I do not remember to have noticed before. The first of the four very cold nights my Fahr. thermometer registered 11° of frost, which did not seem to have any injurious effect on the Peonies. This was followed by a night almost as cold, the thermometer's lowest point being 22°. Then began the mischief, and the two next nights, and occasional frosts since, completed it. The only blooms we are likely to have, if we have any on these shrubs, will be a few on the lower and most protected shoots. Perhaps some other of your correspondents will give their experience with reference to this and other of our spring-blooming shrubs.—B. S., Rutlandshire.

*Chelanthus elegans*.—This is one of the most graceful and elegant of Ferns, and one which only requires an intermediate temperature in which to grow to perfection; in fact, like most cool house Ferns, it is more liable to suffer from too much heat than too little. Well-furnished plants of it in 6-in. pots make fine objects in vases, and will last in good condition much longer than the inmates of a stove temperature. A compost of loam, peat, and silver sand and a little leaf-mould suits it admirably.—J. Gaoxh, Heatham.

## NOTES OF THE WEEK.

**Portrait of Mr. Marnock.**—A Committee has recently been formed for obtaining an oil portrait of Mr. Robert Marnock, the well-known landscape gardener. The following gentlemen form the Committee:—Rev. Canon Hole, Professor Bentley, and Messrs. T. Spencer Wells, John Noble, John Waterer, George Paul, J. F. Meston, Harry Veitch, and Wm. Robinson. As it is probable that many who know Mr. Marnock and his work have not received any communication as to the intended presentation, the Committee have thought it well to announce publicly that subscriptions to the Marnock Portrait Fund will be received by the Treasurer, Mr. John Waterer, Bagshot, Surrey; or the Hon. Secretary, Mr. Wm. Robinson, 37, Southampton Street, Covent Garden, London, W.C. No further announcement will be made. The portrait will be executed by an artist of known excellence, and will be presented to Mr. Marnock himself.

**Hardy Plants at Tottenham.**—Among the plants now in flower in Mr. Ware's collection are *Armeria juniperifolia*, a little Mossy kind, with delicate little rose-lilac heads of blossom; *Narcissus pallidulus*, a Spanish species allied to the Hoop-petioled *Narcissus*; *Primula arctotis*, a distinct and handsome dwarf species; *Scolopis Biglowi*, a very curious plant from the western part of North America; and that very pretty little Squill-like flower which used to be grown (although always rare) about London under the name of *Puschkinia scilloides* before the coarser plant that now bears that name came into cultivation. The true name of this little plant is still uncertain, but we hope soon to publish it.

**Pot Roses in Covent Garden.**—Healthy little plants of the Rose called General Jacqueminot, grown in 6-in. pots, have this week been exposed for sale in the Central Avenue, Covent Garden. They were from 6 in. to 9 in. high, bushy, and well furnished with blooms, of which each plant bore from six to eight. Beautiful under all conditions are early Roses in pots, but when seen in a miniature state like those just referred to they are more interesting than in the form of larger specimens. For the conservatory or for rooms, or even dinner-table decoration, such plants would be found to be most valuable.

**Choiysia ternata.**—A good specimen of this useful greenhouse plant is now in flower in Messrs. Veitch's nursery at Chelsea. It is about 2 ft. high, and as much through, and bears about twenty clusters of white, sweetly-scented blossoms closely resembling those of the Orange, for which it makes a very good substitute. On account of its hardy character and its easy culture, this plant should be extensively cultivated. A coloured figure of it was given in *THE GARDEN* (see Vol. XII., p. 232).

**Magnolia conspicua in the Conservatory.**—Where easily-grown and effective-flowering plants are required for conservatory decoration this might be used with advantage. Although perfectly hardy, its blossoms usually get cut out-of-doors by frost long before they arrive at maturity; if, therefore, plants were grown in pots, or even large tubs like those in which we often find *Camellias*, and moved indoors early in winter, a profusion of snowy blossoms in February and March would be the result. When in flower such plants would associate well with *Almonds*, *Prunesses*, and similar subjects.

**Portrait of the late Mr. J. C. Loudon.**—The Council of the Linnean Society received four members of the London Portrait Committee (Sir Joseph Hooker, Mr. Marnock, Dr. Masters, and Mr. David Wooster), and Mr. Markam Spoforth, and Mr. R. C. Saunders, on Monday afternoon, when Sir Joseph Hooker made over the portrait of the late Mr. Loudon to the Council for the Society, briefly touching on the merits of the works of their late distinguished Fellow. The Council expressed their great gratification at receiving so valuable a gift, and considered the Society would be most fortunate in possessing so valuable a work of so eminent an artist as Mr. Linnell. The likeness is a singularly striking one; and as the picture has been in the possession of the artist ever since it was painted, it is in an admirable state of preservation.

**Amaryllids in the London Nurseries.**—From a decorative point of view the Amaryllids of our greenhouses are amongst the most useful, as well as showy, of winter and spring-blooming, bulbous-rooted plants, and they now form one of the most attractive features of our London nurseries. Although no pains have been spared to improve the varieties by cross-fertilisation, yet it is stated by many who are competent to judge that the improvements made are not so important as might have been expected, considering the labour and trouble expended on them. With a view to induce growers to continue their efforts in raising new kinds, a series of prizes are being offered for the best seedlings, which are shown from time to time at the Royal Horticultural Society's meetings, at South Kensington; and it has also been requested that old kinds should be shown as

often as is convenient, for purposes of comparison. Few plants are more difficult to get into bloom at a given time than Amaryllids are; hence, probably, the reason why they have not been shown at our London exhibitions in such quantities as other plants. Lately, however, there has been a great improvement in this direction, and it is now hoped that Amaryllids will be brought into prominence, and good results be obtained.

**Orcchids at Chelsea.**—Messrs. Veitch's nursery in the King's Road, Chelsea, is just now well worth a visit. The Orchid houses are full of the choicest blossoms, the names of most of which have been published in *THE GARDEN* last week (see p. 326). There is also a large collection of Hyacinths, Tulips, and other bulbs in full bloom. The hard-wooded plant houses, too, are brilliant with *Azaleas*, *Rhododendrons*, and *Heaths*. The large *Camellia* house is also still very attractive.

**Ixora Duffii.**—In our description of this new species (see p. 312) it was inadvertently omitted to be mentioned that it was introduced by Messrs. Veitch. It is stated in their catalogue, just received, to be a native of Strong Island (or Ualan), one of the Caroline group, in the Pacific Ocean.

**White Bouquet Flowers in Covent Garden.**—Amongst the numberless white flowers used in bouquets in Covent Garden Market just now few are more beautiful than those of the *Tabernamontana*. They are as double as those of a Pink, and their petals are beautifully imbricated. The *Tabernamontana* is a plant of easy culture, showing well in a stove or warm greenhouse temperature; and if planted out against a wall or otherwise, yields an abundance of blossoms in value little inferior to those of the Cape Jasmine.

**Camellia Augusta superba.**—Amongst the many kinds of *Camellia* now in cultivation few are superior to this one. It grows freely and blooms profusely, and its flowers, which, when fully expanded, often measure 5 in. in diameter, are well-formed, waxy, and of a rich pink colour. Their petals, too, do not drop so readily as those of many less attractive kinds. In even small collections this is a variety which should always find a place.

**Spiræa Thunbergii.**—As a margin to shrubby borders, or planted in isolated clumps, this hardy and free-flowering *Spiræa* is worthy of extensive culture. Blooming, as it does, for many weeks along with *Primroses* and *Daffodils*, its long garlands of small white blossoms are seen in such company to good advantage, and its wreath-like branches are very useful in a cut state. Notwithstanding the cold and showery weather that has been experienced during the past few weeks, it still continues to bloom profusely in several of the London nurseries.

**Plant-lore of Shakespeare.**—Many readers of *THE GARDEN* will be pleased to know that "The Plant-lore and Garden-craft of Shakespeare" (reprinted, with additions and corrections, from *THE GARDEN*), by the Rev. Henry N. Ellacombe, M.A., Vicar of Bitton, Gloucestershire, will be published shortly. In this work every passage is quoted in which Shakespeare names any tree, plant, flower, or vegetable production. A short account of each is given, identifying Shakespeare's plants with their modern representatives, with illustrations from contemporary writers, and with notices of any points of literary, botanical, and historical interest connected with the plants named. If only as a work of reference we feel sure the book will be welcome to many. We hope to speak of it again on its appearance.

**The Art of Grafting and Budding.**—A re-issue of M. Balle's useful work on this subject has just been published by Messrs. Macmillan & Co., of Bedford Street, Covent Garden. It is, as is now pretty well known, full of illustrations representing the different modes of budding and grafting, and will be found a trustworthy guide to the inexperienced in such matters. It is, indeed, the most complete and trustworthy work on the subject, and shows a practical modes of grafting and budding.

**Botanical Instruction in Berlin.**—The educational authorities of Berlin possess an enormous garden in one of the suburbs of the city for the purpose of supplying all the schools with fresh botanical specimens. The distribution takes place regularly after April 1, and over 4,000,000 plants are required for botanical instruction in the course of the year.

**Clapham Common.**—The Metropolitan Board of Works, as conservators of this common, have, in compliance with the wishes of the resident inhabitants of Clapham, assented to preserve the common in its present park-like form, and the proposed conversion of a part of it into a public recreation ground is now abandoned. The Board purchased the manorial rights and other interests in the common at £17,000 to avert its being built over, and to preserve it as an open space for the public.

## NOTES FROM KEW.

**Hardy Herbaceous Plants.**—The weather not having of late been very favourable, there is still a scarcity of outdoor plants. Tulipa Greigi, from Turkestan, is the finest of all the wild Tulips; its glaucous leaves are copiously spotted with oblong blotches of a chestnut-brown colour, and are much waved towards the margin; the large flowers are bright crimson, with a black and yellow blotch at the base of each of the six divisions. A variety of the European Valeriana Phu, with golden leaves, is at present one of the most conspicuous objects in that part of the Herbaceous Department, and is sure to be a favourite with all who have a leaning towards variegated plants. Three species of Giant Fennel, *Ferula communis*, *F. gigantea*, and *F. conspiciua*, are particularly beautiful; they are strong-growing plants, and their magnificent, dark green, feathery leaves have not been injured in the slightest by the late frosts which have done so much harm to many denizens of the hardy flower border. For isolated groups on lawns, &c., few plants can compare in grace and beauty with the species whose names we have just given. *Fritillaria Munbyi* is a remarkable dwarf Fritillary with large, drooping, dark purplish-red, bell-shaped flowers, the outer surface of the six divisions of the perianth being rendered more striking by a broad band of green which runs throughout their whole length.

**Greenhouse Plants.**—*Sonchus platylepis* is one of those peculiar arborescent Sow Thistles from the Canary Islands, which, from their size and strange form, constitute striking features in the landscape; the large, bright yellow flowers of *S. platylepis* are produced in an umbellate head, and are both striking and handsome. *Boronia serotina*, with its neat little leaves and large, deep red flowers, is one of the most charming of the greenhouse plants from New South Wales. *Rhododendron formosum*, a very neat-habited and free-flowering species, from the mountains of Sillbet, in Eastern Himalaya, has large and highly-fragrant white flowers, tinged with yellow and rose on the inner surface and striped with reddish on the outside. *R. formosum* var. *magnificum* has flowers somewhat larger than those of the type. *R. Falconeri* is a noble Indian species from the summit of Tongo Mountain, 10,000 ft. above the level of the sea; the leaves are very large, and the broadly bell-shaped corollas are white with a dark purple blotch at the base of the interior. *Agapetes buxifolia*, from the Dupla Hills on the eastern frontier of Bhotao, is a fine evergreen, leafy bush, with Box-like leaves and tubular, bright red, axillary flowers; in a wild state it grows epiphytically upon trees at elevations of from 2000 ft. to 3000 ft. *Paltenea stricta* is an Australian member of the Pea family, and is one of the few cultivated species out of the fifty or sixty kinds known to botanists; its yellow and brown Pea-shaped flowers are freely produced on the upright, twiggy branches. *Stylidium fruticosum* is a little Australian plant of much interest; the pink flowers are plentifully produced in upright racemes; the column, formed by the union of the style with the two stamens, is extremely irritable; it springs up with great force and shifts at once to the opposite side of the flower when touched. *Bossiaea linophylla* is one of the most elegant of all the Australian Leguminosae; its branches droop somewhat after the style of the Weeping Willow, and are clothed with brilliant yellow flowers, the standards or upper petals of which are marked with purple at the base. Three very fine shrubs and very valuable ones for greenhouse decoration are *Eriostemon scaber*, *E. myoporoides*, and *E. nerifolia*; all the species of this genus are desirable plants. The three just named have white flowers, others have reddish, lilac, or pink blossoms.

**Stove Plants.**—*Eranthemum tuberculatum* is a very free-flowering small shrub, with neat little leaves, and pure white flowers, with a long narrow tube. *Franciscia violacea* var. *grandiflora* is very showy, with its large deep blue blooms. *Centrostemma multiflorum*, or, as it is sometimes called, *Cyrtoceras reflexum*, is a handsome climber, from Java; the large umbels of white, yellow-tipped flowers resemble those of some Hoyas. *Allamanda nerifolia*, from tropical America, takes up little room, and makes a noble appearance with its showy flowers, deep, almost golden, yellow, streaked with orange.

**Orchids.**—*Epidendrum aurantiacum*, from Mexico and Guatemala, has numerous, large, rich orange-coloured flowers; in a wild state it grows on exposed rocks on the precipitous brows of ravines, where it is subject to great extremes of heat and cold. It has also been found on the trunks of the deciduous Cypress (*Taxodium distichum*). *Cattleya Skinneri* is a splendid species, with large, very lovely lilac-purple flowers. Skinner says it inhabits the hot damp coasts of Guatemala, &c., is always found on very high trees, and is most difficult to get at, except after a storm, which may have chanced to hrow down some of the largest forest trees. The inhabitants call it Flor de San Sebastian, and eagerly search for its flowers to ornament

the temples and shrines of their favourite saints. *Panisea uniflora* is a little Orchid from the hot valleys of the Sikkim Himalayas; its leaves are in pairs, the sepals and petals are membranous, and the tongue-shaped lip is pale orange-yellow. *Lycaste orureta* has large, powerfully-scented orange-yellow flowers, larger, and on longer stalks than those of *L. aromatica*. *Coslia Baneriana* is a West Indian plant, with long pseudo-bulbs and long Grass leaves; the white flowers are borne in short upright spikes. *Leptotes bicolor* is a pretty little Brazilian epiphyte, with fleshy, rush-like leaves, and large, white, purple-lipped flowers. *Dendrobium fimbriatum* var. *oculatum* is a Nepalese species, with large golden-yellow flowers, the beautifully-fringed lip bearing a dark, blood-coloured, eye-like spot in its centre.—↑

**Lime Trees at Longleat.**—The terrific hurricane that swept across this part of the country in October last uprooted from 200 to 300 trees on the Longleat estate. Fortunately, the old ornamental trees in the park did not suffer very severely. Five Limes uprooted were the worst casualties in the park; three of them were standing in an exposed position, and were, consequently, wide-spreading, bushy-headed trees, and had short, rough, faulty butts more or less decayed at the core. These were sold some time ago for £28 the lot. The other two were growing in a grove, and were exceptionally fine, long, clean, sound timber trees. The longest measured 122 ft., and the other 114 ft. from the root to the topmost twig; the stems ran up clean without a branch or break 63 ft. and 58 ft. respectively; and the total contents of the two trees were 350 ft. They were bought the other day by a London firm for pianoforte work, the price being £50 for the two trees just as they laid in the park.—G. BERRY, Longleat.

**Primula amena in Pots.**—It has been strongly forced upon my notice this year that the best way to secure robust groups of flowers and foliage in pots from this beautiful Primula and its varieties is to allow the clumps of roots to remain in the same pot two years together, and then break them up and re-pot after the foliage had died down. To get a fine show in this way it is desirable to have enough of stock to be able to break up clumps in alternate years so that some established for the second year would always be ready to bloom. About nine good, strong, single crowns planted in an 8-in. pot will give a good head of bloom, but it will be far better the second year. I find that these Primulas make but little root-growth before the blooming period, and, indeed, if it is desirable to shift at all, I think it is better to do it after the flowers have died down, as the chief root work is done during the summer. Still it is evident that these Primulas, like nearly all hardy ones, prefer rather to be starved than pampered, and probably throw up more flowers having brighter colours than is the case if there be an excess of root room. Single crowns are now flowering freely in 3-in. pots, and do not care to be kept too moist; if each of these get a shift into 3½-in. pots presently they will flower finely next year. In breaking up an established clump it is easy to select the strongest crowns and to pot those separately; the weaker ones can then be potted up thickly, and will soon make plenty of stock. *Primula amena* forces badly, but under ordinary circumstances commences to bloom early in April. Some of the new seedling kinds are much earlier than others, one of the lacinated forms named Pink Beauty having been in bloom since the middle of March, whilst others are nearly a month later.—D.

**Giant Arum Lilies.**—Some grand specimens of this useful plant just now in bloom in the entrance hall of Bedford House, the residence of Mr. A. J. B. Goodwyn, illustrate forcibly its noble decorative qualities when the plants are of large size, full of vigorous flowers, and leafage. The culture of this Arum is by no means difficult. It will even thrive amazingly in limited pot space; but the luxuriant growth that displays its finest features is best got out of richer soil, more space, and plenty of moisture. The group in question stands in a cool hall in front of a disused fireplace, and, fringed by a few dwarf-flowering plants, presents a marked effect in efforts at indoor decoration. Few plants, perhaps, at this time of the year would more fittingly associate with this Arum than strong, well-bloomed specimens of the Chinese *Dielytra*, one of the most handsome and graceful of all early spring plants. The pendulous growth of both foliage and flower would effectively support the drooping and noble foliage of the Arum, whilst the handsome white spathes project from the mass of luxuriant leaves with a grace that words fail fully to describe. Plants that are so nearly aquatic in habit are doubtless difficult customers to feed in accordance with their entire needs in an entrance hall, but the need might be met by placing the large pots in zinc pans; and, further, in occasionally running a damp sponge over the leaves to keep them free from the dust that will inevitably rise in the best conducted house.—A. D.

## TREES AND SHRUBS

## UNMUTILATED SHRUBS.

The accompanying illustration is from a photograph of a portion of a shrub garden, where the plants, well chosen and well grown, were allowed to grow in a natural, untortured manner. It is curious and most depressing to note the dreadful way in which shrubs generally are grown, or rather mown both above and below. Owing to the bad influence of habit, the very men who ought to protect and encourage this beautiful shrub-life are continually employed in taking the most direct means to make all beauty impossible; and this not merely in small gardens, but in Her Majesty's parks, where many acres of these dismal shrubberies may be seen. Ten shrubs stand where only one could find room to grow well, and each of the ten so mutilated above with knives and below with the spade (wholly needless in any established shrubbery), that each remains for life in the scare-crow stage. Very often the planter is to

blame for putting in six plants where one would do. That even the meanest shrub should be allowed to attain its full development unmutilated by the knife or spade, and uninjured by its neighbours, is a rule that might be safely laid down in many a garden.

## POPLARS, ASPENS, AND COTTON-WOODS.

By Dr. JOHN A. WARDER, North Bend, Ohio.

In an interesting account in the "Journal of Forestry" of what you in England are pleased to call the Black Italian Poplar, I see that you refer it to the species *Populus monilifera*. With your popular names we are not expected to be familiar, and as we have the Lombardy Poplar from Europe, now accepted as a form of *Populus nigra* of that continent, the words Black Italian\* would lead us to think of the Lombardy, long believed to be *Populus glabata* of Aiton. Indeed, one of our best informed American dendrologists, Mr. Meehan, seems to have been of this mind, since in the November number of the "Gardeners' Monthly" he ventures to correct your citation from London, and gives *Populus nigra* as the proper name for your tree. In this I do not concur, for a careful reading of your article gives evidence of a plant very different from the Lombardy, which is essentially a densely clothed pyramidal tree, rarely if ever having a "clean hole." You may be right in referring your tree to *Populus monilifera*, though, unfortunately, this is one of the questionable species, respecting which botanists are not fully in accord. At this distance, and with the meagre evidence presented, omitting all botanical characters except the habit and habitat, it may be thought presumptuous for anyone to express an opinion, but it is modestly suggested that some other American Poplar may have been introduced into Scotland, and that your tree may be *Populus angulata* of Michaux, or his *Populus monilifera*, which last he calls the Virginia or Swiss Poplar, and says it is extensively cultivated for timber in Europe, espe-

cially in Switzerland and France. The Carolina Poplar, *P. angulata* of Michaux, is commonly planted in Belgium; either of these might answer the description of your tree. The Poplars are not esteemed in this country where hard woods abound, and are preferred for construction; but in the great prairie regions, where the scarcity of woodlands is forcing the people to plant, and where millions of trees are annually set out, the rapid growth of Cotton-woods and their easy propagation from seeds and cuttings make them favourite pioneers for the future forests which must be planted. This, too, is following the natural indication, for in our progress westward from the wooded regions of the Ohio valley the Cotton-wood is the proper arboreal form, and while almost all others disappear, these continue to recur along the streams to their very canons at the base of the Rocky Mountains.

However, in the beginnings of an American forestry, yet to be developed, we advise the planting of Cotton-wood first to act as windbreaks, under the shelter of which adjoining lands may afterwards be planted, with many other species which would have inevitably encumbered to the dry blasts from the prairies and open plains. With your leave, a brief conspectus of the Poplars of this country and Europe is here presented, as the result of a recent study of the genus with the aid of such works as were at hand in my limited library, and supported by my own observations. In this article they will be divided into the three very natural groups of Poplars, Aspens, and Cotton-woods.

## Poplars.

*POPULUS BALSAMIFERA* (Tacamahaca, or Balsam Poplar) is a very distinct species. This is essentially a northern form, being found as far north as the Great Slave Lake, in latitude 63°. Tree of medium to large size, with open, straggling branches; leaves are on roundish petioles, oval, coriaceous, dark green above, rusty brown beneath. Though unseemly, it is somewhat cultivated.

*P. CANDICANS* (Balm of Gilead, Heart-leaved Balsam Poplar) is now considered merely a variety of the above. This form is seen chiefly in cultivation, though it has little to recommend it. The buds of both these are large, and abundantly covered with a balsamic resin that has been used in medicine.

*P. ANGUSTIFOLIA* is described by Mr. S. B. Watson as a common tree in the Rocky Mountains. It is now grouped with *candicans* and *balsamifera*, of which it is a very distinct Western form. Different trees and locations present quite a variation in the foliage, some leaves being ovate, while in other trees they are nearly linear, and with a drooping spray, the resemblance to a Willow is very striking, as seen on the Platte River or Denver Colorado. Nuttall considered this a good species, and says it becomes a noble tree on the western coast.

*P. TRICOCARPA* is another Western form found in Truckee Valley, Nevada, and elsewhere in the heart of the Rocky Mountains, as well as on the Santa Clara River, California.

*P. NIGRA* (European Poplar) was not recognised by the Michaux and Pursh, though they found a form of it growing in New York City and on the Hudson River, near Albany, which was described as the *P. Hudsonica* by Michaux, and by Pursh as *P. betulifolia*. There is now no doubt about its having been introduced from Europe, where it grows to a large size, and with *P. alba* is much used along the banks of the Danube in reclaiming low and overflowed lands. The thickets arrest the debris of floods, and furnish abundant material for the fascines used in the weir-drows and levers placed along the river for the improvement of the navigation of that noble stream.

*P. DILATATA* (Aiton), the Lombardy, or Italian Poplar, is no longer looked upon as a species in this country, but merely as a variety or sport from the *P. nigra*. This plant is extensively grown as an avenue tree along the highways of Southern Europe, where it appears to be a great favourite, notwithstanding its formal habit. It does not appear even there to be valued for its timber, and is never seen in forest plantations.

The Lombardy was very early introduced into this country. In 1784 it was planted by William Hamilton, Esq., on the site of the Centennial Exhibition (vide Watson's "Annals of Philadelphia"), and extensively planted elsewhere, particularly in the streets of towns and cities. In the Eastern States very large trees may yet be seen in good condition, but in the Western States, especially in Northern Illinois and Wisconsin, it has been largely planted in fence rows and wind-breaks with fine effect. In our soil, however, the tree does not promise to be long-lived. The plants in this country are all staminate or males, and have been multiplied by cuttings. How is it in Europe?\*

\* This question is already answered by my friend and jury colleague at Vienna, Giovanni Carlo Sismorio, who says this Poplar, which he also calls the Cypress or pyramidal, and *P. Italica* Dur., is considered only a variety of *P. nigra*. No firmer plants are known. He adds that it is much cultivated in Lombardy, and particularly along the Po. In evidence of its antiquity he quotes Ovid,—"Manuale d'Arte Forestale," 1872, p. 137.—J. A. W.

\* Nuttall calls this the Italian Poplar, or Lombardy. "Am. Sylva," vol. i, p. 55.

### Aspens.

The Aspens, or Abeles, form a distinct group; they are usually smaller trees, as we see them here, especially the native species.

**POPULUS TREMULOIDES** (Quaking Aspen), is a small tree seldom more than 20 ft. to 30 ft. high, and a few inches in diameter; and in the north it becomes a mere shrub. A form of this species in the valleys of the Rocky Mountains springs up spontaneously in the greatest abundance wherever the woodlands have been burned over. The older trees have stems of from 50 ft. to 60 ft. in height, and are used in construction. This plant is almost unique as a deciduous tree among the evergreen Conifers of that extensive region. Generally speaking, this species has little value, but there are some peculiar forms of this and the next that are cultivated for effect in gardens and parks.

**P. GRANDIDENTATA** (the Michigan Poplar of the nurserymen's catalogues) is a much finer tree than the last, and also northern in its habitat. On account of its rapid growth, this tree has received much attention among western tree planters; and though only a Poplar, considerable merit has been accorded to it as a fencing material. The poles cut in early summer and tested have been found to last ten and twelve years when nailed to posts as a fence; they are, however, like all their kind, deficient in strength and easily broken.

**P. CANESCENS** (or more correctly *P. alba Abele*) is the common White or Grey Poplar of Europe, with its many forms or varieties of Abele, Athenian, Maple-leaved, and Silver Poplars. Though widely diffused and planted everywhere, and wonderfully multiplied by numerous suckers in their new homes, these are all believed to be of European origin. If correctly understood, however, my good friend Prof. Karl Koch, of Berlin, who has made a life study of trees, considers this species to be American, or common to both hemispheres. His valuable work is just now, unfortunately, not at hand. In Northern Europe the White Poplar becomes a noble tree, attaining the height of from 90 ft. to 100 ft., and a diameter of from 5 ft. to 6 ft., as seen in the Praterst, Vienna, Austria. The timber is much used in the construction of buildings and for other purposes in Europe, and the tree may be found valuable to our own western planters. Michaux claims two distinct trees, the white and the grey, attributing superiority to the latter.

**P. TREMULA** (Trembling Poplar or Aspen, the congener of our *P. tremuloides*) is a European tree of small size and of little value, except to cover denuded tracts as a restorer of the soil, preparatory to the introduction of some other more valuable species.

### Cotton-woods.

These form a characteristic group of the family, and are believed to be essentially American in their origin. Many have been transplanted into European soil, and thrive as well in their adopted home as though to the manor born. In their native land many of the Cotton-woods attain majestic proportions, and they are not without their value. The great logs were easily wrought into canoes by the aborigines and early settlers. They provided food for the native beavers as well as material for their subaqueous structures, and the pioneers of the West often helped to sustain their live stock during winter by the coarse forage furnished by the soft wood and large, almost succulent buds of the branches of trees out down for the purpose. The lumber, though inferior for most purposes to the hardwood species, was, and is still, used to a considerable extent in some parts of the country, and the Cotton-woods are planted more numerous than any other trees in the new forests that are rapidly spreading upon the borders of the great plains. These will effect the double purpose of furnishing abundant supplies of fuel and timber in a few years, sheltering the open country, rendering it more habitable as well as more productive in cattle and crops. But, best of all, they will enable the forest planter to introduce other and more valuable kinds of trees for the future wants of the people that are destined to cover these vast areas, that have been heretofore but desert steppes, so far as human habitations were concerned, and only roamed over by hordes of savages and by herds of the ruminant buffalo of the plains. With great diffidence the determination of some of the species has been reached by the writer, who gracefully bows to the magnates of botanical science; but where even these are in doubt, who shall decide? There is some uncertainty as to the designations given to these plants by botanists, some of whom, perhaps, had only herbarium specimens, and the unsatisfactory descriptions of non-scientific, though intelligent, travellers from which to make up their diagnosis.

**P. ANGULATA** (the Carolina Poplar).—Michaux says this species, which he first met under the name of Carolinian Poplar, was found in the south of Virginia, and also on the Mississippi and Missouri rivers, growing with the Cotton-wood, his *P. canadensis*. He describes it as a tall-growing and upright tree, which is the character of the

Carolina Poplar as now known. The buds are short, dark green, and destitute of the viscid resin found on these of the Cotton-wood proper, and on most other Poplars. This is believed to be the tree so prevalent in Belgium, where it is planted along the lines of the canals, for which position it is peculiarly adapted by its upright habit, that is persistent even when grown singly.

**P. CANADENSIS** (the Cotton-wood) is considered by our excellent botanist, Dr. Gray, to be the *P. monilifera* of Aiton, and the same also as the *P. laevigata* of Willdenow. However, Wood's No. 5, *P. monilifera*, after Aiton also, seems to be different, and he gives its habitat, "on the Hudson, near Troy, New York," and quoting Dr. Beck, "apparently native." Michaux found this species as far north as latitude 43°. It is abundant in the Black Swamp of north-western Ohio, and fine trees may be seen on the bank of the river below Detroit, Michigan. Michaux describes the tree as larger than *angulata*, and the bark as thicker and more deeply furrowed, having also a rounder head, and with the boughs more numerous branched. This character of the outer bark has attracted the attention of the fishermen on our great lakes, who utilize it as a substitute for the more costly bark of the Quercus alba, or Cork. Sections of this substance, often 3 in. thick, turned into oval form and perforated, are used as floats to their gill-nets. Michaux reports this species rare on the Atlantic slope, but very common in the Mississippi valley, especially above the mouth of the Arkansas. The Cotton-wood is the chief source of the steamboat fuel used on our southern rivers.

**P. MONILIFERA** (the Virginian or Swiss Poplar), does not appear to have been found in this country by Michaux, father nor son, but they say it is extensively cultivated in Europe, especially in Switzerland and France, though the males only are found there. The young shoots of this species are angular. Comparing it with the Cotton-wood, M. Foucault says the leaves are smaller and less distinctly heart-shaped; the young shoots and twigs are smaller and less angular, becoming cylindrical in the third year, and the limbs are less divergent than those of the Cotton-wood. It also grows faster, and succeeds in drier soil, hence its popularity in France. The wood is said to be softer than the Cotton-wood of Michaux, or *P. canadensis*.\* Dr. Torrey found it in Western New York, on Lake Oneida, and on the Genoa River.

**P. ARGENTEA** (or the Cotton Tree), and according to Gray the *P. heterophylla*, is found in the Middle, Western, and Southern States. Michaux refers to Fort Massac, on the Ohio River, and to a large swamp in Southern Illinois, as its habitats. The tree is large with thick bark, and the shoots are round, the leaves very downy when young, becoming large when expanded, and having the lobes at the base overlapping each other. The wood is described as inferior, becoming yellowish at the heart. These trees would probably receive the common name of Cotton-wood among our Western wood-choppers; indeed, they bear a very close resemblance and have close analogies, which might very properly be referred to a conference of eminent botanists and foresters for a settlement of the questions which now exist. The sub-group of Poplars, which has been consolidated, embraces kinds more dissimilar than some of the Cotton-woods that are still recognised as distinct species.

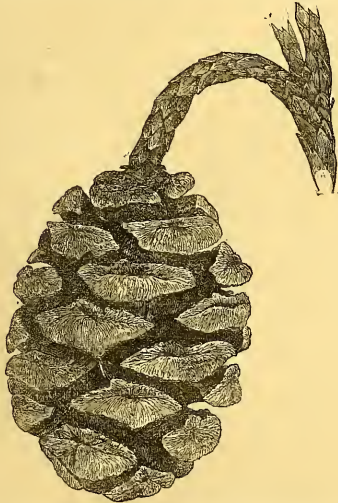

In this hasty review of a numerous genus, which occupies so large a space in the northern temperate regions, the endeavor has been made to compress a great deal within the limits of an article for the "Journal of Forestry." Perhaps too much has been attempted, and much certainly has been introduced to enable the reader to follow intelligently. For the sake of brevity, all new botanical descriptions have been omitted, but these can readily be found by the student in the works of the authors referred to in the text.

### THE "BIG" TREE.

So much as been written about this vegetable wonder since its discovery by Lobb, in 1853, that there is scarcely an excuse left us for more than mentioning it. Philosophers and poets of the highest modern order have treated us to some of the finest English measure respecting it and its more immediate surroundings. They have given us the imaginary size and height of its larger members, and now the prosy, matter-of-fact chief of the State Geological Survey of California (who was paid for his dry figures) has reduced the "big" trees to an actual average height of 250 ft., the maximum height being 325 ft., thus bringing it within the level of the Oregon Red Cedar (*Thuja gigantea*), *Picea grandis*, and *Abies Menziesii*, plants of which have been found—according to reports in THE GARDEN—that measured from 318 ft. to 325 ft. But though

\* This species is cited as *P. monilifera* (Moench) by Sirrioni in his *Mammal*, p. 237.

thus reduced to a height in common with its fellow-inhabitants of the North-West Pacific slope, it is yet known to contain within its thick shaggy bark more timber than any other known tree. Twenty-five years have elapsed since its introduction, and now one-year-old seedlings can be bought for £10 or even less per 1000, a price at which it finds a ready sale. Indeed, at this season of the year it is scarcely possible to find a respectable well-grown plant from 3 ft. to 6 ft. high in any nursery in Britain. I may mention that 3 ft. of the hundreds of thousands, that are annually raised from seeds a moderate percentage dies in the first and second years of their existence whether grown under glass or in the open ground. When out-of-doors the death-rate is greatest towards the end of summer, when the plants are growing rapidly, and when the soil is pretty well charged with moisture, and the atmosphere warm, moist, and sunless. At such a time and under such conditions the plants are succulent and completely gorged with crude sap, and it is probable that, owing to the want of sunlight to partially elaborate and eliminate the sap, it either bursts or rots the cells, and hence decay arises often only in a mere branchlet or branch, but frequently throughout the whole plant. Whether this be

One of the "Big" Trees (Sequoia—Wellingtonia—gigantes).

the correct explanation or not, certain it is that an abundance of sunlight and a partial drying of the soil will prevent the spread of the evil. Sunlight is not at the bidding of the arboriculturist, but he can, for the benefit of his young Sequoias, select a naturally well-drained light soil in which to grow them, and the less manure given at this stage of their existence the better.

As an ornamental plant in a small garden, this giant Sequoia (*Wellingtonia gigantea*) is not a success, or if so, only for a short time. Avenues of it have been planted, and, as respects the health and uniformity of the growth of the plants, with the best ultimate results; but the judgment in making use of the formal Sequoia for such a purpose is somewhat doubtful. Single specimens when in good health look well in extensive parks; and I lately saw it to advantage in the grounds at Stancliffe, near Matlock, where a few plants were growing on a steep, almost vertical bank, out of an undergrowth of Hollies and other shrubs. They stood out in bold relief against the romantic, yet artistically-adorned, cliff, from which, I presume, the place takes its name. It is as yet too expensive to be extensively planted as a common timber tree, but the day is probably not far distant when it may be profitably used for that purpose. Unfortunately I am unable

to speak of the quality of the timber. Its home is so far outside the home of civilisation, that I fear its timber has never been thoroughly tested. Its wood, however, is known to be soft and brittle, and of a light Cedar-brown colour. The woods of several of the members of the sub-tribe *Taxodium* (*Parlatore*), to which it naturally belongs, are of great economic value, and this is especially true of its nearest relative, *S. (Taxodium) sempervirens*, the Redwood. The Sequoia has proved to be perfectly hardy everywhere in Britain, for, although the foliage sometimes gets browned, it is more frequently the effect of wind and exposure than of cold. In its native mountains it has to endure a much greater degree of cold than it ever experiences here; but, tall as it is, it is so completely immured in the deep glens of the Sierras, that wind seldom reaches it. It is unreasonable to suppose that the young of a plant that has been thus tenderly nurtured for probably thousands of years are unlikely, when grown in Britain, to submit to less tender treatment. They require shelter from cutting winds, and must have it. Like the majority of plants of great commercial value, the Sequoia has its varieties. These are white-twigged, golden-twigged, golden variegated, and pendulous-branched kinds, all of which are very pretty in their way, but the latter, *S. gigantea vera pendula*, so named and distributed by the Messrs. Little & Ballantyne, Carlisle, is generally allowed to be a great horticultural acquisition.

The accompanying figure is from a drawing by Walter Dawson, of a California-grown cone. GEO. SYME.

**Cattle Poisoned by Eating Green Yew.**—That living Yew is as injurious to cattle as its drier state has been most fully exemplified on the estate of Geo. A. Everitt, Esq., Knowle Hall, Warwickshire, a very valuable horse and cow having succumbed to its poisonous properties, while a large number of other cattle were so severely injured by eating it that for the season they were comparatively worthless as milking cows. This occurred during the winter of 1876-77. The cow had broken through a fence into a covert in which Yew formed a part, and had, judging from the contents of the stomach when opened, eaten freely and died in apparently great agony a very short time afterwards. The horse had cropped the green ends of the branches of the trees that were hanging over the field in which it was grazing in company with the other cattle that were injured, and was being led into the stable a very short time afterwards when it fell and immediately expired. The fact of cows not being able to reach so high as the horse, and consequently failing to consume so large a quantity, prevented them from sharing the same fate. It is scarcely needless to state that all Yew trees within reach of cattle have been taken away on the estate, and the greatest care is observed in strengthening the fences and otherwise preventing ingress to any place in which the deadly shrub is growing—a hint that may advantageously be taken by all those who have charge of cattle, for, although a number of years may expire (as in the present case) without the animals eating the Yew, yet they are, of course, always liable to do so, and "prevention is better than cure." With regard to the common Laurel, we have here several large clumps that are periodically eaten by the cattle without, up to the present time, any apparent injury being done to them.—F. W. SILVER, in "Gardener's Chronicle." [It seems singular that the cattle should have received no injury from eating the leaves of the Laurel, which contain notable quantities of prussic acid.]

**Continental Forests.**—Elsass and Lothringen (Alsace and Lorraine) have long been famous for their wealth in forests. According to the report issued by the Imperial Commissioners of Woods and Forests, the entire forest lands of the newly-acquired province represent a value of about twelve milliards of marks. No less than 460,573 hectares of these forest land are State property, and are estimated to be worth 500,000,000 marks, or £25,000,000 English. In the year 1876 the woods yielded an income of 6,944,000 marks to the Treasury. The report has a table of the average annual value of a hectare of forest in Continental countries. In Elsass-Lothringen it is reckoned at forty-three marks, in France twenty marks (25 francs), in Prussia at nineteen marks. The cost of administration is far higher in the latter country.

**The Eucalyptus in California.**—Last season the Central Pacific Railroad Company planted 300,000 Gum trees on the lines of their roads. This winter they intend to plant 700,000 more. These set out by the company around their shops in Sacramento last season having made such rapid and healthy growth, the company are now planting 2000 additional trees, placing them in every available nook and corner around the works and along the track by the slough.

**Germination of Acorns.**—In this place (Lansing, Michigan) white Oak acorns germinate in autumn. The radicle pushes out and down into the leaves or soil often 3 in. or more. The petioles of the cotyledons grow out from the shell about  $\frac{1}{4}$  in. This enables the plumule to find plenty of room to start in spring. It is quite common to find two embryos in one acorn, and three embryos are not very rare.—"American Journal of Science."

## DISUSED GRAVEL PITS.

THERE are few who are not familiar with those tracts of land which exist near almost every large town usually called commons, heaths, or greens, and who are unacquainted with the necessity there is for retaining them as open spaces for public recreation. It cannot be too widely known that these commons, with their trees, shrubs, and plants, assist materially in purifying the vitiated atmosphere emanating from all populous districts. They are, so to speak, so many filtering beds, doing their work silently but surely. The principal use of these open spaces hitherto appears to have been to supply gravel, sand, turf, loam, peat, &c., for the neighbourhood in which they are situated, and to form grazing ground for a few horses, cows, sheep, &c., certainly giving no adequate return, considering their extent and value. In many cases they have been hampered by old and what should be obsolete laws, rendering them useless, or comparatively so, to all concerned. Within the last few years, however, a movement has been made in the right direction, and, so far as regards the metropolis, a goodly number of broad acres have been secured in perpetuity for the recreation of its teeming population, and that, too, at what may justly be termed moderate cost considering their immense sanitary value. What primarily strikes us upon going over these open spaces is the neglect into which they have fallen. Happily, however, the remedy is fast being applied, and great credit is due to the public spirit exhibited in the matter. It is, of course, both impossible and unadvisable to at once convert them into public parks with all their modern expensive adjuncts, but everything seems to tend in that direction, and that, too, in spite of cost, at least, so far as regards those which are in proximity to the great centres of commerce. So far, however, as respects the conversion of these commons into public parks, we must for the present rest and be thankful, and turn our attention to other works which may with advantage be carried out, such as drainage, fencing, formation of roads and paths, renewal of turf, &c. While, however, the absolute necessity for these works will be self-evident, there are others equally important which may escape attention unless brought prominently before those in whom the care of these open spaces is vested, and amongst these I venture to name the re-forming and planting of disused gravel pits. These afford, without doubt, one of those chances which rarely occur of doing a great deal of good work at a trifling cost. Upon some of the commons near London these pits are very extensive, and would, if properly treated, form landscape features of a high order. At present they are bare and unsightly, with the exception of a little Furze and Broom. Generally but little soil remains, 'tis true; still, much may be done with a knowledge of what is suitable for planting in such situations. In the majority of cases little need be done so far as the surfaces are concerned; in a few instances it may be necessary to slope down the banks, an operation which must, however, be carried out with great care, and only where absolutely necessary. In some instances water might be made to assist the designer; and in my opinion, where it is available and can be obtained at little cost, these pits would afford an excellent opportunity of displaying it to advantage. In all cases where soil is available the slopes should be covered to a uniform depth with it, say, at least, 1 ft. If any difficulty be experienced in getting soil, its use may be limited to simply putting some in each hole in which trees or shrubs are to be planted. It will thus be seen that much may be done at a trifling cost in the way of laying out such pits to advantage. The planting should be done firmly and somewhat deeper than usual, the nature of the soil being generally sandy. It is almost impossible to conceive what a great change the skilful carrying out of this work would effect; hill and dale could be worked out in miniature, and where water could be made available, really beautiful little landscapes might be created. This would be a simple and natural method of dealing with these pits, which, at present, are decidedly unsightly. I should most certainly deprecate any attempt at filling them up to render the ground available for cricket or football. The improvement which such changes would effect, in addition to the very moderate expenditure which they would incur, should, I think, recommend them to the notice of all interested in the matter of open spaces. The

list of trees and shrubs suitable for planting is a very large one. Conifers of various descriptions might be made to play an important part. Birch, Willows, Poplars, &c., are also extremely pretty in such positions, whilst Tamarisk, Broom, and similar subjects have likewise a very graceful appearance. My object, however, is not so much to give a list of trees and shrubs available for planting as to direct attention to the desirability of doing something towards the decoration of these disused gravel pits. CHARLES DENNIS.

*Southwark Park.*

## GRAVEYARD GARDENS.

THERE are few open spaces either in town or country that present features more depressing than those found in cemeteries or country graveyards. A few sombre trees may be seen here and there sometimes planted with judgment, sometimes without, but generally of a heavy, funereal aspect, and nearly all the rest is a wilderness of mounds, headstones, pretensions tombs, and monuments, much long rank Grass, and seldom any attempt to produce elements of beauty or of cheerfulness. That this is largely the case in rural graveyards is patent to all who care to visit them. A modern graveyard, on the other hand, resembles a newly-built neighbourhood, where all is in a transition state; the more recently erected tombs are all clean, the more recently made mounds are bare clay and gravel; there is little that can be termed sacred, but much that is tawdry. We want an entire revolution in our graveyards; we want their sombre and harsh aspects abolished, and instead thereof a purer and more fitting respect paid to the memories of the departed by converting the precincts of their last resting-place into a pleasant garden. To sweep away all the evidence of the stonemason's craft would be a worthy beginning, and with that all mounds and wooden erections, however humble or however emblematic; these I would replace with simple zinc plates supported by wire and iron supports, around which might be trained Ivies, Roses, Clematises, Honeysuckles, and all kinds of hardy climbers, thus leaving the name plates exposed and so fixed as to enable a future generation to take them off, and at any time re-write them. The surfaces of all graves should be little gardens, surrounded by an edging of wirework or some other elegantly made material, and on each should be cultivated a few dwarf flowers, such as the taste of the surviving relatives might dictate or their circumstances enable them to obtain. Here at once are introduced elements of beauty and cheerfulness, and not least of cheapness, as the requisites may be obtained at a comparatively trivial cost, whilst the attention necessary in all future time may well be the duty of the graveyard attendants, who should receive a sufficient salary to enable him to keep his garden so neat and so pleasant as to make it at all times a loved resort of the living. Only one such a grave garden have I yet seen; it is in a humble churchyard, and is now all abloom with pretty spring flowers, Daisies, Primroses, Forget-me-nots, Hepaticas, and topped over with fine Cocoa-nut fibre refuse, and enclosed with a low edging of wirework. To maintain the neatness is but a labour of love, and grave gardens will more fully than in any other way serve to perpetuate a sentiment for the dead, which should ever be that of fond remembrance. A. D.

**Weather Proverbs.**—The late trying weather has done less harm among spring plants than might have been expected. Some of the more succulent kinds, like *Dentaria digitata*, have been cruelly out, while *Orobus vernus* in sheltered situations is little hurt. The Japanese *Rosa Regeliina*, being in full leaf, has some of its points quite browned. The weather has been spoken of as quite exceptional. Some lines I learnt from my mother, who said that they were considered very old in Lanarkshire, would seem to show that in Scotland, at least, very severe weather was to be expected at the beginning of April. The lines are these, and I hope the Scotch is about right:—

Said March to Aprel,  
I see twa hogs at yonder stile;  
If ye'll gae me days three,  
I'll fa on means to gar them dee.  
The first of them was wind and weat,  
The second of them was sna and sleet;  
The third of them mak sic a freeze,  
Made all the birds' nebs stick to the trees.  
When they three days were past and gae,  
The silly pair hogs cam birplin hame.

The three bad days have often been noticed in England, but the season being earlier, they usually come in the last week in March. I may add that hogs mean yearling sheep.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

## THE FLOWER GARDEN.

## VARIEGATED NEW ZEALAND FLAX.

(PHORMIUM TENAX VARIEGATUM.)

In the *Revue Horticole* of March 1 M. Carrière gives the following account of the variegated variety of the New Zealand Flax, of which the annexed is an illustration: This plant is one of the most vigorous of the varieties of *Phormium*, and is readily recognised by the size of its leaves, which are larger than those of any of its congeners. In addition to this, they spring obliquely from the stem, growing in an arched form, sometimes even bending over at the extremities. They are variegated with beautiful yellow streaks from one end to the other, the markings being separated by green lines. The flower-stalks often grow to the height of 6 ft. or 7 ft., and are covered with long, reddish bracts, which soon become dry. The flowers are numerous, and the bracts soon fall off, often before the blossoms have opened. The flowers are thickly crowded together, and are of a dark brick red. The seed

The Variegated New Zealand Flax in Flower.

vessels are borne on short stalks, and are of a dark reddish-brown. The specimen from which the annexed figure was taken was planted out in the open air in the Paris Jardin Fleurist. It was well protected from cold during the winter. Although a large number of shoots have been taken away from it every winter, for the purpose of keeping up a supply of fresh plants, it is still more than 3 ft. in diameter. Last year it was artificially fertilised, and produced a large number of pods full of excellent seeds. If sown as soon as they are ripe the seeds soon spring up, but, up to the present, all the sowings that have been made have never reproduced the variegated kind, the leaves in every case being plain green. In spite of this circumstance M. Carrière recommends his readers not to neglect sowing the seed of the variegated kind, for although there seems little chance of obtaining specimens of the striped variety amongst the seedlings, the resulting plants are much more vigorous and the leaves much larger than is the case with the parent species. C. W. QUIN.

**Dwarf Gladioli.**—Those who care for useful and exceedingly beautiful plants for cutting late in summer, both from the conservatory and open border, should try *Gladiolus nanus*, a delicate salmon-coloured hybrid, 18 in. in height, with crimson spots on the lower petals. M. Van Houtte, in his catalogue, states that when grown out-of-doors it requires protection with litter, but my patches of it here have been uncovered throughout the winter, and are now very robust, and none the worse for the sharp frosts which they experienced last month. The price of *Gladioli* is so small, the better kinds being only 10s. per 100, that they are within reach of those who possess the smallest gardens.—E. F., *Petigards Hall, Swaffham*.

**Ivy on Stakes.**—The illustration (see p. 286) recalls to my recollection some excellent examples of this style of growing Ivy, which I saw recently on a Grassy slope by the edge of ornamental water—dense masses of Ivy with no visible supports. I was inclined to think that they had overgrown and smothered some low bushes, but on inquiry I found that it was only a single plant of Ivy that in the first instance had been tied to a stout stake and afterwards allowed to train itself. This it has done effectually, and some beautiful symmetrical heads of glossy foliage, thickly interspersed with jet black berries, formed very pleasing objects presentable at all seasons. Doubtless all the vigorous-growing, plain-leaved varieties of Ivy would conform to this mode of culture, but if variegated varieties be employed, some means of restricting the roots must be adopted, or over-luxuriant growth would in most instances be found to cause them to revert to their original forms.—J. GROOM, *Henham*.

**Old Pelargoniums for Planting in the Flower Garden.**—Where large quantities of Pelargoniums are required for summer decoration, it is much better to retain a good supply of old plants than to trust exclusively on fresh-struck cuttings. When the beds are cleared in autumn we go over all the sorts that are desired for the following season, and, selecting all the healthiest plants, cut them down quite close, shortening the long straggling roots; they are then packed thickly into cutting boxes in fine, light soil, and kept rather dry. During the winter they are kept as cool and airy as possible in fruit houses at rest, and in spring, when vegetation becomes more active, they are shaken out. The best-shaped plants are potted for vases and window boxes, and the remainder is tied up in Moss with a handful of soil and set closely together in brick pits, where they can be fully exposed on favourable occasions until required for planting out. By using a good proportion of these plants the beds may be pretty well filled at once, and an early display of bloom secured. In moist seasons young plants are liable to run too much to leaf instead of to flower, whereas old out-down plants flower profusely in all seasons, while for single specimens in vases plants with dwarf, bushy habit are indispensable; and few plants so well withstand the trying conditions under which they are thus placed and furnish such good results as these. Single specimens in small vases of distinct colours, or large vases filled with mixed varieties and edged with the beautiful trailing varieties of the Ivy-leaved section, will be found as continuous and satisfactory as any plants grown.—J. GROOM, *Henham*.

**Plants that Flowered in March.**—The following is a list of plants which flowered in March. On looking back, I find that in January twenty species, belonging to thirteen Natural Orders, opened their flowers; in February, forty-seven species belonging to nineteen Natural Orders; in March, we have a total of seventy-three species, belonging to twenty-six Natural Orders. They are as follows: March 1. *Vella Pseudo-Cytissus*, *Mycotis alpestris*, *Scilla bifolia alba*, and *Dentaria digitata*. 2. Large double Daffodil, *Primula purpurea*, *Cardamine trifolia*, and *Viola collina*. 3. *Puschkinia scilloides*, *Saxifraga hispida*, and *Corydalis cava*. 4. *Lamium levigatum* and *Dielytra canadensis*. 5. *Berberis nepalensis* and *Hyoscyamus orientalis*. 6. *Narcissus polyanthus* and *Anemone apennina*. 7. *Corydalis bracteata* and *Milla uniflora*. 8. *Muscari sygca*, *Othonna cheirifolia*, and *Orobus vernus plenus*. 9. Double Periwinkle, *Orobus alpestris*, *Palmatoria sibirica*, double *Narcissus*, and N. bicolor. 10. *Anemone hortensis*, *Hyacinthus amethystinus*, *Alyssum saxatile*, and *Fritillaria montana*. 12. *Erythronium giganteum* and *Narcissus multiflorus*. 13. *Porsythia suspensa*, *Narcissus biflorus*, and *Iberis sempervirens*. 14. *Anemone nemorosa*, *Myrrhis odorata*, and *Narcissus Basilman-major*. 15. *Iris pumila*, and *Ceanothus Veitchianus*. 16. *Odonis vernalis*, *Muscari botryoides album*, *Helianthemum arcuatum*, and *Doronicum Columnæ*. 17. *Porsythia viridissima*. 18. *Anemone palmata*, *Ranunculus montanus*, and *Potentilla verna*. 19. *Scrophularia verna*. 20. *Primula decora alba* and *Apongeton*. 21. *Kerria japonica* and *Menziesia empetriformis*. 22. *Lilium grandiflorum* and *Hannuculus amplexicaulis*. 23. *Narcissus Trewianus*. 24. *Fritillaria Melegaris*, *Stellaria Holcista*, and *Geranium fumaricæfolium*. 26. *Rhododendron Chamæcistus* and *Centranthus ruber*. 27. *Lnaria rediviva*, *Anemone bracteata*, and *Narcissus angustiflorus*. 28. *Fritillaria contorta*,

Saxifraga cespitosa, and Cydonia Gonjardi. 29. Ranunculus gramineus and Primula decora. 31. Corydalis nobilis and Narcissus incomparabilis plenus.—H. W. MOORE, *College Botanic Garden, Dublin.*

## ROSES.

MAY QUENNET, figured (see p. 286), is the best rosy-magenta I have ever seen, La Rosière the best dark, or say equal to John Keynes. Duchesse de Vallombrosa, from the coloured engraving, does not take my fancy as much as Captain Christy, but perhaps the delicacy of the blush colour may be impossible to show. In many of the suburbs of our towns the soil is poorly adapted for the culture of Roses, and therefore it must be made so by liberal dressings, in the autumn of the year, of very rotten manure composed of whatever is most easily procured; and decayed leaves and old turf form a good addition. A few useful and hardy kinds may consist of Safranot, Solfaterra, Céline Frestier, and Devoniensis for climbers; for standards choose Gloire de Dijon, John Hopper, Madame Falot, John Keynes, Mrs. Bosanquet, Jules Margottin, Eugène Appert, Charles Lefebvre, and Madame Rothschild. These I always grow, and for general use think them equal to any; but if the intending Rose-grower possesses over so small a greenhouse, he can without heat grow Maréchal Niel, an abundant bearer, under favourable circumstances, splendid in shape and colour, and with very full centres. The only other Rose for the greenhouse is Niphotos—unfit for out-of-doors, but perhaps the most delicately white of white Roses.

EUGÈNE E. P. LEEGE.

Litton Cheney, Dorset.

**Late Pruned Roses.**—Those who deferred pruning until late in March this season have reason to congratulate themselves, as the bright weather in the early part of the month induced rapid growth, and had they been pruned close all the buds would have been forced into growth, whereas where unpruned the leading shoots have carried off the superfluous sap, and plenty of dormant buds are left, unscathed by the late inclement weather, for although we do not as a rule experience such severe frosts as in more inland places, I find that it has been sufficient to leave its mark on Roses as well as on other plants, and those who pruned early will probably find that their supply of Rose blooms will be more limited than those who adopted the late method.—JAMES GROOM, *Henham.*

**Roses that Bloom Freely, and Roses that do not.**—We have covered the back of our conservatory wall, which is brick about half way up, the remainder being glass, inside with Roses, and more than half of it is devoted to a fine old plant of Gloire de Dijon, which produces an abundance of fine blooms, of which I have counted more than 600 on it at one time. By the side of it I have a strong four-year-old plant of Reine d'Or which last year bore a few blooms. It made good growth each year, and last season some of the shoots measured from 12 ft. to 15 ft. in length. I tied them down exactly as I did those of Gloire de Dijon, and expected a profusion of bloom. Gloire de Dijon is just coming into flower, as usual, but Reine d'Or shows nothing but leaves, which I admire, but I want flowers as well. Climbing Devoniensis I have growing up an iron rod in a border in the front of the conservatory; it is of the same age and quite as strong as Reine d'Or, and it too has not yet bloomed. I have pruned down to the hard wood, but no further. Will some of your readers who have had better success with these Roses kindly give me a hint or two in reference to them?—WILLIAM HOUGH, *Oaklands, Hyde, Manchester.*

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Calceolarias in Trenches.**—The readiest way of protecting these from late spring frosts is to transplant them into trenches, similar to those used for late Celery. We have just transferred our stock with good balls of earth into trenches 3 ft. wide and 1 ft. deep; a few cross bearers are then laid over the trench, and at night or during hail or snowstorms they are covered with long canvas screens, or evergreen branches which be substituted until the beds are cleared for their reception.—J. GROOM, *Henham.*

**White Flowers.**—A young friend found at Ribyl, late in the summer of last year, a flower of the Scabiosa arvensis perfectly white. We have also met with a root of Ononis arvensis, the flowers of which were white. The lovely little Harebell, or Bluebell (*Campanula rotundifolia*), I have often met with white, as well as blue; indeed, we had large tufts of both colours growing in our garden. The Scilla nutans is also often to be met with white, and even pink. We have from childhood been taught to call the Scilla nutans the wild Hyacinth, and the Campanula rotundifolia the Bluebell; this latter name is in Staffordshire mostly applied by the country people to both plants without any discrimination.—E. EDWARDS, in "Science Gossip."

## THE INDOOR GARDEN.

## INDOOR WINTER-FLOWERING PLANTS.

AMONGST winter flowering plants requiring a temperature of from 55° to 60° *Poinsettia pulcherrima* may be justly considered indispensable. It begins to flower during the depth of winter, producing immense heads or clusters of bracts measuring sometimes as much as 18 in. or 2 ft. in diameter, and remaining in perfection for several months. It is readily propagated by means of cuttings or eyes, which should be inserted as soon as the flowering season is over, or say early in March, and as most growers prefer young plants, the old ones are generally discarded as soon as the success of the inserted cuttings or eyes can be ascertained; but, if desired, old plants may be retained with advantage another season, and when that is the case they should be carefully cut in, and for a time kept dry until the wounds have fairly healed, when the pots containing them should be plunged in a slight bottom-heat in order to induce the production of young shoots. When these are 1 in. or 2 in. in length the plants should be re-potted, or the same sized pots may be used again with a portion of fresh soil. They will then form suitable plants to flower the second season. Cuttings should be formed of the young shoots, selecting such as are somewhat short-jointed and not too strong, while the stronger or partially ripened shoots may be split down the centre and cut into pieces of about 1 in. in length, each having an eye or slightly developed bud in its centre; these, like the cuttings, should be inserted in well drained pots filled with a mixture of leaf-soil and sharp silver sand, and should be placed on a slight bottom-heat under a hand-glass in the propagating house. Nearly every cutting or eye will grow, and when roots have been freely formed they should be potted off singly into small pots and shifted into larger ones as may be required. All should be in the pots in which they are intended to bloom by the middle of August. Plants occupying pots some 6 in. or 8 in. in diameter, bearing each a single head of bloom, will be found to be exceedingly useful for decorative purposes, while two-year-old plants should occupy larger pots, and will produce several heads of bloom which are useful in a cut state; they will be found to keep long in good condition when placed in water. The only difficulty likely to be experienced is keeping them in a dwarf state. In order as far as possible to do that, the plants during the summer months should occupy a cold pit, and should be kept as near the glass as possible with abundance of air, and they should be lightly shaded during bright sunshine. Early in November they should be taken into the stove or warm conservatory, and they will generally be in full beauty at or soon after Christmas. As a method of obtaining very dwarf flowering specimens of these plants, the top portion of the bracts may be cut off to any desired length as soon as the bracts are perceptible; the portions so removed should be inserted as cuttings in small pots of sandy soil, and placed in a close propagating case where they will soon form roots; they should then be gradually exposed to the atmosphere of the structure in which they are placed, and when well rooted they should be re-potted into larger pots. Plants may thus be obtained of any desired height, but large and fine heads of bloom can hardly be expected to be the result of this method of treatment. The soil most suitable for these plants is a mixture of turfy loam and peat or leaf-mould—about two parts of the former to one of the latter.

There is also a variety of *Poinsettia* with white bracts in cultivation, and a very marked contrast it makes to the scarlet kind. Of late, too, as is well known, a double-flowered variety has been added to collections. This is found to be somewhat later than the ordinary kind in coming into bloom, and, being equally persistent, considerably prolongs the season during which these fine winter plants are in perfection.

*EUPHORBIA JACQUINIEFLORA* belongs to the same Natural Order as the *Poinsettia*, and is, like it, an exceedingly useful winter-flowering plant, beginning, as it does, to open its bright scarlet flowers about Christmas, and continuing in great beauty until the middle of March or even later. The blooming shoots, too, when cut and placed in water have the property of remaining long in good condition. It is somewhat straggling

in habit, and young plants of it are generally preferred to older ones. Therefore, cuttings of it should be inserted as early in spring as they can be obtained. When the flowering portion of the shoots has been cut, young shoots will soon after that be produced, and these should be taken off with a heel, and will soon root if inserted in a mixture of silver sand and finely-sifted leaf-soil; or the lower portion of the shoots which have borne flowers may be formed into cuttings, and will root freely. These, when well rooted, may be potted singly in small pots, or, in order to obtain bushy or well-furnished specimens, three or four may be placed in one pot. As soon as the small pots are filled with roots they should be shifted into their flowering pots, which need not exceed 6 in. in diameter. During summer the plants may occupy a cold pit, and should be kept as near to the glass as possible, and removed into the stove early in November. A suitable soil for them may be composed of about equal parts of turfy peat and loam, with a portion of silver sand, and the pots used should be well drained.

**HEBECLINIUM LANTHINUM.**—This requires a stove temperature. Its season of flowering is during the months of December and January. The flowers are produced in graceful plumes of a soft mauve colour, and as they are produced in considerable abundance, the plant is exceedingly useful for decorative purposes, as well as for the production of flowers for cutting. It is easily increased by means of cuttings, which should be inserted early in spring; they should be potted off singly as soon as they are well rooted, and the plants should be grown on as rapidly as possible. They are by no means particular as to soil, and may be successfully grown in peat or in a compost similar to that generally used for Pelargoniums and other soft-wooded plants. Plants in 6-in. pots raised from cuttings inserted early during the preceding spring are generally found very useful for purposes of decoration, and, if larger specimens be desired, such plants may be cut back when they have ceased flowering and grown on for another season. During summer they should occupy a cold pit, kept somewhat close, and should have abundance of water.

**SERICOCRAPHIS GHIESBREGHTII.**—This is also a winter-flowering plant requiring similar treatment to that recommended for Hebeclinium. Its flowers are produced in long depending racemes of a rich scarlet colour. Well-grown plants of it have a peculiarly graceful appearance, which render them very useful for decorative purposes. It is easily increased by means of cuttings, which should be put in early in spring.

**ERANTHEMUM PULCHELLUM.**—This is a very old winter-flowering stove plant, invaluable on account of the colour of its flowers, which are bright blue. It is of easy culture, and is readily increased by means of cuttings; it will succeed in any ordinary, not too rich, soil.

**JUSTICIA SPECIOSA.**—This is also a plant which flowers during the depth of winter. The *Justicias* are nearly all easily grown, and if cuttings of them be inserted early in spring, they will form useful flowering plants during the ensuing winter. The flowers of *J. speciosa* are of a light purple or pink colour, and are useful in a cut state.

**CYPRIPEDIUM INSIGNE.**—This pretty terrestrial Orchid may be grown in an ordinary greenhouse temperature, where it will generally flower in August. It does better, however, where it can be afforded the temperature of a stove, in which it will generally bloom twice during the year, and seldom fails to do so during the month of January. A soil consisting of turfy peat, a portion of loam, and a few lumps of charcoal appears to suit it. The flowers, which are large, are very ornamental, and, like those of all the *Lady's-slippers*, peculiar in form. They remain long in perfection, more particularly when produced in winter, and even when cut and placed with other flowers in water they have been known to keep fresh for upwards of a month. The plant is easily increased by division.

**CENTRADENIA FLORIBUNDA.**—This is an old, easily-grown stove plant, and, considering its merits as a decorative plant in winter, it is strange that it is not more extensively grown than it is. Its flowering season may be said to embrace the entire winter, or at least six months in the year. It forms itself into a compact globular bush, its numerous shoots requiring aid from

neither stake nor tie, while each branch furnishes a continuous supply of neat pale pink flowers. Pots of some 6 in. or not exceeding 8 in. in diameter appear to be the size most suited to it, and it succeeds in a soil consisting mostly of light rich loam, with a portion of either peat or well-decayed leaf-soil. Early in April the plants, although still in bloom, should be cut close in, when it will be perceived that young shoots are beginning to develop themselves as the base of the old ones; these form the flowering portions of the plant for the succeeding winter. Plants of this should now be kept somewhat dry for a time, without, however, entirely withholding water. When the young shoots have attained to the length of 1 in., more or less, they may be slightly thinned out, and these, if desired, may be formed into cuttings, which will root freely if inserted in the usual method and placed under a hand-glass in the propagating pit. The old plants should be taken out of their pots, and their balls should be considerably reduced, and they should be returned to the same pots with the addition of fresh soil, or pots of larger size may be used if thought desirable. It will thus be seen that the same plants may be grown for many years. Cuttings inserted in April will make good specimens in 6-in. pots for the second winter, and to encourage their growth they should not be allowed to bloom until that time has arrived. A somewhat close pit is a suitable structure for them in summer.

**CENTRADENIA ROSEA.**—This is, I believe, an earlier introduction than *C. floribunda*, and what has been said respecting the latter applies also to *C. rosea*. The flowers are of the same colour, size, and shape as those of *C. floribunda*; the habit of the plant is also the same, or nearly so, but the foliage is of a somewhat darker shade of colour. Could a variety of either of these plants be by any means obtained bearing flowers of a more decided colour, such as an approximation to scarlet, it would doubtless be considered as an invaluable acquisition for decorative purposes.

**BEGONIA INSIGNIS.**—This is an old species of a somewhat straggling habit of growth, but it blooms during the depth of winter. Its flowers, which are pink, are very useful in a cut state. Old plants of it should be cut close down about the end of March, and afterwards re-potted; they will again furnish flowering shoots for cutting during the ensuing winter, and cuttings of them may at the same time be inserted, which will produce plants sufficiently strong to bloom at the same time.

**BEGONIA MANTICATA.**—This is also an old but very handsome species, which generally commences to flower early in January. The blossoms are thrown well up above the foliage, which, as well as the flowers, is of a very ornamental character. In any structure where a minimum temperature of 55° can be maintained a few plants of this *Begonia* cannot fail to produce a pleasing effect during the months of January and February. It is propagated by means of cuttings, but, as the shoots are of a succulent character, the cuttings, after being made, should be allowed to dry for a few days before they are inserted; when this has been done, the pots containing them should be placed upon a shelf in a temperature of 60°, and when they have become well rooted they should be shifted into larger pots as may be found necessary.

**BEGONIA METALLICA.**—This pretty and distinct plant blooms early in spring, but the blossoms are, possibly, of less importance than the leaves, which are very ornamental, the upper surface being of a dark, shining, metallic colour, while the under sides are pale green beautifully veined with bright red. When in a position in which the foliage comes between the eye and the light the effect produced by it is remarkably pleasing. Altogether, the plant is very ornamental at all seasons of the year. It is increased freely by means of cuttings inserted in a mixture of sand and sifted leaf-soil.

**BEGONIA FRUEBELI.**—This is one of the most distinct and beautiful of the tuberous-rooted section. Its flowers, which are produced well above the foliage, rival in colour even the most brilliant of the scarlet *Pelargoniums*. The upper surface of the leaves is bright green, while the under side is thickly covered with white hairs. When intended to flower during winter the tubers will at rest should be kept as cool as possible, in order to prevent them starting too early. When they have

fairly commenced growth, however, they should be re-potted and grown on in a cold pit, keeping the plants pretty close to the glass, and by the end of September or early in October most of them will be more or less in bloom. They should then be placed in a structure in which the temperature will not be allowed to fall much under 55°; under such conditions they will continue to produce their large bunches of brilliant scarlet blooms throughout the winter. Begonias are not particular as regards soil; they will, however, thrive best in a compost formed of, say, two parts light, rich fibrous loam, and one part peat, or leaf-soil. P. GRIEVE.

Culford, Bury St. Edmunds.

**Free-flowering Cereuses.**—I am glad to see Mr. Croucher, who is so well qualified for the task, directing attention to some free-flowering Cereuses in last week's GARDEN (see p. 290). Such notes as these might be extended to the great advantage of cultivators, and the solid enrichment of gardens. A list of the best Cactusee to grow for decorative effects, with cultural instructions, might tend to restore these plants to their proper place in general collections. In the olden times, when Mr. Green's Cactusee used to hold their own against Mrs. Lawrence's stove and greenhouse plants, and Mr. Farmer's Orchids at Chiswick and the park, almost everyone grew a few Cacti, while a fair collection of them was by no means rare. Some of the commoner sorts were also exceedingly well shown. I remember my late friend, Mr. W. Allan, then gardener to Lord Rendlesham, showing an enormous plant of *Cereus speciosissimus* with over fifty open blooms on it, and as many or more large buds. Even the night-flowering *Cereus* was then comparatively common, and cultivators used to invite their friends to meet and watch this, and enjoy to the full the almost overpowering, but delicious, perfume of this species. I shall never forget my experience of this sort, nor a fact which I thought I discerned at the time, viz., a sort of momentary glory or luminosity proceeding from the flower when at its meridian. This, of course, was years before the luminosity of flowers was heard of. Has Mr. Croucher any facts to offer on this head? Apart altogether from the scientific interest attached to Cacti, which is very great, they deserve to be more generally cultivated than they are for their decorative value, and I trust that Mr. Croucher will comply with my suggestions.—D. T. FISHER.

**Broken Rocky Margins to Artificial Water.**—These offer opportunities for charming effects to the planter happy enough to possess them. Islets of this kind artistically formed constitute a pleasing feature in good water, and they have a use of which some of their designers never thought, in the culture and preservation of a variety of hardy flowers, quite at home in such places. It is often possible in such situations to establish little colonies of bog, marsh, or rock plants, which could not so easily be grown elsewhere. The safety from encroachment by coarser plants, the complete exposure with at the same time abundant moisture, and the power of isolating a species or a family where that seems desirable, make it clear that such spots might be made much better use of than leaving them to Briars and weeds, though even with these they are charming.

Two blooms of a very fine variety of *Cactleya amethystina* have been sent to us from Down House, Blandford, by Sir William Marriott.

## PLATE CXXIII.

### THE LONG-LEAVED BUTTERWORT.

(*Pinguicula Vallisneriifolia*.)

THIS beautiful species differs from others of the genus in its clustered habit of growth, six, eight, ten, or even twelve crowns being sometimes densely massed together in one clump. Its leaves are of a pale yellowish-green, sometimes very thin in texture and almost pellucid, linear or linear-oblong, erect in the tufted plants, and undulated at the margins. Towards the end of the season they become much elongated, not unfrequently measuring 4 in. or 5 in., and occasionally even 6 in. or 7 in. long. The flowers, which are large, are of a soft purple or lilac-purple, with large white or pale centres. The lobes are more spreading than in *P. grandiflora*. Dripping fissures and ledges of calcareous rocks (frequently in tufts) suit it perfectly. It requires very free drainage, continuous moisture, and a very humid atmosphere. It comes from the lofty mountains of Spain.

Amongst other species worthy of note may be mentioned:—

**The Great Irish Butterwort** (*P. grandiflora*).—This rivals the preceding in beauty. Its flowers are more compact, nearly if not quite as large, and uniformly of a decided blue-purple. The leaves, which are broad and spreading, lie flat upon the rock or soil. It prefers the shady side of a moist, mossy rock where the face is steep and the narrow chinks are filled with rich loam. If planted in earth alone, where the drainage is imperfect, we find that *P. grandiflora* often—indeed usually—perishes in water. The white centre of the flower is much smaller than in the preceding species. The blossoms are borne four or five from one crown, the crowns being usually solitary—a natural

Broken Rocky Margin to Artificial Water.

result of their dense, wide-spreading leaves.

**The Alpine Butterwort** (*P. alpina*).—This differs from all the other species in having white flowers, with more or less lemon-yellow stains on the lip, and having its lobes sometimes tinted with pale pink. It is smaller than *P. vulgaris*, which it resembles in general habit, but has more tapering leaves, of a reddish-brown hue beneath. It roots firmly, by means of strong woody fibres, in peaty soil, mingled with shale or rough gravel, in shady humid positions, such as are afforded by high rockwork with a north aspect, or the shelter of a north wall.

**The Common Butterwort** (*P. vulgaris*).—This is too well known to require description. It grows freely in any sunny position in rich moist peat or peaty loam. A small form, with leaves almost exactly resembling those of *P. alpina*, both in form and colour, occurs in Alpine bogs in the north of England, which may possibly prove to be the *P. leptoceras*.

**The Pale Butterwort** (*P. lusitanica*), found on the west coast of Scotland and in Ireland, is smaller than any of the preceding, and has pale yellowish flowers. It grows in peaty bogs exposed to the sun.

For the opportunity of figuring this pretty and distinct species of Butterwort we are indebted to Messrs. Backhouse, of York, who grow such plants very successfully.

GARDEN BOTANY.

(Continued from p. 318.)

FORMS OF ROOTS.—Some idea of the diversity of form as-

95.—Young Turnip with a tap root.

sumed by roots may be gathered from the paragraphs on germination, but many roots do not develop their characteristic

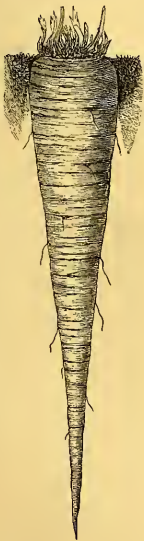

Fig. 96.—Tap root of Carrot.

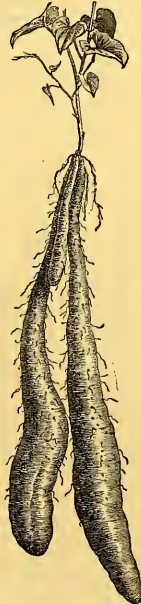

Fig. 97.—Tubercles of Dioscorea Batatas.

root, as in Grasses, the Melon (fig. 91), &c., and the tap root, as in the Oak (fig. 90) and the Turnip (fig. 95). The tap root, which is the direct prolongation of the radicle, may soon be replaced by other roots from successively higher parts of the base of the stem, as in the Date Palm and many others, or it may ramify itself, and these ramifications soon exceed it in size, as in the majority of dicotyledonous plants, or it may increase to an enormous size, and only bear lateral branches in the form of slender fibrils, as the Parsnip and Carrot (fig. 96). In some instances the tap root soon ceases to elongate, as in the Turnip, and grows very thick. Between the most delicate of fibrous roots and tap roots of great volume there is every intermediate gradation. The tuberous roots of some of the Yams (fig. 97) are sometimes 3 ft. or 4 ft. in length, and upwards of 40 lb. in weight. Asparagus has crowded, fleshy, cylindrical roots; the Cucumber produces an intricate network of very slender fibrous roots. The roots of the Dropwort are fleshy, with distensions here and there. Our native Orchids have fleshy, spherical, or palmate tubercles, and the common Flewort (*Ranunculus Ficaria*) owes its popular name to its cluster of short, round, fleshy roots.

Fig. 98.—Mode of rooting of many Palms, the so-called stills of the *Paxiuba* Palm.

**NORMAL AND ADVENTITIOUS ROOTS.**—It has already been explained that the root system of Palms often consists of a succession of roots produced farther and farther from the original base of the stem after the disappearance of the radicular or tap root. All roots which are not tap roots or ramifications of a tap root are termed adventitious, and some botanists call them abnormal, but the latter term is misleading. The three rootlets or radicles which the embryos of some Grasses push forth almost simultaneously are just as much normal as the single radicle of the Oak; and it is open to question whether they should be called adventitious, inasmuch as they appear at determinate points. But the successive roots of Palms and Screw Pines (*Pandanus*) and many other trees do not. Some of the Palms (fig. 98) are ultimately borne several feet clear of the ground, in consequence of the lower ones dying away, by the stout adventitious roots which succeed each other higher and higher up the trunk. Many climbing, trailing, and Epiphytal plants emit adventitious roots either from their joints, as in the runners of the Strawberry plant, or between the joints, as in the Ivy (fig. 99). The adventitious roots of Ivy serve more as a means of attaching the plant to rocks or trees than as organs of absorption. Their mode of growth, however, is that of true roots; and when the plant is trailing on the ground, they act as roots. The Couch Grass (fig. 100) possesses the power of emitting adventitious roots in a wonderful degree, and is in consequence a good sand-binding plant. In the Primrose (fig. 101) the original roots die off, and are replaced by adventitious roots higher up the stem, as in some Palms. The trunks of Tree Ferns are often completely covered with a dense mat of short roots. Many Orchids produce aerial adventitious roots (fig. 102), and also some Aroids, especially

forms until they reach a later stage of growth. Young seedling plants exhibit two distinct types of root, viz., the fibrous

species of *Philodendron*, which climb to a great height and send down long, cable-like roots from high up in lofty trees. In some Orchids, as species of *Angraecum*, they acquire a green colour, and perform, it is stated, the functions of both roots and leaves.

**DURATION OF THE ROOT.**—The duration of the root is not always of the same period as that of the plant itself, or rather what appears to be the duration of the plant. Many herbaceous plants which we regard as of perennial duration really renew their root-stalks annually, or probably sometimes less frequently, according to circumstances. Thus the tuberous roots of *Orchis mascula*, &c., are annual, or new ones are produced when the previous ones flower, or else the plant perishes. The tubercles formed this season are a reservoir of food for the flowers which proceed from it next season, and then they are exhausted and decay, but usually not before others have been formed at their side. These plants are therefore perennial in one sense, though annual in another. Sometimes the new tubercles are not, from some cause or other, sufficiently matured or vigorous enough to produce flower-stems, in which case leaves only appear. Many perennial plants renew themselves by spreading, or are perennial in the sense only that they reproduce themselves underground, for

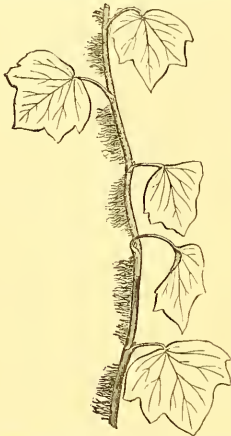

Fig. 99.—Climbing stem of Ivy with adventitious aerial roots.

as new parts appear the old die away. As explained elsewhere, the original roots of some Palms and the common Primrose die off, and are succeeded by adventitious ones successively higher up the stem. With some exceptions, then, it may be stated that the roots of woody plants are permanent, whilst those of herbaceous plants are either annual, biennial, or renewed.

**ROOTS OF PARASITICAL PLANTS.**—True parasites are distinguished from epiphytes, which merely grow on other plants, by the fact that they bury their roots in the tissue of the species upon which they prey. The Mistletoe is parasitical on the branches of various trees, from a Pine to a Poplar, and in section the tissue of its roots can be discerned with the naked eye when it differs in colour and density from that of the nurse plant. The Broomrape (*Orobanche*) are root parasites attached by slender threads to the roots of other plants. The most remarkable parasitical plants are the *Rafflesiaceæ*, which consist of little more than flowers and a few scales growing in the branches or superficial roots of trees. *Rafflesia Arnoldi* has the largest flowers of any plant, being upwards of 3 ft. across, whilst those of *Pilostyles* are small, thickly studding the branches of the shrubs and trees upon which they grow, and were formerly supposed to be abnormal flowers of the nurse plants themselves. The seeds of Mistletoe germinate on the tree, and it is the primary root that penetrates the

tissue and absorbs the nutriment required from the nurse plant; but seeds of Dodder (*Cuscuta*), another class of parasites, germinate in the ground, and as soon as their stems come in contact with a suitable nurse plant they attach themselves by means of adventitious roots called haustoria, the original root then dying away. The seedling Dodder dies quite young if it does not find a suitable nurse plant.

Fig. 100.—Couch Grass with adventitious roots. Fig. 101.—Primrose with adventitious roots.

**THE DEPTH TO WHICH ROOTS PENETRATE.**—Comparatively little is yet known, and less has been published on this subject, although one of great importance from a practical point of view. This is, perhaps, owing to the fact that opportunities seldom occur for ascertaining the depths to which roots penetrate, except at the death of a plant, when there is rarely a sufficiently strong inducement to take the trouble. In cultural operations deep tilth always tells its own tale and brings its

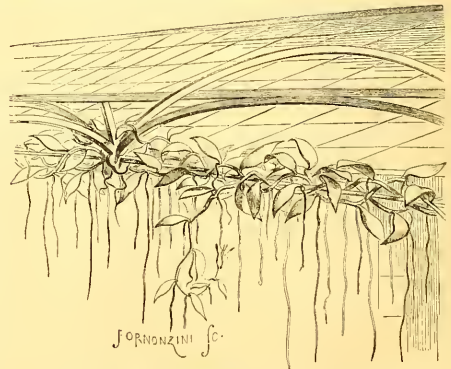

Fig. 102.—Vanilla stem emitting long, cord-like aerial roots.

profit, especially in dry seasons; and in this we have a clue to the secret of the value of deep roots. The roots are able to reach a much greater depth in search of water, and whatever it contains in solution; consequently, the plant is not dependent upon the moisture of the superficial layers of soil for its nutrition. Untilled soils also differ greatly in their nature and permeability, so that the production of roots and the conse-

quent age and size of a plant depend more upon this than the actual root-forming power of the plant itself. But there are some plants, both herbs and trees, which naturally root very deeply if not interfered with. It is especially such species that develop a large primary root or tap root that penetrates to a great depth in the soil; but it is not these alone, for the slender, fibrous roots of Wheat are often longer than the straw; and sand-loving and seashore plants have a relatively large root system. Trees that are raised in a nursery, and once or twice transplanted before being placed in their final destination, usually have their tap roots shortened as quite young seedlings, in order to make them produce a close network of fibrous roots. This is done to ensure success in transplanting, and in most cases a very large per-centage would die if they were permitted to form a large tap root. The tap root once cut or broken does not elongate any more, and it is replaced by two, or three, or more secondary roots, which eventually attain a large size, but probably never go so deep in the ground as the tap root would. Therefore the trees of artificial or planted woods and forests, whilst having the advantage of some amount of digging, suffer from the disadvantage of shallow roots. They are more easily blown down, and in dry seasons suffer from want of water, which enfeebles them and prevents them from over attaining large dimensions and great age. There is, then, something to be said in favour of sowing where the tree is to stand, when this is practicable, and where there is any danger of drought exercising an adverse influence. Among ordinary field crops there is none, perhaps, which roots on an average to so great a depth as Sainfoin. I once had an opportunity of tracing the roots of Sainfoin downwards in a newly-formed cutting for a railway. Some of them reached a depth of 7 ft. or 8 ft., and the average depth of the roots through the field was 5 ft. I have also traced the roots of Wheat to a depth of 7 ft., and there are records of it reaching a much greater depth. Thistles root very deeply in gravelly and chalky soils, and this would account for the enormous crops of these plants which often spring up where excavations have been made, as the smallest scrap of the roots of some species will grow when brought near the surface. This seems more probable than the turning up of seed from a depth. The Grape Vine sometimes forms roots of extraordinary length. Duchartre mentions that Lardier states they have been traced to a depth of 40 ft., as well as those of the Caper (*Capparis spinosa*); and we occasionally read in horticultural papers of Carrots, Parsnips, and Beet-root 6 ft., 9 ft., and even 12 ft. long. One striking example of the advantage gained by enabling crops to root deeply may be given. The summer of 1870 was exceedingly dry, and in many parts of the country there was not sufficient Grass in the meadows to be worth the trouble of mowing, although the price of hay was sure to be very high during the following winter. Drs. Lawes and Gilbert subsequently published an account of the effects of the drought on the crops of the experimental Grass plots, &c., at Rothamsted. These plots are variously manured (for the experiments are still continued), the same kind of manure being applied to the same plot year after year. There are also two plots which have remained unmanured ever since the experiments were commenced, about twenty-five years ago. In 1870 the unmanured plots yielded a crop of 5½ cwt. of hay per acre, or 17 cwt. under the average yield for fifteen years. A plot manured with sulphates of potass, soda, and magnesia, and nitrogen in the form of equal parts of the muriate and sulphate of ammonia, produced nearly 1½ tons, or more than a ton under the average. A third plot, manured the same as the last, with the exception that the nitrogen was applied in the form of nitrate of soda, yielded a crop of 56¼ cwt., or less than 1½ cwt. below the average of the previous fifteen years. These extraordinary results led to an investigation of the amount of water in the soil at different depths on each plot, and the depth to which the roots had penetrated. It was found that the herbage of the unmanured plot was relatively very shallow-rooted, and the herbage of the highly-manured plot to which ammonia salts were applied was not, on the whole, deeply rooted, nor was the clayey subsoil very much disintegrated. But the subsoil of the plot to which the nitrogen was applied, in the form of nitrate of soda, was much more friable and disin-

tegrated, and the roots had penetrated deeper in search of water. Those of *Bromus mollis* reached a depth of 4 ft. The soil was taken out in 9-in. layers to a depth of 45 in., and the lower layers of the unmanured plot were much more highly charged with moisture than those of the other plots, especially of that with deep-rooted herbage, which yielded nearly an average crop. These facts simply point to the importance of deep-rooting and certain manuring under exceptionally climatal conditions, but indirectly they reveal the advantages of intelligent, over-haphazard culture. W. B. HEMSLEY.

## THE FRUIT GARDEN.

### FORCING PEACHES AND NECTARINES.

THE culture of these under glass, so as to secure a supply of fruit from the middle or end of May until those on open walls are ready for use, is not an operation that necessarily shortens the lives of the trees thus forced, as our earliest house, in which an abundant crop is now stoning, contains as luxuriant and prolific trees as any need be—certainly altogether in better condition than trees on open walls. As Peaches naturally luxuriate in a much higher summer temperature than that of this country, what we call forcing, if carefully done, more nearly approaches their natural conditions than our open-air culture, where a continual struggle for existence against adverse climatic conditions is going on, for where a steadily progressive temperature is maintained under glass the growth is uniform and satisfactory, but on open walls the sudden fluctuations to which such trees are liable in the early stages of growth, when wood and foliage are in a tender, immature condition, so check the circulation of the sap and reduce the energies of the trees, that they are in the worst possible condition for resisting insect and other pests that invariably attend a weakened constitution.

We adopt the ordinary routine of culture with satisfactory results. We prune as soon as the leaves have fallen, and this important operation I always perform at two distinct seasons, viz. I go over the trees immediately after the fall of the leaf and cut out any bare or exhausted branches, shortening the young bearing wood according to its strength; and again, after the crop is set and thinned, I take out all the unfruitful wood that is not required for producing bearing wood, for one of the points to guard against is training in too much wood. It is not the quantity of shoots that can be crowded into a given space that will yield the most abundant crop, but the most perfectly matured wood, for if evenly distributed from bottom to top it will need but a very thin "set" of fruit to prove when fully matured an abundant crop, for, as a rule, Peaches would be vastly benefited by having one-half the bloom-buds removed before expansion. About this season the borders should be examined and, if at all dry, thoroughly watered and top-dressed with enriched new loam. Painting and cleaning of both houses and trees must be performed when the trees are dormant, and the temperature should be kept as low as possible in winter in order to ensure perfect rest, as the more thoroughly this is observed the more rapidly will the trees respond to the quickening influence of an increased temperature when the growing season has arrived. We usually shut up our earliest house the first week in December, but, unless the weather is severe, very little fire-heat is applied before the new year, for, owing to the trees having been gradually brought to an early period of active growth, they naturally start with but little excitement. A moist, steadily progressive temperature is what should be looked to until the blooms are expanded, when a light, dry, buoyant atmosphere of from 45° to 50° minimum to 65° maximum is maintained, with ample ventilation, but avoiding cold draughts and cross currents. The blooms are regularly looked over each day and fertilised with a camel's-hair brush, as, during the first six weeks of the year, bees and other ordinary fertilising agencies cannot be relied on to perform that work; we invariably get, however, as abundant a "set" of fruit in the earliest house as in the latest. The pollen of some kind (notably the small-flowered section) is much more abundant than in the case of large-flowered varieties, and in artificial fertilisation this can be as easily utilised

as by insect agency. As soon as the fruit is set a moister atmosphere is maintained, and a good drenching with the syringe after a bright day cleans the foliage, dislodges old blooms, and encourages rapid growth. Disbudding and thinning the fruit must be gradually performed until the crop is set out with methodical regularity; for, in addition to having the crop regularly distributed, the trees invariably swell off the fruits more evenly than if they were left thin in one part and thick in others. The distance between the fruits must be regulated by the size of the variety, but nothing is gained by overcropping, as a fine crop is much more valuable than an unlimited number of undersized fruits, either for home consumption or for market. The annual growth should be lightly tied to the trellis, so that the leaves may be fully acted on by light and air without shading the fruit too much.

Fly, both green and black, which is so great a pest on open walls, seldom affects trees in good condition under glass, but if observed, fumigation should immediately be resorted to. Great care must be exercised as regards temperature during the stoning season, when extremes of all kinds must be avoided; but after the fruit is stoned a higher temperature may safely be indulged in. Sun heat should be economised as much as possible, by shutting up early in the afternoon, and plenty of root and atmospheric moisture must be applied until the fruit commences to change colour, when a cooler and drier atmosphere must be maintained. Under such conditions the fruit will ripen off high flavoured and well coloured; any leaves overshadowing it should be gently turned aside, but on no account should they be taken off, except from soft, lateral growths.

As soon as the crop is gathered the trees should receive a good washing with the garden engine, and every means should be adopted to thoroughly ripen off the current year's wood. Selection of early or late varieties, according to the season at which they are most required, is of the utmost importance, as some of the best mid-season and late Peaches and Nectarines submit but indifferently to early forcing. JAMES GROOM.

*Henham.*

### ARCHED TRELLISES OVER GARDEN WALKS.

HAVING in a previous number of THE GARDEN advocated the desirability of having garden walks covered with these trellises, and having at the same time pointed out the method by which the system might be made available for almost every garden where espalier work is worth putting up at all, I intend to follow up the matter by describing a light, cheap, portable, yet sufficiently strong trellis—a trellis containing no more iron, yard for yard, than a well made iron hurdle, without even a rivet, the only mechanical appliance used being a few screws and nuts—a trellis which could be made and conveyed to any distance, and not occupy a tithe of the bulk and nothing near the weight of common hurdles, and one that may be put up and taken down with almost as much ease as a tent. The theory on which the above trellis is proposed to be constructed is this: that any material assuming the form of an arch is infinitely stronger than it is possible for it to be in any other form; hence a very light arch will sustain comparatively a very heavy weight. It would require a very strong trellis to stand 15 ft. high; but turn this height over as an arch, and it could scarcely be made too slight. Trees, too, having been trained and grown for some time on an arched trellis would almost be self-sustaining. Acting on these premises, let me now endeavour to describe a trellis which will meet such requirements. Fig. 1 represents strong wrought iron,  $1\frac{1}{2}$  in. square forming one-half of an arch, whose chord or width at bottom is 6 ft., and the height to the crown of the arch 7 ft. (the scale adopted is arbitrary, but trellises of less dimensions would be of little utility). The lower part, as will be seen at B, is rounded, and passed through a strong large block of timber (or stone if it be had on the place). A screw at the end with a strong nut, as at E, braces the bent bars and block firmly together, as on this half-arch, when joined to a similar one opposite (as at G, fig. 2), lies the strength of the whole structure. A strong stay or strut is added of the same strength, as at C, fig. 1, and screwed together as at D. This arch, which may be called the principal, being fixed, a similar one is put

up at the other extremity of the proposed trellis, which may be 40 yards or 50 yards in length. There are few walks in gardens of greater length than this without being intercepted

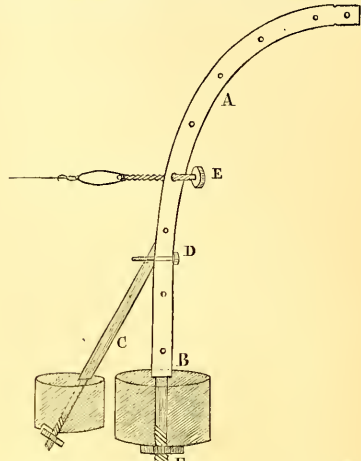

Fig. 1.—A, section of main straining arch of 1 in. or  $1\frac{1}{2}$  in. iron, perforated for tightening screws, as at E, screwed to a strut, as at D; let through blocks of wood or stone, C, B, screwed at bottom, as at F.

by a cross walk. At intervals of 6 ft. or 8 ft. throughout the whole length arched supports are placed (as at H, fig. 2). These are also made of two parts, and spurred as at I, fig.

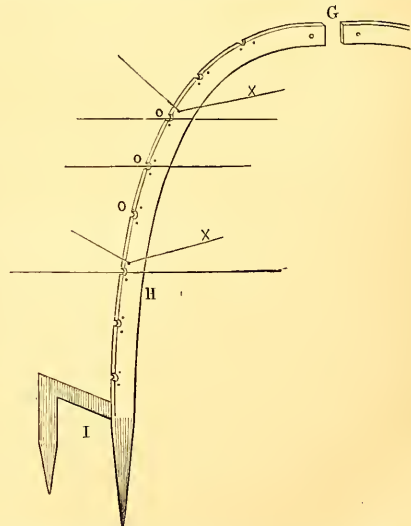

Fig. 2.—Section of bearing arch, H, showing how two are screwed together, as at G; spurred, as at I; grooved for wires to lie in, as at O O O; small holes for copper ties, with the wire shown, as at X X.

2, just as we see in a common hurdle. These supports are made of  $\frac{3}{4}$ -in. iron and 1 in. wide, or what is commonly used as the upright bar in hurdles; indeed, the end of a tall hurdle, bent over to form half an arch, will convey a tolerably good

idea of what I am describing. These supports are made with the iron edge upwards; this is important, as an arch made of iron in this manner will be as four to one in regard to strength compared with a similar arch with the iron flat. Another important reason for having these supports made with the iron edge upwards is, that the longitudinal wire forming the main training portion of the trellis is laid on the top, and not passed through holes in the supports, small indentures, 1 ft. apart, being made on the upper edge of the supports for the strained wires to lie in, as at O, fig. 2.

Let us now assume that the principal arches at the ends and the intermediate supports are truly and properly placed, good wire, such as that used for telegraph purposes, should be attached to the tightening screws at the end arch, as at E, fig. 1, and passed over the top of the supports to the straining arch at the opposite end, attached to the screws, and tightened, a sufficient length of screw being allowed for that purpose. Commence at the top of the arch and work downwards; each wire, when strained, should lie in the small spaces made to receive it, and should be retained there by a tie of pliant copper wire, two small holes being made for this purpose; this wire is shown at X, fig. 2. One simple crossing of the copper wire will be all that is needed, with a tightening twist or two

at the ends, which should be laid in on the under side of the iron support, and the trellis is complete. One advantage, and an important one, in this method is that the whole of the arches are made in parts. It will at once be seen that this must save a vast amount of labour in the manufacture compared with the trouble of having the arches of one piece. Given, the width of the walk, and the height of the trellis required, a templet or mould of wood, representing one

half of the arch, would be all that is required; and this simplification of the manufacture of the trellis must of course add to its cheapness. The transit of material would also be facilitated, as a very long length of trellis would lie in little space. The wire, of course, would lie in coils, and the half-arches would be braced together. Were these slender arches of one piece, they would be almost certain to get out of shape on a journey. Another advantage of the trellis is, in having the wires laid on the top of the arches instead of being passed through holes needle fashion, as is the case in wire fencing. Should a wire by any chance be broken, it will at once be seen how simply it can be replaced, and the neatness of the whole will depend on the exactness in grooving the arches for the wire, so that the latter may lie in straight, parallel lines. Of course, being put up so easily, it could, if necessary, in like manner be taken down; untie the copper wire, and loosen the screws, and the work is done. Light and airy though this trellis may appear from description, owing to its unity it is calculated to bear more weight than will ever be laid upon it; and although all the work of training, &c., will be done from beneath, still I should have no hesitation in scrambling over it, if necessary, from the simple reason that every pound weight brought to bear on any part of a wire is distributed over its entire length.—THOMAS WILLIAMS, *Ormskirck*.

## FERTILISATION OF STRAWBERRIES.

MR. HINDS in his remarks on this subject (see p. 307) forgets that all Strawberry growers are not circumstanced like himself, and that there are many who cannot either give their plants the time or the temperature that he speaks of, in which case the directions I gave with respect to artificial fertilisation would be applicable. He remarks that "anyone possessing ordinary powers of calculation, with a little practice, by making allowance, as regards time, by starting his plants earlier at the first, might do away with the necessity of giving high temperatures," and he sees in my suggestions on this head simply an inclination "to raise difficulties for the self-gratification of overcoming them," from all of which it may safely be inferred that Mr. Hinds is simply measuring his neighbour "a peck out of his own sack." It so happens that my remarks on the fertilisation of Strawberries were suggested by a letter which I had had from a gentleman who was anxious to force Strawberries, but had no better accommodation for them than the shelves of a hothouse, where the temperature had necessarily to be kept at a higher figure than was suitable for Strawberries, and my advice to him was similar to what I gave in THE GARDEN. I told him to compromise the matter as regards temperature as far as possible, and to be sure and fertilise the flowers. Such a state of things, it appears, Mr. Hinds had not contemplated. The practice of artificial fertilisation may be a century old, as Mr. Hinds states. I did not affect to be the discoverer of the

practice, but I think I am not far wrong in stating that Mr. Hinds' experience in that respect, in Strawberry forcing generally and as a horticultural writer, is confined to a very fractional portion of that period. As regards temperature, I do not know what Mr. Hinds means by a "strong heat," which would, he says, "simply be the ruin of imperfectly ripened plants," but I say that Strawberries will succeed perfectly in the temperatures which I have given in my former paper, and which were 60° at night, and from 75° to 80°

by day when in flower, provided fertilisation is resorted to, as I am prepared to demonstrate. C.

## FRUIT TREE PROTECTION.

THE following system of protecting fruit trees, devised by M. Cordival, is described in a recent number of the "Revue Horticole," from which the accompanying illustrations are taken:—"The hook L (fig. 2, enlarged) is fixed to the bracket by S D (fig. 1), and serves to hold up the canvas and keep it properly stretched. It is made of a thick piece of iron wire soldered to the bracket. The first and last rings of the upper portion of the curtain are naturally attached to the hooks of the first and last bracket G and D (fig. 1), the rest of the hooks being placed about 16 ft. apart (S fig. 1), and holding the iron rod upon which the rings run that support the curtain. Two screw rings, like those shown at G and P (fig. 1), are firmly fixed in each of the lateral walls running at right angles with those which are to be protected. It has not been thought necessary to show those in the wall on the right of the cut. To these four eyes are fixed the two rods H and B, over which the curtain rings are first run. Fig. 1 also shows at E an enlarged representation of the pin N (shown still larger in fig. 3), which keeps together the two loops of the wire, which has

M. Cordival's Mode of Protecting Fruit Trees.

been purposely broken in this place and rejoined by the pin N, as shown in fig. 3. The two other ends, F and F' (fig. 3), are fastened to the eyes in the parallel walls. The two loops of wire are placed just under the bracket D (fig. 1). The wire on the right side at the point P (fig. 1) must be left of sufficient length to allow of a hook being made in it to drop into the eye of the first screw ring. The same remarks apply to the other point B (fig. 1), where the curtain is intended to protect espaliers, the whole distance between one lateral wall and the other. A raiidisseur serves to stiffen the two wires H and B (fig. 1). The wire pin (E fig. 1, N fig. 3) serves to fasten the curtain when it is necessary to close it. One of the two rods takes the ring A (fig. 1), and the pin is placed in the loops. In order to fasten the upper rings to the hooks G S D (fig. 1) the stick with a ring hook is used. The curtain is opened by slip-

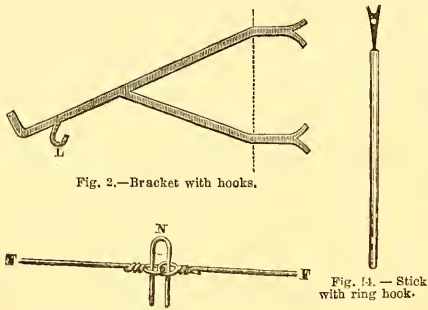

Fig. 2.—Bracket with hooks.

Fig. 4.—Stick with ring hook.

Fig. 3.—Iron wire with the pin in position.

ping the rings off the hooks, and pushing them along with the ring hook, and may be drawn and fastened by the same means. It may be added that the roof, so to speak, of the shelter is made of straw mats, but roofing felt would no doubt answer every purpose.

C. W. QUIN.

**Low Temperatures for Vines.**—Herewith I send you a recently-set bunch of Grapes and a leaf (Black Hamburgh) from a house where the temperature has been nearer 45° than 50° every night while the Vines were in flower. It will be seen that both are perfectly developed. After such experience, repeated year after year, I look upon the advice yet given by some writers, to give Muscats a temperature of 75° and Hamburgs only 5° less as a night temperature, as simply advice to burn coal to no purpose, which nobody should pay the least regard to.—J. S. W. [No Vines leaf could be more vigorous or healthy than that above referred to. It measured 13 in. one way and 1 ft. the other. The bunch, too, was as regularly and well set with berries as a bunch of Grapes possibly could be.]

**Fruit Gardens and Fruits of Turkestan.**—"Gardens," says Mr. Schuyler in his book on Turkestan, "constitute the beauty of all this land. The long rows of Poplar and Elm trees, the Vineyards, the dark foliage of the Pomegranate over the walls, transport one at once to the plains of Lombardy or of Southern France. In the early spring the outskirts of the city, and indeed the whole valley, are one mass of white and pink with the bloom of Almond and Peach, of Cherry and Apple, of Apricot and Plum, which perfume the air for miles around. These gardens are the favourite dwelling places in summer, and well they may be. Nowhere are fruits more abundant, and of some varieties it can be said that nowhere are they better. The Apricots and Nectarines, I think, it would be impossible to surpass anywhere. These ripen in June, and from that time until winter fruit and Melons are never lacking. Peaches, though smaller in size, are better in flavour than the best in England, but they are far surpassed by those of Delaware. The big Plums of Bokhara are celebrated through the whole of Asia. The Cherries are mostly small and sour. The best Apples come either from Khiva or from Sussak, to the north of Turkestan; but the small white Pears of Tashkend are excellent in their way. The Quinces, as with us, is cultivated only for jams and marmalades, or for flavouring soup. Besides Water Melons, there are in common cultivation ten varieties of early Melons and six varieties which ripen later, any of which would be a good addition to our gardens. In that hot climate they are considered particularly wholesome, and form one of the principal articles of food in summer."

## GARDENING FOR THE WEEK.

### Indoor Plant Department.

**Orchids.**—A house full of Orchids, with the greater portion in flower simultaneously, has a fine appearance, but with most people a succession over a longer period is preferable. Cultivators of these plants who have no experience in growing them for exhibition, and consequently have generally the whole of their stock coming into bloom without attempting to retard any portion, often complain that they have during the spring more in flower at once than they require, with a corresponding scarcity later on, yet are afraid of attempting to retard any under the impression that the plants may be thereby injured. A few hints on this subject may not be out of place at the present season, when the flowering of a good many species can be delayed for several weeks beyond the time the plants would bloom if allowed to remain in the houses in which they make their growth.

**Orchids that will Bear Retarding.**—As a rule it may be taken that all such species of Orchids as naturally rest after completing their growth before lowering will bear without injury being treated so as to retard their blooming; these include all such plants as flower from the ripened pseudo-bulbs in the way common to most *Dendrobies* and *Cattleyas* possessing the habit of the Mossia varieties, as *C. Skinneri*, *C. lobata*, *Chysis*, *Angulos*, *Brassias*, most *Epidendrums*, *Houllettias*, *Lælia purpurata*, *Lycastes*, some *Odontoglossums*, many *Oncidiums*, *Schomburgkias*, *Scuticarias*, *Stanhopeas*, *Trichopliasis*, and others of similar habit. These either flower from the preceding year's growths or push up their flowers from the young growths in the first stage, as in the case of *Odontoglossum citrinum*, *Chysis*, *Limnæoides*, *C. bracteata*, *C. cæca*, &c. Plants of such habit as these may always be kept back without injury by keeping them for some weeks beyond the usual time of their starting in as low a temperature as they can stand, at the same time using no more water either to the roots or in the atmosphere than is just sufficient to prevent excessive shrivelling. In the case of *Vandas*, *Aerides*, *Saccobulbiums*, *Phajus*, *Phalenopsis*, *Cypripediums*, *Cymbidium*, *Angraecums*, and other heat-requiring plants, all that can be done to retard their flowering is to defer increasing the temperature for a few weeks later in the spring than would be done if the plants were brought on in the usual way with an increase of heat as soon as solar heat increases; this can be done by placing a few of the plants at the extreme coolest end of the house in which they are grown, or in any house where the temperature can be kept 6° or 8° lower than the East Indian house, but with these warmer sections too low a temperature must not be risked. When the retarding process is carried out within reasonable limits, and confined to such kinds as will bear it, I have generally found that the plants, so far from suffering from it, grow stronger afterwards, and, by resorting to it, a much more even supply of flowers can be had.

**Orchids that do not Bear Retarding when their Flowers are Pushing.**—With all the species that bloom about the time of the season's growth completing, before going to rest, it is not safe to attempt retarding after growth has once commenced, further than that a portion may be grown a little cooler than the rest. But, although in the case of many species and families, this might often with advantage be carried out with whole collections, inasmuch as many are grown with more heat than is well for them, yet the cool treatment, especially in the case of plants that are growing, must not be carried too far, or the general growth will be deficient, and weaker than it ought to be. With plants possessing this habit the retarding process should be begun at the other end of the season, that is, in not letting them start into growth so early, by which means they will naturally flower later.—T. B.

**Conservatories.**—Azaleas are coming rapidly into bloom. Such as have been forced, and have done blooming, may be re-potted, placed in a warmer house, and syringed twice a day. *Rhododendrons* in conservatories that have been kept above 40° during winter are now in great beauty; such as are grown in pots, and are required to bloom at once, should be subjected to a little higher temperature than that in which they have been placed. Successions of *Cytisus racemosus* should be kept up by means of fortnightly introductions to the forcing pit. There is no difficulty now in supplying tallies in flower. If from the abundance of root and moisture is all that is requisite until the spathes are formed. Divide the roots of such as have produced suckers, and pot each separately; they should never be dried off. *Imantophyllum miniatum* is now in great splendour, and should receive a little weak manure water while in flower, especially if the roots are much confined. *Hebeclinium ianthinum* is one of the most desirable of conservatory spring-blooming plants, for its great *Ageratum*-like, lavender-coloured flower-brusses are very striking and distinct from those of its associates. It forms a large bush, and without making many leaves; therefore the roots should be kept within small bounds, and should be fed with manure water. The bright weather of the past fortnight has driven bulbous plants quickly out of bloom, except where well shaded. Liliiums of the speciosum section growing should be kept as yet but sparingly watered; a position for them near the glass is of immense importance in all cases, except in that for the latest supply, which may be set out-of-doors. Pot *Peperomia* in a warm mixed with some well-decayed manure; keep the soil moist, and shake the plants frequently to the roots. *Tropæolum canariense* makes a fine pot or dwarf trellis plant for a cool conservatory if sown in heat in March and potted on as required. The specimens of *T. tricolorum* that have done blooming may be turned out into a cool house; do not apply any more manure water to those still indoors, otherwise the ripening of the corrus

will be retarded. Plants of *Veronica Andersoni* that have been kept a rest for the past two months may now be shaken out, re-potted, and the shoots shortened back a little. A few plants of *Plumbago capensis* should be pruned, potted, and kept in a little heat until they make fresh growth. Train *Clematises* to trellises or rafters; these form magnificent permanent climbers either for indoor or flower garden purposes. *Fuchsias* should be started into growth as occasion requires. They like a moist heat, and the shoots should be pinched as they advance in growth. *Coleuses* must be kept near the light, potted as they require it, and pinched in order to maintain symmetry of growth. Prune, pot, and start *Daturas* into growth, and use the best ripened parts of their shoots for cuttings. *Salvias* make good indoor decorative plants, especially *S. splendens*; there is a rest back the branches, pot, and start the plants into growth in moderate heat.

**Hard-wooded Plants.**—Plants that have been potted recently will require close attention in respect to water. It is much more difficult to determine the condition of the soil as to its requirements in this respect with plants that have been recently potted than with such as are established. All the stock should be gone over every day, and it is quite as necessary to use water that is something near the temperature of the house the plants are grown in as it is in the case of stove plants. Every plant house ought to be provided with a tank sufficiently large enough to hold a supply of water for one day at least. This is all the more necessary where spring water is used. The larger-sized plants that are required for blooming later on ought, if possible, to be separated from the smaller stock, to give an opportunity of top-dressing and syringing them more freely in the atmosphere easily obtained by syringing in the afternoon in bright weather the paths, stages, and outside of the pots, and shutting up the house an hour or two before the sun is off the glass. This must be accompanied, except in the case of newly-potted plants, with all the light available, otherwise weak, attenuated growth will be the result. It is not good practice to syringe overhead, even during the season of active growth, any varieties of plants that are subject to mildew, for it has a tendency to increase the evil. Such plants as are not liable to its attacks, or to the ravages of red spider, ought to have the syringing done over them very lightly every evening after a sunny day during their growing season. This will apply to *Pimeless*, *Chorozeas*, *Eriostemons*, *Gompholobiums*, *Acrophylum venosum*, *Polygals*, &c. It frequently happens that a vigorous plant will throw up one or more strong shoots that have a tendency to impoverish the rest of the plant. These should be stopped in time by pinching their points out or bending down.

**Amaryllids.**—Plants of *Amaryllis* that are now pushing up their flowers must be well supplied with water; weak liquid manure will be of great assistance to them, especially the deciduous kinds, that make the greater portion of their leaves for the season simultaneously with the flower-stem; they should have plenty of light, otherwise the leaves will be drawn up, a defect which no subsequent treatment through the season can remedy, and it is upon the production of the greatest quantity of healthy foliage that the next year's flowering is in a great measure dependent. The nearly-allied *Valloia purpurea* will now be making its growth; the soil must not be allowed to become dry, or the plants will be much injured. This may be useful late summer and autumn, flowering plants we possess; it is also one of the best window plants that can be grown, requiring little space and thriving well in an ordinary sitting room. If a few plants could be placed in a *Vinery* at work, or in any position where they will receive a somewhat greater heat than they would in an ordinary greenhouse, they will flower earlier, and by subjecting another portion of the stock to cooler treatment they will afford a succession of bloom. *Valloias* may be increased very fast from the numerous offsets they produce, which are readily separated from the lateral bulbs without disturbing them. If these offsets be now taken off and inserted (six or eight together) half their depth in 4-in. pots filled with sandy soil and subjected to ordinary greenhouse treatment, they will grow on and make fine, healthy, blooming plants in the course of two or three years.

#### Flower Garden.

**Auriculas.**—These are, for the most part, in full flower, and in order to preserve them as beautiful as possible, the house should be kept cool and the atmosphere moderately moist. The largest proportion of flowers have to be content with the accommodation afforded by a cold frame or frames. Mr. Alexander Meiklejohn, for instance, who grows something like 1500 plants, has cold frames only to bloom his plants in and to grow them from November until October, and yet he has sent me pips of some of his sorts as fine as I have seen anywhere. Frames are very convenient for another reason, that one of them can be removed from the more exposed positions where the *Auriculas* have been during the winter and early spring to the shade of a wall facing north. When the plants are in bloom they may be placed in the shade, not before, else the pips of many of the sorts will not open kindly, notably *Yrue Briton* (Hepworth), *Lancashire Hero* (Lancashire), *Feveril of the Peak* (Walker), *Smiling Beauty* (Heap), *Charles E. Brown* (Heady), and many others of the very best sorts. The frames must be shaded with some light material, as the expanded pips of *Auriculas* thrive up if exposed to half-an-hour's sunshine. The plants are now making vigorous growth, and must be well supplied with water at the roots, taking care not to allow any to fall upon their beautiful mottled foliage, as it is very easily disfigured. Some of the varieties, such as *Miss Arkley*, *Maggie Lauder*, *Taylor's Glory*, *Topsy*, &c., have such beautifully frosted foliage, that even without the flowers they command admiration.

**Polyanthuses.**—These are in flower rather earlier than the *Auricula*, and require very similar treatment. I find they succeed best in a cool, shady position, making strong leaves of good substance. This fine old flower has been sadly neglected, and the varieties cultivated very nearly half a century ago were much superior to those that have been raised recently. I saw splendid examples of *Buck's George IV.*, one of the oldest sorts, placed in competition at Newcastle-upon-Tyne on April 3, and it stood superior to all the new sorts exhibited. *Cheshire Favourite*, *Crownshaw's Exile*, *Bullock's Lancer*, and *William IV.* are far behind it. I find that green fly is a very troublesome pest at this season, and when the nights become warm red spider attacks the leaves. I have destroyed both by dipping the plants overhead in soft soapy water. The flowers remain the longest in good condition if the plants be removed to a frame behind a north wall when the first pips on the trusses are fully open.

**Carnations and Picotees.**—We have not yet been able to remove these from under the glass lights, the weather being too cold to admit of it. The plants are not yet sufficiently advanced to require the sticks to be placed to them. When this is the case it is necessary to place them outside, as the sticks are in the way of the glass lights. The frames are a very welcome protection to the plants at this season, as the keen frosty winds, sometimes with snow or hail, does much injury to them. The plants require a fair supply of water, but cold rains or melting snow, when the roots have become more than they can absorb already, is about the worst way to apply it. As previously advised, keep the frames clean, remove all weeds from the soil, and decaying leaves from the plants.

**Pinks and Pansies** in beds should now be kept in a healthy growing state. Neither of them suffer from inclement weather if the soil is sweet, and in a condition to promote the growth of healthy roots. I have all the weeds picked out by hand, and the surface of the soil stirred up with a small Dutch hoe or light fork. Where sparrows are abundant, they pick off the young leaves as they are formed. If this is the case, they may be checked by stretching a line of white crocheted cotton along the rows about 6 in. or 9 in. above the ground. Rabbits are also very fond of Pinks, and the leather-coated grub does much damage to the plants. It feeds at night, and must be sought for with a lantern. Press the soil firmly round the neck of each plant with the fingers if it has been loosened by the action of frost.

**Hollyhocks** should now be planted out if they have been duly exposed to the open air a week previous to planting. I presume that the ground where they are to be planted has been prepared by trenching during the winter or even the previous autumn. This plant is a gross feeder and must have a good supply of rich manure in the soil, and at planting time I like to dig out a hole large enough to hold three or four spadefuls of rich, light compost; the plants seem to start away more strongly when they can grow into this. Place the permanent sticks to the plants at once; it will save time, and the roots will not be injured, as they might be if stout sticks were thrust through amongst them, when the plants have become so slenderly. If there be any traces of red spider upon the leaves it would be best to dip the whole plant in a pail of soapy water; or if this be not practicable, sponge them over. Spring-struck plants may not all be quite ready to plant out, but no time should be lost in getting them forward enough.

**Dahlias** are much more tender and will not stand frost. It is not possible to plant them out with safety until the end of May, but in other respects the same treatment as that advised for *Hollyhocks* will answer for them.

**Tulips.**—The beds ought now to be covered with the usual canvas covering, to keep the frost off, especially if the leaves be wet; the frosts are very keen, and will do injury to the wet leaves if the water be frozen in their axils. Those who have glass lights to spare will find them very useful protectors, as they may come on night and day.—J. DOUGLAS.

**Bedding Plants.**—If *Calceolarias* wintered in frames have not been transplanted farther apart in fresh free compost, do so at once, and pinch off all flower-spikes and tall shoots, it being necessary to encourage a dwarf growth. Such as were propagated in boxes in heat this spring and are now well rooted should also be transferred to frames and set farther apart than they have been. Well-rooted plants of *Polias* raised from cuttings, and seedlings that have been pricked off thinly into boxes, and which are now beginning to touch one another, should likewise be transplanted into a frame set on a hard bottom into which 6 in. deep of light rich soil has been put. *Ageratums*, *Topseulums*, *Verbenas*, *Gazanias*, &c., should be similarly treated, and care taken to protect them from frost at night. *Pelargoniums* should not be planted in this manner; on the contrary, they should be kept in pots in a cold frame; where two plants are growing in each pot, however, separate them, and pot them singly, and keep them in a close frame for a short time afterwards. The variegated-leaved kinds, such as the bicolors and tricolors, should be kept in rather warm quarters. The propagation of these may yet be proceeded with, and the cuttings potted singly before their roots are more than 1 in. long, otherwise they might get broken. *Dahlias* may still be increased by means of division of the old roots or from cuttings; after they are well-rooted, plant them amongst some rich free soil in a frame and protect them from frost. Keep *Echeverias* in cool houses or pits, or arrange the pots or boxes containing them on the floor of some cool Peach house or *Vinery*. Those increased by means of the side shoots, leaves, or seeds, could be raised carefully in a moderately warm place, so as to encourage a good growth before they are planted out. The little yellow variegated *Mesembryanthemum*, now so common in our flower gardens,

although tolerably hardy, thrives admirably in heat—a course that should be resorted to in order to have cuttings that will make good plants before bedding-out time. An ordinary greenhouse is, however, sufficient protection for it in winter and spring. Alternantheras are deservedly admired as carpeting plants. They should, therefore, be propagated for that purpose as expeditiously as possible, and the greener the foliage the more easily will the cuttings strike root. *A. amena* has this year been rather sparing of young wood; it is, therefore, difficult to obtain a stock of it. *Iresines* and *Coluseses*, especially *Verschaffelti*, should be propagated, potted singly, pinched, and kept near the glass in a warm frame or house. *Perilla* should be pricked out into boxes, and kept near the glass in any of the fruit houses in which there is a little heat. In the case of *Stocks* and *Asters* sown on gently-heated hotbeds or in boxes, the sashes should be tilted up a little night and day, and the seedlings shaded from strong sunshine. As soon as they are fit to handle, prick them out into other frames or into a well-sheltered south wall border, with a few *Broom* or *Spruce* branchlets stuck in front of them. *French* and *African* *Marigold*s and *Tagetes signata* *pumila* should be raised in heat, and, after they have come up, should be pricked off into boxes or pans, which should still be kept for a time in heat. Such hardy plants as have been wintered

*Mossy lawn* is liked by some on account of its elastic nature, but the great objection to it is that a dry spell of weather kills it, and gives it a sombre brown hue. There is no better season for destroying *Moss* than during the April showers; it cannot bear manure, and many kinds, such as super-phosphate, guano, &c. in small quantities, applied as surface-dressings, are recommended for destroying it, but such applications cause the Grass to grow too strong. Newly-slaked lime in a dry powdery state, mixed with an equal quantity of loam, is by far the best remedy. If a dressing of this be applied after mowing it will destroy the *Moss*, and will strengthen the Grass without causing it to grow too strong. Care must be taken that the loam with which the lime is mixed is fresh, or it may contain the seeds of weeds, and thus, in removing one evil another might be substituted. Keep the Grass regularly mown. Where a machine is used there is nothing saved in labour by letting it grow too long before it is cut, as the work is then double. Nothing is more common than to see these machines set too low, so that they cut the *Grass* in places right down to the very roots, giving the whole a patchy and unsightly appearance, and, when dry weather happens to set in, these close-cut places are almost bare of Grass. The machine should be set so as to avoid this.

A Tropic Beach.

indoors should be transferred to the open ground at the earliest convenience.

**Lawns and Pleasure Grounds.**—Take advantage of showery weather to have all the walks thoroughly weeded. Small Grasses are the worst to contend with on walks, but where they are removed before they have time to seed—and this they will do whilst very small—they can be kept under with little labour. The use of salt, either applied in a dry state or in the shape of hot brine, is often resorted to for the destruction of weeds on walks, but, except in localities near where it is made, it costs more than hand-weeding, and, however applied, its effects are objectionable in causing the surface of the walks to look black and damp. Keep the walks well rolled whilst moist, and an impression can be made upon them. Weeds such as *Dandelion* and *Plantain* will now show most objectionally on the Grass, and regular and persistent use of the “spud” is the best method of eradicating them. Some do not dislike to see the common *Daisy* on their lawns, but nothing looks so well as the *Grass* alone; and when these plants exist in numbers not too great to cope with, I advise their being cut out by the roots, for when the crown of these is destroyed they do not, like deep-rooted plants, push again as long as they have strength. If *Daisies* are found, even in small numbers, and are not kept down, they quickly increase to a serious extent where a mowing machine is used, for these implements throw the flower-heads over the ground, where, even in an immature state, the seeds will vegetate. A

#### Kitchen Garden.

An additional supply of *Broad Beans* and more *Peas* should now be sown. Of the latter, if *Champion* of *England*, *Veitch's Perfection*, and one of the tall kinds, such as *Emperor* of the *Marrows* or *British Queen*, are all put in at once, a successional crop will be obtained. Unless where the land is wet, *Peas* at this and subsequent sowings should be sown in shallow trenches, so that the soil covering the seed should be about 1 in. below the surface level at each side; this will admit of the liberal application of water, which, in dry weather, is necessary to them. To further assist them a quantity of manure should be worked in deeply at the bottom of the trenches. Do not sow too thickly. At this and the succeeding sowings half the quantity of seed required earlier, or when there was more to fear from the depredations of slugs and birds, will now suffice. More *Spinach* should be put in between the rows of *Peas* or any vacant spaces, and a little more *Turnip* seed, if required, should also be sown. Of *Seakale*, if a sufficient quantity of roots be not at hand for planting, seed may now be sown, making holes with a dibber, and covering it with 1 in. of soil. Drop three or four seeds in each hole, which should be 1½ ft. apart in the row, with a similar space between the rows, these distances asunder being best suited to the proper development of plants of this description.

**Box Edging.**—The principal objections to *Box edging* are that it affords a harbour for slugs and renders it difficult to apply salt to the

walks for the destruction of weeds, or to apply it as a manual dressing to the ground which the Box encloses; but apart from this there is no edging that equals Box in appearance when well kept. It is frequently allowed to become too large through inattention to cutting, or by permitting it to remain too long without replanting. The present is a good time for either replanting or making up any deficiencies that may exist through the Box having died in places; the latter mishap generally occurs where the land is of a heavy, wet, retentive nature, and insufficiently drained, or it is killed through vegetable crops being planted too near it. If the haulms of Potatoes overhang it during the summer, or if Cabbages, Beet, or anything of similar character be too close, it gets killed. Where any considerable portion of the Box is dead it is much better to take up the whole and replant, as where the dead portions are simply replaced it has a patchy look. A Box edging that is well planted in a workmanlike manner, and one in which the operation is indifferently performed, produce as great a difference in effect as that resulting from good and inferior work in any gardening operation. As many may not have had any experience in Box planting, a few hints may be of use. In the case of existing edgings in the usual position, viz., bounding gravel walks that require to be thus treated, the first thing is to remove all the gravel from the sides, placing it in a ridge in the middle of the walk; take up the whole of the Box, which should be heeled in to prevent the roots drying until the ground is prepared; commence at one end and dig over where the Box has stood and is to be replanted about 1½ ft. or 2 ft. in width, breaking the soil line as the work proceeds, leaving the top quite level or with a gradual rise according to the more or less sloping position of the ground. Care must be taken to have the surface thus dug off the right height proportionate to the ground which the edging is to enclose; if too high, it will have an awkward appearance, and if too low, it gets smothered through the rains washing the soil down upon it. This condition as to the requisite height is after it has been made solid by treading and beating with the back of the spade. Draw the line from end to end, quite straight or gradually curved as the course of the walks requires, with a spade open a trench cutting straight down so as to have it perpendicular on the off side, drawing the soil inwards; this trench should be the full depth of the spade, then commence with the Box, dividing it by hand, it will split up readily, and care must be used to secure a portion of roots to all that has to be planted; begin planting it in a thin continuous line with the tops about 2½ in. or 3 in. above the surface, filling in the trench as the work proceeds with the soil that was taken out to form it, treading it with the feet solid so as to make it lie quite close. After the planting on both sides of the walk is done, replace the gravel, adding more if required; a little practice will enable the operator to plant the Box in a continuous, even line all equal in height and breadth. All the subsequent attention necessary for some time will be in the matter of watering the Box in May or June if the weather be very dry.

#### Extracts from my Diary.

April 15.—Sowing Cottager's, Asparagus, and green Curled Kale; also the following sorts of Broccoli, viz., Snow's Winter White, Osborn's Winter White, Leamington, Carters' Champion, Knight's Protecting, Wilovee and Carters' Summer. Earthing up and putting sticks to French Beans in pots. Thinning out Carrots in frames; also Lettuces, Radishes, and Turnips. Getting frames ready for Melons that had previously been occupied by Radishes.

April 16.—Sowing Cox's Golden Gem, Golden Perfection, and Pragnell's Green Flesh Melons; also a collection of Everlastings. Pricking out Leeks, Chervil, and Borage. Potting Caladiums, Balsams, and young Vines. Earthing up Potatoes in frames; also putting a little earth over choice ones peeping out of the ground. Turning over gravel walks where they have become green, in order to give them a fresh appearance.

April 17.—Sowing Radishes; also Carters' Giant White Cos and All the Year Round Lettuces. Sticking Peas, and afterwards earthing them up a little. Getting all bedding plants out under south walls, to be taken as fast as they become fit for exposure. Hoeing amongst all growing crops at least as the weather will permit. Tying up radishes to blanch. Looking over Pines, giving them water, and tying up any that require it. Tying in shoots in every Peach house.

April 18.—Sowing two rows of Scarlet Runners in deep trenches, so that they may be easily protected from frost; also Nasturtiums, Mignonette, Larkspurs, and Convolvulus; and likewise a collection of Antirrhinums. Pricking out Lettuces, Celery, Asters, Stocks, and Tagetes. Planting out spring-sown Cauliflower plants; also Carters' Giant White Cos and All the Year Round Lettuces. Tying down young shoots in early Vineries, and thinning the Grapes where required.

April 19.—Potting plants of Scented Verbenas, Tricolor Pelargoniums, and Tomatoes. Shifting young Vines, just struck from eyes, into square blocks of turf for planting. Giving Cucumbers and Melons a little top-dressing, picking off all false blossoms, and stopping them where required. Clearing off Broccoli stumps and other vegetable refuse. Manuring the ground and getting it dug up as fast as is convenient.

April 20.—Potting off seedling Ageratum, Solariums, and Petunias; also Alternantheras, Coleus, Verbenas, Vegetable Marrows, and ridge Cucumbers. Mowing and cleaning up pleasure grounds, and rolling down all gravel and turf that require it. Hoeing between rows of Potatoes, Onions, and Carrots. Giving manure for Celery a final turning. Weeding, Box edgings, and cleaning up kitchen garden. Fruit in use for dessert: Pines, Strawberries, and Apples.

Dorset.

W. G. P.

#### A TROPIC BEACH.

In "At Last," Canon Kitegley thus writes of a Tropic beach (see opposite page) which he visited in Trinidad:—"I scrambled down on a gravelly beach, and gazed up the green avenues of the brooks. I sat amid the Balisiers and Aroumas, above still blue pools, bridged by huge fallen trunks, or with wild Pines of half-a-dozen kinds set in rows: I watched the shoals of fish play in and out of the black logs at the bottom: I gave myself up to the simple enjoyment of looking, careless of what I looked at, or what I thought about at all. There are times when the mind, like the body, had best feed, gorge if you will, and leave the digestion of its food to the unconscious alchemy of Nature. Whether on a Scotch moor or in a Tropic forest, it is well at times to have full faith in Nature; to resign yourself to her, as a child upon a holiday; to be still and let her speak. She knows best what to say. And yet I could not altogether do it that day. There was one class of objects which I had set my heart on examining, with all my eyes and soul; and after a while I scrambled and hewed my way to them, and was well repaid for a quarter of an hour's very hard work. I had remarked Palms unlike any I had seen before, staring the opposite forest with pale grey-green leaves. Long and earnestly I had scanned them through the glasses. Now was the time to see them close, and from beneath. I soon gessed (and rightly) that I was looking at that Palma de Jagua (Jessenia) which excited—and no wonder—the enthusiasm of the usually unimpassioned Humboldt. Magnificent as the tree is when its radiating leaves are viewed from above, it is even more magnificent when you stand beneath it. The stem, like that of the Coco-nut, usually carries the height of a man ere it rises in a shaft for 50 ft. or 60 ft. more. From the summit of that shaft springs a crown—I had rather say, a fountain—of pinnated leaves; only eight or ten of them; but 25 ft. long each. For three-fourths of their length they rise at an angle of 45° or more; for the last fourth they fall over, till the point hangs straight down; and each leaflet, which is about 2½ ft. long, falls over in a similar curve, completing the likeness of the whole to a fountain of water, or a gush of rockets. I stood and looked up, watching the innumerable curled leaflets, pale-green above and silvery-grey below, shiver and rattle amid the denser foliage of the broad-leaved trees; and then went on to another and to another, to stare up again, and enjoy the mere shape of its most beautiful plant I had ever beheld, excepting always the *Musa Ensete*, from Abyssinia. Truly spoke Humboldt, of this or a closely allied species: "Nature has lavished every beauty of form on the *Jagua* Palm." Once—I should know the spot again among a thousand—where we scrambled over a stony brook just like one in a Devonshire wood, the boulders and the little pools between them swarmed with things like scarlet and orange fingers, or sticks of sealing-wax, which we recognised, and, looking up, I saw a magnificent *Bois Châtaigne* (Carolinae insignis)—Pachira, as the Indians call it—like a great Horse Chestnut, spreading its heavy boughs overhead. And these were the fallen petals of its last night's crop of flowers, which had opened there, under the moonlight, unseen and alone. Then we emerged upon a beach, the very perfection of typical Tropic shores, with little rocky coves, from one to another of which we had to ride through rolling surf, beneath the welcome shade of low shrab-fringed cliffs; while over the little Mangrove swamp at the mouth of the glen, *Toucou* rose sheer, like McGillivuddy's Keeks transfused into one huge oresser. We turned inland again, and stopped at a clear brook, running through a grove of *Cacao* and *Bois Immortelles*. Afterwards we turned up into the loveliest green trace, where, I know not how, the mountain vegetation had, some of it, come down to the sea level. Nowhere did I see the *Melastomas* more luxuriant; and among them, arching over our heads like parasols of green lace, between us and the sky, were tall *Tree Ferns*, as fine as those on the mountain slopes. In front of us opened a flat meadow of a few acres; and beyond it, spur upon spur, rose a noble mountain, in so steep a wall that it was difficult to see how we were to ascend.

The Progress of Botany.—A Belgian journal of horticulture has given some curious figures showing the rapid increase in our knowledge of the vegetable kingdom. In the Bible about 100 plants are alluded to; Hippocrates mentioned 234; Theophrastus, 500; and Pliny, 500. From this time there was little addition to our knowledge until the Renaissance. In the beginning of the fifteenth century Gesner could only enumerate 800, but at its close Bauhin described 6000. Tournefort, in 1694, recognised 10,146 species; but Linnaeus, in the next century, working more cautiously, defined only 7294. In the beginning of this century, in 1806, Persoon described 25,000 species, comprising, however, several minute fungi. In 1819, De Candolle estimated the known species at 30,000. London, in 1830, gave 81,731 species, and in 1846 Prof. Lindley enumerated 66,435 diotyledons and 13,952 monocotyledons—in all 80,387; but in 1853 these had increased to 92,920, and in 1863 Bentley estimated the known species at 125,000.—"Lancet."

## ANSWERS TO CORRESPONDENTS.

Questions from correspondents who do not send their names and addresses in full (not necessarily for publication) cannot be answered. The questions are usually submitted to good practitioners in their several departments. Whether questions are answered or not in this department, we shall be greatly obliged to our readers who being able to help our correspondents, will kindly furnish answers. Questions cannot always be answered in the same week in which they are received.

**Scale on *Ceanothus rigidus*.**—I have two or three good plants of this *Ceanothus* against a wall which have done very well for the last six years, but they are now covered with scale, and the plants are going back very much in consequence. I shall therefore be much obliged if you will let me what to do in order to get rid of this pest.—A. B. W. [You had better prune the plant in closely, and scrub the remaining shoots with soft soap and Tobacco water, using a small stiff brush for the purpose. Apply a little rich soil to the roots in order to encourage vigorous growth, which will also still further be promoted by keeping the root well supplied with water in dry weather, and by frequently syringing the foliage.]

**Malformed Rose Bloom.**—I send you a malformed Rose blossom, and will be glad to hear if such has been noticed before. The tree is, I believe, a *M. lutea* *Eugene Verdier* (scotless), and has this year borne eight or nine good flowers. It is growing in a pot in my greenhouse (moderately heated), and is trained downwards, owing to its rampant growth.—J. R. S. [Such cases as that which you have sent are not uncommon. They show the close connection that exists between leaf-buds and flower-buds in certain stages of their existence, and are usually the result of sudden transitions of temperature.—M.]

**The Swamp Magnolia.**—I have recently purchased a few plants of *Magnolia glauca*, of which I am a great admirer, and shall be glad if you will kindly let me if it requires any special treatment. [*Magnolia glauca* like a peat soil and a moist situation, sheltered and sunny. The flowers are powerfully scented, their scent resembling that of the Lily of the Valley.—G. B.]

**Adiantum Farleyense and its Culture.**—Can you inform me why this Fern does so badly with me? I have tried it in the best peat and loam which I can get, but the fronds grow yellow, and the young ones come up very sickly. It is in a small house, kept at about 60° with other Ferns, which do very well. Wherein have I failed in reference to this one?—J. W. [Your best plan will be to shake the plants out of the pots they are now in, remove the greater portion of the soil without injuring the roots, and re-pot in good-sized pots one-third full of drainage. Use a compost of tarty loam, leaf-mould, broken crocks, and a little charcoal and plenty of sand. Keep the crowns of the plants a little higher than the level of the soil, and place the pots on a piece of slate. Shade from direct sunshine, pay strict attention to watering, always using it in a tepid state, and do not syringe too much water over the foliage.—S.]

**Crisp Celery.**—How can Celery be made crisp? Ours is beautifully white and well tasted, but decidedly not crisp. Frost, it is said, will do it, but we have had some pretty sharp frosts, and yet the Celery is flabby as ever, and I have eaten Celery elsewhere far better than ours.—M. [In order to grow crisp Celery the manure put into the trenches should be as rich and rotten as possible. [Crispness] be any straw or dryness in the manure, the Celery is sure to be pipy, and not crisp. Another great point is never to let the plants suffer from want of water or liquid manure, both when first planted out; and during dry, warm summers, some varieties of the dwarfer kinds of Celery are more rusty and crisp than the larger-growing sorts. Amongst whites, *Saintincham* and *Turnor's* are memorable belong to this class; and amongst reds *Sulham Prize Pink* and *Major Clarke's Red*.—W. T.]

**Heating Small Greenhouses.**—I am about erecting a greenhouse for Grapes about 15 ft. long, and am puzzled to know how to heat it in a convenient way. Would you kindly recommend the best kind of stove suitable for the size of house just named, and tell me whether it will be necessary for the well-being of the Grapes that artificial heat be kept up all the year round?—R. S. O. [Very few small stoves are quite satisfactory. As a rule, they make the air too dry, and gas is apt to escape either from the furnace or the pipes. The best which we have seen are those of *Watson, Read, Shrewsbury*, and others, in which the fire is surrounded by a water jacket, or there is a combination of stove and small hot-water pipes. *Read's* stove and hot-water apparatus, often advertised and illustrated in *The Gardener*, is one of the simplest, safest, and in the end cheapest methods of effectually warming such structures. For such hardy Grapes as *Hamburghs*, grown in a greenhouse, heat may be given from February to the middle of May, and again probably in September and October, which will be all that is necessary.—D. T. Fish.]

**Procuring Hardy Flowers.**—Will you kindly inform me where I can obtain the flowers recommended in "Hardy Flowers"? I have a large shrubby which I wish to plant with hardy pansies in a tub, such as you recommend in part 3, also a large piece of boggy ground; the difficulty is, where to obtain the plants named. [Your best course will be to visit some of the large London nurseries for herbaceous plants, or in any case procure their catalogues; see also our advertisement columns. It is to be regretted that our large districts of England and Ireland there are no nurseries where a good collection of hardy flowers may be obtained. Improvement is very much checked from this cause. We do not doubt that it would pay to devote "a quarter" to the very finest hardy herbaceous and Alpine plants only—a few hundreds of the best now known. Anybody who compares the interest now taken in hardy flowers with what was taken a dozen years ago may well be surprised at the change. We

believe that every year will see an increasing demand for these plants, and that the progress ten years hence will be far more marked than that of the past ten years. Nurserymen, however, as well as others, must help towards this end; indeed it is their interest to do so.]

**Spot on Pelargonium Leaves.**—The leaves of my Pelargoniums turn spotted. What is the cause of such a disaster?—T. F. [Oild and dano.—3.]

**The Silvery Cedar of Lebanon.**—Will any of your readers kindly inform me where I may purchase plants of this, of which there is a fine specimen in the Pinetum at Dropmore? I have tried to find it in a good many nurseries but in vain.—O. L. [This beautiful glaucous variety is, I believe, very scarce in the trade. Try Messrs. Lawson & Co, of Edinburgh; Mr. Richard Smith, Worcester; or Messrs. Barron & Son, Elvaston, Derby.—B.]

**Artificial Manures for Potatoes.**—1. What is the best artificial manure for early Potatoes (*Magpie's Prolific*) in a sandy soil? 2. What quantity of the manure is necessary per acre? 3. Should the manure be mixed with ashes or mould?—M. [1. Amies' chemical manure is said to be the best artificial manure for Potatoes. 2. I have grown good sound crops of early Potatoes on a light soil by using 4 cwt. of the best guano, mixed with 2 tons of dry mould or wood-ashes, but no coal-ashes should be used, as they produce rough scabby skins on the tubers. 3. Another good manure for Potatoes on light soils is a mixture of 2 bushels of salt, with 12 bushels of soil, and 1 1/2 cwt. of nitrate of potash to the acre. On light soils salt is an excellent fertilizer.—W. T.]

**The Blue Wood Anemone.**—I enclose a few blooms of *Anemone nemorosa corolla*. This appears to be of nearly the same colour as *A. Robinsoniana*, according to description of that variety, but it has not so many petals, nor does it appear to be so robust. Can you help me in this matter? After all, perhaps *A. Robinsoniana* may be nothing more than a selection from my variety. I had the pleasure of paying 2s. 6d. for 1 in. of root and one leaf of *A. Robinsoniana*, so I hope that a treat is in store for me, if I am spared a few years longer.—JAY AYE. [The plant which you send seems very like the form known in some gardens as *A. Robinsoniana*, but it is so much shrivelled that it is difficult to judge. It is much to be desired that plants sent by post should be wrapped in gutta-percha paper or tinfoil, in order to prevent evaporation.]

**Artificial Manures for Vines.**—What is the best artificial manure to obtain for making manure water for Vines? and in what proportions should it be applied? I have been recommended to use dissolved bones, and have tried the same without much apparent result. My Vine-brier is an outside one, but protected from too much wet and rendered warm by covering it with old cucumber frame lights, which I take to be a combination of the advantages of inside and outside planting.—W. [Genuine Peruvian guano is the best artificial manure with which we have yet met for Vines, being safe, permanent, and quick in its action. Two pounds of guano dissolved in 30 gallons of water will be found to be about the right proportion, though much depends on the strength and vigour of the Vines. In any case caution is requisite, in order not to overdose; better use it weak, and give an extra watering, than give a strong dose to, as it were, surfeit them.—W.]

**Moss on Gravel Walks.**—I am troubled with Moss growing on a gravel walk in front of my house. I believe that this is owing to the drains being old and out of order, and next autumn I intend renewing them. In the meantime I am recommended to put down salt to kill the Moss. Can any of your correspondents tell me if it will have the desired effect, whether this is a good time of year for putting it down, and if there be any special method of application? Or is there any other remedy? Weeding only keeps the walk clean for about a week.—B. P. [Salt will kill Moss on gravel, but this is not the best time of the year to put it on; later on will be better, and select a time likely to be dry for a few days, with sun-heat if possible. When rain washes the salt off before it lies on the walk for a time it is not so effectual in killing either weeds or Moss. Care must be taken not to spread the salt too near Box edgings or turf, or it will injure them. Perhaps the most effectual way of using salt for destroying weeds or Moss on a gravel walk is to put a quantity of it in a boiler with water, and when dissolved pour the liquid on the walk with a watering-can through a good wide rose, and let the water be as hot as possible.—W. T.]

**Names of Plants.—R. S. O.**—The *Spurge Laurel* (*Daphne Laureola*). Is the enclosed a species of *Anemone*? It is grown in a wild sort of shrubby here.—S. W. D. BANKS, *Argentea*. [It is the *Anemone Windflower* (*Anemone hepatica*).]—*F. F., Kent.*—*Now Zealand Flax*; it should be easily obtained among your good nurserymen. *F. A. L.*—*Grevillea juniperina*, an Australian shrub. *Mies M.*—*Anemone fulgens*. *T.*—The creeping *Forsythia*—*Nos* (*Opheodorus versal*). *JAY AYE*—We will try to ascertain. This genus is generally wrongly used. *H. W.*—It is very doubtful what species is meant. *J. G. D.*—*Anemone hepatica*. *W. P. M.*—We do not undertake to name more than three or four plants at a time, and we never name florists' flowers, such as the several forms of *Antirrhinum*. The sweet-scented florist is *Jasminum Sambac*, the *Rhododendron* with the large leaf *R. Falconeri*. The other *Rhododendrons* next week.

## THE KITCHEN GARDEN.

### SOWING MAIN CROP AND LATE PEAS.

TAKING one year with another, I suppose scarcely anybody has too many Peas much after July. No matter what kinds are grown, or what system of culture is adopted, a full crop cannot always be depended upon. Either a withering drought occurs and causes many of the pods to be abortive or only half filled, or the growth may be checked by mildew, which even the best culture, in some seasons and situations, fails to prevent; or else, on the other hand, the weather is damp and sunless, and the growth becomes lanky and weakly; and in either case the result is too many instances, with late-sown Peas, is far from satisfactory. Of course there are many things which the cultivator can do to encourage the crop and to counteract the difficulties which it has to encounter—such as sowing only on well-prepared land; placing the rows at considerable distances apart, with other lower crops intervening; planting in a fully exposed situation; and, above all, planting the Peas thinly in the drills. In this way the foundation is laid for a sturdy growth, that will in a difficult season not be without its influence for good. On porous soils, too, there is an advantage in planting in trenches in which 6 in. of well-decayed manure has been placed, and well mixed and blended with the soil. In no case should rank or long manure be used, unless the trenches are prepared some time previously, say two or three months before the Peas are sown. The word trench may perhaps to some minds convey a wrong impression. When the Peas are sown, the surface of the soil covering them need not be more than 2 in. or 3 in. below the natural level, so that trench in this case means a slight hollow just sufficient to retain moisture round the plants. Mulching with half-decayed manure is another valuable expedient for Peas or any other crop on a porous soil; in fact, with well prepared stations for the rows, and the mulching applied before the heat has drawn all the moisture from the land, there should not be much necessity for watering. I am disposed to think that, as watering in the kitchen garden is often done, it is too generally lacking in thoroughness to be of much benefit. In sowing successional crops of Peas, the common arrangement is to make the successional sowing just as the previous one is coming through the ground; and, as a rule, no doubt this acts fairly well. But for late Peas I am in favour of sowing freely, during April, such kinds as *No Plus Ultra*, *British Queen*, and *Emperor of the Marrows*, without attaching much importance to what has gone before or may come after, being guided entirely by the land at disposal and by the probable demand. If well and liberally treated, the Peas I have named, or such kinds as *G. F. Wilson* and *Veitch's Perfection* if dwarfier sorts be desired, sown in April, will do well; and if the pods be carefully gathered when fit for use, the plants will assume a perpetual or successional character, that gives better results than is often obtained from late-sown Peas of the large Marrow kinds. A moment's reflection will make this clear. The late Marrow, of which the *British Queen* may be taken as the type, requires a genial growing season to enable it to get a good grasp of the soil, and to build up its growth in a sturdy manner; but when sown much later than April, the heat forces it prematurely into bearing before anything like a full and natural development has been reached; hence it often perishes with mildew almost without bearing any crop at all. One of the best Peas for sowing in May and the first half of June is *Huntingdonian*. *Laxton's Supreme* bears well as a late-season Pea, although not of first-rate quality. *Standard* and *Marrow*, two of *Laxton's* recent seedlings, are also excellent, being very free bearers, strong in habit, and of medium height, or rather below if anything. I am not urging anyone to altogether discontinue the later sowing; I only wish to lay stress upon the importance of getting in a good breadth not later than April. Late-sown Peas may occasionally do well, but early-sown crops may invariably be relied on; and if at any time there should be a surplus, it is better to have them gathered and given away than permit them to remain on the plants to produce exhaustion; if this happen, the bearing powers will be effectually checked, as nothing weakens a plant so much as seed-bearing; therefore, to make the most of a crop of Peas, the pods must be gathered green.

E. HOBDAY.

### LABELLING KITCHEN GARDEN CROPS.

I FIND it to be an excellent plan not only to name each variety of vegetable grown in the kitchen garden, but also to add the date of sowing or transplanting, as by referring to these dates when the crop arrives at perfection one may get many useful hints for future guidance. For instance, *Cauliflowers* or *Broccoli* we have out from the open ground for years past with scarcely an interval or blank in the supply. But, in order to do this, the sorts must be well selected,

the dates of sowing and transplanting must be known to a certainty, and situations to suit various soils and seasons must be selected with care, or a protracted drought in summer will cause as great a failure as a protracted frost in winter, and the same applies to all crops. Peas may come in too quickly or at too long intervals apart, even if sown at what was supposed to be the most favourable date for ensuring a constant supply; and if we have no trustworthy reference to depend on, we cannot correct the error in succeeding operations. Celery and such crops as are liable to prematurely run to seed if sown too soon, and which we are also anxious to have fit for use as early as possible, can only be grown satisfactorily through close observation to apparently trifling details of culture, and by classifying for special purposes. The labels for all such crops should be at least 1 ft. 6 in. long and 2 in. wide, made of soft yellow dead planed quite smooth and painted white, and the name should be written in large characters with Wolf's garden pencils. Such labels defy the weather and remain perfectly legible as long as any crop will stand in one position. Herbs, salads, and medicinal plants ordinarily grown in kitchen gardens should have the name by which they are most generally known conspicuously placed on each bed or compartment, so that it may be readily found by the most casual observer. It is only by such means that one can satisfy oneself which varieties of vegetables are really distinct and which are not. A constant supply does not depend on the number of varieties which one may have, nor even on "complete collections," but on the best sorts in each class.

Henham.

JAMES GROOM.

### IMPROVED DANDELIONS.

THE leaves of the Dandelion, from the remotest time, have been used as a spring salad; but, being so plentiful in Corn fields, meadows, and on roadsides, the plant itself is seldom cultivated. Immense quantities of it are brought daily by rail to the Paris markets, coming occasionally from districts as far off as 300 or 400 miles. It is used in a green and also in a blanched state, the former from meadows, the latter the produce of roots buried in autumn by the plough. Occasionally, when rivers overflow, they leave a thick layer of rough mud, straw, weeds, &c., on the surrounding meadows, and when this deposit is raked off, Dandelions, beautifully white, are found under it. Lately, however, their cultivation has greatly increased, even in gardens where they are grown as an ordinary vegetable. Three varieties are now cultivated. 1. The common Dandelion, the leaves of which are all radical and lie nearly flat on the ground, from 2 in. to 8 in. long, deeply serrated, light green, dark green or brownish, according to locality and soil. Some botanists have supposed that there are several species of the wild Dandelion, but that is not the case. 2. Large-leaved Dandelion, the leaves of which are numerous and larger and more substantial than those of the common kind. The plants are also better furnished with foliage and produce a better crop. It is, in fact, an improvement on the common kind; but, nevertheless, it is seldom met with. 3. Cabbaging Dandelion, in which the centre or heart is entirely filled up with small leaves, which, as they increase in growth, show a tendency to turn inwards, like an *Endive*. By means of careful selection, this kind might easily be greatly improved.

Dandelions, we know, are not difficult to grow. They should be sown in April or May in a well-prepared bed in rows 4 in. apart. The young plants, if too thick, should be thinned out, and they should be kept clean by means of frequent hoeing. In October clean the bed and remove the greater part of the leaves, and spread over the whole from 3 in. to 4 in. of light soil, sand, or leaf-mould. As soon as the young leaves show themselves above the top-dressing, the crop is ready for use. The soil should then be removed, when the leaves will be found to be beautifully blanched. They should be taken up with the top of the root attached to them. The improved sorts should have a little more room than the common kind. Another and perhaps a better way is to sow in April or May, and to transplant into another bed the best of the seedlings, subsequent cultivation being the same as that described above. Sometimes the full-grown roots are taken up in October and transplanted close together in another place, an operation which does not disturb their growth, and the produce is the same during winter. Roots tied into bundles in October may be forced in a cellar, like the *Barbe de Capucin*, to the produce of which Dandelion has a great similarity. In America, where much attention is paid to the culture of Dandelions, after the

plants have become fully grown in the autumn, a frame is put over them, and some are even forced, in order to obtain an earlier crop. In the open ground it takes about a month to blanch the plants, much depending of course on the character of the soil and the weather.

Growers who care only for the roots sow in October in drills 1 ft. asunder, thinning the young plants to 3 in. apart. The following autumn the roots are taken up, cleaned, sliced, dried, and sent to market. The roots are ground and used as a substitute for or mixed with Coffee, like Chicory.

When Dandelion is used for salad it is dressed with salt, pepper, oil, and vinegar, or boiled and eaten with meat. The leaves must be washed and well dried before being used; this is very important if good quality is looked for. If got from a meadow, select, if possible, plants with short, deeply serrated, brown leaves, which are far superior to those having long, pale green foliage, grown under hedges or in the shade. Dandelions, I am glad to say, may now be seen daily in Covent Garden Market. Should the plants bought be faded, dip them in water, and in a few hours they will revive. D. GUIHENEUF.

**Ducks and Slugs.**—Some years ago ducks were tried for the purpose of destroying slugs in a garden in Berkshire in which I was employed; the result was not only complete failure as far as eating the slugs was concerned, but the destruction caused by their webbed feet was something enormous. It is astonishing the distance they will travel in search of worms; and, so far as my experience went, I found these to be their favourite food. Nearly everything in a small estate was either broken down or eaten by them. Some of the borders which were planted with herbaceous plants were thoroughly spoiled, and in one instance a large bed of cuttings of trees and shrubs which were very promising had hardly a bud left upon them after the ducks had promaded over them a few times. They also got into the frames when air was given, and did no end of damage. The consequence was, we had soon to disperse with their services and adopt the lime cure, the lime being, however, always mixed with soot, salt, and gas ashes, sown as one would sow Grass seeds about three times a week on those evenings on which we considered it most likely to find the pests abroad. The quantity sown was at the rate of three bushels per acre. The result of this application was through success as regards keeping the slugs within bounds, and I do not remember that anything suffered from its use. Under any circumstance we found it immeasurably superior in every way to the duck remedy.—CHARLES DENNIS, *Southwark Park*.

I can assure Mr. Smith (see p. 304) that it is no delusion that ducks eat slugs. We have five ducks that were hatched in the middle of August to run about in the autumn and follow the diggers in winter and spring. After the ducks are full-grown we keep them in the pen, only letting them out when wanted, and they seem to know their work as well as we do. We never feed them previous to letting them out. When uncovering the Asparagus beds a week or two back, the surface of the bed under the manure being pretty well covered with slugs, the ducks were let out, and they picked up every one, and so hunted the manure through that not one could be seen; in fact, our walks used to be alive with slugs on damp mornings, and now we seldom see one anywhere. We use no other means to destroy them, so I feel sure that we must give the credit to the ducks. Young ducks only should be used; the first lot should be hatched as early as possible, and the second in August; the latter will supply eggs to breed from for the August following. Where it is not convenient to have ducks in the garden I employ Mr. Garland's plan (see p. 304), which, though old, is a very good one. Salt put in the oven and dried answers equally well as quicklime.—JAMES SMITH, *Waterdale*.

There are "slugs and slugs" and "ducks and ducks." The slug which worries me most here is the one with a dusky brown or black back and yellow stomach; I forget its specific title at the present moment. It is a regular pest. Except on very warm, moist nights it lives some 6 in. or more beneath the soil, where it revels amidst patches of the rarest bulbs and roots of the choicest perennials, continuing its depredations with uninterrupted immunity throughout the winter, except in exceptionally severe weather, when the ground is frozen some depth below the surface. Lime is simply useless as a remedy against this slug, except on mild, moist nights. I have destroyed hundreds on such nights by scattering patches of bran about the borders and going round with a lantern and a tin basin after dark, into which I put the slugs and pour boiling water upon them. It is very back-breaking work, but effectual. Ducks do not fancy this slug; and if they did, could not get it, for it comes to the surface after they have gone to bed. They are fond of the

common grey slug, but they are very bad gardeners. I found that they browsed the Carnations almost as clean as sheep, picked off the heads of Primroses, Polyanthuses, &c., wholesale, and paddled about the beds till they looked like Cornfield paths. In fact, the cure was as bad as the complaint. Lime is very effectual when fresh, but it makes the beds look unsightly for a day or two. I stick to the bran and the basin and the 'bull's-eye lantern in spite of the back-ache.—H. HARPER CREWE, *Drayton-Beauchamp Rectory, Tring*.

While there is no doubt that lime on moist, warm nights must prove extremely useful in killing slugs, I think the remedy so liberally provided, and so effectually used by Nature in the shape of frogs, &c., is far more efficient than the lime nuisance, and also preferable to ducks, from the fact that ducks take daylight for their hunting time, while frogs use the night time; having a lively recollection of frog music in the Rice lands of Barmah, I cannot recommend them as songsters, but I think their merits as assistants in the kitchen garden are greatly overlooked. As a small amateur, who knows that night time will place his helpless enemies within the reach of a trowel, I can calmly walk round with a hand-lamp and spread them out; and I recommend this in preference to salting or liming.—LONDON STONE.

I quite agree with Mr. Smith's recommendation to employ ducks for the destruction of the slugs. I have also found that peewits are equally useful for the same purpose. I remember one instance in which a quantity of young peewits were obtained and kept in a common garden frame till they were old enough to run about. After cutting their wings, to prevent them from flying away, they gradually grow tame, and were very efficacious in devouring not only slugs, but all kinds of garden pests. During severe weather in winter they were kept in a frame at night and let out in the daytime, and a piece of ground was dug almost daily to supply them with food. Immediately on seeing a fork or a spade in use, they would run eagerly to devour whatever might be turned up. I prefer them to ducks, as they are not so unsightly, never in the way, and, last, but by no means least, they seldom interfere with growing crops.—O. H. KITCHING, *Cokethorpe Park*.

**Poisoned Seeds.**—"Prepare seeds before sowing with red lead to protect them from birds," &c. This advice, so often repeated in kitchen garden operations, seems to me to call for a protest. Considering the solvent powers of distilled water, and the fact that kitchen crops are generally gross feeders, such indiscriminate use of poison is likely to lead to unpleasant results, which could be avoided by the use of some safer pigment. Paris green is not the one I would suggest; and perhaps the Americans who advocate such a free use of it for the destruction of the Colorado beetle may yet find, with our gardening friends at home, that poisonous metals are not the safest things to place in the path of that active solvent of them, rain water. With regard to flowers, I think metallic salts, &c., open out a wide field for experiment, and in that direction I trust the arsenic and red lead sprinklers will be content to travel.—LONDON STONE.

**Vegetables for a Clay Subsoil.**—Situated as we are, under clouds of smoke and chemical vapours, with a subsoil of clay yards deep, it requires both time and attention to select the sorts of vegetables most suitable for cropping such a soil, as many of the better kinds do not yield even one-third of a crop. Allow me, therefore, to enumerate such varieties as may be relied upon to produce, with proper attention, satisfactory results, commencing with Broccoli, which depend so much on the character of the winter and the method of cultivation. Frogmore, Knight's Protecting, Dwarf Russian, and Brimstone we find to stand well. Brimstone is, however, most to be trusted. Amongst Cauliflowers, Autumn Giant is quite at home, and also Walcheren, for August sowing. Negro, or dark or pale-dun Kidney Beans answer well. Amongst Lettices, Wheeler's Tom Thumb and All the Year Round have proved to be very good, but all the Cos varieties under ordinary cultivation are poor. Peas, being most important, require extra attention, for if the seed get starved before it comes through the soil, a poor crop may be expected. A trench, a spade deep and about 1 ft. wide, should be taken out, and filled up with leaves or littery manure, and covered over with soil; on this sow the Peas, which will thus be kept dry and warm. McLean's Little Gem, sown thinly, three rows on a 4-ft. bed, with a few branches between the rows, produces good crops, and comes in early. In fact, it is a useful little Pea and well-flavoured, and as it only grows from 12 in. to 18 in. in height, it may be sown in any snug corner. Laxton's Alpha and Advance may be both sown on the same day, as the latter is eight to ten days later than the former; both are good in flavour, and abundant bearers. For the general crop, Champion of England, Yorkshire Hero, and Prince of Wales, peas should be selected; and for late crops, Ne Plus Ultra and Omega, combining, as they do, quantity and quality. Omega only grows about 3 ft. in height, and is very desirable where Pea stalks are scarce.—JAMES SMITH, *Waterdale*.

## OPENING OF THE GARDENS AT KEW.

SIR T. LAWRENCE at a recent meeting at Kew said, "Some time ago Sir Henry Peek and himself, accompanied by Mr. Marsh Nelson, went down to Kew Gardens and spent several hours with the assistant curator. Since then they had been in communication with various friends in the House of Commons, who would be likely to sympathise with their views and assist in supporting them. They came to the conclusion that the earlier opening of certain portions of the gardens was an entirely reasonable one. He strongly advised them, if they could gain the point of earlier opening, not to press unduly the taking down of the wall. He should do his utmost to support their views in Parliament, and he trusted that they would succeed." [It is pleasing to note that Sir T. Lawrence comes to the conclusion that must be evident to every one who, on the spot, looks into the question on its merits and with reference to the interests of horticulture generally. The question of the wall is local merely, and of little importance compared with that of the opening of the gardens at reasonable hours.]

— We find the following concerning this matter in the "Journal of Botany" for April. The testimony is peculiarly valuable, as coming from a gentleman occupied in the same way as what may be called the scientific portion of the Kew staff. As will be seen, the journal in question takes precisely the view taken by the various horticulturists who have written to us on the subject, that the closing of the gardens through the best part of the day is undesirable, and in the interests of science needless. It says—"The Botanic Gardens at Kew have hitherto been closed to the public till 1 p.m. This is found so troublesome by those chiefly interested that an effort is now being made by horticulturists and other semi-scientific people with little leisure to obtain an earlier hour of admittance. Up to the present time, however, this has been refused, the chief reason given being that it would seriously interfere with the strictly scientific work of the garden, which is carried on during the morning. Such is, at all events, the ground taken in a memorial sent round for the signature of botanists, emanating from two well-known lecturers, and advocating the continuance of the existing regulation. If such a result were likely to follow the public opening of the gardens in the morning, it would be in our opinion a sufficient reason for refusing to make the change; but we are convinced that the danger is wholly apprehension. Besides the officials themselves, we believe we are not wrong in saying that the number of persons engaged in any definite scientific work in the gardens at Kew (we do not speak, of course, of the Herbarium) is exceedingly small. Into the causes of this it is not necessary to enter, but it is obviously undesirable that everybody else should suffer in order that half-a-dozen artists and experimenters in fertilisation may be undisturbed. What more easy than to rail off any spot (it is not asked to have the houses open) where special work is going on? Besides, there is the new Jodrell Laboratory in the gardens, built expressly for the use of the very persons in whose interests it is sought to continue to keep the whole of the gardens closed till the afternoon. Wishing, as every botanist must do, to see the utility of the magnificent gardens at Kew increased, we cannot but think that their earlier opening is much to be desired on behalf of a large class of persons not likely to abuse the privilege; we hope, also, to hear of scientific work of an experimental kind being done in the new Laboratory."

— "Science," we are told, requires that Kew Gardens be closed to the public for half the day. Up to about luncheon-time the authorities inside the walls, whoever they may be, are supposed to be in a "brown study"—absorbed in abstruse speculations on such subjects as the accumulation of water in the stoke-holes, the manuring of the flower beds, and the spelling of plant names. If we could look over the walls we should no doubt see a multitude of students and philosophers walking to and fro in the grounds during the forenoon. About noon the *savants* betake themselves to their cells to ruminate upon their morning's experiences, and in order also that they may not be contaminated by contact with the ignorant public, who are then permitted to invade their sacred haunts. Seriously, we do not suppose anybody believes for a moment in the plea of "science" put forth by the Kew authorities. It is a serious inconvenience to horticulturists and others that the gardens should be closed during the best part of the day; and the public will, now that they have taken the matter up, no doubt insist upon them being opened at a reasonable hour in the forenoon, unless a better reason for keeping them closed, as hitherto, than has yet been given, is furnished.—The "Gardener."

— Last summer I was one Sunday afternoon in the Herbaceous Department in Kew Gardens writing down a few lines about a plant with which I met there, and in which I was interested, when the man on duty came to me and said, very politely, "Notes or remarks

in writing are not allowed in this department." On my remonstrating, he said, "It is the most stupid order I ever received, but, as it is my duty, I must see that it is observed."—A FRENCHMAN.

— It would be wiser for Mr. Gerard Noel to consent with a grace to the opening of Kew Gardens at ten o'clock in the morning instead of at one. The Richmond folk are resolved not to be agitating until their wishes in this respect have been complied with, and there is no valid reason why they should not be. The excuse that it would involve additional expense is really too absurd to be seriously urged. What would the cost of two or three extra keepers amount to?—"Truth."

— It will, no doubt, interest your readers to know that, through the exertions of the Kew Gardens Public Rights Defence Association, Her Majesty's First Commissioner of Works has consented to open these gardens at ten o'clock in the morning on all bank holidays. The public will therefore be admitted at that hour on Easter Monday next, when the Association hopes that visitors will show their appreciation of the boon by constituting themselves protectors of this valuable public property, and thus assist the association in its efforts to obtain further concessions.—CHARLES COLMAN.

The present agitation regarding the opening of Kew gardens to the public at an earlier hour than heretofore has drawn the attention of horticulturists to Kew, and some interest and curiosity have been manifested in the doings and functions of that establishment as a national institution supported by public money. It is claimed for it that it is a great scientific establishment—the greatest and best of its kind in the world, and no doubt it does accomplish a certain amount of scientific work, but it may legitimately be asked, Does it do all it might or ought to do in this respect, and has it ever taken that leading position, in regard to practical and scientific horticulture in this country, which such an institution might reasonably be expected to take? In a standard work on general subjects we find that a botanic garden is defined as "a garden devoted to the promotion of botany, and in which plants are collected and cultivated in order to scientific study. The various economical applications of botany, however, in agriculture, manufactures, medicine, &c.," the same authority states, "are almost always kept particularly in view; and one great object of a botanic garden is to bring to a country useful foreign plants, to determine the question of the suitability to its climate, and to introduce those which may be cultivated with advantage." Are these the functions of Kew? may we ask; and if so, how far has it fulfilled its duties? An answer to the question is as desirable as it would be interesting. As a matter of fact, but a very vague notion prevails at present among agriculturists and horticulturists as to the uses of Kew, and neither reckon it of much account in their respective lines of industry, and Kew manifests about an equal indifference in them. There is no institution of the kind about which the general public know so little as Kew; and were it not for the occasional notes that THE GARDEN and other horticultural papers publish concerning it on their own responsibility, multitudes would be absolutely ignorant concerning its doings. It is not to Kew nor to our botanic gardens that gardeners turn for information and instruction, but to the nurseries and private gardens throughout the country. Kew no doubt contains a very large collection of plants, and, so far as it goes, we daresay is a well enough conducted establishment; but what London said of it long ago is, we are afraid, still true to a certain extent. Speaking of botanic gardens generally, and Kew in particular, and its duty and obligations to horticulture and gardening in this country, he says "the policy of this garden for a number of years past is considered as highly reprehensible; being supported by the public, it ought to have been devoted to its service."

It is almost needless to suggest the uses to which such an establishment as Kew might be put as a scientific institution and great public garden. At present it may be described as a place where a great collection of plants correctly named, perhaps, is maintained, and where a disproportionately small amount of scientific and other instruction is imparted, but concerning which exceedingly little is known. In addition to this, of course, the public have admission to the gardens under certain restrictions, but a comparatively small section only can take advantage of the privilege. To those who live at a distance from London, Kew is an institution known little more than by name. Other public societies and institutions publish their transactions,

but how often do we hear anything about Kew? Probably, it is "the greatest" institution of its kind in the world, but does it do a proportionate amount of good work? In speaking of work we do not, of course, allude to the superficial gardening done at Kew—its "bedding" and ornamental gardening, or its lessons in garden culture. In the first, it always has been a mere copyist, and it is well known that nobody goes to Kew to get a lesson in plant culture. We find, on reference to works on such subjects, that the Garden of Plants in Paris is invariably spoken of in high terms as an institution which may be regarded as holding a first place on the Continent "both with reference to the strictly scientific study of botany, and to the care bestowed upon the introduction and diffusion of useful or beautiful plants from all parts of the world. There exists in France," we are told, "what may be called a system of botanic gardens—one at least in every department to which plants are sent from the Jardin des Plantes, and from which, as they continue to be multiplied, they soon find their way into the hands of nurserymen and private cultivators." One can easily imagine the good that might have been accomplished in this way by our own botanical gardens under a similar organisation, but such work has, in this country, been left to horticultural societies and private enterprise. Chiswick and the Royal Horticultural Society has now and then made a spasmodic attempt to fulfil a similar duty; but from it, and from all other kindred societies, Kew has stood coldly aloof. The *exclusiveness* of Kew has, in short, ever been a drawback so far as gardening is concerned. The same impartial authority quoted above regarding the Jardin des Plantes, without intending any satire, briefly describes Kew in the same page as a British national institution "possessing one of the richest collections of plants in the world, and one of the chief glories (?) of which is now its immense Palm house finished in 1848, and which is 302 ft. in length, and the central part of it 100 ft. wide, and 66 ft. high." This is all the impartial chronicler has to relate concerning it. If we turn to another hook on Paris, we learn something of the more useful features and arrangements of the Jardin des Plantes, and which, it would appear, might be copied with advantage by similar institutions in this country. It is there stated that although the Jardin des Plantes "is quite inferior in point of beauty to any of our large British botanic gardens, it contains some features which might be introduced to them with the greatest advantage. Its chief merits are that its plants are better named than in any other British garden. It possesses several arrangements which enable the student to see conveniently and most correctly all obtainable useful plants infinitely better than in any British botanic garden, and it displays very fully the vegetation of temperate and northern climes, and, consequently, that in which we are most interested, and which is the most important for us." In addition to its remarkable collection of Pears, a large division, we are told, "is devoted to the culture of plants used as food and in commerce. The chief varieties of all garden crops, from Radishes to Kidney Beans, are to be seen; the various species of Rhubarb; all important varieties of Lettuce; in a word, everything that the learner could desire to see in this way. It is not merely the plan of the thing that is sensible and good, but the way in which the work is carried out. The annuals are regularly raised and put out, the ground is kept perfectly clean, and it is, in fact, the best place I have ever seen in which to become acquainted with useful plants. Such arrangements, well carried out and cut off by judicious planting from the general verdure and chief area of any of our great public gardens, would be of the greatest service." Another division, the same writer states, is "chiefly devoted to medicinal and useful plants of all kinds, arranged in a distinct way. First we have the Sorghums, Millets, W heats, and cereals generally—all plants cultivated for their grains or seeds. Then come plants cultivated for their stems, from *Polymnia edulis* to *Ullucus tuberosus*. Next we have the chief species and varieties of the Onion, such plants as *Urtica utilis*, the Dalmatian *Pyrethrum rigidum*, and, in a word, almost anything likely to interest in this way from *Lactuca perennis* to the esulent *Hibiscus*." If in one or more of our botanic gardens in each of the three kingdoms such an arrangement as the above could be carried out, even on a moderate scale, what

good purposes horticulturally and agriculturally might it not fulfil! Looking at botanic gardens generally in Great Britain, they may truthfully be described as the sleepest horticultural institutions in the country. Some of our so-called "botanic gardens" are indeed a libel on the name—mere gaily grounds they are, and absolutely barren of interest in either a scientific or horticultural point of view, and which have hardly, at any time, assisted or promoted the interests of horticulture, though ostensibly existing for that purpose. In fact, our botanic gardens both great and small have stood still, comparatively, in their isolation, while horticulture in all its branches has elsewhere been advancing with rapid strides. J. S. W.

**Espalier Apple Buds Killed on Galvanised Wire.**—The cause of the buds of Apple trees being killed on galvanised wire (see p. 282) can scarcely be attributed to lightning, inasmuch as in many of our best gardens the greater part of the fruit trees are trained on galvanised wire. There are miles of such wire espaliers in use in different parts of the country, and, as far as can be judged generally, no harm results from their use, whether they be covered with fruit trees, Roses, or other plants. Even if lightning were the cause one year, it is improbable that it would be so every year.—C. S.

—Mr. Lamond's idea (see p. 282) of galvanised wire and lightning is incorrect. The solution of it is that, in the course of time a portion of zinc wears off from the wire, and then it at once becomes, under moisture, a miniature form of galvanic battery, and this current is fatal to vegetation. For example, place round the edge of a lawn, on the Grass, a few lengths of croquet hoops. After a time the Grass will die wherever it is placed; of course, I refer to the galvanised iron wire.—WILLIAM SOPER, 283, Clapham Road.

**Our Fruit Crops.**—The weather still continues harsh and cold, with the wind due east, or nearly so. For a few days after the sharp frosts of April 1 the weather promised to relent, the wind veered round to the south, and the air felt soft and balmy. Soon, however, a hard east wind set in, accompanied by the brightest sunshine—about the very worst possible weather for the frost-bitten trees. It is pitiable to note how much harder the petals of Peaches, Apricots, and Plums are than their pistils; the former are as hardy as ever, while the latter are dead since April 1. A great many of the Plums are also utterly black in the hearts, and, of course, also killed. Apples seem to have escaped for the present. With the experience of recent years before us, it is of no use ignoring the fact that no fruit is safe until after the middle of May.—D. T. FISH, *Bury St. Edmunds*.

**Fruit Prospects near London.**—In the market gardens round Isleworth and Hammersmith the fruit trees now in bloom present an interesting sight. Plums, especially early kinds, such as Prince of Wales, are literally covered with fully-expanded blooms, which, as yet, do not appear to be seriously injured by the frosts which we have lately experienced. Apple blossoms seem even more plentiful than last year, and there are reasonable hopes entertained that this may prove a plentiful fruit year, at least, as far as the London market gardens are concerned. Gooseberries are in full leaf, and the fruit does not appear to be injured. Peach trees on walls are in full bloom, and many of them have set their fruit.

**Transparent Gage Plum.**—How many cottagers' hopes of a crop of Apricots are blighted by the present weather, whereas if they had planted the Transparent Gage Plum, which blooms later and is more hardy and prolific, in all probability a good crop would have been secured, as well as an equally valuable fruit both for home consumption and for commerce.—W. N., *Newark*.

**Mulching for Fruit Trees.**—For many years past I have mulched fruit trees with the long manure as brought from the stables. In the matter of bush trees, such as Gooseberries and Currants, it serves two or three purposes: first, it manures the land; secondly, it keeps the soil cool and moist; and, lastly, it keeps the fruit clean. The heavy summer rains, unless the trees are mulched, splash the fruit and make it useless. Peaches, Nectarines, and Apricots all share in this annual dressing, which, I believe, does much good and saves watering.—R. GILBERT.

**The Weather at Bury St. Edmunds.**—A little mistake occurs (see p. 308) in reference to the weather. I am made to say "this is the lowest temperature experienced here since the last day of December, 1874, when it fell to 16°." This ought to have been 6°. I wrote it with a clypher prefix, thus 6°, which is usual with meteorologists to prevent mistakes in summing up, &c., to obtain mean or average temperatures.—P. GAYLE.

No. 335.]

[Vol. XIII]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—Shakespeare.

### MY WILD GARDEN.

We find Crocuses to be very effective in the wild garden, and by having some of them in shady places their flowering season may be prolonged; in fact, they will grow almost anywhere. We have them peeping through deep tufts of Saxifrages, and beautiful, too, they are grown in this way. Single tufts, such as one generally sees in ordinary flower borders, should be avoided. The Hepatica, like the Crocus, is also quite at home in the wild garden. We select a place for it under an Oak tree, trench it two spits deep, and let it lie undisturbed for a month. The trenching is then repeated, mixing with the soil some stones of various sizes, and some leaf-mould. When the flowering season is over we plant the Hepaticas from 1 ft. to 18 in. apart, then place some loose stones partly round each plant, and in autumn the falling Oak leaves collect in sufficient quantities amongst the stones to keep the plants warm through the winter. In spring the flowers push through the leaves, which we never remove. A few Primroses, Scilla sibirica, Star of Bethlehem, Dog's-tooth Violet, and similar plants might be intermixed with the Hepaticas. Pheasants are enemies to Crocuses, and rabbits to Hepaticas. To protect the latter, the best plan is to surround the group with  $\frac{1}{2}$ -in. mesh galvanised wire netting. Hepaticas, particularly *H. angulosa*, like, just now when in bloom, the flickering shade of the Oak branches, and in summer the leafy boughs are not too dense for

Crocuses in the Wild Garden.

them; on the contrary, they afford just shade enough to moderate the scorching rays of the sun. Two or three groups of them in the wild garden are very attractive, and it is only by having them massed in this way that their beauty can be fully seen. Not less than from 100 to 200 plants should be put in a colony, and should they not appear to grow well for the first two or three years, be patient, and do not disturb them; they will ultimately thrive, as a permanent home will promote their happiness. What may, however, flourish well in one place may not answer in another. There are varieties of climate, aspects, and soils which practical experience alone can teach one best how to appropriate. The most eligible ground for the wild garden is that with an undulating surface, and if it contains rocks and water so much the better—in fact, any place possessing a wild character, even an old quarry. Deciduous forest trees are most necessary, and so are evergreen ones, especially Conifers. Under the boughs of a Silver Fir, for instance, might be planted *Oxalis Acetosella*, from  $\frac{1}{2}$  ft. to 2 ft. apart. This is not too wide, as in a couple of years the ground will be well nigh covered all over with it right up to the trunk of the Fir, and all the attention that it requires is when any weeds appear to exterminate them. Take another Fir and plant under it *Linnaea borealis*; then select a deciduous tree and plant under it in like manner the sweet-scented Woodruff; and under another tree plant Aaron's Beard. Again choose another tree of the Fir tribe and plant under it the major Periwinkle, and amongst it a few common Ferns, such as *Lastrea dilatata* and others. In about three years the ground will be quite covered. Under

another tree plant the lesser Periwinkle; the single blue and white are better than the double kind. Some Crocuses and Daffodils introduced amongst these have a pretty effect. If none of these Periwinkles be at hand, purchase a dozen or two, and plant them on a piece of ground in the kitchen garden, where they will grow vigorously; and, by cutting the shoots off as they grow, they can be made into cuttings. Put them in beds 4 ft. wide, in rows 4 in. apart, and let the cuttings be 1 in. asunder in the rows. By attending to this for a year or two, Periwinkles may be had by the thousand. If there be an evergreen shrubbery for a background, for shelter, or to check any current of wind, a mass of Periwinkle or Aaron's Beard, from 4 ft. to 6 ft., extending outwards from the base of the shrubs with an irregular outline, has a fine appearance, especially if the shrubbery contains flowering plants, such as Tree Paeonies, *Kerryas*, *Weigelas*, or flowering Currants.

TWENTIS.

### FREE-FLOWERING CACTI.

I HAVE much pleasure in complying with Mr. Fish's request (see p. 335), and will begin with the so-called night-flowering Cereuses, the blooms of which rank amongst the finest of those of all Cacti. The plants belonging to this class are climbers, and do best in a stove or warm greenhouse, in a soil consisting of good rough loam and peat, with a dash of sand in it. Where it is necessary to move them about, a good plan is to grow them on an old Fern stem, or to get a wire cylinder and fill its centre with Moss and peat for them to root in; and if managed in this way they will do well in very small pots. To ensure their flowering give them plenty of light, and do not fall into an error, which is unfortunately too common, viz., that of starving these plants. A drop of manure water at times will be found to be a great help, as will also surfacing the pots with some dried cow manure, and the syringe should be freely used during the summer time. The best flowerers are *Cereus McDonaldia*, creamy-white; *C. triangularis*, the same in colour and one of the largest; *C. grandiflorus*; *C. hamatus*, cream-coloured; *C. Schrankii*, rose; and *C. pterogonus*, a dwarf climber, with white flowers, the purest white amongst the Cactus tribe. Next come the *Phyllocacti*, all of which do well in a greenhouse temperature. They may be trained on a trellis or in pots, with wires or sticks, but I find sticks best, as the iron rusts and injures the roots. They like a rough but strong soil, and plenty of water when growing, but when they have made their growth they should be well exposed to light and air. The best sort are *P. crenatus*, white; *P. Ackermannii*, deep red; *P. Edwardsi*, rose; *P. phyllanthoides*, rose; and *P. nitens*, cream coloured. In this section there are many hybrids, but I have not seen anything to equal the *Cereus speciosissimus*, which ought to be placed amongst *Phyllocacti*. At Sudbury House we have many hybrids, but the raisers have aimed only at producing large flowers without symmetry. To the more rigid forms of Cacti, *Cereus validus*, a kind with flowers of a pale rose colour, is a grand addition, and possesses a most delicate scent. All the kinds of *Echinopsis* have good flowers, and they are plants which can be grown very easily. *Echinocactus Ottonis*, yellow; *E. mammillosus*, white; and *E. bicolor*, rose and purple, are gems only requiring to be seen to be admired. "Cacti are more curious than beautiful," says one; "What freaks of Nature these are!" says another, alluding to the plants in the Succulent House at Kew; but, for my part, I think all Cacti beautiful. I am acquainted with several who grow all of these plants, and I know from experience that they derive as much pleasure from them as do other amateurs from collections of other kinds of plants. When Mr. Fish asks if I have no facts to offer as to the momentary glory or luminosity in the Queen of the Night, he touches a cord, which leads me to say, "Yes." But will people believe them to be facts? Well, never mind. I have noticed the emanations to which he alludes in the *Cereus triangularis* and *hamatus* especially many times; so have I also in some Orchids and Rhododendrons. Luminosity is most apparent in the more delicate tints, such as white, pale, rose, and yellow; and it is most vivid when the flowers are fully expanded.

J. CROUCHER.

Sudbury House, Hammersmith.

## NOTES FROM KEW.

**Hardy Shrubs and Herbaceous Plants.**—The more genial weather that has prevailed since the last notes were written, the less intense night frosts and the increasing power of the sun which the lengthening days of April bring with them, have, notwithstanding a modicum of east winds, had a favourable effect upon shrubberies and out-door plants generally. The Lilacs and other well-known shrubs are rapidly putting forth their leaves, while the yellow flowers of *Berberis* or *Mahonia Aquifolium*, and the *Forsythias*; the brilliant crimson or reddish-pink of the Ribes, and, above all, the orange-coloured flowers of *Berberis Darwini* are striking indications of the rapid approach of spring. Prominent also among the shrubs or dwarf trees is the purple *Magollia* (*Magollia purpurea*), a deciduous plant of Japan, with fragrant flowers, the inner segments of which are white, while the outer are tinged with purple. This is not a handsome plant in itself; its deciduous character makes it less valued as an effective shrub than many of its fellow species, who retain their glossy leaves throughout the year, and whose flowers are far more handsome. In some parts of the gardens the Larch trees are just now very beautiful with their soft, dull crimson female catkins, and the delicate green of the young leaves. Amongst herbaceous plants that are now pushing their way through the ground and developing their flowers, in some cases before their leaves, *Anemone pennina* claims notice. It is a pretty little plant of Southern Europe, and has become naturalized in a few localities in Britain. The flowers are numerous, of a light bluish colour with a slight tinge of lilac. *A. Hudsoniana*, a North American species ranging from Hudson's Bay to the Western declivities of the Rocky Mountains, as well as in several other parts, has small flowers varying in colour from white, purple, deep red or yellow. The Kew plant is a splendid deep crimson, and is most attractive at a time when showy out-door flowers are scarce. *Hepatica acutiloba* is also a North American ranunculaceous plant, growing in woods and on the sides of hills and mountains. The leaves are cordate, with from three to five entire, acute lobes, and the flowers are small and white. The whole plant is used in medicine in its native country. *Sinapis arvensis*, an Algerian crucifer, in a neighbouring bed, is producing in abundance its yellow flowers, the general appearance of which is so characteristic of plants of this great family. A charming little Wallflower is *Cheiranthus mutabilis*; the flowers are borne on an erect stalk about 6 in. high, and in colour and general appearance much resemble the purple Candytuft. A very pretty dwarf roseaceous shrub is *Spiraea Thunbergii*. It is a native of Java and Japan, and grows to a height of from 3 ft. to 6 ft. The Kew specimen is of a much smaller size. The leaves are narrow and pointed at both ends, sharply toothed towards the apex. The little white flowers are plentifully produced, and the whole plant has some general similarity to a *Deutzia*. An interesting plant is *Potentilla* alb., with its thread-like procumbent stems, and its oblong leaflets in fives on the lower leaves, and threes on the upper; its pedicels are axillary and terminal, and the flowers, as its specific name indicates, are white. The plant is a native of Middle and Southern Europe and the Caucasus, and has been recorded, but with doubt, as having been found in Wales. Amongst the *Boraginaceæ* two plants attract our notice: the first, *Lithospermum orientale*, has ascending stems branching out at the base and spreading over the ground. This gives the plant a very ragged appearance, and were it not for the small, golden yellow, star-like flowers, it would have little to recommend it. The flowers are prettily arranged in leafy, terminal clusters. The other plant referred to is *Anchusa sempervirens*, the evergreen Alkanet, a well-known inhabitant of waste ground in many parts of England, but, though well known, none the less beautiful, or even less suitable to occupy a place in the garden; for its salver-shaped beautiful blue flowers make it an attractive plant at this time of the year.

**Greenhouse Plants.**—In the beds and on the shelves of the Winter Garden many interesting plants are already in flower. An Australian proteaceous plant (*Hakea acicularis*) attracts notice from its irregular or twisted perianth, the tube of which is curved under the limb. This is a character of the *Hakeas*, which, added to the flowers being borne in sessile, axillary clusters, as in the species under consideration, and the silky pubescence of the pedicels, together with the rigid foliage, make these plants striking objects in collections; this species is found in New South Wales, Victoria, and Tasmania, and grows to the size of a tall shrub or small, bushy tree. Another shrub or small tree, native of the same colonies as the preceding, is *Pomaderris elliptica*, belonging to the Order *Rhamnaceæ*; the leaves are elliptical, smooth on the upper surface but clothed on the under side with a very short white tomentum. The flowers, which are cream-coloured, are borne in umbellate clusters. A very fine plant of the well-known *Sparmannia africana* is growing in the Winter Garden; it is thickly clothed with its large, heart-shaped leaves, and, for the foliage only, is a noble plant. The white, long-stalked flowers, with the golden filaments tipped with purple

anthers, make this plant a valuable one where there is sufficient room for it to grow to any size. *Myrsine africana* is a low, much-branched shrub, bearing copious, globose, sessile clusters of small red flowers in the axils of the leaves. It is a native of the mountains of Abyssinia and the country of the Nile, and is found also at the Cape. *Fuchsia procumbens*, as its specific name indicates, is a prostrate plant; it is a native of New Zealand, in the damp forests of the Northern Island, and in Middle Island on the Canterbury Plains. It has very small, broadly-ovate, or almost rounded leaves, and axillary, solitary flowers set on long, slender drooping peduncles.

**Stove Plants.**—*Aesclepias curassavica* is flowering freely in the new range. It is a very pretty Swallow-wort, native of the West Indies and Tropical America. The bright orange-red flowers are both attractive and singular; the five petals are bent down towards the stalks, and within the petals are five peculiar cup or boat-shaped processes, which form the corona; from each of these is a curved projection, within which are the five stamens; the filaments unite into a tube, at the summit of which are five anthers adhering to the stigma. The plant is called *Ipecacuanha* in the West Indies, in consequence of the roots being used by the natives as an emetic. Two very beautiful species of *Scilla* are *S. cupaniensis* and *S. natalensis* var. *sordida*. The flowers spike in the first-named species is about 1 ft. high, and the flowers are arranged in a cluster at top. The second has a long, slender, erect spike of about 1½ ft., upon which the delicately-formed and splendid pale blue flowers are arranged alternately along the sides spirally with mathematical precision. *Pelargonium lobatum* is worth cultivating for the sake of its peculiar little flowers, the petals of which are blackish, with a slight metallic lustre edged with yellowish-white, the anthers standing up in the centre of the flower against the dark background.—†.

## DEGENERATION OF DOUBLE CINERARIAS.

In the spring of 1875 I purchased from a leading London nurseryman half-a-dozen named varieties of double *Cinerarias*, which had been propagated by him by means of cuttings taken from the best and most distinct and fully double of a batch of seedlings raised from the seed sent out, I think, by Messrs. Hasage & Schmidt, of Erfurt, in the previous year. Of this half-dozen varieties only one, named *King Alfonso*, was really double or worth anything, the others having all reverted and already degenerated into either inferior single or worthless and irregular semi-double flowers. The one variety above named, however, was a really good double flower, resembling a fine purple double Groundsell (for which flowers, indeed, the first batch of cut blooms of these double *Cinerarias* were actually mistaken by the London nurseryman to whom they were sent by the Erfurt firm before he had read their accompanying and explanatory letter). This variety I continued to propagate by cuttings in the autumns of 1875 and 1876 with perfect success; the young plants flowering the following spring, and remaining fully double, were much admired. I therefore imagined that in this variety, at least, I had a perfectly constant double *Cineraria*, and last autumn again got half-a-dozen healthy cuttings off the old plants, which had been cut down after blooming. When, however, these came into flower in my greenhouse this spring I found, to my great disappointment, that the degeneration was after all only a question of time, and that *King Alfonso* was no better than his fellows, as on all the half-dozen plants there was not a single fully double flower. It is therefore, to my mind at least, pretty evident that those who want double *Cinerarias* must grow them each year from seed, out of which, if carefully saved, they may always expect a certain varying proportion of double-flowered varieties, but the perpetuation of these from year to year cannot be depended upon with any certainty whatever. W. E. G.

**Fraxinea magnifica** as **Small Plants.**—Frequently the *Fraxineas*, when grown at all, are found in the shape of old straggling plants, and although they flower freely under these conditions, they are much more beautiful when seen in the shape of vigorous young plants full of bloom. In the large conservatory at Pine-apple Nursery there is now a number of plants of several new seedling kinds grown in 4-in. pots. They are about 6 in. high, and each bears eight or ten large purple blossoms or buds. The foliage is large and healthy, rendering the plants very effective.

**Cyanophyllum magnificum.**—This beautiful decorative stove plant is not generally found in such good condition as it might be. It is very subject to mealy bug, and its leaves often become dry and torn and the beauty of the plant spoiled. In Messrs. Low's nursery, at Clapton, there is just now the finest display of plants of this *Cyanophyllum* we have ever seen. They are growing in small pots in a moist, warm temperature, and appear to grow as rapidly as a common *Fuchsia*.

## NOTES OF THE WEEK.

**Prizes for Asparagus.**—With a view to improve and extend the culture of Asparagus throughout the United Kingdom, it is proposed to give a series of annual prizes, extending over a period of seven years. These prizes will be given in London, Edinburgh, Dublin, and the north and west of England in consecutive years. They are given with the object of having thoroughly tested in all parts of the country the plan adopted near Paris of planting wide apart, and without much expensive preparation. This system may be carried out in the smallest gardens, in fields, or fruit gardens, without the considerable preliminary expense and preparation usually considered necessary for the formation of Asparagus beds. The competitors will, however, be free to adopt whatever plan of culture they may think most suitable to their soil and locality. It is, however, wholly impossible to produce Asparagus of the first quality by the crowded system of planting in use in private gardens throughout the United Kingdom, and there is reason to believe that much rich manure given before planting is not only needless, but injurious. In the Paris system little or no manure is given at the time of planting. The plants—one-year seedlings—are planted in shallow trenches 3 ft. apart in the line, and the lines about 4 ft. apart. There is no loss of space under this system, as a light crop is taken off the ground between the lines when the plants are young. In free, loamy soils of fair quality many excellent growers make no preparation of the ground before planting. In England the plantings may be best done in April and in May, according to locality. Manure is not usually given till the plants are established, and then only over the roots. Asparagus is also grown as single plants, and also in single rows. As large single plants it is often grown in the Vineyards, or here and there among small fruits, or in any open spots of ground. In these cases the plants are often several yards apart, or sometimes quite isolated. Equally suitable places are offered by our squares of ground occupied with small fruits, not to speak of many other positions. In single rows is also a good way, the plants in this case being 3 ft. apart. With a view to give sufficient time to all who would like to compete, the first series of prizes will be given three years from the present planting season, and will be continued annually till 1887. The prizes will be given under the auspices of the horticultural society in each locality named. In the sixth and seventh years of the series, viz., in 1886 and 1887, the competition will be held in London, and will be open to American, French, Dutch, and all other Continental growers in addition to those in Britain. The prizes at each annual competition will be as follows: For the best hundred heads, first prize, 5 guineas; second, 4 guineas; third, 3 guineas; fourth, 2 guineas; fifth, 1 guinea. Extra special prizes will be added, open to all comers, in the international year's competition. A full and well-illustrated account of the mode of culture these prizes are designed to encourage, with particulars as to places of meeting, dates, &c., is in preparation for gratuitous distribution, and will be duly announced in the horticultural and agricultural journals. The essential thing to be done now is the planting, which may be pursued during the present month in the south of England, and in May in the north. The prizes are offered by Mr. W. Robinson. The judges will be appointed by the horticultural authorities of the respective shows. Each competitor will be requested to state in a form, which will be furnished to him, the nature of the soil and sub-soil, age of the plantation, and other conditions under which his Asparagus is produced. Each competition will be open to growers in any part of the United Kingdom.

**The Yellow Dog's-tooth Violet.**—This pretty plant, common in America, is now flowering in our correspondent's ("Oxon") garden at Henley-on-Thames. It is very seldom seen in flower in this country, though there would seem no reason why it should not be plentiful. It was one of the plants that was almost annihilated during the height of the bedding mania, and probably very few sound roots have been since introduced.

**General Index to "The Garden."**—In reply to several correspondents who suggest the desirability of having a general index to all the volumes of THE GARDEN already published, we may state that we propose to publish a general index to THE GARDEN at the end of each twenty volumes—at the end of the last volume for 1880, and on the completion of every subsequent twenty volumes. Considering the very full weekly and half-yearly indexes which we now publish, anything further would be unnecessary and confusing. The half-yearly indexes of the first twelve volumes are all in print, and if bound up together would supply the place of a general index.

**Lecturing and Music at Kensington.**—The sounds of loud voices and loud music are no addition to the attractions of the conservatory of the Royal Horticultural Society's garden at Kensington—certainly not in the case of those who go there to see any

new or rare plants, and who may desire to speak to their friends about them. The council room is the place where new and rare plants are seen to best advantage, so long as the noises above referred to are generated in the conservatory. It is a great mistake to allow the distractions of either music or talking to exist where people wish to have undivided attention for the plants. There is no reason why they should not be elsewhere in the same garden.

**Blandfordia grandiflora.**—This is flowering with me. Has it ever blossomed in England? I have been told it has not.—MAX LEICHTLIN, Baden-Baden.

**Moss Roses in Covent Garden.**—Trusses of blossoms and partly-expanded buds of the Moss Rose may now be seen in the central avenue of Covent Garden. It is evident that these have not been produced in the open air, a fact which suggests that these most beautiful of Roses might be had in abundance at this season by growing large plants of this Rose in tubs or pots placed in an orchard house or similar structure. Their treatment merely consists in keeping their weak growths thinned out yearly, and in occasionally removing some of the old stems. They are easily increased by means of layers or division.

**Dendrobium luteolum.**—Messrs. Low & Co., of Clapton, have now a fine display of this desirable Orchid in their nurseries. It is a plant of easy culture, light and graceful habit, and for two or three months in succession yields an abundance of delicate sulphur-coloured unique blossoms. When fully expanded its flowers last in a cool temperature for several weeks. Wherever Orchids are grown at all this Dendrobium should find a prominent place.

**Rhododendrons at Chelsea.**—In Messrs. Veitch's nursery there are just now several of the tender Rhododendrons in full flower, and which make a striking display. Among them *Henriana* is bearing a profusion of large bell-shaped blossoms of the purest white, delicately spotted in the throat with yellow; *Countess of Haddington*, delicate blush; and the ivory-white *Jasminiflora*, still one of the best in its class, is laden with sweet-scented blossoms.

**The National Rose Society.**—The schedules of the coming shows of this Society, to be held at the Crystal Palace on June 29, and at Old Trafford, Manchester, on July 6, have come to hand, and, as far as we can judge, the prizes and other arrangements are in every way satisfactory; it may therefore reasonably be hoped that this year the finest displays of Roses ever witnessed will reward the labours of this Society.

**Gentiana verna in Pots.**—The blue *Lobelia* and many of the *Campanulas* are often grown in pots for decorative purposes, but none of them are so beautiful as the hardy *Gentian*. If grown well in a cold frame near the glass, and in good, rich, sandy loam, this *Gentian* may be made to form pretty little tufts of bright blue blossoms in spring, and would supply a colour of which there is at this time of year a scarcity. We lately saw some grown in pots in one or two of the principal London nurseries.

**Rudaea macrophylla.**—A quantity of plants of this now make a good display in the Pine-awlet Nursery, St. John's Wood. They are grown with single stems 8 in. or 9 in. long, furnished with glossy green, Magnolia-like leaves, and surrounded by large clusters of white, woolly blossoms. In a bud state the flowers resemble those of the Orange, but when expanded they are in shape like those of a *Stephanotis*, but of course much smaller. This plant, which is sometimes seen under the name of *Psychotria leucantha*, is old but by no means common, and is one which should be grown extensively where good flowering plants are in request. It requires an intermediate temperature, liberal culture, and it never fails to yield large masses of blossoms, which last for many weeks in perfect condition.

**Hybrid Daffodils.**—The collection of hybrid Daffodils shown by the Rev. J. G. Nelson, of Norwich, at South Kensington on Tuesday last, showed forcibly what excellent results, in the way of effect, may be gained in our gardens by planting varieties of even the commonest of hardy flowers. The blossoms of many of the kinds shown were equal to many of the choicest Orchids, and some of them were so large and pure as to form no mean rival to the handsome *Encharis amazonica*. Their colours varied from the purest white and the most delicate cream colour to the brightest golden-yellow; and in size and form they were in every respect perfect. Such kinds as these, besides being the most valuable subjects for planting in masses on borders, or in isolated clumps on lawns and bare places, are well worthy of being planted or otherwise cultivated in the cool conservatory. Brought into bloom early, their blossoms would probably be even more delicate than when produced naturally in the open ground, and they are much more worthy of having attention and trouble bestowed upon them than many of the common *Narcissi* generally used for pot culture.

## GARDEN DESTROYERS.

## CATS v. MICE IN GARDENS.

SOME of your correspondents appear to be in a state of considerable perplexity as regards mice and their depredations, at which I am but little surprised. Nature has ordained that we should be plagued by mice, but she has likewise provided us with a remedy in the shape of a cat. I should like to know what offence cats have been guilty of that they are put on one side by the gardening world, and their places filled by more or less clumsy contrivances which our little enemies are much in the habit of treating with contemptuous indifference. Let those who may be overrun with mice cast traps on one side and put the case into the hands of cats, and they will never have occasion to repent of misplaced confidence. No garden should be without its cat, one or more in proportion to its size. These cats should be accustomed to travel about the whole establishment. It is, however, a common practice to keep cats out of the houses or frames. This is wrong, and occurs often under the mistaken notion that they will cause some damage, which, however, will never occur if they are not driven or frightened. I have often been amused to see the delicate care with which a cat will tend its way amongst plants, never so much as disturbing a pot. Some may say, this is all very well, but cats do not always go where they are most needed, and before they get scent of the mice the damage is accomplished. My answer is, make them go where they are required, which can be easily done in the following manner:—Always keep in stock a red herring or two, and wherever it is suspected that the enemy is at work, strewn a few small pieces about in the evening. Repeat this two or three nights in succession and there will be no more mice thereabout for some time, as the cats in searching for the herring (which will invariably attract them the first night) will be sure to catch them. Many have doubtless noticed one peculiarity as to the depredations of mice, and that is, whatever they attack they persistently return to and make an end of it before touching anything else. It is sometimes in vain to bait traps in the most tempting manner, or place poisoned baits in their path. They will often completely ignore all such inducements, and return again and again in the most exasperating manner to the one thing of which they have thoroughly got a taste. It was a case of this kind which first induced me to try the herring cure. A pit of Strawberries was attacked, and although every means was tried in the way of trapping and poisoning it was of no avail. As a last resource the frames were left partly open, and the pit strewn with small pieces of herring, and in two or three nights the mice had entirely disappeared. In this case I had to depend upon neighbours' cats, but it was a lesson by which I so profited, that I have never since needed to set traps to any extent. Whether it be Peas or Cress beds, or Strawberry plantations, they may be entrusted in this way to the care of the cat; and by persistently following out this system, the plague of mice will be reduced to a minimum.

By/lect.

J. CORNHILL.

## SPARROWS IN AMERICA.

SPARROWS, since their introduction into America, have, it seems, been petted and fed regularly by the authorities in the cities and large towns, under the impression that when they increased in numbers they would keep down the legions of caterpillars and canker-worms that infest the trees in the public parks. It is, however, reported that the caterpillars and larvae are left to multiply on the trees untouched by the Sparrows, and that they are as busy amongst the buds of fruit trees and in Wheat fields as in the old country. They are also said to drive away all the native song-birds, such as the Baltimore and Orchard Orioles, Blue-birds, Purple Martins, and Cat-birds. Mr. Allen, one of the most celebrated of American ornithologists, states "that the rapid increase of the Sparrows in America will soon call for legislative action to hold them in check, and that the introduced Sparrow is to a greater degree gregarious than most of our own species of the same family, and subsists only upon an insect diet exceptionally. With their known predilection for the buds of fruit trees and for ripening grain—to say nothing of other depredations they are known to commit, respecting which we have testimony from the Old World as well as at home—have we not burdened ourselves with a tenfold worse pest than the caterpillars prove to be? The Sparrows are hence a needless and deleterious addition to our fauna it may be no easy task to eradicate. Instead of being pampered and protected, they should be, if not at once expelled, at least left to take their chances in the struggle for existence without the advantage of the shelter and food they now find so abundantly for them by unwise human foresight." It may be remembered that, in one of the back numbers of THE GARDEN, I

mentioned that the introduction of the Sparrow into America would turn out to be a great mistake, and they are now finding this out.

Welbeck.

WILLIAM TILLEY.

**Destroying Slugs.**—In the gardens of which I have charge I am happy to say slugs are scarce, but with a neighbour they are just the reverse, and it is a hard matter to keep them down, though many reputed remedies for them have been tried. Lime has been used abundantly, and at the most favourable times. Leaf traps have been laid for them, and I have seen as many as two gallons collected in this way; notwithstanding this, however, they are as plentiful as ever. Salt is another remedy which has been tried. After a square of ground is cleared of the Cabbage tribe a good dressing of salt is given just before it is dug, with the view of destroying the eggs under the surface. In the gardens under my care last autumn I had all vacant ground dressed with a heavy coating of the best lime which I could get; it was turned in with the spade as hot as it could be used. The lime was employed in preference to manure, with a double object in view, i.e., destruction of all insects with which it came in contact, and the prevention of clubbing. This last is my greatest enemy, and the best remedy which I have found for it is trenching, and I hope also to derive great benefit from the lime.—A. J. SAUNDERS *Bookham Lodge, Cobham.*

—There are gardens and gardens. No doubt the "duck on 'r" might suit the rough-and-ready style adopted by some, but would hardly suit those who have borders of choice Alpines, perennials, &c. From considerable experience I can testify to the efficacy of Mr. Harpur Crewe's remedy, given in THE GARDEN (see p. 350), viz., bran traps. The plan adopted by me is this: Pieces of glass about 4 in. square are set at intervals of about 10 ft.; every afternoon a pinch of fresh bran is placed on each. A tin bowl, containing a little water with a handful of salt in it, is taken round about ten o'clock, and the slugs are just swept off into the bowl. The process is very simple, and about fifty traps can be cleared easily in half-an-hour. It is very important that the traps should remain in the same position, as those slugs that arrive after the nightly visit are sure to be early the next one. On a favourable evening the average will be from ten to twenty on each trap. If the traps are not going to be visited, they should, without fail, be set, as our enemies are then enticed from their more natural food, and our favourites are spared. Mr. Harpur Crewe is right about the backache, but this plan reduces that to a minimum. It is well to use only a small quantity of bran, as the birds are rather apt to scatter it during the day. The traps, if judiciously placed, are not unsightly.—A. K., *Eastcott Cottage, Pinner.*

—I have been sadly troubled with slugs, and lime, soot, and ashes were for a long time my only remedy. Now I use Kennet salt, which I find to be both a good manure and a complete cure for slugs. It answers well for Onions, and Carrots and Parsley are very much benefited by using it as a top-dressing. It is also a deadly enemy to wireworm.—D. LAMOND, *Arthursstone, N.B.*

**Popular Remedies for Snake Bites and Scorpion Stings in the East.**—There are a number of plants growing in Greece and other parts of the Levant which, owing to their bearing more or less resemblance in form or colour to a snake or scorpion, are in accordance with the ancient doctrine of signatures which still obtains amongst the common people, supposed to be remedies for their bites. They are called by the modern Greeks *phidhrostanta*, *phidhokhrita*, or *phidhorice*, that is to say, snake plant or snake root. Most of the snakes in Greece are harmless, the only ones whose bite may lead to fatal results being the *amodytis* and a kind of viper known as the *ekhidna*. Amongst those plants which are known to have the greatest efficacy in cases of snake bites are the *Solanum melongena* or ordinary Aubergine, *Heliotropium hirsutum* and *supinum*, *Scorpiurus elnata* (the beautiful Scorpionides or Scorpion plant of Dioscorides), and *Arum Draconculas* (the *Drakonotum* of Hippocrates). The leaves and fruits of these plants are made into a poultice and applied to the wound. Whenever these plants are found anywhere in a decaying state they give off an odour resembling that of putrid meat, which is perceptible at a great distance. The *Arum Draconculas*, whose stem is spotted like the skin of a snake, is also used both as a remedy and as a preservative against snake bites.—X. LANDEER, *Athens.*

**The Elder Bush Cure for Gooseberry Caterpillars.**—Some years ago I became acquainted with a simple plan of keeping the Gooseberry caterpillar at a respectful distance, namely, that of planting here and there amongst them a bush of the common Elder. I was at first sceptical, and waited until I watched the result for three years, during which time there was not in the garden, under my observation, any caterpillars, while in others roundabout, minus the Elder bushes, they abounded.—T. SMITH, *Wexley.*

## THE FLOWER GARDEN.

## ROSES ON PALINGS.

ONE of the prettiest and most useful purposes to which the Rose can be turned as a climbing plant is to cover palings or iron fences. The accompanying illustration represents a portion of a long fence in the Waltham Cross Nurseries, formed of common deal lathes, which, otherwise bare and cheerless, is made attractive and beautiful by a covering of Roses, which, when well-grown and judiciously encouraged by careful pruning, gracefully entwine themselves in and out the pales. The varieties best adapted for this purpose are to be found amongst the Noisettes, Hybrid Chinas, and Tea-scented classes, together with some few of the Bourbons. If the exposure be northerly or the fence high, many of the Boursault, Ayrshire, and Evergreen Roses will be found very suitable. The following list embraces all shades of colour, and will give a succession of flowers throughout the summer and autumn:—*Noisettes*—

Roses on Palings.

Celine Forestier, yellow; Fallenberg, crimson; Aimée Vibert, white; La Biche, flesh; Reve d'Or, coppery-yellow; Bouquet d'Or, salmon-yellow. *Hybrid Chinas, &c.*—Blairi No. 2, blush-pink; Charles Lawson, rose; Chenedolé, bright crimson; Madame Plantier, white; Paul Ricaut, crimson; Vivid, bright red. *Tea-scented*—Gloire de Dijon, salmon; Belle de Bordeaux, pink; Belle Lyonnaise, canary-yellow; Madame Berard, salmon-yellow; Sombreuil, white; Madame Trifle, salmon. *Bourbons*—Souvenir de la Malmaison, pale flesh; Sir J. Paxton, bright rose. When pruned the plants should not be much cut back, but rather have the weak shoots removed altogether, as it is masses of flower in preference to individual fine specimens that are to be sought after.

ARTHUR W. PAUL.

**Pruning Roses.**—The method of pruning Roses usually adopted cannot be considered a good one; for, instead of the trees increasing yearly in size and vigour, they are, when established, kept nearly at

the same size. What plant is more lovely isolated on an open lawn than a spreading, naturally grown Rose? The best I ever saw had simply their heads relieved of the weakest shoots, the strong branches being allowed to grow at will. In a few years large branching heads, furnished with long garlands of blossoms, were the result.—C. S.

## ROSES AND THEIR CULTURE.\*

THIS is a little book on a well-worn subject, suitable for amateurs who are desirous of excellence in the art of Rose growing. The coloured plates are, however, not so successful as could be desired, and not equal to the letterpress. Amid the great confusion that reigns as to the distinct species of Roses, it is not surprising to find that *Rosa villosa* and *Rosa rubiginosa*, in the chapter on "leading species of Roses," are put down as separate species instead of being placed under the heading of *Rosa canina*, from which they hardly differ, excepting in their scented leaves; while *Rosa indica*, *borboniana*, and *sempervirens*, the origin of our autumn Roses, are classed as belonging to the summer-flowering *Rosa canina*, from

which they differ very greatly. The various lists of Roses towards the end of the book are most carefully compiled, and worthy of all praise, but it is to be regretted that the author's evident friendship to one eminent nurseryman should blind him to the equal excellence of Roses raised by other English growers. The old plan, too, of training Roses horizontally on wires—espalier fashion—as one would fear trees, is surely at the present day unworthy of recommendation. These slight defects once mentioned, we again repeat that the book is full of information and experience, and may be read with interest.

E. H. W.

## PLANTS FOR INTERMIXING WITH ROSES.

Roses are unsurpassed in their attractions by any flowering plants in cultivation when in bloom, but they have an uninviting appearance when their principal display for the season is over, which is not compensated for by the limited number of flowers which even the most continuous bloomers among the Hybrid Perpetuals, assisted by the Chinese and Noisette varieties, produce. This, of course, is not apparent in the case of

\* By W. D. Prior. London: George Routledge &amp; Son.

such plants as are introduced into mixed borders, where the rusty condition which their foliage assumes in the after part of summer is not so prominently noticeable as when they occupy beds or borders by themselves. But to do full justice to Roses they require such liberal applications of manure as will not agree with the majority of flowering subjects, yet much may be done to render Rose beds and borders attractive from early in spring up to the end of autumn without in any way interfering with the flowering or general well-being of the Roses.

**Appropriate Flowers for Planting amongst Roses.**—In the selection of such plants as are adapted for this purpose it is necessary to consider not only the habit and form of the subjects chosen generally, but it is of equal importance that they are such as either possess an immunity from the principal insects with which Roses are so much infested, or that are easily kept clear from their depredations.

**Perennials Suitable for Mixing with Roses.**—In beds of Roses where the plants were pegged down I have found nothing more effective than the common White Lily (*L. candidum*), and the different varieties of *L. canadense*, three or four bulbs planted together in the openings between the Roses. They are equally suitable for using in this way amongst half or full-sized standards, but when associated with these the Roses should not be planted very close, or the Lilies are liable to be in the way of anyone moving amongst them for the purpose of attending to their requirements. To follow these, Gladioli are in every way adapted, as to the time they will come into flower, succeeding, as they do, both the Roses themselves and the Lilies, should they be used as well, and like them, their erect, non-spreading habit of growth, and the ease with which green fly can be destroyed by syringing should it get from the Roses to them, adapts them well for growing in this way. Gladioli for the purpose should now be planted; the Lilies when the tops have died down. Single plants of *Campanula pyramidalis*, at intervals in the spaces between the rows of Roses, are also very effective. These should be raised from seeds sown in May out-of-doors in the open ground, and grown on through the summer; they should then be taken up, potted singly, wintered in frames, and planted out amongst the Roses in May.

**Annals for Mixing with Roses.**—The best of these that I have found adapted for the purpose are Ten-week Stocks, sown about the middle of April, and again at the end of the month, grown on three or four plants together for a time, in 4-in. or 5-in. pots, and then planted out without disturbing their roots. The rich condition of the soil necessary for the Roses keeps the Stocks growing and flowering longer than under ordinary treatment. French and African Marigolds are especially suitable for this purpose. They can be flowering long, grow freely, and are proof against aphides or other insects, as far as I have ever observed. These should be sown at once, a few seeds each in 5-in. pots, and planted out about the middle of May. Mignonette, either sown now in pots and afterwards transferred to the Rose beds, or sown at once where it is to remain, will, by keeping the plants thin enough, continue flowering till near autumn.

**Suitable Plants for the Margins of Rose Beds.**—For the outer edges of Rose beds, in addition to spring bulbs (Snowdrops, Crocuses, Narcissi in variety, and Scillas), Pansies, Myosotis, Violas, and Daisies, kept in the reserve ground, and now, when the Roses have been pruned and mulched, planted at suitable distances apart, will keep on making a display for a considerable time; but it is with the plants that come into flower when the bloom of the Roses begins to wane that the best results will be derived, and by employing such as I have named above, Rose beds need not have the shabby look which many so often present when the first flush of bloom is over. As will be understood from what I have said, there should be no attempt to plant so as to cover the ground, as this would interfere with the ordinary work in attending to the Roses, as well as with gathering their flowers; but enough may be done to give the ground devoted principally to Roses a cheerful appearance all through the season without much cost in either labour or material.—T. BAINES.

#### RICE-PAPER PLANTS.

SUB-TROPICAL gardening has been objected to by many because the plants used in it are of such a tender nature that they are destroyed by the first frost; or, if preserved, require much room and heat to keep them successfully during the winter. But, however, much this may apply to some, it certainly does not to *Aralia papyrifera* and Sieboldi, both plants of stately beauty and grandeur of foliage. *A. Sieboldi* is not only an excellent decorative plant for prominent positions, such as the centres of circles or as single specimens on lawns, but it is likewise a most valuable subject to use in a small state for the embellishment of room windows, halls, or staircases, where, owing to its hardy, enduring character, and the great substance of its elegantly-divided glossy leaves, it will stand for months without in the least becoming shabby or appearing to suffer in any way. As this most useful variety admits of ready increase by means of seeds, and may be raised and grown in any ordinary frame, it is a plant within the reach of all; and, if sown now, will form a good decorative subject for next winter's use, and come in capitally for planting out the following spring. There

is scarcely a shrubby border anywhere but what might be greatly improved by having a few *Aralias* interspersed among the Evergreens, where their fine bold outlines and distinct character would do much to add to the effect of any herbaceous plants growing in front. In most districts the *Aralia Sieboldi* is perfectly hardy, so that there need be no hesitation in leaving it out if the positions in which it is placed are at all sheltered and exposed well to the sun, so as to ripen and harden the growth. The variegated form of this *Aralia* is an exceedingly ornamental plant, having beautifully-marked creamy-white edges to the leaves; but, as it does not come true from seed, and can only be slowly propagated by cuttings, it is as yet unfortunately scarce and dear. Its merits, however, are such that no one who sees it will begrudge its price, as it is one of those really good plants that there is always a satisfaction in possessing. Not only is the foliage of these *Aralias* of a most pleasing form and colour, but after they attain size and strength, they annually produce fine heads of bloom; and, being laden with crystal globules they sparkle when the light shines on them like so many diamonds, and are a great attraction for bees. The best way to increase the variegated variety is to make an incision partly through the stem, and then to bind up the cut with some Sphagnum or common Moss mixed with fibry peat, which should then be kept moist to encourage the formation of roots. As soon as these have got well hold the head may be severed, which, if then potted, will soon make a handsome, well-furnished plant. Once the top is removed in this way, the old stem will break again, when all the side shoots, except one of the strongest and best situated, may be taken off with a heel, and treated as ordinary cuttings by being placed in sharp sandy soil, and kept close where they can get a gentle heat. I have tried seedlings of these several times, but, like variegated Hollies, they always come up Albino and die off; and an attempted cross has as yet led to no satisfactory result. Where sub-tropical gardening is attempted, *A. papyrifera* is almost indispensable, as it is one of the most strikingly ornamental plants that can be used either for groups or masses, or as single specimens in conspicuous places; but, as its leaves are of immense size, it should be so placed as to be out of reach of strong winds, or they get lacerated or blown about, and bruised in such a manner as to cause much disfigurement. Like all plants of similar habit and with large-spreading foliage and of quick growth, *Aralias* are gross feeders; and, in order to induce a full development and bring out their beauty, rich deep soil should be afforded, and, when the weather becomes warm, plenty of liquid manure administered—to prevent the escape of which by evaporation it is a good plan to mulch around the stems with horse or old Mushroom manure, leaf-soil, or anything of the kind that will not have an unsightly appearance. The readiest way to propagate *A. papyrifera* is to make use of all the larger portions of the roots, which may be cut up into pieces from 2 in. to 3 in. long, all of which, if buried in sandy soil and put into a hotbed, or where they can get a little warmth, will start and make fine young plants by bedding-out time if kept gently growing on. Although perhaps not so serviceable as *A. Sieboldi* for indoor decoration, on account of its woolly leaves taking up dust and being difficult to clean, *A. papyrifera* is a grand looking object in large conservatories during the winter. It is likewise useful, in smaller sizes, to stand out among others on the stages of a greenhouse. Being a native of the island of Formosa, it is much too tender to endure our winters in the open air; but, although this is the case, so tenacious of life is it that it may be stowed away almost anywhere with safety, so long as it is out of the reach of sharp frost! Any shed, therefore, will do, as the worst that can happen is the loss of a few leaves, which are soon renewed when planted out, and which grow all the stronger for the few months' rest they get when so treated. In France, where great numbers are grown, they are wintered in caves and turned out in spring, after being started and gradually inured to the light, after which they soon grow away at a great rate, and become clothed with fine foliage.

As a town plant for windows, and one that will endure almost any amount of hardship, I know of nothing better or more cheerful-looking than *A. Sieboldi*, and the wonder is it

is not grown more extensively and sold for the purpose. A sponge or brush may be quickly run over the leaves, which are then made free from dust, and have a bright, polished appearance. S. D.

OPEN-AIR VEGETATION IN MARCH, 1878.

DURING March the thermometer was fifteen times at or below the freezing point, indicating collectively 132°. The six lowest markings were on the mornings of the 9th, 15th, 26th, 27th, 28th, and 29th, when 23°, 23°, 24°, 23°, 20°, and 18° were indicated; while the six highest morning temperatures were on the 1st, 2nd, 3rd, 4th, 11th, and 21st, when 45°, 43°, 45°, 47°, 43°, and 44° were indicated. During the last twenty-three years 1252° of frost were collectively registered during the March months, the average of these months being 54°. The greatest amount of frost was during March, 1877, when 130° were registered, and the lowest was during March, 1861, when 22° only were recorded. The weather in the early part of the month was particularly fine and agreeable, and open-air work and vegetation progressed favourably; but the latter part of the month was cold and frosty, accompanied with frequent hail and snow showers, but with little or no rain. It is much feared that considerable damage will be done to the fruit crops by recent frosts, as happened last year, many trees being in blossom, owing to the previous fine weather. In my notes on open-air vegetation for February I stated that numerous plants, Alpine, herbaceous, and shrubby, were in bloom; 118 species and varieties were collected in flower on the 12th of March; but on the 31st of that month only eighty-five species could be procured, and of these many were in a miserable condition. All open-air Rhododendron flower beds, chiefly the varieties of R. Nobleanum, have been destroyed, as well as the young leaf-buds on the larger central growths of many of the finer or Sikkim sorts, which are expected to produce flowers for the following year. Of these many, which are quite black in the heart, will ultimately fall off, and the smaller side buds or growths will afterwards come forward; but the latter are never sufficiently strong to produce flower-buds, unless all superfluous shoots be removed, which is rarely done. This neglect as to disabudding is the cause of many of the Sikkim Rhododendrons originally raised from seed getting into a dense or twiggy condition, which is much against their flowering. Many trees and deciduous shrubby plants are far advanced in leaf; Roses, both pruned and unpruned, are much out up; the effects of the sun after frosty nights is telling on them, as well as on many species of Conifera, particularly the genus Pinus, the leaves of which have had a severe browning.

On the rock garden seventy-five species of plants flowered during the month, but of these many were of short duration. The most interesting were *Corbularia nivalis*, *Fritillaria avanensis*, *Iris reticulata*, *L. persica*, *Chonodoxa Forbesi*, *Paschkinia scilloides*, numerous *Scillas*, all the known varieties of *Saxifraga oppositifolia*, *Corydalis angustifolia*, *Primula*, *Epigaea repens*, *Soldanella montana*, *Hutchinsia alpina*, and *Polygala Chamæobuxus*. It is curious this year to observe the *Leucojum vernum*, *Galanthus plicatus*, and *G. nivalis*, as well as other early bulbous plants, covered with fruit evidently caused by the fine dry weather experienced while they were in bloom.

Of the forty-two plants whose time of flowering has been recorded for these last twenty-eight years, the following sixteen flowered during March:—

	1878.	1877.
<i>Bulbocodium vernum</i> . . . . .	Mar. 1	Feb. 16
<i>Arabis albidæ</i> . . . . .	" 1	Mar. 17
<i>Theris Gibraltarica</i> . . . . .	" 2	" 18

<i>Narcissus pseudo-Narcissus</i> . . . . .	" 18	" 8
<i>Hyoscyamus physaloides</i> . . . . .	" 23	" 16

**Ferdinandia emimens** as a Flowering Plant.—People have hitherto only looked upon this as a fine-foliated plant for sub-tropical bedding, but it bears very pretty flowers at this season, and has the

additional merit of blossoming in a small state, and the flowers last a long time either left on the plant or cut. Last spring I had a number of late-struck plants left when the planting was completed. As they were looked upon as surplus stock no particular care was taken of them, and they consequently remained in the small pots in which they were potted from the cutting pots. They were moved into a greenhouse in the autumn; in March they commenced flowering, and their large clusters of Daisy-like blossoms springing from the top of each plant have quite a unique appearance. It was no doubt the perfect ripening of the wood that has caused them to flower so freely.—E. HOBDAV.

**What is *Primula altaica*?**—Some years ago I bought a plant of *Primula altaica* of Mr. Wheeler, of Warminster. I have long since lost the original plant and progeny, but have had sundry seedlings from it, all of which are gone, with the exception of two plants. At one time I had a very fine seedling, which I called *altaica atropurpurea*. I have an impression that the plant I originally bought at Warminster was the true *P. altaica*, as it was so different in habit and size of flower from the ordinary *Primrose*; and you are aware that at one time all the choicest herbaceous plants were carefully hunted up by Mr. Wheeler. I do not think that the plant now sold under the name of *P. altaica* has any right to be so called. Last Saturday I called at the Warminster Nursery, and found there were still two or three plants under the old name, but they seemed to me to be much degenerated. I brought away a plant, and enclose you blooms (1) of same; also of the only seedling I have left (2), and one which appears to be a hybrid (3). You will observe that the foliage is much smaller, as well as the flowers, and that each petal has a small blotch on it. I shall be glad to have your opinion as to this being the true *P. altaica*.—JAY AYE. [Neither of the plants in question have any resemblance to the true *Primula altaica*, though they have for years been erroneously called so by horticulturalists; they are merely forms of *P. vulgaris*. The true *P. altaica* belongs to the *P. farinosa* section of the genus, and is intermediate in appearance between *P. farinosa* and *P. sibirica*. It has narrow, oblong-lanceolate, leaves, sub-entire or slightly dentate, and a many-flowered umbel of small, pinkish flowers, turning paler with age (carneo-albescens). The outer flowers of the umbel are drooping, and, so far as I am aware, it has never been introduced. It is, as the name implies, a native of the Altai Mountains, in Central Asia. I would just remark that, from the now increasingly common practice of calling the Japanese or Chinese *P. cortusoides amœna* simply *P. amœna*, there is great danger of another equal mistake developing. The true *P. amœna* (which is a native of the Caucasus) belongs to the *P. denticulata* section, and is closely allied to *P. purpurea* and the provisionally named *P. pulcherrima*.—J. BACKHOUSE, York.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Neglected Plants.**—Mr. Fish's question (p. 301) about the neglect of *Fuchsia* may be enlarged to many other plants, and particularly to the *Catalpa*, to which reference has lately been made in THE GARDEN. The *Catalpa* has grown in Gray's Inn Gardens to a large tree; and also at Sunbury, adjoining the high road, and it has always surprised me that it was not propagated and made as common as the Chestnut. I may also ask Mr. Fish why he never mixes the *Deutzia scabra* with *Fuchsia*; it grows like a Willow, and is propagated simply by sticking slips in the open ground; and every cottage garden might have it, but you seldom see the plant. The gardeners have literally shelled it, because *gracilis* is tender and needs their attention. In about 100 years it will become common!—KENSINGTON.

***Clematis indivisa* Out-of-doors.**—Mr. Alfred O. Walker, Nanty Glyn, Colwyn Bay, Conway, writes, in the "Gardeners' Chronicle," as follows:—Notwithstanding suwosters and cold winds, *Clematis indivisa* is in full bloom on the side of my house facing S.E. and unprotected. It has hundreds of flowers expanded, and I need not say is a most beautiful object. I suspect it is much harder than is generally supposed, and being evergreen and growing very rapidly, it is no exaggeration to say that it is one of the finest climbing plants ever introduced.

**Auriculas as Table Plant.**—Alpine Auriculas make charming table plants, and are worth the special attention of those amateurs who love to take a good plant into the house and change it quickly for another before damage is done by dust, fires, and gas. I was amused the other day on entering an artist's studio to find that he had fitted up a garden in a skylight by putting shelves on each side, and he put up a ladder and brought down to me some of the most delicate Alpine Auriculas, as clean and perfect as if just ready to compete against Mr. Turner's Alpines at a show. We have always a few thrifty plants that are grown in the greenhouse with *Lachenalia* and such-like expressly for the table, and they give no trouble and pay as well as any plants of their class. It is a very easy matter to raise a stock from seeds, but those named are cheap, and give the assurance of the finest qualities without the risk attending the raising of seedlings.—S. H., in "Gardeners' Magazine."

\* Read by Mr. James M'Nab before the Botanical Society of Edinburgh, March 11.

## TREES AND SHRUBS.

## THE WILD BLACK CHERRY.

(PRUNUS SEROTINA.)

My attention has been called to the capabilities of this tree for economic planting by finding it growing at various points on the New England coast, in the most exposed situations, on the poorest soil, and often within the direct influence of the salt spray. Naturally the wild Cherry extends over a wide territory; it is found from the Great Slave Lake in the north to Florida, and from the Atlantic to the Mississippi. Through all the Northern and Middle States it is a common forest tree; but, in the rich lands watered by the Ohio and its tributaries, the wild Cherry attains its largest size, and develops its best qualities; and it is still not uncommon to find in the less thickly settled portions of the west specimens 80 ft. to 100 ft. high, and from 3 ft. to 4 ft. in diameter. A slow-growing tree on the poor soils of the seaboard, the wild Cherry increases with great rapidity in the rich deep lands which it prefers. An examination of many specimens cut from trees grown in Northern Illinois and in other portions of the West shows an average annual increase of wood over  $\frac{1}{2}$  in. during the first twenty years; beyond that age the growth is naturally less rapid; but on this point I am unable, from want of sufficient material, to speak with exactness.

The wood of the wild Cherry is comparatively light, the specific gravity of the dry wood being but .454, while that of Black Walnut equally dry is .539 (the average of two specimens), or 18 per cent. heavier. It is close grained, compact, and not liable to warp. Of a dull, light red tint, which deepens with age, it in time almost rivals the best mahogany in colour. For these qualities, and because it works easily and advantageously, the wood of the wild Cherry is highly valued by the cabinet maker. It is also now largely used for interior finish; and it is the only American wood employed in making what is known as "ebonized" work, that is, furniture dyed black in imitation of ebony. Cherry is still considered the best wood for window sashes. The application of wild Cherry to the finish of expensive interiors is of but recent date, and promises a large demand for this wood, while for cabinet-making the annual consumption is rapidly and steadily increasing, although still far behind the more popular Black Walnut, which, in spite of its sombre colour, still supplies the material for fully three-quarters of all the hardwood furniture made in the United States. The following table of the actual prices in the Boston market of the principal American woods employed in cabinet-making will show the comparative estimation in which they are held, and will furnish an intimation of the probable supply of first-class material for this purpose:—

	£	s.	d.
Black Walnut	15	12	6 per 1000 ft.
White Oak	13	10	0
Cherry	12	10	0
Butternut	10	8	4
White Ash	8	6	8
Sugar Maple	8	6	8

The wood of the wild Cherry when dry burns well, without snapping, but it is soon consumed, and, from its lightness, is inferior to nearly all American hard-woods commonly employed as fuel. In heat-giving qualities, Hickory, the American standard, is 84 per cent. its superior. The amount of ash left after wild Cherry is burned is remarkably small, being only eighteen hundredths of 1 per cent. of the weight of the dry wood consumed.

The facility with which young plants of this tree are raised from seed, the ease with which they may be transplanted, their hardiness, rapid growth, and power to resist rough usage, render the wild Cherry a valuable subject for forest-planting on a large scale, while the great and increasing demand for the wood insures a certain and profitable sale for all that can be raised. In many portions of New England the wild Cherry can be successfully cultivated, and, wherever the soil is moderately deep and rich, it will be a safe and profitable tree to plant. In the Middle and Western States it will, I think, be found one of the most satisfactory and useful timber trees that can be employed in forest-planting, and, although not a native of the States beyond the Mississippi, its great hardiness and adaptability to various soils lead me to hope that the wild Cherry will succeed in the treeless regions of Kansas and Nebraska as well as the less valuable trees which have generally been planted there. The fact that the wild Cherry is the favourite home of the American tent caterpillar, which preys on its foliage, and, unchecked, finally injures its growth, is the one serious drawback to this tree. Great as this objection is, says Mr. Sargent in his "Notes on Trees and Tree Planting," it will disappear before energy and concerted action.

## A NEW JAPANESE TREE.

(PTEROSTYRAX HISPIDUM.)

WE have the rare pleasure of introducing to our readers figures of the fruit and flowers of a new shrub or low tree of the highest value for our gardens. They are shown life-size in our illustration, as sent to us from Mr. Luscomb's richly stored gardens in Devonshire. They fall in graceful clusters of creamy-white, and have a delicate and grateful odour. The leaf outlined on our plate is also life-size, and shows that the foliage—at least that of young plants—is large and handsome. The fruit sent to us by the Rev. H. N. Ellacombe from his garden at Bitton

Fruit of *Pterostyrax hispidum*.

has been drawn by Mr. Hyde. Mr. Ellacombe states that with him the plant is perfectly hardy, and that it grows rapidly, making long shoots each year.

## CAMELLIAS IN JAPAN.

HAVING read in THE GARDEN some remarks on "Camellias in the Open Air," I thought that it might interest your readers if something was said respecting Camellias in Japan. I therefore put some questions to my son-in-law, who resided for ten years, as an engineer, in Japan, and he has answered them as follows:—I have seen Camellias in a wild state in the south of Japan from 31° lat. to 35° lat., and at about 1180 ft. above the level of the sea. At Ikouno (35° lat.) they withstand, in winter, about 13° Centigrade below the freezing point. The climate there is very damp in summer and very dry in winter, and the ground where they grow is generally covered in winter with from 13 in. to 4 ft. and even 5 ft. of snow. In summer the heat does not exceed 34° Centigrade above the freezing point in the shade. These Camellias are generally single, but some are semi-double, red, white, and shaded. They grow in shaded parts of the woods around Ikouno, Province of Tasma (where I resided), amongst other trees and shrubs. They do not grow very tall in the woods just named, but at Nagasaki, Province of Satsuma, I have seen a wood planted with Camellias, the stems of which were 1½ ft. in diameter and about 26 ft. in height. They are also cultivated in the open air as far as 40° lat. north. I

A New Japanese Tree (*Pterocarya hispidum*). Flowers creamy white.

have seen them at Kouhota, Province of Aquita, on the west coast, near the sea, which is frozen there every winter from fifteen days to a month, the temperature, of course, falling as low as 15° Centigrade below zero, and they receive no artificial shelter; but there the snow covers the ground nearly the whole winter. The *Sasanqua* is the hardiest, and blooms before the others. The ordinary *Camellia* begins to bloom about the beginning of January, according to the latitude. The maximum cold is from Jan. 15 to the end of February. Those in the shade are not at all affected by the cold. I have seen, at Ikouno, the expanded flowers covered with snow in the morning before sunrise, and the snow melt under the influence of the sun, without affecting the flowers. But in open situations the cold makes the petals drop when the flowers are half expanded. It is in the Isle of Kiusiu that *Camellias* are most numerous.

*Lijons.*

### FENCES FOR PUBLIC PARKS.

In the matter of fences for public parks and recreation grounds what should be aimed at is—first, durability; secondly, utility; and, thirdly, appearance. If possible, however, these three qualities should be combined. Among the different kinds of fences which we see in use are—post and rail, post and chain, close and open palings, ornamental wood, and wire fencing in great variety—some with wooden posts, others with iron standards set in wood blocks or concrete—some, from their peculiar shape, simply put into the ground and tightly rammed—some with the wires free, and others in which the wires are fixed to the standards with wedges. Then we have many kinds of iron fencing—some on low walls, others fixed in stone—continuous rod and bar fencing, iron hurdles, and, lastly, walls ornamental or otherwise. All these have separate uses—some adapted for one position, some for others. As must be patent to everyone who will give the subject close attention, it is useless to erect a fence in a place to which the general public has access, either for its lightness or its ornamentation. Such fences are sure to be destroyed within a very short period, and are a continuous source of expense and annoyance. Durability and utility, therefore, demand primary consideration, and, as it is doubtless difficult to choose a fencing possessing these qualities, a short description of the different kinds in use may in some degree assist those who are unacquainted with the matter.

Commencing with the simplest form, viz., post and rail or chain fencing, I may state at once that the only quality requisite in this case is that the posts should, if of wood, be perfectly sound, *i.e.*, free from shakes or sap. They should be 3 ft. or 3 ft. 6 in. above ground, and at least 2 ft. 6 in. or deeper in the ground, in proportion as the soil is solid or otherwise; and they should also be well rammed, kept in an upright position, and placed at from 10 ft. to 15 ft. apart. The iron rails must not be less than 1 in. square, and they should be sufficiently long to reach three posts, *i.e.*, two spaces of 10 ft. or 15 ft. They should be run through the posts about 6 in. from the top, holes having been previously made for that purpose, or they may be fixed in grooves on the top and fastened with iron straps. If chains be used, they must be either carried through the holes or placed on the top of the posts, where they should be wedged or fixed with staples or T-pieces. The use of such fences is to prevent riding or driving over turf, and also as a protection at the margin of rivers, lakes, ditches, or other dangerous places. This, or similar fencing, made entirely of wood, is also used to protect newly-planted trees both in open spaces and private parks. The next kind which we have to consider is what may generally be termed wood fencing, of which there are many varieties, some plain, cheap, and durable; others elaborate and expensive. Let us take first closed fences and open fences, made of cleft Oak palings, and sawn posts and rails. These consist of posts, and two, three, or four rails morticed into them, according to the height which it is necessary the fence should be. To the rails are nailed the upright palings, and it will be found that what are called patent rose-headed nails are the most suitable for this purpose. Nails are sometimes galvanised to prevent oxidation, but this, in my opinion, is a

mistake, inasmuch as they draw easily, whereas those not so treated retain their hold much more surely. It is true, the oxidation in some instances causes the wood to become stained, especially when not well seasoned, but the advantage gained by the firmer hold more than compensates for this in public parks, where fences are so liable to get damaged. This kind of fencing is much used as boundaries for private parks, for dividing cottage gardens, and for similar purposes. The open palings are generally employed for protection to plantations; they are materially strengthened by having a band of hoop-iron nailed along the uprights staves parallel with the rails. These fences, when made of thoroughly seasoned materials, are very durable, and the cost moderate. Wood fencing of an ornamental kind is generally open, consisting of a top-rail, sometimes protected with iron work. Examples of this kind of fencing may be seen in Regent's Park and elsewhere. Ornamental fences are also used for the front gardens of villas, &c., but for such purposes they are not so suitable as iron.

We now come to wire fencing, which, except for boundary or outer fences, is suitable for almost every position in the park or pleasure ground, whether public or private. Such fences are light, handsome, durable, erected with facility, can be made of any reasonable height, close enough to keep out cattle, &c., and, last, though not least, are remarkably cheap. Wire, like wood, fences are made of various forms, but there are qualities in some kinds which render them preferable to others. The stability of a fence, and the facility with which the wires can be loosened, in order to allow cartage of materials, &c., when necessary should never be overlooked. In this particular some have the advantage of others. As before mentioned, some fences have their standards fixed in wood blocks or concrete, others simply in the soil well rammed; and here again I maintain there is a great advantage, as any ordinary labourer can repair, refix, and put in an upright position any posts or standards which may have become deranged. It must be evident that when the wires are wedged in the standards or these latter are fixed in concrete, the matter is not so easy. It must not be supposed because the standards of some fences are simply put into the ground that they are not so stable as others; the peculiar shape renders them very firm indeed. Wire fences are, as a rule similar to wooden ones in regard to one point; that is, they consist of standards having holes for the wire strand to pass through. At one end a retaining pillar with stays is solidly fixed; at the other it is what is termed a winding pillar, provided with pins for winding the wire up tightly. These pins should be so made that the work of tightening or loosening may be done with dispatch. The length of wire between two straining posts will depend upon the straight or curved character of the fencing. When the curves are very sharp it is necessary to fix stays to the standards, as additional support against the strain. Where gates are required it will be found necessary to fix suitable posts. When standards are fixed in concrete the character of lightness is often carried too far for the sake of appearance, necessitating the wedging of at least two wires in a fence 3 ft. 6 in. in height. This, I do not hesitate to say, is a great disadvantage, rendering the fence difficult and troublesome to repair, and forming a rigid and impassable fence, so far as wheel traffic is concerned. The inconvenience of this will be better understood when I state that 600 ft. or more are sometimes strained in one length, and it must always be borne in mind that fences in public parks are subject to heavy strains and rough usage, being therefore very liable to damage. These fences can be made from 1 ft. to 8 ft. in height, or even more, and the only further remark I need make respecting them is that I think they are worthy of the consideration of those in whom the control of public parks and similar institutions is vested. Another kind of fencing about which little need be said is what is named continuous rod and bar fencing. It is easily fixed, and consists of standards with forked feet, which are driven into the ground at regular intervals, every fourth or fifth being stronger than the intermediate ones. These standards are bored to receive the bars; the top one is usually made round and in various lengths, the ends of which are placed in a thimble fixed in the stronger standards and pinned. The thimbles are made sufficiently long to take the ends of two bars. The flat bars below are simply lapped end on end and

wedged. I would never recommend this kind of fencing for public parks or similar places, as it soon gets out of order if submitted to pressure.

Another and most important kind of fencing, one which I would strongly recommend to the notice of those who have the care of public or private parks, and, indeed, all similar places, is iron hurdles. I cannot too strongly recommend these where a rigid and most durable fence is required; one which an ordinary labourer can fix and remove. I know of few fences more suitable for many positions, such as to encircle plantations, as protection for outer belts of trees and shrubs planted at the margin of parks, round trees in exposed situations, &c. They are not very ornamental, but, as regards durability and utility, they will hold their own against any others; they will bear any amount of rough usage, are easily repaired, and, if coated over occasionally with black varnish, have a very fair appearance. Iron hurdles are usually 6 ft. in length, have three standards and five round bars. The two end standards have forked feet, and the centre one pointed. Care should be taken to have the bars strongly riveted, as the stability of the fence will very much depend upon this. The end standards are bored for small bolts, so that when fixed they really form a continuous fence. The hurdles should be made very strong, and capable of bearing great pressure.

We now come to another kind of fencing more varied, perhaps, than any of the preceding; I allude to iron fencing. This is made in a most simple, and also in a most elaborate, way, and the cost is in proportion. This kind of fencing is usually adopted for boundaries of parks, private residences, &c., and is fixed in various ways, viz., on low walls, on stone bases or in concrete, and level with the ground. It is usually put up in panels and fixed in the stone with metal. These fences are intended to be thoroughly protective, and should therefore be made very strong. High strong stays should be added on the inner side to each standard, and ornament should not be added at the expense of strength. In exposed situations the ornamental portions are sure to become damaged. Where light ornament is needed it should consist of wrought iron, and in no instance of cast. Some idea may be formed of what a strong fence should be by noticing the one opposite the Temple on the Thames Embankment, at Buckingham Palace, and in Park Lane. Examples of light fencing are frequent enough, and do not need description.

As to walls, they are not very desirable features in landscape gardening, but they may be necessary in some situations, as, for example, to hide very objectionable objects, and they should in all cases be clothed with Ivy or other climbing plants; thus treated, they are much improved in appearance. Walls may be either plain or ornamental, and should harmonise with surrounding objects.

There are many places, also, where either high or low live fences may be desirable, such as Thujas, Euonymus, Box, Privets, Quicks, &c., and when neatly kept, these are very ornamental. All fences have their particular uses, but I think it will be found that some are far more suitable for public parks than others. To recapitulate, we want durability and usefulness, combined with as much ornament as is consistent with the surroundings. One word with respect to gates. Whether at the entrances or within the park, they should always be made with due regard to strength, especially as respects locks and bolts. As a rule, this is very much neglected; and, assuming the gates to be well and strongly made in other respects, it depends entirely upon these to render them perfect for the purpose for which they are intended. When gates are very heavy, they should run on a rail to prevent wearing.

Southwark Park.

CHARLES DENNIS.

**Rhododendron occidentalis** and **Pickeringia montana**.—These are two of the most beautiful flowering shrubs of California, and are found on the summits of the low hills to the north of the bay of Monterey, generally among other shrubbery, but in the shade. The *Rhododendron* is deciduous, the latter evergreen; the former bearing large masses of sweet-scented white flowers, which are often shaded with yellow, and rarely with pink; growing in rather dry ground, it sends down large deep roots, which supply it with abundant moisture, though blooming in a rainless summer. It sends

up numerous shoots from a knotty root crown, and from its appearance would seem to be hard to transplant. My experience, however, is to the contrary; for, after hacking a plant to pieces with an axe, I managed to get a few stems, each with a piece of the crown and a stray rootlet, and after being carried two days on horseback, they were potted in old cans; now, a year afterwards, they have filled their cans with a mass of fine roots, and having just shed their leaves, show a fine lot of buds for next year. The *Pickeringia* blooms similarly to *Swainsonia*, but the flowers are much brighter and the racemes longer. I believe it blooms six months in the year, and where it does well is very handsome, often growing 8 ft. high; its leaflets are about the size of those of the *Clinanthus*, and are glaucous-green; the stem is beset with thorns, and if the plant would submit to trimming, would make a fine hedge. I have been able to find but three seeds (says a writer in the "Gardeners' Monthly") in several years' experience with the plant, though as its immense truncate roots seem to sprout freely wherever they are exposed, I presume it might be propagated by the root.

### A LEAF FORK.

The fork shown in the annexed engraving is made of tough Ash, with ten teeth, 3 ft. long, and slightly turned up. The head into which the butts of the teeth are inserted is 30 in. long. A light cross bar of tough wood is fastened to the teeth, about 8 in. from the head, by

means of copper wire and a screw to each finger. A handle is provided and fixed in its proper place, being flattened somewhat to keep it from turning in the hand. The handle should be braced by two strong wires. With such a fork leaves may be loaded very easily and rapidly.—"American Agriculturist."

**Larix Knapferri**.—Is this species hardy? A plant I had last year perished though in a good dry position. Have any of the plants of it distributed formed good specimens near London?—J. B. [This may be said to be hardy under ordinary circumstances, although it often loses its leading shoots through growing on too late in autumn. It is of very slow growth when young; even when in permanent quarters, and in favourable situations it makes only moderate progress. There are no large specimens of it in this country, and even young fair-sized plants of it from 10 ft. to 15 ft. high are scarce. A warm, dry, sunny site should be selected for it if possible.—G.]

**Shrubs for the Sea-shore**.—I live on the west coast of the county of Ayr, and my experience enables me to state that I would plant, next to Sea Buckthorn and Australian Pines, common Hollies; then evergreen Oak, Arbutus, Noble or Sweet Bay, and the finer evergreens, Pines, &c., all of which will live and thrive, notwithstanding the salt in the air, if they have only protection from the wind. The evergreen Oak (on a dry soil) grows with us into a splendid tree, and should be planted more extensively than it is in England. The *Araracia*, *Taxus*, and *Cypress* tribe will not form specimens without shelter from the wind, although 20° degrees of cold do no harm whatever.—D. M. J., in "Field."

**Arbutus tomentosa**.—Two plants of one of the *Arbutus* family—a species not common in private collections in this country, so far as I know—are now in good bloom in the Glasnevin Botanic Gardens. *Arbutus tomentosa*, or the hairy *Arbutus*, is the shrub to which I invite attention as well worthy of addition to collections of ornamental evergreens. The first description which I read of it is in the volume of Curtis' "Botanical Magazine" for the year 1834, where a coloured plate of it is given, t. 3320. There we are told that the plant was found at the mouth of the Columbia River, and was noticed by Mr. D. Douglas growing in different rocky places, extending from San Francisco in the south of California to Puget Sound in the north. It first flowered in Great Britain in the Glasgow Botanic Gardens, in December, 1833, in a conservatory. One of the plants mentioned above as now in bloom at Glasnevin has been for several years against a wall in the experimental enclosure, and the other is in the open ground in the bed with other kinds of the same group; and both are many feet high. The shrub has copious foliage and abundant small bunches of white flowers, in size and shape like those of many well-known Heaths; and it seems to be as hardy as others of the *Arbutus* family familiar to us in Ireland. Why its culture has been so much neglected in this country I can understand, by knowing that a like fate has befallen many other lovely ornaments.—J. ADAIR, in "Gardeners' Record."

## PLATE CXXIV.

## ANNUAL ASTERS.

(WITH COLOURED FIGURES OF TASSELLED VARIETIES)

Drawn by F. N. FITCH.

SEEDSMEN offer under the term *Victoria*, *Pæony*-flowered, *Crown*-flowered or *Cocardeau*, *Chrysanthemum*, *Bouquet*, *Emperor*, *Porcupine*, and *Quilled*, some two dozen kinds of these *Asters*, that are largely increased in each case by several diversities of colour, so that a complete collection of all the kinds offered by any one Continental grower would probably comprise some 200 or more forms or hues of colour. So much variety is bewildering rather than otherwise, inasmuch as it is scarcely possible to select the best kinds at a guess, or to grow all in a circumscribed space. There are several distinctive methods by which the *Aster* may be classed, such as comparative height, habit, character of flower, suitability for exhibition, for pot culture, or for bedding. Tall *Asters* comprise the fine *Pæony*-flowered, the tall *Chrysanthemum*, the *Emperor*, the tall *Victoria*, the *Quilled*, and a few others. Kinds of medium height are found in the dwarfer forms of the *Victoria*, the *Cocardeau*, the *Rose*, and the *Porcupine*; the dwarf forms comprise the short *Chrysanthemums*, the dwarf *Pyramidal*, and specially the dwarf *Bouquet*, which is one of the most beautiful of all for pot culture. The best bedding kinds are found in the medium-growing *Victorias*, the *Rose*, and the dwarf *Chrysanthemum*, as these vary from 9 in. to 12 in. in height, and form good bunches of blooms on each plant, and collectively fine masses of colour. The dwarf *Bouquet* kinds, whilst specially good for pot culture, are also valuable as edgings to beds of taller kinds. For pot culture for exhibition the best are the medium-growing *Victorias*, as these, if of a good strain, possess unequalled quality, and present handsome and even heads of bloom. The distinctive forms, as found in these flowers, are those in request for exhibition purposes, as it is the custom in schedules to invite exhibits under the heads of *Incurved*, *Reflexed*, and *Quilled* flowers, or in some cases it is expressed as *flat-petalled* and *quilled*, and in others as *French* and *German*, the *French* including the *flat-petalled* kinds and the *German* the *Quilled*. These latter distinctions are, however, too arbitrary, and are giving place to those previously named being more easily comprehended. The best examples of the incurved flowers are found in what is popularly known as *Truffaut's Pæony*-flowered *Asters*, formerly esteemed a grand exhibition strain, but which has given way, to some extent, to the more even and massive *Victoria*. An incurved flower shows all the tips of the petals converging inwards, as is seen in a *Chrysanthemum*, and the more solid and rotund the form of the flower, the better its prospect on an exhibition stand. All of these have flat petals, and, as a rule, have broader petals than any other kinds have. Examples of these are seen in the two flowers on the left in the accompanying illustration; not flowers drawn to order, or painted as florists think they ought to be, but as they really are, truthful to Nature, and showing no attempt to improve upon it. The grand bloom seen in the centre of the plate is a true type of the *Reflexed* or, as it is sometimes termed, *Tasseled* flower. This is further an exact type of the best forms of the *Victoria Aster*, which, regarded as a show kind, or for general decorative purposes, is perhaps the best of all *Asters*, and one that will give to all who grow it entire satisfaction. The two *Asters* depicted to the right are very good representations of the *Giant Emperor* kinds, which are, to some extent, intermediate between the *Pæony*-flowered and the *Victoria*, as some of the blooms are partially incurved. Other *Reflexed* kinds are the *Chrysanthemum* and the *Rose*. Good exhibition blooms of these kinds should have full centres, size, bright and varied colours, and a compact, dense body of evenly-laid petals. Where, as is sometimes the case, twenty-four varieties of *flat-petalled Asters* are scheduled, it is neither possible nor desirable to find all the twenty-four kinds exactly as typified in the centre flower. Variety is essential, and this can only be had by the introduction of some flowers of the incurved form. This, however, serves farther to show in striking contrast the relative beauties of the distinct forms of flowers. The most complete examples of solidity and perfection of form

are found in the *Quilled* varieties, as these would appear to be made rather than grown. Though not more than half the size of the *flat-petalled* kinds, they present a mass of *quilled* petals most evenly set, and in outline almost semicircular. One is almost inclined to believe that such perfection of evenness could only be obtained by artificial means. It is, however, but the result of that constant care in seed selection which is ever the aim of the grower, who prides himself in putting before the public things that are of the finest kind, and of the most meritorious quality. The *Cocardeau*, or *Crown*-flowered, *Asters* are partly *flat-petalled* and partly *quilled*, the outer margin of the petals being of a dark red or blue, and the centre disc of pure white. These are grown more for their novelty than as presenting special decorative features. This bi-coloured form is, however, also found in some of the finest show-*quilled* kinds, rendering them both valuable and attractive. The charming *Bouquet Asters* are also of a semi-*quilled* character, the petals being stiff and closely set. The blooms are of medium size and very compact, and most acceptable for nosegays. For this latter purpose, however, those who grow the *Victoria* forms will find that the later blooms that start out from the main stems are admirable, the clear bright hues and excellent forms being exceedingly effective however employed.

*Asters* usually bloom through the months of August and September, and are therefore most fittingly described as autumn flowers. The date of blooming can with some degree of accuracy be secured by the time of sowing the seed, which should range from the end of March to the end of April, as may be desirable. Classed as a tender annual, although in reality fairly hardy in the autumn, it is necessary to sow the seeds under glass, and if a gentle warmth can be given to assist the germination of such as may be imperfectly matured or are rather aged, so much the better. Sown in pots, pans, or shallow boxes, in fine sandy soil, in any frame or cool house, at any time in the month of April, good seed should germinate freely; and it is most necessary, to ensure a robust blooming plant, that the young seedlings should be pricked out into a frame or other sheltered place as early as it is safe to do so, that the plants may get strong and stout before being placed in their blooming quarters. *Asters* like rich soil; they are, in fact, like the *Balsam*, gross feeders, and prefer both manure and moisture. A rich soil induces robust leafage and rapid root action, and when so excited, the flower-stalk is not so soon developed. If properly treated, the *Aster* should always be well established in its positions before the upward direction of the stem of the plant is developed. *Asters* make fine bedding masses, and admirably succeed some of the late spring-flowering plants that bloom freely until midsummer. When too late for ordinary bedding plants a good body of *Asters* removed with balls of soil from the bed where first pricked into and well soaked with water soon makes a fine mass of colour, and such a brilliant and varied display of bloom is produced as scarcely any other bedding plant can give. Although it is a common rule to write of some kinds as best adapted for pot culture, yet it is by no means a good plan to give to any pot culture, as the *Aster* lifts even when in full bloom better, perhaps, than any other annual. Given the size of pot to be filled, and three or six plants may be lifted from the open ground with small balls of soil and be packed in as close as possible together in the pot, the soil fixed firmly around them; let the plants stand for a short time in a shady place, and not a bloom will hang its head or a plant flag, and once established these will continue fresh and beautiful for several weeks. Six good plants with some five or six expanded flowers on each, packed into a 10-in. pot, form grand bunches for the verandah or corridor, or, indeed, for any situation where not too much exposed to heat or wind; whilst from nine to twelve plants of the beautiful *Bouquet Aster* may be planted thickly in pans or vases. These latter, grown in any fashion, are so very neat and effective that no garden should be without them in the late summer months. The cultivation of the *Aster* for exhibition purposes renders more than average care and attention necessary. The soil should be deeply and heavily manured, the plants strong, robust, and free from all aphid or other insects, water freely during the hot months of July and August, and especially at the blooming time if drought prevails. The plants should be placed in lines at sufficient width apart to enable the required attention

NEW TASSELLED ASTERS

in the shape of watering, mulching, tying up to sticks, thinning, shading, &c., to be given. Each stem should have its separate support, as it is of the first importance to keep the blooms from damaging each other. The centre bloom should at all times be removed, as this is invariably coarse, and a strong plant not allowed to carry more than five flowers; four perhaps would be better. A week before the blooms are required for show temporary shades made of card, linen, or similar material, should be placed over the blooms, as the desired purity and freshness of colour depends much upon the exclusion of the sun's rays or heavy rains for several days before the time of cutting. Asters may be set up on green painted, sloping boxes in lines of three or four deep, as may be desired. Nest, circular pieces of white paper—sometimes these have ornamental edgings—should be used to back up each bloom, as these undoubtedly lend a certain air of elegance and refinement to the group of flowers. Exhibition blooms should show good size, fine form, full centres, solidity of petals, and variety of colour. The saving of good seed by home growers is not a matter of difficulty; indeed, it is not that Continental growers excel us in quality but in quantity, as it is too frequently the case that we get heavy rains just about the blooming time. As the massive double flowers absorb much moisture, it is difficult during dull weather to expel this until too late to save the flower from rot or decay. Seed that will reproduce blooms of the finest quality may be saved here, and, indeed, is saved, as all our finest Quilled Asters are the products of home-saved seed. Experience has shown that, because of the lesser quantity of petal with which the Quilled Aster is loaded, the seed is much more freely produced by them than with the Victorias or other fine flat-petalled strains. The blooms should be thinned, and seed saved from the best flowers only, and should not be cut until the seeds are showing signs of ripeness; then laid out to fully dry on sheets of paper. They may soon be cleaned out, and the seed extracted and stored. Asters, as a rule, sport but little, this element being most found in the bicoloured flowers.

A. D.

[The blooms from which the annexed plate was prepared were supplied by Messrs. Saltmarsh & Son, of Cheltenham.]

**The Patent Perpetual Mouse-trap.**—Allow me to direct Mr. Fish's attention (see p. 278), as well as that of other readers of THE GARDEN, to this excellent mouse-trap. The bait, which may be a Pea or Bean, a bit of meat, or, what is possibly best of all, a bit of toasted cheese, is temptingly fixed to a peg in full view; this is approached by a kind of bridge or inclined plane, balanced at the centre, and as the mouse passes over it it tips up and encloses him. This circumstance naturally somewhat alarms him, and he feels indisposed to partake of the bait for which he has risked so much, and at the same time finds that he cannot possibly retrace his steps; but he perceives an aperture to the left, and through this he quickly passes and finds himself in a somewhat commodious compartment, from which, however, unfortunately for him, there are no means of exit whatever. In passing into this compartment, too, it is so arranged that he must necessarily tip up the inclined plane or bridge, and the trap is again set and the bait exposed to the view of his friends outside, who, envying him on account of his supposed good fortune, are by no means slow to follow him, and one after another find themselves immured in the same dismal chamber, from which only death will set them free. To make matters even worse for them cannibalism appears to flourish among their manifold vices, and, like the historical cats of Kilkenny, only the tails of some of them are to be found in the morning to tell the tale of their sad fate. Alive and dead, I have taken out as many as six at a time.—P. GRIEVE, *Culford, Bury St. Edmunds.*

HERE is a specimen from a volume just published by Hulme:—

And to himself he drew a Bramble spray,  
And in its study passed some hours away;  
Its setose stem and ternate leaves, the leaflets cuspidate,  
The prickles small, and foliage so evenly serrate,  
All seemed to point it out to be the *Rubus glandulosus*,  
And not, as he at first had thought, the *Rubus fruticosus*.

The author is very pleased with them, and considers they combine "the poetic element with the strictest analysis of the professed botanist."

## GARDEN BOTANY.

(Continued from p. 341.)

**THE FUNCTION OF THE ROOT.**—The function or office of the root in the economy of plant life is to absorb the elements which, after undergoing certain chemical changes, form the nutrient matter required for building up the plant; and as nearly all the food of plants is taken up through the roots, it follows that the elements necessary must be within their reach. This is more fully explained in the paragraphs relating to the feeding of plants. Roots also serve to attach or fix plants in the medium whence they draw their nourishment. Some few aquatic flowering plants are not fixed; amongst them our native Duckweeds (*Lemna*) and the tropical Water-weed (*Pistia stratiotes*). But these plants are almost confined to stagnant water, and therefore they move only with the wind. Sometimes the root acts not only as an organ of absorption, but it also serves as a storehouse for the assimilated food for a certain period. This may be seen in many biennial plants, such as the Carrot, Parsnip, Parsley, each of which forms a large tap-root during the first season, in which is stored a quantity of nutrient matter. Early in the following season the plant throws up its flowering stem, using for this purpose the accumulated food in the root. The tuberous roots of our native Orchids answer the same purpose. The liquid nutrient is absorbed through minute superficial cellular outgrowths, termed root-hairs, and not mainly through the spongy tissue of the root-cap, as was formerly supposed.

**ROOTLESS PLANTS.**—There are few really rootless plants, but *Aldrovanda vesiculosa*, an aquatic plant belonging to the Sundew family, and a native of the south of Europe, is entirely destitute of roots. The leaves are furnished with little bladders, which serve to float the plant, and also, it has been asserted, to entrap insects, which are dissolved and absorbed for the nutrition of the plant. This assertion cannot be received as a proven fact. Among our native plants the Utricularias, or Bladder-worts, are rootless; and *Epipogum* and *Corallorhiza*, two rare Orchids, have no true roots, though they are replaced by fleshy excrescences. The rare and minute Duckweed (*Lemna arbuscula*) is also rootless, and *Pistilotum triquetrum*, a Lycopodiacean epiphyte, is in the same condition. In these cases absorption of the nutriment must necessarily take place through some other part of the plant.

## Root-stocks.

**DEFINITION.**—We have seen that it is impossible always to separate stem formations from root formations, because we frequently have to speak of a combination of stem and root. Root-stock being a term used by gardeners, and also by many botanists in botanical descriptions, it will here be employed generically, and tubers, bulbs, rhizomes, &c., as so many species of root-stock. The term is also applicable to the perennial part of all herbaceous plants, inasmuch as it consists not only of roots, but also of the crowns or buds from which the stem or leaves spring. Root-stocks differ widely in their nature, both when in active growth and when dormant in winter; and the same kind of root-stock when growing and when not growing. It may consist of roots and crowns, the latter being reduced to the base of the stem, just sufficient to hold the roots together, as in the *Dahlia* (fig. 103), or of stem alone, as the tuber of a *Potato* (fig. 93), or of roots and stem more equally developed, as in the rhizome of *Solomon's Seal* (fig. 116). The above-ground stems of all root-stocks produce flowers only one season, and then die down, to be renewed the succeeding season. Their vegetative period is brief, as in many bulbous plants, or it may extend over two-thirds of the year, as in the underground *Artichoke*. The root-stock usually makes fresh roots, too, as well as stems, the previous ones being perennial or dying away annually. Further than this, the whole of the underground root-stock, whatever its nature, is gradually renewed and replaced by new growths, the old parts decaying and disappearing; so that no herbaceous plants are permanent in the sense that woody plants are, though they may be perennial. The principal forms of root-stock desirable to distinguish in practice are separately described, beginning with those in which the root portion predominates, and proceeding through the various modifications until we reach those which are mainly

stem formations and partly above ground, forming the connecting link between root-stocks and true stems. What may be termed the ordinary root-stock consists of crowns (buds) and fibrous, fleshy roots, and it extends itself by lateral shoots, which make a short horizontal growth, forming independent roots, and then grows erect. At the end of the season they die down almost to the roots, leaving the axillary buds of one or more of the lowermost leaves, and from these buds the ensuing year's growth proceeds.

**BIENNIAL TAP-ROOTS.**—The root-stocks of such herbaceous biennial plants as the Carrot, Parsnip, &c., have a tap-root of considerable dimensions, surmounted the first season by a crown of leaves only, or occasionally it may throw up a flowering stem the first year, but in the ordinary way a large quantity of food is stored up in the tap-root the first season, after which the leaves die; and the following spring a new tuft of leaves appears, from the centre of which the flower-stem rises, and numerous fibrils are emitted from all parts of the tap-root. As the fruit approaches maturity the substance of the root is exhausted, and it finally perishes. The root-stock of the Turnip and some varieties of Mangel Wurzel is partly above ground, differing only in this from the Carrot, &c., though some writers regard it as a tuberised stem.

**TUBERCLES.**—Tubercle is the name often applied to the tuberised branches of tuberous roots like those of the Dahlia,

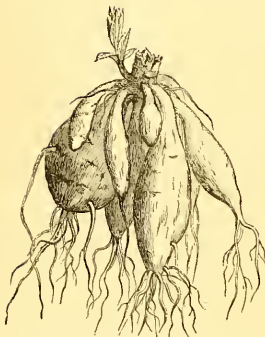

Fig. 103.—Root-stock of Dahlia with tuberised roots.

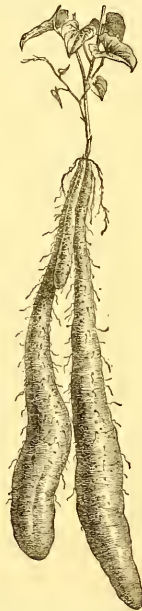

Fig. 104.—Root-stock of a Yam (*Dioscorea*), showing the tuberised branches (tuber-cles) of the root.

many of the terrestrial Orchids, &c., to distinguish them from true tubers; and perhaps no better term can be devised. The club-shaped tubercles of the Dahlia (fig. 103) are the most familiar of this kind of root-stock. New ones are formed each season, and the contents of the previous year's tubercles more or less used up in the spring growth of the stems, the remainder decaying. It will be seen that not all the roots become tuberised; and fibrous rootlets proceed from the base and other parts of the surface of the tubercles. The roots of some species of Dahlia, though fleshy, are not at all tuberised. In the Yam (fig. 104) the tubercles are exceedingly long, often 3 ft. or 4 ft., and

the fibrils are scattered, not principally collected at their lower extremities. The root-stocks of our native species of *Ophrys* and *Orchis* have two, variously shaped, tuberised roots. In some species they are lobed and somewhat hand-shaped, and are termed palmate, and in others they are spherical. These tubercles are of annual duration; and when the plant is in flower, the one from which the flower-spike proceeds has already begun to shrivel, whilst the other is plump and smooth. This is the new tubercle from which the next year's flower-spike will rise. It is an offset growth with a bud at its apex which grows out the season following that during which it is produced, and in due course it gives birth itself to a new tubercle. When growth commences in spring a number of slender roots are formed at the junction of the bud and tubercle. Tuberous roots are not uncommon both among dicotyledons and monocotyledons, but they are always easily distinguished from tubers. The root-stocks of *Pig-nuts* (*Conopodium denudatum* and *Carum Bulbocastanum*) have only one tubercle.

**CORMS OR SOLID BULBS.**—A corm is a solid expansion of the base of the stem, enclosed in a tunic or coat, differing so much as to afford characters for distinguishing species or groups of species. The *Crocus* (figs. 105 & 106) and the *Gladiolus* bulbs are

Fig. 105.—Corm of *Crocus*, with several corms in course of formation on the top, and a tuft of roots at the base.

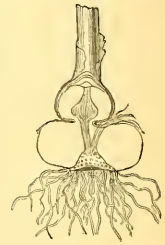

Fig. 106.—Vertical section of the lower part of a *Crocus* plant, showing the roots attached to the remains of the old corm, which is connected with the present corm, and on the latter at the base of the leaves the new corm is in course of development.

of this nature. The corm is of annual duration and throws up one or more tufts of leaves; and as many new corms are produced on the top of the old corm of a *Crocus* as there are tufts of leaves (see fig. 105). In fig. 106 we have a section of a corm bearing only one tuft of leaves. At the base is a cluster of roots issuing from the remains of the old corm; above this the present year's corm, bearing the leaves and the beginning of next year's flowering corm. The renewal or reproduction of the corm of *Gladiolus* is similar, so that each successive corm is formed on the remains of the old one, and is nearer the surface of the ground. The corm of *Colchicum* is different; it throws up a tuft of leaves in spring, and after these have decayed in autumn the flowers appear. In this case the renewal bud is lateral, near the base, and the leaves form the beginning of the new corm. Occasionally buds appear on other parts of a corm. Though the corm in itself is essentially annual and flowers only once, it is not monocarpic (once-flowering) in the sense that *Groundsel* and *Agave* are, because each successive new corm is a continuation or ramification of the same axis. It differs from a rhizome in its vertical instead of horizontal growth, and in dying off earlier at its older end, and from a tubercle in the new part being formed at the base of the flower-spike.

**BULBS.**—A variety of very differently constructed root-stocks are popularly known as bulbs. They are stem formations, and are usually produced underground, sometimes near the surface and sometimes at a depth of several inches; but some are partly above ground, or almost wholly above ground, as the *Onion*. Like corms, some bulbs are annual and flower only once, but the old bulb is replaced by a new one formed on the same axis, and therefore the axis is polycarpic (flowers more

than once). On the other hand, some bulbs themselves are of perennial duration.

**TUNICATED BULBS.**—The Hyacinth bulb (fig. 107 to 109) is a perennial bulb consisting of the concentric sheathing bases of the leaves, attached to a short discoid stem or axis, at the base of which fresh roots are annually produced. It is enclosed in membranous coats, hence this kind of bulb is called a tunicated bulb. The flower-spike is not quite central, as in the Onion, which only flowers once, but proceeds from the axil of one of the leaves. In the Hyacinth the leaves appear at the same time as the flowers, but in some other polycarpic bulbs, as *Amaryllis*, the leaves are often produced at a different season

Fig. 107.—Tunicated or coated bulb of Hyacinth, with a new bulblet near the base.

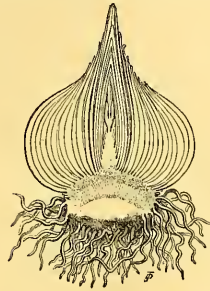

Fig. 108.—Vertical section of a Hyacinth bulb, showing the discoid stem, from the lower part of which the roots proceed, and from the upper part the closely sheathing bases of the leaves.

from the flowers. This kind of bulb reproduces itself from little buds, which are formed in the axils of some of the concentric scales or leaf-bases close to the axis. These buds are similar in appearance and structure to the parent bulb, and, in course of time, as new leaves are formed in the centre of the bulb, and the outer ones decay and the bulblet grows, it is pushed outside (as seen in fig. 107). Finally it becomes detached, and commences an independent existence. An Onion bulb does not differ materially in structure and reproduction from the Hyacinth, but it is monocarpic (flowers only once), and the flower-stem is terminal from the centre of the bulb. It flowers the second season, and in flowering the substance of

Fig. 109.—Cross section of a Hyacinth bulb, showing the concentric sheathing bases of the leaves.

the bulb is absorbed. The Tulip bulb is tunicated and of annual duration, and the scales or plates are closely applied to each other, so that the bulb is almost solid. Like the Hyacinth bulb, the Tulip has roots only from the base, but the flower-stem proceeds from the centre of the base of the bulb. When this dies down, the flowering bulb for the next season may be found on one side of its base, and within the same tunics, and also the rudiment of the second year's bulb. These bulbs flower the third season. In some species the accessory bulbs thrown out from the bases of the old ones are sessile, whilst in others they are borne on short branches.

W. B. HEMSLEY.

**Venus' Looking-glass.**—This, the *Campanula Speculum* of old authors, has been produced with double flowers. It is said to come true from seed.

## GARDENING FOR THE WEEK.

### Indoor Plant Department.

**CAMELLIAS** will now be making their growth, and must be well supplied with water at the roots and also syringed overhead freely. Many do not succeed well with these plants, which get into a yellow unhealthy condition, in which state they make little growth and few flowers, and, where such is the case, although they will bear a deal of bad treatment without dying outright, it is a somewhat difficult matter to bring them round. One of the principal causes of this state of things is often attributable to their receiving an insufficiency of water, especially a whilst making their growth. At no season, however, will the *Camellia* bear getting too dry, the large amount of leaf surface which the plant possesses causing the moisture to evaporate with great rapidity. Moisture must be applied through the roots, which, if in too dry a condition, fail to perform the work required of them. It is not advisable to pot *Camellias* at the present season, unless they are suffering seriously for want of root-room. Moving them now is sure to interfere more or less with their flowering. If it be absolutely necessary, avoid as much as possible interference with the roots. In potting, whether the soil used be loam or peat, add as much sand as will keep it from becoming sour, especially as it will be necessary to ram the new soil so to make it as close as the existing ball of the plant, otherwise the water afterwards given will escape through the new soil. Whilst making growth shade is indispensable. Attend carefully to plants that are intended for summer flowering. Large *Fuchsias* should be supplied with a stout central stake to support them, and the shoots should be stopped, so far as is required, to furnish the plants and give them when in flower a dense well-furnished appearance. If in small pots the application of weak liquid manure once a week will assist them, but for these plants it must not be overdone, or it may have an effect of causing both the advancing flowers and leaves to fall off. Young *Fuchsias* that have been struck during the autumn and winter should be moved into their flowering pots. These plants will succeed the larger ones in blooming. *Petunias* should be kept stopped so as to make them bushy. These are useful for summer flowering, as they bloom for a length of time after flowers are scarce. *Azaleas* now in flower will require shading from the sun; and this is also the case with *Cinerarias*, *Amaryllids*, *Acacias*, *Cytisus racemosus*, *Hotenias*, *Deutzias*, and other similar plants. If aphides make their appearance, fumigate at once. Amongst a general collection of plants this requires constant attention. Slight and frequent fumigations are much the best, but if two or three gallons of Tobacco water be kept at hand in a vessel, so that any small plants that are affected can be dipped, and larger ones syringed, a considerable saving of both labour and material in fumigation will be effected, and the disagreeable smell of the Tobacco be avoided. Where means exist for forcing flowers in winter provision should at once be made to have the necessary plants coming on for the purpose. *Epacris*, *Acacia Drummondii*, *Cycloclonus*, *Genistas*, *Abutilons*, *Bouvardias*, *Polypodiums*, *Coronillas*, *Mycas*, *Convolvulus*, and the sweet scented *Daphne indica*, if encouraged to make their growth early in the summer, and their wood is well ripened in the autumn, can, with little heat, be brought into flower through the winter. If mildew happens to exist on the ripe wood of last year, it will most likely attack the young growth as soon as the plants begin to move. This applies to such plants as *Boronia pinata*, *Hederaea tulipiferum*, and *Leschenaultia hiberna*. If such should occur dust with sulphur at once. *Azaleas* that have been much affected with thrips last summer would be much benefited by a good washing with Tobacco water now, as the eggs that were deposited in autumn will soon come to life under increased temperature. To such stove plants as are in active growth give water freely both at root and overhead, and keep the atmosphere moist by frequent sprinklings on all available surfaces. A little shade, when necessary, prevents scorching. Air should be given in the morning, and the house should be shut up early. Pot a few *Gesneras*, *Gloxinas*, *Achimenes*, and *Caladiums*, and place them in heat to succeed those previously started.

### Indoor Fruit Department.

**VINES.**—Insects are liable to make their appearance in Vinerias in the hot weather advances, for heat and fresh air seem to favour their development as well as that of the Vine. Red spider is frequently a very troublesome pest, and when once established it is difficult to eradicate. If it appears on the Vines at an early stage of their growth it is certain to do a great deal of harm before the wood and fruit are matured, and it is best to use every endeavour to prevent it, if possible, from gaining any footing at all. A sweet, humid atmosphere, and a consistent state of damp at the roots, assists greatly in keeping it down. Indications of its presence are shown by the leaves on the lower side becoming somewhat dingy or brown. It requires careful examination to see them where only a few exist. As their number increases delicate veins are run from vein to vein on the back of the leaf, and they are then more easily seen. Thrips is another miniature Vine pest, capable of doing a considerable amount of evil. It is larger in body than the spider, but somewhat long and very slender. The young are white, and the old black, in colour, and they fly from one place to another. Their favourite resorts are the points of young fresh-growing shoots; they eat small holes in the tender leaves, and some parts become almost transparent where they have been at work. The growth of the part which they attack is generally arrested, and this assumes an unhealthy appearance. Syringing is of some use, but to exterminate them from the house in which they are must be fumigated with Tobacco smoke for two or three evenings in succession, the house should be filled until the smoke is so dense that the hand cannot be seen at a

distance of 2 ft. from the eyes. A washing with the syringe or garden engine should be given to the leaves after the fumigation is discontinued. Mealy bug, when established, is one of the worst insects to clean from Vines. Little or nothing can be done towards its destruction while the Vines are in leaf. A look-out should be kept for it throughout the growing season, and the Vine marked, wherever it is seen, for cleansing when the Vines are pruned and dressed. The same remarks apply to young Vines in pots as well as old-established fruiting ones. None of the insects except from their intrusions, but are all generally liable to their ravages. Phylloxera vastatrix might be mentioned in addition to these enemies; but the comprehensive descriptions of it already given in THE GARDEN render more than a passing allusion to it unnecessary.

**Pines.**—Whilst insects infest the wood and leaves of many plants, the Pine is all but vermin proof. When care is taken not to place any other plant near them years may elapse before a single insect is seen upon one of them. Stove plants are sometimes set about spare corners in the Nursery, and in such cases bug and scale are not slow to change their quarters. It is very difficult to remove the bug from amongst the foliage, especially if it finds its way down about the base of the leaves. It is preferable to destroy a few plants to get rid of it, if the others are clean, rather than keep all and have the whole infested. Small suckers may be washed with a brush and soap and water, when they are taken from the plant and before they are transferred to their sucker-pots. Brown scale is an enemy common to many Pines. Its presence appears to do little or no harm, and is more inclined to attack itself at the apex than further down the leaves. It may be brushed off; and, if the plant be dipped into water heated to 130°, the scale will not survive. The white scale is more destructive than the other, and is considered the worst pest which affects the Pine. It eats the leaves, and has a very irritating influence on the plant. It multiplies fast, and spreads to every nook and corner to which it can get the slightest access in a very short time. The remedy recommended for the brown scale will do much towards keeping the white kind in check. Where this fails it is doubtful if the house will be perfectly clean until an entirely new stock is introduced.

**Peaches.**—Where Peaches have stoned the houses may be kept warmer and the moisture increased so as to push on the second swelling of the fruit; this is the period when lost time can safely be made up by extra forcing if ripe fruit is wanted by an early date. The trees should be gently syringed early in the morning and about three o'clock in the afternoon. With the sun early on the glass ventilation must be seen to in good time, or the heat will be too strong at the apex of the house and will damage the foliage. A good watering may now be given with guano water or other liquid manure, or the manure may be spread on the border and washed in by watering, which must be done thoroughly, as the want of sufficient moisture will cause the fruit to look pinched, and finally to fall off; it will also cause the fruit to gum at the second swelling, disfiguring it, and totally spoiling its appearance for dessert. In houses where the stoning process is in progress it is equally to be remembered that the trees at this period must be indulged in, and care must be taken that the number of fruits is not in excess of the capabilities of the trees to mature them thoroughly. Trees that are overtaxed this year may show it the next season by refusing to yield a crop. Early York is still one of our best early Peaches; Royal George and Noblesse, in the same house, are equally good, though later. Attention may be given to pinching and training in the young wood in early houses, overcrowding being avoided. It is not necessary to be rigidly particular in tying in early; the growth may be allowed considerable freedom for a time while the fruit is swelling, but it should be tied down before the ripening period, so that the rays of the sun upon the ripening fruit may not be obstructed. No more spray should be allowed to grow than is absolutely necessary. In unheated houses the syringe may now be freely used during all fine after-noon weather. Dishwashing requires attention, and if small colonies of black aphides should make their appearance in places, and it is not thought worth the expenditure of Tobacco to thoroughly smoke the houses, a few puffs of Pooley's Tobacco powder will be found effectual for a time; it should be applied after the trees have been syringed. Although it is not so effectual a remedy for fly as fumigation, it is the safer one while the young foliage and fruit is still tender. The set of fruit in cool houses have been remarkably rapid this season, the first anthers which burst being sufficient in each flower to fertilise the future fruit, the rest of the anthers withering immediately and not bursting at all. This we attribute to the very favourable weather. Proceed to thin the young fruit in good time, and do not waste the energies of the trees upon a mass of useless fruit grown to the size of Peas before they are thinned out.

**Melons.**—We do not wait for a full crop of fruit to set on the earliest Melon plants, but are content with two or three on a set to begin with, and when these have half swelled, more will set in abundance. It will be necessary to impregnate by hand the blossoms in the earliest house, choosing the middle of the day, when ventilation is active, though the process may be equally effective in the morning or afternoon, even when the house is saturated with steam, provided the flowers are not actually washed with water. So that there be no lack of moisture at the root, especially when the fruit is swelling, as dryness will be the sure forerunner of rot, and of badly-swelled and badly-flavoured fruit. Do not unnecessarily wet the necks of the plants at the surface of the soil, a pot split into two halves, which are inverted and placed round the stem of the plant, so that it comes through the hole of the pot, will be found a good safeguard against wet from the syringe or heavy watering. A succession should now be planted, and more plants raised from seed to fill up pits by-and-by when bedding plants have been removed.

## Flower Garden.

**Bedding Plants.**—Such sub-tropical plants as Cannas, Solanums, Wigandias, Chamapucee, and Humex elegans should be well attended to; these are free-growing subjects, and, if allowed to become pot-bound, some time must elapse before they move freely after being planted out. Golden Pyrethrum, variegated Arabia, Golden Thyme, and similar plants may with advantage be at once planted out in the places they are to occupy, if the beds are at liberty; this will be so much done when the time for a general planting out arrives, and the plants will thus be getting gradually established, and be rendered sooner effective. Where sub-tropical plants are grown, two of the best and most distinct for standing side by side, and forming an effective contrast, are *Acacia lanthana* and *Sisyrinchium*. These should be largely employed, but, even here, seasons should happen to be unfavourable for this sort of planting, these two never have the forlorn appearance that some subjects have. Nor should the old *Ricinus communis* (Castor-oil plant) be lost sight of; it is a plant which looks well in any situation where it is not too much exposed to the action of wind.

**Transplanting Evergreens.**—It will now be necessary to push forward the transplanting of these as vigorously as possible. Operate first on those that are most advanced; Hollies, Yews, and the majority of the Conifers that make their growth later, may be left till the end of the month, as the season is not an early one, and some shrubs are backward. The longer Hollies are left, provided they are transplanted before growth actually commences, the more certain they are to succeed. The thing is to catch them just as they are on the move, and before the wood buds burst; if the roots strike very rapidly, through the soil, the plants, by the growth of young wood and leaves, will be liable to rot, the state of the atmosphere should be watched, and, if possible, dull, damp weather chosen for the operation. This is the more necessary if the plants have to be carried any distance, as a dry state of the atmosphere would cause them to flag, and the tender roots would be liable to injury if allowed to get at all dry. It is of the greatest importance, therefore, that the plants should not be kept out of the ground longer than is absolutely necessary for their removal from place to place. When there are large numbers to transplant, the men engaged at the work may with advantage be divided into two gangs, the one in digging and preparing the holes, planting, watering, &c., while the others are engaged in lifting and forwarding the plants. In this way the work can be carried on rapidly, and large numbers may soon be disposed of. Before filling in see that the soil is well washed among the roots, and allow all to settle for a night or so before finally filling up with dry soil. This will prevent the moisture from escaping, and keep the roots in a much more favourable condition than if they had been entirely covered in before watering. Indeed, this is a bad practice, as the soil is sure to crack open, and let in large volumes of dry air that soon absorbs all the water that may have been given at the time of planting. To prevent this, and to keep the roots in a generally uniform state, they should receive a good mulching of half-rotten litter. The importance of this to newly-planted trees and shrubs cannot be overrated; and we would urge on all engaged in planting not by any means to neglect this very necessary precaution if they are desirous of ensuring success.

## Kitchen Garden.

Cabbages and Cauliflowers have started actively into growth; the hoe must, therefore, be kept at work amongst them, as nothing is more productive of good to vegetables than a clean and frequently-stirred surface. Make a general sowing of Cauliflower, and prick off into a warm corner or border those sown last week, as soon as they are fit to handle; and, in the event of cold or wet weather occurring, hand-lights, frame sashes, or hoops and mats may be employed for their protection. The main crop of Beet may now be sown; but in warm countries, towards the end of the month will be soon enough. It likes an open situation and trenched ground that has been manured for the previous crop. Thin Parsnips when they appear, but not finely; some growers prefer sowing early in this month, but even about London Parsnips are sown at the same time as the spring Onions, for they take a long time to germinate and they are not liable to rot. Where Chicory is held in estimation as a salad plant a sowing of the seed should now be sown in rows, 13 in. or 15 in. apart; drop a few seeds at intervals of a foot under the end of the row, and, when up, thin the plants out to one in each place. By thus giving them room enough the roots acquire double the strength which they attain when grown thickly; one good plant produced in that way will furnish as many leaves fit for use as three small ones. All the attention required afterwards through the summer is to keep the hoe going sufficiently to destroy weeds as they make their appearance. Of Chervil a little should now be sown thinly on well-prepared soil, and covered lightly. In 13 in. or 15 in. apart, and Scotchzera may all be sown towards the end of the month, in rows 14 in. apart, putting the seed in thin, and still further thinning the plants if too close when up. Through the summer keep the surface well stirred with the hoe. For mere appearance sake, to make the ground smooth, the rake is often used immediately after the hoe; but amongst culinary vegetables this need never be done, unless it is necessary to remove weeds that have got much larger than they ought to have been allowed to grow before the hoe was used. Ground rakes, when used, when not become hard and hot by dry weather and sun, lose moisture by evaporation much faster than that which is loose and open for 1 in. or 2 in. deep, a condition that also best fits it for absorbing the falling rains. By frequent surface stirrings, too, the crops get the full benefit of any manure that may have been applied, instead of helping to support, as it often does, a vigorous weed growth.

## Extracts from my Diary.

April 22.—Sowing G. F. Wilson, Veitch's Perfection, and Sutton's Giant Emerald Marrow Peas; also Carters' Mammoth and Long Pod Beans. Pricking off Asters, Poppies, Stocks, and Viola. Potting off Dahlias, Verbenas, and Heliotropes. Clearing of the stumps of green Curled Kale and other Greens. Manuring the ground and getting it dug up for other crops.

April 23.—Sowing Veitch's Autumn Giant Cauliflower; also Veitch's Autumn Self-protecting and Snow's Winter White Broccoli. Putting in cuttings of Alternantheras and Coleas. Potting on Melon plants, Capsicums, and Tomatoes. Removing bedding plants from pits to convenient places to harden. Thinning Carrots and Radishes on early borders. Renovating linings round frames. Taking the guards off Peas somewhat advanced and putting them over newly-sown ones.

April 24.—Sowing Radishes, Mustard and Cress, French Marigolds, Celosia japonica, and Cockscombs. Planting out Golden Feather Pyrethrum into rough frames. Looking over Pelargoniums and other bedding plants, and stopping them where required. Thinning out Lettuce plants and planting out the produce of an earlier sowing. Watering all the Potatoes and Carrots in frames that require it. Getting out trenches for early Celery and hoeing amongst growing crops.

April 25.—Sowing Turnips, Spinach, and Melons. Potting off Alternantheras, Coleus, and Mesembryanthemms. Looking over all Straw-

berries that are well set, and picking off all weak blossoms and deformed fruit. Earthing up Potatoes in frames. Thinning out Turnips and hoeing amongst them. Looking over Peach and Nectarine trees on walls and washing them with Quassia-chip water to kill green fly. Sticking Peas and earthing them up a little.

April 26.—Potting off a collection of Gourds, Sweet Basil, and Marjoram. Pricking off Snow's Winter White and Veitch's Autumn Self-protecting Broccoli; also Autumn Giant Cauliflower into frames. Giving all Rose trees that are infested with green fly a good washing with Quassia-

chip water. Earthing up Beans in pots. Looking over Cucumbers and Melons, picking off all false blossoms, and stopping them where required; also fumigating them in order to kill green fly.

April 27.—Potting on ridge Cucumbers and Vegetable Marrows. Looking over Vinerias and tying down shoots and thinning the Grapes where required; also tying in all young shoots in early Peach houses and Fig houses. Mowing and cleaning up the pleasure grounds and rolling down all gravel and turf that require it. Forking amongst early Potatoes and turning over manure for Celery. Thinning out Spinach and tying up Lettuce. W. G. P.

Dorset.

## A FINE DAY IN JUNE.

By T. A. AUGUIN.

A GLANCE at this pretty print convinces one of the appropriateness of the title. What a blaze of sunshine! how everything seems to swim in the burning heat! while scarcely the faintest cloud hangs near to veil the sun's intense rays. Irresistibly the mind returns to the blinding glare and clear heat experienced in the south of France in the month of June, and recalls, perhaps, many such a scene where the river, shrunken to half its winter size, slowly winds along under some rocky

bank crowned with scanty evergreen Oaks, the more distant hillsides, planted with Vines and Olives, basking in the fierce heat, which to them is so grateful. To have such a picture to gaze upon some cold, dark, winter's day is indeed a treat, and helps us to remember that "behind the cloud the sun is shining." Mons. Auguin may be complimented on so faithful a rendering of that which in England, at least, is welcomed as a prize without alloy—a summer's day in June.

E. H. W.

## THE KITCHEN GARDEN.

## LOW WINTER TEMPERATURES FOR CUCUMBERS.

THE growth of Cucumbers is now an established commercial enterprise of considerable magnitude; therefore, any change that will reduce the fuel bill, without deterioration in point of produce, will be welcomed alike by the market gardener and private grower. To the latter a few shillings more or less is comparatively unimportant when there is any object at stake,

but to the former every shilling tells when accounts come to be balanced up. Therefore, if a reduced temperature both at top and bottom answers as well or better than a high one, a point of some importance is gained. Omitting cases that might be termed exceptional, for which no hard and fast line can be laid down, the cultivation of the Cucumber might with advantage be worked on a different principle from that which is

generally adopted, but, in order to avoid misconception, it would be well to remember that experience, recommended in general terms, is not always applicable to circumstances of a purely individual character.

If Cucumbers are to be grown for a particular purpose, it is best to set about the matter by timely forethought than to have recourse to mechanical pressure. For example, the month of August is a good time to make provision for an autumn supply, September for mid-winter, and a planting in October will yield a supply for the following March. In the case of private growers, two plantings might be made, viz., one early in September for winter, and another in October for the following spring. Much, of course, depends on means at command. The autumn-grown plants should be kept quite hardy by giving plenty of ventilation, and using little fire-heat until absolutely necessary. The trellis should be completely covered, and the plants in vigorous health, with abundance of Cucumbers in various stages of growth by the end of October; and the bottom-heat would be best regulated on the same principle as that which governs the top. A confined, burning, dry bottom-heat is as bad for the roots as the same conditions

A June day.

would be for the portions above ground. A neighbour, who is an extensive grower for market, has pulled away the brick wall in front of the bottom-heat pipes in all his houses, thus allowing a free circulation of heat equal alike at top and bottom. Where the pulling away of the wall would be an eyesore, "traps," if not already there, might be put into the wall, that might be opened to allow the heat free circulation. The night temperature should range at from 60° to 70°, just giving sufficient warmth to keep the plants moving and the Cucumbers swelling slowly, and in case of boisterous weather, when heat radiates rapidly, the temperature may safely be permitted to fall to 55°, say at six in the morning. A high dry temperature harbours red spider, and a high moist one is the forerunner of blotched leaves and deformed fruit. Plenty of warmth and moisture should be given only when circumstances are favourable, thus retaining, if possible, the hardy character induced by the conditions recommended for autumn culture. A good command of heating surface is, however, always desirable. The soil in which Cucumbers succeed best, either in summer or winter, is a rich loam that has been stacked up for at least six months with alternate layers of cow manure; the latter, of course, in proportion to the quality of the loam. Add to this a liberal mixture of horse manure and rough leaf-mould; the two latter encourage the formation of roots, while the stronger elements feed them. In order to secure a good supply of Cucumbers in March there is no plan equal to planting a house in October, and in winter barely keeping them moving till the turn of the year. The night temperature will be high enough at 60°, say at ten in the evening, and it may safely be allowed to fall to 50° at six in the morning. With the turn of the year heat and moisture may be increased, and on every favourable day advantage should be taken of every ray of sunshine to raise the temperature to 85°, having the atmosphere at saturation point at the same time; a speedy return will thus be effected. It is considered sharp work in our climate to cut fruit from seedling plants raised in spring by the first or second week in April. The seeds are sown from Christmas onwards, but there is little gained by making a start before the 1st of January. The plants from which we are cutting fruit just now (April 6) were planted early in September last, and supplied Cucumbers all through the winter. The night temperature seldom exceeded 60°, and was often as low as 55°, and even 50°, at six in the morning. Eight or ten weeks ago one-half of the plants were cut in close to the main stem, as they seemed to be distressed. In a week or so they showed signs of activity, and were then hurried along with heat and moisture. They are now as green as Leeks and fruiting in bunches at every joint, while plants raised from seed last January are barely showing fruit. Not only do I think we waste heat unnecessarily in winter, but I also think plants that are in vigorous health are impaired, and in some cases ruined by it. A high temperature for Cucumbers between November and February is not required, because in reality all that is requisite is to keep the plants in motion. Real progress must take place either before November or after January; therefore by means of forethought much heat may be avoided, making allowances for individual circumstances.

W. HINDS.

#### THE FRENCH MUSHROOM TRADE.

The epicure who enjoys so much a *croûte aux champignons* does not dream of the amount of work which has been gone through in order to gratify his tastes. There are in the neighbourhood of Paris from 250 to 300 Mushroom growers, who live underground at a depth of from 60 ft. to 100 ft. below the surface. This subterranean world is reached by shafts furnished with upright ladders, up and down which the labourers are constantly passing. It is also down these shafts that the manure for the beds is thrown, and when spent it is sent up again in buckets by means of a rope and pulley. In some of the galleries the labourers can work upright, but there are others which are barely 4 ft. high. In these latter the labourer is obliged to work half doubled or on his knees, pushing his wheelbarrow full of soil or manure before him in the same posture. He also has to look after the beds and gather the Mushrooms lamp in hand, and work his way cleverly along the narrow paths between the beds, many of which are barely 8 in.

or 10 in. in width, without once straightening himself. When the beds are made, trimmed, and "soiled," the watering has to be regularly performed, no easy task when it is remembered that every drop of water has to be brought to the foot of the shaft from above, and then carried by hand along the galleries often to the distance of 600 ft. or 900 ft. The life of the Mushroom grower is really a hard one, and the Mushroom eater, while swallowing his dainty productions, rarely gives him sufficient credit for his efforts. It is not all profit either for his employer. First of all, he has to pay a heavy rent for his quarry, from £6 to £24 per month, according to its size. The cost of the manure and its transport form a large item of expenditure, and his crops very often fall through one or other of the causes detailed above. Luckily for him, the Parisian epicure is excessively fond of Mushrooms, so that, profiting by this amiable weakness, the Mushroom grower often manages to bring up and educate a large family, and yet be able to lay something by for old age. We know one Mushroom grower who owns property in Paris, but all his brethren are not so fortunate. The daily production of Mushrooms in and around Paris may be reckoned at 25,000 kilogrammes (about 25 tons), which at 1 fr. per kilogramme gives 25,000 fr. or £1000 per day, or close upon £400,000 per annum. The whole produce goes to the market, to the preserved vegetable manufacturers, or to the provinces. Formerly Mushrooms were sold in the markets in sieves or small flat baskets. M. Bourget, of the Rue de la Petite-Truanderie, agent and manufacturer of preserved provisions, was the first to introduce the system of selling them by weight. His firm uses over 200,000 kilogrammes, *i.e.*, 200 tons, of Mushrooms per annum, either for preserving or for sending into the country. His country orders for fresh Mushrooms often reach as much as half a ton per day. Growers make special arrangements with preserved vegetable manufacturers at a price all round of from 120 fr. to 125 fr. per 100 kilogrammes, *i.e.*, from about £2 to £2 10s. per cwt., the contracts being for six months or a year. In the markets they are sold by auction as they arrive. Mushrooms are sent into the provinces in baskets holding from 15 kilos. to 20 kilos. They are carefully packed in hay or straw, so as to keep them from breaking or chafing. The baskets are carried in special vans, which travel the whole distance, so that there is no need to disturb the baskets during the journey. A few figures will give an idea of the importance of the Mushroom-growing trade of Paris and its neighbourhood. M. Gérard, a grower at Houilles and the quarries near St. Denis, employs nineteen horses and fifty labourers. His daily expenses amount to 500 fr. (£20). He has 8000 metres (4 miles 160 yards' run) of Mushroom beds in his different quarries. M. Renaudot, of Méry-sur-Oise, occupies the most important Mushroom quarries of this district. He receives from Paris a vanful of manure every day, or about 300,000 kilogrammes (300 tons) per month. He has 3500 metres (a little over two miles run) of beds, and sends 18,000 kilogrammes (18 tons) of Mushrooms to the Paris markets every month. We may also mention M. Poussart, at Gouvieux, in Picardy, who employs ten horses and thirty workmen; M. Monin, at Les Moulineaux, ten horses and ten workmen; M. Brique, Paris, two horses and eight workmen; M. Moutin, Paris, ten horses and thirty workmen; M. Victor Grillet, at Vitry, has two horses and six workmen. He has 12,800 metres (about 6 miles' run) of beds in his three quarries. M.M. Gardien, at Vendôme; Busse, at Saumur; Baloché, at Caen; Dupuis, at Lille, produced large quantities for the supply of their own districts. In order not to be troubled with the details of the daily sales, the larger Mushroom growers make contracts for six months or a year with one of the agents of the markets. The agent engages to take the whole crop at from 100 fr. to 125 fr. per 100 kilogrammes (£2 to £2 10s. per hundredweight) according to the season, for the price of Mushrooms falls sensibly when the new year's vegetables begin to arrive in the market. The Mushroom grower, on his side, guarantees a certain minimum of production, and binds himself not to sell to other agents. There are in Paris fifty agents who have the monopoly of this trade, and who supply the groengrocers' shops and restaurants, the stalls in the markets, the manufacturers of preserved vegetables, and, to a certain extent, the provinces.

M. LACHAUME.

## CULTURE OF THE PARSNIP.

It may be stated generally that all edible plants grown for their underground roots alone, such as Parsnips, Carrots, Salsify, &c., do best in a deep, loose, not over rich, or at least not recently manured, soil. If manure be used at all for these crops, it should either be buried deeply, or be of such a nature that it will easily blend and mix with the soil. I have never found any disadvantage to arise from the moderate use of artificial manures, or soot, lime, salt, or any other substance of a similar nature, whose tendency it is to become quickly absorbed and distributed in the land; always, of course, supposing the land required such aids, and that is a question which must be left to individual judgment. Parsnips in garden culture are a good successional crop to autumn Cauliflowers or Broccoli, or, indeed, any crop that can be cleared off before Christmas to give time for the thorough preparation of the land. This is a matter of the greatest importance for root crops. A soil that has been deeply worked and freely exposed to the fertilising and enriching influence of the atmosphere is immeasurably superior for all root crops to ground that has lain dormant and sealed up through the winter; but it should not be worked when the surface is wet, as land, especially if of an adhesive nature, if trampled when wet takes a long time to recover its natural tone, such as the roots of plants delight to spread in. From the middle of February to the middle of March—according to season and locality—is the most suitable time to sow Parsnips, selecting a time when the soil is in good working order; for to put seeds of this kind into the land in wet weather is usually the prelude to an indifferent crop. Sow in drills 1 in. deep and 15 in. apart, and thin out the young plants to from 6 in. to 9 in. apart in the rows. The more space the plants are given, the larger the roots will grow; but large roots, except for some special purpose, are not always the best for the table; nor will they in all cases give the best result in bulk of crop according to the area of land occupied. The most useful crop is composed of regular, medium-sized roots, and these are more likely to be secured by thinning moderately. As soon as the young plants appear, run the Dutch hoe through the spaces between the rows to break up the crust; and in a few days draw a small-bladed hoe through the drills, leaving the plants in small patches 6 in. or so apart. In another week or ten days they may be singled, drawing out all weak plants. This is a better plan than singling out at the same time the hoeing is done, as removing at one operation all the shelter which near association with each other has given them sometimes checks and retards those that remain, especially if the weather be cold. Frequent stirrings of the surface soil until it is covered with the growth of the plants will be exceedingly beneficial, and cannot be overdone. The frost in our climate is not severe enough to injure Parsnips, and it is a common practice to leave them in the ground till after Christmas; but they keep equally well if taken up in November and pitted as Carrots, Beets, &c., commonly are; and it gives an opportunity for getting the land prepared for the next crop in good time. I do not know how it is, but Parsnips have never received the attention they deserve, either as a garden or field crop. They are very nutritious—more so, I think, than either Carrots or Turnips; they certainly occupy the land rather longer than the latter, but that is scarcely a disadvantage, and could easily be managed in arranging the rotations. I certainly think they would pay the small occupier who kept cows, for stock of all kinds (including poultry) eat them readily; and they do not, when given to milch cows, impart that disagreeable taste to the butter that Turnips do. They are much less subject to insects or diseases than most other crops, and seldom or never fail in producing a good crop on well-prepared land. Four pounds of seed will be sufficient for an acre; and, if labour were scarce and dear, by having the drills a few inches further apart, most of the surface stirring and clearing of the crop could be done with the horse hoe; and in field culture they fit in well, in place of Potatoes or Carrots, for a change. H.

## COMPARISON BETWEEN THE DUTCH AND ARGENTUEIL ASPARAGUS.

ACCORDING to M. Lieben, a large number of persons do not yet understand the difference between the Argentueil Asparagus and the most celebrated kinds grown in other localities, such, for instance, as the Dutch variety. The following comparative calculations will enable us to consider the matter in a clearer light than before. The trials were on thirty fine stools of each variety, all of them being of the same age (seven years), and grown side by side in the same soil, and under the same conditions of culture. In the case of the Early Argentueil variety, the first gathering was made on April 3, and the total crop produced by a stool in 42 days consisted of 29 heads, weighing 3 lb. 6 oz. The value of this quantity at the ordinary rate of the Paris market would be as nearly as possible that of half

a bundle, the whole bundle generally weighing from 6 lb. 10 oz. to over 7 lb., but of the 29 heads there were 10 small ones, 11 of medium size, and 8 large ones, which would fetch about 2s. 5d. in the market, or say 1s. 3d. for the value of the half bundle, but as the latter do not fetch so high a price as the former, this sum must be reduced to about 10d.

DUTCH ASPARAGUS.—In the case of the Dutch Asparagus, the first gathering was made on April 20, and the total crop produced by a single stool in 42 days consisted of 24 heads, weighing only a little over 1 lb. 5 oz. The value of this quantity at the ordinary rates of the Paris market would be about that of one-fifth of a bundle. The heads were not very fine, 8 being very small, 10 medium size, and 6 rather large. The ordinary price for Asparagus of this quality would be about 1s. 2s. per bundle; the value of the crop, therefore, would be only about 3d., instead of 10d., as in the case of the Early Argentueil variety. M. Lieben, wishing to carry his experiments further, made the following calculations with respect to the amount of edible matter contained in the heads of each variety. He consequently weighed about 3 lb. each of the Early Argentueil and the Dutch varieties, with the following results.—*Early Argentueil Asparagus*—Gross weight, 3 lb.; weight after trimming, 2 lb. 5½ oz.; ditto after cooking, 2 lb. 5 oz. These heads were served at table, and, after having been eaten, left 14 oz. of some edible stalk. We may therefore fix the total of eatable matter at 2 lb. 2 oz., taking the gross weight as our starting point. The heads took 12 minutes in cooking, and were tender, sweet, and savoury. *Dutch Asparagus*—Gross weight, 3 lb.; weight after trimming, 2 lb. 5 oz.; ditto after cooking, 2 lb. 4½ oz. When served at the table, these heads left 1 lb. 8½ oz. of uneatable stalk. The total amount of eatable matter in the 3 lb. of this variety was only 1 lb. 7½ oz., as against 2 lb. 2 oz. of the Argentueil sort. They also took 5 minutes longer to cook, and were somewhat stringy and very bitter. As a table vegetable the Argentueil variety is worth nearly half as much again as the Dutch kind, and, as a marketable commodity, it is worth more than three times as much, besides being so much better in flavour. In addition to this, the Dutch variety requires a richer soil and double the quantity of manure. C. W. QUIN.

**Leeks for Use in Spring.**—At this season of the year, when old Onions are getting past their best, and autumn-sown ones are scarcely fit for use, Leeks become especially valuable, and by many are preferred to Onions on account of their mild flavour. The seed should be sown at once, and as soon as the young plants are large enough they should be transplanted in shallow trenches, like Celery, two or three rows abreast, so as to allow of soil being worked amongst them. If planted on level ground deep holes should be made and the plants dropped in, with just sufficient soil to cover them, afterwards earthing them up as they grow. I find the London Flag and Ayton Castle excellent varieties for general purposes.—J. Groot, *Enhnam*.

**The Alpha Early Potato.**—I planted in large pots this early variety of American Potato in the beginning of January, and I find that it is now a good size for use, being as large as an ordinary-sized hen's egg. I put three tubers in a pot when planting them, and they were grown in a pit in which the temperature was only high enough to keep frost out. Altogether I planted from three to four dozen pots, and the same number with the early Kidney variety named Mona's Pride, but on trying the latter, the young tubers are still very small, although grown in the same pit as the Alpha. Alpha was also the earliest to ripen in the open air last year; and although not so well flavoured as the early Ashleaf Kidney, it might be of great use in crossing some of our round early varieties, so as to get early-ripening sorts with better flavour. Alpha, like all the American varieties, is a good cropper, and has a short haulm.—W. TILLERY, *Welbeck*.

**Cross-fertilisation of the Cabbage Tribe.**—I have recently experienced a remarkable example of the extreme difficulty in saving seed of the Brassica family, as mentioned by Mr. Baines in his excellent paper upon the above subject. A very pretty conical-headed plant of a Colewort was allowed to run to seed, but nothing else of the same family was known to be in flower for a distance of at least several hundred yards. The produce was saved and sown, and has been furnishing food for the table during the past winter; but what a progeny! Some were reproductions of the seed parent, but larger, and proved very handsome early Cabbages; others were very fair Coleworts; others had examples of Cotager's Purple Kale, others Green Kale, whilst others resembled sprouting Broccoli, both green and purple. One plant was an exact reproduction of the once popular Dalmatian fronds, and there were many other plants that admitted of no classification. It is probable that bees, which travel long distances, had somewhere found some sprouting Broccoli in flower, and had brought pollen from those to the Colewort plant in question.

Canflowers are not subject to these dangerous crossings, as they bloom in the summer at a time when no other members of the Brassica family do. I have saved seed of the Meroball Canflower for the past six years, and have not at any time found that the produce has in any way departed from its normal character. Where very large breadths of Broccoli, Cabbages, &c., are grown for seed, of course only one kind is grown in a locality, and even if any crossing does take place it is minimised on such a large bulk, but in the case of a single plant the danger of crossing is immensely increased.—A. D.

**Mushrooms in the New World.**—The importance of the Mushroom as an article of diet has never been properly understood

sary to interdict. Particular pains have been taken to represent the types of the edible Mushrooms of America as fully as possible in the Washington Botanical Gardens, a number of collectors having been employed for the purpose in various parts of the United States. Among these may be mentioned Professor Peck, botanist, of New York State, who, in that State alone, gathered specimens of no less than eighty species of Mushrooms, including several new to science.—Report of U. S. Commissioner of Agriculture for 1876.

**Late Celery.**—Something depends upon the kind grown; something also depends upon the time of sowing, but far more, in my opinion, depends upon the attention given from the moment the seeds are committed to the ground until the plants are earthed up. To

Jardinière in Bronze with Flowers and Fine-leaved Plants intermixed.

in the United States, nor is it generally known how abundant our supply of edible Mushrooms is. Many of those popularly supposed to be poisonous are not merely innocuous, but highly nutritious, containing, as they do, many of the elements of animal food. In France, Germany, and Italy the Mushroom forms so important a part of the food of the people, that one distinguished writer has spoken of it as "the manna of the poor." In Transylvania, the oyster Mushroom is so abundant and is so largely used, that tons of it may often be seen in the markets; and in some parts of Germany the Morel Mushroom is so popular, that the people, finding it to grow best on a soil treated with wood-ashes, were accustomed to burn down portions of the forest in order to secure favourable spots for its cultivation; a practice which the Government ultimately found it neces-

have Celery as late as possible without "bolting," the sowing should not take place before April 20, and from that time, whether sown in a frame or on a prepared bed in the open air, it should be grown without checks either from loss of roots in transplanting, or from drought through being insufficiently supplied with water. When the young plants appear thin then out by removing a few at a time, gradually giving them more room as they require it until they finally stand 2 in. apart, and then (if not already done) prepare the trenches, and before the plants rob each other too much lift them carefully and plant them in the trenches. Well water and shade them, taking the shading off in the evenings and replacing it on bright days as long as the plants need it. The planting should be done either early in the morning or late in the evening, or else during a dull day. The soil

should never be allowed to become dust dry. Celery is a marsh plant, and although it may not bolt much before its time if kept too dry, yet there are evils almost as bad as bolting, such as soft pithy stalks, which are mainly the result of checks improperly given. I have at different times grown a good many kinds—so called—but for late use I do not at present know any better than Major Clarke's Solid Red and Sutton's Sulham Pink Prize.—E. HOBDAJ.

### SUBSTITUTES FOR SPINACH.

In situations where Spinach in summer quickly runs to seed, a trustworthy substitute often saves trouble and annoyance. The Perpetual Spinach, or Spinach Beet as it is sometimes called, may always be relied upon, no matter how hot and dry the weather may be. It does not possess the peculiar sooty flavour of the true Spinach, and it is hardly so dark in colour, but otherwise it is a most wholesome vegetable, and is exceedingly prolific, and one sowing will last the year. Sow about this time in drills  $\frac{1}{2}$  in. deep and  $1\frac{1}{2}$  ft. apart. When the young plants appear, thin gradually, using the young succulent leaves, until finally they are left 8 in. or 9 in. apart in the rows, and afterwards the leaves should be gathered in the same way as Spinach. The Spinach Beet is a biennial, and will not flower till May or June of the following year. It is much sought after in some parts of the country, and used with Parsley and Thyme for stuffing salt meat. For summer use only, the New Zealand Spinach is invaluable. It is a half-hardy annual, and, to have it early, should be sown in March in a hotbed. As it does not transplant well, it will be better to sow it in small pots, two or three seeds in a pot; harden off, and plant out in a sunny spot, 3 ft. or so apart, in May, towards the latter end of the month. It may be sown in the border at once, but will not be ready for gathering so early. It is very productive. Two dozen plants will supply a large family, as, when once well established, it grows with great rapidity, especially if it can have a good soaking of manure water occasionally. It will grow on the hottest and sunniest spots, but the leaves are larger and more succulent when well fed. I do not think this plant is so tender as it has been commonly represented to be. We had it quite green here last winter till Christmas (to be sure, the season was unusually mild, but we had several degrees of frost before the bed of Spinach showed any signs of distress), and the seeds, I know, will lie in the ground all winter and grow freely the following spring, as they come up every season on the site of the old bed of the previous year. Lee's Giant Orach may be usefully employed as a substitute for Spinach. It should be sown now in good deep land, and be thinned to at least  $1\frac{1}{2}$  ft. apart. H.

**The Jerusalem Artichoke.**—At the present time many would have found it an advantage to have had a good plot of Jerusalem Artichokes in their garden, since they are now paying a high price for Potatoes, and not very good samples either. The Artichoke has before now been recommended as a partial substitute for the Potato, and, according to authorities on the subject, it is the best that has yet been proposed, because its flesh-forming and nourishing qualities generally are as nearly as possible equal to those of the Potato. Then the plant is very hardy, and, though it always well repays generous culture, it will grow and thrive in almost any soil and situation, and is not subject to any serious disease. If there be a waste piece of ground anywhere in a garden, it is usually allotted to the Jerusalem Artichoke. To some the tubers are not so palatable as the Potato, being more watery; but when properly cooked the Artichoke is an excellent vegetable, which cooks in gentlemen's establishments use only a little less often than the Potato. It is not, of course, proposed to substitute the Artichoke for the Potato; but it is a very desirable kitchen garden crop. In large and small gardens alike a piece of ground might generally be devoted to it. It might, in fact, be planted in some gardens as a hedge to protect other crops, or as dividing lines. In cottagers' allotments, which are often exposed on all sides, it might be used to afford shelter with advantage. Its culture is simple. As has been stated, it is not particular as to soil, but if the ground be deeply dug and manured, as for the Potato, all the better. February and March is the time to plant, and the sets may be planted 4 in. or 5 in. below the surface, about 1 ft. asunder, and 2 $\frac{1}{2}$  ft. or 3 ft. between the rows, which should always run north and south, for the sake of admitting the light to the ground. Little attention is required after the crop is planted, except hoeing between the rows occasionally. At the end of the season, when the stems decay, they may be cut down, and a little earth may be drawn over the rows. The tubers are best used fresh out of the ground; but in case of frost a portion may be lifted from time to time, and stored in dry cell in a cool shed.—H.

### WINDOW GARDENING.

AN interesting lecture was delivered on this subject in Sheffield the other day by Mr. W. K. Marples. In advocating the culture of window plants, said Mr. Marples, I am aware that all who live in large towns labour under many disadvantages. To many, the greatest obstacle is how to grow them, and the want of convenient windows. If I did not know that certain plants, with a little care and attention, might be made to grow in the windows of towns, as well as in country mansions, I would never have undertaken this task. As with man cleanliness is maintained to be next to godliness, so with plants cleanliness is essential to healthiness. Therefore, whatever plants may be growing in the window, the dust of the dwelling must not be allowed to accumulate on their leaves week after week. They should be carefully washed every now and then, with a sponge and tepid water. This should be done carefully leaf by leaf, so as not to injure the plant. This sponging not only keeps the leaves free from dust, but also from insects. Window plants require air, food, light, watering, and rest. To keep plants pout up for weeks and months without any air but what comes bouncing in when the door is open, or whistling through the keyhole when closed, is not the way to keep plants healthy. All plants require air more or less, and although the freshness of the air may be said to be very seldom felt in our large towns, yet, by keeping the leaves of the plant clean, they are the more able to breathe what there is. We now come to the food of plants—soil and water. Of course window gardeners cannot pay the same attention to the food of plants as is practised by professional gardeners. To meet the case, I would tell you that a soil most suitable and most comfortable for all window plants to grow in can be found in any locality where there is a hedge growing. Pull up the first big tuft of Grass from the side of the hedge by the roadside, shake the soil from it, add a handful of sand, and the mixture will suit almost any window plant requiring soil for its cultivation. In potting plants be sure to give them good drainage. To effect this, before putting the soil into the pot, fill up about one-sixth part with rough pebbles or broken brick. This will enable the water to run freely from the soil, and so prevent the roots of the plant getting sour. Press the soil evenly and firmly round the plant, and you have now the chief features in potting all plants. With respect to watering, in summer the plants will require to be almost daily watered, and all soft-wooded plants, before coming into flower, are much benefited by having their leaves well besprinkled with clean water several times a week. This brings us to the training. Plants of the Pelargonium tribe should never be allowed to become leggy; try to keep them as bushy as possible and near to the pot. This can easily be accomplished by nipping off the points of the young shoots after the plant has been potted in spring, and made some progress in growing. This induces it to throw out other young shoots. We now come to the rest of plants. Nearly all plants under pot culture require rest in due season, and that season is usually after they have done flowering. All plants that have flowered during summer, such as Pelargoniums and Fuchsias, are rested by being kept moderately dry at the roots all through the winter. In fact, the Fuchsia should be taken out of the window altogether during that season and placed away in some dryish cellar or shelf, free from frost, to remain there until spring comes round. It should then be brought forth, re-potted in fresh soil, set in the window, and away it goes on the journey of life. Thus, it will be seen, to keep window plants healthy, the leaves must be kept clean; they must have plenty of air, must be potted in good sandy soil, well drained, and have a sufficiency of water during the growing season. Train them carefully, and, after the exertion of flowering, give them a rest.

**The Giant White Runner Bean.**—During the last three years I have grown the Giant White Runner Bean, and have found it so profitable that it is well entitled to the most widely extended culture, and I would certainly recommend those who have not yet given it a trial to do so in the forthcoming season. It does not, let it be understood, supersede the old-fashioned Scarlet Runner, and I have certainly no intention of suggesting that it should take its place, excepting to a very limited extent. My practice has been to sow, instead of say four rows of the Scarlet Runner, two of that Bean and two of the Giant White, and I think this plan might be adopted in many gardens with great advantage. The Giant White is similar in character to the Scarlet Runner, but it differs from it in being more robust in growth, in producing white flowers and larger pods, and in being later in coming into bearing. The pods are remarkably fleshy, as well as being of a great length and width, and are exceedingly tender and delicate in flavour. One of its chief recommendations is its lateness, for in August, when the other Runners sown at the usual time are giving out, it is at its best, and the supplies are then very acceptable. I have grown both sorts mentioned in this note in the same row with considerable success, but, excepting in small gardens where only one good row can be had, it is much the best to keep them separate.—G. S., in "Gardener's Magazine."

## OPENING OF THE GARDENS AT KEW.

It is considerate on the part of Mr. Colman to inform you that Kew will be opened to the public at ten o'clock on bank holidays, but surely *this* cannot be considered a "concession" as regards horticulturists and students who for long years and deliberately have been excluded from the garden. The plan of the Kew authorities is evidently to assume that only the great holiday public are clamouring for admission, this holiday public being at the same time declared to be disturbing for the students supposed to be inside! But the real cause of complaint is not that the holiday public is shut out. This section of the community manages to amuse itself by dancing on Kew Green till the gates are opened. Horticulturists, being of a more serious turn, cannot be expected to kill time in that way; any of them simple enough to go to Kew in the morning or forenoon resort to "hanging about Kew Green." I quote an elegant expression I see in one or two of your contemporaries, who, though lending themselves to the Hookerian desire to keep Kew as much as possible a quiet family retreat, have published a few notes from correspondents who objected to passing their time in a manner so unprofitable and undignified; and that outside the gates of the national garden for *seven and even eight hours* after botanic and national gardens both on the Continent and in the United Kingdom are open to the public freely. As for the recently proclaimed facilities for students, they serve merely to show the narrow-minded spirit with which the question is looked at, and are wholly unsatisfactory. I for one shall never consent to run the gauntlet of whatever flunkey or porter happens to be near the curator's gate to beg so abjectly for what is my simple right. As for the plan of seeking for two householders to certify that the applicant for admission to see the national garden in the forenoon is a *bonâ fide* gardener, whatever that may mean, after one has laughed at it, one asks if the Kew authorities can really value their own or other people's time properly while suggesting such a puerile way of wasting it. Surely a simpler way is to open the gates at all reasonable hours.

J. F.

— The Commissioner of Works, it appears, has sanctioned the opening of Kew Gardens at ten o'clock on bank holidays. Now, while we ought, no doubt, to be grateful for small things, I cannot help thinking that in view of the very general expression of public need for the earlier opening of the gardens all the year round, it is hazardous, not to say unfair, to open only on so special an occasion as an Easter Monday, that is, if the conduct of visitors be intended to be taken as a criterion of the wisdom of early opening. I think it would have been much fairer to have opened them at nine or ten o'clock every day during Easter week. We should then have tested more effectually the merits of the recent agitation. In any case the relieving Kew Green of a crowd of holiday-makers a little earlier than usual on a bank holiday has nothing to do with the question of opening the gardens in the morning of every quiet day. On such days there would be no greater numbers present in the gardens than now on an ordinary afternoon, but the public would have the satisfaction of knowing that the national garden and its contents were open to them whenever they choose to go.

T. G. A.

— The "Pharmaceutical Journal," while as tender with the President of the Royal Society as one might expect, nevertheless tells the truth about the "student" plea. When the plea is put forward that it is necessary that the gardens should be closed during the early part of the day to enable students to pursue their studies unmolested, we do feel warranted in asking whether such facilities are afforded to a large number of students as might be expected? For instance, the Royal Botanic Society acts in a most liberal manner towards students wishing to study in its gardens between the hour of opening and one o'clock, and the privilege is widely appreciated; but we know of no analogous facilities afforded in the public gardens at Kew. It is true that it has been stated that some such privilege is granted upon proper application, but it is evident from the number of failures that have been recorded that there is at least considerable obscurity as to the form in which the application is to be made. Again, there is another direction in which we think the services rendered to science by the establishment at Kew might be profitably extended. For the proper illustration of the numerous courses of botanical lectures now delivered in the metropolis and its neighbourhood, in connection with medical and pharmaceutical schools and other institutions, a large supply of typical plants is requisite. For this we believe lecturers in the metropolis are chiefly again indebted to the liberality of the Royal Botanic Society at Regent's Park, and in some measure to the Apothecaries' Garden at Chelsea, but we are

not aware of a single instance in which these wants have been supplied from Kew. This may be contrasted with the fact that in one of the suburbs of Berlin there is a garden under the control of the educational authorities, from which upwards 4,000,000 of fresh plants are supplied to the schools during the year. In our case no special garden is required, as in the immense grounds at Kew there is room for the cultivation of an ample supply for present requirements. In conclusion, we need scarcely say that these opinions are not put forth in a cavilling spirit, but because we believe that the arguments of the Kew authorities would have been stronger had they rested on a wider basis.

The First Commissioner of Works has consented, it appears (see p. 351), to open Kew Gardens at ten o'clock in the morning on all bank holidays; but the opening of these gardens a little earlier on such occasions can be regarded as no concession whatever to horticulturists, for on such days all who cared to go for the sake of the plants themselves would be sure to keep out of the way. The Kew authorities and certain writers who promulgate their views confuse the interests of the holiday crowds with those of the much less demonstrative persons who go to the gardens for the sake of observation, and who certainly would give no trouble to the authorities. One is a question of a few days, when there may be unmanageable crowds; the real question is that of opening the gardens to quiet people at any reasonable hour they can spare to visit them.—H. M.

Any one would think, from "J. S. W.'s" remarks (see p. 351), that no such arrangements are to be found in the three kingdoms as those which he says may be seen in the Jardin des Plantes, in Paris; but if "J. S. W." should ever happen to be in the neighbourhood of Dublin, and will visit the Botanic Garden, at Glasnevin, he will find an arrangement similar to that of which he speaks, *i.e.*, plants arranged according to what they are used for. In the Jardin des Plantes, if I mistake not, the plants are arranged in their Natural Orders, and the different coloured labels only indicate what they are used for. At Glasnevin one part of the garden is devoted to the chief varieties of garden crops. In the same part of the garden may also be found an excellent collection of plants used in the arts and manufactures, such as those that yield dye and colouring matter, oil, fibre, grains, and forage; also a collection of British and foreign Grasses, and pastures and meadow Grasses. Close to the large Palm house may be found medicinal plants, arranged in their Natural Orders, and a little further on are British plants classed according to their Natural Orders; and there is also an arrangement of plants at Glasnevin, which I have never noticed in any of the other botanic gardens in the three kingdoms, not even in the Jardin des Plantes in Paris, that is, plants arranged according to the Linnean and Natural Systems.—U. G. J.

## OBITUARY.

PERMIT me to place on record the removal of another name from the roll of patriarchal horticulturists. Henry Baines, who for upwards of fifty years or more held the position of Curator of the Museum Gardens at York, passed away on the 3rd of April at the ripe old age of eighty-five, thus severing one more of those links which connect the present with the far distant past. Amongst the elder section of your readers many will, doubtless, have personal reminiscences of this fine old Yorkshire gardener, whose deeply-chiselled, rugged features presented a type of face between our modern Carlyle and the old Greek philosopher Socrates. In the wide county of Yorkshire his name and fame were both well known, and it has been the lot of few to enjoy more respect than he did in his residential city of York, where his name was a household word not only amongst horticulturists, but also amongst archeologists and entomologists. As a sound, practical botanist, his "Flora of Yorkshire," which had gone through several editions, will stand as a memento of his zeal and industry in that special branch of his profession; and those who secured, and they were by no means few, his services as clericone through the archeological treasures of the Museum, or through the quaint and historically-interesting corners of the old city and its world-renowned Museum, must have been struck with the vast store of information which he had accumulated. For the past two years he had been superannuated, and for the last three years almost confined to the house, so that his death will scarcely leave such a gap amongst his old circle of friends as it otherwise would have done, and in truth few of his earlier associates would be left. As we ascend the bill of life friends increase, but as we descend assuredly do they become fewer and fewer till we ourselves, possibly all but alone, pass away. To the many lovers of Alpine and herbaceous plants who peruse your columns it will be interesting to know that he was an ardent lover and cultivator of this class of plants throughout his entire life, and the last time that I saw him, some two years ago, his mind, though then sadly failing, brightened up at the mention of some of his old pets with its youthful glow, and the enjoyable days which we spent when he used to pay his periodical visits to Hull came vividly before his mind. An intimate acquaintance of many years' standing, and a high appreciation of those fine manly qualities which, coupled with his scientific knowledge,

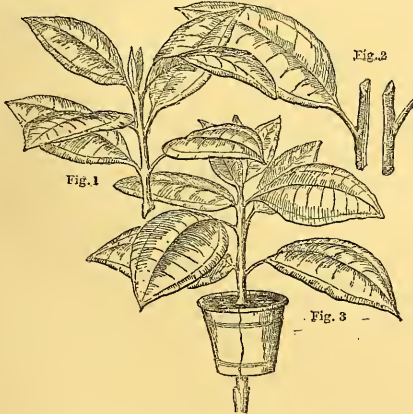

have won for him the right hand of friendship with many, amongst whom I have always felt proud to rank myself, have induced me to pen these few remarks as a tribute to his memory.

JAMES C. NIVEN.

Hull Botanic Gardens.

## PROPAGATING.

**CYANOPHYLLUM MAGNIFICUM.**—This noble-leaved stove plant is increased in three ways. First, take peat and sand finely sifted and fill well-drained pots with it; the cuttings being large, use 3-in. pots. Make the cuttings either as shown in fig. 1, which is a top, or as in fig. 2, which is a single eye; the wood must not be too hard. Cut it down the middle with a sharp knife, place the cuttings firmly in the pots, give a good watering, and plunge them in the cutting box on a brisk bottom-heat. If eyes be used, put four in a pot, with a smaller pot inverted on the top of the sand to hold up the leaves and keep them steady; they must be kept close, moist, and warm, with an occasional opening of the glasses for an hour or two. Fig. 3 represents a good plant if a fine specimen be required without loss of foliage. The pot or box must be cut in half, and a little Moss should be put in the bottom; fix the stem in the centre, and fill in with soil, keeping it moist. A piece of copper wire will bind the pot together. As soon as the roots are seen coming through the

bottom cut the stem half way through; if the top shows no sign of flagging in a week or so cut the other half off. February is the best time for this operation, but if later shade with a sheet of newspaper and syringe overhead two or three times a day.

H. H.

### The Fittonia as a Covering for Stove Beds and Walls.

—There are two varieties of this plant in cultivation—*F. argyro-neura* and *F. Verschaffeltii*. The first has light-green leaves, closely netted with lustrous silvery veins; and the last dark-green leaves, netted with bright-red veins. Both kinds are extremely easy to grow. Cultivated in pots, and treated in the pinched way one often sees the plant, it does not appear to thrive very well; but planted out on the bed among the pot plants, or below shelves, along the margins of paths, it grows strongly, and does not seem to be particular as regards soil, but will succeed either in peat or loam. In one place here it is growing on the floor in common soil, and in another part in the common sand of the bed where the plants are set, and it would be difficult to say which thrives best; but both grow rapidly, and the foliage is both large and fine. Little or no care is taken of it; the stove plants are just set on it or amongst it when moving them about, and it is allowed to take its chance, and quantities of it are cut at times for decorative purposes.—S., Hereford.

## THE FRUIT GARDEN.

### RETARDING FORCED STRAWBERRIES.

FORCED Strawberries, like Grapes and other fruits, need holding back sometimes, but I have always thought it a bad practice to check their progress in the middle of the swelling period. It seems to check development and induce premature ripening, and the consequence is fruit of smaller size than it might have been. It is easy to keep the plants back before they come into flower, but after that period they should be kept growing, if slowly. If it be desired to keep the crop back at a later stage, it should be when the fruit is about finishing colouring, that is to say, if the plants be then moved into a comparatively cool house, they will come on slowly and be better flowered; but, still, they must have a growing temperature. In a temperature of 40° or 45° or thereabout, early in the season, the half-matured fruit makes no progress and deteriorates in flavour. I find it the best plan about this season to let the fruit grow and ripen in not too low a temperature (after it has got to a certain stage), and when it does get ripe, or nearly so, to move the plants into the fruit-room, and keep them cool and dry. Two years ago we almost filled our fruit-room shelves with plants on which the fruit was quite ripe, and it kept until it was all used, which was nearly two weeks. At the present time, in consequence of the movements in our establishment, we have had to place above 100 plants of Black Prince, on which the fruit was dead ripe, in the same place, and they seem to be keeping perfectly. The plants receive no water after going into the fruit-room, but they are in a moist condition before they are taken there, and the fruit-room is aired regularly and kept sweet and dry.

J. S. W.

**The Fruit Crop.**—I have this day (April 12) had a thorough look round my walls with the following result—Apricots, a capital set of healthy fruit; Peaches, as far as can be seen, have also set well; Pears are thinly set with blossom buds, but what there are look promising; Plums are one sheet of fine plump blossoms; Apples, although not open, promise well; Gooseberries are in full flower, but of these we have always abundance.—K. GILBERT, *Burghley*.

—At last we have had a welcome change in the weather in North Notts as far as regards a warmer temperature. Instead of having a rainfall at the date of the deluge in the southern counties, only twenty-eight parts of an inch have fallen here since April set in; the soil, in consequence, is in a very dry state, and on strong soils baked quite hard. On April 17° of frost were registered in the morning, and great injury has been done to fruit trees on walls that were unprotected. Of hardy bush fruits the Gooseberries have been injured the most, all the young fruit on the tops of the bushes being destroyed. Currants were not far enough advanced to receive much injury. Apples, Pears, Plums, and Cherries had been kept back by the cold weather in the last week in March, and I believe have received little injury as yet, and there is abundance of bloom on them to open. It will be very disheartening should there be another failure in these crops this year like the last. We are, however, of late years never safe till the first portion of May is over, for I remember in one year on May 1 that 8° of frost occurred and destroyed the young Apricots, Peaches, and Nectarines on walls, although they were at the time as large as Peas.—WILLIAM TILBERT, *Walbeck*.

—A general look through the large market orchards of this locality shows a magnificent bloom upon Plums and Cherries, nearly all of which is now expanded. On Pears there is a moderate amount of bloom; enough, however, if left unhurt, to furnish a crop. Apples will be finely in flower in a couple of weeks. All the trees look healthy, and the blossom is vigorous. So far, fruit prospects are good, but a drawback must be allowed for the mischief already done by the severe frosts to the earliest Pears, the buds even unexpanded having, to a large extent, been frozen through and the germs destroyed. Under the most favourable conditions, therefore, not more than half a crop can be looked for. Some of the earliest Plum bloom has also suffered, but even on the earliest trees a quantity remained unopened, and doubtless enough of that remains sound and fertile. The Gooseberry crop has very materially suffered, as was inevitable where the fruit had developed sufficiently to be frozen through and through again and again. Some of the Currant blossoms also have suffered, but it will probably be a fair estimate to say of bush fruit generally that there will be, if the weather be favourable, a useful, moderate crop. Apricots are more plentiful than was at first supposed could be possible, and Peaches are not, even on unpro-

teated trees, so much injured as was anticipated. With a continuance of the soft spring weather that now prevails, good crops of Apples, Plums, and Cherries may be looked for, and also moderate crops of Peas and the various kinds of bush and wall fruit.—A. D., *Bedfont*.

### ANSWERS TO CORRESPONDENTS.

**Removing Large Evergreen Oaks.**—Will you be good enough to inform me if I may venture to remove several large Evergreen Oaks which are too near my house, but which I should not like to destroy.—E. W. S. [These are very difficult to move successfully when large] without the aid of a powerful transplanting machine. Far better leave them where they are, unless they have been previously prepared for transplanting by root pruning, and the services of a practical man and a transplanting machine can be procured in the neighbourhood.—B.]

**The Chinquapin (*Castanea pumila*).**—Can any of your readers tell me if this very small species of Chestnut, common in some parts of North America, is in cultivation, and, if so, how it behaves? It is much spoken of in America as a dwarf, edible Chestnut.—W. W. L. [This was introduced into England as far back as 1690. It is quite hardy, but is of very slow growth—in rich, deep soils only attaining the height of a low or very dwarf tree; while in poor and dry soils it does not exceed a height of 6 ft. or 7 ft. Plants of it are probably scarce in the trade. Perhaps in some old-established nursery, such as Messrs. Osborn's, at Fulham, or Mr. Wheeler's, at Warminster, plants of it might be had.—B.]

**Fasciation in Hollies.**—The enclosed was sent from the middle of a variegated Holly tree at Christmas time; can you explain the cause of the growth? Is it confined to Holly alone, or are other trees affected in the same way? and is it a common occurrence?—A. Sussars. [It appears to be a case of early cohesion. Fasciation is common in many trees, especially the Ash, a singular example of which is illustrated in *THE GARDEN* (see Vol. XI, p. 394). It seldom occurs in the Holly.]

**Rhododendrons on Chalk.**—I wish to grow Rhododendrons, but the soil is unfortunately on the chalk. I have heard that they can be grown by digging out basins in the chalk and filling them with peat. Can you give me any idea of what size and depth the basins should be in order to grow the Rhododendrons to a good size in a park?—A. C. [Under such circumstances we should never attempt the culture of Rhododendrons at all, having witnessed miserable failures in the face of much expense and pains. Some of our correspondents may help you.]

**Tree Carnations.**—I shall be obliged for any information you can give me respecting the treatment of these.—F. A. J. [After the plants have done flowering, say in June or July, plunge them in their pots in a shady place, and layer their shoots either into small pots filled with loam, rotted manure, and sand, or in the surrounding soil. When well rooted, pot them into 5-in. or 6-in. pots. When cold weather sets in place them in a cool house or pit, and introduce a few at a time into a heat of from 55° or 60°. By this means a good succession of bloom may be secured. If early flowers be not wanted, the plants must of course be kept in cool airy quarters all through the winter.—E.]

**Badly-grown Marechal Niel Rose.**—What can I do with a Marechal Niel Rose which I have in a pot (in a small house)? About 6 in. from the pot it breaks pretty well, then for about 3 ft. it does not break at all, while above that it is showing bloom. What is the reason of this? The top has been cut off to try to make it break, but it has not done so.—E. A. D. [It is not easy to say why your Marechal Niel does not break satisfactorily. This Rose is very subject to such breaks when grown in pots, but when planted out in a border, it will ramble over the rafters in a greenhouse in a short time, and, owing to the drooping habit of the flowers, they show themselves to the best advantage. Perhaps a shift into a larger pot might throw more vigour into the plant and induce it to break from the bare stem, that is, if there be no border in which to plant it out.—W. T.]

**Wild Gardening.**—I want to know how to get a succession of wild flowers masses on a wooded bank of Beech trees, such as Cowslips, Anemones, or anything that will grow and flourish amongst Grass on a southern exposure? Would it be best to sow seeds on the bank or plant the seedlings out, after being raised, in a border; and what kinds would suit? There are abundance of Snowdrops, common Primroses, and Adonis. Would the blue Anemone do here?—D. H. E. L. [Among Grass it would be best to plant strong seedlings raised separately. The blue Anemone would do well. The summer Snowflake at the spring Snowflake if it can be obtained in sufficient numbers will also do. For a very early flower the yellow Aconite is good. In the case of tubers they are best planted soon after they have died down. Others will do so select the plants you like best, and then choose those that bloom in succession, and they will flower in the Grass.]

**Bitter Broccoli.**—Can any reader of *THE GARDEN* inform me why it is that much of the Broccoli sold in London has a disagreeably bitter flavor? Is it a question of kind, of locality, or does it result from the length of time the heads are cut before they come to market? Or is it owing to the manure used in certain districts? Can any of the good kitchen gardeners whose contributions I notice in *THE GARDEN* enlighten me, and tell me if this bitterness is observable where Broccoli is used fresh from the garden?—Queens.

**Names of Plants.**—J. D., *St. Paul's*.—The stalks had fallen away from the flowers when the latter reached us, and therefore the numbers were

detached, so that we cannot name them. The best way is to send them to some nursery where a good collection is grown. The blooms are very fine; the large red one is the finest and most massive flower we have seen. Its name is *Chandleri elegans*. *Debatteille*.—Apparently *Notelia longifolia*.

**Hardy Plants.**—E., *Richmond*.—Your letter is an advertisement. **Linum viscosum.**—Did not your artist make a mistake in the *Linum* figured in *THE GARDEN* of March 23? It was named *L. viscosum*. Should it not have been *L. salicoides*? The *L. viscosum* which I have grown is pink.—H. HARPER CARWY. [Yes, it was wrongly named; it should have been *L. salicoides*.]

**Wireworm.**—I should be glad of advice on the following matter: I am interested in a garden near Birmingham which is completely infested (not merely infested) with wireworm. Every root of every plant of the Cabbage tribe is simply a hollow tube filled with these pests. Carrot and other root crops cannot be grown. The owner has tried soil, lime, gas-lime, and with no result. Can any of your readers suggest a remedy? Trapping is out of the question, as there are millions of them in every part of the garden. Would the plan of burning the whole soil be the only remedy? and would this be very deleterious, as the soil is light and the subsoil gravel?—W. A., *Gloucester*. [Try nitrate of soda, which is used in quantities by farmers in this locality with the best results. Wherever patches in the Corn crops show a yellow tinge they know that the wireworm is at work, and top-dress the places with nitrate of soda. In the case of garden crops I have no doubt that, if well mixed with the soil in digging the ground, it would help to kill or banish wireworms. They are often brought into gardens with fresh turf loam brought from the fields or roadsides, and I am very doubtful now about fresh soil of such a kind without being well examined, especially for potting purposes.—W. J.]

**Strawberry Culture.**—Which is the most simple way of growing Strawberries? I am told so many ways, each one the best, that I am fairly puzzled. I am told that to plant them in the first instance in a line, like planting Box, and 3 ft. between each row, letting the runners root themselves in the 3 ft. spaces—which they will do, and fruit the following season—is the simplest; of course rooting out the old plants. This is certainly very simple, but I should be afraid they would be overcrowded by this plan; but I am told they produce a plentiful crop of fair-sized fruit. I am told runners that root themselves make the best plants. As I cannot afford much time to be given to pricking out the runners, please tell me if this plan is a good one, or of a better one if equally simple; also if the small-foliated plants are best for a moist climate such as this; and if so, the names of such? I have no space for succession beds—beds for one, two, and three-year-old plants. If the runners were always out, away and the old plants kept, the fruit would get smaller each year, even with manuring highly, I suppose.—H. S., *Argyleshire*. [No; the mode of culture named is not a good one, and ought to become obsolete as soon as possible. Moreover, we must remind you that good Strawberries cannot be had without labour or space in which to grow them. The following is a plan which we have found to be most successful: The earliest runners are selected and layered on pieces of turf let into the ground. As soon as they are well rooted they are severed from the parent plants and transferred to permanent quarters, on well-enriched and deeply-dug ground. They are planted in rows 2 ft. apart, and 1½ ft. asunder in the row. All the runners are kept pinched off during summer and autumn, and the following year they produce a few very fine fruit, but the second year they bear prodigiously, yielding fruit of the largest size and finest quality; the next year they deteriorate somewhat, and after fruiting a third time they are destroyed, thus necessitating successional beds; and, no matter how limited your space may be, you must resolve to have successional beds if you wish to have good fruit. We never yet saw fruit worth the name that had been grown year after year on the same plants and ground. The following are free-bearing kinds, hardy, and good, either for dessert or preserving, and will, we think, do well in your climate, viz., *Vicomtesse Héricart de Thury*, President, *Sir Charles Napier*, and *Sir Joseph Paxton*.—W. W.]

**Seed Adulteration.**—A bill, intitled "An Act to Amend the Adulteration of Seeds Act, 1869," introduced the other day by Mr. Clare Sewell Read, runs as follows: "1. This Act may be cited as 'The Adulteration of Seeds Act, 1878,' and shall be construed as one with 'The Adulteration of Seeds Act, 1869,' and together with that Act may be cited as 'The Adulteration of Seeds Acts, 1869 and 1878.' 2. From and after the passing of this Act section 2 of 'The Adulteration of Seeds Act, 1869,' shall be read as if, instead of the words 'The term "to dye seeds" means to give to seeds by any process of colouring, dyeing, sulphur smoking, or any other artificial means the appearance of seeds of another kind, there were therein inserted the words "The term "to dye seeds" means to apply to seeds any process of colouring, dyeing, or sulphur smoking.' This will prevent prosecutions failing from an ambiguity as to the meaning of the word "kind."

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 17.

Owing to the mild weather which we have experienced, exhibitors were enabled on this occasion to bring out the most tender exotics without fear of injury, and the result was the best show that has been held at South Kensington this year. Its most interesting features were banks of pot Roses, Clematises, and Rhododendrons, from Messrs. Veitch & Sons, and an admirably-arranged group of Orchids, Gloxinias, and other choice flowering plants, together with Palms and other similar graceful-leaved subjects, from Mr. John Wills, of South Kensington.

First-class Certificates were awarded as follows:—

**Amaryllis E. Pilgrim** (Williams).—A superb flower of good form, having smooth petals of a brilliant scarlet, the base of the mid-rib being pure white. One of the best Amaryllids that has been shown for a long time.

**Dietses Huttoni** (Green).—An Iris-like plant, with curious yellow three-petalled flowers.

**Wallichia zebra** (Williams).—A distinct species, having long graceful leaves of a deep green colour, the foot-stalks being zebra-striped.

**Caltha palustris fl.-pl. minor** (Parker).—A double, yellow-flowered, hardy species, well suited extensive culture on water margins.

**Davallia fijiensis** (Bull).—One of the most valuable introductions among Ferns that has been made for some time. It resembles *D. canariensis*, but the fronds are much more finely cut and graceful.

**Megasea purpurescens** (Parker).—A fine kind with glossy green leaves, and bright, rose-coloured, drooping blossoms, borne on fleshy stalks 6 in. or 7 in. above the foliage.

**Grevillea robusta filicifolia** (Rollison).—An elegant plant, with a drooping habit and long, spreading, finely-cut leaves. One of the best plants in cultivation for table decoration.

**Adiantum tetraphyllum gracile** (Bull).—A dwarf Fern, the fronds of which somewhat resemble in colour and form those of *A. pubescens*.

The same award was also made to Messrs. Veitch & Sons for *Crinum bracteatum*.

**New Plants.**—Groups of these were shown by Messrs. Veitch & Sons, Williams, and Bull. In the group from the first-named firm were several new *Gloxinias* of a meritorious description, the best being *Eloipse*, a well-formed, upright flower, of a velvety crimson colour. Mr. Bull had, in addition to plants which received first-class certificates, an elegant *Croton*, from New Guinea, with long, narrow, bronze leaves, elegantly marked with fiery crimson; also several varieties of *Odontoglossum Cervantesii*, and several new *Alcocalcias*. Messrs. Osborn & Sons contributed a new *Draecena*, named *D. Parri*, which appears likely to prove useful for window decoration; it has large, glossy leaves edged with crimson. Messrs. Paul & Sons, the Old Nurseries, Chestnut, sent examples of the golden-leaved *Avellana anrea*. Mr. Wills showed a remarkable, fine variety of *Odontoglossum Andersonianum*. Messrs. Rollison & Sons furnished several new Ferns and Palms; and from Mr. Charles Turner, Slough, came two new Indian *Azaleas*, named respectively *A. Madame de Grove* and *A. Comte de Chambord*, both light-flowered kinds, well worth a place in every collection.

**Roses in Pots.**—A magnificent group of these was shown from Messrs. Veitch & Sons, Coombe Wood Nursery, the plants throughout being well furnished with healthy deep green foliage, and an unusual amount of bloom. Conspicuous amongst them were grand specimens of *Madame de St. Joseph*, one of the best Roses for pot culture; *Amie et Anton*, well supplied with rose-coloured blossoms; *Souvenir de l'Ami*; *Duchesse de Vallombrosa*, and the pale yellow *Marie Van Houtte*, so useful in a bud state for bouquets. *Rubens*, a delicate cream-coloured kind, was much admired, as were also the bright flowers of *General Jacquemont* and *Beauty of Waltham*.

**Cut Roses.**—Messrs. Lane & Sons, Great Berkhamstead, showed excellent bouquets of these. Amongst them were fine blooms of *Mdlle. Marie Rady*, *Baroness Rothschild*, *Boule de Neige*, *Edward Morren*, one of the largest of *Roses*, *Paul Nerou*, the beautiful yellow *Madame Falcot*, and the pure white *Niphotos*, so largely grown for sovent Garden, where it is considered the best of white *Roses*. Mr. J. Walter, Finsane Croft, furnished stands of *Marshall Niel* of the finest description; the blooms were unusually large, well formed, and of the richest golden colour; the same exhibitor also sent good blooms of *Gloire de Dijon*, *Souvenir de la Malmaison*, the pure white *Lamarque*, and other good kinds.

**Orchids.**—These were represented by attractive groups from Sir Trevor Lawrence and Mr. Williams, Holloway. In the first collection was a magnificent plant of the rare *Cymbidium oburneum*, furnished with numerous chaste, ivory-white blossoms, and an example of the curious *Cypripedium cadaverum*, bearing nearly twenty large blossoms, the tails of which measured quite 2 ft. in length. Associated with these were well-flowered plants of the brilliant orange-scarlet *Loelia cinnabarina*, *Odontoglossum radiatum*, a finely-bloomed plant of *Masdevallia Harryana* of unusually bright colour, graceful plants of *Odontoglossum circhosum* and *O. Alexandra*, and a plant of the beautiful *Trichopilia suavis*, which bore nearly a dozen large waxy blossoms. From the same exhibitor also came

numbers of plants of *Freesia Leichthiania*, furnished with abundance of creamy, golden-spotted blossoms. In Mr. Williams' group of *Orchids* were beautifully-flowered plants of *Aerides Fieldingii*, *Vanda tricolor insignis*, the graceful *Dendrobium Falconeri*, and *Masdevallia Lindenii*.

**Amaryllids.**—Groups of these were shown by Mr. Williams and Messrs. Veitch & Sons. They contained both seedlings and well-known kinds. Among the most noteworthy from Mr. Williams were *Eratinum*, an orange-scarlet flower striped with white; *Dr. Hogg*, a large-flowered variety, with broad, bright scarlet petals; *Eloipse*, a well-formed flower, of a brilliant crimson colour; and a light-flowered kind named *strata superba*. In Messrs. Veitch's group were well-flowered plants of *Junius*, an exquisite flower, with smooth, well-formed petals of a maroon-crimson colour; and *Attraction*, an unusually showy kind, with medium-sized flowers of a bright salmon colour, the base of the petals being pure white.

**Clematises.**—These were well shown by Messrs. Veitch & Sons. The plants were in 8-in. pots, and trained, but not too stiffly, on small, conical-shaped trellises, or they were completely hidden with blossoms. For conservatory or room decoration such plants as these are unequalled, and the wonder is that the *Clematis* is not grown more extensively as a pot plant than it is. Among the best varieties in this group were Mrs. S. C. Baker, a good-habited kind, with white-tinged flowers shaded with pink; *Miss Bateman*, a sort with well-formed, pure white flowers; *Justus Victor*, with transparent violet blossoms; *Lady Londesborough*, of delicate mauve; and *Sir Garnet Wolseley*, a variety with showy purple flowers having crimson veins. Associated with these were standard plants of the elegant, green, cut-leaved *Maple Acer polymorphum palmatifidum*.

**Miscellaneous Subjects.**—A group of hardy flowering shrubs from Messrs. Veitch attracted perhaps more attention than anything else that was exhibited, on account of their somewhat novel character. They consisted of double and single-flowered white and scarlet *Thorns*, miniature trees of the common *Laburnum* furnished with abundance of blossom, variegated *Maples*, *Ghent Azaleas*, *Lilacs*, and early blooming *Rhododendrons*. For effect in the conservatory such plants as these are when in flower better than many more difficult to cultivate. Mr. Wills' group, which was an excellent one, contained well-flowered plants of *Odontoglossum circhosum*, *O. triumphans*, and *O. gloriosum*, associated with numerous plants of *Anthurium Scherzerianum*, well furnished with bright scarlet spathes, choice *Azaleas*, and *Lily of the Valley*. These were intermixed with Ferns, *Palms*, *Crotons*, *Draecenas*, and *Cupanias*. The beauty of the group was enhanced by masses of cut blooms of *Marshall Niel* *Roses*, intermixed with *Stephanotis* and *Lily of the Valley* cushioned in Moss. Mr. B. S. Williams sent a valuable group of plants, in which were noticeable large and well-flowered specimens of *Azalea major*, *Rhododendron Comtesse of Haddington*, *Francisca calycina* *maior*; also well-grown plants of new *Draecenas*, *Aralias*, and *Palms*, the beautiful *Leucostemone*, *Gloneria*, *Psychotria lucubra*, and the new Fern, *Microlepia hirta cristata* from the South Sea Islands. Messrs. Rollison & Sons contributed plants, among which were *Arrophyllum apiculatum*, furnished with from twenty to thirty spikes of rose-coloured blossoms, the brilliant semi-double *Azalea Charles Leirens*, and well-flowered plants of *Azalea tuberosa*, and *Tetrachaea ericoides hirsuta*; associated with these were also brightly coloured specimens of *Draecena Baptisti*, the narrow-leaved *D. elegantissima*, and *D. salomonii*, all of which are among the best *Draecenas*. Messrs. Cutbush & Sons furnished a collection of hard-wooded and other plants, among which were profusely-flowered specimens of *Polygala Dalmanii*, choice *Azaleas* and *Rhododendrons*, the beautiful blue-flowered *Hovea Celis*, and a narrow-leaved *Draecena*, which has been shown on previous occasions. Mr. Aldons, South Kensington, also sent a group of decorative plants, consisting of well-bloomed *Heaths*, *Pinks*, show *Pelargoniums*, and brightly-coloured *Cinerarias*, intermixed with Ferns, *Palms*, &c., but they were altogether too crowded to be effective. Mr. Parker, Tooting, exhibited a group of hardy, bulbous, and herbaceous plants, in which were *Androsace coronopifolia*, a profusely-flowered plant, with small white, *Forget-me-not*-like blossoms, a good potful of *Gentiana acaulis*, well furnished with flowers, the elegant *Fuchsia macrophylla*, and several *Irises* and *Saxifrages*. Messrs. Barr & Sargent had an extensive display of *Daffodils*, in which the best known kinds were represented, as well as many valuable seedlings, for which a gold Banksian medal was awarded. The Rev. J. G. Nelson, Norwich, also sent remarkably fine blooms of *Leeds'* seedling *Daffodils*, also cut blooms of seedling *Anemone pulgens* and the double *A. coronaria*. An excellent group of *Auriculas*, *Polyanthes*, and *Primulas* was shown by Mr. R. Dean, among which were many new and well coloured. Mr. H. Hooper, Vine Nursery, Widoombe, sent some good cut blooms of *Pansies*. Mr. Charles Turner, Slough, exhibited a plant of *Polyanthes Orange Gem*, a profusely-flowered kind, valuable for border planting. Messrs. F. & A. Smith, Dulwich, sent cut blooms of *Cinerarias*, exquisite in form, colour, and size. Messrs. Veitch contributed a group of *Obolite* *Oranges* grown in 6-in. pots, each bearing no fewer than twelve to fifteen ripe fruit. Mr. Wildsmith, Hackford, sent a dish of *Heriarte de Thury Strawberries*; the fruit was of large size, well coloured, and of excellent flavour.

**Royal Horticultural Show at Preston.**—A third meeting of the Local Committee of the Royal Horticultural Society was held the other evening at Preston to receive a deputation from the Council of the Society

at London. Mr. Shuttleworth briefly introduced Mr. H. J. Elwes (a member of the London Council) to the meeting, and that gentleman proceeded to explain, at considerable length, the views of the Council on the subject of the show to be held at Preston, and also entered fully into the large amount of labour which it would involve, stating that it would tax the resources and the energy of the Local Committee to the utmost. He was very much pleased, he said, with the beauty of the grounds at Farington Hall, and also with the spot selected for the show, which would, weather permitting, he believed, be a complete success.—Mr. Shuttleworth produced a lengthy list of patrons, which was partly read.—Mr. Elwes announced a grant of £1000 had already been subscribed in London, and that more would be forthcoming if required. With the £500 already guaranteed by the Preston Nursery and Pleasure Gardens Co., however, he thought a sufficient sum had been obtained. He urged upon the Committee the necessity of commencing at once to make a complete and active canvass, for the purpose of providing the necessary funds for the prize money offered in the schedule and the preliminary expenses, and concluded his remarks by stating that the London Council would do all in their power to render the show a perfect success, and a credit to the county and Preston in particular. All details relating to the fixing of the tents were settled. One of them, it may be remarked, will be of such a size, that it will cover about three-quarters of an acre. The real work of this great undertaking may therefore be said to have commenced in earnest, and we do not doubt that the most perfect success will attend the labours of the Committee.

#### SPECIMEN ALLAMANDAS.

THE Allamandas are alike remarkable for their conspicuous yellow flowers and for their bold, distinct foliage, affording an effective contrast to most other kinds of flowering and fine-foliaged plants with which they are ordinarily associated. As exhibition plants they are in their way unrivalled, and a well-grown specimen of an Allamanda is a most telling plant in a collection. Employed as climbers in stoves, they efficiently clothe the pillars, walls, or spaces of roof, and are not only beautiful from a decorative point of view, but afford plenty of flowers, which are often found extremely useful in a cut state. It is one of those plants which liberally repays generous treatment; and in order to display its true character it must be well nourished, and be grown in a congenial atmosphere. Like the generality of climbing plants, it succeeds best in a good, free root-run in a tolerably rich and stimulating soil. If it can be afforded these advantages its culture will be attended with satisfaction. If planted out, it will naturally attain greater luxuriance than when the roots are confined to the narrow limits of a pot; although it may be safely affirmed that flowers of the highest quality can be produced by pot culture. In the formation of specimens it is best to commence with quite small plants, and if they can be had in 3-in. pots, so much the better. Specimen growers, as a rule, like to begin with plants as near the cutting state as is possible, as they are thus better enabled to lay the foundation of a healthy specimen. As much of the vigour of manhood depends upon the care exercised in infancy, so will the future existence of the specimen depend upon the management of the plant in its primary stages of growth. We will therefore suppose that the young plant is well rooted, and the soil well permeated with fibres. In that case it may in March be shifted into a size larger pot, using an open, porous compost of half turfy loam and peat. Let the soil be well sanded in the first stage of growth, as the main object is now to secure a good foundation by multiplying the root fibres as much as possible. Water moderately, and place in a position where there is no lack of light, and where air may be given on favourable opportunities, at the same time avoiding cutting draughts or checks of any kind. In order to lay the foundation for a well furnished specimen, it is necessary to give early attention to stopping the young shoots. It is not, however, advisable to commence this operation until the growing wood is sufficiently robust to admit of its pushing strong laterals when pinched back, for, although, as will be well understood, it is necessary to promote the formation of young shoots, it must not be done at the expense of strength and solidity. It is as well to let the plant grow on until it is well established in a 6-in. pot before stopping, and then pinch back to about six eyes. This will ensure vigorous breaks, which will naturally form strong healthy wood when shifted on. By the end of the season they will have become thoroughly established in 8-in. pots, and should, towards the end of the growing season, be placed where they may get a free circulation of air in order to ripen off the wood. During the winter they

will have to be kept moderately dry, not, however, allowing the fibres to perish for want of moisture. They are to be rested, but not dried off. If a plant is allowed to stand dry for any length of time, it will have the effect of considerably impairing its vital force. Want of vigour when the plants break may often be traced to this cause. The best place in which to winter them is the coolest portion of the stove, or in an intermediate house, keeping them as far removed from the pipes as is possible, for the colder they can be kept consistent with safety, the more strongly will they start into growth again. Early in spring they should be shifted into the pots in which they are destined to bloom, using a good sweet compost of equal portions of loam, turfy peat, and decomposed manure. The shoots should all be pruned back, the number of eyes left to be determined by the strength of the shoot. The generally accepted form of training for this plant is that in which a balloon-shaped trellis is made use of, the shoots being so directed that they cover it with foliage. Some growers, however, merely support the shoots by means of stakes, allowing the plant to assume a more regular and natural outline. The summer treatment will correspond to that which is recommended for the young plants, but as soon as growth is completed, they must have sufficient air and light admitted to them to admit of a thorough maturation of the wood. This is best effected by their removal to an intermediate house. In the case of Allamandas planted out, they should receive as much air and light as is compatible with the health of the other inmates of the structure in which they are growing, for although it is not difficult to induce a strong growth, it must be borne in mind that perfect maturation of the wood is the grand essential for the production of an abundant bloom.

*Bylect.*

J. CORNHILL.

**Ixias in Pots.**—Few spring-flowering bulbs give so little trouble and are at the same time so full of grace and beauty as these; either in pots in the greenhouse or in frames, or in protected beds merely for their flowers for cutting they are alike valuable. They should be potted freely in autumn, six bulbs in a 6-in. pot, in sandy loam and leaf-mould; place the pots in a cold frame or on a shelf in a cold part of the greenhouse; keep the soil dry at first, but give water more freely when the plants are in full growth. In April most of the varieties will flower, and will be very useful, as they are quite different in appearance from most plants at this season. When they have done flowering gradually dry them off, and allow them to rest till autumn, when they should be re-potted as before.—E. HODDY.

**Shakespeare's Own Garden.**—Every one who, under the tuition of the Rev. Mr. Ellacombe, has learnt something of what gardens and gardening were in the time of Shakespeare, will, I think cordially agree with the following passage from the "Athenæum" of March 23:—"Before passing from Shakespeare, we should like to call the attention of the directors or managers of New Place to the absurdity of the garden, which they are supposed to keep up in remembrance of Shakespeare. We chanced to visit it last summer, and, instead of finding an Elizabethan garden with flowers associated with Shakespeare and his times, we saw little but a miserable ribbon border of starveling Calceolarias, scrubby Pelargoniums, and miserable Perillas. Such a garden is a mockery, and would be more suggestive and more pathetic if left wild to the growths of Nature." It is very satisfactory evidence that a salutary turn has taken place in the tide of public taste, when a purely literary journal, such as the "Athenæum," speaks thus, whatever a clique of geometrical garden, clippers may say to the contrary. In the same article occurs the following additional testimony:—"The English garden of to-day still awaits its laureate, and, except where, in Mr. Allingham's 'Therapia,' 'Vase and plot burn scarlet, gold and azure,' we scarcely know of a description of modern 'bedding out,' and we sincerely hope that the present fashion may disappear before the thankless task is undertaken."—G. S. BOULGER, 11, Burlington Road, W.

**Produce of the Seed of Variegated Phormium tenax.**—It is a very singular fact that whereas the seedlings of *Phormium tenax variegatum* all come up green, and nearly devoid of any variegation whatever (see p. 335), those of the beautiful *Phormium Colensoi* invariably come up all white or cream-coloured; and, being totally devoid of chlorophyll, or the necessary life blood of plants, cannot live, but necessarily dwindle away and die after they reach the second or third leaf from the seed leaf. Why these seedlings, being thus destitute of life blood, should thus vegetate or come up at all is a problem yet to be solved.—W. E. G.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### GRAVEYARD GARDENS.

WITHOUT endorsing all that "A. D." says in reference to this subject (see p. 334), I think he has done well in calling attention to it. Sooner or later the subject must have an interest for everybody. I write only as an inquirer, and I shall be very thankful for any hints or corrections that may be given to me. In working out the problem, however, and wishing (to use "A. D.'s" language) "by the culture of flowers to perpetuate a sentiment for the dead which should ever be that of fond remembrance," I would suggest that the following points be attended to: 1. The plants chosen for this sacred use should be of very easy management, for those which are not so will very soon die, or at all events look unsightly, in our hot and parched cemeteries, or in our too often ill-drained and ill-kept churchyards. 2. They should be successional. If there be any pretence of growing flowers over a grave, there never ought to be a time during the whole course of the year when there is not some fresh blossom springing into life. This can easily be managed, but it requires that there should be a proper selection of plants; and there must be relays of some of them in pots in addition to those which remain continually in the ground. 3. The flowers ought as much as possible seem to be growing naturally in the soil, and not just stuck in in a careless, or even in an artificial manner. 4. There ought, I think, to be no glaring colours or startling surprise where our dear ones are lying. No ribbon border is admissible for a moment, but only that which is soft and tender should be used. Though it cannot always be so through the year, yet white should predominate as much as possible over every colour. Drooping flowers are by far the best for a grave. 5. Plants of a compact habit should be chosen, for the space is small; and one plant should never crowd out another. This makes bulbs to be especially eligible, as they can be so easily taken out of the ground and put back again. If these ideas are right, I should be thankful for the names of any desirable plants and bulbs for this purpose, and especially of those which would not occur at once to one's mind. It is easy to think of this plant or of that, but I want to make out a list of those which meet all the five requirements which I have named in the highest degree. The Snowdrop is, of course, just what is wanted, and *Galanthus Imperati* is better than any other species that I know of for use in this way. *Triteleia uniflora*, *Fritillaria Meleagris alba*, *Scilla nutans alba*, *Allium neapolitanum*, *Viola semperflorens*, and *Convallaria majalis* are all appropriate, and succeed with but little care. *Anthericum Liliastrium majus* is an incomparably beautiful and pure white flower, which will soon be coming out. *Lilium longiflorum* and *L. candidum* will do in some places; *Gladiolus communis albus* will be very helpful in summer, and *Cyclamen hederifolium album* will follow in the autumn, with *C. Coum album* to come after and blossom in mid-winter—even while the snow is on the ground. Some of the Hellebores might be added if they could be kept within bounds. I would just say that in my opinion the white Bluebell (*Scilla nutans alba*), which is in blossom at this time, is as good as any plant that can be named for the resting-places of the dead. Its drooping habit, which makes it look as though it were weeping over the grave—its few and easy requirements, and its compact way of growth, seem to say that it should always be found in the churchyard, though I do not remember to have seen it there in a single case. Let any one who mourns over the loss of those who are not lost but have only gone before study how he can best adorn their resting-places here with flowers, and I do not think it is at all out of place to say that his labour will not be in vain. E. F.

received seeds from a correspondent in Japan, bearing only the Japanese native name as above written. From it the Japanese extract the gum or oil with which they render waterproof the paper umbrellas, so much used by all classes of the natives of that country. He describes the culture of this plant as exceedingly simple and easy if sown during the present month in a frame, and, after being pricked off into pots when large enough, ultimately in the month of May or June planted out in the open border of the kitchen garden, where they grow very rapidly, and attain a great size. The flowers appear towards the end of August, and seed ripens thoroughly by the end of September, the plants remaining green till destroyed by the frost. This plant, which belongs to the Labiate family, attains a height of about 3 ft. 3 in., and the foliage is highly aromatic, resembling in appearance that of a gigantic form of *Ocimum Basilicum*. The production of seed would have been very abundant had not the high winds at the commencement of October greatly broken and damaged the plants; still, enough was saved to enable M. de Lunaret to offer a few to any reader of the "Révue" who would like to experiment with the plant, an offer of which, doubtless, many will avail themselves. It is not stated from what part of the plant the oil is obtained, but in all probability it is by crushing the seeds. Perhaps some of the readers of THE GARDEN who have been in Japan may recognise the plant, and be able to tell us more about it.—W. E. G.

### PRIMROSES FOR WASTE PLACES.

The Primrose is undoubtedly the most popular of all our native plants, and, I believe, has given its name to more localities than any other native plant. Every Cockney has heard of Primrose Hill, and I know of one in Shropshire and another in Cheshire, and there are doubtless others. Everybody, too, has read of the sensation caused by the first pot of Primroses which appeared in Australia, and the welcome given to the

well-remembered flower. There are four British plants that grow gregariously that may be said to be national, that is, that give a charm and a character to English scenery, viz., the Furze, when seen by the acre, clothing with gold many of our heaths and commons; the wild Hyacinth, or Blue-bell, covering, as it does, miles of our shady woods and forests; the Wood Anemone, silencing with its million stars our open woods and groves; and, lastly, the Primrose (with a colour truly its own), making the wilderness rejoice, and giving a charm to thousands of barren and waste places. The Primrose is a bank-loving plant, while its relative, the Cowslip, delights in damp meadows and pastures. The Primrose is most at home on steep clayey banks, scars, ditch banks, and sloping, open woods. In Cheshire and Gloucestershire I have seen miles of steep railway banks quite yellow with it. Where this plant exists in profusion, people must be content to see it in its wild state; but there are hundreds of steep banks, pit sides, and open woods, near drives, to which it might be effectually introduced, and its introduction would give a charm to many an otherwise uninteresting spot. Surely the Primrose, and not the Rose, should be the emblem of England! Everybody loves the Primrose, and more poetry has been written about it than about any other English flower. It is astonishing to see the tens of thousands of these plants that are rooted up and carried from the country to our large towns and suburban gardens. No matter how fine a garden may be, or how many flowers people may have, they always seem greedy as regards Primroses. If we go into the country on a fine day in spring, we are almost certain to meet the "squire's daughter," or the "young ladies from the rectory," with a trowel and a gipsy basket loaded with Primroses. Finding the first Primrose and hearing the cuckoo for the first time are among the pleasant events of the year. THOS. WILLIAMS.

*Ormskirck.*

New Japanese Plant, the Zi-Goma.—In the last issue of the "Révue Horticole" a correspondent from Montpellier, M. Leon de Lunaret, calls attention to the above-named interesting plant, of which he had

## NOTES FROM KEW.

**Outdoor Plants.**—Plants of this class are now making rapid progress. Almost daily, especially after warm rains, some fresh shrub or herbaceous plant may be seen in flower. As if by magic, the blossoms of the Greater Periwinkle (*Viola major*) have pushed their purple flowers above the winter carpet of shining green formed by the abundant growth of leaves. The remarkable mildness of the past winter is well exemplified in the shrubberies at Kew, for on all sides the flowering shrubs and trees are plentifully decked with blossoms. Of the numerous *Berberidaceae* shrubs in cultivation, always excepting *Berberis Darwinii*, referred to last week, *Mahonia fascicularis*, when well grown, presents a handsome appearance; its very large and dense clusters of yellow flowers, equally distributed all over the plant, and set in a background of reddish-green leaves, makes it a most useful and showy addition to any shrubbery. Amongst the *Scimmias*, *S. fragrans* is worth a passing note; in habit it is more erect and compact than *S. japonica*, while it produces its flowers with equal freedom. Dense masses of the peculiar *Orobanchaceae* parasite, the Greater Tooth-wort (*Lathraea Squamaria*) are now to be seen springing direct from the Grass at various spots, within a few yards' radius of the Temple of the Sun. In the herbaceous ground several of the *Boraginæ* are now looking their best. *Pulmonaria mollis*, a native of shady places in some parts of Europe, extending from Germany and the Pyrenees into Siberia, is a dwarf, compact plant covered with short, soft hairs, and well furnished with flowers, which are red before expansion and bluish-purple afterwards. Another species now in flower, and equally worth growing, is *P. caucasica*. Several species of *Iris* are now in flower in the border. *I. pumila* is a very dwarf form, with cream-coloured or dingy yellow flowers; it is a native of Central and South-eastern Europe. *I. virescens* also bears dingy white flowers, but *I. aphylla* is a much finer and more attractive species, the flowers being larger and of a fine purple colour. *I. biflora*, from Portugal, also bears purple flowers streaked with white. On the old rockwork are several good plants at present in flower. *Trillium grandiflorum*, with its large, three-lobed, shining green leaves, and its long, pure white flowers, is very ornamental, as are many of the *Primroses*, notably amongst them being *Primula denticulata*, an East Indian species, with a clustered head of small purplish flowers borne on a slender stalk about 8 in. high. *P. oiliata* var. *purpurea* is a dwarf species, with large purple flowers on a very short stalk. A very fine plant for damp situations is *Caltha radicans*; it forms a good compact mass of foliage, and is well covered with large yellow flowers.

**Greenhouse Plants.**—A very ornamental plant for a cool house is *Lavandula dentata*; its leaves are oblong, linear, or lanceolate, bluntly and pinnately toothed, and covered with a short pubescence. It bears loose spikes somewhat tufted at the apex, and the flowers are purple, somewhat similar to those of *L. Stœchas*. The plant is a native of Southern Europe and the Mediterranean region, extending into Northern Africa. *Cornilla glauca* is a plant always worth growing for the sake of its compact shrubby habit, its small leaflets, and its numerous yellow flowers. *Cytisus canariensis* is another Leguminous plant equally ornamental. *Gnidia carinata*, a *Thymelæaceae* plant from the Cape of Good Hope, is also attractive on account of its bunches of yellow flowers, as is *Epacris miniata grandiflora* for its reddish-pink, white-tipped blossoms.

**Stove Plants.**—In the new range climbing up the rafters of the roof several species of *Clerodendron* are finely in flower. Besides the well-known white and red flowers of *C. Thomsonii*, *C. splendens*, a *Sierra Leone* species, attracts notice for its dense masses of brilliant red blossoms and its thick deep green leaves. *C. volubile*, a native of New Guinea, is also very attractive for its white flowers, which have a tinge of pink in the throat, and long recurved and twisted stamens. The showy flowers of these plants are well set off against the deep opaque green of the leaves of all the species. The singular gonytistemmed *Euphorbiaceae* plant *Jatropha podagrica* is more remarkable than beautiful; nevertheless, the orange-red flowers are sufficiently handsome to make it useful for mixing with other plants. Most of the *Gardenias* are well worth cultivating for the extreme beauty of the flowers as for the delicious perfume emitted by them; and *Gardenia intermedia* is no exception to this rule, the flowers being about 1½ in. across and pure white. A decided contrast to this, but equally beautiful from another point of view, is *Scutellaria pulchella*; from the habit of growth, the healthy green of its leaves, and the long spikes of fine blue labiate flowers it has much to recommend it. Amongst *Achimenes*, *A. longiflora alba* is a good variety; its flowers are white, prettily streaked with purple, with a dash of yellow in the throat. Another attractive *Oscareaceae* plant is *Soldanella digitaliflora*; it is fleshy-green throughout, covered with soft hairs, the tube of the flower reddish on the upper side and white on the under; the five lobes of the corolla are folded quite back on the tube, and are of a

light green colour, dotted all over with brown spots; the bifid light green stigma projecting considerably beyond the mouth. Among *Mesembryanthemum* there are but few yet in flower. *M. filamentosum*, however, attracts notice for its numerous, flesh-coloured, star-shaped blossoms. In the *Cactus* house, *Bulbine latifolium*, a *Liliaceae* plant from the Cape of Good Hope, has long spikes of delicate yellow flowers. In this house, also, is a fine-flowered plant of *Sempervivum aureum*. It is a native of Tenerife, and bears its golden-yellow flowers in tufts or heads at the ends of long, fleshy stalks. *Libertia formosa* is a fine *Fridæaceae* plant, with long, Grass-like leaves, and white, three-parted flowers, borne at the end of long spikes. It is a native of Chili. In the *Economic House*, *Carica cundamarcensis* is both in flower and fruit. The plant is almost of the size of a small tree. The flowers are green and inconspicuous, and the fruits are, when ripe, of a yellow colour, about 2 in. long and 1 in. thick, five-lobed, and pointed at both ends. It has an agreeable perfume, and a sweetish, Pine-apple flavour.—†

**Linum candidissimum.**—In a recent contribution to THE GARDEN by Mr. J. C. Niven, on the Alpine and dwarf species of *Linum* (see p. 261), a reference is made to the above plant which is likely to mislead your readers, and which, as no one else has yet drawn attention to it, I beg permission to point out. It is stated in the paper in question that *L. candidissimum* is of South European origin. Considering that the plant is, as Mr. Niven states, undoubtedly but a slight form of the New Zealand *L. monogynum*, the name being a mere garden appellation, it would be a very remarkable thing that the two varieties should occur in localities wide as the Poles asunder. But, as a matter of fact, they are both natives of the same distant islands. About the time the seeds of *L. candidissimum* was first offered, or soon after, I procured a packet of Mr. Arthur Henderson, of the Pine-apple Nursery, who personally informed me that he received the seeds from a surgeon residing in New Zealand. As I have found it harder than the typical *L. monogynum*, it is not improbably a native of the Southern Island, but I have no direct information on that point.—W. THOMPSON, Ipswich.

**Our Woodland Primroses.**—Just at the present time acres of country are completely carpeted with *Primroses*, and no one who cares to admire their quiet beauty can fail to be impressed with the manner in which native plants establish themselves in positions suitable to their individual wants. Even the *Primrose* in its uncultivated state is far better located than it is in gardens. The soil in deciduous woodlands, where *Primroses* are at home, is invariably surfaced with Moss or dwarf herbage that effectually preserves the delicate blossoms from being splashed by heavy rains, while as yet almost leafless branches shelter them from rough withering winds, conditions difficult to obtain for cultivated varieties. I have lately observed some very fine varieties of the wild *Oxlip*, or what is locally called in some places *Ladies' Fingers*. These are usually found growing with the *Primrose* under partial shade, while the *Cowslip* invariably locates itself on open greensward. At this Easter season the common *Primrose* forms one of the most pleasing and natural-looking objects in church decorations, now so universally carried out about this time. Beds of Moss on window-sills, or at the base of the font, with large bunches of *Primroses* gathered with their own foliage interspersed, have a very pretty effect. Tin or zinc tubes for holding water are inserted in the Moss, and in the still atmosphere and subdued light of a church the flowers maintain their freshness and sweetness for a considerable length of time.—J. GROOM, Henham.

**Asparagus in English Gardens.**—THE GARDEN is none too soon in taking the matter of *Asparagus* culture in hand, for there is nothing in the way of vegetable growing in this country that so much needs popularising. By the million, *Asparagus* growing is always regarded as involving a vast amount of labour and expense, a task only to be undertaken by the initiated, and by those to whom expense may be no object. Hence the reason why this delicious esculent is commonly regarded as a luxury. *Asparagus* should be in every garden, and would be if it were generally known how simply it may be grown. Many defeat their object by excess of pains at planting time. An instance of this came under my notice, where money and labour were expended in the production of a huge mound of earth and manure upon which the plants dried up. This mistake originated in the belief that something must be done in a very exceptional manner in order to ensure success. Had the operator only known that he needed merely to draw a drill, and set his plants therein, relying upon after care and management, he would have certainly been spared much expense and mortification, and would have had plenty of *Asparagus*. It is to be hoped that the prizes now offered may tend to dispel the general illusion respecting the difficulties attending the production of good *Asparagus*.—J. CORNHILL, *Duffield*.

## NOTES OF THE WEEK.

**The Rosemary in Spring.**—This shrub is not without value in ornamental planting, and yet it is almost confined to cottage gardens and the herb garden. Some spreading bushes of it now in flower on a bank in the pleasure grounds at Kew, and associated with some bushes of the Double Furze, have a very pleasing effect. This is apparent at some distance, notwithstanding the modest colour of the flowers when examined individually. In the position above named the plant spreads naturally on a Grassy bank, and not on one of those ugly ding surfaces on which no shrub ever can look happy.

**Narcissi at South Kensington.**—Messrs. Barr & Sagden's collection of Narcissi exhibited the other day at South Kensington deserves more than a passing notice. It was the finest and most complete display of its kind possibly ever made in this or any other country. In addition to the better known sorts, there were numbers of fine varieties, many of them real gems, with which the gardening world, as a whole, have but a very limited acquaintance. The delicacy of their tints was only equalled by their fragrance. The exhibition will, I understand, be repeated at the next meeting.—B.

**Caltha palustris minor fl.-pl.**—Under this name we find one of the best varieties of Marsh Marigolds with which we have yet met. It is dwarf in habit, and will stand transplanting without fear of injury. Its flowers are very double and of a showy golden-yellow, and for spring gardening it is, without doubt, the best yellow-flowered plant which can be grown. It is, of course, perfectly hardy, and requires a moist, deep soil. If plants of it be divided in autumn, winter, or spring, it grows freely, and yields a profusion of blossoms for months. At this time of the year all soil is moist generally, and its early flowering character renders it a most desirable plant. It is now flowering freely in Mr. Parker's nursery, at Tooting.

**Dendrobium Falconeri.**—Amongst the different families of Orchids none surpasses in beauty and elegance the genus *Dendrobium*, a genus in which *D. Falconeri* stands at the head, possessing, as it does, a combination of colour and form unsurpassed by any known species. Usually, however, it is a shy bloomer, but, seen as it was represented by a plant in Mr. B. S. Williams's fine group exhibited at South Kensington on April 16, it is one of the most charming subjects ever produced. The plant in question was, as usual, growing on a long thin block or piece of cork, and its small, delicate, drooping, Grass-like, pseudo-bulbs were literally clothed with such a number of flowers as to have the appearance, a short distance off, of a wreath of blossoms suspended in the air. When flowered as this plant was nothing could be more beautiful.—B.

**Hardy Shrubs for the Conservatory or Dwelling House.**—While endless trouble and care are bestowed upon many tender plants, and those difficult to cultivate, in order to bring them to the highest state of perfection, for the embellishment of our conservatories or entrance halls, many of the most effective and most easily grown plants are lost sight of. The group of hardy flowering shrubs shown by Messrs. Veitch & Sons, at South Kensington, on April 16, served to show how even the commonest plants may be made to play an important part in decoration. The white and scarlet, single and double-flowered Thorns, the common Laburnum, Lilacs, and Rhododendrons are easily cultivated, easily brought into bloom early, and for effect they are equal to many of the choicest greenhouse plants. Then there is the *Wistaria*, the beautiful *Magnolia conspicua*, Almonds, Prunuses, and which any one having the most meagre means may grow. With these might be associated many of the hardy Irises, Gentians, Saxifrage, Anemones, Daffodils, and other hardy flowers, and any one having even such a small glasshouse might make one of the best possible displays in spring, at little cost and still less labour.

**The Royal Horticultural Society's Fortnightly Meetings.**—The adverse influence of a previous indifferent reputation has seldom been more unmistakably apparent than in the extremely meagre attendance of the public at the Royal Horticultural Society's fortnightly meetings which have been held during the present spring. Apart from the one or two principal shows held each season, there has never hitherto been anything to equal the rich, varied, extensive, and thoroughly interesting displays now brought to South Kensington at the fortnightly gatherings, and which are likely to be continued, if the subscribers and the public generally will only show by their presence that the meetings are appreciated. But it is uphill work both for the Society and the exhibitors, private as well as commercial, who evidently strip their establishments of all that is attractive in the shape of rare and costly Orchids, stove, greenhouse, hardy plants, and forced shrubs, comprising, as they do, quantities of beautiful plants that are not, and never can, be seen later in the

season. At the last three meetings, especially in the large Conservatory, there has been such a display as has never at this time of the year been made before. Some six or eight of the leading nurserymen exhibited groups so varied and extensive, that any one of them would well have repaid a visit. Yet the visitors came not, and the reason is not far to seek. For some years, at these fortnightly meetings, prizes were given for particular plants then in season, the competition for which was often of the most miserable description; frequently in half the classes in which prizes were offered there were no exhibits, yet these meetings were dignified by the name of shows, and were advertised and placarded accordingly. People came, and after seeing the ridiculous little that was to be seen, often asked, in their solicitude, the way to the show. I have heard many complain, in anything but complimentary terms, not only of the money spent for admission, but also of time lost, and those who said nothing generally bore on their countenances that silent protest quite as ominous as words. Such people naturally kept away afterwards and recommended their friends to do the same. It is, however, to be hoped that those who take a delight in flowers, especially the many beautiful subjects that are forthcoming early in the season, will now support the Society in its endeavours to make these meetings both interesting and instructive.—T. BAINEZ.

**The Variegated Single Kerria.**—*Kerria japonica variegata*, the single-flowered form now in flower in the winter garden at Kew, is one of the most charming of bushes for a cool greenhouse or for planting out in the conservatory. The effect of the numerous golden flowers among the silvery leaves is quite novel.

**Winter Garden for Sweden.**—Messrs. Shanks & Son, of Arbroath, have for some months past been engaged in constructing a winter garden for Gothenburg, in Sweden. It consists of five separate houses, composed of iron and glass, into which the Palms of Africa, the rare exotics of the Tropics and Australia, the Lilies of Equatorial lakes, and a miscellaneous collection of plants will all be placed, each house being heated to a temperature corresponding with that of the countries to which the plants are indigenous. Two of Messrs. Shanks' boilers connected in nearly 2 miles of 4-in. pipe, will be used in heating the houses; while about 40,000 ft. of glass will be used in the roofs and sides. This structure has been designed by Messrs. Shanks, and the material weighs in all nearly 200 tons.

**Wood of Wellingtonia.**—Specimens of the wood of this tree, smoothly planed and varnished, have been sent to us from the gardens at Pain's Hill, Cobham, Surrey, by Mr. Clements. They are exceedingly light for their size, and prettily grained, but the wood, being somewhat knotty and otherwise faulty, does not seem to be of much value as timber. The specimens in question are, however, interesting as examples of home-grown Wellingtonia wood.

**Cinerarias at Forest Hill.**—Messrs. Carter & Co. have sent us, from their Crystal Palace Nursery, out blooms of Cinerarias, as examples of their "strain" of this popular decorative plant. They consist of excellent kinds, with rose-coloured centres, surrounded by white, and broadly margined with brilliant crimson and other colours. One bloom measured 2½ in. in diameter. The selfs were especially good, the colours in some others being of the deepest blue, purple, and magenta, whilst in others they are pure white with a rosy centre. For furnishing out blooms these selfs can be highly recommended.

**The Waverley Market Flower Show in Edinburgh** seems to have been a great success, judging from photographs of it which have been sent to us. They represent a spacious hall 336 ft. in length, and 122 ft. in width available for the show, the total length being 356 ft., and the width 150 ft. In a building of such large dimensions, and well lighted from above, the show, which was an unusually good one and well arranged, had a fine effect, and visitors could see it without being uncomfortably crowded. Flowering and fine-foliated plants were abundant, and there were two fine collections of Conifers—one from the Lawson Seed Company, the other from Messrs. Methven & Sons.

**Saxifrage purpurascens.**—This rare Saxifrage is now in bloom in Mr. Parker's nursery, at Tooting. It is dwarf in habit, its foliage is compact and of a glossy green, and its flowers, being of a bright purple, and produced in masses on stout stems 6 in. or 8 in. in height, render it one of the most valuable Saxifrage for border planting which we possess. It is perfectly hardy, and should therefore become popular.

The number of visitors who paid for admission to the gardens of the Royal Horticultural Society at South Kensington on Easter Monday was 6792 at 2d. each.

### QUALITY *v.* QUANTITY IN PLANT CULTURE.

It is a fact well-known to all lovers of horticulture that well-grown plants, both large and small, are no rarity in this country. A visit to any of the London or large provincial exhibitions, or a glance into any large nurseryman's establishment, will prove that no pains are spared to ensure perfection of growth. In the case of those who grow for sale it is easy to understand that every effort should be made to secure a saleable article, and it is in order to facilitate this object that growers for market are apt to drift into specialities; and a man naturally concludes that if a plant pays him in a small quantity, it will pay him still better if grown upon a larger scale, and he finds that by restricting himself to certain species or genera, he is enabled to so arrange his accommodation as to meet, with the smallest amount of trouble, the peculiar wants of those plants which he may desire to cultivate. In private establishments, where variety is wished for, it is not easy to ensure to each plant those conditions which are most favorable to it. In large places, where there is but scanty accommodation it sometimes taxes the resources of the grower to the utmost. There is, however, one mistake which is often committed, and that is, needlessly multiplying the number of subjects grown. It often occurs that, because a plant happens to be more than usually pretty or striking, that a good lot of cuttings are made to ensure a stock. A good strike being sometimes the result, they are all grown on until it is found that there is not sufficient space for them to develop healthfully. In that case the proper course would be to sacrifice some to ensure the future welfare of the remainder. But oftener the natural reluctance to discard anything in the shape of a healthy plant prevails; they are all kept growing on, and the consequence is a tangled and weedy growth. I have often seen houses crammed in this fashion, not a single plant showing its true character, where the weaker-constituted must eventually succumb—a true case of the "survival of the fittest." Crowding is always bad policy, whether applied to fruit or flower culture; it is certain that whoever may practice it will inevitably pay the penalty in a diminished or inferior produce. How much more satisfactory to possess one plant, sturdy, full of healthful foliage, and, if of a flowering nature, covered with a well-developed bloom, than a number of weakly, debilitated subjects, none of them conveying any true idea of what the plant should really be. And then, again, if we turn to fruit culture, taking, for instance, the Strawberry, the great object would often appear to be to introduce as many plants as possible in a given space. How mistaken this system is anyone may readily convince himself. Take any number of plants, and divide them into two equal portions; the one half shall stand so that they never touch each other during the growing season, the others to be allowed to intermingle their foliage to some extent. Let the produce when gathered be compared and weighed, and the evils of crowding will at once become apparent. There is one rule by which every plant grower may be guided, *i.e.*, keep each plant perfectly free from its fellows; as, even if the full sun and light cannot be admitted to each portion of it, a constant circulation of air is maintained around it, without which substance and vigour cannot be maintained. Those who possess but a limited space for the shelter and growth of plants in pots should be very firm and resolute in this respect; better far to throw away a few plants (which, however, is not at all necessary, as plenty may always be found to whom the gift of a plant is a boon) than, by retaining them, run the risk of spoiling the entire collection. It often occurs that, owing to the efforts at propagation, in which most amateurs delight during the summer, there is at housing time some difficulty in finding proper accommodation for everything. It is then that the great mischief is committed; the plants, looking young and fresh and sturdy, are placed upon the shelves and stages in close and serried ranks. The immediate effect is, of course, charming; a bank of verdure is formed, which looks pretty well up to the time when the days come to their shortest, and inclement weather precludes the possibility of thoroughly ventilating this closely-packed mass. Then comes damping off; the under foliage in some instances dies away, and even plants of a hardier nature become so weakened that they cannot come up to time when the growing season again arrives. Many have to be weeded out and consigned eventually to the rubbish heap. How much better to have made a more vigorous selection at housing time, when each plant, getting its fair amount of air and light, would have been preserved in good health, and would have been a source of real pleasure! One or two plants of a sort will as well afford variety as a larger quantity, and the smaller the amount of glass possessed the more thorough and resolute must the selection be. A collection of the most varied nature, in which hard and soft-wooded plants are indiscriminately mixed, may be kept up in good health by simply attending to these rules, which will equally apply to stoves, Ferneries, &c., as to the ordinary cool greenhouse. Many of the more tender inhabitants of

warm houses fail to preserve their vigour and fresh appearance during the winter owing to their not having received sufficient air and light during the growing season. In the way of bedding plants, where grown upon a large scale, it is much more satisfactory to grow sturdy, bushy plants, each one of which, when planted out, is in a great measure made, and, being full of vigour and health, becomes quickly established, and makes an effect at a much earlier period than small, weakly plants could possibly do. In this, as in every other branch of plant growing, the best policy will be found to consist in systematically placing a restriction upon the quantity, so that the quality may be thereby improved. J. CORNHILL.

*Byfleet.*

### POTTING AND TREATMENT OF CAMELLIAS.

It is sad to see Camellias in a sickly state. I do not know whether it is owing to the way in which the plants are propagated or to early mismanagement, but it is a fact that vast numbers of plants, especially imported ones, die after they are sent out of the nursery, in spite of all that skill and good management can do for them. There are two periods at which the Camellias may be shifted or re-potted, and about which some difference of opinion exists. Here I can only point out the advantages and disadvantages of the two plans. One is to pot the plants as soon as they have made their growth, and before they have matured their flower-buds; and the other is to pot before they have begun to grow, and not when the plants have done flowering. For my part, I prefer the first plan, because growth buds are insured before the plants are meddled with; while by the second plan, unless the plants are very vigorous, there is a chance of their making feeble growth, not to speak of possible accidents. However, both plans succeed well enough in good hands, or when the shifting of the plants is intelligently performed. As to compost, there are plenty of fine examples of Camellias to be found growing in pure, or almost pure, loam, which should in all cases form at least the staple of the compost, and perhaps equally good specimens are to be seen in a compost consisting of loam and peat, or loam and leaf-mould, or all three together. It has yet to be proved, however, that the Camellia naturally grows in anything else but loam with what manure is afforded by the annually shed leaves of the plants, and of the trees under the shade of which they thrive in their native habitat. As regards the operation of potting or transplanting, it should be performed with great care. It should first be ascertained whether the roots are dry in the centre of the ball—a thing exceedingly likely to occur in the case of old pot-bound Camellias; and, if they are, the whole ball of roots should be immersed in a tub of water, and left to soak for four and twenty hours, or longer if necessary. Afterwards the plant should be lifted out, and the ball allowed to drip in some shady corner till it is in a fit condition to operate upon and pot. If the roots are found to be abundant and active at the outside of the ball, they must not be molested much, but the soil may be loosened all over with a blunt peg, just to disentangle the rootlets and induce them to push into the fresh soil. Should, however, the roots be poor and decayed, the effete soil should be carefully removed until active roots are found in considerable quantity. The plant should then be potted in a smaller pot than before; but I do not consider it advisable to reduce Camellia roots in this way under ordinary circumstances. In potting, the soil should be made tolerably firm under the roots and rammed, not hard, but with moderate firmness, round the sides, taking care to leave plenty of room for watering. In tubs and large pots we leave from 2 in. to 3 in., and in smaller pots seldom less than 1 in. Much depends on this, as we have invariably noticed that the work of watering is much facilitated by providing as much space for water as will soak the roots thoroughly at one watering, instead of at twice or three times, supposing the man in charge to take the trouble to go back over his plants so often on the same day, when he has many other things to attend to. If possible, rain water should be given to Camellias, and it should at all events be free from lime. Liquid manure may be given, weak and often, to healthy-growing plants that are known to have plenty of healthy roots; but weakly or newly-potted ones are better without it for a time. Under ordinary circumstances the Camellia needs no special treatment, but will grow and thrive well in an ordinary conservatory or greenhouse where the temperature does not often fall below 40° or 46° in winter, nor rise above 80° in summer. As to shading, I have a conviction that the sun's rays should never directly reach the leaves of the plants at any time, but should always be broken by a thin shading of some kind. We paint the glass in April with whitening, inside if possible, where it will not be washed off, and leave it on till November. In one of the finest houses of Camellias with which I am acquainted the roof is glazed with obscured glass, and that is all the shade the plants get. J. W.

## THE FRUIT GARDEN.

## JOSEPHINE DE MALINES PEAR.

In a recent number of *THE GARDEN* I was pleased to find a few brief notes on some of our more popular winter Pears. The figures are quite accurately drawn, and serve equally well for the respective varieties as grown here. At the head of the list your correspondent places the Josephine de Malines, and it is of this only that I shall now speak. He calls it "a real good Pear" and "the best," and so I think it is in this country. It is, perhaps, not as well known here as with you, and yet we have grown it for many years, although its general dissemination has been singularly slow, and to-day it is quite rarely found in American gardens. But, wherever known and rightly managed it is highly esteemed. Some of the finest specimens of it which I ever saw grew in my grounds here on the Hudson River, a few measuring  $3\frac{1}{2}$  in. in diameter, and weighing over 9 oz. In shape it is flattish conic oblate, irregularly undulated, and frequently approaching hexagonal in the largest specimens; skin yellow when ripe, and minutely and evenly dotted with russet. When perfect it often wears a tempting blush of delicate, inviting red. The stalk is 1 in. or more in length, stout, and obliquely set in a slight cavity; basin large; calyx open; flesh light salmon in colour, especially toward the centre, buttery, sweet, melting, aromatic, very juicy, and having a most exquisite flavour that lingers to bewitch the palate. Many of our pomologists regard it as an early winter sort, but I find no difficulty in keeping it far into April, and even until May, in fine eating condition. As I now write, April 6, I have some fine specimens of it that show no signs of decay. It is, however, very important that the fruit should remain on the tree as long as possible, and then be gathered very carefully and placed in a cold, darkened upper room. In fact, all winter

fruit should be kept in a dry, cold atmosphere—just above the freezing point if possible; it will thus remain unchanged for months; and in the case of Pears, when needed for use, so many as are wanted should be placed in a moderately warm room and kept in the dark, when in a few days it will be found beautifully coloured, and very luscious. In packing, it is well to use dry chaff, fresh dry Maple leaves, or some similar inodorous absorbent, not allowing the fruits to touch each other. No winter Pear can be properly ripened for eating without some care, and doubtless many of our best varieties are thus either indifferently regarded, or unjustly condemned. The tree is commonly a rather slow grower, though very hardy and a great bearer; and yet I have it on large stocks where it grows vigorously enough. It is best, therefore, to work it on vigorous, thrifty roots. The wood is light coloured and close jointed, and a great point in its favour with us is its entire freedom from blight. The fruit is borne in clusters, and a well-laden tree presents a fine appearance during the autumn months.

Kingston, N.Y., U.S.A.

H. HENDRICKS.

**A Palmette-Verrier in Bearing.**—This is a form of tree considered very good for strong soils, and also sometimes for kinds that will not do well on the Quince. In such cases the small forms, such as the cordon and the trees with a few branches trained upright, are not large enough. This Palmette, which, to a very great extent,

has replaced in France the old horizontal tree, is considered one of the best of the large forms. The engraving is from a photograph of a specimen about ten years old, growing in M. Jamin's garden at Bourg-la-Reine.

## THE INDOOR GARDEN.

## ROOF AND WALL CLIMBERS PLANTED OUT.

CLIMBERS form a by no means unimportant feature in conservatories and plant houses, inasmuch as they not only ornament portions of such buildings which could not in any other way be utilised, but, by careful training, they may also be made to act as a partial shade to subjects grown beneath them that require some such protection from bright sunlight. Artificial shadings are all more or less unsightly, and in the case of curved roofs difficult of adjustment. But a living screen may be cut in close before winter, so as to admit a maximum amount of light when most required; or it may be carefully thinned and trained during the growing season, so as to modify or subdue the sunlight to suit the requirements of the various inmates. Wires for training the main shoots should be fixed at regular distances apart, but all appearance of formality should be obviated by allowing a good proportion of the current year's wood to hang down.

Long, pendulous sprays of such subjects as *Passiflora princeps*, *Tacsonia Van Volkxmi*, &c., have a lovely effect, and are seldom destitute of bloom. But the subject to which I wish particularly to direct attention is the advantage of planting out such climbers in an unlimited root-run compared with the restrictive root system attending their culture in tubs or boxes. It is surprising that we should find such unsightly objects either tubs or boxes in houses of modern construction; yet they are not uncommon, and all sorts of screens have to be extemporised to hide

Pear Tree in Palmette-Verrier form.

them, while they would be much better sunk below the ground-level. By making provision for the roots of climbers when the house is first made, as is usually done in Vineries, a permanent root-run is secured, in which the plants grow more vigorously than they would in boxes or tubs. The latter, too, wear out and fall to pieces just as the roots get well established; and, except great precaution be taken as regards a regular and abundant supply of root moisture, insect pests will multiply very fast, owing to the plants being predisposed to their attacks through their growth being checked. Another advantage also attends the planting out of subjects of a permanent character in house decoration, and that is, that the quantity of soil will in a great measure compensate for its quality, for whereas in the restricted area of pots and tubs one is compelled to supply a rich compost to many plants, the same subjects, if planted out in soil of a medium quality, will grow with surprising luxuriance. I am aware that over-luxuriance in many cases tends more to leaf growth than the production of flowers, but if I did dispense with tubs and boxes I would provide bricked compartments, by means of which the roots could be partially restricted, if that were needed, or special provision could be made as regards soil and treatment and the application of moisture equally well as in tubs or boxes, the presence of which detracts from the general effect, and they occupy space that could be more usefully and ornamentally utilised. JAMES GROOM.

### ROSES FOR EARLY WINTER FLOWERING.

Pot Roses that are managed with a view to produce the earliest flowers in winter under glass, that is, such as are well furnished with unexpanded buds out-of-doors in open quarters before being taken indoors, need little forcing; they simply require the protection of a house or pit, slightly above the temperature of an ordinary greenhouse, to induce them to expand. Where Rose flowers are required all the year round there are none that play a more important part than these, filling up as they do the gap between the latest-opened flowers produced out-of-doors and those that come in under the influence of more heat later in the winter. The ability of the plants under consideration to produce flowers at the time required will, in a great measure, depend upon the way in which they are treated at this time of the year. The flowers which they furnish, as will be evident, are not the production of wood made after they are taken under glass subsequent to being more or less pruned, but simply the result of matured buds already formed, with no pruning at all practised in the autumn, this being deferred until the present time. The plants, when done flowering, are removed to a cold pit or house, where they will more readily receive protection. They should now be pruned, the operation being confined to cutting out all weak, worthless wood and shortening the strong shoots proportionate to the size and strength of the plants, remembering that the larger they get the greater the amount of flowers they will produce, and that a score of good specimens in 11-in. or 12-in. pots will furnish not only a far greater amount of flowers than almost an unlimited number of small plants, but that the proportion of large blooms is much greater than from plants of smaller size.

**Potting.**—After being pruned, all that require it should be potted at once, giving more root-room where needed. The soil used should be strong loam with a sprinkling of sand and some good rotten manure, but no leaf-mould or light material, such as is sometimes employed, and which is quite unfit for Roses. See that the drainage is sufficient and well secured against the soil getting down into it. In potting these, which will principally be Tea varieties, it is scarcely possible to ram the soil too hard, neither must the pots be filled so full as not to allow sufficient water, of which they will require a daily application through the summer, enough being given to moisten the whole at once. All such plants as do not need larger pots should be turned out; the drainage should be examined, and as much of the old surface soil should be got away as can be done without interfering with the roots, replacing it with new material, which should also be well rammed in, so as to make it quite solid. Previous to potting the plants would be all the better for being laid on their sides and syringed freely with Tobacco water, to which has been added some Gishurst. I have found this the best wash for Roses, as it not only kills green fly and red spider, but the sulphur which the Gishurst contains is equally destructive to mildew.

**Treatment after Potting.**—The plants, after being potted, should be placed in a cold pit, deep frame, or under the protection of loose lights, in a warm, sheltered position, where they will commence growth, gradually exposing them fully to the air as the roots begin working in the new soil. Later on they should be plunged in a good bed of ashes, sufficiently far apart to prevent any crowding, and to permit of their being attended to with water; the plunging is necessary to prevent their drying up so quickly through the summer, which would occur if the sides of the pots were exposed to the sun and air; there should also be 3 in. or 4 in. of ashes under the pots to prevent the ingress of worms. I much prefer coal-ashes to Cocoa-nut fibre, spent tan, or other material frequently employed, as all these afford a harbour for worms, which the ashes do not. Roses, more than many plants, appear to suffer by their presence in the pots. A few of the strongest branches should be bent down and tied out in a way that will cause them to break from the lower eyes and keep the plants in shape, not with a view to their being formally symmetrical, but so as to induce the production of strong wood from the base, and admit of air and light getting through each plant. As the whole object with this portion of pot Roses is to furnish flowers at the time already stated, all buds that make their appearance through the summer should be picked off as soon as they are formed. The plants must receive regular attention as to the root moisture they require, and should be liberally supplied with manure water, so as to induce the formation of all the strong wood possible; to still further encourage this, insects and mildew must be assiduously sought for and destroyed.

**Potting Autumn-struck Roses.**—Rose shoots taken off early in autumn, and at that time made into large cuttings 6 in. or 8 in. in length, and inserted deeply in cold frames, will by now, if all has gone well, have formed a considerable amount of roots. Those that are required for pot purposes should be taken up very carefully, so as

not to break their newly-formed fragile fibres, and at once potted; 5-in. pots will be large enough, draining them well, and using the soil a little lighter and more sandy than such as is advisable when the plants have got better established, at the same time making it firm. As the plants will have pushed their shoots a considerable length, they should for a few weeks yet be kept in frames, gradually giving more air as the roots lay hold of the soil, and when they are fairly established transfer them to the open air, plunging them in ashes, as recommended for the large specimens.

**Layering Roses.**—One of the chief objections raised against Roses on their own roots is the longer time it occupies to get strong plants, though this does not occur when strong large cuttings are used, put in in the autumn in the way that I have advised; but there is no means by which stout-blooming plants on their own roots can so quickly be had as by layering. Where dwarf Roses are grown, either on their own roots, grafted, or budded low, and the shoots pegged down for flowering in the way recently described, a large number may be had by the end of the season on their own roots without much interfering with the blooming during the present year by layering. Supposing the shoots so pegged down have been left about 2 ft. long and a tongue is made by cutting with a sharp knife one-third of the way through the shoot in a slanting direction towards its point, and about 9 in. from the end, and the shoot at this point is pegged down in the soil, removing the latter so as to get the shoot at this juncture about 2 in. below the surface, using a stout, hooked stick that will hold it securely in the position, covering it up so as to leave two or three eyes at the point bare, these will make strong shoots, forming the head of the future plant, which, during the summer, will push plenty of roots at the point where tongued. Nothing further will be required, except severing from the parent plant in the autumn. The lower portion of the shoots so pegged down, as well as the portion at the point left above ground, will produce strong-flowering growth through the summer; and in this way, as I have already said, the quantity of Roses may be increased to an extent only limited by the number of strong shoots available with very little loss as to the amount of flower during the present season.

T. BAINES.

**Sweet Peas as Basket Plants.**—Baskets of Sweet Peas, suspended in the greenhouse or conservatory, even when not in flower, are elegant objects, so gracefully do their trailing stems and foliage fall over the basket on all sides. To have them in bloom early the Peas should be sown in November in a greenhouse and placed near the glass to induce vigorous growth. About twenty Peas in each 4-in. pot will be sufficient; and when the young seedlings are up and require more space they should be turned out of the pots and planted in the baskets—three or more pots in each, according to its size. The baskets should be thickly lined with green Moss, and the soil used should be rich and light. As the Peas grow liquid manure should be given freely, and the baskets must be hung near the glass.—E. HOBDAV.

**Anthurium Scherzerianum.**—The number of stove plants is now considerable; but the number of really good ones which are at the same time of easy culture is not so great. The above fine species may, however, be included amongst the latter, for we should say it might be grown by anyone who can command an ordinary stove temperature in any of their glass houses. It thrives in a compost of fibry loam, peat, and sand, mixed with a few broken potsherds, and it should have plenty of drainage. In such a compost, with plenty of water during the greater part of the year, it will grow without much trouble. The magnificent and altogether unique scarlet spathe of the plant are attractive objects in a stove, and, either cut or on the plant, they endure the trying atmosphere of rooms for a long period without showing much sign of injury. The plant is frequently raised from seed; consequently, there are quite a number of varieties in existence, the flowers of which differ both in colour and size; but the large-flowered and deep-coloured variety is much esteemed. The plant does not require much shade in summer, except in very bright weather, and great care should at all times be taken of the thick, leathery leaves—the larger and finer they are the finer will be the flowers. When they are young and soft and just pushing up, they are sometimes molested by aphid; but it is hardly necessary to fumigate the plants, as the affected leaves may be easily cleaned with a soft brush.—H.

**Double Cinerarias.**—These, when perfectly double, are very beautiful. They appear to be a little later than the single kinds, and they continue much longer in bloom, sometimes as much as two months. They will in a great measure supersede the single sorts, i.e., if due attention be paid to save the seeds only from such kinds as are most double. They are quite as easily grown as the single sorts, and, if anything, they are more floriferous.—EDMUND A. SAUNDERS, *Abergavenny.*

## PROPAGATING.

## THE ART OF PROPAGATING PLANTS.

WE last week (see p. 375) published the first of a series of notes and articles on propagation, which we believe will prove interesting and useful to a great number of our readers. We hope to illustrate not only the usual way of propagating each plant, but also the various ways in which it may be done, and this on the same block, so that the reader may see the various ways at a glance. The articles will be written and illustrated by propagators in some of our best nurseries. We believe this to be the first systematic attempt to explain the propagator's art, and we shall be grateful to any reader who will henceforward contribute short notes to this department. Questions sent to us on difficulties in propagating rare plants will be forwarded to the best authorities, and answers to them printed in this department of THE GARDEN.

**CAMELIAS.**—These are best increased by grafting (figs. 1 and 2) and inarching (fig. 3). The months of September and October are best for grafting. Get the stocks into the house a fortnight before the operation, cut the scion, as in fig. 1, and make the incision, as in fig. 2; place the graft in such a position as the

Fig. 1.

Fig. 2.

Fig. 3.

bark will meet at the edges, and tie all firmly with matting. If the stock and scion be selected, as in figs. 1 and 2, they will unite quickly and neatly. Put them in a close frame on a gentle bottom-heat in the propagating house. When they have been there three or four weeks the top of the stock may be shortened to throw the sap into the buds. Inarching may be performed in the greenhouse. In the case of a large plant of a good variety which it is desirable to increase, erect a temporary stage on which to place the stocks so that they may not be shaken about; cut off the bark and a small portion of wood, as shown in fig. 3; hold them close together, and bind them round tightly with matting or worsted. Nearly three months must elapse before they are cut away, which must be carefully done with a sharp knife. March is the best month for inarching Camellias.

H. H.

**The Best Baits for Insect Traps.**—M. E. C. Carrière has lately been trying a number of experiments on the best baits for insect traps, and gives an interesting account of them in a recent number of the "Revue Horticole." The results arrived at effectually disprove the truth of the old saying, that we may catch more flies with a spoonful of honey than with a gallon of vinegar. A number of glass fly traps, filled with different liquids sweet and sour, were placed under some fruit trees which were subject to the attacks of flies and other insects. The traps were baited with honey, weak wine and water, beer and water, vinegar and water, pure beer, pure wine, crushed Pears and water, and other liquids; and the victims were counted, after the traps had been exposed for three weeks, with the following results: The trap containing beer and water stood at the head, and contained 850 flies and other insects; pure beer stood next with 631, the crushed Pears, weak wine, and pure wine coming next, pure honey being at the bottom of the poll, with only 17 sufferers. No doubt the odour of the beer and water, which was in a strong state of fermentation, had a great deal to do with attracting the insects.—C. W. QUIN.

## THE FLOWER GARDEN.

## FROM THE BIRTH TO THE DEATH OF THE LILY.

I HAVE said that a Lily is not an annual, a biennial, nor a perennial. Then what is it? It may be said to be somewhat like two biennials joined together, but overlapping one another in their growth, that is, the one portion blooming this year, while the other is growing preparatory to its blooming next year. This apparent anomaly I propose to explain by laying before the readers of THE GARDEN the details of a course of experiments, the most interesting of all that I have made, by tracing the underground growth of the Lily, month by month, from the birth of the germ, throughout its transformations, until the end—the death of the flowering bulb. The best Lilies for an experiment of this kind are those which bloom from June to July; as we have thus the summer and autumn before us for carrying out the more delicate parts of the experiments—the birth of germ, with all such early-flowering bulbs, taking place in July. So that, in marking off by months the existence of such early-flowering Lilies, it will be necessary to commence with July and end with the month of June in the second succeeding year, making in all two years. In order to carry out the experiments in a satisfactory manner, the experimenter should have at his command some fifty or sixty blooming bulbs, which may have been planted singly at the same time in the previous year. The object of this is, that in lifting one or more bulbs every month for dissection, they may all show the true comparative growth that has taken place during the additional time they may have been permitted, one after the other, to remain in the ground.

To begin then with July, we lift a Lily that has just bloomed, and though the scales of the old bulb are now beginning to decay, a number will still be found to be in a comparatively fresh condition, though somewhat loose, flabby, and discoloured. In the midst of these loose scales will be found the new bulb, with its scales closely packed one upon another, clean, fresh, and crisp. We take this new bulb and carefully break off the scales that are opposite to the old flower-stem until we arrive at the young flower-stem with its rudimentary leaves and flowers, which will be found in the centre of the new bulb. At the base of this young flower-stem is the germ, just beginning to wake into life, but so minute as not to be discernible by the naked eye. This must not, however, dishearten the inquirer, as we can bring to our aid a powerful microscope, combined with a vernier-micrometer, and by the assistance of these instruments we can find what we are in search of, namely, the veritable germ itself, little more than the 200th part of an inch, or about the thickness of the paper on which THE GARDEN is printed. We are now introduced for the first time to the true origin of the Lily, and it is here that Nature permits us to contemplate some of her wonderful works, but without as yet enabling us to comprehend the strange mystery—an infinitesimally small object, which, after a time, will reveal itself to the observer in all its loveliness as the counterpart of its queenly parent. Here, too, we ought to pause and reflect on what a mere thread the life of the successional bulb at this time depends; and here also we might very pertinently inquire

## Can Late Planting Injure the Growth of the Germ?

Mr. Groom has drawn our attention to the fact that to the drying-off process, in reference to imported bulbs, must be attributed the cause of so many of them speedily dying out. In this opinion I most heartily concur. But there is also, in my opinion, an additional and a very different cause, to which, I venture to think, no writer in this, or in any other gardening periodical, has as yet given a thought, and that is, the pernicious effects which late planting in imported bulbs has on the growth of the germ itself, and, consequently, on the successional bulb. It is admitted that, according to the present system of collecting and transmitting, we cannot get a supply of these bulbs early enough to enable us to plant them before the spring; and it is also admitted by Mr. Stewart Hardy and other correspondents that, even with the aid of artificial heat, many of these Lilies come into bloom so late as to "have their flowers destroyed by the early frosts." Now it is to this important point that I would wish specially to direct the attention of the reader. It is an ascertained fact that the bulb will not liberate a germ, nor, if liberated, will it begin to vegetate without a considerable degree of heat, and that in its native place the heat, during the blooming and germinating season, is very great indeed. This being admitted, because it cannot be denied, M. Duchartre says, "That all the species of Liliium may be grown in this country in the open air, provided due care be taken to protect the bulbs of the more delicate sorts from frost." Now, among all the known species of Liliium that have ever been introduced into this country there has never been a bulb more delicate, by many degrees, than the infant germ of the most common bulb—a mere film—that has required our summer heat to awaken

into life. And yet, if we desire to make the most of imported bulbs in the open grounds of this country, we are compelled to plant them so late in the season that the flowers are, in many instances, cut off by frost. If, then, the flowers themselves are subject to being destroyed by frost, what is to become of the tender and delicate germ? for it cannot even have any existence until after the flowers have faded in their natural way. June, July, and August is allowed to form the hottest portion of our year, and it is during that period that the different classes of bulbs, according to the dictates of Nature, liberate their germs in this country. Is it reasonable, then, to expect that an object so minute and delicate as the germ will be awakened into healthy life in the midst of cold and frost? The new bulb, or that which Nature intended to be the parent of the germ, is at this time, when the old bulb is blooming, fully developed, that is, it has within itself a young stem composed of rudimentary leaves and flowers. These were destined to be the above-ground portions of the plant next season; but whether they may succeed in blooming more or less favourably, or not at all, must depend on how they may be able to get through the winter. But where, at this time, is the germ—the origin of the plant that should bloom the year after next? In all probability the cold and frost prevented it from being liberated, or, if happily liberated, prevented it from vegetating; and thus the plant, in a very large proportion of cases, dies out the third year. Can we wonder, then, at the complaints that are made that only a portion of the thousands that annually arrive in this country bloom the first year; that they bloom in less proportion the second year; and that, by the third year, we see them no more? It would be contrary to the laws of Nature to expect anything else. We are favoured from time to time with the experience of those who have the means of growing Lilies under glass. But while we admire what they do, and can do, we should not overlook the wants of those who desire to grow Lilies in the open air; for their name is Legion; and they no doubt search the columns of THE GARDEN for guidance on the subject. It must, then, I think, be very reprehensible in any man to advance for such a purpose mere theoretical opinions without the shadow of a single experimental fact to rest upon. I am induced to say this because I have observed for some time that those who adversely point their remarks at me are among themselves entirely at variance with one another, differing in opinion as well as in theory, no two agreeing entirely on any one point, thus proving by the most undeniable evidence that, though this is the year 1878, the time has not yet come when the organic structure of the Lily is to be considered an understood and settled question.

I have enlarged so fully on the Lily during the first month of its existence that little is left to say about the second. All that can be said is that the parts increase in size, but increase so very slowly, though never dormant, that it is not until the end of the third month that we begin to be able to discern the germ or seed-bud, as I would now call it, by the naked eye. During this time the young stem, composed of rudimentary leaves and flowers within the new bulb also increases in size, pushing out the scales of the new bulb, which become more and more consolidated, increasing the size of the new bulb and adding considerably to its weight. This slow proportional increase in all the parts of the bulb goes on during the fourth and fifth months, and it is not until the sixth month that we can have the view of the interior, which is faithfully represented at p. 143, in the woodcut engraved from a photograph of the parts themselves, after having dissected a number of bulbs which were taken up for the purpose on Jan. 1, thus showing the seed-bud when it was just six months old. Hitherto I have written as if the new bulb liberated only one germ or seed-bud; but, as it is a known botanical fact that "plants, like animals, are organised and living beings," and that in the animal creation there are sometimes twins or two at a birth, and sometimes, but very rarely, triplets or three at a birth, so, in like manner, a Lily bulb will sometimes liberate two germs at a birth, and another will, but very rarely, liberate three germs at a birth. In such cases, as I have said in a former paper, these germs spring up close together, and as they grow they spread outwards, making room for their separate growths, and, when fully developed, they show two or three separate crowns, as the case may be, contained apparently within one bulb, as may be seen on inspecting a large number, but, when dissected, they expose two or three separate and distinct new bulbs, nourished, however, by only one set of roots. It is thus that these phenomena have given rise to very mistaken ideas on the subject, as they have often been described as central and side buds. With respect to these two but distinct classes of buds, the experimentalist knows where to find the central bud, even before it becomes visible to the naked eye, but no man can tell beforehand where a side or accessory bud may make its appearance. Central buds I call legitimate germs or seed-buds, side buds I simply call very young offsets, the former always flowering in the fullest manner within two

years from their birth, the latter taking two years or more before they can produce a single flower.

At p. 252, where I am glad to see M. Leichtlin's name, we are favoured with some remarks from him on the subject, but which, for want of space, as I suppose, they appear, to my great regret, to be somewhat ambiguous. At one place he says: "As to the majority, or perhaps as to all Lilies of the Old World, 'Dunedin's' theory seems to apply exactly, as far as the formation of the next year's bulb from the side buds is concerned, but not in relation to the entire decay of the old bulb." M. Leichtlin admits, however, at the same time, that he has carried out few experiments by dissection. Had he done so to any reasonable extent, I think he would have been compelled to admit that my theory, as he calls it, is founded on the action of the legitimate central germs or seed-buds, and not at all on anything that can by any possibility be called side buds, as these, though they may, by cultivation, be made to propagate or multiply the species, have nothing whatever to do with the legitimate or hereditary succession of the old bulbs. At another place he says:—"As to *L. giganteum* and *cordifolium*, I must openly say that I have made no dissections in regard to them, but, from studying these plants in the shape of hundreds of bulbs, as far as growth is visible, it seem obvious to me that these species do not produce annually a new bulb from a side bud, but that the old bulb is enlarged annually by the scales growing larger through the growth accumulating from a central bud; and that during summer, when vegetation is active, another central bud is developed to grow next year." Now, the careful reader cannot but see that this, in a great measure, supports my doctrine. But, as I have stated in the columns of THE GARDEN on various occasions, it is utterly impossible for any man to form a correct opinion of the organization of the Lily by merely examining the outward or visible appearance of any bulb; and, in this case, M. Max Leichtlin frankly admits that he has gone no further. M. Max Leichtlin closes his remarks by saying:—"I am of opinion that 'Amateur' (see p. 198) is right in his views, and that he will certainly be able to prove that the old bulb does not decay every year." I must confess that I am very greatly surprised at such a remark, coming, as it does, from M. Max Leichtlin, my opinion on that point being entirely in accord with that of Mr. George F. Wilson, when he says: (see p. 252) "If 'Amateur' can flower *L. giganteum* twice from the same bulb, he is a fortunate man." I will even venture a step further and say:—"If 'Amateur' will prove that he can flower any one of the Old World Lilies twice from the same bulb, he will prove himself to be a man of no ordinary standing among Lily growers."

At p. 227 "E. H. W." says, "The different ways of reproduction in Lilies are so marked that alone it would afford subject matter for endless remarks and controversy." This is entirely contrary to all my experience, for I have always observed a most interesting and singular similarity in the organisation of all the kinds coming under the denomination of the Lily proper. I therefore feel convinced that if "E. H. W." were to begin with the Old World Lilies, the greater part of which can be had in quantity and at comparatively little expense, and make careful experimental dissections at different times during the year, and then go on to the newer, the rarer, and the more expensive kinds, he would find that what he has now said on the subject would require to be entirely altered; for, as the matter stands at present, his remarks have not carried the subject a single step beyond "the theory which terminates in mere speculation," but rather adds to the "endless remarks and controversy," already going on with so little real benefit to the inquiring Lily grower.

I now come to a remark made by Mr. Groom, which I should like to have cleared up before we get wider apart. At p. 252 he says, "The only point to which I took exception was that of cutting down the flower-stems before the leaves had faded. 'Dunedin' will himself see that there is a wide difference between cutting the stems down in full and fresh bloom and waiting until ten days after the bloom has fallen to perform that operation." As I believe that there is here some misconception, I would take it very kind if Mr. Groom would point out to me the page and passage which has led him to make this remark. I have said somewhere that I have cut down Lilies in full bloom without affecting the growth of the new bulb; and I have also said that, as soon as the bloom is perfected and decaying in the natural way, the new bulb may be transplanted with perfect safety, as at that time it is pushing down its own roots, which are quite sufficient for its nourishment without any aid being required from the old leaves or stems. Mr. Groom will see that I have never professed to illustrate the distinctions that exist between "bulbs of all kinds" and the Lily, but have endeavoured to explain the nature and organisation of the Lily bulb itself, and, as I think, so clearly, as may enable Mr. Groom and other able horticulturists to draw the true line of distinction themselves. This much I know, that great stress has always been laid upon the fact that the foliage

of other bulbous roots should be allowed to grow until it decays in a natural way. But the Lily, I venture to say, is an exception to this rule, though not in general considered so. DUNEDIN.

### BUSH ROSES.

THESE are, as a rule, not nearly so effective as they might be. The usual course is to prune and simply to allow them afterwards to grow in what form they may choose to take. On their own roots, in genial soil, they yearly acquire strength such as necessitates, at the time of annual pruning, the specimens being allowed to get to a larger size, especially in height, the result of which is that the strong shoots, from which the greater portion of the flowers are produced, grow to a considerable height, at which point most of the blooms are borne, leaving the plants comparatively thin and bare at the base. Although it is anything but desirable to train Roses in a way that gives any approach to formality, still such an arrangement of the shoots may with advantage be employed as will keep them well furnished with a fair proportion of vigorous growth and full-sized flowers down to the ground, at which point in-

ALLIANCE & CO.

A Bush Rose.

dividual plants have the greatest breadth, gradually tapering up to the top, as in the accompanying illustration of a well-managed bush Rose, wherein, as will be seen, the form is devoid of undue stiffness, yet such as to produce an effect not possible where the plants are left to themselves. To produce the effect exemplified in the illustration it is necessary to have strong, vigorous plants established for years on their own roots; at the time of pruning, or soon after growth has commenced, a portion of the strongest shoots should be bent down and tied out horizontally to a few sticks stout enough to keep them in position allowing the remaining growths, shortened back to different lengths, to assume the position such as will lay the groundwork for the specimen which later on will be clothed with foliage and flowers. The central branches, according to the more or less strong-growing erect habit of the variety, may require a few sticks to hold them in their places, but the whole of such supports will be effectually hid by the foliage, and no trim outline should be attempted. The illustration is not an ideal conception, but simply a representation of a well-managed vigorous bush Rose. It will be easily understood that it is not desirable to attempt the training of Roses in this way in positions of all descriptions, or where they can much more appropriately be left to assume a wild form; but for beds in the immediate vicinity of a mansion in the more highly dressed portion of the grounds, where they will be in keeping with the surroundings, they at once produce an effect in every way

unexceptionable. By the side of a broad walk either straight or winding, where something is wanted to relieve a too even surface, rows of Roses at intervals more or less far apart, so trained, are infinitely superior to the naked-stemmed, mop-headed standards, so generally used in such situations; in addition to their shape, satisfying the eye in a way not possible with the standards, it is much easier to get a number of bushes sufficiently equal in their growth to keep up the requisite uniformity in the whole than it is with standards, which, when placed singly in rows, are so provokingly subject to a portion growing freely, and the others very little. T. BAINES.

### CUTTING DOWN LILIES IN FULL BLOOM.

I REGRET that "Dunedin" should have misunderstood my remarks about cutting down Lilies. I said nothing about *Lilium candidum*, which, though a Lily, has no analogy whatever, as regards treatment and growth, with many other Lilies. The only safe and sure way to speedily raise good, large, sound, white Lily bulbs is to cut away the flower-stems as soon as they appear aboveground, every inch of growth weakening the bulb; and they should always be transplanted, if they are to be removed at all, the very moment the last flower has faded, cutting away the old stem as low as possible. I had supposed this was so old and well known a custom that I did not allude to it. I wrote: "After thirty years' experience with thousands of bulbs of *L. speciosum* and its varieties." It does no more injury to cut away the flower-stem of *L. candidum* when in full bloom than it does to cut off the flower-spike of a Hyacinth, the flower-stem of a Gladiolus, the flowering-shoot of an Amaryllis, or the bloom of the Guernsey Lily. The leaves are all left, and these are all that are needed to produce a sound and perfect bulb. If this were not so, it would have been discovered long ago. With the Lilies, however, that have no leaves, only such as grow upon the flower-stem, it is quite another and totally different thing. Nature points this out. If the flower-stem of *L. giganteum* be cut away as soon as it makes its appearance, the leaves and bulb will increase in size; but if allowed to grow and bloom it so absorbs the nutriment of both, that nothing but weak offsets are the result. It is the same with the Century plant. When the Hyacinth growers of Haarlem tell us the bulbs are just as good if the foliage be all cut off, or the Gladiolus cultivators of France that cutting away all the leaves does no harm, or the Amaryllid growers destroy all the leaves, and the Guernsey Lily cultivators say the bulbs will flower just as well without making any foliage, I shall believe that cutting down such Lilies as make no root or bulb leaves does no harm. As to *Lilium candidum*, when the flower-stem is cut away the bulb is really greatly benefited, as "Dunedin's" experiment proved, just as removing the flowers or buds from any plant increases its growth and vigour. The leaves all remain, and it is these that nourish and sustain the root. If "Dunedin's" practice be correct with Lilies which have no bulb leaves, then we must have new rules for bulb culture, and the old custom of securing a vigorous, strong, and healthy foliage must be discarded. Boston. C. M. HOVEY.

**Santolina Incana.**—This is one of the most useful of plants for forming edgings or divisional lines, and, being of a whitish-grey tint, it may be employed in many varying combinations. Its habit of growth is neat and compact, and, being hardy, it especially commends itself to those who have but a limited amount of glass structures. Cuttings of it put in under hand-glasses or lights in September make excellent little bushy plants for furnishing beds in spring. By having a good supply of this, and such plants as *Violas*, *Polemonium cornutum*, *Golden Thyme*, and similar plants, bedding-out, as it is called, becomes a more reasonable affair than when all the subjects employed are tender.—J. G.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Tree Pæonies and Frost.**—By way of answer to "B. S.," Rutlandshire (see p. 323), who is desirous of ascertaining the effect of the recent frost on Pæonies, I may state that here they suffered so severely that I don't think they will recover this season. A few Roses that were pruned early were also cut down, and the leaves of Violets were scathed, as if scalded. Anemones, which were in full bloom, had the latter greatly discoloured, but they are again in full beauty. Frost does not appear to affect the herbaceous Pæonies, and though we had from 7° to 10° for several nights, with blinding snow-storms, herbaceous plants generally withstood the storm bravely.—N. FULLER, *Downton Castle, Ludlow.*

**Aquilegia viridiflora.**—As a rule green flowers are not worth growing, but this Columbine is an exception; the sage green of the flower and delicate tint of the leaf form a striking contrast.—A. K., *Eastcott Cottage, Finner.*

## THE KITCHEN GARDEN.

### SMALL v. LARGE KITCHEN GARDENS.

It will be acknowledged by many, we have no doubt, that kitchen gardens are, as a rule, too large—as regards the vegetable quarters at least—for we doubt if any one would willingly curtail the extent of walls devoted to fruit culture; hence some arrangement that would give us the necessary extent of these without extending the area of open vegetable ground is what is needed. Such an arrangement would, of course, depend largely upon circumstances and situation; but that which secured the greatest amount of shelter to growing crops would no doubt be the best. Our own experience would lead us to prefer a greater extent of south wall and, consequently, warm borders, and also an extended northern exposure, to either east or west walls, though we have less objection to the latter. There can be no doubt, we think, that south walls produce the most remunerative crops, if well managed, while their northern aspect can, as every cultivator knows, be utilised for producing later or succession crops of such fruits as Cherries, Plums, and particularly Gooseberries and Currants, which succeed admirably on such an aspect; and north borders can always be turned to excellent account in vegetable culture. This, however, by the way; it is the vegetable grounds of which we wish to speak.

At some places, where the demand is not so very great, the kitchen gardens are frequently five or six acres in extent inside the walls, with a proportionate amount of walks, edgings, and borders—all proportionately expensive to keep, without providing anything like an adequate return. In such places, where the outlay is not measured by a debtor and creditor account, and means are provided to keep the place in good order, it is all very well; but the rule is that such large gardens are not well kept, nor thoroughly economically cropped. They will not bear comparison with any ordinarily well-cultivated market garden, where every inch of ground is cropped and cared for as it should be. Of course we are aware that the two cases are hardly parallel, but there is not so very much difference between them either. Large gardens are not cropped so economically as small ones, for in the former the ground is only filled once, perhaps to the latter's twice, and sometimes three times during the year. In the first, the Potato, the Pea, the Onion, and other large quarters are allowed to stand vacant, or are only partially cropped, while in the latter the crops have to be hurried off the ground at the earliest moment, in order to make room for something else; and, except in the case of crops which come off the land too late in the season to permit a following crop, no ground is ever left vacant. We think every portion of a kitchen garden, including borders and margins, should be cropped. It is a sheer waste of time and money to keep ground vacant on the score of mere tidiness. What, we ask, can be more creditable to a cultivator than a garden well cropped in every part? We have had some little experience on the subject of which we write. Our 3-acre kitchen garden here, inside the walls, has been encroached upon to the extent of at least one-third by hothouses, pits, frames, and other structures, while there has been no decrease, but rather an increase, in the demand for all kinds of vegetables. As a consequence, more economy had to be exercised with the space that remained. The first improvement was to do away with about 1200 ft. of walks, with borders and alleys on each side, which had never been a necessity; and the next was the removal of all the large fruit trees to an orchard field, where they are out of the way and better off, their places being turned into vegetable ground; by these, and various other curblings here and there, we gained about as much ground as we had lost, without increasing the labour of working it—quite the reverse, in fact, for we had fewer walks to keep. To still further extend our accommodation, we do not allow such crops as Greens, Brussels Sprouts, and Savoys, Leeks, &c.—which always necessarily occupy a large extent of land—to remain on the ground till they are quite over. After they are hearted, they take no harm if in spring they are lifted and laid closely in rows by the heels. The Greens are all topped first, of course, and it is only sprouts which push afterwards. As regards the Brussels

Sprouts, they are lifted just before they run to seed, which checks their growth and prolongs the supply. None of the other subjects are injured by lifting, and the ground is cropped as fast as it is cleared. But for this practice, it would be impossible for us to get in our Potato and other crops in time, for we have rarely any fallow ground, unless it be a piece reserved for Onions or the Celery quarter. Manuring and trenching, to a great extent, obviate the necessity for adhering strictly to the rotation of crop principle. Just a word in regard to walks in kitchen gardens. They must be both roomy and convenient, but not many are required, even in the largest gardens. Nothing hinders the working and economical cropping of the ground so much as numerous walks, cutting the ground into small plots. The broader the quarters and longer the rows, the better; and we should never have more than one walk running through the centre of the garden each way, and a walk all round between the fruit borders and the vegetable quarters. Narrow alleys, that can be made or unmade at pleasure, will provide for all other means of communication with the different crops.—“Field.”

### GATHERING MUSHROOMS.

Mushrooms are gathered as they come to perfection, a condition which must be determined by the purpose for which they are intended. The Mushrooms intended for the Paris market must not be under the size of a 2-franc piece on the cap, nor above that of a 5-franc piece. The enormous Mushrooms of 8 in. and 10 in. in diameter, which find so ready a sale in Covent Garden would be a drug in the Paris market, being considered by the French *chefs de cuisine* to be less delicate in flavour than the small ones. The gatherings are made in the quarries at a very early hour. At one o'clock in the morning the Mushrooms are gathered, which at a later hour are sold in the open market. The Mushroom gatherers are each provided with two large baskets, which they carry on their backs knapsack fashion—one to receive the Mushrooms, the other to contain the soil with which to fill up the gaps left in the beds after the gathering. The proper way of gathering a Mushroom is to seize it in one hand by the cap, at the same time giving it a slight twist and pulling it gently upwards, so as to detach it from its roots without disturbing the little Mushrooms that are growing round its base. The gathered Mushroom is dropped into the empty basket, and the hole which it has left behind it is filled up with a pinch or two of soil from the others. In some quarries the gatherers pick the Mushrooms and leave them in little piles on the pathways, or on the beds themselves. They are followed by women, who pack them into baskets, and by men, who fill up the gaps left in the beds. The beds are then smoothed down with the hand, and if they appear to be too dry they are watered. The Mushroom-baskets should be covered over with a cloth, to avoid all contact with the air, which is apt to turn them brown. The contents of the smaller baskets are then packed into larger ones, holding from 10 to 15 kilos. (23 lbs. to 35 lbs.), and sent off to market. Mushrooms of good quality are sold wholesale at 1 fr. 70 c. to 2 fr. per kilogramme, according to the season (1s. 5d. to 1s. 8d. per kilo.). The gatherings are continued daily, but do not yield the same quantities regularly. For instance, a crop of 300 kilos. may be succeeded by one of only 50 kilos, for the Mushrooms require a certain time to acquire a marketable size. The time that one kind will continue to bear depends on the materials employed and the manipulation to which they have been subjected. The inside and outside temperature has also a great influence. In quarries with a low roof the temperature is always high, and vegetation is consequently more rapid. The duration of the crop is from forty to sixty days, and the yield rapidly diminishes towards the end of that time. In quarries with high roofs, or which open on to the level road, the currents of air are weaker and the temperature lower; the vegetation is, therefore, less active and the bed lasts longer, owing to the manure being consumed so much more slowly. In some high-roofed quarries the beds will bear for three or four months. In low-roofed quarries they continue to yield the same amount even when the outside temperature is low; but in those with high roofs a marked check in the production takes place under those circumstances.

In practice, a thick clump of Mushrooms all growing on the same spot is called a rock, or *rocher*, by the French growers. When the whole of a rock has been gathered, there remains in the place where the ends of the stalks were inserted a fleshy mass, forming a kind of platform, round which are generally growing a number of stunted young Mushrooms which have not had sufficient space in which to develop themselves. If this fleshy mass be cut open, we shall find that the inner portion is formed of a semi-ligneous substance, the fibres retaining enclosed the morsels of stone contained in the mixture of mould and quarry rubbish with which the beds were soiled. These stumps or rocks must not be allowed to remain in the beds, but must be cut away carefully, and the gap filled up with soil.

These clumps often interfere with the yield of the bed. First of all, the Mushrooms which spring up on the edge of the clump are generally stunted, or, as the growers say, they lack sap, while others are subject to disease, the first symptom of which is a black spot on the cap. We have dissected several Mushrooms attacked by this disease, and examined them under the microscope. The skin of the cap is spotted with stains of a black or dark brown colour, having spaces of an ochry tint. The cap of the Mushroom is often flattened or otherwise depressed, and when cut open shows a number of black stains, which extend from the inner to the outer surface. The flesh is yellowish-grey as far as the base of the stem, although the skin of the latter preserves its usual colour. The odour is no longer that of the Mushroom, but of a body in a state of putrefaction. The cause of this disease is said to be the want of sap and the wasting away of the nutritive elements of the Mushroom. We must be careful to remove all clumps which show signs of having been attacked by this disorder, which would spread itself over the rest of the bed in a very few days.

The cleaning or stumping of the beds is the removal of the stumps as the Mushrooms are gathered, until nothing remains but the empty soil. This operation is performed by passing a knife around the spot, so as to separate the stump from the bed. The stump is thrown on to the pathway or into a basket, and another workman fills up the gap with soil in the usual way. The holes left where single Mushrooms have been gathered must also be filled up and the paths carefully swept, so that no foreign matters capable of fermentation may be left about. Above everything, care must be taken to remove all scraps of Mushrooms affected with disease, otherwise the infection would spread through the quarries in a very short time. In the case of beds cultivated in the open air, the gatherings are made as in the quarries, with the exception that the Mushrooms intended for the morning's market are generally picked the evening before, taking care to keep them from the light and air, so as to preserve their fruit. The private grower, who gathers for his own table, picks them at his own, or rather at his cook's, convenience, knowing well that the fresher the Mushroom is before going into the pot the more delicate will be its flavour. From a trade point of view, it is most important to gather the Mushroom at the exact moment. If it is too much grown, the stem becomes spongy, and the cap opens and spreads out like an umbrella, and the rose-coloured gills turn brown. In this condition the Mushroom is no longer saleable in the Paris market at any price, although in Covent Garden the large and more open Mushrooms are more eagerly sought after. It is not exactly poisonous, but it is very indigestible. It is not only in the bed that the Mushroom reaches its full size; I have seen Mushrooms which, when gathered, were in a perfect state open up and assume the appearance just described after having been exposed to the air for two days and a half. M. LACHAUME.

**Salt as a Manure for Potatoes.**—Allow me to direct attention to "W. T.'s" reply to a correspondent (see p. 348), where he recommends 20 bushels of salt (half a ton) per acre for Potatoes on light soils. Messrs. Lawes and Gilbert's experiments on salt as a manure prove that 5 cwt. of salt per acre is the largest quantity that should be applied to Mangold Wurzel (which is a marine plant), and 3 cwt. for any other crop; and Dr. Voelcker's experiments also carry out this principle. The Potato contains but a very small amount of

salt in the form of chlorine, and if an acre produced 10 tons of tubers, then about 10 lb. of chlorine (equal to about 20 lb. salt) would be abstracted from the soil by the plant, so that half a ton would be likely to last some few years as a manure. Of course, the principal advantage of applying salt to light soils is that it prevents premature ripening of the tubers on account of its power of attracting moisture, but 2 cwt. or 3 cwt. per acre would be quite sufficient for that purpose, and half a ton would be most decidedly injurious.—JAMES PINK, *Lee's Court, Faversham.*

## THE NATIVE COUNTRY OF THE POTATO.

By ED. ANDER.

THE Société Centrale d'Horticulture de France, at the beginning of 1877, received a communication from M. A. Lavallée on the subject of the history and original habitat of the Potato. M. Lavallée adopts the view taken by M. De Candolle in his "Geographic Botanique." Like the latter, he is satisfied that the Potato was not introduced into Europe either by Hawkins or Drake. They brought home the *Batate* (Sweet Potato) only. Sir Walter Raleigh, who brought the true Potato from the east coast of North America in 1563, did not find it in its native country, but in a region where it had been previously introduced by the Spaniards. The tuber was known in Spain and Italy before Raleigh's day. It is now established beyond dispute that the "Conquistadores" found this *Solanum* cultivated in Peru under the name of "Papa," which it retains there to this day. The historian Acosta is accredited with the first mention of it, in the year 1509. Just as the companions of Quesada, Belalcazar, and Fréde-mann introduced into the New World domestic animals and poultry, which they had brought with them from Spain, and could not find heart to kill even when themselves dying of want, so it is equally certain that they took back from thence to Spain the Potato, which they found cultivated in the cold region of the Andes, and saw to be of great value to the aboriginal population. I agree with M. Lavallée so far as concerns the historic part of his note. But during my travels in the Cordilleras of the Andes I collected some facts which enable me to correct and complete the latter half of his memoir. It is scarcely necessary to add that it is not to M. Lavallée's logic, but to certain of the sources of information on which he relies, that I have to take objection. For a long while it was impossible to discover the native home of the Potato. Humboldt declared that he had searched for it in vain, and had found no such tuber either in Chili, New Granada, or Peru. Ruiz and Pavon, who thought they had discovered it in the last-named country, really only found *Solanum immitte*. In 1822 Messrs. Caldicleugh and Cruikshanks saw *S. tuberosum* growing wild in Chili. Meyer and Claude Gay afterwards collected it in Valdivia and Juan Fernandez. M. A. De Candolle and Lavallée appear to have concluded that *S. tuberosum* does not grow spontaneously in New Granada and Peru simply on the negative testimony of Humboldt that he had not seen it there. I have been more fortunate. I have found authentic specimens of *S. tuberosum* growing spontaneously in three different localities under circumstances which could scarcely mislead a botanist. The first time was on the summit of Quindío, Columbia, near the volcano of Tolima, at an altitude of 3500 metres (11,400 ft.) above the sea-level, and in 4° 34' lat. N. The plant was growing in the form of small tufts in the vegetable humus, almost in the shade of the woods, and amongst the stunted bushes of this Alpine region. The long stalks were half buried and white, and the tubercles at their extremities, or, to be more accurate, the swollen subterranean ends of the haulm, were about the size and shape of small, oblong Nuts, feculent, and rather bitter. The flowers were white, scarcely tinged with purple, and smaller than in our cultivated species; but I attribute their scarcity and want of colour to the impoverishment of the plant in so severe a climate, only 3000 ft. below the eternal snows of Tolima. The second instance was in the Cauca, in the slopes adjoining the Union Mountain, in 1° 33' lat. N., that is to say, close to the Equator. The altitude here is very different from the first case. It did not exceed 1900 metres (6200 ft.). The plant, too, was growing in full beauty in the midst of a luxuriant vegetation of *Siphocampylus*, *Sciadocalyx*, *Ageratum*, *Alonzoa*, *Lamourouxia*, &c. This was in May, 1876. The stalks of *S. tuberosum*, of which I gathered a good many for my herbarium, threw upwards, support ing themselves on the neighbouring trees. Their foliage was vigorous, and magnificent umbels of large-sized flowers, of a deep purple, hung from them. Around the villages in this region the cultivated Potato does not appear under this aspect. It forms low, stalky heads, as in the Potato fields of Europe. The wild plants were numerous, far apart, remote from spots whither they might have been brought accidentally by the agency of man, and had all the appearance of plants "at home." The third case occurred

not very far from Lima, in the Amancaes Mountain, where the *Amaryllis* of the same name grows, and where, in the midst of a very scanty vegetation, the Potato is found growing in abundance. It is equally common in the island of San Lorenzo, near Callao. In both these places it may, of course, have been introduced by human agency, but would it not have been planted it on the most inaccessible and barest declivities where the foot of man had no call to tread? The seeds of the Potato, we know, are not amongst those easily borne along and disseminated by the winds. On the specimens I collected in Peru the flowers were all a pale lilac, the tubers small, oblong, and rather tasteless. I believe the plant to be there in its native home, but this I cannot positively affirm. The original specimens of the plants above referred to are in my herbarium, and at the disposal of those interested in the subject. It seems to me that Humboldt's opinion by itself is wholly insufficient to disprove the existence of the Potato in Peru, Ecuador, and New Granada, and I firmly believe that further investigations will show it to exist in other localities as well as in the same countries.—"Illustration Horticole."

**Leeks for Spring Use.**—I fully agree with Mr. Groom's remarks on this subject. About the middle of May last year an order came from town for plenty of Onions, Turnips, Celery, and Carrots for soup. As regards Onions, a good stock of Leeks and a bunch of autumn-sown Onions were pronounced perfection. Then Carrots were small, Celery bolting, and Turnips nil. This season I have a capital run of autumn-sown Carrots in good order, very late Celery lately blanched, Turnips stored in a cool quarter, and plenty of good Leeks. No doubt Leeks are to be preferred to Onions for soup. The flavour is milder, as Mr. Groom says, and also more full and mellow than that of Onions. I am surprised, indeed, that stewed Leeks are not more popular than they are, for they are equal to stewed Celery, Seakale, or almost any other vegetable. Their greatest merit, however, at this season is their slowness to run. When all other Onion kind is in haste to bolt into seed the Leek stands still, and before it can make up its mind to start into flower it is potted.—D. T. FISHER.

**A Selection of Potatoes for Exhibition.**—In growing Potatoes for exhibiting, as in the case of numerous other things that could be mentioned, it is necessary to have a greater number of varieties than it is intended to stage. Speaking in a general way, the number grown should exceed by about one-third the number of dishes required in the collection to be shown, that is to say, if the cultivator contemplates competing in a class for twelve dishes he should plant eighteen varieties, and for a collection of twenty-four dishes thirty-six sorts. By having one-third more a much greater choice is afforded in the selection of samples when the crop is lifted, and in consequence a much better collection can be formed than would be possible with a less number from which to select. If it is intended to compete in a class for twelve dishes I would recommend the following eighteen sorts, namely:—Blanchard, Red Emperor, Triumph, Radstock Beauty, Salmon Kidney, Purple Ashleaf, Brownell's Superior, Grampian, Lye's Favourite, Snowflake, Model, Early King, Schoolmaster, International Kidney, Rector of Woodstock, Porter's Excelsior, Ashtop Fluke, and McKinlay's Pride. For making up a collection of twenty-four dishes I should recommend the cultivation of the following thirty-six varieties, namely:—Red Emperor, Scotch Blue, Seammell's Glory, Triumph, Trophy, Lady Webster, Salmon Kidney, Purple King, Lye's Favourite, Late Rose, Brownell's Superior, Radstock Beauty, Grampian, Purple Ashleaf, Blanchard, Gibraltar, Ruby, Beautiful Kidney, Snowflake, International Kidney, White Emperor, Early King, Early Market, Taylor's No. 1, Porter's Excelsior, Model, Rector of Woodstock, Ashtop Fluke, McKinlay's Pride, Onwards, Climax, Schoolmaster, Sedilla, Bedford Prolific, Edgecott Seedling, and Breadfruit.—PETER MCKINLAY, Beckenham, in "Gardener's Magazine."

## NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Tall & Dwarf Peas.**—I am pleased to observe that the merits of the tall section of the *Pisum* family are beginning to be generally recognised; short stalks and a short period of bearing are synonymous. It is only by means of varieties that develop a continuous supply of fresh blooms on elongated stalks that one can hope to prolong the period of gathering.—J. G.

**Kennet Salt for Slugs.**—Will Mr. D. Lamond kindly say whether this salt differs from common agricultural salt, and what proportion per rod or acre he finds it safe to apply to growing crops of garden produce, so as to make sure of destroying the slugs without injuring the crops?—F.

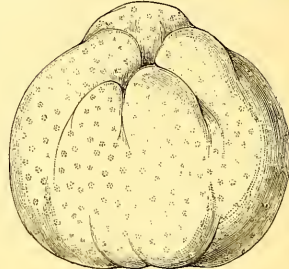

**French Lettices.**—I shall be greatly obliged if you or any of your readers will kindly tell me what are the best Lettices of the Paris gardens.—A. Z. [De Malte, Perpignon, Goutte lente à Monter, Cordon rouge, Crêpe grainé rotte, Blonde de été, Blonde de Berlin, Blonde de Versailles, Grossa brune parvessive, Morine, Passion, Palatine. There are a few of the best Lettices in cultivation.—D. GIBBERNE.]

## PLATE CXXV.

### PYRUS MAULEI.

Drawn by Mrs. DUFFIELD.

For the opportunity of figuring this fine *Pyrus* we are indebted to Messrs. Maule, of Bristol, the introducers of this valuable shrub—one alike ornamental in flower and fruit, and a great gain to our gardens. It is a native of Japan, Messrs. Maule

Fruit of *Pyrus Maulei*.

having obtained the seed from which it was raised through a member of Captain Alcock's Expedition some eight or ten years ago. It is a hardy, deciduous, spiny shrub, the flowers of which are large and, being orange-scarlet, remarkably showy. The fruit, which is produced in great abundance, is a little variable, both in shape and colour, and bright red where fully exposed to the sun. Though uncatable in a raw state, it makes an agreeable conserve, for which and for a drawing of the plant a first-class certificate was awarded at the Bath meeting of

Fruit of *Pyrus japonica*.

the Royal Horticultural Society in 1873. Along with the fruit of *P. Maulei* we have also given an illustration of that of the Japan Quince (*Cydonia japonica*), its relation, in order to show how much they differ. The two plants also differ both as regards leaves and flowers. It may be increased by grafting it either on the Apple, Pear, Quince, or Thorn, and it may also be readily raised from seeds, of which each fruit contains a great many; indeed, through repeated seeding and selection, Messrs. Maule hope in time to obtain fruit of this *Pyrus* fit for dessert. It flowers early in May, but sufficiently late to generally escape frost, and keeps in bloom till June. So handsome a shrub cannot fail to be everywhere a favourite. Those who take an interest in the genus *Pyrus* will find a full account of all the most ornamental species belonging to it in the tenth volume of THE GARDEN (see p. 384).

MAULE'S JAPAN PEAR (PYRUS MAULEI)

## NORTH AMERICAN PINES AT HOME.

The accompanying illustration gives a good idea of the broken shore scenery common to the larger navigable lakes of North America. The tall, spectre-like shafts of the Spruce or Larch, with their short, irregular pinnae, present, it must be confessed, a cold, weird look. But though lacking in what artists would call "warmth," such scenes form a picture that has unfortunately, as far as I have been able to judge, no counterpart in the tame, artificial lake scenery of this country. An intermixture of such subjects with the common-place Weeping Willow, Birch, Beech, Alder, Elder, &c., of our lake shores and islets would give a sprightliness and natural wildness to such scenes. The fallen tree in the foreground furnishes an idea that is seldom carried out. It would be an easy matter to partially uproot plants without killing them, in order to effect

and for the excellence of their timber. The following are the only species and varieties that can be recommended as really hardy enough for our climate in the open air:—

**ANTARCTIC BEECH** (*Fagus antarctica*), sometimes called *F. betuloides*, is an evergreen species indigenous to both sides of the Straits of Magellan, and occurring in vast forests in Terra del Fuego, where it extends from the seaside up to the snow-line of the mountains, and varies in height from about 40 ft. in the more sheltered situations to a scrub-bush of some 2 ft. or 3 ft. in such as are high and exposed. The tree is broad and bushy, with a trunk much thicker than is usual in proportion to its height. Though introduced into this country in 1830, it has not yet been widely distributed, and is still scarce and comparatively little known. Its leaves are much smaller than those of the common Birch, which they so much resemble, that *betuloides* has been regarded by some writers as the most appropriate specific name. It is an interesting species of very slow growth, but worthy

. North American Pines at Home.

this object. The Coniferous trees and shrubs best adapted to grow on the damp margins of lakes, and their low water-logged islets, are *Larix americana*, *Abies alba* and *rubra*, *Pinus Strobus*, our own native Pine, the Deciduous Cypress, the *Glyptostrobus heterophyllus* of China, and *Sequoia* (*Taxodium*) *sempervirens*, the Canadian or Hemlock Spruce, the American *Arborea* (one of the best), the white and red Cedars; and for draping the margins of the islets, the common Savin (green and variegated) and many other species of depressed and prostrate Junipers will also doubtless be found suitable for such a purpose.

GEO. SYME.

## SPECIES AND VARIETIES OF BEECHES.

The hardy species of this genus form a limited but important group of evergreen and deciduous trees, with a wide geographical distribution over the temperate and colder regions of both the Old and New Worlds. They are famous alike for their highly ornamental character

of a place in shrubby borders, growing well in light, dry soils, and useful as a rocky plant. It is also well adapted for training on walls, its spray-like branches and abundant foliage affording great facility for keeping it neat and trim.

**COMMON BEECH** (*F. sylvatica*).—This tree is found over a wide area in North America, in various parts of Continental Europe, where it forms vast forests, and is believed also to be truly indigenous to England. It grows from 70 ft. to 90 ft., and in some cases 100 ft. in height. Its flowers, which appear in May, are of a brown colour, small and inconspicuous. They are followed, however, in most seasons, by an abundant crop of fruit in the shape of small triangular Nuts, commonly called "Beech Mast." An old writer, with great truth, remarks that the Beech is "at once the Hercules and Adonis of our Sylva;" and it is scarcely necessary to say of such a familiar tree that for stateliness and symmetry of outline it has no superior, whether as seen in our forests or ornamental grounds. It grows with great rapidity in moderately dry and even rocky situations, and nowhere with greater luxuriance than in the chalks and marls of England, yielding valuable timber, and that in a shorter time than any

of our other hardwoods. It has long been employed as a hedge plant, both by itself and in combination with Hawthorn, making not only a strong and durable fence, but affording a shelter equal to evergreen shrubs, from the curious fact that, though naturally deciduous, when trimmed regularly as a hedge it retains its decayed leaves during the winter. There are several very distinct varieties in cultivation suitable for ornamental plantations, of which we recommend the following as the most desirable:—

**FERN-LEAVED BEECH** (*F. s. asplenifolia*).—This has its leaves cut into narrow segments having the appearance of Fern fronds. It is a remarkably elegant ornamental tree, with a compact habit of growth, and a great favourite for parks or lawns.

**CUT-LEAVED BEECH** (*F. s. heterophylla*).—Similar to the preceding, but quite distinct, the leaves being more irregularly cut; it is also a very beautiful tree, especially in the form of a single specimen.

**COPPER-LEAVED BEECH** (*F. s. cuprea*).—This differs only from the species in the colour of the leaves, which are light brown or copper coloured.

**PURPLE-LEAVED BEECH** (*F. s. purpurea*).—A grand variety, differing from *cuprea* in its leaves being of a deep, shining purple.

**LARGE-LEAVED PURPLE BEECH** (*F. s. purpurea macrophylla*).—This fine variety has its leaves a richly coloured as those of the last, but very much larger; it is as yet scarce, but without doubt a great acquisition.

**WEeping PURPLE BEECH** (*F. s. purpurea pendula*).—A beautiful variety with pendulous branches, forming, when grafted standard, high on the common Beech, a surpassingly beautiful lawn tree, and one, indeed, well suited for any prominent situation in the garden or other dressed grounds. All the varieties with purple or copper-coloured foliage are invaluable for associating with green-leaved trees, and they have been largely used in the production of the finest landscape effects.

**SILVER-VARIEGATED BEECH** (*F. s. variegata argentea*).—This variety has its leaves freely variegated with silver.

**GOLDEN-VARIEGATED BEECH** (*F. s. variegata aurea*).—This has leaves freely blotched with gold. Both of these variegated varieties are interesting, although in some situations, and notably in such as are moist and the soil rich, they have a tendency to revert to the normal state. When in good character, however, they are very striking.

**CRESTED BEECH** (*F. s. cristata*).—This is a curious form, with small, curled or twisted leaves, crowded into dense tufts. It is of dwarf growth, and well suited for a rock garden or for planting in collections of shrubs of moderate size.

**WEeping BEECH** (*F. s. pendula*).—This is a singularly beautiful tree, with long, weeping branches, forming a magnificent object when grafted on a tall stem and standing alone on Grass. It is of free growth, and soon forms a handsome specimen.

**AMERICAN BEECH** (*F. ferruginea*).—A deciduous species, of from 40 ft. to 60 ft. in height, introduced from North America in 1766. Its leaves are of a bright glossy green tint. This is probably only a variety of *F. sylvatica*, which it very much resembles, the chief differences being the reddish-brown bark, which doubtless suggested the name, and the short, obtuse leaf-buds. It has a similar habit of growth to the common species, and, as far as we have observed, quite as hardy in this country. The following variety, however, is so distinct, that it should never be omitted in even the most choice selection of ornamental trees.

**BROAD-LEAVED AMERICAN BEECH** (*F. f. latifolia*).—This sort has large, broad leaves, similar in form to those of the Chestnut. It is one of the handsomest of the group, of free growth, and very hardy.

HUGH FRASER, in the "Gardener."

### SUITABLE SITUATIONS FOR PLANTATIONS.

PERHAPS one of the most common mistakes made in forming plantations is planting in wrong situations. No intelligent forester will, of course, commit such mistakes if he can help it; but we have only to cast our eyes about us to see how frequently such mistakes are perpetrated. Trees are planted in wet situations and on undrained land, where it is well known they cannot thrive, and exactly similar blunders are committed in the other direction. Take the Larch, for example. It is a well-ascertained fact that it cannot thrive long in a wet soil; but how often do we see it planted in sodden, undrained land, and the trees dying prematurely in consequence. If it has light—that is, if the plantations are not left too crowded—the Larch, as a rule, thrives uncommonly well on dry soil, even though the latter be thin. The finest trees and soundest timber that ever I have seen have always been grown in such situations. In a large tract of Larch plantations not far from here, and which has lately been cut down and

used for colliery purposes, the trees were mostly all sound and good, very few of them exhibiting any decay in the centre, and they would possibly be about eighty years of age. The ground on which the plantation stood is naturally well drained, the soil, thin but not poor, being a fair yellow loam. There are many fine trees of the same age about in the same locality, all in good health, and, where exposed to the light, furnished with branches nearly to the base of the trunk. Where these Larches thrive, however, the common and Silver Spruce grow but very indifferently, the soil being too dry for them. We do not suppose a single Spruce of respectable dimensions or in good health could be found in the same locality; but in another part of the country, where the soil is moister and the rainfall much greater, the Spruces are invariably healthy and form fine trees of great girth, while the Larches are poor and everywhere exhibit symptoms of premature decay. Spruces make a sorry figure when planted for ornamental purposes on dry thin soils and in exposed situations. Of late years a fashionable landscape gardener has been using them extensively on an estate for clump planting on dry knolls along with other subjects, and at the present time more miserable objects could not be found anywhere. Curiously enough, the Deodars (*Cedrus Deodara*) and the Nordmann Spruce seem to thrive well in situations that suit either the Larch or the Spruce. The Deodar suffers a little from exposure, but not nearly to the same extent as many other Conifers. It is an excellent, sure-growing tree, whether the soil be poor or rich, moist or dry, within reasonable limits, and wherever a good solid evergreen fringe is wanted to a plantation it is the tree to plant. The Wellingtonia is not so particular as regards soil, but it is needless to plant it in exposed situations, or I may qualify my statement, and say situations exposed to north, north-east, or north-west, and east winds, which, when they blow with any persistency, make mere naked skeletons of the trees. This, indeed, is the fault of nearly all the more tender Pines. They make noble and symmetrical specimens when sheltered, and are perhaps hardy enough against frosts, but they do not stand the blast successfully. The Holly and the Yew are two valuable trees. They will grow tolerably well in the shade, and in almost any ordinary good soil; but in a dryish, strong loam both do best, the Holly particularly. Though a difficult subject to transplant, I never remember the latter to have shown any signs of distress from drought if the roots had had time enough to get hold of the soil; but the Yew occasionally suffers, owing to the habit of the roots, which spread out close to the surface; and hence the beneficia trees growing on lawns and other exposed places receive from top-dressings, which should be placed over the roots as far as they extend. Still, though there are trees that prefer a dry, and others a moist, situation; as a rule, all timber trees prefer a soil free from stagnant moisture; hence the necessity of drainage in plantations, which may be effected by means of open drains to a considerable extent, if the drains be out in parallel lines at regular distances apart, and kept open by periodical cleanings. I have known extensive woods drained in this way, when doing it in any other way would have entailed much expense.

J. S.

**Broad-leaved Hemlock Spruce** (*Abies canadensis macrophylla*).—This Hemlock has long been known to us, but, like many other fine plants, it has waited long for proper recognition. It is a true Hemlock, as its name indicates, but the growth, though fairly vigorous, does not equal that of the parent. Perhaps the most remarkable quality belonging to it is its colour. The green is decided, but of the darkest character, intensified, and made more remarkable by deep shades and shining lights, arising from the compactness and waxy lustre of the leaves. Differing somewhat from other dwarf Hemlocks, such as *A. pumila* and similar varieties, it is somewhat irregular in outline. Its proper use is in groups, combined with the contrasting colours of the Golden Retinospora and other dwarf Conifers, or planted singly near the borders and curves of walks. The origin of this Hemlock is a little curious. It was picked up over twenty years ago in the nursery of King & Murray, of Flushing, from amongst some common Hemlocks sent to them by a Western firm. This original plant was placed in a conspicuous position, and there it stands to-day, a mass of dark foliage some 15 ft. high, quite regular in form, and in full vigour, which can hardly be said of common Hemlocks of the same age. From this source was propagated all the first stock of plants that were sent out, and even now very few are produced anywhere out of Flushing.—S. PARSONS, in "Country Gentleman."

The Largest Chestnut Tree, probably, in the State of New Jersey was felled recently in Camden. On account of its giant size it was left standing when the land on which it grew was cleared in 1774. For many years this monarch of the ancient forests has been a land-mark in Camden county. It measured 21 ft. 9 in. round the butt.

GARDEN BOTANY.

(Continued from p. 367.)

**SCALY BULBS.**—The bulbs of different species of Lily are very diverse, but nearly all of them belong to the same type as fig. 111. Here the bulb consists of the fleshy leaf-bases, but instead of their being concentric, as in the Hyacinth, they are

Fig. 110.—Naked or scaly bulb of Lily.

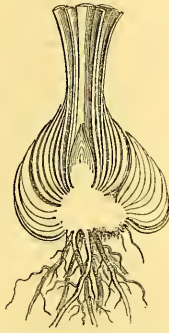

Fig. 111.—Longitudinal section of bulb of Lily.

narrow and scale-like, and often very loose. Such bulbs are termed scaly bulbs. The duration and reproduction of Lily bulbs varies in different species, but they only flower once. A peculiarity of many species is that, in addition to the tuft of roots at the base of the bulb, others are borne on the flower-stem above the bulb. The flower-stem either rises perpen-

Fig. 112.—Plant of Potato, showing stems, tubers, and true roots.

dicularly from the bulb, or, especially if the bulb be weak, it takes a horizontal direction for some distance before it rises aboveground, and sometimes bears several new bulbs on this horizontal portion. In some species the scales of the bulb are all of them the thickened bases of leaves which have appeared aboveground and died down to the thickened part. In other

species some or all of the scales were originally developed as such. Usually one new bulb is annually formed in the axil of one of the scales of the old bulb, and it is either seated within the scale or carried out an inch or more beyond it on a branch (rhizome). In some of the species of the allied genus *Fritillaria* the scales of the bulb are as thick as they are long, and closely packed together; whilst the bulbs of the familiar Crown Imperial (*F. imperialis*) have thin scales, and are very much like those of some of the Lilies. For more complete informa-

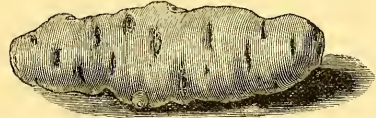

Fig. 113.—Tuber of Potato dormant.

tion on the bulbs of this class I cannot do better than refer the reader to Mr. Burbidge's illustrated memoir, which appeared in *THE GARDEN* in the early part of 1877. A familiar instance of a bulbous root-stock among dicotyledons is afforded by one of the Buttercups (*Ranunculus bulbosus*). It appears to be renewed annually, but in the spring very little usually remains of the old bulb. Two or three years ago, however, myself and several other persons found many of them in the spring which were very well preserved and attached to the new ones.

**TUBERS.**—A tuber is very similar in its nature to a rhizome; in fact, it is a portion of a rhizome very much thickened, or what is technically termed tuberised, which is eventually detached from the slender part of the rhizome; but a tuber under ordinary conditions is of annual duration, that is to say, this year's tuber forms a new plant next year and perishes, or its substance is used up in the early growth of the new plant. The presence of eyes (buds) in the tuber (fig. 113) are sufficient to determine that it is a stem formation, but if we follow the development of tubers from a seedling Potato we have proof of its nature. In germination the cotyledons of Potato seed are hypogæus, that is, remain underground, and the real root, of course, is produced below them. Above the cotyledons, and below the surface of the ground, horizontal branches

Fig. 114.—Mammillaria. Stem fleshy and leafless.

(rhizomes) are soon given off. They bear reduced scale-like leaves and roots, and at intervals become tuberised or enlarged into tubers. When the buds of a tuber start into growth, stems are formed which appear aboveground. On the lower part of these stems, quite close to the tuber, roots are formed, and immediately above them, as in the seedling plant, rhizomes, portions of which are eventually tuberised. The Jerusalem Artichoke has tubers similar to those of the Potato, but they are even more like swollen branches.

**RHIZOMES.**—A rhizome is a perennial, usually prostrate, subterranean stem, which lengthens at one end, and usually dies away at the other, and annually forms new roots, and throws up a flowering-stem or stems and leaves. Rhizomes are of two kinds, determinate and indeterminate, according to the mode in which they grow and extend themselves. An example of an indeterminate rhizome is afforded by the only too-familiar Couch Grass (fig. 115). It elongates by terminal buds, and ramifies in all directions, throwing up flower-stems from the axils of the scales with which it is furnished. The root-stock of the Primrose (fig. 116) is another form of indeterminate rhizome. On the other hand, the rhizome of the Solomon's Seal (fig. 117) is determinate. This makes annual growths from the axil of one of the scales of the previous year's growth; and each season the growth terminates in a flowering-stem, which emerges from the ground after having made a short horizontal elongation underground. The scars of each year's flower-stem are quite prominent, as shown in the figure, and it is to this circumstance, it is stated, that it owes its popular name. Most of the Irises have determinate rhizomes. Another indeterminate rhizome to mention is that of the Horsetail (*Equisetum arvense*, &c.) This often grows downwards in an oblique direction to the depth of 3 ft. or more, and is far more difficult to eradicate than the relatively superficial

Fig. 115.—Indeterminate rhizome of Couch Grass (*Triticum repens*).

Fig. 116.—Rhizome of Primrose.

rhizomes of Couch or Twitch Grass. Some writers extend the term rhizome to the trailing stems of Ferns, &c., and the root-stocks of herbaceous plants which do not elongate underground, but it is better to restrict its application to the limits above defined. Achimenes produce a curious, scaly root-stock, intermediate in nature between a tuber and a true rhizome.

**CONNECTING LINKS BETWEEN ROOT-STOCKS AND STEMS.**—There are some stem formations which cannot well be referred to any of the types of root-stock described above, because they are formed aboveground, though they are essentially of the same nature. In some plants there is a considerable prolongation of the axis below the cotyledons and above the ground. In transplanting seedlings of this kind they are often inserted into the soil up to the cotyledons, and then this part, which would have naturally remained aboveground, is subjected to conditions favourable to the formation of roots, and often does produce them. Aboveground this hypocotyledonary portion of the axis frequently gives birth to branches. In *Cyclamen* it develops into a circular, depressed body, from the underside of which new roots annually grow, and form the top leaves and flowers. The Turnip is intermediate between

the tap-root and this kind of stock. Another remarkable stock is that of *Testudinaria elephantipes*, a South African plant cultivated in the gardens of this country. Whether it is a hypocotyledonary growth I have not been able to ascertain, but it may be. It is a very large woody body, with angular, tessellated protuberances; and from the top the annual climbing stems are given off.

**TRUE STEMS.**—Under this head all the normal aboveground stems are included, no matter what their habit or size, as distinguished from the stem formations treated of under root-

Fig. 117.—Determinate rhizome of Solomon's Seal, showing the scars of three years' stems and the beginning of the fourth year's stem.

stocks. Stems exhibit a marvellous diversity of character in habit, size, shape, duration, internal structure, &c. As we treat of the minute structure of stems elsewhere, it may be passed over here. Branches of stems do not differ in function or structure from the main stem or trunk, and therefore they are included under the general term of stem in contradistinction to leaves, &c. With regard to the length or height of stems, although in popular, and even in botanical, language we speak

Fig. 118.—Simple (unbranched) stem of a Tree Fern (*Dicksonia antarctica*).

of stemless plants, this is not quite correct, because all plants have a stem or axis of some kind. Sometimes the leaves are crowded together close to the ground, as in the Primrose, but the part to which the leaves are attached is a stem, though short. Such apparently stemless plants are termed aculeous or stemless in descriptions, because in one word we are thus able to distinguish and separate them from the whole of those having an evident stem. This one word conveys a general idea of the plant under description. Stem productions bear leaves and flowers; roots under normal conditions do not. We have already enlarged upon this point in the paragraphs re-

lating to roots. Stems are either herbaceous or woody. The term herbaceous is not restricted to soft stems, but includes all stems of one season's duration, in contradistinction to those which are perennial and make distinct woody growth. What we call herbaceous perennials have a root-stock of more than one year's duration, but the flower-stems which they throw up each season are hard and woody in some species, though usually much less so than the more permanent stems and branches of trees and shrubs, even when quite young.

**DURATION OF STEMS.**—Popular classification of plants is based, to a great extent, upon the duration of the stem, whether annual (herbaceous) or perennial (woody), and we speak of herbs, shrubs, and trees. A tree is a woody plant with one stem only springing from the root, and the same species of plant may be both shrubby and arborescent, according to the conditions under which it is growing. Annual and

Fig. 119.—Simple stem of *Chameroops humilis*, typical of Palms.

biennial plants flower only once, those belonging to the latter category normally the second season, whilst the duration of the so-called annuals is from a few weeks to a few months. Besides these two classes of plants, there are other plants which flower only once, though they live several years or many years before they flower. Amongst the most remarkable of these we may note the American Aloe (*Agave americana*), Bamboos, and some Palms. The duration of the stem is here determined by the flowering period, after which it decays and dies. Plants which flower only once are termed monocarpic, literally fruiting only once; and plants which flower more than once are termed polycarpic. The duration of the stem is an important character, and the terms herbaceous and woody convey very distinct ideas to the mind; but it is a noteworthy fact that comparatively few families consist of either wholly woody or wholly herbaceous species. All the members of the Coniferae are woody plants, either trees or shrubs, and the Droseraceae is an

instance of a family in which all the species are herbaceous. As already mentioned, some stems of one season's duration are scarcely herbaceous in texture, and climate often determines the duration of stems. Some plants are shrubby in their warmer habitats, but in their colder habitats their stems are annual, because the frost cuts them to the ground every winter, and therefore they would rank amongst herbaceous plants. Examples of this kind are not wanting in cultivation, for both

Fig. 120.—Decumbent stem of *Veronica serpyllifolia*, with adventitious roots.

Fuchsias and Hydrangeas are successfully grown as herbaceous plants, though in their native countries and in the warmer parts of the kingdom they are shrubby. Something of the same kind happens to some woody plants, which are lofty trees in their warmer habitats, gradually dwindling down until they become prostrate shrubs in their boreal and upper altitudinal limits. Herbaceous plants have annual, biennial, or perennial roots, as we have already explained, but some perennials become annuals in a climate which kills the plant and not the seed. Biennials, if sown too early in the spring, or on poor soil, sometimes run to seed the same season, an occurrence of which every practical gardener has experience. Duration and size of stem is, then, greatly dependent on climate, though different plants in their natural climate are herbaceous and woody. Some trees, as some of the Poplars and Willows, grow very rapidly and attain their full size in 100 years or less, whilst the Yew is 1000 years or more before it reaches its prime.

**HABIT OF GROWTH OF STEMS.**—Stems are erect and unbranched, as in Tree Ferns (fig. 118) and most Palms (fig. 119), or erect and very much branched, as in the Oak, Beech, &c. Some stems are too weak and slender to support themselves erect, and are procumbent (lying flat on the ground), as in the Creeping Jenny, *Lysimachia nummularia*, or the flowering tips of the stems, rise as in *Veronica serpyllifolia* (fig. 120), and they are then called decumbent. Distinctive names are applied to some kinds of stem (branch). Thus naked, slender branches, like those of the Strawberry plant, which eventually bud and root, forming independent plants, are called "runners" (fig. 120a). The name "stolon" has been given to a kind

Fig. 120a.—Runners or Natural Layers of the Strawberry.

of runner which produces leaves before it roots, as the House-leeks, White Clover, &c.; and a "sucker" is a branch developed from an underground bud, sometimes lengthening horizontally for a considerable distance before appearing above ground. Other stems climb by means of tendrils, as the Grape Vine, Pea, &c., or by adventitious roots, as the Ivy. Others, again, twine round the stems of neighbouring plants, as the Scarlet Runner Bean and some of the Convolvulaceae. Some twiners turn in one direction and some in the other, but

into life. And yet, if we desire to make the most of imported bulbs in the open grounds of this country, we are compelled to plant them so late in the season that the flowers are, in many instances, out off by frost. If, then, the flowers themselves are subject to being destroyed by frost, what is to become of the tender and delicate germ? for it cannot even have any existence until after the flowers have faded in their natural way. June, July, and August is allowed to form the hottest portion of our year, and it is during that period that the different classes of bulbs, according to the dictates of Nature, liberate their germs in this country. Is it reasonable, then, to expect that an object so minute and delicate as the germ will be awakened into healthy life in the midst of cold and frost? The new bulb, or that which Nature intended to be the parent of the germ, is at this time, when the old bulb is blooming, fully developed, that is, it has within itself a young stem composed of rudimentary leaves and flowers. These were destined to be the above-ground portions of the plant next season; but whether they may succeed in blooming more or less favourably, or not at all, must depend on how they may be able to get through the winter. But where, at this time, is the germ—the origin of the plant that should bloom the year after next? In all probability the cold and frost prevented it from being liberated, or, if haply liberated, prevented it from vegetating; and thus the plant, in a very large proportion of cases, dies out the third year. Can we wonder, then, at the complaints that are made that only a portion of the thousands that annually arrive in this country bloom the first year; that they bloom in less proportion the second year; and that, by the third year, we see them no more? It would be contrary to the laws of Nature to expect anything else. We are favoured from time to time with the experience of those who have the means of growing Lilies under glass. But while we admire what they do, and can do, we should not overlook the wants of those who desire to grow Lilies in the open air; for their name is Legion; and they no doubt search the columns of THE GARDEN for guidance on the subject. It must, then, I think, be very reprehensible in any man to advance for such a purpose mere theoretical opinions without the shadow of a single experimental fact to rest upon. I am induced to say this because I have observed for some time that those who adversely point their remarks at me are among themselves entirely at variance with one another, differing in opinion as well as in theory, no two agreeing entirely on any one point, thus proving by the most undeniable evidence that, though this is the year 1878, the time has not yet come when the organic structure of the Lily is to be considered an understood and settled question.

I have enlarged so fully on the Lily during the first month of its existence that little is left to say about the second. All that can be said is that the parts increase in size, but increase so very slowly, though never dormant, that it is not until the end of the third month that we begin to be able to discern the germ or seed-bud, as I would now call it, by the naked eye. During this time the young stem, composed of rudimentary leaves and flowers within the new bulb also increases in size, pushing out the scales of the new bulb, which become more and more consolidated, increasing the size of the new bulb and adding considerably to its weight. This slow proportional increase in all the parts of the bulb goes on during the fourth and fifth months, and it is not until the sixth month that we can have the view of the interior, which is faithfully represented at p. 143, in the woodcut engraved from a photograph of the parts themselves, after having dissected a number of bulbs which were taken up for the purpose on Jan. 1, thus showing the seed-bud when it was just six months old. Hitherto I have written as if the new bulb liberated only one germ or seed-bud; but, as it is a known botanical fact that "plants, like animals, are organised and living beings," and that in the animal creation there are sometimes twins or two at a birth, and sometimes, but very rarely, triplets or three at a birth, so, in like manner, a Lily bulb will sometimes liberate two germs at a birth, and another will, but very rarely, liberate three germs at a birth. In such cases, as I have said in a former paper, these germs spring up close together, and as they grow they spread outwards, making room for their separate growths, and, when fully developed, they show two or three separate crowns, as the case may be, contained apparently within one bulb, as may be seen on inspecting a large number, but, when dissected, they expose two or three separate and distinct new bulbs, nourished, however, by only one set of roots. It is thus that these phenomena have given rise to very mistaken ideas on the subject, as they have often been described as central and side buds. With respect to these two but distinct classes of buds, the experimentalist knows where to find the central bud, even before it becomes visible to the naked eye, but no man can tell beforehand where a side or accessory bud may make its appearance. Central buds I call legitimate germs or seed-buds, side buds I simply call very young offsets, the former always flowering in the fullest manner within two

years from their birth, the latter taking two years or more before they can produce a single flower.

At p. 252, where I am glad to see M. Leichtlin's name, we are favoured with some remarks from him on the subject, but which, for want of space, as I suppose, they appear, to my great regret, to be somewhat ambiguous. At one place he says: "As to the majority, or perhaps as to all Lilies of the Old World, 'Dnedin's' theory seems to apply exactly, as far as the formation of the next year's bulb from side buds is concerned, but not in relation to the entire decay of the old bulb." M. Leichtlin admits, however, at the same time, that he has carried out few experiments by dissection. Had he done so to any reasonable extent, I think he would have been compelled to admit that my theory, as he calls it, is founded on the action of the legitimate central germs or seed-buds, and not at all on anything that can by any possibility be called side buds, as these, though they may, by cultivation, be made to propagate or multiply the species, have nothing whatever to do with the legitimate or hereditary accession of the old bulbs. At another place he says:—"As to *L. giganteum* and *cordifolium*, I must openly say that I have made no dissections in regard to them, but, from studying these plants in the shape of hundreds of bulbs, as far as growth is visible, it seem obvious to me that these species do not produce annually a new bulb from a side bud, but that the old bulb is enlarged annually by the scales growing larger through the growth accumulating from a central bud; and that during summer, when vegetation is active, another central bud is developed to grow next year." Now, the careful reader cannot but see that this, in a great measure, supports my doctrine. But, as I have stated in the columns of THE GARDEN on various occasions, it is utterly impossible for any man to form a correct opinion of the organization of the Lily by merely examining the outward or visible appearance of any bulb; and, in this case, M. Max Leichtlin frankly admits that he has gone no farther. M. Max Leichtlin closes his remarks by saying:—"I am of opinion that 'Amateur' (see p. 198) is right in his views, and that he will certainly be able to prove that the old bulb does not decay every year." I must confess that I am very greatly surprised at such a remark, coming, as it does, from M. Max Leichtlin, my opinion on that point being entirely in accord with that of Mr. George F. Wilson, when he says: (see p. 252) "If 'Amateur' can flower *L. giganteum* twice from the same bulb, he is a fortunate man." I will even venture a step further and say:—"If 'Amateur' will prove that he can flower any one of the Old World Lilies twice from the same bulb, he will prove himself to be a man of no ordinary standing among Lily growers."

At p. 227 "E. H. W." says, "The different ways of reproduction in Lilies are so marked that alone it would afford subject matter for endless remarks and controversy." This is entirely contrary to all my experience, for I have always observed a most interesting and singular similarity in the organisation of all the kinds coming under the denomination of the Lily proper. I therefore feel convinced that if "E. H. W." were to begin with the Old World Lilies, the greater part of which can be had in quantity and at comparatively little expense, and make careful experimental dissections at different times during the year, and then go on to the newer, the rarer, and the more expensive kinds, he would find that what he has now said on the subject would require to be entirely altered; for, as the matter stands at present, his remarks have not carried the subject a single step beyond "the theory which terminates in mere speculation," but rather adds to the "endless remarks and controversy," already going on with so little real benefit to the inquiring Lily grower.

I now come to a remark made by Mr. Groom, which I should like to have cleared up before we get wider apart. At p. 252 he says, "The only point to which I took exception was that of cutting down the flower-stems before the leaves had faded. 'Dnedin' will himself see that there is a wide difference between cutting the stems down in full and fresh bloom and waiting until ten days after the bloom has fallen to perform that operation." As I believe that there is here some misconception, I would take it very kind if Mr. Groom would point out to me the page and passage which has led him to make this remark. I have said somewhere that I have cut down Lilies in full bloom without affecting the growth of the new bulb; and I have also said that, as soon as the bloom is perfected and decaying in the natural way, the new bulb may be transplanted with perfect safety, as at that time it is pushing down its own roots, which are quite sufficient for its nourishment without any aid being required from the old leaves or stems. Mr. Groom will see that I have never professed to illustrate the distinctions that exist between "bulbs of all kinds" and the Lily, but have endeavoured to explain the nature and organisation of the Lily bulb itself, and, as I think, so clearly, as may enable Mr. Groom and other able horticulturists to draw the true line of distinction themselves. This much I know, that great stress has always been laid upon the fact that the foliage

of other bulbous roots should be allowed to grow until it decays in a natural way. But the Lily, I venture to say, is an exception to this rule, though not in general considered so. DUNEDIN.

### BUSH ROSES.

THESE are, as a rule, not nearly so effective as they might be. The usual course is to prune and simply to allow them afterwards to grow in what form they may choose to take. On their own roots, in genial soil, they yearly acquire strength such as necessitates, at the time of annual pruning, the specimens being allowed to get to a larger size, especially in height, the result of which is that the strong shoots, from which the greater portion of the flowers are produced, grow to a considerable height, at which point most of the blooms are borne, leaving the plants comparatively thin and bare at the base. Although it is anything but desirable to train Roses in a way that gives any approach to formality, still such an arrangement of the shoots may with advantage be employed as will keep them well furnished with a fair proportion of vigorous growth and full-sized flowers down to the ground, at which point in-

A Bush Rose.

dividual plants have the greatest breadth, gradually tapering up to the top, as in the accompanying illustration of a well-managed bush Rose, wherein, as will be seen, the form is devoid of undue stiffness, yet such as to produce an effect not possible where the plants are left to themselves. To produce the effect exemplified in the illustration it is necessary to have strong, vigorous plants established for years on their own roots; at the time of pruning, or soon after growth has commenced, a portion of the strongest shoots should be bent down and tied out horizontally to a few sticks stout enough to keep them in position allowing the remaining growths, shortened back to different lengths, to assume the position such as will lay the groundwork for the specimen which later on will be clothed with foliage and flowers. The central branches, according to the more or less strong-growing erect habit of the variety, may require a few sticks to hold them in their places, but the whole of such supports will be effectually hid by the foliage, and no trim outline should be attempted. The illustration is not an ideal conception, but simply a representation of a well-managed vigorous bush Rose. It will be easily understood that it is not desirable to attempt the training of Roses in this way in positions of all descriptions, or where they can much more appropriately be left to assume a wild form; but for beds in the immediate vicinity of a mansion in the more highly dressed portion of the grounds, where they will be in keeping with the surroundings, they at once produce an effect in every way

unexceptionable. By the side of a broad walk either straight or winding, where something is wanted to relieve a too even surface, rows of Roses at intervals more or less far apart, so trained, are infinitely superior to the naked-stemmed, mop-headed standards, so generally used in such situations; in addition to their shape, satisfying the eye in a way not possible with the standards, it is much easier to get a number of bushes sufficiently equal in their growth to keep up the requisite uniformity in the whole than it is with standards, which, when placed singly in rows, are so provokingly subject to a portion growing freely, and the others very little. T. BAINES.

### CUTTING DOWN LILIES IN FULL BLOOM.

I REGRET that "Dunedin" should have misunderstood my remarks about cutting down Lilies. I said nothing about *Lilium candidum*, which, though a Lily, has no analogy whatever, as regards treatment and growth, with many other Lilies. The only safe and sure way to speedily raise good, large, sound, white Lily bulbs is to cut away the flower-stems as soon as they appear aboveground, every inch of growth weakening the bulb; and they should always be transplanted, if they are to be removed at all, the very moment the last flower has faded, cutting away the old stem as low as possible. I had supposed this was so old and well known a custom that I did not allude to it. I wrote: "After thirty years' experience with thousands of bulbs of *L. speciosum* and its varieties." It does no more injury to cut away the flower-stem of *L. candidum* when in full bloom than it does to cut off the flower-spike of a Hyacinth, the flower-stem of a Gladiolus, the flowering-shoot of an Amaryllis, or the bloom of the Guernsey Lily. The leaves are all left, and these are all that are needed to produce a sound and perfect bulb. If this were not so, it would have been discovered long ago. With the Lilies, however, that have no leaves, only such as grow upon the flower-stem, it is quite another and totally different thing. Nature points this out. If the flower-stem of *L. giganteum* be cut away as soon as it makes its appearance, the leaves and bulb will increase in size; but if allowed to grow and bloom it so absorbs the nutriment of both, that nothing but weak offsets are the result. It is the same with the Century plant. When the Hyacinth growers of Haarlem tell us the bulbs are just as good if the foliage be all cut off, or the Gladiolus cultivators of France that cutting away all the leaves does no harm, or the Amaryllid growers destroy all the leaves, and the Guernsey Lily cultivators say the bulbs will flower just as well without making any foliage, I shall believe that cutting down such Lilies as make no root or bulb leaves does no harm. As to *Lilium candidum*, when the flower-stem is cut away the bulb is really greatly benefited, as "Dunedin's" experiment proved, just as removing the flowers or buds from any plant increases its growth and vigour. The leaves all remain, and it is these that nourish and sustain the root. If "Dunedin's" practice be correct with Lilies which have no bulb leaves, then we must have new rules for bulb culture, and the old custom of securing a vigorous, strong, and healthy foliage must be discarded. Boston. C. M. HOVER.

**Santolina Incana.**—This is one of the most useful of plants for forming edgings or divisional lines, and, being of a whitish-grey tint, it may be employed in many varying combinations. Its habit of growth is neat and compact, and, being hardy, it especially commends itself to those who have but a limited amount of glass structures. Cuttings of it put in under hand-glasses or lights in September make excellent little bushy plants for furnishing beds in spring. By having a good supply of this, and such plants as *Violas*, *Polemonium coeruleum*, *Golden Thyme*, and similar plants, bedding-out, as it is called, becomes a more reasonable affair than when all the subjects employed are tender.—J. G.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Tree Pæonies and Frost.**—By way of answer to "B. S.," Rutlandshire (see p. 323), who is desirous of ascertaining the effect of the recent frost on Pæonies, I may state that here they suffered so severely that I don't think they will recover this season. A few Roses that were pruned early were also cut down, and the leaves of Violets were scathed, as if scalded. Anemones, which were in full bloom, had the latter greatly discoloured, but they are again in full beauty. Frost does not appear to affect the herbaceous Pæonies, and though we had from 7° to 10° for several nights, with blinding snow-storms, herbaceous plants generally withstood the storm bravely.—N. FULLER, *Dawnton Castle, Ludlow.*

**Aquilegia viridiflora.**—As a rule green flowers are not worth growing, but this Columbine is an exception; the sage green of the flower and delicate tint of the leaf form a striking contrast.—A. K., *Eastcott Cottage, Pinner.*

mere appearance sake, as if for the next fortnight it lays sufficiently open to permit sun and air to penetrate it, it will be in a much better condition for planting than it otherwise would be. Continue gradually to harden off bedding plants of all sorts by transferring them from the close, warm atmosphere of the propagation house to cold pits and frames, and afterwards to sheltered situations in the open air, where they can have the protection of mats or other materials when danger from frost is apprehended. Annuals which may have been sown some weeks since in heat, will now be fit to prick out into pans, boxes, or frames. Keep them for some time somewhat close until they become again established, when they may become gradually hardened to full exposure to the open air, when advantage should be taken of the first opportunity after a good fall of rain to plant them out where they are intended to flower. Seeds may also be sown now, upon a shady border in the open air, of such plants as the Sweet William, Wallflowers, Anemones, Pansies, Polyanthuses, and Alpine Auriculas; or such seeds may be sown in pans or pots under glass, and planted out when large enough to be handled. Keep beds of Carnations, Ranunculuses, or Tulips free from weeds and decaying leaves, and carefully support the flower-stems, &c., by stakes whenever this may be found necessary. Patches, or beds, of the various kinds of Violets should now be broken up, and strong well-rooted runners should be selected; these should be pricked out into light sandy soil on a shaded border, and should be well supplied with water until they are fairly established. It is always advisable to form fresh beds of these plants every year, as young plants are always found to bloom more profusely than old ones, and they also furnish much finer flowers. Amongst the finest of these sweetly-scented flowers is the Neapolitan variety,

the open air, or the plants turned out of the pots and planted in the soil permanently. In some cases it may be advisable to re-pot a few, and to keep them growing for conservatory decoration, or for planting in the outdoor Fernery, after their fronds have been formed indoors.

**Wall Climbers.**—It frequently happens that flowering plants, such as Roses, Clematises, or others that are employed for clothing walls, are indifferently trained at the commencement, by which inattention they very soon get nearly or quite bare at the bottom, making the best growth and producing almost all their flowers at the top of the wall, however high that may be. In growing fruit trees on walls the skilful operator is careful to train a sufficient number of strong branches low down in a horizontal position so as to balance the growth and to keep the bottom of the wall as well furnished as the middle and top. If the same care were taken with flowering plants when employed for the purpose of covering walls the subsequent effect would be much more satisfactory. Where large plants have been allowed to run up and become naked at the bottom there is no resource but either partially or wholly heading them down. Those consisting of a few strong and the remainder weaker branches should have the strong ones headed down near the base of the plants, which will cause them to break out, and the shoots they produce may be arranged so as to clothe the bottom of the wall, retaining the weaker growths, which will obviate the bare appearance that results from a total cutting back. Over the walls of buildings or on those of a considerable height a very good effect may be produced by planting Pyracantha, Cotoneaster, Pyrus japonica, and other plants of a similar character, in order to clothe the bottom of the wall with Clematises, Honeysuckles, Jasmines, Passifloras, or Wisterias to train over the top. Where any alteration is required in

Oak Fence (Worcestershire).

although it seldom succeeds well in the open air in this country, but requires the assistance and protection of a frame; where, to induce it to produce blooms early in the spring, it should be planted near the glass, and the temperature of the frame should be slightly increased by means of fermenting materials placed around it. The double and single Russian kinds are very useful and quite hardy, as are also the varieties known as the King and the Queen of Violets. The former is a fine, large, double, dark blue sort, and the latter, with flowers equally large and double, is in colour nearly pure white; while the Czar is a fine, hardy, robust sort, producing a profusion of single blooms at an earlier period than any of the other sorts, and is, perhaps, slightly less sweet-scented than some of them. There are, also, in addition to the sorts already mentioned, several other valuable varieties, including some novelties, which are highly recommended. The present is also a suitable time to cut and regulate the margins or Grass verges of walks and clumps, &c. This operation should be carefully performed with the edging iron, with the assistance of garden line and pegs, and this should be done every season, or at least once during every two years, although a deep raw edging to a walk is exceedingly objectionable, yet the level of the sides of the walk, so as to admit of the Grass shears being applied, and these should be used on every occasion when the Grass is mowed.

**Hardy Ferns.**—Remove any old leaves that may be on deciduous kinds out-of-doors, and loosen the surface soil about them, making it at the same time clean and neat. Roots of these may yet be safely transplanted in shady nooks. Hardy Ferns wintered in frames and greenhouses should have their old fronds cut away, the mould on the surface of the pots cleared off, and the pots themselves either plunged in the Fernery in

wall coverings the present will be found a good time to attend to it. There is one cause through which wall plants, especially Roses, frequently suffer to such an extent as to render it impossible for them to have a pleasing appearance—this is through such insects as green fly or red spider being allowed to increase upon them unchecked. From the warth which the wall affords, these pests generally appear upon such plants as they can live upon earlier than on those growing in an open position, and as rain has but a poor chance of effecting the removal of the insects, on account of the shelter afforded by the wall, the plants are almost wholly dependent upon the use of the syringe or garden engine for their riddance from these marauders. A plentiful supply of clean water alone, if applied sufficiently early and continuously as required, will keep the insects in check, but if a good look-out be kept so as to detect them when they first make their appearance in spring, and a thorough syringing be given with Quassia or Tobacco water, it will generally be found an effectual preventive. Climbing plants that thus receive sufficient attention thrive and flower very differently from those that exist under a state of neglect.

#### Kitchen Garden.

A sowing of French Beans may now be made on a warm border. It is not, however, advisable to put in many until the beginning of May, as they are liable to be injured by the weather; neither is it advisable to sow at all until May where the land is of a cold, retentive nature; but in such localities, when this vegetable is particularly desired early, a fortnight may be gained by at once planting a couple of Beans in 4½-in. pots, and keeping them under glass until the third week in May, after which there will be little danger from frost. At this early sowing do not cover the seed more than 1 in., for if sown deeply, and the weather becomes

very wet, it will rot. The Paris Red Flageolet is one of the best of dwarf Beans, being good in quality and a heavy cropper. A few Runner Beans may also now be sown in a dry situation, but do not at present risk too many. They are generally grown in rows 6 ft. apart on tall sticks, but it is not necessary that they should have sticks of great length, unless where these can be procured at little or no cost. Ordinary Pea-sticks, say 4 ft. in height, will answer very well, pinching off the points of the shoots as soon as they get to the top of the support, and in this case the rows do not need to be more than 4 ft. apart. They will, however, do well without any sticks. If the rows be planted 3 ft. apart, the seed 9 in. asunder in the rows, and they are simply allowed to lay on the ground, they keep breaking out and flowering all through the season, and the quantity of Beans which they produce would not be credited by those who have not seen them grown in this way. A few more rows of Turnips may now be sown, and for the general crop none are better than the Red-topped American Stone, already recommended for the earliest sowing. As with most other vegetables, it is much the best practice to grow Turnips in rows. Sowing in this way takes a little more time, but any loss in this is saved many times over by the facilities given for the use of the hoe in place of hand-weeding, which must in a great measure be resorted to where such crops are sown broadcast. Another sowing of the different sorts of Broccoli before advised should now be made; also one of Cauliflower, both Summer and Veitch's Autumn Giant. More Lettuces should likewise be sown, and they are to be sown now, and all through summer, these should be sown in rows where they are to be grown. The ground for them should be well manured; the rows should be 15 in. apart, the seeds put in thin, and, when large enough to handle, they should be thinned out to 1 ft. or 15 in. apart. Another sowing of Broad Beans may be made where these are required late, but such as are put in now will not bear so well as those sown earlier. Pot Marjoram, Sweet Marjoram, Thyme, and Sage should now be sown on ground previously well prepared for them by fine raking, as owing to the seeds being so small they will not be lost if the surface was rough; after raking, smooth the surface with the back of the spade, then sow the seeds and cover lightly with sifted soil. A little Beet may now be sown for an early supply, but do not yet sow the principal crop, as it is liable to run to seed if sown early. Sow in ridges 15 in. apart; where the soil is shallow it may be drawn into ridges about 6 in. high, and on these sow the seed, four or six together, in shallow holes 1 ft. apart, covering them not more than 3 in. deep. A little more Cabbage seed should also be sown, using on this quicker than the small-growing Cooconut, a kind which comes to maturity quicker than the large varieties. These will form good heads for use all through the autumn, planted on ground on which the first Potatoes and other early crops have been grown. One of the principal things to be observed in a well-managed kitchen garden is to always have in readiness something to plant in the places of such crops as have just been cleared off. Keep the hoe going wherever it can be used when the weather is dry. The ground occupied by Gooseberries, Currants, and Raspberries should be well hoed before weeds attain any considerable size.

#### Extracts from my Diary.

April 29.—Sowing two rows each of Carters' Champion and Painted Lady Runner Beans; also Mustard and Cress. Putting in cuttings of Double White Primulas. Planting a three-light frame with Vegetable Marrows to be ready in early. Levelling down Celery trenches and getting them ready for Peas. Forking amongst Potatoes and getting them earthed up where required. Giving all the newly-planted Cauliflowers and Lettuces plants a good watering; also all newly-planted Fruit trees and shrubs.

April 30.—Sowing Canadian Wonder French Beans. Potting off Coleus and Alternantheras. Planting out Carters' Giant White Coo and All the Year Round Lettuces, and thinning out those left in the seed bed to 1 ft. apart. Digging out Celery trenches and getting manure into them. Looking over all Strawberries that are fairly set, picking off all weak and late blossoms, and giving them weak guano water three times a week. Looking over Peach houses, tying in all young shoots, and syringing them freely night and morning.

May 1.—Sowing Veitch's Autumn Self-protecting Broccoli. Pricking off Celery, Stocks, Asters, and Violas. Thinning out and tying down young shoots in Vineries and thinning out the Grapes where required. Clearing off Broccoli stumps. Manuring the ground and getting it dug up. Thinning out and hoeing amongst Turnips and tying up Lettuces to blanch.

May 2.—Sowing Balsams, Cinerarias, Calceolarias, and Primulas. Transplanting white Spanish Onions brought forward in pots. Washing Roses on walls with Quassa-chip water, in order to kill green fly. Removing the coverings off Apricot trees, and thinning the fruit where set too thickly. Spawning and moulding over a Mushroom bed under a north wall. Cutting out all Rhubarb flower-stalks as fast as they appear. Renovating all linings round frames.

May 3.—Sowing Spinach, Cardoons, Early Snowball Turnips, and a little Endive. Potting Balsams and Caladiums. Looking over Cucumbers and Melons, stopping them, picking off all false blossoms, and earthing them a little where required. Getting out drills and planting early-sown Leeks. Thinning out Parsnips, and hoeing the ground amongst them.

May 4.—Sowing Asters, Stocks, Mignonette, and other annuals. Looking over Peach trees on open walls, disbudbing them, and washing them with Quassa-chip water, in order to kill green fly. Mowing and

cleaning up pleasure grounds, and rolling down all gravel and turf that require it. Watering such Pines as require it; also inside Vine borders. Hoeing amongst all growing crops. Fruit in use for dessert: Pines, Apples, and Strawberries. W. G. P.

Dorset.

#### RUSTIC FENCES.

WANDERING, some years ago, in the neighbourhood of Worcester, I was shown what, in the absence of any other distinctive name, I shall call a "Saxon" fence. As the annexed illustration will show, it is an ordinary open paling, but constructed of grotesque pieces of split wood fastened in a wilfully conspicuous manner with wooden pegs. Its picturesque appearance and thorough fitness of purpose prove that some, at least, of our forefathers possessed a keen sense of the beautiful. Let us examine this fence in detail. In the first place the materials are found on every estate, and generally when so found are consigned to the firewood heap, from the supposed impossibility of using them for any other useful purpose. But as this fence consists of split wood (the more gnarled and contorted the better) it can be made, to a great extent, from such refuse as old hollow trunks and twisted boughs, of no value for timber. With these some fairly straight wood should be used, or the fence will possess too much Japanese grotesqueness, and will lose one great element of its beauty—fitness. Although refuse wood is used, it should consist of hard-wood timber and fairly sound, or by the time our humid climate has beautified it with Moss and Lichens it will need renewal. The pins or trenails must, of course, be made of good heart wood, as, being so slight, they would soon decay if made of sappy material. One great advantage of an open fence consists in its suitability for climbing plants, whose beauty on a close fence is partly lost, as one does not get those side views of leaves and sprays which an open fence affords; and the distance, in this case, is able to lend enchantment to the view. In a close fence all is seen at once, and that all—foreground. Another advantage in the use of such unshaped wood is the infinite variety which it affords in place of the wearisome monotony of the ordinary open fence, where each opening and pale are counterparts of the others. In the Saxon fence, on the contrary, no one part is a repetition of any other; and, from the facilities which it gives for varying its height without incongruity, the sky line can be made as varied as it is necessary, and that is surely another greatly neglected element of beauty in modern "mechanical" ornament. For Clematis or other screens the construction of a similar skeleton or framework would afford a good opportunity for displaying individual ability and taste; and if varieties of Ivy were allowed to climb partly up it, such screens would remain objects of beauty all the year round, as I have found Ivy to flourish even when covered in summer by *Convulvulus* (*Calystegia sepium*). A few sprays of the Ivy might be allowed to climb to the top and bloom, but in that case the beautiful shape and venation of the leaves would be lost. In or near towns rustic work is a mistake, as Lichens and Moss will not grow while soil finds too ready a lodgment on every inequality. LONDON STONE.

[For a beautiful photograph, from which the annexed illustration of this fence was prepared, we are indebted to Mr. Richard Smith, of Worcester.]

**Aucuba Berries.**—The introduction of the male varieties, by which we have been enabled to fertilise the flowers of our large out-of-door bushes, has not been attended with such good results from a decorative point of view as was anticipated, for, unlike the Holly and other showy berry-bearing plants, until the following spring, when the young foliage soon overgrows them. In order to have them in really good condition at Christmas they must be introduced to a glass structure in autumn and treated similar to *So-anum* *capitatum*.—JAMES GROOM, *Hendon*.

**Seed Variations of *Phormium tenax atropurpureum*.**—The dark purple form of the New Zealand Flax having seeded freely in the nursery of Messrs. Thibaut & Ketteler at Secaucus, last autumn, much curiosity was felt as to whether the peculiar deep colouring of the parent would reproduce itself in the seedlings. As yet this is apparently not the case, as the young plants which have come up very freely are either completely green or cream-yellow, which, as stated in last week's *Gazette*, cannot live. Whether the green seedlings will assume the deep purple tint of their parent at a later period of their existence remains to be seen.—W. E. G.

## ANSWERS TO CORRESPONDENTS.

**Planting Irises.**—When is the best time to plant Irises, bulbous as well as rhizomatous?—B. [Bulbous Irises should be all in the ground by October; September is even preferable for some kinds. The evergreen Irises you can move at almost any time; but early in autumn is best for the vigorous growing varieties of the Germanica type. I. Kämpferi, cristata, and others of similar character should be planted soon after they have done flowering so that they may get well established before winter.—A. P.]

**Diseased Grapes.**—In my Vineyard, I have, among others, one Vine of West's St. Peter's that for two years before beginning to colour has had most of the berries covered with round, dark, nearly black spots, which, to some extent, disappear when the Grapes colour, but seem to leave the skin so tender that half the Grapes are cracked. As none of the other Vines have been similarly affected, I am puzzled to find the reason, and beg to trouble you on the subject.—J. D. [The probability is that the spots complained about are caused by the atmosphere being overcharged with moisture. Reduce this just before the Grapes begin to colour, and by free ventilation keep the atmosphere buoyant and sweet; the spots will not then trouble you, and the Grapes will colour all the better.—W. W.]

**Destroying Woodlice.**—Can anyone recommend any effectual means of destroying woodlice? My Orchard house is infested with them.—F. B. [Many ways of destroying woodlice are given in Quid's "Garden Receipts," and amongst them boiling water poured into the crevices into which they retire during the daytime is said to be a good plan. Care must, however, be taken not to let it injure the plants. Trapping with eliced Potatoes might be tried.]

**Evergreen Hedge.**—What is the best kind of plant of which to make a hedge for the purpose of hiding a roof? I should prefer it to be evergreen, and it would have to be ultimately from 10 ft. to 14 ft. in height. The soil is strong and well drained, with a gentle slope from north to south, the line of the proposed hedge being the same. I have thought of Holly and Yew, and was in doubt between them; the former, as it sheds its leaves at times, is littery, and the latter, I am told, is slow of growth. A friend recommends Thuja Lobbi.—B. [I have tried Cupressus Lawsoniana for making an evergreen hedge in a kitchen garden, and have found it to be excellent for that purpose. It grows quickly and bears clipping and pruning well, and when in flower it is highly ornamental. Thuja Lobbi, I have no doubt, would also answer, but it does not grow so fast as the Lawson Cypress.—W. T.]

**Landscape Gardening.**—You would do me a favour if you would kindly tell me what would be the necessary instructions to enable a youth of eighteen years to study landscape gardening. He has served four years under a practical gardener, but he wishes also to have a knowledge of landscape work.—J. H. [He ought to work at ground-work as a contractor, and also under a good landscape gardener, and be taught also to travel a good deal abroad as well as at home if he wishes to become a good landscape gardener. See chapter on Park Monceau in new edition of the "Parks and Gardens of Paris" (Macmillan), where what a landscape gardener ought to know is outlined.]

**Worms on Lawns.**—How much salt should be sown per acre on lawns to keep down worms, of course so as not to injure the Grass?—J. H. [The usual quantity of salt for a dressing on lawns to keep down worms is from 5 to 7 bushels per acre; but in any case salt is a dangerous remedy, and liable to do more injury than the evil which it is intended to cure unless very cautiously applied. When put on in a dry state it is liable to be washed into low-lying portions by a sudden downpour of rain, and kills any vegetation with which it comes in contact; it is, therefore, safer to apply the minimum quantity in a liquid state, and to repeat the application after a week, when it will prove a stimulant to the Grass or any crop to which it may be applied.—J. G.]

**Mesembryanthemum cordifolium and Sparrows.**—Last year I edged two beds with this plant, and was greatly troubled with sparrows eating off the leaves. They completely stripped the plants, for which I was obliged to substitute others. My first crop of Beet was sown in the same way; they eat off the plants as soon as they came up. I should like to have the advice of your correspondent on this subject. Is there any way by which I can protect these two useful and ornamental plants?—C. H. Kircrain, Colchester Park. [The only safe mode of saving the Mesembryanthemum from sparrows would be to stretch a small piece of netting over the edging till the plants acquired size and strength. After sparrows have brought up their young they go in flocks to the beds to dig for grain, and are not so troublesome in gardens as during the month of May and June. The net could then be removed. Findings of white-worms stretched over the edgings might be tried, as these, I trust, keep sparrows off early Peas, and they do not like scot if spread thinly over the foliage.—W. T.]

**Romneya Contleri from Seed.**—Is this Poppywort difficult to propagate from seed? I got packets of seeds of it from two different seedmen last year, and they did not come up; and this year I have sowed in heat, and no sign of them. I saw it in flower at Glasnevin, out-of-doors, in last January.—F. O. [Romneya Contleri is not difficult to raise from seeds; but, like those of so many other American perennials, the seeds are slow and irregular in their germination. Ordinary greenhouse temperature is sufficient, in which a few of the seeds will start after a month's rest or upwards, and successive crops will appear for at least a year subsequently. More than ordinary care must be taken in transplanting, the seedlings being tap-rooted. If only a few plants are wanted, the best plan is to sow very thinly in thumb pots, and, as soon as a few seedlings have attained the height of 1 in. or so, the ball of soil should be carefully divided, so that each plant can be separately potted without

disturbance of the delicate root fibres; or the method pursued with Mignonette may be followed. All the seedlings may be thinned out but one, and that may be allowed to grow till the pot is full of roots and a shift is necessary.—W. T.]

**Wellingtonia Cones.**—The illustration of the cone of the Wellingtonia (see p. 333) is a very beautiful one. We have a tree of it here bearing a large number of cones. Is this a common occurrence?—CAMBRIDGE.

**Insects.**—W. G. Your beetle is Olorhynchus caelestis, an insect well known for its destructive properties.—Grab in Orchard House.—T. C. [It is impossible to say what is your best to do unless one knows the particular grub in question; kindly send us a specimen.]

**Procuring Argentine Asparagus.**—Will you kindly inform me where I can obtain some Asparagus (Argenteus) seed, as mentioned in p. 371, of April 29?—J. E. P. [From M. Godfrey Lebeuf, Argenteuil, Seine-et-Oise, France.]

**Names of Plants.**—I send you a dried specimen of a tree, the name of which I should like to know. I took it from a tree in the streets of Niamos from 20 ft. to 40 ft. high, of which there were many. It was called Alishier, which, I believe, is the French for Crataegus. I never recollect having seen the tree before, and was struck by its appearance, although the leaves were not fully expanded on the 6th inst, when I collected it.—DALBERTIE. [It is the Alishier de Fontainebleau of Spach, and the Aria latifolia of French gardeners.]—J. G. [We cannot undertake to name plants without their flowers.]

## QUESTIONS.

**Flower Tubes.**—Can anyone tell me where the tubes with elastic mouths for holding flowers in water are to be procured?—T. S.

**Tarred Fruit Trees.**—I have got some wall fruit trees which have by some means become smeared by pitch or tar. Will some of your readers kindly help me out of my difficulty by informing me how to clean them thoroughly?—ALPHA.

**Out-Door Camellias.**—I should be glad to know what Camellias are suitable for growing out-of-doors? what is the best time for planting them out? what soil had I better give them? and what aspect?—RAMALING, Surrey.

**Myrtles.**—How can I get Myrtles to flower? I have several large flowers, and whether I keep them in a greenhouse, or put them out-of-doors all summer, it seems quite the same; they produce no flowers, though the foliage seems quite healthy and green.—H. K. M., Argyleshire.

**Grass Cover.**—We want a rack-growing Grass, to live under trees, as covert for pheasants. I have seen such growing in the south of England, where it had the local name of Strawberry Grass. It was very rough at the edges; so much so, that it would cut the hand if drawn through it rapidly. What was this? Can any of your correspondents say?—T. W.

**Hybrid Crotons.**—Will some of your readers kindly give me a hint as to the quickest mode of flowering Crotons? I wish especially to flower C. volutum; having three or four plants of it, I would sacrifice one to the experiment. I was thinking of starving the plant for about a couple of months in a small pot, and then placing it in bottom-heat (tan), but would be glad of some information on the subject. I have successfully crossed C. majesticum with C. Wiesmanni, and have one very fine young plant, now about 10 in. high, promising well both as regards habit and colour. I have also crossed C. Wiesmanni with C. interruptum; the seedlings in this case are only about a month old, but from what I can see at present I am sure I am going to have some good ones.—E. M.

## TREE CARNATIONS.

ARE these only suitable for the greenhouse, or are they hardy enough for open ground culture?—P. T. [To have tree Carnations in full perfection they should be treated as greenhouse plants, and may be had in flower the whole year round. We have some of Miss Jolliffe at present in 6-in. or 7-in. pots, with fifty blooms on each. These are plants that were planted out last spring in mixed borders, and lifted early last winter; the remainder have continued to flower the whole season. In mild localities or warm sheltered positions I see no reason why these beautiful flowers should not prove as hardy as many of the plants used for border decoration, as their continuous habit of flowering renders them very serviceable after the ordinary Carnations are over.—J. G.]

"F. A. J." requests information (see p. 376) as to the treatment of Tree Carnations, and as many are interested in their culture besides your correspondent a few remarks may be useful. First, let us speak of the propagation of the plants. "S" recommends layering them in June or July; that is one way, but not by any means the best way. If good sized plants be wanted to flower in winter, they must be propagated from cuttings in February or March, and for succession in April and May. Layering is a slow and tedious process; I take the small size growths, and place ten or a dozen of them in a 5-in. pot in fine soil. They are put in just as you would Verbena, and they strike roots in about eight days in a propagating house, where the temperature is about 55° at night; but to make certain of their doing well the cutting pots should be plunged in a gentle bottom-heat, and if a hand-light be not available to place over the pots, a square of glass will answer the purpose. When the cuttings have formed roots I pot them off into thumb-pots, replacing them in heat,

which should not be higher than 55° at night, and a lower temperature would answer equally well. They would even do in a cold frame, only growth would not be so rapid. When the plants have grown 6 in. or 9 in. in height they should be stopped, and attention must be paid to re-potting them as soon as the small pots just named are full of roots. I need not say that they will not do well if they suffer from any cause, such as inattention to watering, careless potting, or allowing them to become pot-bound. I find the best compost to be turfy loam four parts, one part rotten manure, and one part leaf-mould, with some sand added, unless the loam be of a sandy character. Tree Carnations delight in a porous soil, and I find that they are fond of some pounded charcoal. I keep them under glass until May or even the beginning of June if the weather be cold. By the end of July they will have grown so much that they may be shifted into their blooming pots. The strongest growers will require 8-in. or 9-in. pots; those of a weaker constitution about 7-in. ones. To each plant must be placed a stout stick, to which the main stems must be tied closely, and also the side growths; but the latter must not be drawn up too closely. The pots may either be plunged or not. If plunged in Cocoa-nut fibre refuse, so much water will not be required, but they do equally well if the pots are not plunged. Many of the earliest-rooted plants will produce flowers before Christmas; others will come on in rapid succession. Some will open their flowers in an ordinary greenhouse, but I find that they do best in a temperature of about 50° at night, with a rather dry atmosphere. Tree Carnations are sometimes attacked by green fly, and if under glass, the best plan is to fumigate until this pest is destroyed. If the plants be out-of-doors, I dust with Scotch snuff or Tobacco powder. The shoots may also be dipped in soft, soapy water sufficiently strong to kill the flies without injuring the growths. I never layer Tree Carnations; I would as soon think of layering Zonal Pelargoniums. The only ones that I have found difficult to increase by means of cuttings have been the Prince of Orange and Ascot Yellow Picoetes; these two I propagate both ways, as one seldom has too many of them, especially the latter. For all ordinary requirements it is not necessary to grow a large number of varieties, and the most useful are those that have the following points, viz., substance of petal, a stout calyx that does not split, decided colours in the flowers, and a floriferous habit. The best white flowers are Guelder Rose, La Belle, and AVALANCHA. Empress of Germany is all white, except a few delicate stripes of pale rose; it is a grand flower. Rose-coloured flowers are nearly as useful as white. The best are Annie Williams, Miss Jolliffe, King of the Belgians, and Rose Perfection. Scarlet and crimson flowers of the highest merit are to be found in *Alégitère* (a new sort, dwarf in habit, and most floriferous), Prossrino, Grenadier, and Scarlet Desfance.

J. DOUGLAS.

#### OPENING OF THE GARDENS AT KEW.

THERE is an old Scotch proverb which says, "Aim at a silk gown, and ye'll maybe get a sleeve," that applies in the present instance to the Kew question. The agitation to procure the opening of Kew gates at an earlier hour than heretofore is likely to result in gardeners and others, at least, being admitted at any hour of the day. I see the director has intimated through a contemporary—an intimation which is insufficient for the general public—that by applying at the curator's office they will be admitted, and nothing is said about the certificate of respectability that was to be obtained from "two respectable householders," an idea which must surely have been suggested by a parish relieving officer or some such functionary about Kew, and which has been a source of considerable mortification to the craft. It is creditable to Sir Joseph Hooker that it was always his "wish and desire that horticulturists should have entire facility of admission" to the gardens morning and afterwards, and the question now is, Who frustrated his good intentions? Was it any of his subordinates? If so, the sooner the matter is explained the better. It is simply disgraceful to think of the multitudes that have had to turn their backs on Kew gates, or "hang about Kew Green" till the gardens were opened, while it was all the time the "wish and desire" of the director that they should have every facility of admission afforded them. Through some error on the part of the visitors, or their "applying at the wrong gate," they did not enjoy the advantage of the privilege, we are now told, but we know a great deal better than that. When, pray, was such a rule ever publicly intimated? The admission now made by the director is a damaging one. Here are a great body of horticulturists and others clamouring for a privilege which, it is now admitted, should never have been denied them, and which it was the express wish of the director they should fully enjoy. Who, let us ask, is to blame for defeating the intentions of Sir J. Hooker? J. S.

— Sir J. Hooker at last makes it clear in a contemporary that gardeners may obtain admission to the gardens at Kew in the forenoon.

"The access to all persons visiting the gardens for study and improvement of whatever kind—whether botanists, horticulturists, artists, foreigners, or persons from a distance, in pursuit of any special inquiry or information—will be put upon a systematic footing. It has always been my wish and desire that such persons should have entire facility of admission in the morning, but it is possible that, through application at the wrong gates, or other misapprehension in some cases, such admission may not have been obtained. I think it may be useful, therefore, to state that all such visitors should call at the curator's office, and, after signing their names and stating the object of their visit in a book kept for the purpose, should enter the gardens by the office gate." This is a little better than the almost absolute exclusiveness that has hitherto been the rule at Kew. But it is not what the public have a right to expect. However, even for the above many of the horticultural fraternity will be grateful.

— The agitation in favour of admitting the public to Kew Gardens during the whole of the day, instead of the afternoon only, is daily gaining strength. The chief, and we might almost say the only argument advanced by the opponents of the proposed change is, that it would interfere with the studies of botanists. There can be no question as to the value and utility of botanical research, though whether, as it is carried on at Kew, it is productive of more benefit to the public than the opening of the gardens in the morning would be is a matter of opinion. It would be interesting to know how many botanical students attend at the gardens daily, in what their studies consist, and what is the net result of their labour. We might go even further and suggest that, as they are supposed to be working in the public interest, and at the expense of the public, that public has, at least, a right to be informed as to what they are doing. Some little coteries of scientific men are apt, when subsidised by Government, to diverge into the paths of dilettanteism, and the very honesty of their intentions makes them unconscious humbugs, inasmuch as they are anxious to do something, no matter what, to justify patronage. Apart from these considerations, however, it seems to us that the objection is weak in itself. We fail to see that the students would suffer very much from the presence of the public. People do not, as a rule, go to Kew to visit the Herbarium, and if they did, it would not be difficult to assign sound reasons for excluding them during part of the day. But, with this exception, we believe the restrictions to the free use of the gardens might be abandoned. It is true that the National Gallery closes its doors upon certain days of the week to all except students; but the latter may be seen upon other days quietly pursuing their studies in the midst of a crowd of visitors.—"Examiner."

**Violets Everywhere.**—You may have noticed that a clump of Violets amongst shrubs, or in some other odd place where it ought not to be, will be found at this time of year as full of flowers as if a shower of blue hail had fallen on that particular spot. And you may also notice that an odd plant of Parsley that escapes destruction amongst Onions, or Cauliflowers, or Daffodils, will be grandly curled, and will throw out its great, handsome leaves with a vigour unknown to Parsley in the row, as if to say to all beholders, "Behold how heterodoxy invigorates the constitution!" Taking note of such things in the days of my youth, I adopted very early in my career a plan of securing Violets in endless quantity by the very simple process of planting them anywhere, anywhere, and everywhere. The main requisite to the production of Violets in the ordinary method is fresh soil; hence, in the routine culture, the borders must be refreshed with leaf-mould and charr'd rubbish, and more or less of old hotbed manure. But the heterodox method does not include any preparatory measures. All our Ivy edgings and banks are studded with clumps of Violets and Woodruff; Violets are objectionable when mixed with Ivy, because of their coarse, obtrusive leafage in the summer, but Woodruff is in every way acceptable, and ought to be mixed with Ivy edgings and knolls everywhere, even if there are miles of them. As for the various sorts of Violets, I have all that have been brought out of late years, from the noble *Czar* to the *Cleveland* set, and the curious oblique and double varieties. But when I multiply Violets by the thousand and ten thousand for mere amusement, and make all my banks and hedges, and the ground under Hollies and other shrubs a continuous Violet carpet, I never trouble to look for the named sorts. I tug and tear at the common blue and common white varieties that are (or should be) found in every garden; and it will be time enough to make miles of Violets out of the named sorts when the common ones fail to satisfy me.—"Gardener's Magazine."

**Apricots on Spurs and Young Wood.**—I find that in spite of the bad weather we have a good crop of Apricots set, but they are all on the young wood that was nipped in quite closely—the blooms, in fact, touching the wall while from spurs all the blooms have dropped off frost-bitten. This I regard as a proof that the wall, or rather the latent heat contained in it, affords the greatest amount of protection to wall crops. We adopt the old nail and shred system. Will anyone tell us how wired walls have fared this year?—J. G.

## SOCIETIES AND EXHIBITIONS.

## ROYAL BOTANIC SOCIETY.

APRIL 24.

THIS, the second spring show of this Society this season, was quite equal, if not better than the last, and considering the unfavourableness of the weather, there was a good attendance of visitors. The exhibits, which were tastefully arranged, consisted of Pot Roses, Azaleas, Clematises, and miscellaneous collections of plants.

**Certificates of Merit** were awarded as follows:—

**Pansy Fred, Perkins** (H. Hooper).—A distinct kind, with large flowers, having violet-coloured petals, striped with clarat, the centre being blotched with rich velvety-black, surrounded with rosy-crimson. One of the most novel and attractive kinds in cultivation.

**Rose Boieldieu, H. P.** (W. Paul & Son).—A large and well-formed flower, of a deep rosy colour. Likely to prove a good exhibition variety.

**Rose Mrs. Laxton, H. P.** (Paul & Son).—A free growing kind, having deep green leaves, and beautifully formed, dark, velvety crimson blossoms; evidently a valuable variety for pot culture as well as for exhibition purposes.

**Azalea Madame Lefebvre** (Turner).—A pure white-flowered variety of singular merit, and well worth a place in every collection.

**Wallichia zebrina** (Williams).—Described in THE GARDEN of last week.

**Ixora hybrida** (Williams).—A compact-growing variety, and one which produces large trusses of delicate lemon-coloured flowers on every small shoot. A valuable addition to this useful class of plants.

**Dracœna Bausei** (Williams).—A garden hybrid raised in the Anerley Nurseries, having broad revolved leaves of a glossy bronze colour, broadly margined with bright crimson. An excellent vigorous-growing kind.

**D. Mrs. Bause** (Williams).—A narrow-leaved kind of the terminalia type, with a drooping habit. Valuable for vases or market purposes.

**D. Renardii** (Williams).—A kind conspicuous for its dwarf, compact habit of growth and its short, broad leaves, which are of a light glossy green colour, beautifully banded and striped with rosy-crimson.

**Lastrea aristata variegata** (Veitch).—A valuable Japanese species, having a delicate variegation at the base of the pinnae.

**Rhipidopteris peltata gracillima** (Veitch).—A great improvement on the type, the fronds being larger and having finely cut pinnae. An excellent plant for culture in pans.

**Dioscorea retusa** (Veitch).—A South African species, of free growth, having a peculiar twining habit, and bearing abundance of cream-coloured catkin-like blossoms. Excellent for twining round umbrella-shaped trellises.

**Hæmasthanus Keilbreyeri** (Veitch).—A variety from the South Coast of Africa, bearing large trusses of bright scarlet blossoms, the stamens being much longer than the petals, and tipped with golden anthers. One of the most curious, as well as showy Hæmasthanuses that have been exhibited for a long time.

**Grevillea filicifolia** (Rollisson).—Described in THE GARDEN last week.

**Adiantum Lawsonianum** (Veitch).—A dwarf-growing garden variety, having peculiarly small pinnae, very bright and elegant. One of the most distinct Maiden-hair Ferns that have been raised in this country.

**Gloneria jasminiflora** (Williams).—An attractive and valuable stove plant of easy culture, and one which bears a profusion of white sweet-scented Jasmine-like flowers throughout the winter and spring months.

**New Plants.**—These were shown by Messrs. Veitch & Sons and Mr. B. S. Williams. In Messrs. Veitch's group were several new Crotons, the most valuable one being C. Challenger, a species from the South Sea Islands, having long, graceful leaves, richly marbled with golden-yellow changing to bright rosy crimson as they become matured. From the same firm also came an excellent plant of the useful *Euryclæa australis*, from Queensland, a coloured plate of which was given in THE GARDEN lately (p. 472, Vol. XI.). This was beautifully in flower, as were also several new *Hemantidæ*. In the same group were, moreover, brightly-coloured plants of *Phyllanthus roseo-pictus*, *Acalypha Macleanæ*, and a beautifully-crested variety of *Lomaria* named *L. discolor biglandifida*, together with plants of the miniature *Otaheite Orange*, laden with fruit. Mr. Williams showed a fine specimen of the beautiful *Gloneria jasminiflora*, from Brazil, covered with large clusters of ivory-white, jasmine-like blossoms, several new *Azaleas* of a meritorious description, and various *Amaryllides*.

**Orchids.**—A good collection of these was shown by Mr. Heims, gardener to F. A. Philbrick, Esq., who had a healthy specimen of *Dendrobium thyrsiflorum*, bearing nearly a dozen large clusters of white and golden blossoms, well-flowered examples of *Oncidium Marshallianum*, *Odontoglossum cirrhozum*, O. *Alexandra*, O. *Rozeli* and its white variety, and the beautiful white *Cypripedium nivenum*, bearing the largest and most perfectly-formed flowers we have ever seen.

**Roses.**—These were well shown by the leading growers. The best collection came from Messrs. W. Paul & Son, Waltham Cross, to whom

an extra prize was awarded. Among the best bloomed plants were the white *Madame Alfred de Rougemont*, the beautiful bluish-coloured *Captain Christy*, the rich cream-coloured *Maria Van Houtte*, and the brilliant kind called *Fisher Holmes*. Messrs. Veitch sent a group in which were several remarkably well-flowered plants of *Madame Victor Verdier* bearing blooms equal in form and colour to many often seen in June; *La France*, *Madame de St. Joseph*, and the pure white *Madame Villermoz* were also equally good. For eight *Roses* in pot Messrs. Paul & Son, Cheshunt, obtained the first prize, with well-bloomed plants of *Souvenir de Elise*, *Dupuy-Jamain*, *Madame Lacharme*, and others. An extra prize was also awarded to Messrs. Paul & Son for a group of *Roses*, in which were well-flowered examples of *Madame Victor Verdier*, *Charles Lefebvre*, and *Chantant* kind, associated with these were eight-coloured kinds as *Marquise de Mortemart*, *Coline Forster*, and *Madame Villermoz*. The first prize for new *Roses* was gained by Messrs. Paul & Son, who had several valuable and attractive kinds. Mr. Turner also showed new kinds. In the amateur's class for six pot *Roses*, Mr. James, of Isleworth, was first with well bloomed healthy plants of *La France*, *John Hopper*, *Edward Morren*, and others.

**Auriculas and Polyanthus.**—Twelve excellent plants of *Auriculas* came from Mr. Charles Turner, the Royal Nurseries, Slough. The foliage was large and healthy, and the flowers, both in form and colour, all that could be desired. The most attractive kinds (self) were Mr. Turner's own seedlings—*Charles Perry*, a large purple-edged flower, with pure white petals, associated with these were *White*, *White*, and *Sarah*, violet-purple. Mr. Roberts, gardener to W. J. Perry, Esq., Fulham, also sent plants of *Auriculas*, as did likewise Mr. Heims, gardener to F. A. Philbrick, Esq. Mr. J. Levesley, Isleworth, showed a group of gold-laced *Polyanthus*.

**Cinerarias.**—The first prize for these was deservedly awarded to Mr. James, Isleworth, who had dwarf healthy plants, 2 ft. through, and in a mass of large, brightly-coloured blossoms of the finest form. Mr. Levesley contributed an extensive group of seedling plants, dwarf in habit, and bearing brightly-coloured flowers, an excellent strain for market purposes. Mr. Ratty, gardener to R. Thornton, Esq., Sydenham, also showed some well-grown plants.

**Alpine and Herbaceous Plants.**—These were shown by Mr. Roberts and Mr. Wheeler, and consisted of common border flowers of no particular merit. A collection of bulbous plants from Mr. Roberts contained well-flowered examples of *Trillium grandiflorum*, a good variety of the *Paget's Narcissus*, *Stella*, and some *Androsace*.

**Azaleas.**—The best of these came from Mr. Turner, Slough, who had medium-sized, well-bloomed plants. The most attractive light-coloured kind was *Nonpareil*; *Madame Van der Cruyssen* was the best purple, and *Flag of Truce*, a well-known double white-flowered kind, was admired for its delicacy and profusion of blossom. The same exhibitor had also a group of small plants consisting of new kinds, some of which will doubtless prove superior to many already in cultivation.

**Miscellaneous Subjects.**—The best group of miscellaneous stove and greenhouse plants came from Messrs. Rollisson & Sons; it consisted of well-grown *Azaleas*, *Erica*, *Everblastings*, choice *Orchids*, large *Palms*, *Cycads*, and *Tree Ferns*, the whole being edged with *Maiden-hair Ferns* and similar plants. Mr. B. S. Williams, Holloway, had also an excellent collection of miscellaneous plants, among which were noticeable unusually well-bloomed specimens of *Franciscusa calyculata*, *Yandæ*, *Azaleas*, &c., all of which were rendered more effective by being interspersed with choice *Palms*, *Ferns*, and fine-foliaged plants. Good examples of *Giant Cycas* were also shown in this group. Messrs. Cutbush, Highgate, sent an interesting group, in which we noticed well-bloomed *Rhododendrons*, *Azaleas*, *Polygals*, &c., interspersed with *Palms*, *Aralias*, *Pandanads*, and other fine-foliaged plants, for which an extra prize was awarded. Messrs. Veitch & Sons showed an attractive group of *Clematises* (blues), *Fair Rosamond* and *Lacie Levening* (whites), and *Lady Londborough* (violet). Adjoining these *Clematises* was a group of *Giant Azaleas*, and the new species *Azalea mollis*; also several excellent *Rhododendrons*, and three round baskets filled with plants of the beautiful hardy *Gentiana acanthis*, showing how attractive it is when grown in masses; with the above were, likewise, plants of cut-leaved *Acer*. Mr. James, Isleworth, had nine excellent show and fancy *Pelargoniums*, fresh in foliage and flowers, for which a first prize was deservedly awarded. A good group of *Amaryllides* came from Mr. F. Knowles, gardener to H. Little, Esq., Hillingdon, Uxbridge.

**Cut Flowers.**—Messrs. William Paul & Sons had excellent stands of cut *Roses*, amongst which the most noteworthy were *Paul Verdier*, *Souvenir d'un Ami*, *La France*, *Niphetos*, the rich creamy-coloured *Madame Hippolyte Jamin*, and the dark crimson *Louis Van Houtte*. Mr. Walker, The Nurseries, Thame, Oxon, showed remarkably fine stands of blooms of *Maréchal Niel*; also stands containing well developed blossoms of climbing *Devoniensis*, *Gloire de Ducher*, *Jules Margottin*, and others. Cut blooms also came from Messrs. Paul & Son, amongst which were examples of *Clematis* varieties, *Elise Massé*, of *C. Belle Lyonnaise*, likewise a box of *Maréchal Niel* in excellent condition. Mr. Hooper, Bath, furnished a large group of *Pansies*, amongst which was every imaginable form of flower. The blooms were in some cases unusually large, and the colours both rare and bright. To lovers of *Pansies* this offered an excellent opportunity for selecting sorts. Cut blooms of *Himalayan Rhododendrons* were sent by Mrs. Vriean, of Singleton, near Swansea. The flowers, which were delicate and well formed, had been cut from plants growing in the open air.

## NATIONAL AURICULA SOCIETY'S EXHIBITION.

This was held at the Crystal Palace on Thursday last. The plants were numerous and generally good, the selfs attracting the most attention. Gold-laced Polyanthuses were numerous and beautiful, and the attractions of the show were enhanced by a collection of well-flowered Azaleas, Show and Fancy Pelargoniums, and fine-foliated plants from Mr. Charles Turner, the Royal Nurseries, Slough, to which an extra prize was awarded. The chief prizes for Auriculas were won by the Rev. Mr. Horner, Kirkby-Malzeard, Ripon, and Mr. James Douglas, gardener to R. Whitbourn, Esq., Loxford Hall, Hereford. The first prize for fifty plants, not less than twenty varieties, was gained by Mr. Douglas, who had well-grown, healthy plants and fine symmetrical flower-spikes. Conspicuous among the selfs was Marquis de Lorne, a large showy flower of a magenta colour, with well-defined, smooth paste; Metropolitan, a bluish-purple flower with very white paste. Among grey-edged kinds, the best were Beauty, Confidence, and Marie. Mr. Charles Turner was second with smaller plants of the best varieties, including Mammoth, Clipper, and Charles Perry. Mr. Llewellyn Neath was third. There were several other collections of a showy character in this class, but the blooms were coarse and inferior, although excellent for border planting. In the class for twelve plants dissimilar there were numerous exhibitors. The first prize fell to Mr. Horner; Mr. Douglas was second, and Mr. Simonite, Rough Bank, Sheffield, was third. The first prize in the class for six plants was also won by Mr. Horner, the second by Mr. Simonite, and the third by Mr. Douglas. The plants in this class were fairly good, but the trusses were smaller than in the class for fifty. In the class for four plants dissimilar there was least competition. Mr. Horner was first, Mr. Douglas second, and the Rev. B. J. Marquetts, Lillington, Upminster, ham, third. In the class for two plants dissimilar, Mr. Horner was again first, with two grey-edged kinds in good condition; Mr. Barlow, Slattocks, Manchester, was second; Mr. Simonite, third. For one specimen (green edged) Mr. Horner was again first, with an excellent plant of Col. Taylor. Mr. Simonite was second with Hudson's Apollo, and the third prize was won by Mr. Douglas, who had Lancashire Hero in good form. For one specimen (grey edged) there were some seventeen exhibitors. The best came from Mr. Horner. It was a well formed flower, with well-defined paste and golden tube. The same exhibitor also obtained other prizes in the same class with good kinds. For the best white-edged variety, Mr. Horner was first with Catharina, a fine kind, bearing small flowers of exquisite colour and shape. The same exhibitor also obtained the second prize with John Simonite and the Smiling Beauty. The best self also came from Mr. Horner, who had a well-flowered plant of Pizarro, a brown-coloured kind, with a velvety edge and well defined paste. The second prize was won by the same exhibitor, with a beautiful blue-edged kind named Meteor Flag.

**Prize for American.**—In the class for twelve plants, Mr. Turner was first with even, well-grown plants; Mr. Douglas was second; and Mr. Barlow third. In the class for six plants, Mr. Turner was also first with King of the Belgians, a striking variety, with a reddish-crimson edge and bright yellow paste, one of the best Alpine kinds in cultivation. Queen Victoria, Mercury, and Sensation were also good; these plants bore several spikes of blossoms, and were admired, probably, more than any others in the show. Mr. Douglas was second, with well-flowered, showy plants of Beatrice, Silvia, and Neatness. The best single specimen came from Mr. Charles Turner, Slough. It was a large-flowered kind, of a deep purple colour, with white paste and small, well-formed tube. The same exhibitor was also second with Mariner, and Mr. R. Dean was third with Captivation.

**Polyanthuses.**—The best six plants came from Mr. R. Dean, who had beautiful gold-laced varieties of excellent form; Mr. Barlow was second, and Mr. John Beswick, Middleton, third. For two specimens the best came from Mr. Beswick and Mr. Barlow. In the competition for single specimens there was over twenty exhibitors. The best came from Mr. Brownhill, Sale, who showed a variety named Cheshire Favourite, a beautiful gold-laced sort; the same exhibitor was also second with the same kind, and the third prize was won by Mr. Barlow. A horticultural certificate of merit was awarded to Mr. G. Smith for Polyanthus Admiral Hornby, a beautiful gold-laced flower of fine form and colour.

In the extra classes Mr. Douglas showed an excellent group of plants with varied flowers, which were much admired; and Mr. Ware, Hale Farm Nurseries, sent a collection of Polyanthuses, Primroses, and a new white Viola named White Star, which is likely to be largely grown for bedding purposes.

Mr. Henry Hooper, Vine Nursery, Bath, showed a large collection of cut blooms of Pansies, which attracted much attention on account of their varied forms and rich colours.

An excellent collection of Primulas was shown by Mr. R. Dean, Ealing, among which were many improved and beautiful kinds.

**The Dreaming of Plants and Animals.**—Mr. Francis Darwin, lecturing at the London Institution the other week on the analogies of plant and animal life, said:—“There is one—but only a fanciful resemblance—between the sleeping plants and animals, namely, that both have the power of dreaming. I have been sitting quietly in the bathhouse at night, waiting to make an observation at a given hour, when suddenly the leaf of a sensitive plant has been seen to drop rapidly to its fullest extent and slowly rise to its old position. Now in this action the plant is behaving exactly as if it had been touched on its sensitive joint; thus some internal process produces the same impression on the plant as a real external stimulus. In the same way, when a dog dreaming that he will yelp and move his legs as if he were hunting a real instead of an imaginary rabbit.

## GARDEN DESTROYERS.

## IS THE SPARROW A FRIEND OR AN ENEMY?

Mr. TILLEY makes out a strong case (see p. 356) against the sparrow, but is it a fact that his depredations so much exceed his good deeds that his banishment would be a boon to horticulture? Now, I would ask, Upon what does the sparrow live in the summer months during the breeding season? From May to August there is but little grain; on what, then, does he subsist and feed his young? In the neighbourhood of towns and farmyards he may, it is true, carry on his depredations during the whole year; but sparrows abound everywhere, and in the lanes and fields insect life must form the chief food. Is it really a fact that the sparrow systematically attacks the buds of fruit trees in the same manner as the billfinch? If such be generally the case, those in this neighbourhood must be exceptionally well behaved, as I have never perceived any symptoms of such conduct. If such were the case, taking into consideration the numbers of these birds which one everywhere sees, fruit growing would just be an impossibility in this country. For one fact I can vouch, viz., that where they find caterpillars in any quantity they will greedily devour them and feed their young upon them. Several years ago some Strawberry plantations were covered with the larvae of a small moth to such an extent that they threatened their entire destruction. I noticed, however, that those situated near some buildings where the sparrows had nests became in a short time comparatively free, and I found that they searched for and destroyed the larvae with avidity. They were busy amongst the plants all day long, and were so ravenous for the larvae that they would come within arm's length. Seeds that were sown in the vicinity they scarcely seemed to notice. I particularly watched these birds at work, and observed them fly away with at least a dozen larvae at a time—taking them to their young. As the sparrow is an inordinate feeder, it may be imagined that a pair must destroy an enormous quantity of insects during the season. On another occasion I was greatly plagued with small slugs even in frames, but they were ultimately found out and almost exterminated by the sparrows. The fact seems to be that, this bird being a great feeder, it will devour almost anything, attacking grain crops and seeds in 'the ground, and occasionally other things, with rapacity; but I feel convinced that an insect diet is just as much to his liking, and that he rids us of a vast quantity of noxious insects during the summer months. Let anyone make this experiment: If a crop be much infested by caterpillars, strew a few dead crumbs in the vicinity; the sparrows will then soon be there, and will in a short time destroy them. With all due deference to our American friends, I am inclined to believe that the sparrow will not eventually be found to be such an unmitigated evil as he is now reported to be. One may have too much of any good thing, and the Americans are just finding this out. Let them leave the sparrow to take his chance in the battle of life, and the balance of power will soon adjust itself.

J. COANHILL.

**Slugs.**—There has been a good deal of correspondence of late about slugs, and many have been the recommendations, and amongst others ducks, but I have not seen mentioned what we consider the best of anything to clear our gardens of these pests, and that is the common green plover or peewit. If any one has a walled garden where they can be confined, these afford the most pleasant and sure remedy. They do no damage whatever, and clear off slugs, wire-worm, and Gooseberry caterpillars most completely. I got them when young, and allow them to run about the garden; they get very tame, and are kept from flying away by having one wing clipped. After moulting they leave us, and some years back one bird confidently returned to his old haunts and nested in the Strawberry bed.—J. P., York.

—I received the enclosed interesting communication with the Bristol postmark on it; it must have come from that great authority in all matters horticultural at Bitton. It appears to have been printed in the Transactions of the Royal Horticultural Society, and is headed, “On Destroying Slugs in Gardens,” by Mr. John Wilmot, F.H.S. Read May 12, 1812. It shows that our fathers had the same trouble with slugs that we have, and that much the same means for destroying them were then used and recommended. The communication is as follows:—“The usual way of killing slugs practised at present is with lime strewed on the ground very early in the morning, or late in the evening, the thermometer not below 45°; they then are found in moist weather in abundance, on the surface of the soil, when scattering lime fresh slaked or pulverised will destroy a number of them, excepting rain comes to their assistance, which too frequently frustrates the design. As the principal time of their committing their ravages is in a rainy or a moist season, the very weather is unfavourable to the application of the lime, as it will act

no longer as a caustic, after lying on the damp ground even for half-an-hour. At the suggestion of my friend, Mr. Whately, the celebrated surgeon, I was induced to make a trial of lime-water, which I found greatly to exceed my expectations. I now not only propose, but strongly recommend it on an extensive scale, as I can prove it a saving of £9 out of £10, and it will entirely rid the land of those noxious vermin. The plan I recommend is to take a small portion of fresh Dorking lime and pour on it some hot water; when thoroughly dissolved, add water sufficient to make it pass through a fine rose of a water-pot. Previous to the preparations let a woman take some Peas haulm (I give that the preference), or any large leaves of the Cabbage tribe, and lay them a pole distance from each other. If the weather permit they will be found in abundance collected under the haulm, &c., both for shelter and food, as we always find them prefer vegetables in a state of stagnation to those luxuriant in growth. When properly collected let a boy take up the haulm, &c., and by a gentle shake leave the whole of the slugs on the ground. The woman with a water-pot and rose must then pour a very small portion of the liquor on them, and the boy in the meantime must remove the haulm, &c., to a different spot in the intermediate space. By pursuing this plan for one week (when the weather is favourable) I am perfectly satisfied the whole of them may be destroyed, as the least drop of the liquor will cause immediate death, whereas with lime they frequently leave a slimy matter behind and escape. In the flower garden it will be found a great acquisition by watering the edging of Box, Thrift, &c., for wherever it penetrates it is certain to kill, even in a rainy season. The first thing to be considered in any new experiment is the trouble and expense attending it, for however certain and efficacious the remedy, it is frequently overbalanced by the expense. In the plan I propose the application is simple, the effect certain, and the expense trifling, which are objects worthy our consideration, as four middling-sized watering-pots at one time will be found sufficient for an acre, allowing one pot to forty places, and when it is considered that a piece of lime, about 2 lb. weight, is sufficient for one pot, we may conclude that to any extent (even in agriculture), including labour, &c., the whole amount will not exceed 5s. per acre, to be passed over four different times, which, if properly pursued, I am certain will rid the land of the whole of them at any season of the year, excepting frosty weather. The haulms, if not used after the crop of Peas is over, may be dried and put away for that purpose; the expense will then be found nearly as stated for one acre (everything convenient):—

Trouble in laying haulm, &c., woman and boy	s. d.
half a day each	... .. 1 0
Removing ditto four different times, one quarter of a day each time	... .. 2 0
Lime	... .. 1 0
Total expense	4 0

Thus for 4s. per acre they may be totally destroyed, however numerous. I can vouch for the statement being correct, having practised it to an extent this winter, and strongly recommend it to the Horticultural Society."—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

— Among the numerous suggestions of your correspondents for getting rid of these pests, I do not think anyone has mentioned the use of a hedgehog in a walled-in garden as a good remedy. I got one in the spring of 1876, and in that year I certainly was less troubled with slugs than before. The hedgehog soon made himself at home, and as the winter approached curled himself up in a bundle of leaves to hibernate. A few warm days in February, 1877, tempted him out, but he soon retired to sleep, and did not again stir till June. During my absence from home for a few days he got into a box exposed to the sun, and, being unable to extricate himself, was either starved or roasted to death. The result of his loss soon became apparent, for the slugs last season and this spring have been as troublesome as ever. I shall certainly, therefore, procure another hedgehog.—W. J. T., *Bristol.*

— No doubt hungry ducks will eat slugs, but I have always found that they prefer a Pea to a slug. Just now, when slugs most abound, our friends the birds all feed on worms on the lawn, and not one is seen picking up the slugs in the kitchen garden early or late; but when the Strawberries get up the Grass lawn will be wholly deserted, and the fruit garden infested. It is too often thus, that natural forces and tendencies seem to work contrary to the wishes and interests of cultivators. The birds, for example, all just now prefer worms to snails; by-and-by they will greatly prefer fruit to either. And the ducks, which might just now feed upon slugs, prefer to eat Peas, Lettuces, and Cauliflowers instead.—D. T. FISH.

**The Hop as a Vegetable.**—Although so much grown for its well-known use, and often seen as a climber in small gardens, the

Hop is little known in England as a vegetable. In Belgium it is used as a vegetable is almost universal. The young shoots are cut as soon as they are 2 in. or 3 in. above the ground, and boiled in salt and water; they are then dried, and sprinkled with the juice of a Lemon to keep them white. Before serving, put them again over the fire for a few minutes, with salt and plenty of butter, then add eggs mixed with milk, when they may be eaten like Asparagus, to which they are not inferior. Managed in this way, it makes a most delicate and refined dish. The young shoots of Hops are generally cut twice for the sake of strengthening the plants; therefore it would not be advisable to grow Hops for their shoots to be used as a vegetable only—when they could be gathered in Hop-fields, in gardens, and even in a wild state, all of which are equally good. If this were well known, many of the inhabitants of Kent would add a wholesome dish to their tables, and might even make money by sending the shoots to market.—D. GUIHENEUF.

**Women Gardeners.**—The Geneva correspondent of the "Echo" says:—A new species of instruction classes for women has recently been in great favour in Switzerland, more especially in the great orchard districts of the Thurgau, Bern, and elsewhere. This is the so-called "Gomiesbankurs." A scientific gardener gives practical lectures on the cultivation of fruits and vegetables, and an experimental field is granted for practice. Such a course was instituted last week in the busy town of Burgdorf, where Pestalozzi began his great educational revolution eighty years ago. No fewer than 100 women and girls have already given in their names as students. The general crash of manufacturing industry is filling the air with speculations and proposals for the fuller use of the land as a means of livelihood.

**The Preservation of Hothouses.**—Assuming that the houses have in the first instance been constructed of good materials, the question of their future preservation is summed up in one word—paint. In the large majority of cases hothouses are ruined for want of paint, and do not last out above half as long as they might do. It is quite a common thing in gardens to see good houses that have not received a coat of paint for ten or a dozen years, or more, and which are in many places quite rotten in consequence, and ready to fall to pieces. It is needless to point out the evils of such a penny-wise-and-pound-foolish practice; but we would say that those who are not prepared to keep their hothouses in order and repair should not build any. Both plant and fruit houses are now constructed as simply as possible for the sake of light. Rafters and sashes are reduced to the smallest dimensions consistent with safety and stability, and if they are kept regularly painted they will last for many years; but a year's neglect to paint, when painting is required, may ruin all. A good deal, of course, depends upon the use the house is put to. Dry, airy greenhouses, conservatories, and such like do not require painting inside so often, but outside they should be painted as often as required—once in two years, or thereabout; whenever the woodwork is beginning to show through the paint, or rather, we should say, before. Orchard houses, stoves, hot-pits, and all structures in which much steam is produced, and which are frequently washed and scrubbed to keep down insects and filth, need painting considerably oftener. Paint only will prevent such structures from rotting in a very few years. The drenching atmosphere penetrates into every crevice, socket, and joint where it can find a leak, and decay is not discovered until serious mischief has been done. Painting should always be done at a dry season of the year, and before the work is begun the house should be emptied, well ventilated, and thoroughly dried. We should recommend damp hothouses to be painted one coat inside every two years, or every three years at the farthest; and if three coats can be afforded, all the better. The paint does not cost a great deal, nor does the work of putting it on.—S.

**Beetles and Cockroaches.**—These troublesome pests almost invariably congregate and increase rapidly in any heated structure to which they obtain access; they are often a great source of annoyance in forcing houses, where they attack fruit and also the leaves of various plants, especially those of young seedlings. I have lately tried several kinds of pastes and powders, but the most effectual remedy is strychnine mixed with barley meal, to which sufficient grease is added to make it into a paste. This, if set in saucers near their haunts, will be speedily cleared up, and the smallest portion will prove fatal to them.—JAMES GROOM, *Henham.*

**Planting the Pampas Grass.**—This should not be planted before the middle of April in the north; but in the south the beginning of the month will answer. I have planted large quantities of it both in the autumn and spring. The autumn-planted plants, unless very large, were almost all failures; the spring-planted ones nearly all succeeded. I have observed the same in the case of the New Zealand Flax, which requires similar treatment to the Pampas Grass. I find that the different variegated varieties grow with great luxuriance when planted out-of-doors here, and that the variegation remains perfect.—ARCHIBALD FOWLER, in "Gardeners' Chronicle."

No. 337.]

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### FLOWERS FOR THE WORKING CLASSES.

Those who reside in neighbourhoods almost entirely inhabited by the working classes must have noticed how eagerly the barrows of flower vendors are invaded on Saturday evenings. Flowers, however simple, have an influence in the right direction, and those who can assist in distributing them, or in imparting a knowledge of their culture among the poor, will by so doing render a real service to the community. In London the working classes have, it is true, to conduct their garden operations under great difficulties—such as confined areas, cold piercing draughts, a scorching sun, or an entire absence of that luminary, so far as its direct rays are concerned, an atmosphere laden with dust and soot, the difficulty of getting suitable soil, &c.; still, in spite of all these a little knowledge of the treatment and selection of plants would greatly assist in overcoming them. How many bare walls would be improved by being covered with Vines, Virginian Creepers, Ivy, or Euonymus, all plants of easy culture, the only conditions necessary being good drainage and a small quantity of ordinary soil mixed with about one-third of well-rotted manure. The shoots should be placed against the wall in upright parallel lines at regular distances apart, care being taken that the shreds are long enough to allow the wood to swell freely.

In summer, too, Convolvulus, Canary Creeper, and other Tropæolums, Sweet Peas, Scarlet Runner Beans, and some few others may be used with good effect in like positions; these are easily cultivated, and within the reach of all. Plants in pots or boxes require particular attention in many respects. More failures probably arise from over-watering than from all other causes put together; by far the greater portion of those who constitute the working classes consider that water is a cure for every ailment, and consequently they administer it in such doses as are sure to be detrimental. In the case of seeds another common source of failure is burying them too deeply, so that, although germination commences, they are too weak to push through the soil. Small seeds cannot be covered too lightly, but care must be taken that the surface of the soil does not get dry; they should therefore be placed in a shady position until they are well out of the ground. Sowing seeds too thick is another error, as no sooner do the seedlings appear than they damp off or grow up so weakly as to be useless. Very many annuals, such as Asters, Stocks, Zinnias, Phloxes, dwarf Nasturtiums, Flax, Indian Pinks, Mimuluses, ornamental Grasses, &c., may be grown in pots or boxes with ordinary care. These may be sown in April.

Daisies, Heartsease, Aubrietias, &c., for spring flowering should be sown in July or August. The class of plants termed half hardy, such as Pelargoniums, Verbenas, Balsams, and others, should be purchased in May in each year, as some difficulty would be experienced in keeping them through the winter. In every case where plants are grown in pots or boxes good drainage should be ensured, and the scorching rays of the sun prevented from striking directly upon the pots or boxes, as the roots of the plants would be injured thereby. This can be effected, in the case of boxes, by having a double side, and filling the space with Moss or some such material. Pots can be either plunged in boxes or have some artificial covering which would materially assist in keeping the plants in a healthy condition. It must also be borne in mind that the foliage should be kept clean. A compost formed of ordinary garden soil, mixed with one-third leaf-soil or well-rotted manure, and a little silver sand would suit nearly all kinds of plants for the positions mentioned. I am of opinion that if small prizes were offered at certain periods of the year for window gardening among the poor, they would very much assist in creating a demand for such flowers as could be easily grown. Some such prizes are, I believe, given by a few local societies, but such instances are rare. A great deal of good

would be done by making them more general, and all interested in the matter would, by imparting a knowledge of plant culture, or assisting in a pecuniary way confer a boon on the poor.  
*Southwark Park.* CHARLES DENNIS.

### TULIPS AT FOREST HILL.

THE most brilliant display of these popular spring flowers to be found near London may now be seen at Messrs. Carter & Co.'s nursery at Forest Hill. Here are upwards of 50,000 bulbs of the best kinds, growing in light rich soil, to which, together with good bulbs, may be attributed the unusual excellence of the flowers. The ribbon fashion of planting Tulips so much in vogue is altogether objectionable, and although some beds here are planted in this way, owing to the colours being tastefully arranged, the effect is not so formal as that generally seen; and, moreover, these beds are greatly relieved by large plots of ground being planted with mixed sorts irrespective of height or colour. These beds at once suggest that the more naturally Tulips, as well as all other plants, are arranged, the more pleasing and beautiful is the effect. Early, mid-season, and late kinds are here planted in such a way that a succession of bloom is gained all over the space covered with them for the longest possible period, which is a much better plan to adopt, especially in private gardens, than that of planting each bed with a separate kind, or such as will come into bloom at one, for Tulips, under the best of circumstances, do not last for a very long time, and, unless early and late sorts be planted together in beds, the season of bloom is indeed a short one. Among the most attractive kinds we noted Vermilion Brilliant, a kind resembling the well-known Scarlet Duc Van Thol, but its flowers are much larger and brighter in colour, and the plant is rather dwarfier. Kaiser Kroon is perhaps the largest-flowered Tulip in cultivation; its flowers are of a bright scarlet and orange colour. It is a tall grower, and for attractiveness it is unequalled. The best striped kind is Royal Standard; its flowers are crimson and white, of medium size, and very showy. Wouvermann is one of the most distinct kinds in cultivation; its flowers, which are of a bright claret colour, are large, well formed, and last for a long time. The best double white kind was one named Murillo, very dwarf, and exceedingly useful for small beds. Queen of the Violets is a sort well worth extensive culture, on account of its violet or rosy-pink blossoms. One named Rose Gris de Lin we admired more than any in the whole collection; its blossoms are of medium size, delicate pink in colour, the petals being tipped with white. We also noticed several kinds with silver or golden-edged leaves which were both novel and interesting. Any one wishing to ascertain which are the best varieties of Tulips would do well to inspect this collection, in which kinds to suit all purposes may be found. S.

### HARDY FLOWERS AT TOTTENHAM.

THE Hale Farm Nurseries are just now well worth a visit on account of the number of beautiful hardy plants which they contain being now in bloom. Besides large beds of Daffodils and other subjects frequently met with, there are many plants now in flower of a rare description; among other noteworthy subjects may be mentioned the beautiful *Houstonia corulea*, which is seldom seen in good condition. It grows here freely in light sandy soil, the plants being in habit similar to a miniature *Lobelia*. Its flowers, which are of a lovely lavender colour, remind one of those of a *Forget-me-not*, but they are stiff and waxy, and last for a considerable time in perfection. The abundance in which they are produced from Moss-like tufts a few inches above the ground renders this one of the most charming of rock plants. There is also a white kind equally deserving of special culture. *Symphandra Wanneri* is also a good plant just now in bloom. It bears pyramids of large drooping bell-shaped blossoms of a lovely blue colour from 6 in. to 9 in. in height, and is altogether a desirable plant. We also noticed the Golden Dog's-tooth Violet (*Erythronium americanum*) in bloom, and *Phlox setacea* at-purple-pure, one of the best of the rose-coloured dwarf *Phloxes*, was a mass of blossom. Large beds of P. Chelsoni are now snowy white with bloom, and *Trillium grandiflorum* in sheltered situations is laden with flowers. *Saxifraga peltata* is in excellent condition; stalks of it 2 ft. high are surmounted by massive heads of bloom. *Dodecatheon splendendum* often erroneously called *D. integrifolium*, is just now coming into bloom, and is in every way much superior to the latter variety, which is also just now in flower. *Primulas*, likewise, form an attractive feature, large beds of P. *cortusoides*, P. *intermedia*, and P. *ameza* being masses of blossom; established plants of the former variety are furnished with over forty strong spikes of flowers. P. *capitata* is a valuable new kind of the variegata type, bearing whorls of deep blue near blossoms one above the other. The beautiful Bird's-eye *Primrose*, P. *fariosea pyramica*, is also very pretty. Its rosy-pink flowers are

produced in round clusters about 2 in. above the foliage; they are of better form and deeper in colour than the type, and the plant is devoid of that white powder found in the ordinary kind. Anubrietas on the rockwork represent large banks of blossom, and it is satisfactory to find that, by careful fertilisation and selection, some greatly improved varieties are now to be found. The flowers are more than double the size of the older kinds, whilst in colour they are much brighter. The best of the early Ranunculuses, *R. amphlexicaulis*, is covered with pure white blossoms as large as a florin, and the distinct *Viola pedata*, with its small pale blue flowers, which is seldom seen in good condition, is flowering freely, as is also its white variety. Both kinds are quite distinct from other *Violas*, on account of their claw-like, light, deeply-cut leaves. The species of *Tulips* are also in fine condition, as are likewise large beds of the Sea Thrift (*Armeria cephalotes rubra*), and seedling and other *Iris*s. A good plant on the rockwork is *Erysimum pumilum*. It grows in compact dwarf tufts, covered with bright sulphur-coloured flowers, and spreads freely; it might be used for spring bedding with advantage.—C.

**Gold-laced Polyanthus.**—It is right that seekers after the fine old named Gold-laced Polyanthus should be put on their guard against unprincipled persons, who, taking advantage of the increasing interest felt in this flower, are palming off mere seedlings as named varieties. A few days ago an amateur grower of the Polyanthus residing in Edinburgh sent me pips of ten named flowers, which he had received from a florist in the midland counties purporting to represent such fine varieties as Earl of Lincoln, Exile, Cheshire Favourite, Beauty of England, Kingfisher, &c., not one of which were true to name. Seeing that good prices were paid for these spurious varieties, it is to be regretted that lovers of Polyanthus should be victimised in this way. From another cultivator I got other pips, but all spurious, and, I fear, traceable to the same source. Next week I will send you notes of some of the named varieties I have discovered during the past year, and, lest it might be said that perhaps I do not possess *bona fide* examples of the old varieties for comparison, but may have been deceived also, allow me to state that my flowers are all too beautiful not to be true; that they answer to published descriptions of them; and, further, I have obtained them all from trustworthy sources. Perhaps an announcement of the fact that some of the originals at least exist may prevent any further attempts at deception.—R. DEAN, *Ealing, W.*

**Free and Shy Blooming Roses.**—Mr. W. Hough (see p. 336) has made a mistake in planting such Roses as Climbing Devoniensis and Reine d'Or in his conservatory. They are somewhat shy bloomers in the open air, unless under special treatment, and they bloom even worse under glass than outside. Reine d'Or flowers pretty freely with us closely pruned in and trained on a warm south or west wall. Climbing devoniensis I could do nothing with until I trained it round a tall chimney belonging to one of the furnaces, and left it to ramble almost at will in a free, unrestrained manner. Treated thus, it produces immense numbers of flowers; but neither this nor Reine d'Or should be planted in a conservatory. The dwarf Devoniensis flowers freely enough planted out under glass, and is exquisite in bud and in fragrance. Instead of Reine d'Or plant *Maréchal Niel*, which flowers even more freely under glass than *Gloire de Dijon*. The three *Nephetes*, *Solfaterre*, *Celine Forestier*, and *Lamarque*, also flower freely under glass. The latter is one of the best Roses in cultivation for conservatory purposes, and is quite worthy to rank with *Maréchal Niel*. In such positions it is pure white, large, and very fine when open with the most lovely buds. *Nephetes* is also finer planted out under glass, creamy-white, large, and beautiful. Among other Teas suitable for such purposes, and that bloom very freely under glass, are *Adam*, *Satanet*, and *Souvenir d'un Ami*.—D. T. FISHER.

**Romneya Coulteri.**—I was quite unware, until I saw it stated in THE GARDEN, that the seed of this plant would come up in a month. In my experience it generally takes ten or twelve months. In fact, it is one of those seeds that usually lie dormant a year after sowing; and this class of seeds also requires to be kept moist during the whole time. Therefore, thumb-pots would be just the very worst size in which it could be sown, as, from the great number of times they would require to be watered ere the seeds came up, the soil would be either quite soured or rendered inert; far better to sow in large pots or pans, and place them in the dark, covering them close, in order to prevent evaporation. They might be examined now and then, so as not to let them get too dry, and, in due time, the seedlings will appear, when they can be removed to the light. This plant can be quite safely potted off in the following simple way: As soon as a plant is fairly above the soil, thrust down by the side of it the point of a stick (I use the ivory handle of a budding-knife, because it is always in the waistcoat-pocket handy),

and gently raise it up, letting it remain thus for two or three days; then put it into a single pot. Plants of this kind, however, require a good deal of care until they are a year old.—T. SMITH, *Newry*.

**Tree Pæonies, Dielytras, and the Frost.**—I can quite confirm "B. S.'s" remarks (see p. 328) on this subject. These beautiful plants, the Tree Pæonies, have seldom suffered so much as this season. It does not seem so much one frost as many in succession that does the greater mischief on these occasions. Successive frosts seem to act like a succession of blows; these, continuing on one spot, wound or bruise the tissues. So frost after frost sinks deeper and deeper, until the plants are crippled or destroyed. The Tree Pæonies are very much crippled here and in the neighbouring gardens of Mr. H. Porteus Oakes, of Nowton Court, near Bury St. Edmund, who has one of the finest collections of Tree Pæonies in the neighbourhood. But the Dielytra is still more severely punished, and is, in fact, out down level with the ground; it will doubtless break again and flower later. This lovely plant is generally frosted here, but no severities of our spring climate seem able to teach it to flower later. The early Forget-me-not (*M. diastiflora*), that seemed quite dead on April 1, has recovered so rapidly that most of it is already in flower. I never remember to have seen such a striking illustration of the rapid recovery of any plant or flower. Crown Imperials have suffered so severely that they do not seem as if they could recover.—D. T. FISHER.

**Double Auriculas.**—Doubtless, that singular occurrence that has from time to time shown itself in the Chinese Primula, the common Primrose, and, in a very isolated degree, in the Polyanthus, has also appeared in the Auricula, and we now possess some eight or nine really double kinds. How these originated is a matter worthy of patient inquiry, but the duplication does not appear in the best flowers, and probably owes its development to cultivation, which has the power of multiplying the number of petals so as to gradually constitute a perfectly double flower. The first appearance of an extra petal issuing from the tube of the flower is marked by the florist, who sees therein the foundation of a race of double kinds; seeds are saved, and the result is a few flowers that are more distinctly double than the parent. A few years more and we have perfectly double flowers, but it frequently happens, as in the case of the Chinese or common Primrose, for instance, that the result is entire barrenness. In the double Auriculas some, such as the purple, black, and bronze, are so double that no pistils or stamens are visible; others produce, on the same stem, flowers that are both double and semi-double, and some of these latter produce seed-pods, and thus promote the spread of other kinds. The fine double yellow will sometimes seed and reproduce itself, and sometimes colored single flowers. Of double kinds now existing there are yellow, black, purple, white, maroon, lilac, mauve, hrunze, &c., of which both yellow and lilac are now seeding. Some of the newer kinds are of Continental origin, but are fairly robust growers, and will be better known in a year or two. Being naturally slow propagators, it will not be possible to offer these to the public for some time to come.—A. D.

**Graveyard Gardens.**—With reference to "E. F.'s" remarks (see p. 379), I think any flower border on the top of a grave should be permanent, and require no gardener's hand to change the flowers at different seasons, and that spring flowers and the beauty of spring are most suitable to the associations of a grave. I think the following would make a lovely border, and contain nothing that, if planted at moderate distances, would become weedy or run into others, and would continue to take care of themselves as long as it is likely the planter's eye would watch them. In peat and silver sand (a good deal of sand, to keep it sweet) plant *Gaultheria procumbens*, with *Lilium tenuifolium* dotted among it, *Trillium grandiflorum*, *Gentiana verna* (not acutis), which flowers the easiest, *Scilla sibirica*, and *Iris reticulata*. In loam, not too heavy, as it becomes heavier by wet and sour, plant *Heleborus maximus* (it would not spread, as "E. F." fears), *St. Bruno's Lily* (the largest flowered one), *Silene alpestris*, *Lencoum vernum* and *æstivum*, *Cyclamen Coum* or *Atkinsi* and European, *Anemone stellata* and *hertensis*, *Crocus Sieberi* and *Imperati*, *Triteleia*, *Scilla nutans*, *Gladiolus*, and *Violas* which "E. F." mentioned, spread far too much, and would overrun one another.—J. R. D., *Stamford Hill*.

**Iris pumila for Spring Gardening.**—Where this style of gardening is carried on, this beautiful Iris should in all cases be used. Few plants are more effective; it grows regularly, and, if planted in good sandy soil, never fails to yield an abundance of sky-blue blossoms. We saw an isolated bed of it lately in the gardens at Wimbledon House completely carpeted with flowers, a condition in which it has been for a long time past, and in which, to all appearance, it will continue for some time yet to endure. The plants will bear transplanting yearly if used here, but they are best left undisturbed.—S.

## NOTES OF THE WEEK.

**Primroses for Waste Places.**—In Mr. Williams' interesting note on this subject I saw no allusion to what seemed to me the most important thing to say about the matter—the need to naturalize the many beautiful new and old forms of the Primrose, now obtainable in gardens, and often shown in a feeble condition at shows. Many of these are splendid in colour, and have constitutions quite as vigorous as the common Primrose. There is little need to plant what is so abundant in many places already, but there is nothing better worth doing in the way of wild gardenizing than planting in copses, banks, and similar places some of the lovely varieties to which I allude. Even some of the vigorous yellow kinds would be desirable.—A. P.

**Paris Exhibition.**—M. Truffaut, the well-known nurseryman at Versailles, writes to us, under date of May 1, as follows:—"From my own observation, having passed the day at the Exhibition, I feel sure, although many houses are not yet ready, there will be a good show of plants for the first international exhibition on the 15th inst. But what struck me the most was the conservatory built by Mr. Boyd, of Paisley, and furnished by Mr. Wills. This is certainly, at the present time, one of the chief features of the Exhibition. The English exhibits in this department do the greatest honour to your country."

**Spring Flowers at Tooting.**—I send you herewith cuttings from my two beds of *Anemone fulgens*. The fogs of the last two days have not improved them, but a more glorious sight in the sun is hardly conceivable. You will observe there are two varieties—the one with nine to twelve petals I call fulgens, and the one with twenty to thirty petals I call fulgens multipetala. I also send you some flowers of *Romulea Clusii*, a Spanish species, now blooming profusely in my grounds and very pretty, the flowers being large and rosy-lilac in colour with an orange throat. I send you leaves of Emperor and Empress Narcissus, in order to show that in plants which have been undisturbed for two years the foliage is broader than in those which are transplanted.—P. BARR.

**New Mignonette.**—Mr. Gallop sends us from Brighton specimens of his new Mignonette, which is very distinct in appearance and very fragrant, even when grown in ordinary soil, and flowered so early in the season. It is a good sign to see attention devoted to distinct or improved varieties of such plants as the Mignonette.

**Conifers at Dropmore.**—We have received from Mr. Titmuss, gardener at the Old Palace, Croydon, photographs of two of the most remarkable Conifers at Dropmore, viz., the Douglas Fir and the *Arucaria imbricata*. The first is stated to be 108 ft. in height. Its seed was sown by Mr. Frost, who is still gardener at Dropmore, in December, 1827. Of the *Arucaria*, which is upwards of 60 ft. in height, a coloured plate will be found in the ninth volume of THE GARDEN (see p. 84). It was planted in 1830.

**Indian Azaleas at Chelsea.**—These form a very attractive feature just now in Messrs. Veitch's nursery. Large houses filled with medium-sized plants in full flower may now be seen, as well as hundreds of noble specimens fit for show purposes. These latter are much more effective than such plants usually are on account of their being allowed to grow in a more natural manner than ordinarily, so their leaves as well as flowers can be seen. All the best old kinds, as well as many valuable new ones, both single and double, are here represented, and these embrace every shade of colour to be found in Azaleas.

**Plants at Nevry.**—I send you flowers of *Piptanthus nepalensis*, *Eurybia gummosa*, *Hovea Celsi*, *Correa cardinalis* in flower since October, and *Chamaecerasus grandiflorus roseus* from the open ground; also a branch of Mr. B. S. Williams' stove shrub, which he says requires the same treatment as *Ixoras*, viz., *Toxicophloeum spectabilis* also from the open ground where it has passed the winter. I likewise send a cutting of the same from a large plant wintered in a cool house where it was with other plants frozen quite hard once or twice. It will be seen that the colour of the foliage is quite different from what we usually see in a warm house, being a rich warm brown like that of a Copper Beech. I also send you a cut specimen of *Fuchsia splendens*, a number of plants of which were wintered in a cold frame are now coming beautifully into flower.—T. SMITH.

**John Waterer's Bagshot Cherry.**—I send for your inspection specimens of a new Cherry which I sent out to the trade a year or two ago. It is called *Cerasus Watereri*, or John Waterer's Bagshot Cherry; it is one of the very best flowering spring trees which we possess. The quantity of it which we have as yet distributed is very limited, and therefore it is but very little known. Blooming, as it is, in our nursery just now, it is really a magnificent plant; it makes a fine standard tree, and I believe it will become most useful as a

forcing plant, as it could be got into flower so early.—JOHN WATERER, Bagshot. [A more floriferous or beautiful early-flowering shrub or small tree could not possibly be found than this Cherry, the examples of it sent to us being literally masses of blossom. The flowers, too, are individually large and tinged with pink, especially in the bud state. It closely resembles the St. Julian Cherry, figured in THE GARDEN (see p. 436, Vol. X.) under the name of *Cerasus Juliana floribus roseis*.]

**Large Berberis Darwini.**—I saw, the other day, in a garden in this neighbourhood, an isolated, unpruned, ununtillated, symmetrical specimen of this handsome shrub which measured 63 ft. in circumference and about 22 ft. in height. It rests upon green turf, and fairly represents what this Berberis may become under suitable conditions if left to itself.—T. SMITH, Nevry.

**New Dendrobium.**—A new Dendrobe is now in flower in Messrs. Veitch's nursery at Chelsea. Its flowers are golden-yellow, the throat being a little deeper than elsewhere. The lip is furnished with a long fibry fringe, which renders the flowers quite novel in character. The plant grows freely, and will doubtless prove a free bloomer. When plentiful this Dendrobe will find its way into every collection of Orchids. It is named *D. Brymerianum*.

"The Parks and Gardens of Paris."—A new edition of this book, which has been out of print for several years, has just been issued by Messrs. Macmillan.

**Arnebia echioides.**—Dr. Moore sends us flowering specimens of this bright yellow Borage-wort, which is one of the most ornamental of the rarer herbaceous plants at Glasnevin. The dark spots on the petals give a very bright effect when the flowers first expand; they afterwards gradually disappear as the flowers get older.

**Cymbidium eburneum.**—Of this beautiful Orchid Mr. William Ball has lately imported a large quantity, some of which, we understand, are to be disposed of at Stevens's. Importations of Orchids are at all times welcome even should their worth and beauty be unknown, but to receive an abundance of kinds known to be both beautiful and valuable, is much more satisfactory. What are called Indian Crocuses (*Pleione*) and numerous other good Orchids are also to be offered at the same sale.

**Single-flowered Petunias in Spring.**—For conservatory decoration these easily-grown plants are of great value, for, in addition to their effectiveness, they supply colours possessed by few other plants. We lately saw a quantity of them in full bloom in Messrs. Carter's nursery at Sydenham. The seed, sown early in the year, produced plants which were encouraged to make growth, and at the time of our visit they were in 6-in. pots, large and spreading, and loaded with rich and variously coloured blossoms.

**Plants in Flower at Colchester.**—Our Narcissi have been fine, so has *Tulipa Greigi*, but it is now nearly over. *Trillium grandiflorum*, *recurvatum*, and *erythrocarpum* are grand; so is *Iris iberica*. We expect about 100 blooms of this *Iris*. *Fritillaria recurva* is just opening; also *Iris pumila* and its varieties *gracilis*, *azurea*, and *lutescens*. *Narcissus Bulbocodium* is fully out, with *Dodecatheon elegans*, *Orobis mascula*, *O. foliosa*, and *O. spectabilis*. *Corydalis bracteata*, *Habenaria rotundifolia*, and *H. dilatata*. *Primula japonica* and *Darlingtonia californica* are also showing flower.—A. W.

**Double-flowered Rhododendron.**—I send you a double flower of *Rhododendron Dalhousie* from a truss of bloom in which there are one single and three double flowers. Has there ever been recorded an occurrence so singular?—A. HOSSACK, Ragley Gardens, Alcester. [The bloom sent is incomparably the handsomest double *Rhododendron* we have ever seen. It reminds one of a double white *Brugmansia* in miniature.]

**Magnolias at Tooting.**—Large plants of these make a fine display just now in Messrs. Rolleston's nursery. Their bloom buds were little injured by the late frosts, and they are now one sheaf of blossom. The principal kind is *M. conspicua*, but a sort named *M. Soulangiana*, trained on a wall, is the most effective. Its flowers are produced in great profusion all up the branches, and, being very large and suffused with pink, afford valuable blooms for use in a out state. The wonder is that this and other varieties are not used for forcing more extensively than at present. They submit to forcing equally well as a Ghent Azalea, and they may be had in bloom without difficulty at Christmas. In proof of this, a large branch furnished with bloom-buds, placed in a tank in one of the Fern houses in the nursery above alluded to a few weeks before Christmas, opened its blossoms perfectly, and came in very usefully at that comparatively flowerless season of the year.

**John Waterer's Exhibition of Rhododendrons.**—This is to be held in Cadogan Square, adjoining Prince's Cricket Ground, during the present year. It promises to be a remarkably extensive and fine exhibition.

## NOTES FROM KEW.

**Hardy Trees and Shrubs.**—To the Natural Order Ericaceæ we are indebted for many of our best hardy-flowering shrubs, and at this season numerous members of this family are putting on their floral adornments. Thus one cannot but be struck with the fine plants of *Arbutus Andrachne* that are now covered with large bunches of white, cup-like flowers, broad at the base and contracted at the opening; the bright evergreen leaves, and the remarkably clean-looking, smooth, reddish bark give to this plant a striking character. *Vaccinium amarum* in the pleasure grounds is very fully covered with its blossoms, which are similar in form and size to those of *Arbutus*; instead of being white, however, they are tinged with red, and the pedicels themselves are red. *Menziesia petrifolia* is a dwarf and exceedingly pretty bush from North America, the rosy-purple, bell-shaped flowers are borne near the tops of the short branches, which are thickly clothed with leaves, much resembling (as the specific name implies) the Crowberry (*Empetrum nigrum*) of the moors and rocks of the mountains of Great Britain. *Amelanchier canadensis* is one of the prettiest early-flowering trees, showing up well in clumps or shrubberies its sprays of white flowers, the red calyx lobes and red stalks of which make the species conspicuous either amongst deciduous or evergreen shrubs. It is the Service or June Berry of the Eastern United States, and is found mostly by the banks of mountain streams. Arrows are made from the strong wood, and the berries are eaten either cooked or in a fresh state when ripe. The Cherry Crab (*Pyrus baccata*) is now one mass of snow-white blossoms; it is a very handsome small tree, and is well worth a place in any shrubery. Its beautiful fruits are freely produced; the early falling away of the calyx lobes and the very glossy, glabrous leaves abundantly distinguish this from the Siberian Crab and its varieties. The Chinese Crab (*P. spectabilis*) is another Asiatic species of great beauty; it is the most handsome of the section to which it belongs, and is covered with a profusion of fine, rosy-pink flowers. The slender twigs of the South European *Prunus* (*Cerasus*), *Mahaleb* var. *chryso-carpæ*, are densely clothed with corymbose racemes of fragrant white flowers; the habit is very graceful, and, altogether, this little tree is a very desirable one. The evergreen *Laburnum* (*Piptanthus nepalensis*) is a fine bush, and its erect, terminal racemes of large yellow flowers are very striking; it, however, requires in our climate a somewhat sheltered position.

**Hardy Herbaceous Plants.**—The *Ranunculus* family affords a large contingent of extremely valuable flowers at the present time. *Ranunculus acris*, sometimes called Fair Maids of France, is a handsome plant, about 2 ft. high, with pure white flowers. A double variety of this, in gardens, is known as White Bachelor's Buttons. *R. millefoliatus* has finely-cut leaves and large golden-yellow flowers; it is a native of Sicily. *Trollius europæus*, the Globe-flower of the mountain pastures and coops of Britain, has charming lemon-yellow flowers, whilst *T. asiaticus* has dark orange. The South European *Anemone palmaria* has golden-yellow, Buttercup-like flowers, and is a very pretty species. *Waldsteinia sibirica*, a dwarf, Rosaceous perennial, with Strawberry-like leaves and short panicles of bright yellow flowers, is a charming species for the front of the herbaceous border. *Hutchinsia alpina* and *Schizoregia podolica* are pretty little white-flowered Crucifers of similar size and habit; both do well on rock-work and flower freely. *Anemone balcanica* is a minute Sandwort from the Balearic Islands; it clings to stones almost as closely as most Mosses, and its star-like pure white flowers are beautifully set off by the dense carpet of small dark green leaves. *Ohonca cheirifolia*, a remarkable dwarf Composite from the Mediterranean region, has very glaucous leaves and bright yellow flowers. *Polemonium reptans* is a pretty, dwarf North American perennial, the light blue flowers of which are borne on short panicles; it is perhaps the earliest of the genus. Among Narcisus the most attractive are those given below. Two forms of the Hoop-petticoat Narcisus, bearing the respective varietal names of *conspicua* and *tenuifolia*, are very pleasing; the latter is about half the size, in all its parts, of the former; both are natives of South-west Europe. *N. aurantiaca* is a robust variety of the South European *N.* incomparabilis, and has an orange-coloured corona and sulphur-yellow perianth. *N. pseudo-Narcisus* var. *bicolor* resembles the common Daffodil in size, &c., but it flowers much later than the type, and the corona is bright yellow, whilst the perianth is pale sulphur. Amongst Irises the most charming of the species not previously noted is *Iris nudicaulis*, from Silesia and Bohemia; it is a very handsome rather dwarf species, with dark purple flowers. *Uvalaria grandiflora* and *U. sessilifolia* are North American perennials, and are both beautiful and interesting; the former has stems about 18 in. high and perfoliate, light green leaves, from the axils of which spring the pendulous, yellow flowers, 1½ in. to 2 in. in length; the latter is a much smaller species with whitish flowers. The bruised leaves of *U. grandiflora* are in America accounted a remedy for the bite of the rattlesnake.—†

## THE FRUIT GARDEN.

## THE GREATER HARDINESS OF PETALS THAN PISTILS.

This is a matter that has hitherto received little or no attention; yet it is one of the most prominent and deceptive features of this and almost all our fruit failures. Walking round the garden, and looking on the trees that were fairly protected, the inexperienced might think that the accounts of the fruit failures had been grossly exaggerated. Peaches and Plums look bright and fair as before, and Apricots, having so far accommodated themselves to frequent failures, have expanded their second or reserve forces of bloom to make up for the almost complete wreck of the first and main crop. But all is not gold that glitters, nor all fruit that looks like it. These floral appendages, that look so bright and gay, are but flowers on the birch of Death. The pistils, stamens, ovary are all wrecked, or so crippled that fructification is impossible. The very persistency with which the more ornamental appendages of vitality (the petals) cling to the trees is one of the worst possible signs of the hopelessness of a crop of fruit. Were the blossoms set, or likely to set, the petals would quickly fall off; but they cling on to the last, as if loth to give up all for lost. Even not a few of the second bloom of Apricots seem imperfect, and many of the buds seem to have been loosened from the trees by the frost before opening, so that the merest touch or the gentlest breeze causes them to fall; still, no doubt, a few of these may set. Of course I am writing of trees properly protected. Those left to themselves seem to have no chance whatever. Apples seem to stand still since the frosts; still, as they are abnormally late, it is hoped they are safe; there will be a fine bloom. Early Plums are wrecked, but the later ones seem safe, and are expanding rapidly now, so that the trees are white as a sheet. Cherries are also a glorious show, and look safe and sound. Late Pears also look more hopeful; most of the early ones are wrecked. Gooseberries have passed through pretty well, doubtless owing to the snow, which laid thickly on the bushes. Currants are also unusually late, and seem all right. Strawberries also look promising, so that, should the remainder of April and May up to the 20th prove genial, perhaps a half crop of out-of-door fruit may yet prove one of the welcome blessings of the season. But a month of danger is yet before us, and almost everything depends on what weather that month may bring. The growth of everything in the open air has been remarkably slow up to the present time, and in that fact there is much hope that the great English fruit crop for all classes in England—that of the Apple—may escape being wrecked; and, if so, there is every symptom of its proving plentiful.

D. T. FISH.

**Fruit Prospects.**—Notwithstanding the prognostications of the prophets, I think we are likely to have average crops of most fruits this year where the blossoms have escaped the late frosts, and provided they escape after this date, April 27, which we may hope. Some kinds of Apples and Pears are full of bloom, and others are quite barren; this is especially the case with Pears. The most floriferous Pears are *Doyenné d'Été*, *Napoleon*, *Broome Park*, *Williams' Bon Chrétien*, *Althorpe*, *Crassane*, *Barré d'Amant* (a good Pear in our high latitude), *Chamnotel*, *Bœurré Clairgeau*, and *Easter Bœurré*. Such as the *Forelle*, *Marie Louise*, *Bergamotte*, *Hacón* (incomparable), and *Knight's Monarch* are quite barren. The most promising Apples are *Devonshire Quarrenden*, *Bradick's Nonpariel*, *Irish Peach*, *Golden Pippin*, *Boston Russet*, *Claygate Pearmain*, *Pearn's Pippin*, *Cooke Pippin*, *Adam's Pearmain*, *Lamb Abbey Pearmain*, *Lord Suffolk*, and the *Codlins*; the latter two are sorts which rarely fail. Cherries are as full of flower as ever I saw them; but are too early in bloom for this district unless the weather turns out exceptionally favourable. Plums are middling; Strawberries, Gooseberries, and Currants look fairly well.—J. S. W.

**Tan Cure for Gooseberry Caterpillar.**—I have no experience as regards the Elder bush cure for this caterpillar (see p. 356), but 4 in. of tanner's bark spread around the stems and over the roots in the autumn I have found to be a complete cure. It either kills the larva or keeps it from getting out; and either way the result is a cure, the simplest and best I have found. I have little faith in frightening or charming such pests away by any sort of counter-charm; but if Elder boughs will drive or keep away flies from horses' ears, why should not permanent plants among Gooseberries have a similar result as regards caterpillars? Why, indeed? Only I can say this, that Tomatoes do not drive away wasps from luscious fruits, as many have affirmed; and I have never found the wasps even stop to notice the Love Apples when any ripe Peaches or Pears were in the way. Hence, I am also sceptical about the Elder plants.—D. T. FISH.

## BERRY HILL, TAPLOW.

WE have more than once spoken of this place as interesting from a landscape-gardening point of view, and now have much pleasure in giving a view in and plan of the ornamental part of the grounds. The charm of the place is owing to its possessing considerable variety of vegetation, often disposed in an artistic manner, and at the same time having abundance of breadth and turf about the house. The elements of the landscape picture are simple, there being no natural features to help the designer beyond a little gentle undulation of the ground. Such charms as it possesses are within the reach of all having a few acres of ground. The water is artificial, but has in outline or in the grading of its banks nothing in common with the unpleasant ponds which are too often the result of efforts in this direction. The house is on a gentle eminence, and the views across the lawn, both to and from the house, are often pretty. As may be noticed, the terminations of the water are well concealed; but perhaps the most instruc-

## TREES AND SHRUBS.

## RHODODENDRONS ON CHALK.

I OBSERVE some inquiries on this matter by "A. C." (see p. 276), and also note the advice "not to attempt to cultivate them at all on the chalk." This is rather too sweeping, as everything almost turns on the character and depth of the soil over the chalk. The greater part of the gardens here are on the chalk, which varies in depth from 1 ft. to 4 ft. from the surface. Yet Rhododendrons thrive well in the natural loam that overlies the chalk and better still, in woods where the *débris* of fallen leaves forms a patulum in which their roots delight. "A. C.'s" proposed plan, however, of digging pits in the chalk and filling them with peat in which to plant Rhododendrons is not a good one. A better course is to form good masses of soil over the walk of considerable size and depth, and to plant these raised beds with Rhododendrons. The larger the masses the more telling in a park; and if the soil could be laid between 2 ft. and 3 ft. deep the plants would thrive all the better. The sides of the newly-raised beds might

Berry Hill: View across the Water and Lawn to the House.

tive feature of the plan (see p. 413) is the absence of needless walks. In this respect it is a charming contrast to the French gardens made hideous by curvilinear walks interlaced throughout their whole surface, and of which we have given several specimens in THE GARDEN. Here it may be noticed that one outer walk leads to all the important features of the place, and the lawn is consequently unbroken. How many gardens that might be beautiful are spoiled by needless walks! It must be a very large garden, arranged in this or any similar manner, which requires more than one walk. The place is charmingly planted, although no additions have been made to its collections since its owner, Mr. John Noble, removed to Park Place a few years ago. The garden was laid out by Mr. Marnock, and owes much of its beauty and interest to the good taste of its owner in matters of planting and garden design. Mr. Noble has since formed another beautiful garden at Park Place, Henley-on-Thames, of which we hope soon to publish some views. The names, being engraved in the plan, make it self-explaining.

be furnished with Ivy, Periwinkle, Cotonaster, or, better than all, the variegated Japanese Honeysuckle, or *Berberis Darwinii* pegged down. The surface of the beds should be flat, or even slightly hollow in the middle, and if the soil be dry and clay be come-at-able, the sides might be puddled round with clay, and also the bottom in extremely dry places; but neither will be useful in a general way. The form of the bed will retain the moisture that falls upon it, while its elevation above the surrounding surface will protect it from the opposite extreme of stagnant water at the roots. It is the want and the excess of water far more than anything in the soil or subsoil that prevents the growth of Rhododendrons on the chalk. Another point of much moment as regards the culture of Rhododendrons is shade. This is easily provided by planting in clumps of trees already established, or by planting some Oak, Sycamore, or other trees a season or two before the Rhododendrons are planted. Oaks seem to agree with Rhododendrons better than any other trees, and if tolerably tall trees be planted in the prepared beds, they will afford a useful shade at once. One great benefit derived from mass planting, as here proposed, is, that the plants shade each other from the first. Rhododendrons naturally cling together in masses, and those who plant thinly

in the open ground, even in the best soils, generally have to submit to a slow growth for some years in consequence; but in unfavourable soils and in ungenial places the penalty paid for the thin distribution of plants is the death of many and a severe check to all. The Rhododendron is a surface-rooting, shade-loving plant; and it follows that, set out thinly on or off the chalk, it suffers severely from the sun on its stems and roots; hence, the worse and more exposed the position, the thicker Rhododendrons should be planted. This lesson was well learned many years since. An avenue on either side of a green walk and also a mass of Rhododendrons were planted simultaneously. Naturally, the finest plants were selected for the avenue or line; but the effect of isolation was so marked that the massed plants took the lead at once, and the open lines never got within any fair distance of them afterwards. Neither is there any waste of money or plants in this thick planting, as few shrubs transplant with more ease than Rhododendrons, and before any great overcrowding takes place, it is easy to thin with such discretion that neither the plants taken nor those left shall greatly feel it. In unfavourable localities I should, however, prefer thinning with the knife rather than the spade; and no plants do better in thick masses than Rhododendrons. In fact, once they reach this state, they seem almost independent of soil; and if they have trees overhead, or a few leaves scattered amongst them every winter, they will thrive and flower on almost any soil, however bad or barren. Water, however, they must have. For more Rhododendrons are killed by drought than starved through unsuitable soils. During dry summers, on thin barren soils, the plants should be drenched with water, especially in East Anglia and other dry districts; for, in general terms, it may almost be affirmed that as is the rainfall so is the size and luxuriance of these grand plants, and nothing astonished me more than the literal forests of Rhododendrons to be met with in Inverness-shire and other parts of the Highlands of Scotland. Many of the Rhododendrons in the north are more like our grandest specimens of Portugal and English Laurels than the usual run of Rhododendrons one meets with in the south. Therefore, if cultivators could irrigate their Rhododendrons a few times during hot dry summers, or, as the farmer expressed it about his Mangles, "turn a river over them," they would doubtless thrive in hundreds of localities where they now refuse to grow. Soil is of less moment than shade and moisture. Every one knows these plants thrive in peat; it is less generally known that they flower even better and thrive almost as well in good loam than in peat. They will live in clay and in soils little else or better than sand, especially if the latter be dressed with cow manure in a decomposed state. Perhaps the best soil of all is that composed of equal parts of peat, loam, and leaf-mould, pretty freely intermixed with pure silver sand. Red pit sands are generally objectionable, as the iron found in some of them is as bad or worse than chalk for Rhododendrons. D. T. F.

**Shrubs for Mixing with Fuchsias.**—I quite agree with "Kensington" (see p. 359) that *Dentzia glabra* is an excellent bed or border plant far too scarce in cottage and other gardens. We have some grand plants of it here among Rhododendrons, and its noble drooping masses of white, towering far above their bright colours, are beautiful in the extreme. The double *Dentzia* is equally beautiful, but less white. It, however, flowers later, and continues much longer in flower, and it is one of the best shrubs that has been introduced in modern times. Being, however, a *Dentzia*, it has been forced to death in not a few gardens, a purpose for which it is not adapted, and far inferior to gracilis, which is inimitable for that purpose. The latter also does well out-of-doors in warm localities, and is extremely beautiful where it thrives in the open ground. The *Dentzias*, however, flower earlier than the *Fuchsias*, and so far could hardly add to their beauty, though the foliage is good and the habit graceful. Perhaps some of the *Spiræas*—such as *S. arifolia*—would be a better match for *Fuchsias*. Still, *Fuchsias* need no support, as of them it may truthfully be said none but themselves can be their equals, and amongst them there is a marvellously rich variety of form and colour. But masses of *Dentzias*, *Syringas*, *Almonds*, *Lilacs*, *Spiræas*, *Rhododendrons*, *Azaleas*, and other shrubs of moderate size, and well posted here and there on the Grass, have a magnificent effect. I also quite agree with "Kensington" about the *Catalpa*, which is a fine tree where it thrives and can find room. To do it justice, however, it needs much space. Among other beautiful, moderate-sized, choice neglected trees may be named the *Magnolia conspicua*, which is in full flower early in April, and one of the most beautiful and sweet of the *Magnolias*, only second in size and fragrance to *M. grandiflora*. Such trees as these, the *Ailantus glandulosa* and several *Asclepias*, form a most welcome addition, and a pleasing contrast to the *Thorns*, *Laburnums*, *Lilacs*, and *Laurels* that so often form the entire furniture of small gardens.—D. T. FISHER.

## THE PRIVETS.

By GEO. GORDON, A.L.S.

THESE grow freely in any kind of soil; they bear clipping well and form good hedges, for which the best are the Italian Privet and the oval-leaved one from Japan, especially the last, which grows twice as fast as the Italian Privet, and is more robust. It is also sub-evergreen, or in mild seasons quite evergreen. It commences to grow very early in spring, and in the neighbourhood of London is fast superseding all others for forming hedges. When planted singly, as bushes, Privets also form very ornamental objects, as they flower most profusely. The Indian Privets (*Ligustrum robustum* (spicatum), pubescens, bracteolatum, vestitum, nepalense (Wallachi) lanceolatum, longifolium, and virgatum) are all tender, and are seldom met with, except in botanic gardens, where they are treated as greenhouse shrubs. They are of little use as decorative plants.

**Common Privet** (*Ligustrum vulgare*).—This is so well known, that it is only necessary to state that there are several varieties of it; the most distinct of which are the yellow-berried, the variegated, leaved, and the Italian or evergreen one, which retains a portion of its leaves all winter.

**Oval-leaved Japan Privet** (*L. ovalifolium*).—This forms a robust, upright shrub, 6 ft. or 8 ft. high, and retains a portion of its leaves all winter. The latter are tolerably large, oval, somewhat pointed, quite smooth, and of a deep shining green on the upper surface; the flowers are borne on rather close panicles, and are produced in July and August. Of this there is a fine, erect-growing, golden variegated variety, which in gardens bears the absurd name of *L. californicum*. This kind, as I have said, is now common as a hedge plant about London.

**Chinese Privet** (*L. sinense*).—This forms a tall, deciduous shrub, 8 ft. or 10 ft. high, with an ample, spreading head. Its leaves, which are much smaller than those of the oval-leaved kind, are oblong-lanceolate, somewhat pointed, and tomentose; the flowers are borne in rather large, loose, terminal, villous panicles, and are produced in great profusion in August. Of this the *L. Stauntoni* is a variety, and it bears the names of *chinese*, *ibota*, and *ibota villosum* in gardens. There is a fine variegated variety of it, the leaves of which are edged with gold.

**Japan Privet** (*L. japonicum*).—This is a low-spreading, evergreen shrub, from 3 ft. to 5 ft. high, with broad, oblong-ovate, somewhat pointed leaves, grooved along the middle on the upper surface, quite smooth, and of a deep glossy green above; the flowers are in rather largish, compound racemes, with the pedicels spreading. It is the dwarfest of all the species, and forms a very neat shrub, which flowers in July and August. Its synonyms are *L. latifolium* and *L. Sieboldi*. There are three or four varieties of it, one of which has tricoloured leaves.

**Leathery-leaved Privet** (*L. coriaceum*).—This is a distinct Japanese kind, with thick, glossy, dark green leaves, and quite a dense habit of growth. It is known in gardens under the name of *L. glabrum*.

**Shining-leaved Privet or Wax Tree** (*L. lucidum*).—This is an old inhabitant of our gardens, and forms an erect, twiggy, sub-evergreen shrub, from 10 ft. to 12 ft. in height. Its leaves are rather large, broad, and of a deep glossy green; they are ovate-oblong, pointed, smooth in the adult state, and shining. The flowers are borne in large, spreading, thyrsoid panicles and terminal. It is a native of China, and flowers in September and October. Of this there is two varieties, one with much larger bunches of flowers (*L. floribundum*) than the type, and the other with variegated leaves.

## JUGLANS LONGIROSTRIS.

THIS variety of *Juglans* about to be described is certainly one of the most remarkable in the genus, more especially from a scientific point of view. It is one of those plants which show, better than any amount of argument, how far types may extend, or rather that their extent is illimitable. In an article, condensed from a paper by M. E. A. Carrière in the "Revue Horticole," on the Walnut and its varieties, which appeared in THE GARDEN, Vol. IX., p. 361, it was shown that the American and Asiatic types *nigra* and *regia* are closely connected by a long series of intermediate species. Nothing, says M. Carrière, in a recent number of the "Revue Horticole," confirms this view of the question better than the fact of the sowing

which has produced the *Juglans longirostris*, having been made with the seed of the common Walnut, none of the other seedlings being exactly like the parent tree. They all differed in form and general appearance by the size, shape, and nature of the fruit, by dimensions and form of the leaves, and even by the absence of the well-known characteristic odour peculiar to the Walnut trees of all countries, such as *regia*, *nigra*, *cinerea*, &c. It may be noticed that these species, which have long been thought to be geographically distinct, are now found to be closely connected. For instance, in the far east of Asia and Manchuria, and possibly elsewhere, there exist certain forms which nearly approach *Juglans nigra* and *cinerea*, of which they are the analogous forms, and which seem to unite these types to *J. regia*, which itself appears under a great number of different forms. Amongst these there are several varieties that bear fruit, the shells of which will not divide; we must, in fact, break the shell

ing, as they do, additional connecting links between the two great groups of Walnut trees. M. Carrière promises to give an account of these interesting varieties. In the meantime he informs us that one of these so closely resembles the Hickory or Pecan-nut tree of Louisiana (*Carya olivæformis*), as to be easily mistaken for it. C. W. QUIN.

THE AMERICAN CORK, OR WESTERN ROCK ELM.

(*ULMUS RACEMOSA*.)

THIS tree is found growing with the common American Elm, and in situations similar to those selected by that tree, from the southwestern county of Vermont westward to Illinois, and from the Ohio northward into Canada. It is common in New York, along the banks of the Mohawk and its tributaries, in Yates County, near Penn Yan, and occurs in many parts of Ohio and Illinois; but it is in the southern peninsula of Michigan, Wisconsin, and the province of Ontario that the Rock Elm is most frequently met with. This species will be readily distinguished by the disposition of the flowers, which, unlike those of other Elms, are borne in racemes 1 in. to 2 in. long, and composed of several clusters of two to four flowers together. It may be distinguished also from the common American Elm, at all seasons of the year, by the thick corky ridges which extend along the young branches. The wood, too, will be found to be very dissimilar from that of the American Elm. Its specific gravity is '832, while that of American Elm is but '649, or 22 per cent. lighter. It is almost as heavy as the best Eastern Hickory, 4 per cent. heavier than the best San Domingo Mahogany, and 26 per cent. heavier than second-growth Eastern White Oak. The wood is fine grained, compact, and shows but little of that inclination to splinter which renders the wood of the American Elm unfit for many purposes of construction. The heart-wood, which is buff in colour with reddish tints, is susceptible of high polish, and is warm and agreeable in tone. Architects and cabinet-makers, to whom specimens have been submitted, speak of it with unqualified praise for furniture-making and interior decoration, for which purposes its hardness, strength, and beauty seem to particularly adapt it. The wood of this tree is unknown in the Eastern markets, but considerable quantities of what is called Canada Rock Elm are annually exported into Great Britain from Canada; but, judging from the descriptions of it, I am inclined to think that this is nothing but American Elm, or perhaps a mixture of the two, as lumbermen do not well distinguish this species, calling all Elm grown on high and dry land Rock Elm, and all that is produced along the river banks and in damp situations Bastard Elm.

Although still unknown in the East, the wood of *Ulmus racemosa* is highly valued in those portions of the Western States, where it is abundant enough to form an article of commerce. It is very largely employed in the manufacture of heavy agricultural implements, such as ploughs, mowing and threshing machines, and similar articles, in the construction of which the best White Oak is used in the East. In spite of its weight and strength, this wood is very flexible, and, when properly seasoned, retains any shape into which it has been bent, a quality which finds for it important employment. In some parts of Michigan, Rock Elm is largely used for the frame-work of chairs, and for the hubs of wheels and the heavy beams of stump pullers it has no equal. It is used for the slats of stock-cars, and for this and other purposes large quantities are annually consumed by the railroads. Indeed, the wood of this tree is generally employed wherever it can be procured, and where a material combining at once strength, toughness, and solidity is required. Should it reach the Eastern markets, the qualities which have caused it to be eagerly employed wherever it is known will find for Rock Elm a ready sale here; while, unless the opinion of those experts to whom specimens have been submitted is a mistaken one, it will be one of the most valuable, as it is one of the most beautiful, of American woods for the architect and cabinet-maker.

Taking the standard of weight as the best test of the heat-giving quality of any wood, and of the length of time it will continue to burn, Rock Elm is barely surpassed as fuel by Hickory itself. The specific gravity of Eastern second-growth Hickory is '838, that of Rock Elm '832, and that of second-growth Eastern White Oak '662; so that, applying the test of weight, Rock Elm as fuel is worth only 1 per cent. less than Hickory, while it is worth 26 per cent. more than White Oak, the best fuel which now ever reaches this market in any quantity. Actual experiments show that this wood burns slowly, with a bright, steady flame, and without snapping; ash equal to sixty-seven hundredths of 1 per cent. of the dry wood consumed is left after burning. As is to be expected of a tree yielding such heavy, close-grained wood, the Rock Elm grows very slowly. Specimens before me, cut from trees grown in Michigan, show that the annual layers of wood vary in width from one-sixteenth to one-eighth

*Juglans longirostris* (one-fiftieth the natural size).

in order to get at the kernel, which is so shut in by the ligneous walls of the mesocarp, that it is difficult to extract it at all. The most striking example of all these modifications of the original type *Juglans regia* is the *Juglans longirostris*. The tree has thin branches which grow nearly upright, forming a tall narrow pyramid. The bark of the branches is glabrous, of a shining black colour, that of the young shoots being equally glabrous, but of a dead green tint speckled with greyish-white. The buds are of a rusty greyish-red. The leaves are compound, and in some cases grow to the length of more than 16 in. The fruit stalk is covered with extremely short hairs of a light green colour. The fruit is borne on a short stalk, narrow at the base, but widening towards the middle, beyond which it decreases in size, again finishing in a long point or beak (*longirostris*). The surface is slightly sinuous and covered with short down; the shell is woody, and the surface is more or less gibbous and rugose. The form just described is not the only remarkable variety found amongst this crop of seedlings. Three out of these are specially interesting, form-

of an inch, and that the tendency of this tree is to grow more rapidly with increasing age. One stem, only 5 in. in diameter, shows sixty-seven annual layers, but this specimen doubtless grew in unfavourable soil, as a tree of the American Elm growing with it gained but 6 in. in sixty-five years. Never a common tree, the Rock Elm is fast disappearing from even those parts of the country where formerly it was the most abundant, and steps should at once be taken to propagate and plant what must be considered, in spite of its slow growth, one of the most valuable of American timber trees. I cannot learn that the Rock Elm has ever been cultivated, except in the new arboretum of Harvard University, where seedlings, three or four years old, are perfectly hardy, and are growing about half as fast as American Elms of an equal age.

The methods employed to propagate and cultivate the American Elm will be found equally successful with the Rock Elm, which will, I am confident, find itself at home in any part of the United States, and in any situation where the American Elm will thrive. The cultivation of the Rock Elm cannot, however, be recommended in those portions of the country infested with the canker-worm, which will doubtless attack indiscriminately the foliage of all the North American Elms. Sargent's "Notes on Trees and Tree Planting."

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Outdoor Camellias.**—In reply to the inquiry concerning these (see p. 400), allow me to state that the best aspect for Camellias is a south or south-west one, sheltered by a bank or wall. They flourish in a compost consisting of two parts fibrous peat and one part good loam, with an addition of sharp sand. Planting from pots may take place at any period, but about July is the best time, as the wood is then well ripened. Duke of Devonshire, Halfida, Chandleri, Florida, imbricata, elegans, Alberti, Double White, Donkelaar, Countess of Orkney, Mathotiana, and Lady Hume's Blush are the best for outdoor culture, but in severe weather the flowers will be often damaged, unless temporarily sheltered.—W., *Exeter*.

—Almost any strong growing kind of Camellia should do well in the open air in Surrey if the situation be moderately sheltered from strong winds, and especially from the north. In planting out as an experiment it would not be advisable to select new or expensive kinds, and specially not plants that have been subjected to heat or forcing. It would be well to have good, well-hardened plants, some three or four years worked, as those when too often established would make the most robust growth. It has been too often the rule to turn out into the open ground old half-starved plants that are relegated to outside treatment from want of house room. If from such plants some disappointment should result, the Camellia should not be blamed. Such kinds as the Old Double White, Double Striped, Mathotiana, Lady Hume's Blush, &c., thrive satisfactorily in Hampshire, where the soil is a mixture of peat and loam, and where both Rhododendrons and Pinuses grow luxuriantly. Trench the soil deeply, let it be moderately manured, sweet, well drained, and of a sandy texture, and Camellias will doubtless do well. The Camellia is a very hardy shrub, as in the open air it does not begin to make its new growth until the most dangerous frosts are over. The plants may require a year or two before they make a good start, but when once established their future prosperity may be regarded as assured.—A. D.

**Fagus antarctica and Fagus betuloides.**—In Mr. Fraser's article on Beeches (see p. 391), he states that these two names are synonyms of one species. Possibly the same species may in gardens bear sometimes the one and the other, but it is a fact that they belong to very distinct species, both inhabiting the extreme south of South America. *F. antarctica* is a deciduous tree, and grows at a greater elevation than *F. betuloides*, which has thick, glossy, evergreen leaves. Both species were introduced into this country by the Antarctic Expedition, and are as easily distinguished from each other as the Evergreen and Turkey Oaks.—V. B. *Hemelst.*

**Holly Berries and Hard Winters.**—The popular notion that an abundance of Holly berries denotes a severe winter was evidently at fault last season, as the trees are still loaded with berries and coming into bloom for another crop. It is singular how the birds select particular trees for their first meal, clearing them entirely of their crop and shunning the next tree altogether. They are evidently fastidious as to flavour, for, as far as external appearance goes, there is not a shade of difference between the trees selected and those rejected.—J. Gloom, *Henham*.

**Berryless Hollies.**—I have been told that the Hedgehog Holly never bears berries. This year on a tree of this kind, near this town, there were half-a-dozen berries, of which I had one, and have set the seed contained in it.—H. S. N., *Bishop's Castle, Shropshire*.

## THE INDOOR GARDEN.

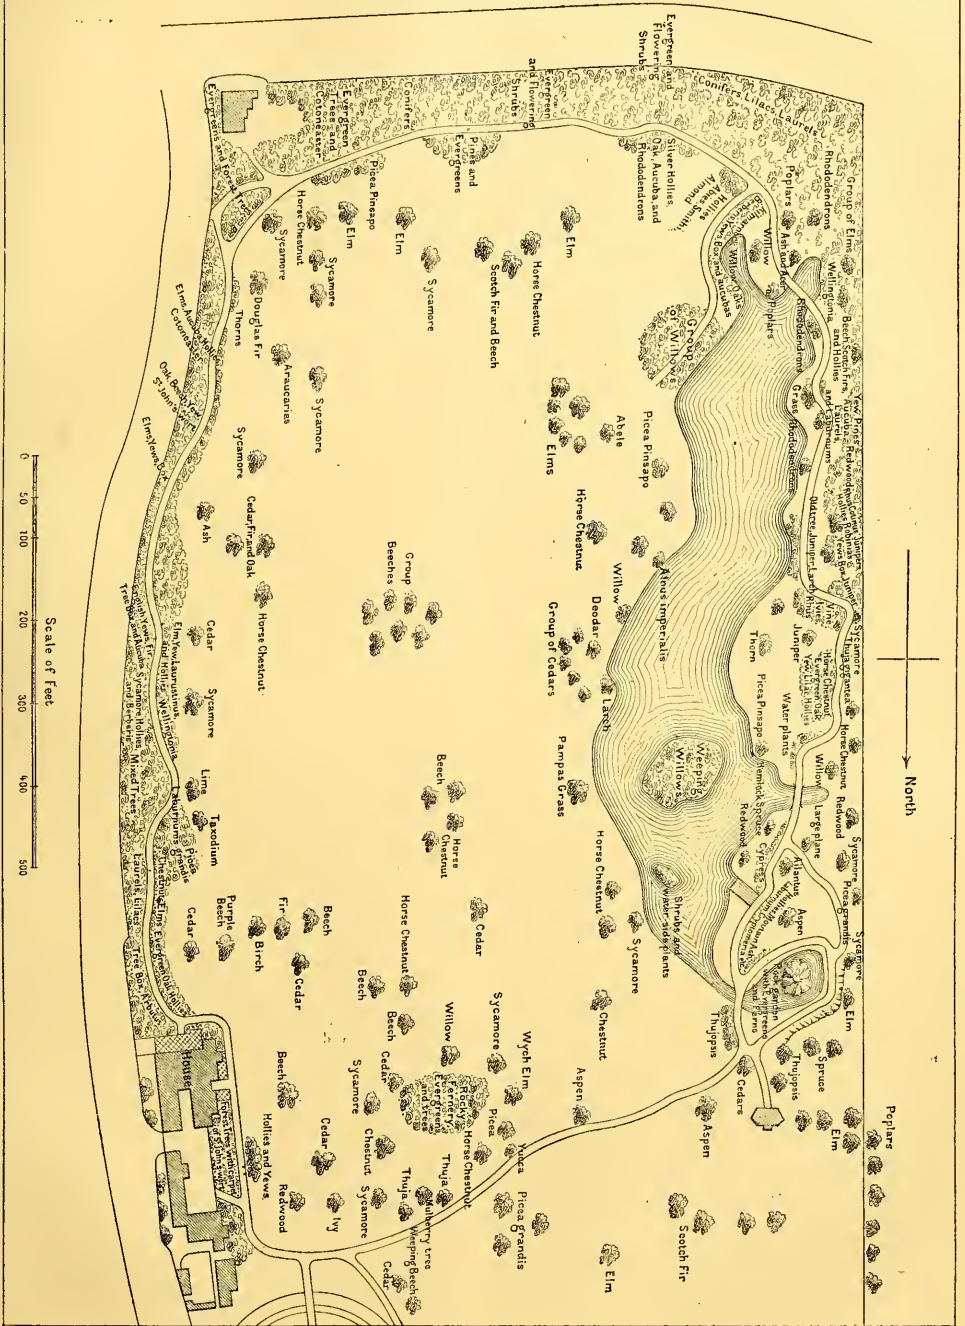

### TENDER ANNUALS AND OTHER DECORATIVE PLANTS.

SEEING the great dearth there is of greenhouse plants that bloom during the summer and autumn, and the few available for decorative purposes at those seasons, with the exception of Fuchsias and Pelargoniums, it has occurred to me that a list of such plants as may be raised from seed sown now, together with a few remarks thereon, may be of service to many readers of THE GARDEN. One advantage in growing plants of this class is that they can be got up quickly at a very small cost, and as fresh ones can be raised every spring, there is no necessity to winter them, a great consideration with many who have only very limited accommodation under glass, and who therefore desire to make the most of the room they have. Taking them in alphabetical order, the first that occurs to me is

**ACACIA LOPHANTHA**, a plant of singularly graceful habit and outline, and one that is particularly well adapted for table decoration or for placing in windows, as there it shows off its elegant foliage to the greatest advantage. Not only is it good for either of these purposes, but it forms an admirable relief to the flatness and general uniformity of others on a stage when set so as to show clear above them; and half-a-dozen used in this way do much to give a finished look to any house in which they may be used. By sowing annually at this time of year, plants of this Acacia may be had with straight, single stems furnished with leaves down to the pot, and when in this condition they are exceedingly ornamental. The seeds, being somewhat hard, are rather slow in germinating, but in this they may be hastened by soaking them for twelve hours or so in warm water, after which they should be sown in sandy soil and placed in a brisk heat, such as that of a Melon or Cucumber frame. A rich, light loam suits them best to grow in, and 6-in. pots are quite large enough for the first season, but if extricated plants are required they may be had by liberal shifts and feeding them well with manure water.

**AMARANTUS TRICOLOR, SALICIFOLIUS, AND HENDERI** are also very desirable, and, like the Acacia just alluded to, come in admirably for table decoration, but to fit them for this purpose they must have plenty of light, so as to impart to their leaves those rich, brilliant tints of colour for which they are so justly admired. Not only must they have an abundance of light, but the atmospheric moisture should be in proportion, otherwise they are sure to suffer from the attacks of red spider, to which they are very subject, and which, if not kept in subjection, soon spoils their beauty. The best and easiest way of growing these Amaranthus is to plunge them in a pit or frame by themselves, and keep them well syringed overhead, and if this is done daily at two or three o'clock when shutting them up, they will soon make handsome little specimens that will be highly ornamental in the greenhouse or conservatory. Being moisture-loving subjects, they should have plenty of water and free drainage to admit of it passing away quickly, and this, with a rich loose soil and liquid manure occasionally, will keep them in perfect health till cold weather sets in, when they begin to die off. Seeds sown at once in heat will soon be up, and, in potting off the plants, the most promising only in point of colour and habit should be selected, as they are very sportive in their character, and vary much in their markings. Besides these that are so valuable for the beauty of their foliage, there is that fine old annual the

**GLOBE AMARANTUS**, better known, perhaps, as *Gomphrena purpurea*.—The flower-heads of this resemble those of Clover in shape and size, but are far richer and more varied in colour. The group to which it belongs contains plants well deserving of more general cultivation, forming, as they do when well grown, neat, branching, bushy little plants, varying from 1 ft. to 2 ft. high, each shoot terminated with one or more of their symmetrical globular heads. These, if cut before they have attained their full size and maturity, will retain their fresh-looking appearance for a considerable period, and are, therefore, most useful to mix with Everlastings and Grasses of different kinds, with which they associate well and do much to enliven. These Gomphrenas are of easy culture,

PLAN OF LAWN AND PLEASURE GROUND AT BERRY HILL.—(see p. 411).

and do best when growing if placed in a pit or frame where they can be plunged in a bed of gently fermenting material, the genial moisture from which, being discharged with such regularity, just suits them. The next situation most agreeable to them is a warm house, where they can be placed away from draughts or dry currents of air, and kept syringed occasionally till they show flower, when any damping overhead should at once be discontinued. To have fine masses of them, the best way is to put three plants triangularly in 6-in. or 8-in. pots, and, if the different colours be grown together, they form a very pretty contrast, and have a much better effect. Those that blend best are the purple and white or purple and yellow, both of which come true from seed, which should be got at once and sown in a brisk heat, and the plants nursed on in the same near the glass, so as to keep them from drawing up weakly and spindly. They delight in a rich vegetable soil, and require plenty of water all through the season, the want of which soon causes them to present a starved appearance, and prevents them from producing their blooms with anything like the freedom or size they otherwise would do.

*BROWALLIAS* (elata and Roezli) are most valuable for blooming late in the autumn or through the winter, which they will do freely if kept near the glass in a temperature varying from 50° to 55°. For working up into bouquets they are unsurpassed, their slender stems and numerous lovely small blue or white flowers rendering them particularly well adapted for that purpose, and, what is equally in their favour, they are very lasting in water, as, when using them last year, I found at the end of a week they were as fresh as ever. As pot plants, too, they are exceedingly ornamental, and, in order to have a regular succession, seed should be sown about the middle of June and again at the end of August or even later, which will carry on the supply up to the following April or May. Those sown first will do best grown outdoors after they have got a fair start, which should be afforded them by keeping them close in a frame for a few days after being potted, when any sunny sheltered position will suit them. Being rather spare and fragile in their habit, they produce the finest display by being placed three in a 7-in. or 8-in. pot; but those required for winter work may with advantage be confined to a size smaller, as then less water and root-room are required. During the summer months they require a free use of the syringe, as in hot weather they are subject to red spider, which, if allowed to effect a footing, soon spoils their appearance.

*BALSAMS* are too well known to need a word in their favour, as they are grown more or less successfully in almost every garden, and if a good strain be obtained and the plants well managed, nothing is more showy and beautiful than those of the Camellia-flowered section; besides having blossoms of great size and fullness, some of them are as handsomely marked as a Carnation, while others are of a brilliant self colour. To have fine, sturdy, well-furnished specimens, with the lower branches resting almost on the rims of the pots, they must be grown in full sunlight, close up to the glass, and have plenty of air on all favourable occasions. This will keep them stocky and short-jointed, so that every branch and lateral will stand stiff and erect without any support, as all Balsams should. To grow them really well, they require a little bottom-heat, such as may be afforded by any gently fermenting material, and at every shift into larger pots they should be dropped lower, so as in the end to bury up the stems to the first joint. So gross-feeding are they in their habit, that they will take almost any amount of liquid or solid manure if administered in a mild form and at proper and suitable intervals of time. When large plants are required, it is a good plan to pick off the first bloom-buds that show, as then their strength and energy are concentrated in developing growth and in becoming better established.

*CHILIES*, such as Prince and Princess of Wales, are of that exceedingly ornamental character when well fruited as to be among the very best plants which it is possible to have for winter decoration in a warm greenhouse or room, so beautifully bright are the yellow pods with which they are laden. Used with *Solanum capsicastrum* for dinner-table decoration, the contrast between the coral red berries of the one and the colour of the other is very effective, and, being of a similar style of growth, the two associate well together, and are deserving of exten-

sive cultivation for the above-named purpose alone. Although they may be raised and perpetuated by cuttings, the best way is to sow seed annually, and this should be done at once in light soil, and then placed in heat, where, if kept moist, it will quickly germinate, and soon be ready for potting off. This should be done in small pots, in a mixture of loam and leaf-mould in the proportion of three parts of the former to one of the latter, together with a little sand to keep it open and porous. These *Chilies* are more natural looking and show off to the greatest advantage when grown as standards about 1 ft. or so high; and to get them in this desirable form, the side shoots must be nipped out as they show, in order to drive them up with clear stems till they reach the limit fixed on, when the tops should be stopped and young growth encouraged. The thing then is to get them to flower freely and set a good crop of fruit, and this may be done by plunging the pots in any light pit where the plants can have full sunshine and plenty of room between, so as to admit of a free circulation of air amongst them. What artificial heat is needed after the end of May may be afforded by closing the lights early in the afternoon; but if they can be afforded a slight warmth from a lining, they will be all the better for the assistance given them. In winter they require a temperature ranging between 50° and 60°, or the leaves are apt to become discoloured and to fall off.

*CELOSIA PYRAMIDALIS* produces splendid feathery plumes, ranging in colour from bright crimson to pale yellow, and the plants are of singularly graceful habit, the inflorescence drooping over in the most elegant manner, and having of such a velvety appearance, they are exceedingly showy and attractive. Compared with these, the old Cockscomb, from which these originated or are allied, is a stiff, formal-looking plant, and is fast losing favour, as these are so much better in every respect. When well grown they form grand-looking decorative subjects, and are most valuable either for the greenhouse or conservatory; besides which, they are specially suitable for cutting, as owing to their peculiarly dry nature they last quite fresh-looking for a considerable length of time either in or out of water. Seeds sown now will afford plants that will come in towards the end of August, and these in a warm house will last in full beauty till quite late in the year. No place suits better to grow them in than a pit or frame, where, if closed early and heavily syringed, they will keep clean and soon make fine plants. Their habit is so symmetrical and their growth so uniform, that they require no stopping or training, and should be allowed to take their own natural course entirely, as it can in no way be improved.

*CAMPANULAS*, such as *C. pyramidalis* and *C. Medium calycanthera*, make a grand display during the spring and early summer months, and, being hardy, they may be grown in any border and lifted late in the autumn for potting. Those who have not seen the latter in flower can form no idea of their beauty, as they are distinct from any other *Campanulas* in having a large salver-shaped frill at the base of the bell, which gives them a very ornamental appearance. This saucer-like appendage measures, when fully expanded, quite 3 in. across, and, the blooms being produced in great profusion up the entire length of the many-branching stems, there are few plants more showy or serviceable. *C. pyramidalis*, better known as the Chimney *Campanula*, comes in later, and is altogether of a different habit, the flower-stems being more erect and much taller, towering from 3 ft. to 5 ft. or more when the plants are strong and healthy and well fed with liquid manure. The colours of these two latter are pale blue and white, but in *C. Medium calycanthera* there is a wider range, as they comprise almost every shade, so that a packet of mixed seed will afford great variety. These should be sown at once under a hand-glass or cold frame, and when up and large enough to handle, planted out in rich deep soil on a warm, sunny border, from whence they can be lifted and potted, and then kept in a cool house or pit to bring them slowly on.

*LANTANAS* are exceedingly showy, free-flowering plants that come in admirably during the summer and continue on till quite late in the year. The trusses of these are generally borne in pairs and have much the appearance both in size and shape of *Verbenas*, but are richer in colour, and the habit of

the plants more bushy and woody. For greenhouse or conservatory decoration they are of great value; the only drawback they have is that they are anything but pleasant when touched or rubbed against, as they then exhale a rather disagreeable odour. Seed should be sown at once, and the plants pushed on in heat in full sunshine, as it makes the growth short-jointed and hard, and induces an abundance of flowers.

*MARTYNTIA FRAGRANS* is a very desirable annual for pot culture, affording large, tubular, Gloxinia-like flowers that are beautifully spotted and marked, and altogether of a very showy character. Being somewhat tender, it is necessary to raise it in heat and grow it on in the same temperature till it comes into bloom.

*PETUNIAS*.—Of the many plants that may be raised from seed and got up to a flowering state in a very short space of time none are more generally useful than the double *Petunias*, which, grown in pots in an open position outdoors, flower with the greatest freedom when brought under glass, and, being so rich and varied in colour, do much in making a house gay and attractive. Even the single forms are deserving of cultivation for the same purpose, so beautiful are their markings, many of them being marbled and striped in the most fantastic manner possible. By keeping them plunged in a sunny spot they can be brought in as required and a constant succession kept up till Christmas or later. If sown at once they may be had in flower two months hence, but if large plants are required the way is to nip out the points of the shoots and give them a shift into larger pots. The soil that suits them best is a good fibry loam, in which they should be potted firmly and not overdrained.

*RHODANTHE MANGLESII* is one of the prettiest of all annuals for decorative purposes indoors, and forms charming, neat little groups for small stands or vases, where, when laden with lovely pink, satiny-looking flowers, it is highly effective. The newer variety, named *Prince Bismarck*, is likewise very desirable, being more double and having the merit of lasting longer in bloom. To get them to bloom early in spring, at which time they are most valued, seed should be sown in August, and the plants wintered on light, airy shelves near the glass in a warm house where the temperature does not fall much below 50°. Raised now, they will flower in two months or so hence, and last till late in the autumn. *Rhodanthes* delight in rich vegetable soil, and should be potted in a mixture of at least half leaf-mould or peat and loam in well-drained pots. Any cold frame, where they can be shut up early, will suit them at this season if not kept far from the glass.

*SCIZANTHUS PAPILIONACEUS* and *RETUSUS* form beautiful pot plants that bloom profusely and are highly ornamental, especially the first-named, the flowers of which bear a close resemblance to butterflies, so rich are their markings. Both varieties are very bushy in their habit, and range from 1 ft. to 2 ft. high, so that they are well adapted for small houses and for window decoration, where, from their gay and varied colours, they are sure to be highly appreciated. Sown in autumn, they are easily wintered in an ordinary greenhouse, and then come in at a time when flowers are scarce. To have fine specimens they should be grown three in a pot, and if of mixed colours, as they are almost sure to be, they will be all the more interesting and make a better display. *Scizanthuses* are plants of very easy culture, and will do well in almost any kind of soil that is open and free.

For the roof of the house where a few strings or fine wires can be strained *Ipomœas* may be grown, but these must have a sunny position assigned them to induce them to flower freely. *Tropæolums*, too, of the better class form showy roof-climbers, and when restricted for root-room, as they are in pots, are exceedingly floriferous, so much so, indeed, as to be rarely out of bloom. It will thus be seen that by the expenditure of a few shillings for seed, a greenhouse may be filled with gay flowers to take the place of *Camellias*, *Azaleas*, *Epacrises*, and such like when they are set out-of-doors to ripen their growth. Besides those enumerated, there are many others that might be mentioned, but these are the principal and best. S. D.

## CLEAN FLOWER-POTS.

GARDENERS seldom disregard the importance of clean flower-pots for all kinds of plant culture. Amateurs scarcely devote enough attention to it, and therefore are troubled with many failures in consequence. Plants are soon affected with disease if grown in dirty pots; the soil soon becomes waterlogged, sour, and Mossy, and the minute rootlets refuse to absorb moisture and nutriment from the walls in which they are imprisoned. Two things lead to deterioration in pots—one, and perhaps the chief, the excessive porosity and softness of the material of which they are made; and the other, defective drainage. Pots made of good hard clay, even in size, with sides of moderate thickness, if a trifle dearer, are at least much the cheapest in the end, as these neither get dirty so soon, nor are so brittle, and therefore last much longer. Plants should never be allowed to remain too long in the same pots; frequent shifts both promote health and free root action; and the cleaner and sweeter the pots, the more active will that root action be. Even apart from this, however, dirty pots are unsightly in any amateur's plant house; and if it be not desirable at all times to shift a plant into a clean pot, much good may be done by clearing out the Moss on the surface of the soil and re-dressing it with fresh material, and also by giving the outsides of the pots a good scrubbing in water. In large gardens, where many thousands of pots are employed in plant culture during the year, wet days are usually made available for washing them, and it is by no means unpleasant work during the dog days. In winter, however, several hours of pot-washing in very cold water is neither pleasant, nor does it lead to good results. A boiler or copper should be at all times available for pot-washing; and where a large quantity has to be got through, an abundant supply of hot soft water should be at hand. Two tubs should be used—one full of tepid water, in which the pots are placed to soak an hour or two before being washed, and the other full of hot water, in which the actual cleansing is done. If the pots be but moderately dirty, a wisp of bast or hay will make an efficient cleanser; but for very dirty, Mossy pots, a brush is the most effective. A semi-scalding in hot, strong soda-water not only assists in the rapid removal of dirt, but destroys parasitical Mosses and causes the pots to dry off at once; they are thus ready for stacking as fast as they are washed. Amateur plant growers should cleanse their pots in the same way, but of course there are fewer to clean; nevertheless, it is well to wash thoroughly, and get each pot as clear from dirt as possible. No person having any regard to the requirements of plant life would ever use pots that have not been properly cleansed. A. D.

## NOTES AND QUESTIONS ON THE INDOOR GARDEN.

*Croton Prince of Wales*.—Among all the many *Crotons* which have been introduced of late years, this is one of the handsomest and most distinct. It is of a free branching habit. The leaves are pendulous, arching, and slightly twisted; some of them present a complete spiral form, ending in a small, pointed elongation of the midrib, the edges of the leaves being always beautifully undulated. The colour of the leaf is almost entirely pale yellow, margined and mottled with bright carmine, with occasional irregular blotches of light green. The midrib and petiole are bright magenta. It was introduced by Mr. Williams from the South Sea Islands, and cannot fail to be largely grown for dinner-table and other decorative purposes.—S.

*Primula amœna*.—The hardness and easy culture, as well as the effective character of this *Primula*, render it one of the most valuable of dwarf decorative spring-flowering plants. In order to have vigorous plants of it in full bloom it is necessary to divide the old shoots every year into small pieces, and pot them in equal parts of torfy-loam and leaf-mould, adding plenty of road sand, or in lieu of leaf-mould well decayed cow manure may be used with advantage. Good drainage, plenty of water, air and light are also essential. Thus managed, healthy, vigorous plants, well furnished with Fern-like leaves, and a profusion of showy rose-coloured blossoms, may be obtained. A number of plants placed 5 in. or 6 in. apart in deep pans make also effective objects for placing in vases or on pedestals. As a basket plant too this *Primula* may be used with advantage.—C. S.

*Selaginella Brownii*.—This is one of the most useful of the Club Mosses; it is dwarf and compact in habit, of a hardy character, and, either in pots, pans, or planted out, it is worthy of culture in every garden.—S.

*Amaryllis virginialis*.—To this beautiful genus of plants this is the most valuable addition which has been made for many years past, and of all the forms lately sent out by Mr. Williams this will, without doubt, become the most popular. It is a very free-blooming variety, the scape usually bearing four or five large flowers, which are thick in substance, of fine form, and of the purest whiteness. It is without doubt the most chaste and beautiful of the family.—C.

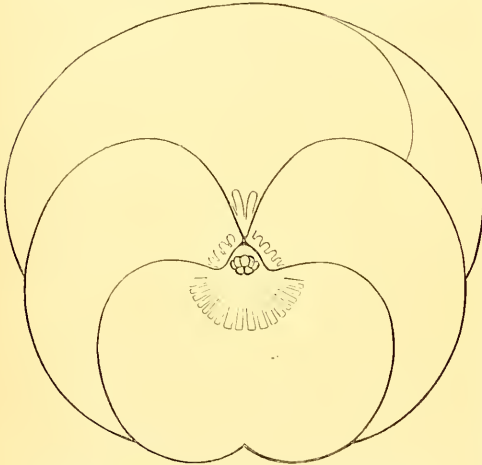

## PLATE CXXVI.

## PANSIES.

Drawn by H. NOEL HUMPHREYS.

HAVING recently given (see p. 122) a plate of Fancy Pansies, we now supplement it by one of what are called show varieties. In this, as in the case of the Fancy Pansies, we have deliberately preferred to draw Pansies gathered in an unfavourable season, and in size inferior to what is sometimes seen just as they arrived, rather than encourage the gross misrepresentation of these plants, which has been the rule for many years in floricultural periodicals. This misrepresentation sometimes arose from certain rules, as to size and form, being communicated to the unfortunate artist who had to draw the flowers. The kind of hybrid, arising from the attempt to draw the ideal from the flowers, resulted in such abortions as that of which we give an outline on this page—the said outline being more pleasing than the plate from which it was traced. The right course in the matter is to ask artists to paint what they see, and, indeed, those who respect themselves or their art will not do otherwise.

It will be seen that six of the flowers are termed selfs, that is,

Tracing of Pansy Lady Ross, as figured in a horticultural periodical.

they are entirely composed of one colour, excepting the blotch. For many years there were only dark, white, and yellow selfs, but now primrose, blue, and crimson have been added; and we hope that enterprising raisers will not rest satisfied until they have succeeded in introducing still other shades, as there can be no doubt that the strong aversion shown by competitors to admitting innovations of any kind into their competition stands has been one of the principal reasons why this class has never become so popular as the Fancies. The other classes in this section are white and yellow grounds, and in them the object aimed at is to have the belting on the upper and under petals of a uniform shade of colour. The colours in the Show Pansy are not so startling as in the Fancy, but the former has been known longest to cultivators, and many of the old florists still consider this group the only one worthy of being classed amongst florists' flowers; and there are enthusiastic florists who will continue to grow and improve them in spite of the strong feeling which has sprung up in favour of their more showy and attractive companions. There can be little doubt that numbers have been deterred from growing Pansies of all classes by the elaborate and expensive treatment recommended by some authorities; whereas it is a fact that many are killed by over-feeding and the introduction

of fresh soil, containing the eggs of grub and wireworm, which would have succeeded perfectly in any ordinary garden soil. No one need fail in the propagation of Pansies, as cuttings taken off during the summer and autumn months will root freely in any shaded border or frame, and in the south will stand quite well without any covering, while even in the cold northern districts they require only the slightest protection in winter. If planted out in autumn they will flower much earlier and stronger than when allowed to remain in the cutting beds till spring. The raising of Show Pansies from seed has long been a favourite amusement of many gardeners and amateurs, but it is principally to a few nurserymen that florists have to look for a supply of new varieties likely to surpass those already in existence. The treatment of the Show Pansy for competition may be given in a few words. The ground, which ought to be open and airy, should have been deeply cultivated and well manured for the previous crop. The plants may be arranged in beds, according to taste, from 9 in. to 12 in. apart each way, planted deeply in the soil, and watered occasionally during the summer, as they may require it. A mulching of old manure from a spent hotbed will strengthen the plants, and considerably increase the size and beauty of the blooms.

The Pansies from which our plate was drawn were supplied by Messrs. Dicksons & Co., of Waterloo Place, Edinburgh, who have good collections of these flowers. E.

## BOTANICAL GARDEN AT ATHENS.

From Patras I proceeded up the Gulf of Corinth to Corinth, thence across the isthmus to Kalamaki. *Pinus halepensis* was abundant on the surrounding hills; a very handsome red Poppy, with large central black blotches, and *Lagurus ovatus* were observed by the roadside, and *Urtica pilulifera* on the sandy shore. From Kalamaki a small steamer, passing between the islands of Ægina and Salamis, brought me in four hours to the busy port of the Piræus, within a short drive of Athens, which I reached soon after mid-day. Here I had the advantage of becoming acquainted with Professor Orphanides, whose little botanical garden was replete with interest. He possesses one of the finest collections in existence of Orange and Lemon trees, including between seventy and eighty varieties; also a fine series of the bulbous plants of Greece. The Athens Botanical Garden is unsatisfactory as regards its general order and aspect, and appears starved for want of funds. The collection of Greek bulbs is, however, very complete; they are mostly grown in pots. There is also a fine series of trees and shrubs, which, however, might have been easily arranged with a better intention to picturesque effect. *Biota orientalis*, *Pinus halepensis*, *Cupressus pyramidalis*, *C. horizontalis*, *C. Tournefortii*, *Schinus molle*, and very large Poplars are its only main features. Very little forethought seems to have been exercised in the arrangement of the general collection as regards ultimate size and grouping. It includes *Cratogeomys japonica*, *Juniperus atica*, a very pretty species with the habit of *Picea picea*; *Casuarina quadrivalvis*, *Ephedra distachya*, *Gleditchia triacanthos* and *G. ferax*, *Anthyllus Barba-Jovis*, a curious small shrub; *Ebenus cretica*, *Photinia arbutifolia* and *P. serrulata*, the latter a very striking plant, with white cymes of flowers and bright crimson leaves; *Maclura aurantiaca*, a singular spiny tree, allied to the Mulberry, with large warty fruit as large as an Orange; *Coccolus laurifolius*; *Ulmus euberosa*, and *U. excolta*; *Melanthus minor*, with scarlet and green flowers; *Rhus viminalis*, *Olea chrysophylla*, with small yellow fruit; *Solanum auriculatum*, a striking shrub with bright green soft foliage; *Viburnum suspensum* in fruit, &c. There is also a fair collection of herbaceous and economic plants, including several beds of Saffron, which I notice because they bore a profusion of ripe capsules and perfect seed, a fact of very rare occurrence with *Crocus sativus*; indeed, Major Trevor Clarke assures me that the cultivated Saffron has heretofore not been known to produce seed. I could not distinctly ascertain whether these beds were from a wild or cultivated source, but I believe from the latter.—G. MAW, in "Transactions of the Botanical Society of Edinburgh."

Singular Chinese Teapot.—In a recent number of THE GARDEN (see Vol. XII., p. 591) you gave a figure of a Japanese vase made of a gourd. There is in the museum at Kew a singular Chinese earthenware teapot, the body of which represents a Pomegranate, the handle a Fruit of *Trapa bicornis*, the spout a piece of jointed Bamboo, and the feet a Walnut, a Nalumbum head, and, I think, a Lichen.—J. R. J.

PANSIES AS THEY ARE.

- 4. George White (primrose self.)
- 5. Bluestone (blue self.)
- 6. Janey Anderson (white self.)
- 7. Jane Grieve (white ground.)
- 8. Robert Black (dark self.)

## THE LATE JOHN KEYNES, OF SALISBURY.

SINCE John Keynes, of Salisbury, was taken from us and from his flowers, we have thought it would be well to publish a well-engraved portrait of him, with some account of his work. This it is difficult to narrate in exact chronological order, owing to the absence of data. His friend Mr. Dodds, for many years gardener at Fisherton, informed us that he first became acquainted with Mr. Keynes in 1830, and that he was then a successful cultivator of the Auricula, Polyanthus, Pink, Carnation, Picotee, and Ranunculus. Of Tulips he for several years had a good bed; but the force of his youthful floricultural ardour went out toward the Carnation and the Pink; he grew them well, and was a most successful exhibitor. Mr. Dodds states that not long since Mr. Keynes showed him the first prize he took for Pinks, for he had treasured it up as a memento of precious value. About 1831-32 Mr. Dodds had one of the best collections of Dahlias in the west of England. In 1833 Mr. Keynes, in conjunction with Mr. Dodds, began to grow seedling Dahlias, and the first Salisbury Dahlia Show took place about 1836. At this exhibition Messrs. Brown, of Slough (who were once the occupiers of Mr. Turner's nursery there) exhibited a then fine Dahlia named *Desdemona*; and Mr. Squibb, a florist at Salisbury at that time, had the Hon. Mrs. Harris, which Mr. Dodds describes as "a wonderful flower; we have never had anything like it in colour since." The first seedling Dahlia Mr. Keynes raised was named *Ovid*, very similar to a recent variety of Mr. Turner's bearing the same name. This he sold to Mr. Mountjoy, then a well-known florist residing at Ealing, for the sum of £60. At that time Mr. Keynes had no conveniences for propagating his Dahlias, and he used to let Mr. Squibb have his roots to propagate from for a sufficient number of plants at planting-out time. This arrangement went on for two or three years, when it was discontinued by Mr. Squibb, as Mr. Keynes bargained to have the best plants. That circumstance made Mr. Keynes a nurseryman; for, as he remarked, "If I am compelled to put up glass in which to propagate my Dahlias, I must sell plants to pay for it." Mr. Dodds thinks it was in 1836-37 that he commenced business, growing only Dahlias at that time. In 1838 Mr. Dodds' whilom foreman, Hincxman, became Mr. Keynes' propagator, and remained with him till 1856, when the present foreman of the Castle Street Nursery, John Wyatt, who was also foreman under Mr. Dodds, became foreman to Mr. Keynes, and remained with him till his death. Mr. Keynes was always much attached to Wyatt, and was a liberal and kind master to him. Mr. Dodds thinks it was about 1838-39 that Mr. Keynes published his first catalogue. In 1842 he sent out Prince of Wales Dahlia, a seedling raised by Mr. Dodds, and up to 1862 he sent out Mr. Dodds' seedlings, which he continued to do until the time when the latter left Salisbury; and it need scarcely be stated Mr. Dodds has raised some sterling flowers. It was in 1845 or thereabout that Mr. Keynes became the proprietor of the Castle Street Nurseries, previously known as Moody's Tree Nursery. At that time he had little or no practical knowledge of the nursery business, but his energy and perseverance conquered all difficulties, and he soon became a good man of business. He possessed the great advantage of having been well trained in business habits from an early age

in a very lucrative brush manufactory, which he continued to manage for many years after he became a nurseryman. Business to him was a source of great pleasure; he had great confidence in himself, and his industry in business was astonishing; he kept all his books, it is said, up to a short time before his death. Mr. Dodds remarks: "In all the years in which I knew him—and they were close upon fifty—I never found him unemployed." In 1841 Mr. Keynes was afflicted with a severe attack of rheumatic fever; and, to show the energy and perseverance of the man, in the autumn of that year, at his own risk and with very little help, excepting what Mr. Dodds could give him, he arranged and held a Dahlia show at Stonehenge, in the middle of Salisbury Plain. "I shall never forget it," states Mr. Dodds; "there were over 10,000 people present; it was a complete success;" and yet Mr. Keynes could only move about with the aid of two sticks. After the dinner he was lifted on to the table to make a speech. It was a remarkable gathering of the then leading Dahlia cultivators—George Glenny, Edward Spary, Charles Turner, Widnal, and many others were present, and the proceedings were most enthusiastic. Mr. Keynes, Mr. Dodds, and Mr.

John Keynes, of Salisbury.

Turner (then with Messrs. Brown, of Slough) each won a ten-guinea tankard." Those were days of keen enjoyment and intense excitement among Dahlia growers. Eventually the Dahlia declined in cultivation, and then Mr. Keynes took up the culture of the Rose. How successful he was both as a grower and exhibitor is well known; and within a few weeks of his death he gave orders for another new house to be built to grow Tea Roses in, and at the time of his death it was nearly completed. Carnations and Picotees were at one time largely grown by Mr. Keynes, and he used to take high honours at Carnation shows twenty years or so ago. At one time he raised and named a number of promising seedlings. Up to the year of his death he used to send out new Dahlias, mainly of his own raising. He was particularly fortunate with the fancy class, and did more than any florist of his time to improve them. In 1877, the year of his death, he exhibited in London and else-

where something like sixteen new Dahlias of his own raising of great beauty and attractiveness, and of these Bessie Ford, Charles Wyatt, Henry Bond, and Louisa Neate bid fair to take high rank among exhibition varieties. He was also a most successful cultivator of pot Vines, and did a large trade in them. How can we better estimate his character than in the words of his friend Mr. Dodds?—"I never knew a man more beloved and respected than my late friend; he was so straightforward as a man of business, and so steadfast in his friendship. He was very shrewd, and his advice was much sought after. In his native city he was honoured and respected by all classes. There was no show or affectation in his bearing; indeed, he hated everything of the sort. He was of the plainest manly, and always doing good in some way. Very many in Salisbury will miss him sadly. He was most liberal in his many acts of real charity, and they were numerous, but all performed in a quiet and unostentatious manner." In November, 1876, he was elected Mayor of Salisbury, and served his year of office to the satisfaction of his fellow-townsmen, having previously been a member of the Municipal Council of the city for a long period. D.

## THE KITCHEN GARDEN.

### HOW TO LENGTHEN THE ASPARAGUS SEASON.

ASPARAGUS, although indigenous to Britain, does not, when cultivated, enjoy an immunity from the blighting effects of unfavourable springs, such as we have of late years experienced. During the present season at this place on several occasions all the heads about to break through the surface of the soil have been entirely destroyed by frosts; and although the soil is naturally of a light and warm character, conducive to the early development of most kinds of crops, the middle of the present month of April has, nevertheless, passed before a single head of Asparagus has been fit to cut in the open air. Notwithstanding this, however, an almost daily supply of this delicious vegetable has been kept up since soon after Christmas until the time just mentioned, and this has of course been accomplished by culture under glass; not, however, by the old method of taking up the plants and forcing them in a hotbed, a plan which it is seldom advisable to pursue, unless in cases in which Asparagus may be desired in the very depth of winter, or where old, worn-out beds are being done away with. A bed has for many years been in existence here, surrounded by a low brick wall, having under it a flow and return hot-water pipe, and when forcing is about to commence the bed is covered with glass lights, the ends of which rest upon the retaining walls; and, if the weather be severe, the glass is covered with mats or dry litter, and is always uncovered when a ray of sunshine is likely to be secured. By keeping the pipes moderately warm for about three weeks, the heads generally begin to appear, and the plants, being now fairly excited, it is seldom found necessary to continue the use of fire-heat further than occasionally warming the water in the pipes, so as to keep up, to some extent, the temperature of the soil. It is generally considered that the Asparagus cut from this bed is quite equal, if not superior, in quality to any that is cut here in the open ground at a much later period of the season. The formation of this bed was, of course, in the first instance attended with some expense, which it has, nevertheless, amply repaid. Still, all intending cultivators may not feel inclined to incur this outlay, and a similar result may be secured by following some plan similar to what I will endeavour to describe. Let a situation be selected, and proceed as follows:—Throw out two trenches, each 3 ft. wide, and leave a space of 4½ ft. between them, so that from the centre of one trench to that of the other will be just 6 ft. The trenches should be 2½ ft. deep, and in the central part of each a 4-in. hot-water pipe should be laid; these must be connected to a small boiler, which should be placed at one end of the trenches equi-distant from each. The trenches should, if possible, run north and south, and may, of course, be of any desired length; and, if the ground has an inclination, the furnace and boiler should be placed at the lower end. Should the land, however, be perfectly level, it will then be necessary, in order to facilitate the circulation of the hot water, to give the flow pipe a gradual rise of a few inches towards the further end, where it must be connected with the return pipe in the bottom of the other trench, and here, also, the expansion cistern should be placed. The hot water, it will be seen, is made to flow up the centre of one trench and to return to the boiler by the other. The pipes should be surrounded and covered with small stones, flints, or brickbats; and upon these should be placed turves with the Grassy side downwards, or a layer of littersy manure, so as to prevent as far as possible the superincumbent soil from filling the interstices between the flints or brickbats. The trenches should now be filled in with highly-enriched soil to within 6 in. of the level of the surrounding ground, and in the central part of the trenches, at a distance of 2½ ft. from each other, the plants should be carefully planted, so that they will occupy the central part of a shallow trench in order that water, liquid, or other manures can be readily supplied to them at any time, while the somewhat wide space between can be occupied for at least the two first seasons with such low-growing crops as Spinach or Lettuces. One-year-old Asparagus plants are always to be preferred to older ones, and during the two first seasons no attempt should be made to force them, neither should any of the heads be cut; but, on the contrary, the

plants should have every attention as regards watering during dry weather, and once or twice during the season they should have a liberal dressing of salt, while, to prevent the shoots from being broken off close to the surface of the soil by wind or by their own weight, a few Pea sticks should be thinly inserted in the soil on each side of the plants. This will be found to prove an effectual support to them. When the plants have thus had liberal and careful treatment during two summers, they will generally be found strong enough to undergo gentle forcing during the following spring, and when this is about to commence a short stick or peg should be inserted in the centre of each stool, and the shallow trench in which the plants are growing should now be levelled in. The pegs will still indicate the exact position of the stools, over each of which an ordinary hand-glass should be placed. The hand-glass should not be less than 2 ft. across, and those with movable tops will be found most convenient. The entire surface of the soil around the hand-glass should now be well mulched with littersy manure 1 ft. or not less than 6 in. in thickness, while a portion of light littersy material should be in readiness with which to cover the hand-glasses during frost. This should, however, always be removed during sunshine, in order to secure any benefit likely to be obtained from solar influence, while the water in the pipes should be kept moderately warm. This may, of course, be easily ascertained by moving the top or lid of the expansion cistern, which should be placed so as to afford facility for such examinations. If gentle forcing be commenced, say, about the middle of January, Asparagus will generally be fit to cut during the second week of February; but it is unadvisable to force rapidly during the first season. As the same plants may, in this way, be forced for an indefinite number of years, it will be found that they gradually acquire a more early habit, and that they are more easily started into growth after they have become accustomed, as it were, to the process of forcing.

As soon as Asparagus becomes sufficiently plentiful in the open air the cutting of that under hand-glasses should be discontinued. The glasses should be removed, and as the object of levelling in the trench is in order that the necessary length of white or blanched stalk may be obtained, the loose soil may be again withdrawn into the space between the lines, when the plants will again occupy a shallow trench, and should at once have a dressing of salt, which should, as the season becomes more advanced, be followed by a thorough soaking of liquid manure and a heavy mulching of good stable or pig manure. As the stalks grow they should be secured against injury or breakage by a few stakes, as has already been recommended. Treated thus, the plants will be again in proper condition for forcing on the return of the following spring; and this forcing may be annually repeated for many years without the health of the plants suffering in any perceptible degree. A result, to some extent approaching what has just been described, may be obtained by the use of fermenting material without hot-water pipes. This method of forcing, however, demands more labour, is attended by considerable litter, and the results are less certain and satisfactory. The lines and the plants should be the same distance from each other, as has been recommended, and the hand-glasses should also be used in the same manner. Between the lines a trench should be thrown out about 3 ft. wide and nearly to a like depth, removing the soil to the ends of the rows, or to any other convenient spot, as it may again be required to fill up the trenches. When forcing is about to commence, the trenches must be filled with warm fermenting manure. This will require to be frequently turned, and must occasionally have fresh material added to it, so as to maintain the necessary degree of warmth to stimulate the roots of the plants into activity. P. GRIEVE.

*Culford, Bury St. Edmunds.*

**Parsley Canker.**—This season Parsley has failed in many places from the only disease that affects it at all seriously, and that is canker at the root. When this disease attacks the plants it generally kills them. Its appearance is soon detected, as the leaves turn yellow and the plants droop, and finally perish. If they be pulled up they will be found to be nearly eaten away at the root. Sometimes it attacks

the plants almost as soon as they come through the ground, when it always does most mischief; but it appears at all stages. What causes it has not been exactly ascertained, but it is known that generous culture is one of the surest preventives, though, at the same time, Parsley does not like an over-rich soil. It, however, likes a change of ground. One of the worst cases of canker which I ever saw happened on ground on which an excellent crop of Parsley had been grown the previous year; the first year it was good, and the second a complete failure. The soil which Parsley prefers is a rather light, deep, and fairly rich one. The seed should be sown pretty early for the first crop, as it takes a long time to come up—three weeks nearly, even in warm weather. It is a good plan to dig and sow at the same time, and I always prefer to cover the seed by hand with some light rich compost. In this way it is sooner induced to make good growth. The plant is not very particular as to situation, but I imagine that canker is always worst in dry and sunny exposures and in poor thin soils; a partially shaded situation suits it best. The winter crop, which should be sown in May or June, according as the locality is late or early, is the most important, and the plants should be well thinned out, so as to encourage good foliage and a hardy constitution. Some say that Parsley is best left unthinned, but that is a mistake, in the case of winter crops at least. When thick in the row and retarded the leaves are soft, and perish as soon as severe frost sets in.—CHEF.

### CUCUMBER CULTURE IN FRAMES.

As many frames will soon be empty through bedding and other plants being turned out of them, one of the most profitable crops with which they can be re-filled is Cucumbers. Early in spring or late in autumn Cucumbers in frames are often difficult to manage properly, but throughout May, June, July, August, and September they may be very successfully cultivated in cold frames with very little trouble or expense. Early in spring Cucumbers require a large hotbed on which to start them freely into growth, but for the next five months only a very small hotbed is necessary for that purpose, just sufficient to start the plants at first being enough. This is a great advantage, because in many instances material to make hotbeds cannot be had in quantity, and in many cases it is difficult to procure at all. There are, however, few places in which some material or other cannot be had with which to form a hotbed. It is well understood that leaves and long litter manure make the best hotbeds, but where these cannot be had, a hotbed that will grow Cucumbers well may be made without them. As lawns and patches of Grass in front of houses now require cutting, the Grass that comes off them forms an excellent material for the purpose. Old leaves of any description, tan, sawdust, shavings, and, indeed, anything of that description, may be mixed with the Grass, and if not mixed in greater quantity than the Grass itself, it will heat satisfactorily. All the material put together should be thrown into a heap for a week, and turned every other day during that time. In forming the bed, if the frame be 4 ft. by 6 ft., make it 7 ft. by 5 ft. From 1 ft. to 18 in. at the front, and 2 ft. or 30 in. at the back, is a good height, and the material must be trodden down very firmly. When finished, the frame may be set on the top, and the material may be packed around the frame about 3 in. up from the bottom, but a lining up to the top is not necessary at first. When matters have been brought to this point, the Cucumber plants will be required. These cannot be raised without a little bottom-heat, and where no other means of supplying this is at hand but the newly-made bed, the best way is to sow the seed where the plant has to grow, and thus save potting and shifting. Cucumbers delight in a rich soil. A mixture of half cow manure and half good loam is a good compost in which to grow them. When the loam is heavy a little leaf-soil should be added. Where none of these are obtainable, they will grow even in road scrapings, especially when there is a good quantity of horse manure amongst them. In sowing the seed on the hotbed only a little mound of this material should be made at first. Five or six shovelfuls will be enough, but it must be beaten firmly, and be allowed to lie on the top of the bed for a day or two before putting in the seed. Two or three seeds should be put in each mound, if the frame be a large one, but a one-light frame should only have one mound in the centre of the light. A hole 2 in. deep may be made with the finger and the seed inserted. No water is required, as a rule,

until after the plant shows itself; great care must, however, be taken that no snails are harbouring about the frame, or they will soon destroy the plants. At first only sufficient ventilation is required to let the steam escape, but when rough leaves are formed, more attention must be paid to giving air, in order to prevent the leaves from scorching. As soon as the roots are seen peeping through the mounds, more soil and manure must be added to them; a depth of 3 in. is enough to add at one time. Cold soil is liable to check the tender roots; therefore when a fresh dressing has been applied, water immediately with water heated to 85°, and whenever it is necessary to water at any time only use water heated to that temperature.

Supposing the bed to be made and everything done as described the first week in May, abundance of Cucumbers may be secured by the latter end of June. Making the bed a month earlier would, of course, produce an earlier crop. Should the plants show signs of flagging from want of heat, a lining about 18 in. thick can be put round the frame, consisting of the same materials as those of which the bed was originally made. One plant is sufficient for one light; but, where there are three, all of them should be pretty well advanced in growth before any of them are pulled out, and then the worst should be taken. When it is seen that one plant will not fill the light, two should be left. The leading shoot of one should go to the back; that of the other to the front. Stop them when they touch the frame. Laterals must be well kept in by pinching them frequently. As soon as the largest leaves show signs of becoming yellow they should be taken off in order to give room to the young ones, young shoots and young leaves being always preferable to old ones. The plants must not be allowed to bear too many fruits at one time, especially at first. After they have been bearing for some weeks liquid manure should be liberally applied to keep up the strength of the plants. Careful watering at the root keeps red spider and other insects better in check than anything else. Admitting plenty of air on one hot day, and neglecting to give any another, soon ruins them, and so does giving abundance of water at one time and allowing them to become dust-dry afterwards.

Where there are any other means of raising the young plants, the seeds may be sown singly in 3-in. pots three weeks or a month previous to making up the hotbed. By plunging the pot in a bottom-heat of 65°, the seed will soon begin to germinate. When the bed is made up, a mound of soil must be put in the centre of the sash, and the plant must be turned into this out of the pot. Last year we cut 300 Telegraph Cucumbers from a two-light frame 6 ft. by 8 ft. The young plants were raised in pots, planted out in April, fruited in May, and were thrown away in August, as we had plenty of younger plants in other frames. None of the fruit was shorter than 15 in., many of them 20 in., and some of them 2½ in. They were treated exactly as above described. No particular temperature was adhered to, this being entirely regulated by the weather. Telegraph, Lion House Improved, and Volunteer are three excellent sorts for frame culture. CAMBRIAN.

### FRENCH COOKS AND HOME PRODUCE.

THERE is no greater tyrant in a gentleman's establishment than a French cook, for which particular reason many ladies and gentlemen will not engage their services if they think it will comport with their dignity to dispense with them. That is about the whole secret of the matter, for it is now well known that English cooks—women as well as men—are hardly, if at all, inferior to French cooks, as is demonstrated in many an establishment. But French cooks are popular, and there is no class of servants who can sell their services on such advantageous terms. They take liberties with their employers (as shall be explained) in a manner and to an extent which, in the case of any other domestic, would not be tolerated. As a nobleman remarked to his agent not long ago: "They come here to spoil the Gentles; but, you see, we cannot do well without them; and they sulk if they have not their own way." This remark was made in reference to a discussion as to whether the cook should use the produce of the home farm instead of buying his goods from the dearest market, from which he, however, derived his perquisite in the shape of discount. There are honourable exceptions, no doubt; but few French cooks will use the produce of the home establishment if they can help it. The bacon and the mutton are either too fat or too lean, geese, turkeys,

and fowls generally are the same, and even butter and eggs, the latter fresh laid, are inferior to what Monsieur can buy from the market perhaps fifty or a hundred miles away. This is no exaggerated picture. I have in my eye more than either one or two establishments to which this description applies exactly. I could name one good-natured nobleman who has paid his French cooks just what they asked, and who has had half-a-dozen or more during the last twenty years, but who has never yet succeeded in pleasing any of them with the produce of his own farm, which he naturally desires to use. No one cook has he ever had who has not been asked to use the mutton, bacon, fowls, butter, and eggs from the farm, and no one cook has he ever had who could make these things do, and the consequence is that he has always been reduced in the end to the necessity of selling his own farm produce at wholesale prices in the market while his cook buys at the highest retail prices. I can imagine someone asking why are such things permitted; but those who know anything about a gentleman's house well understand how that happens. He would do the same with the garden produce, as I happen to know, but the gardener is generally capable of looking after the cook and spoiling his excuses, ingenious though they may be. One thing, however, puzzles both employers and gardeners, and that is, that when the establishment moves to London, where, as a rule, company only dine and never stays and, consequently, fewer people to supply, the garden cannot keep up the supply, though what did in the country is supplied in town by hamper twice or three times a week on a lavish scale. I could name some well-known establishments that spend hundreds of pounds every London season in Covent Garden, though the proprietors' own gardens were sufficient almost to supply a small town with fruit and vegetables, quantities of which are sent to their London houses about every other day.

The duty of a cook, or any other servant similarly situated, is to try and make the home produce go as far as possible, and it is a lamentable thing if gentlemen cannot make their servants conform to such reasonable conditions. The chances are, of course, that Monsieur may decline to engage with a lady or gentlemen who stipulates that he must exert the skill he is supposed to possess, and for which he is so well paid for exercising, in order to make the home produce available for home use; but, if he does, then the plan is to let him go. I am aware of the difficulties that would beset the experiment of the kind—the cook can, of course, "spoil the broth" and throw the blame on the materials he is obliged to use, but they can be counteracted in that direction as well. I knew of one French cook who could never serve up a home-grown fowl as it ought to be, but when he was permitted to buy them from the poulterer himself they were excellent. When, however, it came out that Mr. Cook had fallen into a trap, laid for him by the farm steward, who had served the poulterer with the very birds with which he had supplied the cook, there was a collapse. We have known another cured by a candid offer from the employer to the cook to submit the question of the quality of the home produce to arbitration—the cooking for the experiment to be done by a third and impartial person.

AN OLD GARDENER.

#### DISEASES OF MUSHROOMS.

The "molle" or "mole," as it is called by the French growers, attacks the Mushroom very vigorously, making great progress in a very short time. The Mushroom, when attacked by this disease, loses its shape, falls upon the stem, and seems to form one spongy mass with it cut off at the top, and full of granular matter. The skin which covers this shapeless cottony mass is pure white at first, but speedily changes to a yellowish-brown as it rots away. It emits a disgusting odour, and the inside becomes filled with brown threads, sure signs of decomposition. Sometimes the edges of the cap turn upwards, instead of downwards, and the gills become united into a spongy mass, which sticks to the edges of the cap. At other times the decaying mass exudes a quantity of reddish liquid. As soon as the Mushrooms attacked by this disease come into contact with the air they turn brown, and exhale an odour resembling that of putrefying meat. A diseased Mushroom, in its first stage of growth, presented at the base of the stem the appearance of being composed of a network of filaments, the spongy nature of which soon reveals the evil. The skin was still white, as was also the inside of the tissues. The smell was not yet that of putrefaction; but as soon as the Mushroom became exposed to the air the rusty-brown colour soon appeared, and decomposition set in with great rapidity. When the disease only shows itself in a few isolated cases, the Mushrooms so attacked must be promptly removed both from the

beds and the quarry. The first loss is the smallest, for if the disease be allowed to spread, the whole of the bad and diseased spawn must be removed and carried away to a distance. The causes of the disease are but little known, the opinions of practical Mushroom growers being divided on the matter. Some attribute it to lack of cleanliness when the beds are being broken up. Others say that the remains of old manure mixed with the soil of the quarry generate dampness underneath the beds, and as this moisture cannot be absorbed by the stone surface beneath, it gives rise to the "molle." According to this hypothesis, the remedy would be to thoroughly scratch the surface of the ground on which the bed rests if it rests on the bare earth. If, however, it is built on a layer of broken stones, this layer must be thoroughly broken up with a pickaxe, the whole of the surface, to the depth of 6 in., being removed and replaced by entirely new materials. Others say that the "molle" is the consequence of the beds being too much crowded together in a confined space. According to them, the vapours produced by the fermentation of the manure become condensed on the walls, and, mixing with the natural infiltrations, fall upon the beds, and bring about the decomposition of the manure. They base their opinions upon the fact that it is in the summer, when the heat is great, that the "molle" makes its appearance in quarries with low roofs, and that it is much more rare in quarries which have high roofs and strong currents of air circulating through them. But in any case, no matter what may be the cause, the remedy is the same, that is to say, to thoroughly break up and remove the surface upon which the beds are built. I may add that, out of the large number of quarries that I have visited, I have never once met the "molle" in a new quarry; while M. Gérard, after having sustained heavy losses, was obliged to abandon a number of coal-pits in which he had for a long time successfully carried on the Paris system of Mushroom growing. From this fact, we may draw the conclusion that, in the long run, the air of those quarries which are badly ventilated becomes so charged with miasmatic or fungoid germs, that they must be abandoned. The only remedy yet found has been to renew the beds and their foundations. It is just possible that strong disinfectants would remove the evil, but this remains to be proved.

M. LACHAUME.

#### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Cauliflowers Buttoned.**—Nursing the plants too much during winter to withstand exposure in spring without a check, in my opinion, causes buttoning. Last October half our autumn-sown Cauliflowers were transferred from the open border to a frame, the other half being left in the bed where the seed was sown to take their chance during winter. Those in the frame were never protected, unless when actually necessary. Still, many of the plants soon became tall and tender, and about the end of March, when they were being hardened off, or left open altogether, previous to planting, many of them buttoned. I have seen this happen before in frames and under hand-lights, and I think that the cause of buttoning is very evident, especially as not one of our plants which stood in the open border all winter had buttoned. Throughout the winter not one of them lost a single leaf, and every one of them remained as dwarf and healthy as an autumn-sown Cabbage plant. They were planted out about the middle of March, and their leaves will soon meet in the rows, although they are growing 1 ft. 8 in. apart. In fact, those that were wintered out have all along proved so satisfactory that we have given away all our protected plants, as we do not want them.—CAMBRIAN.

**Scarlet Runners in Trenches.**—This is the best season for sowing a full crop of this prolific and useful vegetable. We usually follow late Broccoli with Runner Beans, and if the crop be not cleared off, a trench is dug out between every third row of Broccoli (6 ft. apart) and well manured, and the seed is sown thinly. After Broccoli are all cleared off, a good heavy dressing of partly decayed manure is applied all over the ground, the result being that drought is but little felt.—J. GROOM, Henham.

**Petunia Death to the Potato Bug.**—More than a dozen of our friends have written to us stating that Petunia plants—any 20 of our ordinary cultivated kinds—will drive away or kill the Potato bugs, as they know by actual test, while it hardly seems natural, there must be some truth in the matter. Wm. Gavin, of Prince Arthur's Landing, Ont., writes:—"We have no Potato bugs in this locality, owing, I believe, to a wild sort of Petunia which grows in uncultivated places. It is believed that this plant is very poisonous to the bugs, they being very fond of it."—Vicks' Magazine."

## PROPAGATING.

**DRACÆNAS.**—There are two ways of increasing *Dracænas*—the first (fig. 1) by cutting off the top, which should be put in single pots in equal parts of peat, loam, and sand, well mixed together; give a good watering and plunge the pots up to their rims in a good brisk bottom-heat in the propagating frame, keeping them close for two or three weeks, and giving a slight sprinkle of water overhead every morning. They take about two months to get well rooted, when air may be gradually given them, and they may be turned out of the frame. Keep them, however, on a gentle bottom-heat for a week or two, when they can be potted and placed in another part of the stove, and will soon make fine plants. By cutting up the stems, as shown in fig. 2, and putting the pieces in well-drained pots, or pans just covering them about  $\frac{1}{2}$  in. with fine soil over the tops, they will soon begin to grow if plunged in a good bottom-heat, and

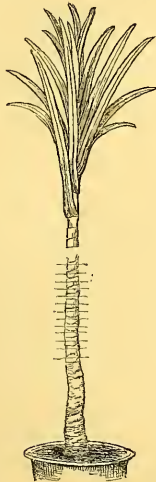

Fig. 1.

Fig. 2.

treated in the same manner as the tops. Sometimes they push forth numerous growths according to the strength of the stems; these all root, and each one when cut away will make a plant. The old bottom will push out several shoots, which may also be used for cuttings. *Dracænas* may be increased all the year round, but the best months are May and June.—H. H.

**Cinerarias from Cuttings.**—Although propagating *Cinerarias* from cuttings is by many considered a troublesome and needless way of obtaining plants, yet such a method has its advantages. The magnificent plants shown by Mr. James, of Isleworth, every spring are grown from cuttings, stopped once during the winter, potted into 5-in. or 8-in. pots, nearly tied out, allowed abundance of air, and from soon after Christmas till the end of March large spreading specimens covered with large bright blossoms are the result. Such plants are much dwarfier and more effective than plants raised from seed, and, moreover, they are much more suitable for supplying cut flowers.—C. S.

**Sympathy and Antipathy.**—It is well known that certain objects excite an instant horror in the minds of persons to whom they are antipathetic, and this in a manner quite distinct from the affectionation of fright. Some remarkable instances of real sympathy and antipathy are collected by Milingen in his book on "Mind and Matter." Amatus Lusitanus relates the case of a monk who fainted when he beheld a Rose, and never quitted his cell while this flower was blooming. Orfila (a less questionable authority) gives the account of the painter Vincent, who was seized with violent vertigo and swooned when there were Roses in the room. Volpi relates the history of an officer who was thrown into convulsions and lost his senses in consequence of Pink's being shut up with him in his chamber. Zimmerman tells of a lady who could not endure the feeling of silk and satin, and who shuddered when touching the velvety skin of a Peach. Effects of this kind are, in the majority of instances, purely physical; in some cases, however, the imagination is first affected.—The Daisy."

## GARDEN BOTANY.

(Continued from p. 395.)

**SHAPE AND CONSISTENCE OF THE STEM.**—The trunks and branches of trees and shrubs are usually round (terete), and afford very few distinctive characters; but in some classes of plants ordinal, generic, and even specific distinctions are afforded by the shape, &c., of the stem. The *Cactaceæ*, for instance, have, with few exceptions, thick, fleshy stems (see p. 393), and the leaves are represented by minute scales. Species of *Cactaceæ* are characterised by the shape of the stem, as spherical, columnar, fluted, angular, terete, flattened, and a variety of other forms. Some of the African and Canary Island *Euphorbias* have fleshy, Cactus-like stems, and the curious South African *Stapelias* are of the same character. Grasses, most of which are useful plants, differ among other things from the almost useless Sedges, which they closely resemble in outward appearance, in having usually cylindrical stems, hollow between the joints, whilst it is characteristic of Sedges to have angular, solid stems. The trunks of dicotyledonous trees diminish in size upwards, and the hardest wood is in the centre; monocotyledonous stems, on the contrary, are nearly of the same diameter at the top as at the base, and the wood is densest near the circumference. These differences arise from diverse modes of growth of these two great classes of plants, which are explained elsewhere. Many other characters in the shape and consistence of the stem might be pointed out, but it is unnecessary, as few special terms are in use to designate them.

**SIZE AND LENGTH OF THE STEM.**—In some plants we find the stem reduced to a small, disk-like body, on which the leaves are crowded, and the stems of some of the gigantic Conifere of North America rise to a height of 200 ft. and 300 ft., and even more. The tallest trees hitherto measured are some of the Australian Gum Trees (*Eucalyptus collosa*, *E. amygdalinus*, &c.), which sometimes attain the enormous height of nearly 500 ft. Baron Mueller mentions one which was 295 ft. up to the first branch, and more than 40 ft. in girth at the base. In size of trunk the Baobob trees surpass all others, but they are not proportionately lofty. The African Baobob has been found with a trunk 90 ft. in circumference, and the largest girth of the Australian Baobob on record is 85 ft. The length and diameter of stems depend, of course, so much upon soil, situation, and climate, that size is only a secondary character, and can only be approximately given, except for individual plants.

**PSEUDO-BULBS.**—The thickened perennial stems characteristic of many of the epiphytcal *Orchids* are called pseudo-bulbs, or false bulbs. They are to all intents and purposes stems, but the distinctive appellation is justified by the fact that important specific characters are afforded by their diverse forms. Occasionally the branches of a stem are so modified, as to resemble leaves, as in the Butcher's Broom (see p. 396). Each of these leaf-like branches springs from the axil of a minute leaf, and the flowers are borne on the centre, as the figure shows. This shrub is the only woody monocotyledon native of this country, and its stems, although woody and persistent, make all their growth in one season. *Xylophylla latifolia* is a dycotyledonous shrub, with leaf-like branches, bearing flowers on their margins. It is in cultivation in this country.

**SURFACE OF THE STEM.**—The surface of herbaceous stems is hairy or bristly, clothed with chaffy scales or prickles, or quite smooth and naked, &c. The bark of shrubs and trees is smooth, as in the Beech tree, deeply furrowed and corrugated, as in the Oak, peels off (deciduous), as in the Plane, armed with prickles, as in Brambles and Roses, and presents a variety of other characters.

**MODIFICATIONS OF BRANCHES.**—In the paragraph on the shape of stems, the leaf-like branches of *Ruscus* and *Xylophylla* are mentioned. Some of the branches of the Blackthorn, &c., are short, and terminate in sharp points. These are called spines, to distinguish them from prickles, which have their origin in the bark, whilst true spines proceed, like other branches, from the wood beneath the bark. Some writers regard the tendrils of the Grape Vine, Virginian Creeper, &c., as arrested branches modified for a certain purpose.

**FUNCTION OF THE STEM.**—Generally speaking, the stem possesses no special function of its own, and is simply the axis upon which active organs are seated. It is the channel through which the liquid food, absorbed by the roots, passes to the leaves. In some plants it fulfils the functions of the leaves when the latter are absent, and is then usually of a green colour.

#### The Appendages of the Stem.

The stem of a seedling plant, as we have seen, develops from a bud, called the plumule, which is formed at one end of the embryo; in dicotyledons, between two seed leaves or cotyledons. As the stem is pushed forth it remains simple, as in most Palms, or in course of time it ramifies very much, as in the Oak; and as stems or branches elongate, they bear at intervals, sometimes very short, leaves of various kinds. It has already been pointed out that perfect plants are often developed not only from seed, but also from small fragments of root, stem, or leaf. Knowing this, we are in a measure prepared to find that it is impossible, generally speaking, to exactly define the different organs borne by the stem (and branches), that is to say, in the same manner that the members of an animal may be defined. The bodies borne by the stem, though sufficiently distinct in most instances, sometimes pass gradually from one into the other, so that it is impossible to say where one leaves off and the other begins; and, as is shown below, the ordinary leaf form often replaces other organs. In fact, some or all of the parts of a flower often develop as green leaves. Such being the case, it is usual to speak of the organs borne by the stem as appendages, which present various modifications according to the function they perform, and which receive their designations from their function or purpose. Briefly, it may be stated that all kinds of leaves and all parts of flowers are of the same origin, and develop alike from a primarily indistinguishable organ or outgrowth of the stem. By the same rule the entire plant is said to consist of an axis and its appendages; the axis may be simple, or bear secondary, ternary, or a greater number of lateral axes. All modifications of the stem come under the general designation of caulome, and leaves, whether scale-leaves, foliage-leaves, or floral-leaves are termed phylloles in contradistinction.

**BUDS.**—All elongations of branches and stems, and the production of leaves and flowers, originate from buds, and there is no essential difference in the properties of an embryo bud (plumule) and other buds. But two kinds of bud may be distinguished, namely, flower-buds and leaf-buds. Already in the autumn the difference between the two is easily seen, and thus it is possible to say whether the Apple trees and Plum trees, &c., will flower profusely the following spring. The flower-buds are much thicker and less pointed than the leaf-buds. Buds, then, are either undeveloped, barren branches or flowering branches. Flower-buds usually develop one or more leaves as well as the flowers. The fact that a single bud will grow into a plant having all the properties of the parent is made use of in propagating rare varieties, and varieties of delicate species on plants of a more vigorous species. Occasionally a badly selected bud will produce a flower at once when it grows out, but there are always two or three leaf-buds below it, which, under favourable circumstances, will subsequently grow into branches.

**SEED BUDS (EMBRYO BUDS) DO NOT INVARIABLY REPRODUCE PLANTS IN THE LIKENESS OF THE PARENT.**—Seeds give birth to individuals of the same species, and in some cases they may be depended upon to reproduce a variety, distinguished from other varieties of the same species by the colour or size of its flowers, or some other character. But the variety must be what is termed "fixed." If it be wished to propagate a certain variety of Rose, Potato, or Pelargonium, &c., it can only be done with certainty from buds of the stem, that is, either single buds, or cuttings, or tubers bearing buds. A seed-bud (embryo) is the result of sexual impregnation or confluence, and, consequently, may combine the characters of dissimilar parents.

**POSITION OF BUDS.**—The normal position of buds is at the tips of the branches (terminal), or on the sides (lateral). The latter are commonly axillary, that is, in the angle formed by the upper side of the base of a leaf with the branch; but flower-

buds are sometimes extra-axillary. Should the vicissitudes in the life of a plant, or part of a plant, seem to require it to ensure its perpetuation, buds are formed on other parts of branches, or even on leaves or roots, as described above. All such buds are termed adventitious, because they appear at uncertain places. Adventitious buds are produced much more freely by some plants than others. Bryophyllum (fig. 124) is an example of a plant whose leaves under certain conditions give birth to numerous buds. Some trees, if cut down to the

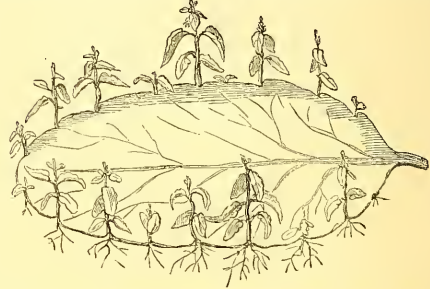

Fig. 124.—Leaf of *Bryophyllum calycinum*, with buds produced on its margin.

main trunk, will soon develop numerous branches where the section is made, as many species of Willow (fig. 125), Poplars, &c., but a Fir or Horse Chestnut treated in this way soon dies. The position of flower-buds has to be considered in pruning fruit trees and flowering shrubs, especially whether they are terminal or axillary. Again, the characteristic branching of different trees depends upon which and how many of the buds grow into branches each season. In the Horse Chestnut we have a tree of formal habit with few stout branches, from the fact that growth is mainly confined to the ends of the branches. Altogether, the growth of the Horse Chestnut is

Fig. 125.—Pollard Willow.

singular. The flowers, it will be remembered, are borne at the extremities of the branches, and the leaves are borne in opposite pairs. If each season the buds from both leaves of the last pair grew into branches, there would be a succession of forked branchlets gradually more and more crowded; but what almost invariably takes place is this, the branches of the inflorescence die back eventually close to the last pair of leaves, and only one of the two lateral buds is developed, and, being so near the end, it soon appears to be terminal. It often happens, however, that a shoot does not bear flowers, in which case it presents at the end of the season's growth a true terminal bud and two lateral ones immediately below the terminal one, having their origin in the axils of the uppermost pair of leaves. The succeeding ramifications depend upon the growing out of all three, or only one of these buds, and the production or not of flowers.

**BUDS SOMETIMES REPLACED BY DECIDUOUS BODIES.**—Normal buds are persistent, and grow into branches on the plant where they are formed, or remain dormant; but in some plants, in the place of normal buds, bodies resembling very small bulbs are formed. In course of time they fall off, and eventually grow into independent plants. The Pile-wort (*Ranunculus Ficaria*—fig. 127) is a common instance in which this provision

Fig. 126.—*Ranunculus Ficaria*, having bulbils in the axils of the upper leaves instead of true buds.

for the propagation of a plant occurs. It may, in this plant, at least, be regarded as a provision for the propagation of the species, because the plant seldom, if ever, ripens seed in this country.

**NAKED BUDS AND SCALY BUDS.**—The buds of most of our native trees and shrubs are covered with scale-like leaves, which are thrown off when growth commences in spring. They are very conspicuous in the Horse Chestnut, and of a very beautiful texture in many of the Fir trees. In the former they are covered with a glutinous exudation, and the inside in many other trees is clothed with a soft down, which may serve as a protection from cold and other adverse influences. The buds of herbaceous plants are protected in a different way, but they have usually no deciduous scales.

**TRANSITION FROM BUD-SCALES TO PERFECT LEAVES.**—Although the bud-scales of the Horse Chestnut, for example, are very different from the summer leaves, they are regarded by botanists as modifications of the same organ with a different function. This view is supported by the fact that in some plants, the Red Currant, for instance (fig. 130), there is a gradual transition from the outer scales to the perfect leaves, in which there are intermediate stages, which might be called highly developed scales or imperfectly developed leaves.

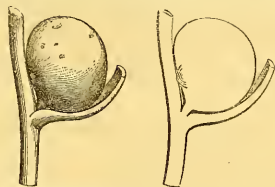

Fig. 127.—Bulbil of *Ranunculus Ficaria* (enlarged). Fig. 128.—Longitudinal section of bulbil.

**ACTIVE BUDS.**—Generally speaking, buds, especially in woody plants, are formed one season, and do not shoot until the following; but in many annual plants, for instance, they suffer no check. There is no pause between their formation and evolution; growth is continuous. Such buds are termed active buds, in contradistinction to the dormant buds of other plants, which await the warmth of spring before they unfold.

**LATENT BUDS.**—It is necessary to distinguish between dormant buds and latent buds. As a general rule, a bud is more

or less fully formed in the axil of each leaf of all perennial woody plants; but, under ordinary circumstances, not all of them shoot the following spring. As spring approaches, those nearest the tips of the branches begin to swell, and finally burst and grow out into leafy branchlets or inflorescences, or both. From the lower part of the previous year's shoots, from the rudimentary buds formed in the axils of the leaves farthest from the tips, no growth is made; but these rudimentary buds possess, nevertheless, a certain amount of latent vitality, varying, for different plants, in intensity and durability, as well as in capability of being stimulated into activity. Buds which shoot the season following their formation in the ordinary course of Nature are simply quiescent in obedience to the general repose in vegetation, and may be termed dormant; whilst those which would grow out only subject to extra-

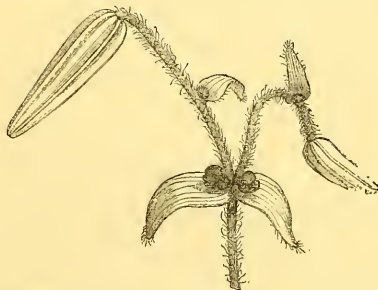

Fig. 129.—*Lilium bulbiferum*, with bulbils in the axils of the leaves and bracts.

ordinary conditions are latent buds. Sometimes the lowermost buds of a previous year's shoot give birth to two or three small leaves, and the successively higher ones to increasingly more vigorous growth; or, according to the nature of the plant, flowers and fruit may be developed from some of the lower buds. But as almost every genus, or even, we might say, species, presents peculiarities of its own in growth, it is obvious that we can only generalise here. It will, however, be clear to all that before a person can prune trees and shrubs properly or advantageously, he must have some acquaintance with their normal mode of growth and their vital powers when subjected to pruning. The reasons for pruning are not always the same, it is true, but the importance of doing it properly

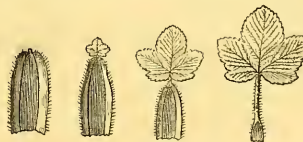

Fig. 130.—Bud-scales from the same bud of Red Currant, showing gradual transition to perfect leaves.

remains much the same, although some plants will bear almost any amount of cutting without injury to their lives. By removing the tips of shoots, buds which would otherwise remain latent, or, at most, make a feeble shoot, are stimulated into vigorous growth. Latent buds, again, must not be confounded with adventitious buds, mentioned above, which are produced on almost any part of some plants possessing great vital energy.

**LEAVES (Foliage Leaves).**—By foliage leaves, as has already been pointed out, is meant those parts of a plant popularly known as leaves, as distinguished from floral leaves, or the leaves forming the flowers. Now, although the phyllome, as it is termed in vegetable morphology, is the basis alike of foliage leaves and floral leaves, it is necessary, in descriptive botany, to retain not only such popular distinctive terms as leaf, petal, &c., but also to use a great many other names not

commonly employed, to designate certain parts, besides distinguishing a large number of the principal types of modification exhibited by each and all of these parts. In botanical descriptions of plants the term "leaf" is employed in almost exactly the same sense as everyone quite unacquainted with botany understands it; but this is not the case, as we shall explain in the proper place, with regard to the use of the term petal, &c. Botanists, however, make one noteworthy exception to the ordinary conception of a leaf which has already been mentioned, but it may be well to repeat it here. The so-called leaves of Ferns, whatever their consistence, configuration, dimensions, and other characteristics, are called fronds. On the other hand, the same terms are used to denote their different shapes, cutting, &c., as for the modifications of true leaves. In some botanical and horticultural publications, especially Continental ones, the leaves of Palms and Cycads are called fronds, whereby

length. Besides the name of Carob Beans, these pods are also commonly called Locust pods, or St. John's Bread, names by which they are well known in this country.

## THE LIBRARY.

### BIBLE PLANTS AND THEIR HISTORY.\*

WORKS on the natural history of the Bible are by no means scarce. The subject has been attacked from all points by authors of various attainments with varied success. A perfect knowledge of the Hebrew and Greek languages, together with a thorough knowledge of plants, are qualifications not possessed by many, but, nevertheless, very necessary for a clear and unprejudiced elucidation of biblical botany; and,

The Carob Bean Tree (*Ceratonia Siliqua*).

the term loses its special distinctive significance. It is applied to the leaf-like expansions of Ferns because they differ from ordinary leaves, inasmuch as they bear the reproductive organs on some part of their surface.

W. B. HEMSLEY.

**The Carob Bean Tree** (*Ceratonia Siliqua*) is a Leguminous tree, wild and extensively cultivated in the countries bordering on the Mediterranean. It has a fleshy fruit, which is imported into this country in considerable quantities for cattle feeding. The seed was the original carat of jewellers, and in many other respects it is an interesting tree. It forms a branching tree about 30 ft. in height, having wood of a pretty pinkish hue. Its pinnate leaves are composed of two or three pairs of oval blunt-topped leaflets, of a leathery texture, and a shining dark-green colour. The flowers are in small red racemes, and are succeeded by flat pods, from 6 in. to 1 ft. in

even with this knowledge, great discrimination is needed to be able to fix a certain Hebrew name to a distinct plant, in consequence of the same name being often applied to different plants, and *vice versa*. The same thing occurs throughout the vegetable kingdom generally, and in modern times often causes no little confusion. Mr. Smith's book has several advantages over those that have preceded it. First, it is very convenient as regards size; and next, the different plants are readily found under their popular or English heading, to which follows the Hebrew word. The author's knowledge of Bible plants, which, as he tells us in his preface, he has long studied, and, with one or two exceptions, were, before

\* "Bible Plants and Their History" with a Review of the Opinions of various writers regarding their Identification. By John Smith, A.L.S., ex-Curator Royal Botanic Gardens, Kew. With ten Lithographic Plates, by W. H. Fitch, F.L.S. London: Hardwick & Bogue.

his loss of sight, known to him in a living state, has enabled him to form some opinions which he has here left on record. We think he has done right not to overload a book of this kind with too many botanical terms. It is absolutely necessary that the Latin scientific name should be given in every case where it is possible, and this the author has done. The plan of the book will be best understood from the author's own words. He says:—"I deem it best to follow the original Bible classification of Grass, herbs, and trees; by so doing the allied modes of growth and products are brought together better than by either a scientific or alphabetical arrangement. Each subject is headed by its English and Hebrew names, followed by a quotation of the verse or verses in which it occurs in the Bible, the subject under consideration being printed in italics, in some cases being followed by its Hebrew name in parenthesis." The scientific names and the family to which each belongs, the native countries and the principal uses of the plants, both ancient and modern, are also given. The book is well got up, and will, we have no doubt, be in the hands of all who love plants for their own sake, as well as of those specially interested in their ancient history. It certainly deserves to rank as one of the best of Mr. Smith's many publications. It has evidently been a labour of love to him, and therefore is entitled to all respect. J. R. R.

**Poems of Places\*.**—This is the first part of a series of pickings and gleanings from the poets, a handy, well-printed, well-bound work, in two vols. of 500 pp. The scheme of the work is good, an alphabetical arrangement of all places found in poetry and song being given, and the poem appended, generally at full length, giving the author's name. A map of England and Wales, the countries to which the matter in these two volumes is limited, is inserted as a frontispiece to each volume, and contains only names of places, &c., celebrated by poets, and referred to in the book. The editor, the poet Longfellow, promises us more volumes of the same character dealing with other countries, till the "voyage round the world," described by Montgomery, "shall be brought to a safe and happy end."

**Artificial Manures†.**—This invaluable work on artificial manures (by Alfred Sibson, F.C.S.) tells us how to make, buy, value, and use them, and also gives us full information as to what kinds of cereals and root crops are most benefited by them. There is a useful chapter on the use of compound or special manures, in which cultivators are told how to make the mixtures themselves for all kinds of cereals and root crops; how to apply manures to the soil to the best advantage is also clearly pointed out. This is important, as when the fertilising elements are so placed in the soil as to allow of their exercising their full effects on the crop, that alone will often determine the practical superiority regarding two or more manures otherwise much alike. Mr. Sibson concludes with the advice that it is as bad policy to starve our soils, as it is our live stock.

**The "Maison Rustique des Dames‡."**—This is a work worthy of being known in England. The authoress enters fully into every detail connected with a household from a French point of view, and although there are some chapters which are not in harmony with English ideas or customs, still this fault is well counteracted by the useful hints and numerous receipts which could be carried out with advantage in every home. A good receipt given for cleaning decanters, or other crystal bottles, is as follows:—Place a few pieces of the Pellitory plant-leaves of Jerusalem Slicke, or Borage, in the bottle, then half fill it with cold water; shake it well, so as to thoroughly cleanse it, and afterwards rinse it with clean water. There are several receipts for taking fruit, and other stains out of linen; also for the starching of linen, so as to give the same brilliancy to it as French laundresses do. The receipts given for cooking vegetables and fish are particularly good, numbers of them are not to be found in any of our works on cookery. The authoress also gives receipts for several simple diætic quizes unknown in this country, and which would prove agreeable changes in our ordinary menus. There are also several seasonable menus for each month in the year, both for innocuous and dinners. The chapter on slight ailments, with prescriptions for their treatment without medical advice, and many useful ones for the immediate remedies necessary in cases of accidents, &c., will be found to be of great value in a country house when situated far from a town. The "Maison Rustique des Dames" contains also directions for gardening, the care and management of poultry, &c.; also full instructions for a dairy. It forms, in fact, a complete and useful manual.

## GARDENING FOR THE WEEK.

### Flower Garden.

ALTHOUGH our springs of late years have rendered early bedding out undesirable, it is not too early to decide how the garden shall be planted, and to make arrangements accordingly. What may be termed the massing system has had its day, and it is evident that something fresh must soon be introduced. We would have masses of colour in suitable situations, but we would have them subdued and tastefully toned down by means of foliage, so as to form a rich, quiet, harmonious whole. Even ribbons, if a mere repetition of the same plant *ad infinitum*, cease to charm; and the same holds good in the case of panelling and carpet-bedding, where gaudy colours are employed. The secret of gardening decoration does not consist in crowding hundreds or thousands of plants, however scarce or valuable, into a given space. No; it lies more in the judicious use of appropriate plants, and in so lighting them up by means of colour that each shall enhance the beauty of the other. For this purpose expensive materials are unnecessary; it is the arrangement rather than the plants individually which charms. One man with a handful of flowers from the hedges will often produce an exquisite bouquet, while another, with flowers however choice, may fail. Tasteful application of the material which may be at command is what is wanted. Spring-flowering plants, although now doing good service, will soon require to be removed to the reserve garden, the ground in which should be put in order to receive them; add to it a little thoroughly decomposed manure, leaf-soil, or peat, as the case may be. Before planting, and not requiring to be shaded, such plants as Arabis, Anemone, Arabis, Daisies, &c., allowing sufficient space between the plants for proper development without crowding. Bulbs must be removed in as perfect a manner as possible, being careful not to bruise the leaves in the operation; and on no account remove the flower-stems, as they greatly assist the maturation of the roots. Water freely and protect from sunshine for a few days with evergreen branches. Plant out spring-struck Hollyhocks, and divide and re-plant Neapolitan and late-flowering Violets. Centaureas should be planted in the beds in pots, as they grow more compactly, colour better, and are more manageable in winter.

**Auriculas.**—These being now in full beauty, some pains must be taken to retain the bloom for as long a period as possible. If the plants be behind a wall facing the north, the glass being not requiring to be shaded, except for a few hours in the afternoon. Air must be admitted freely by tilting the lights against the wind, and when the air is quite calm it is well to remove the lights altogether. In this position I find the flowers more liable to suffer from damp than from any other cause and unless the structure be heated, which ordinary frames are not, there is no other way by which the damp can be combated, except by careful attention to the ventilation. I find the flowers to remain in good condition for a long time in a span-roofed house running north and south. In our house there are ventilators at both sides and the top lights all move, so that if the wind be blowing either from the east or west, plenty of air can be admitted without any injury being caused by its blowing directly upon the plants. As the latter go out of flower remove the pips and seed-pods, unless it be intended to save seeds, but do not break the stalks over, in case the part that remains should rot down to the centre and kill the plants. If the pips only be removed, allowing the foot-stalks to remain, there is no danger, as the stalks wither off in a dry state, and they can be drawn out without injury. It is also a good plan to remove the plants from the blooming house as they go out of flower; it will not be necessary to shade, unless from very hot sunshine, and the plants may be freely exposed to the wind.

**Carnations and Picoetes.**—We have just gone over our stock of plants and sown the seed soil in the beds, at the same time picking out the weeds and removing any decaying leaves. The plants are still under the glass lights, from which we do not care to remove them as long as we can spare the lights, but they are wanted for another purpose, and very shortly the plants must be placed out-of-doors. Meantime the flower-stalks have grown considerably, and before the plants can be fully exposed it will be necessary to stake them. Plants in beds require looking after now; stir the soil, remove weeds, and press the plants if they seem loose gently into the ground.

**Gladioli.**—If, from bad weather or any other cause, the main collection of Gladioli has not been planted, it is still time to do so. If it be intended to grow good spikes for exhibition the bulbs must be planted in beds, and it is useless to make the attempt unless the soil is rich, but it must have been enriched, if possible, six months before the time of planting. Crude manure in contact with the bulbs, or even near them, is sure to cause mischief. Bulbs of the commoner sorts may be planted in Rose beds, amongst Rhododendrons, or in the herbaceous border. This is also a good time to sow seeds of Gladioli; they hybridise easily, and, if the best sorts be crossed, there is a certainty of at least 10 per cent. being as good as the parents. I sow in 7-in. pots, using good loam, a little leaf-mould, and rotten manure. I plunge the pots to the rim in a bedch in which there is a gentle bottom heat. The seeds will vegetate in a fortnight if the glass lights be kept rather close. As soon as the seedlings appear aboveground more air must be admitted, and as they gain strength and the weather becomes favourable the lights may be removed altogether. They must not suffer from want of water at the roots, and when the leaves turn yellow in autumn the small bulbs may be shaken out from the soil; they will vary in size from a small Pea to a Fibert, and nearly all of them will throw up a flower-spike the following season.

**Pansies.**—In order to have a few blooms of these early it is necessary to grow the plants in pots, and to give them the shelter of a frame. It is but seldom that the flowers can be had clean when the plants are out-of-doors, but the intervention of a glass light preserves them in all their purity. As in the case of Auriculas, I prefer having the frames behind a north wall; less light is in that case required, and the flowers can be enjoyed even during the brightest sunshine. The shoots should be pegged regularly over the surface of the pots, and when they take an upright position they must be tied to neat, regularly-placed sticks. After all that has been said about destroying slugs there is no better plan than to look over the frame at night and pick them up by hand, throwing them either into a pot containing a little salt or dry lime. I also like to see the colours of the flowers tastefully arranged; they vary much, and more so now when the fancy has had been so much improved in colour and colouring, and the forms are indispensable to the colour may be. The yellow, white, and dark selfs, and the various shades of white and yellow grounds form a varied group even without the fancy kinds. See that the plants are well supplied with water at the roots, but none overhead.

Pinks, Pansies, Carnations, Picotees, and other small-growing plants in beds out-of-doors must not be neglected; the soil should be stirred between the rows when the weather is favourable, and if the plants be loose press them into the ground with the fingers; remove withered leaves or any decaying portions; look for slugs and the leather-coat grub at night when they are feeding. J. DOUGLAS.

### Indoor Plant Department.

**Conservatories.**—In these the finer kinds of Rhododendrons are now in great beauty, and none more so than the Sikkim, waxy, crimson-flowered R. Thomsoni. Some which have started into growth, and are planted out, must be well supplied with water; all decaying flowers and seed-pods should also be removed from them, unless it be desired to save seed, and even in that case only a few heads should be left on each plant. A few days more flowering remove from the conservatory, Camellias, Azaleas, Myrtles, Aracarias, Eugenias, and similar plants put out in beds and borders are now growing freely, and consequently require extra attention in the way of watering. Keep up a succession of blooming plants from other houses and pits; many stove plants, indeed, may be transferred to the conservatory while in flower, and if they are placed in the warmest part of it, they will continue longer in beauty than if left in warm houses; after flowering, they should be replaced in their former quarters. Pot on plants of double Petunia, using light, sandy loam and well-decayed manure for the purpose. Plants in constant bloom, and in a cool position, and, used in that way, a strong, rich, moist soil and cool position suits them best. Lemon-scented Verbenas also make good conservatory plants, as do likewise well-grown and well-flowered Heliotropes.

**Cinerarias and Primulas.**—A little more Cineraria seed should now be sown to succeed the earliest batch; also Primula seed to furnish plants in bloom for the winter. Those who have not had much experience in raising Primulas from seed, frequently find a difficulty with them, as the seeds are very tender, and must only be very slightly covered. A good method is, after filling the seed-pans with finely-sifted soil, consisting of three-fourths loam and one of leaf-mould mixed with a little sand, and making the surface firm, to sow the seeds evenly, not using any covering of soil, but laying over the top a little chopped Sphagnum; a sheet of glass placed on the top will keep the soil sufficiently moist to cause the seed to vegetate. As soon as growth has commenced the Sphagnum must be removed, otherwise the young plants will become drawn; gradually expose them to the light.

**Pot Roses.**—During weather such as we had a short time ago, there is a little difficulty in managing Roses under glass. When the sun gets powerful, even if the wind be cold, to keep the heat reasonably down it becomes necessary to give air, which, if not admitted with great care, so as not to come in contact with the tender foliage, is certain to produce mildew. This the experienced eye soon detects by the slight curl and puckered appearance of the leaves, and when once detected there must be no delay in immediately dusting the affected plants with sulphur, first damping them with the syringe, and being particular that the powder reaches both upper and under surfaces of the leaves. Any delay in taking means to destroy mildew will result in the plants being seriously weakened for the ensuing year, as it spreads rapidly, and the vitality of the affected foliage is soon destroyed in a way that causes its prematurely falling off, and whatever loss of leaf occurs root action will be affected in like proportion. Where Roses are grown as roof climbers in greenhouses and conservatories, mildew is almost certain to attack them about this season, especially where the house is kept a little warm by means of fire-heat, so as that naturally suits the Roses into growth before there is enough light and sun to give vitality to the leaves, and a necessity for giving air to the other occupants of the house to a greater extent than the Roses like, will with them also have the effect of producing mildew; and being, as they are removed a considerable distance above the eye, unless closely examined, half the leaves may be destroyed before it is discovered.

**Rose Insects.**—Mild winters are invariably the precursors of springs in which insect pests are plentiful. Rose Maggots especially are more than usually abundant, particularly on Roses, the leaves and young shoots of which in their first stage are of a pale green colour. These they seem to attack in preference to such as have their young growth strongly tinged with brown or red. This pest seems to be proof in a great measure against any insecticide, although there are some washes that render

the shoots more distasteful to it than others, but when once it exists food it must and will have, and I have found no means of preserving the young buds, except pinching with the finger and thumb. Those who only grow a limited number of Roses in somewhat confined gardens will generally find their plants suffer more than those grown in quantities in open situations. As soon as ever the leaves are detected in any way disposed to curl, the grub should be at once sought for, or they quickly descend to the heart of the young shoot. A free and regular use of the syringe or garden engine with clean water will prevent the necessity for using so much insecticide, and although the continuous application of water costs more in labour, it is still the cheapest in the end.

**Red Spider on Roses.**—There are no plants in existence more liable to red spider than Roses, especially when grown up the rafters and on the roof. To cope with this there is nothing like a thorough washing with the syringe at least twice a week, or still better, with the garden engine, but the latter must not be used with such force as to injure the young leaves. The unavoidable wetting that this occasions, the plants underneath, many of which do not require it, is the frequent cause of Roses when employed as roof climbers not having sufficient water applied in this manner overhead, and it is the chief drawback to their being grown over other plants in this way, but when they are thus used there is no alternative but these continued washings, otherwise the miserable appearance that they invariably have through a great portion of the season makes them rather an eyesore than an ornament, and at the same time causes them to be the direct means of communicating red spider to every plant upon which it will exist grown underneath them.

**Disbudding Roses.**—The practice may not be general, but years ago it occurred to me that weak-growing varieties, which often make a number of shoots never strong enough to flower, and these in their turn too weak to produce flowering wood in the coming year, would be better for having such weak growth thinned out as soon as it began to push, thus concentrating the energies of the plants in the shoots retained, which thereby attain so much more strength and vigour than they otherwise would. This practice I have since followed with the best results, especially in the case of standards, where the heads become so much less crowded. If the work be judiciously done, proportionate to the strength of the plants, in the weakest growers confining the shoots to the fewest number, and with all carrying out the operation before the growths have attained any considerable length, and in this way robbing the plant, there will at the winter pruning be few shoots that will need removing altogether, the work being simply confined to the necessary shortening of the stronger ones retained. Not only has this a considerable influence in strengthening the shoots that are kept for the current season, but it equally increases the production of flowers. T. BAINES.

### Indoor Fruit Department.

**Pines.**—To make fruit swell off freely, now that the days are long and light, ought to be no difficulty. All that is required is method in the way of applying necessaries, such as tepid manure water, charging the atmosphere with ammonia and humidity, kindly airings occasionally, and never shading if well swelled, finely-coloured fruit is aimed at. Talk of shading, indeed, in our cloudy, dark, humid climate, where the general complaint always is, "what little sun we get! Oh, no; to deprive our fruits of that is against all natural reason and law. Succession plants in every stage of growth should now get their full share of heat, humidity, and air, with a warm humid atmosphere. Air freely night and day, in order to get strong robust plants.

**Vines.**—The Vines in the early houses will now be ripening, and some air left on at night will assist the colouring process. In the succession houses, when the Vines are in flower, good fire must be kept up, and plenty of air given when the weather permits. Thinning the berries as soon as they are fit, stopping the laterals at a leaf or two above the bunches, and removing all superfluous shoots will be the main points now to attend to in the latest Vineries.

**Peaches.**—The fruit in the earliest Peach house will now be at its second swelling, and the border must be examined to see that the moisture is sufficient, especially where the roots are all inside the house. An abundance of manure must be given when the fruit is colouring, and the water at the roots gradually discontinued. The trees in the late succession houses must be syringed every afternoon, and a moist atmosphere kept to prevent red spider from injuring the foliage. Soft water, at a temperature as high as that of the house, should be used for this purpose, for hard water stains the foliage and fruit with carbonate of lime, and spoils the bloom on the fruit when ripe. The thinning of the fruit must be attended to, and the quantity left on be regulated by the health of the trees. I find the best soil for Peaches is the heavy, heavy, heavy soil, such as can be procured, is the turfy loam from old pastures or the sides of roads, and no manure or compost of any kind added to it. Peach trees grown in such soils never make too gross or unhealthy wood, and they can always be kept up to the desired vigour by an addition of fresh soil to the roots and liquid manure during the time the fruit is swelling. All leaf-mould, old tan, or any compost or soil that is likely to bring funguses into Peach tree borders should be strictly avoided when making them, for when fungus fastens on the roots of Peach trees it soon renders them unhealthy and unproductive.

**Figs.**—As the first crop of fruit will be about ripening, the supply of water to the roots must be diminished, and only sufficient given to prevent the second crop from dropping. The trees grown on the walls after the winter coverings are removed will want their wood thinned and all

the shoots left nailed or tied in. Syringe with Tobacco water, or fumigate should the black aphid make its appearance on the trees.

**Orchard House Fruit Trees.**—In true orchard houses, that is, where no artificial heat is employed, the temperature must be ruled by the weather. It is advisable, therefore, on bright sunny days to close the lights early in the afternoon, to secure a higher temperature for the night. Disbudding and pinching all strong shoots, and thinning the fruit where set too thickly, will be the routine for this month. Green fly and red spider must be eradicated by fumigation or syringing with Tobacco water.

**Cucumbers and Melons.**—A steady bottom-heat will still want keeping up, and by attention to syringing and a moist atmosphere the foliage will appear clean and healthy. The fruits on both Melon and Cucumber plants often set too many at a time, and require thinning, so as not to weaken the plants too much. Put pieces of straw or glass under Melons grown in frames, to prevent the damp soil from rotting the young fruit. When Melons are grown in pits, and the plants trained on wires or trellises, the fruit when getting heavy must be supported on a square piece of wood with a piece of string fastened to each corner tied to the wires, leaving plenty of room for the fruit to swell to their full size. Plants in frames will still want covering up with mats at night, and continued till all danger from cold weather is over. The ridge Cucumbers sown in May will want planting out by the end of the month, and a suitable sown or bed made with hot manure will be preparing for their reception. Vegetable Marrows will likewise want planting out at the same time and in the same way.

**Strawberries.**—When the fruit is all gathered from forced Strawberries, the plants are often huddled together in some exposed corner and neglected; but such plants, if taken care of and planted out, will furnish fine fruiting plants next year in the open air. Some varieties likewise when planted out early produce a good crop in the autumn, notably Sir Charles Napier for one. If the ground cannot be got ready for planting them out till other crops come off, and the pots are wanted, the plants may be shaken out and packed closely together, with a little mould sprinkled amongst them, when they will be safe till planting time, if supplied with water in dry weather. Take advantage of favourable weather to clean between the plants, and to mulch them properly in good time. Where the soil is light and open, tread it firmly previous to mulching.

#### Kitchen Garden.

**Sowing Scarlet Runners, French Beans, Kale, Peas, &c.**—A full crop of Scarlet Runners should now be sown. It does not need any considerable length of time to elapse between this sowing already advised, as if the first happens to suffer through frost, those now planted will succeed them without any loss of time. At the same time put in some more dwarf Beans. Green Curled and Cot-tager's Kale should now be sown; these will come in for planting upon ground vacant from the early crops of Potatoes, Peas, &c. The Cot-tager's Kale should be grown in every garden, large or small; it is as far superior to any other variety of the Kale tribe as a spring Cauliflower is to a winter Broccoli. The seed is generally mixed, some of the plants coming up quite green, whilst others are tinged with purple. These latter only should be planted, as, both in flavour and texture, they are much superior to the green and but little inferior to Brussels Sprouts.

**Cauliflowers, Brussels Sprouts, and Broccoli.**—When spring-sown Cauliflowers and Brussels Sprouts have got about 3 in. high, they should be thinned out in the seed-beds so as to leave them 6 in. apart, or if transplanted into a nursery bed at the above size, it will be still better for the plants. The beds to receive them should consist of light, open soil, tolerably rich, and about 6 in. in depth, on a hard surface of ashes; so managed, they will attain size and vigour by the time they are required to be finally planted out, and can be moved to where they are to be grown even in dry weather, as they will be found with a far greater length of roots than when allowed to remain in the seed-bed until the time of planting. The final planting can also in this way be longer deferred, thereby giving additional time for the clearing of the ground they are to occupy, which, especially in small gardens, is an advantage worth considering. Another sowing of summer Cauliflower, as well as some more Veitch's Autumn Broccoli to succeed the first sowing, should be made; also more Broccoli to come in through the winter and spring. All seeds of this description should always be given an opening away from trees and walls, and from the influence of which these vegetables are often sown, the effect being that the plants always become drawn and weakly. When the ground is dry on the surface, any that has been cropped for some time should be hoed over as soon as there is an appearance of weeds; by thus disturbing them directly they vegetate, much less labour is involved in their destruction than if they be permitted to attain a considerable size. Use the implement freely, so as to stir the ground 2 in. or 3 in. deep, leaving the top as loose and open as possible, which will assist the growth of the crops.

**Preparing Ground for Spring-sown Cabbages, Brussels Sprouts, &c.**—Prepare the ground by digging it well, and by giving it a good dressing of manure for planting with the spring-sown Cabbages of the best sorts and Brussels Sprouts, as it is important to get these in as soon as they are planted as the plants are of the Brussels Sprouts which become larger, and the produce is proportionately greater—if planted early. The ground for Celery should also be prepared at the present time. It is much better to have this in readiness before the time

for planting has arrived, as it should be put in during showery weather if possible, which can be taken advantage of without delay when the ground has been made ready beforehand. The usual way of planting is in trenches, with from one to three rows in each. For the earliest, the three row system causes a saving of ground, but it is not suitable for withstanding the cold of winter, being more difficult to protect, more exposed to wet, and consequently more liable to rot. In wet heavy land, if winter crops, single rows are best; in such as is dry and tolerably light, two rows in a trench may be grown. Upon the number of rows it is intended to grow together will depend the width of the trenches. If three rows are planted the trench should be 4 ft. 6 in. in depth; for two rows a 3-ft. trench is necessary; and, for a single row, one of 2 ft. wide will suffice. The space between each trench will require to be proportionate to the width of the trench, so as to afford soil sufficient for earthing up, without coming so near the plants as to injure their roots—a mishap that often occurs in Celery growing. It is of importance to keep this in view, especially for the late or principal crop. Single rows, to stand through the winter, should have a space of 2½ ft. between each trench, or if 3 ft. all the better. For double rows allow 3½ ft. between them; where three rows are to be planted 4½ ft. will not be too much for them. In each case the trench should be formed by removing about 9 in. of the soil to the width required, and laying it up between each trench in the usual ridges; then put in each trench 6 in. of good manure—such as has become thoroughly rotten is by many considered indispensable, but that which is half rotten is equally good, provided it does not contain too much straw. For dry light land a mixture from the stables and cowshed is the best; the latter, being cooler, keeps the plants growing better in hot dry weather. Dig the manure in with 10 in. of the bottom soil of the trench, or a little more if there be sufficient depth without reaching that which is bad and unsuitable, and thoroughly incorporate the manure with the soil. Ground so prepared some time beforehand, so as to get soaked with rain, is in a much better condition for planting than if only made ready immediately before the plants are put in. The ridges between the trenches, especially where double rows of Celery are grown, will answer for a row of Lettuce, which will be cleared off before the Celery requires earthing up. For this purpose the middle of the ridges should be hollowed a little so as to hold the water which the Lettuce will need in dry weather; and here also manure water will be of use, as the ridges cannot well be manured for the Lettuce.

#### Extracts from my Diary.

**May 6.**—Sowing Dwarf Green Curled Savoys, and the following sorts of Broccoli—Walcheren, Veitch's Autumn Self-protecting, Carters' Champion, Wilcox Late White, Cattell's Elopiae, and Leamington. Potting on Cockscombs, Celosias, young Cyclamens, and *Deutzia gracilis*. Hoing up all weeds and suckers amongst Raspberries, leaving six canes to a root for training. Digging out a trench and getting it filled with fermenting material, and otherwise getting it ready for ridge Cucumbers and Vegetable Marrows.

**May 7.**—Sowing four rows of the following sorts of Peas:—Giant Emerald Marrow, Dr. McLean, Ne Plus Ultra, and Omega; also two rows of Johnson's Wonderful Longpod Bean. Giving all Broccoli, Turnip, and other seeds a dusting with wood-ashes early in the morning to keep down the fly. Digging all flower borders ready for planting. Turning over gravel walks in back shrubberies to give them a fresh appearance. Looking over all Strawberries that are well set, picking off the weak and late blossoms, and trying up Lettuces to blanch.

**May 8.**—Sowing Primulas, Cinerarias, Stocks, Asters, and *Humea elegans*. Potting on *Chrysanthems* and *Azaleas*. Pricking off Veitch's Autumn Self-protecting and Snow's Winter White Broccoli and Autumn Giant Cauliflower. Leaving on air night and day in early Vinery in which the Grapes are colouring. Clearing early Potato Frames, and getting them ready for Melons. Digging out more Celery trenches, and getting the manure into them.

**May 9.**—Sowing a little Borage for succession; also Leeks and Mustard and Cress. Potting Balsams and spring-struck Fuchsias. Stopping all young shoots on Fig trees. Staking and tying out old Fuchsias for exhibition. Planting out three trenches of Red and White Celery to come in about the middle of August. Hoing amongst Strawberries, and cutting up clump from litter as it comes from the stalks for mulching them. Looking over Peach trees on wall, picking off all curled leaves, and disbudbing them where required.

**May 10.**—Potting a batch of young Vines; also Melon plants. Staking and tying up *Mignonette* in pots. Planting French Beans in cold pit previously brought forward in pots. Looking over stoppings, tying, and staking, and thinning the Grapes where required. Thinning Turnips, Carrots, and Spinach. Renovating all linings round frames, looking over all Pines, and watering them where required.

**May 11.**—Planting out Sweet Basil into a rough frame for protection. Looking over Peas and house and tying in all young shoots; also Cucumbers and Melons, picking off all false blossoms, and stopping them where required. Hoing amongst all growing crops. Sticking three rows of Peas and getting them earthed up. Mowing and cleaning up the pleasure grounds, and rolling down all gravel and turf that require it.—W. G. P., Dorset.

Two children died in Lurgan on Tuesday week from poisoning, caused by eating wild Parsnips in the field.—"Irish Times."

## OPENING OF KEW GARDENS.

You have published a great many letters lately on the subject of Kew Gardens, most of which, while professing to bear only on the question of the early admission, are full of objections to the present management of the gardens. Will you kindly allow me space for this letter, in which I wish to state a few reasons for entirely disagreeing with the conclusions of your correspondents. Into the general question of the early opening of the gardens I do not wish to enter. I can quite understand that many residents of Kew and the neighbourhood would wish it, but I think the question may be safely left in the hands of the Director and the First Commissioner. On that point, however, I must remark that I should have been glad if your correspondents had not mixed up the question with arguments which savour more of personal pique than of sober argument. No controversy is ever served by personalities, and if Kew Gardens be the wretched establishment, horticulturally and scientifically, that some of your correspondents seem to wish to prove them to be, then it can be scarcely worth such an agitation to gain admission to them; and I hope, also, that we shall hear no more of the foolish argument that the people pay for them, *ergo* they have a right to use them as they please. That is merely the argument of the little street Arab whom Leech once drew for us in "Punch," who refused to cease gazing at the Life Guardsman on the plea that "We pays for you, and I may look at you." But the point on which I entirely join issue with your correspondents is in their complaints of the exclusiveness of Kew. This complaint is first applied to the non-opening of the gardens, and then is, by an easy process, extended to the general management. To this I answer—I have had experience of Kew for several years. I have had experience also of most of the botanic gardens in Great Britain, and of very many Continental gardens. From all of them I have received not only civility and kindness, but great liberality; but I can say, without any hesitation, that from none have I met with more uniform civility, kindness, and liberality than from Kew. And when I speak of liberality I do not mean only, or chiefly, in the distribution of plants, but especially in the readiness with which information is given on any subject, and with which ready access is granted to all parts of the institution. I have also some acquaintance with other of our public departments, and I say, without any hesitation, that I know of no public officer who tries so hard, not only to do the work of his office efficiently, but also to make it thoroughly popular, as Sir Joseph Hooker. I believe that if he thought that botanical science, or even a love of plants, would be extended by the early opening of the gardens he would be the first to advocate it. At present he believes that these objects are best served by retaining the morning hours for the work of the staff and for students, and admitting the public in the afternoon; and I feel very sure that he is a better judge of these matters than any who have not a share in the actual work. I know it may be said that from my being personally known at Kew I meet with more liberal treatment than others might expect. That may, to some extent, be true now; but I met with the same civility and attention when I made my first application as a complete stranger.—HENRY N. ELLACOMBE, *Bitton Vicarage*.

I have been intending to write to THE GARDEN for some time to protest against the way in which many of your correspondents are attempting to make use of the present agitation for the purpose of disparaging the management of Kew. From the style of argument which has been used, I am convinced that many of those writers are entirely ignorant of what is being and always has been done at Kew, and some of them are evidently inspired with an unaccountable feeling of hostility towards the Director. I find to-day that Mr. Ellacombe has already written to THE GARDEN to show how different is the real state of the case from what has been alleged. I need say no more, as his name and experience will have much more weight in the matter than my own. I may add, however, that having had personal experience of the botanic gardens of Paris, Berlin, Genoa, Turin, Palermo, Karlsruhe, Brussels, and Amsterdam, I can say without any wish to disparage those gardens that there is nothing like the same amount of civility, liberality, and intelligence displayed in any of them that there is at Kew; and, further, that I have found no public institution in Great Britain which seems to do as much for the convenience and assistance of the public as Kew does. Of course it is not in every way perfect; but who expects perfection in anything?—N. J. ELWES.

We publish willingly these notes from gentlemen so well known in the cause of garden progress—the more so as they do not use the untenable "arguments for the gardens being closed till the afternoon." We, however, while making known the courtesies met with by our correspondents, and, no doubt, by many others having similar tastes, may remind them that Mr. T. Baines and other able horticulturists whose names we are not

at liberty to mention here, have written to us of failure even to obtain admission to the gardens before the afternoon. Our correspondents will also remember that few of the general public have had that personal acquaintanceship with the officials which ensures such kindness as they acknowledge. A public garden can only be fairly judged in relation to the public in every degree. The rigid rules that have hitherto been in use at Kew have naturally led to irritation of feeling and to questions as to the nature of the horticultural work done at Kew which claimed an exclusiveness for the pursuit of the work, long departed from in the case of other public gardens. We believe all this feeling would subside if the gardens were opened when the flowers open—in the morning—and should advise the Director and First Commissioner to make an experimental trial for a few weeks. They would find that only quiet people would trouble them—people whose presence would simply make the vast solitudes of the gardens a little more animated and picturesque. We believe there are, wholly apart from personalities to which our correspondents allude, good reasons for opening the gardens throughout the day, and here-with subjoin a few of them lest they should be forgotten in the heat of argument.

We take no interest in the subject from the point of view of the holiday-maker, who seems to us to be treated liberally, but from the point of view of the vast number of people, horticulturists and others, who care for gardens, trees, and flowers. Numbers of persons come from our colonies and from America to whom a visit to Kew is important, and we speak from experience when we say that the plans of such people are very often deranged and their time wasted by the rules which exist at Kew. To horticulturists who come from distant parts of the country the same thing happens. Kew is a very large place, which cannot be seen in an afternoon, and these men are often forced either to lose more time than they need do, or not to see the gardens as they ought. The gardens are open at one o'clock, which happens to be either the luncheon or the dinner hour of most English people; and, therefore, they may be said to be practically closed for an hour or so later. In the short winter days this amounts to virtually closing the gardens altogether. Throughout the whole of the winter and spring the most agreeable time to visit Kew would be the bright morning and noon. In summer, too, many people would be charmed to go in the early morning, if allowed to do so. When only one visit can be paid to Kew there is literally not time, even in the summer days, to see the place properly. Public gardens elsewhere of any importance open at reasonable hours. The gardens at Edinburgh, Dublin, Paris, and Lyons are all open early in the morning, and we hear nothing whatever of "science" suffering in consequence, though those gardens are much nearer to the cities than Kew is to London, and therefore more likely to be overcrowded. The gardens lose more than half their value to the public if they are shut up for half the time people might visit them. The question of the slight expense necessary is no reason for not opening the gardens, because, if we mistake not, it would not be difficult to mention various departments at Kew in which great expense is incurred for matters of much less importance than the opening of the gates to the public. To form a national garden at an enormous cost, and support it with a revenue of over £22,000 a year, and then to deliberately shut the gates throughout the best part of the day for as much as seven and eight hours after other botanic gardens are open to the public, is neither wise nor just. As to the so-called "scientific" work which has been urged as an excuse for keeping the garden shut, if that mean horticultural work, such as sending plants to the colonies, it is done in the propagating houses or packing-sheds, which are always private. If it mean such scientific work as is done in books or reports, it is done in the officers' rooms, in the library, or in the herbarium, with none of which the general public wish to interfere. The fact of work going on in these places does not show that people might not be admitted to the gardens now deserted through so many hours of the day. We find a scientific journal, the "Journal of Botany," saying—"Besides the officials themselves we believe we are not wrong in stating that the number of persons engaged at Kew (we do not, of course, speak of the herbarium) is exceedingly small. Into the causes of this it is not necessary to enter, but it is obviously undesirable that everybody else should suffer

in order that half-a-dozen artists and experimenters in fertilisation may be undisturbed." As well might we have a churchyard closed or a public way stopped because an artist was employed in sketching the church or a landscape. The interests of the "students" have been supposed to be antagonistic to the admission of the public, but the fact is, students have hitherto been excluded from the gardens in the morning, and it is well known that the botanical classes of the medical schools in London receive specimens and liberal assistance from small gardens in London of a non-public character, such as the gardens of the Botanic Society and the Apothecaries' Company, and not from Kew. It is necessary to say so much, in consequence of statements that teaching could not be carried on in the gardens if the public were admitted. But if it were the fashion for botanical classes to assemble at Kew in the morning, all the botanical pupils and all the botanical teachers in Europe might be simultaneously engaged in these large gardens without interference on either side by or with the public. Except on holiday afternoons, we have never yet seen the gardens at Kew in any other condition than would allow any number to study to their hearts' content. It is now announced that all persons visiting the gardens for study and improvement will be admitted before one o'clock if they call at the curator's office and sign their names, stating the object of their visit, in a book kept for the purpose. If this is the only result of the agitation it will be a gain to horticulturists. Many of them have written to us lately, among them some of the ablest in England, of having gone to Kew and been turned away from the gates. We think, however, this concession wholly inadequate, and unworthy of a great national establishment. It is impossible, as it is undesirable, to draw the line between horticulturists and the general public as regards the right of entry to a public garden. If any art or science appeals to all directly and forcibly it is that illustrated in such gardens as Kew, and it is therefore much to be desired that no needless restriction be placed on its enjoyment. In great museums and galleries, where the whole surface has to be cleaned every day, there is need for reserving certain working hours for the purpose, but even in such large and magnificent galleries as those of the Louvre this is arranged for at such hours as do not inconvenience the public. In such great galleries and museums the reason why they are not open for a longer time every day than is now the case is often the difficulty of lighting them efficiently without danger to the structure or injury to its contents. In the case of a garden but a small portion of its surface will undergo cleaning on any given day, and as far as the lighting, that is done by the sun himself. It is therefore strange that a garden like Kew should be closed to the public at a time when the National Gallery and the British Museum have their doors wide open. There is good reason why it should be opened hours before and hours after them, just as in other cities public gardens are opened early in the morning, while the doors of the adjacent museums may not be opened till after breakfast.

W. R.

**Tabernaemontana camassa.**—None of the varieties of this genus equal this in usefulness, or can be so easily obtained. It grows freely in a warm house, and in a very small state yields an abundance of pure white, sweet-scented flowers, rather smaller than those of the well-known *T. coronaria*. We lately saw a quantity of plants of it growing in 4-in. pots in Mr. B. S. Williams' nursery at Holloway, and, being in full bloom, they made quite an effective display. On some of the plants, not more than 6 in. high, we counted nearly thirty blossoms and buds. The flowers of this variety, moreover, last a long time, and it should be grown in every garden in which a warm house exists.—S.

## OBITUARY.

We have to record, with regret, the death of Mr. RANSLEY TANTON, of The Nursery, Epsom, which took place on the 26th ult., at the early age of forty-three. He had taken an active part in the decorations which were got up on the occasion of Lord and Lady Rosebery's return from their wedding tour, and dropped down dead from a diseased heart. In his early days Mr. Tanton was employed in the gardens at Chiswick, and, for a short time, in the Society's best days, as librarian at 21, Regent Street. The Nursery will, we believe, be carried on as usual, by his widow.

## ANSWERS TO CORRESPONDENTS.

**Eucharis amazonica.**—For these last five years I have had a dozen pots of this *Eucharis*, and have, up to the present time, not had more than three flowers. They have been, and are now, in the Pine pit, and I am informed that the bottom-heat is insufficient for it. Can you give me any information as to these plants, and what amount of forcing they require to flower them?—J. J. [Remove them at once into a cool house, and keep them rather dry at the root for a month or six weeks; afterwards place them in your Pine pit in bottom-heat, and give them plenty of water, and they will no doubt flower satisfactorily. Weak liquid manure water applied when they show bloom will greatly assist them.]

**Evergreen Hedges.**—The best evergreen with which I am acquainted for rapidly forming a good hedge or screen is the *Colchic Laurel*, which grows better and quicker than any *Conifer*. If this be well planted in good rich soil it will run up 3 ft. or so each year, and is, withal, very handsome.—T. SMITH, *Newry*.

**Flower Tubes.**—In reply to "T. S." (see p. 400) I think he can get what he asks for by applying to Mr. J. C. Hamerton, 3, Pierie Terrace, Finch Road, Losells, Birmingham.—Geo. Boss, 10, *Quinton Road, Richmond*.

**Hybrid Crotons** (see p. 400).—The best way to induce C. voluntia to flower is to give it every encouragement in the way of heat and moisture, and thus make it grow as quickly as possible.—W. H. G.

**Ants.**—Can any of your readers suggest a simple remedy or means of destroying and exterminating these destructive pests where they are completely overrunning grounds, hothouses, greenhouses, and plants, by harrowing themselves into the pots where the plants are growing?—J. J. M. [In "Garden Receipts," published by Macmillan, Bedford Street, Covent Garden, you will find collected together many different ways of killing ants.]

**Strawberry Runners.**—I have a number of well-rooted Strawberry runners left over from last year's planting; they were packed closely together on a piece of hard ground last autumn, with a little light soil placed amongst them; they are looking very strong and healthy now. Will they be of any use for making fresh beds this year? or would it be better to throw them away and take fresh runners this summer? In the event of making use of last year's runners, would it be advisable to plant them out in rich soil under a north wall now, and remove them to their final places in August, as the ground intended for the new beds is now planted with early Potatoes?—G. M., *West Malvern*. [Leave the plants where they are; put a little more soil round them and a little short manure among them; keep them well supplied with water until the ground is ready for planting. They will make better plants than this year's runners, and if the bloom be kept picked off them it will be an advantage.—W. S.]

**Names of Plants.**—B. S.—These are the plants commonly known as Paris Daisy, no doubt from being frequently grown in the flower-gardens of Paris. The fine-leaved glaucous kind is *Chrysanthemum fontinalium*, the other *C. frutescens*; sometimes they bear the name of *Argyranthemum*. P. J. NEWCOMB.—1, *Forsterianum*; 2, *album*; 3, *glaucum*; 4, *reflexum*; 5, *anglicum*; 6, *lyodium*. It is difficult to correctly name *Sedum* without flowers. J. E.—The summer Snowflake (*Leucopogon aestivum*). J. WALBRUN.—As far as can be ascertained by the dried-up specimens received, No. 1 is *Mentha arvensis* or *Corv. Mint*. It is by no means an uncommon occurrence for beds of the culinary Mint (*Mentha viridis*) or Spear Mint, or, as it is sometimes called, Lamb Mint, when allowed to remain undisturbed for several years, to become overrun by this variety. How this result is brought about is not quite clear; but it is possible that the self-sown seed of the cultivated sort (*Mentha viridis*) may produce this variety, which may be used for culinary purposes, but is found to be inferior to the true Spear Mint. Where it occurs it is therefore advisable to make a fresh bed upon a fresh piece of ground, taking care to avoid the use of plants of the spurious variety. No. 2 appears to be *Mentha viridis*, not *Mentha piperita*, which it only grows for the sake of its essential oil, and is not used for culinary purposes.—P. G. W. M.—Ivy-leaved *Palargonium elegantissimum*. Begonia next week. S. P. GUILFORD.—Dried up, but probably *Alonsoa Warcewiczii*. W. V.—*Genista agillatis*. YOUNG GAARDNER.—1, *Centropogon Lucianus*. 2, Apparently *Lithospermum prostratum*. 3, *Rhodiodesendralbous*. OCHRTO.—The drawing sent of the plant you had for *Odontoglossum cirrhosum* is *Mesospidium sanguineum*.

## Questions.

**Slugs and Wireworm.**—In THE GARDEN (see p. 390) Mr. D. Lamond says that Kennel salt destroys slugs and wireworm. I cannot get any salt by that name. Does he mean the potash manure Kalmitt, and in what quantity should it be applied? In the same number "W. A." recommends nitrate of soda for wireworm. In what quantity is it to be applied?—A. SWEETMAN.

**Holly Timber.**—Into what purpose can this be converted by machinery, and the most profitable? By machinery I mean that worked by steam.—O. F.

**Plums shedding their Blossoms.**—Can any of your readers tell me the reason why Plum trees in an orchard house drop their blossoms just as they are setting?—A. H., *Guildford*.

**Nectarine Trees shedding their Fruit.**—Our Nectarines on the back wall of a Peach house, which are at the size of Peas, fall off. I have examined the borders, and it seems all right as regards moisture. Can you tell me the cause? They are not shaded by the other trees.—A. I.

**Rust Preventives.**—I have a small boiler for heating a greenhouse not set in brickwork. Is there any composition with which I can cover it that will prevent its rusting and retain the heat?—L.

## GARDEN DESTROYERS.

CATS *v.* MICE.

WITH all due deference to Mr. Cornhill (see p. 356), it will, I think, be generally admitted that cats are but indifferent gardeners. About London, where they visit us in tens and twenties, or even more, they are a great nuisance. Seed-beds are their favourite resorts, in consequence of the fineness of the surface-soil, and, unless well protected, they are sure to become materially damaged. The havoc caused by them, too, among bedding plants during the hardening-off season, when they are left exposed, is very great. Cats, of course, will destroy mice, but it will be well to consider whether the good which they do in that respect will counterbalance the damage which they incur. I have a lively recollection of the damage done by cats in several large gardens in the country where I have been employed. One of their favourite amusements was to sharpen their claws on the stems of Camellias, Vines, Peach trees, climbing plants, &c., in some cases killing them outright. In early spring, too, when butterflies made their appearance, puss would wait until one had alighted upon some choice flower, and then pounce upon it, often to the certain destruction of both plant and flower. Where plants happened to stand somewhat closely together, much damage was always caused by cats dodging after mice. One cat would be of little use in a large establishment, and if several were kept much damage would be done. Farther, cats in the country find sufficient food without the trouble of seeking it among flower-pots, and it is very difficult to teach them what you want them to do. In town gardens cats scratch over the surface of flower-beds, uproot small plants, break off the tops of Hyacinths, Tulips, and other bulbs; and woe beside a batch of bedding plants, in either greenhouses or frames, if two or more cats should get in. On this matter I can speak with confidence, our annual average loss being some hundreds of plants. Cats also break a good deal of glass. We find little difficulty in destroying mice by spreading poison upon bread, and also using a few traps of the most improved patterns baited with cheese or bacon. In the case of seeds, to which mice are partial, we protect them by covering the pots or pans with glass until the seedlings appear aboveground. Cleanliness tends very much to prevent the increase of mice. There should be no accumulation of old straw or similar materials about houses or adjacent sheds, and all kinds of rubbish should be removed to a distance. A little gas-tar may also be put in their launts with advantage.

Southmark Park.

CHARLES DENNIS.

—The advice offered by Mr. Cornhill (see p. 356) on the subject of admitting cats into gardens cannot, I think, be received without caution. He suggests that, where gardens are troubled with mice, the owner should keep cats, and, not content with this, that they should besides entice their neighbours' cats to come and assist in destroying these pests by placing pieces of red herring about the grounds to tempt them in. Now cats are useful animals in a house, stable, or granary, but, to my mind, the less one is troubled with them in a garden the better. What can be more unsightly, on walking round one's ground in the morning, than to see the well-kept gravel paths disfigured by patches of earth, thrown on them during the previous night by cats? or, perhaps, a beautiful *Nemophila* bed on one's lawn, which was but yesterday a blaze of flower and the admiration of all, flattened down like a field of Barley after a thunderstorm. Mr. Cornhill seems to have been much interested in watching the movements of cats, as he tells us that they will "wend their way among plants, never so much as touching one of them." This may be true when all is quiet; but suppose a mouse, disturbed at its meal on some choice bulb, should, at a sight of a cat, suddenly dart for refuge behind some pots of flowers—a scrimmage follows of course, and what then happens to plants that may stand in the way? Or let an adventurous "tom" on looking in at an open conservatory window, discover a "wen" busy at her work amongst the spiders, or a robin feeding her brood in a nest which she has built in one of your hanging baskets; then in a moment down go your lovely *Maréchal Niel* and the pretty *Dentzia* with which you had intended to decorate the breakfast table on some particular occasion. One word also as to red herring baits. There are other animals beside cats that would soon be attracted by them, and if used here, or near any large town, one's garden would become the resort of half the curs of the neighbourhood.—F. CORNELL, *Merwood, Parkstone.*

—Few will question the usefulness of cats about a garden. But, unfortunately in many establishments it is more difficult to retain cats than it is to destroy mice. Gamekeepers, who I suppose must act in self-defence, are more deadly enemies to cats than cats are to mice. I have, therefore, while recognising the great usefulness of cats, given them up, and now trust to traps.—J. M.

## RANSOMES &amp; SIMS' LAWN MOWERS.

This noted firm, whose great manufacturing depot is one of the places of interest at Ipswich, has, as is well known, a world-wide reputation for its agricultural machinery—from steam engines, of all sizes and capacities to ploughshares, and they are now among the foremost manufacturers of lawn mowers. I have been struck with the excellence of their machines on several occasions, and, as a consequence, I am now in possession of four of Ransomes' "Automaton" mowers; and as gardeners and others are always interested in such matters, I daresay they will be glad to hear my opinion of them. One does not usually pay much attention to what the makers themselves say of their own machines, but in the present instance the makers do not exaggerate when they state that their mowers are "thoroughly strong, well-made, and durable." In this respect they are not excelled, and I have worked all the others and speak from experience. But though they are strong, they are also light, and work easily and noiselessly, and, what will be regarded as a great advantage, they "rib" the Grass in cutting less than any machine I have yet tried. Indeed, where the lawn is cut as frequently as it should be, they do not "rib" at all. This, I suppose, is owing to the speed at which the knives travel, and their taking a shorter grip of the Grass; I do not profess to explain the matter scientifically, only record the fact. One thing I can state—the men who work the small machines here take to the "Automaton," and that is saying a good deal, for mowing-machine work is no child's play anywhere, and the machine which is easy to work will always be the favourite. Ransomes' "Reversible" lawn mowers are handy little machines, and new. They can be worked either side upwards, which reverses the action of the cutting barrel, and brings a fresh set of edges into use, which is a new and important feature. Of course, Ransomes' machines have all the usual improvements, and one of the best is the manner in which the knives are held—which is by an arm at each end—and the ease and facility with which they can be adjusted to the plate. Adjusting the knives and raising and lowering them is a work which the men have often to do, and it is important that they should be able to do it readily and without making mistakes. From a gardener's point of view, I can thoroughly recommend these machines.

CHEF.

**The Marnock and Other Portraits.**—I am glad to see that it is proposed to present Mr. Marnock with his portrait. I can never forget his courtesy and kindness alike as director of the Regent's Park Botanic Gardens and conductor of the "Gardeners' and Land Stewards' Journal," while his genius and success as a landscape gardener have been highly appreciated and admired by all lovers of good taste. Can nothing be done to provide, by subscription or otherwise, good engravings of such portraits as that of Mr. Marnock, Lindley, London, Rivers, and Veitch? so that gardeners might be able to adorn their too often bare walls with these and other representative men whose presence in their homes could hardly fail to inspire them with greater enthusiasm and perseverance in their often all too arduous profession. I should like to see this matter of good engravings of our famous leaders carried out with such spirit as to bring them within reach of all classes of practical gardeners, as well as amateurs and the general public.—D. T. FISHER.

**Professor Balfour's Testimonial.**—A meeting of Edinburgh graduates was held at the house of Dr. Duckworth on the 15th April to promote the above object in London and elsewhere. It was announced by Dr. McIntosh, of Murchy, that about £250 had been already collected from friends and former pupils of Dr. Balfour. A most excellent portrait of the Professor has been painted by Sir Daniel Macnee, President of the Royal Scottish Academy, and this is to be presented to the Senate Hall or Library of the University. It is desired to procure a replica of this, from the same hand, as a gift to Dr. Balfour's family, and additional subscriptions for this purpose are now sought. It is believed that the scheme only requires to be known to the numerous pupils of the zealous and beloved Professor of Botany, scattered all over the world, to ensure a ready response. It was thought fitting thus to mark the kindly services of Dr. Balfour, who had acted as Dean of the Medical Faculty for more than thirty years, and had recently retired from that office. Subscriptions may be sent to Mr. David Smith, Treasurer of the Royal Society of Edinburgh.

**Spain and the Phylloxera.**—Notice has been given by the Consulate-General of Spain in London that, in order to prevent the introduction of the Phylloxera (in addition to the restrictions already in force, and without prejudice to any further measures it may be found requisite to adopt), the Spanish Government has prohibited absolutely at all Spanish ports the importation of every kind of live plants and packages used for the same.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### SEASIDE VEGETATION IN ORKNEY.

HAVING read with interest in one of the March numbers of THE GARDEN (see p. 203) some notes regarding Veronicas and other subjects growing near the sea at Worthing, I have thought that it might interest some of your readers to hear what can be done with similar and other plants at the other end of the kingdom, viz., in the Orkney Islands. Here, in an old-fashioned but charming garden we have Veronicas against a west wall growing to the height of 8½ ft.; *Araucaria imbricata*, 19½ ft.; *Rhododendrons*, 10 ft.; *Fuchsia Riccartoni*, 15 ft.; North American Currant (*Ribes sanguineum*), 10 ft.; all within a stone's throw of the sea. The Veronicas are fully exposed to sea and wind; but the others are sheltered, to a certain extent, by a sea wall. In the general treeless aspect of these islands such a garden is much valued. Elms, Sycamores, Mountain Ash, and Chestnut are all thriving, and a pretty effect is gained in early summer from masses of *Laburnums* which line the plantations, under which whole sheets of lovely blue Wood Hyacinths spring up year by year. Holly, too, grows to a fair height. Behind the shelter of this small woodland, Nature, aided by art (years ago), has produced a constant succession of beautiful surprises, which occur all through the grassy slopes from January to June. First we have Snowdrops, then Crocuses, different coloured Primroses, Jonquils, Lilies, Tulips, year after year, without receiving any other attention, or causing any inconvenience beyond leaving the Grass rather long uncut, in order that the plants just mentioned may have well died down before they are interfered with. In summer the Maiden Blush and many other Roses may be met with all over the place, and lately a large bed of new Hybrid Perpetual Roses has been planted, which promises to add much to the delights of the garden. A picturesque old Vinery, with none of the modern improvements, still affords an excellent and an abundant supply of Grapes, and some Fig trees trained on an espalier the full length of the house yield an average crop, and form quite a feature in this quaint old fruit house. In the greenhouse (also by no means a modern structure) a Myrtle planted out has grown to the full height of the house; and as a *Maréchal Niel* Rose planted a few years ago is now running all over the rafters, and showing plenty of flowers, the effect of the pale delicate yellow of the Rose blooms against the glossy, dark green leaves of the Myrtle will doubtless prove before long a pleasing feature. Planting is now being carried on on a larger scale than hitherto in another part of this island, but, owing to the high winds that prevail, trees make but slow progress unless they are at first protected by a wall, which I see few of your correspondents advocate. The plan pursued here now is to outline all the windward sides of plantations with, first, Sea Buckthorn, then *Pinus maritima*, behind which other trees are used, but the dry, cold spring, which was the season chosen for planting most of these subjects, has left traces of its presence in the brown appearance of nearly all the Silver Firs and other evergreens. Any plants likely to lead to success in planting in a windy, exposed country, with a generally mild climate, and where frost is comparatively unknown, will be gladly received.

*Westness, Rousay.*

ROBERT HENDERSON.

### A GARDEN OF HARDY PLANTS.

THE part which THE GARDEN has so ably and consistently performed since its establishment—that of advocating the culture of the choicer kinds of hardy plants, many of which have been too long neglected—has proved eminently successful in many cases, to the real advantage of gardening. A neighbour of mine, who has a fair-sized piece of garden attached to his residence, now devotes the whole of it to the culture of hardy plants; and he has gathered together a collection at once extensive and inte-

resting. In addition, he has built himself a house for those requiring some protection, to preserve their beauty from harm through frost and rain. This house is small and nearly square, being 10 ft. by 12 ft. It is span-roofed, amply ventilated, and sunk 2 ft. below the ground level, access being had to it by means of steps. A kind of brick stage, on which is a bed of Cocoa-nut refuse, runs round the house, and this is about 3 ft. from the ground. It is surprising what a number of plants can be staged in this small and serviceable house; and, as he is away from home all day, he finds it of great advantage to plunge the pots nearly to their rims in a bed of Cocoa-nut fibre. I selected a few of the gems of the collection, and will commence with the variegated and ornamental-leaved plants, which, when grown in this way, are charmingly effective. I may mention *Euphorbia dulcis* fol. var., a dwarf evergreen plant, having the foliage broadly margined with white; a pretty silvery-foliaged Veronica, said to be quite distinct from *V. icæna*; *Phormium tenax variegatum* (Veitch's variety); *Santolina incana*; the silvery-variegated *Ophiopogon spicatus* and the yellow-margined *O. Jaburani*; *Libertia pulchella*, a distinct and pretty plant, with a yellow band running along the centre of each dark green, lanceolate leaf; the curious *Hypericum balearicum*, a most interesting little shrub, with singularly-formed leaves; *Ligularia Kämpferi* fol. var.; a golden-foliaged *Helichrysum*; *Opuntias*; choice varieties of *Saxifrage*, *Sedums*, and *Sempervivums* growing in small pans, and forming an edging to borders round the house; the square-stemmed *Andromeda tetragona*; the white and yellow-variegated *Thymes*, both of which are charming in winter and early spring; *Bambusa Fortunei*, *Aspidistra lurida variegata*, *Geranium argenteum*, *Spiræa Ulmaria* fol. variegata, *Nertera depressa*, various *Funkias*, and others too numerous to mention. Flowering plants were represented by hardy *Cyclamens*, Terrestrial Orchids, species of *Primula*, *Hepatica*, *Galanthus*, *Narcissus*, and *Tulips*, &c. All these plants were in admirable order, and, like a good collection of Auriculas, they served to illustrate the value and advantage of a round of constant attentions. It is practically impossible to enter this house at any time of the year without seeing much to interest and gratify. The out-door garden outside, it is true, a few fruit trees that are valuable as affording shade, but no other trace of a kitchen garden was to be noted. It was laid out in slightly raised beds of varying shapes, all appropriately edged with rockwork or some such material, and devoted entirely to the growth of choice hardy plants. Here and there are mounds for *Sedums*, *Helianthemums*, and other trailing plants; also ponds for hardy aquatic; and, indeed, various little surprises of a pleasant character. A plantation of *Phloxes* here, another of *Pyrethrums* there; *Lilies* and *Gladioli* further on; also clumps of choice *Aquilegas*, &c. Particularly noticeable was the pretty *Ranunculus acontifolius* plenus, very early in bloom; *Gemm occoccinum* flore-pleno, *Gallardia grandiflora*, *Linum flavum*, *Alyssum spiosum*, *Primula marginata*, blooming finely on the shady side of a stone; *Gentiana acaulis*, *G. verna*, &c. There is so much of interest in this garden, that one could visit it weekly, and see something fresh and new at each visit. Against the walls of the residence were unpruned *Roses*, *Clematises*, &c.; in the forecourt garden were a few beds out in the Grass and borders flanking them on either side, and these were filled with hardy plants for permanent service. The beds and borders are never empty; they render services in an unbroken succession; and if some plants decline at the proper time, others are pushing forth some feature of interest to take their place. In such a garden slugs and snails are apt to be troublesome, and they are voracious in the matter of *Funkias* and other herbaceous plants growing in perforated zinc, 4 in. or so in height, placed round the plants. Slugs and snails carefully avoid sealing these metallic ramparts, and the plants are enabled to flourish unhindered by such attacks. I never visit this garden without coming away full of enthusiasm. Like the house, it requires constant attention; but it is labour sweetened by a high reward. There is no sameness or monotony about its varying features; a pleasant freshness of interest is never absent from year's end to year's end. D.

### THE JAPANESE GARDEN AT THE PARIS EXHIBITION.

THIS promises to be of great interest to the visitors to this gigantic show. Besides the peculiar specimens of dwarf and distorted vegetation for which the Japanese are so celebrated, there will be a large number of every-day agricultural and horticultural productions and ornamental plants. Besides numerous specimens of different kinds of cereals, we are to have several varieties of Plum, Peach, and Kaki trees, Haricot Beans, Turnips, and other fruits and vegetables. Amongst ornamental trees and shrubs there will be specimens of Cherry trees with double violet flowers, but both belonging to the

two types which have been so long known to horticulturists as *Cerasus Sieboldi* and *Cerasus Lannesiana*, as well as a very interesting variety of Weeping Peach tree, bearing very dark double flowers. We may also mention amongst the ornamental plants several collections of herbaceous *Pæonies* which, unhappily, do not bear flowers; also several so-called Tree *Pæonies*, of which only a few bear any well-shaped flower-buds. Unfortunately, these plants have greatly suffered from being transplanted, as well as from the long journey which they have made; they will, therefore, give but a poor idea of the beauty of their flowers when grown under favourable conditions. The greater number of these varieties, however, are to be found already in certain horticultural collections. Another collection, which will be of equal interest, can hardly be properly appreciated, owing to the specimens shown being extremely small. These are the Japanese Maples, properly so called, with their finely-cut leaves of various tints. A very good idea, however, may be formed of the value of these trees as ornaments, a large number of them being now known to European horticulturists. Besides the plants already enumerated, there are a large number which cannot at present be noticed, but of which we shall give an account hereafter. Several of the houses erected in the Japanese garden will give an excellent idea of how such structures are raised in Japan, as well as of the profitable and ingenious way in which the Japanese utilise the Bamboo, a plant which plays a most important part in the domestic economy of the dominions of the Taiocon. Amongst the materials used in the erection of these houses we may find a large number of specimens of planks and beams, most of which seem to have been cut from trees belonging to the *Coniferae*, very probably from the *Pinus Masoniana* or *densiflora*; these will give a good idea of the colossal dimensions acquired by certain species belonging to this genus. One of the beams mentioned above measured no less than 6 ft. 6 in. in diameter. C. W. QUIN.

#### DIELYTRA SPECTABILIS.

This has been termed one of the "finest herbaceous plants in cultivation." It is simply perfect as a decorative plant in the open border; and in pots, when well managed, it is invaluable for conservatory and greenhouse decoration. A good cultivator once remarked, "There is, perhaps, no other plant known which combines the character of so many distinct genera as the *Dielytra*, for, while the root and leaves exhibit a familiar resemblance to the *Pæony*, the flowers display to the curious observer the combined qualities of the *Monks-hood*, the *Iris*, the *Orchis*, and the *Foxglove*; thus we may imagine that Nature, in her floral freaks, has ways and means for fulfilling the great command—multiplying, replenishing, and adorning the earth by producing annually superior and inferior varieties and sub-varieties yet unknown to mankind." The flower of the *Dielytra* well repays examination, for it is simple in appearance, yet perfect in its way, being composed of a calyx, corolla, stamens, and pistils. The calyx, which is a simple scale-like substance, falls away when the flower is about half expanded, leaving exposed two outer petals, which form the principal corolla, and serve as a spathe or envelope for the more tender part of the flower. Let a blossom of it be closely examined, and it will be seen that each of these parts resembles separately the flower of the *Monks-hood*, and terminates in a long folded point, which is reflexed, forming, as it were, a pair of wings, which, when seen at a short distance off, tend to give the flower a light, fantastic appearance. The inner perianth or central column of the flower is formed in like manner as an *Iris*, while the stamens are united at the bases into two distinct sets of three each, which cling to the inside of the outer petals, thus forming a sort of wirework to keep the petals in their proper positions, and tapering upwards until they reach the top, where they are again drawn together, and the fructifying bodies arched between the spoon-like extremities of the two inner petals, the opening and closing of which are influenced by the sun's rays when the flower is in the zenith of its beauty.

At the spring show of the Newcastle-on-Tyne Horticultural Society on April 3, one of the features of the show was the *Dielytras* in pots. It was not so much on account of their great size as for their admirable growth and splendid heads of flower that they were so much admired. The effect was most pleasing; the numerous rosy-pink coloured flowers were borne on pendulous racemes all over the plants. These plants had had to undergo a certain amount of forcing, but they bore no

traces of it; indeed, they might have been lifted from the open border, so clean, robust, and natural did they look. Nor were the plants in very large pots. I have been flowering some in 6-in. pots in a cold conservatory, and they have been charming. The roots were divided in the autumn, and carefully planted in a cold frame in a good light soil. When I potted them in February they were just starting into growth. I used a good yellow loam, leaf-mould, and some manure, giving the pots plenty of drainage, so that water could pass away freely. They have had plenty of water; a little liquid manure given occasionally gave a fine colour to the blossoms. When the plants go out of bloom they will be placed out-of-doors for a time, and in July planted out in a prepared bed in the open ground. By keeping them in pots till that time opportunity is afforded for taking off young growths round the main stems, which root freely in a light and very sandy soil in a gentle bottom-heat. An increase can also be had by dividing the roots, but when this is done a year's growth should be given to the plants before they are employed for forcing purposes.

I have not seen the white variety for a long time. Its decorative value is much below that of the common form, which will, perhaps, account for its so rarely being seen under cultivation. D.

*Cortusa pubens*.—A good specimen of this new *Cortusa* may now be seen on a rockery at Kew. It is, apparently, a suitable companion for the better known *C. Matthioli*, which had hitherto been the only species of the genus in cultivation. It is a native of Transylvania, and much resembles the latter species, but differs from it principally in its more compact habit, colour of flowers (which are pink, changing to a lighter hue, but which are borne in the same umbel-like form), and by the whole plant being beset with a short, dense pubescence; it also appears to be more floriferous. It is a decided acquisition to our hardy plants, and doubtless will succeed under the same conditions of culture as *C. Matthioli*, which thrives well in a compost of sandy loam enriched with well decomposed leaf-mould or manure, a plentiful supply of water in spring, and not much exposure to direct sunlight.—W.

Tree *Pæonies*, *Dielytras*, &c., and the Frost.—I have a few, a very few, bloom-buds left on my Tree *Pæonies* that look as if they would open in due time; but, with regard to the *Dielytras* and *Crown Imperials*, I appear to be more fortunate than Mr. Fish (see p. 406). The former, which the soil here seems to suit, are now (May 7) just coming into bloom, and were not at all affected by those terrible frosts which we had in March; and the *Crown Imperials*, though they were prostrated for a time, recovered on the return of mild weather. The bloom-buds were not then fully developed, but the flowers, when they opened (those of the red kind only), had, some of them, a rather washed-out appearance. *Myosotis dissitiflora* was not at all affected by the frost. Elevated ground, such as mine, often escapes injury when more favoured localities suffer severely from hard frosts.—B. S., *Uppingham*.

The Late John Keynes, of Salisbury.—You have been remarkably successful in your likeness of this genial horticulturist and good man. There are men you only meet once or twice in a lifetime, and yet remember with sufficient vividness to recall at sight evermore. Among the few such that have affected me thus was John Keynes. Your memoir of him is also most interesting. What a good example it affords to young men, and to us all in this luxurious age! How quiet and gentle he always seemed! Active amongst the most active, he yet appeared almost unmoved by the bustle and excitement of great shows or social meetings. I wish, in this age of book-making, some one would undertake to write wisely, truly, and well the lives of our horticultural worthies, say from Loudon to Keynes, or any definite period. Such a work would prove as useful as it would be interesting, and would illustrate afresh the axiom of how little the world knows of its greatest men; for many horticulturists have been indeed great—alike in their characters, their work, and the far reaching influence of the latter in the world at large.—D. T. FISH.

Spring Snowflakes.—Last year I got from abroad several hundred bulbs of this beautiful spring plant, but have been much disappointed that very few indeed have flowered. "E. F." (see p. 251) says they did not flower the first year after planting with him. Is this the experience of others also? If so there is comfort in thinking that one's labour has not been thrown away. Along with the importation of Snowflake I received roots of many species of *Orchidæ* and other hardy interesting plants that I have not seen, in any nursery catalogue.—P. NEILL FRASER, *Murrayfield, Edinburgh*.

## NOTES OF THE WEEK.

**Large Marechal Niel Rose.**—What do you think of a *Marechal Niel* Rose 58 ft. in length with upwards of 2000 blooms on it? I was in Mr. J. L. Wall's garden, Redland Lodge, Bristol, on Tuesday last, where I saw a glorious sight of *Tea Roses*, the best I have seen this year, and amongst them was the *Marechal* I have mentioned—truly a glorious Rose.—B.

**Lilacs, Bird Cherry, and Sweet Brier in Hedges.**—A very good notion is being carried out at Longleat by the forester, Mr. Berry, who plants the above-named and other like trees and shrubs and climbers at intervals in the hedges that surround the numerous cottage gardens on the estate. Already many of these have grown into the flowering stage, and it may be easily imagined what a beautiful result they afford and how much more they promise. A like plan with thoroughly hardy and excellent fruit trees would be excellent, as in that case one would have both flower and fruit.

**Oncidium concolor.**—Plants of this *Oncidium*, a coloured figure of which was given in THE GARDEN (see p. 58) may now be seen finely in bloom in Messrs. Veitch's nursery. They are growing on suspended blocks, from which their graceful spikes of bright yellow blossoms droop in a very effective manner.

**Cerasus Watereri.**—I can quite confirm from personal experience the description given (see p. 407) of this *Cherry*. We have two small trees of it, which we had from Mr. John Waterer in the spring of 1876, and they are just now a mass of blossom, quite lovely in tint, and as large as a *Primula*. I am convinced if this tree were more widely known no one would feel their garden to be complete without it.—Mrs. F. RICARDO, *The Friary, Old Windsor*.

**Clianthus Dampieri.**—Of all plants this is one of the most difficult to cultivate. Nurserymen seldom can keep a stock of it, and good flowering specimens of it are of rare occurrence. The best plant of it which we have seen for a long time is now in flower in Mr. Williams' nursery at Holloway.

**Azalea flambeau.**—Of all the Indian *Azaleas* now in bloom in the London nurseries, none is so brilliant and showy as this. Its flowers are dark crimson, and, though not so large as those of some other kinds, are of great substance, and consequently they last in good condition for a much longer period than those of a more flimsy texture. Wherever really good brightly coloured blooms are required in spring this *Azalea* will be found indispensable.

**Gardenia Stanleyana.**—This plant, so seldom met with, is now finely in bloom in the Victoria Nurseries, Upper Holloway. It is a straggling grower, and its character is wholly unlike that of a *Gardenia*. Its flowers are produced from the joints of two-year-old wood, and whilst now in flower the bloom-buds for next year are observable on last year's wood. Its flowers, which are sweetly-scented, resemble in shape and size those of a trumpet Lily, the tubes being 8 in. or 9 in. long; the petals are recurved, white, and spotted with bright crimson, and the inside of the tube is green and mottled with dark brown. Though it cannot be considered a very useful plant, it is nevertheless well worth growing where a large collection of stove plants exists.

**Newmarket Pink.**—This new forcing Pink is now finely in bloom in Mr. Ware's nursery at Tottenham. Of its colour it is doubtless the most useful kind that has yet been raised, and one which will, when better known, be largely cultivated by all who require good Pinks and plenty of them early in the year. Cuttings of it struck in spring, planted out during the summer in good soil, and lifted and potted in the autumn, make fine bushy plants, furnished with from thirty to forty large, double, rose-coloured blossoms in April.

**New Variety of Dendrobium superbiens.**—There is now in bloom in Mr. Williams' Victoria Nursery, Holloway, a very different form, if not a different species, of the new *Dendrobium superbiens* from those which have hitherto flowered. The pseudo-bulbs are more than double the thickness, more like the mature bulbs of *Cyrtopodium Andersoni* than those of any hitherto known *Dendrobium*. The flowers on this plant are not so dark as those on the one which Mr. Williams first bloomed, the petals being paler on the margin. The leaves on the young growths are also of a much thicker and more leathery description. This *Dendrobium* appears to differ in habit from other species by the way in which the flower-stems in every case push out leaves and form a pseudo-bulb after the flowers have fallen off. It is usual to see many of the species form young plants from the nodes of the old bulbs that have not flowered. The *D.* noble section and, to a still greater extent, the old, but when well managed, beautiful *D.* pulchellum constantly do this in quantity; but in the case of the plant under notice the growth goes on from the stems which have produced the flowers. *D.* Jamesianum was in bloom in the same house, bearing large white flowers, with a deep

orange-red blotch on the base of the labellum. In the same house, too, was a grand example of the finest-coloured, large-flowered form of *Odontoglossum vexillarium*, bearing five spikes of its lovely deep pink-coloured flowers. Even the comparatively pale smaller-flowered forms of this plant are very handsome, but they pale in beauty beside the deep-coloured varieties.—B.

**Gloxinias at Chelsea.**—Arranged in a cool house, adjoining the Orchid houses in Messrs. Veitch's nursery at Chelsea, is a large collection of these attractive plants, which now make a fine display. They consist of choice-named kinds of every variety of colour, and some valuable new seedlings may also be found among them.

**A New Laurustinus.**—In the Holloway Nurseries may be found a new *Laurustinus*, which will prove valuable for early forcing. Its flowers are double the size of those of the ordinary kind, as are also the trusses, and, being of the purest white colour, they cannot fail to be appreciated early in spring either for conservatory decoration in a cut state.

**The Paper White Narcissus.**—None of the *Narcissei* are more valued in the London flower markets than *Narcissus papyraceus*. Its blossoms are sweetly scented, of snowy whiteness, and they last in good condition for a long time. When used in bouquets they are as effective as many choicer flowers which are much more difficult to obtain. It is grown largely in Messrs. Carter & Co.'s Crystal Palace Nursery, where long beds of it are just now a mass of blossom.

**Gloneria jasminiflora.**—This elegant new plant, now finely in bloom in the Victoria and Paradise Nurseries, will, when better known, doubtless be found in every garden in which stove plants are grown. It is, however, a difficult plant to propagate, a circumstance against its speedy distribution. Like many of the *Franciscas*, it flowers so profusely from every small shoot that few little growths are made, and consequently few vigorous cuttings of it can be obtained. For months in succession established plants of it continue to yield a profusion of large clusters of blossom of snowy whiteness, and they last longer and are even choicer in appearance than those of the white-flowered *Bonardias*.

**Polygala Dalmaisiana as Small Plants.**—Though often found in the form of large specimens, this useful *Polygala* is seldom seen in the shape of bushy little plants, such as could be used for vases or for table decoration. For these purposes, however, it is well adapted. It should be grown in the form of a standard, with a stem 6 in. or 8 in. high, and if the shoots are stopped a good bushy and gracefully drooping head, bearing a profusion of bluish-purple, Pea-shaped flowers, will be the result. We saw it grown in this way in Messrs. Outbush's nursery, at Highgate, where, associated with *Azaleas* and similar plants, it was exceedingly effective.

**A New Masdevallia.**—An elegant new *Masdevallia* is now in flower in Mr. Bull's nursery at Chelsea. Its nearest relation is *M.* *Denisoniana*, but the flowers are much larger than those of that kind. It is exquisite in form, and the colour, which is rich violet-purple surpasses in brilliancy that of any other *Masdevallia*.

**Tree Carnation Ia Belle.**—The snow-white, sweet-scented flowers of this *Carnation* are more prized in the London flower markets than those of any other kind, and deservedly so, for when the plants are subjected to good culture the blooms come perfect in form and are more effective in bouquets than even flowers of *Gardenias* or *Stephanotis*. Wherever *Tree Carnations* are grown this kind should have a foremost place. It is now flowering freely in the principal nurseries about London.

**Jasminum ligustrifolium.**—When in the form of standards this is one of the best *Jasmines* which can be grown, either for conservatory or indoor decoration. It has Privet-like leaves, and bears abundance of white sweet-scented blossoms, which are invaluable for bouquets. It is of easy culture, and succeeds well in a cool house. Standard plants of it in 6-in. pots may now be found in some of the London nurseries loaded with blossoms.

**Orchids at Holloway.**—There is a good display of Orchids just now in Mr. Williams' nursery, at Holloway. Among the most striking may be mentioned *Dendrobium Jamesianum*, a species which bears rich salmon-spotted, white flowers, some of which measure 4 in. across. *D.* *Palmeri* is also bearing unusually large flowers beautifully coloured. We likewise noted the fine variety of *D.* *superbiens*, to which reference has just been made, and plants of *D.* *Devonianum*, the latter on suspended blocks, and bearing long wreaths of handsome flowers. On a specimen of the lovely *Odontoglossum vexillarium* we counted five strong flower-spikes and some thirty unusually large and finely-formed flowers, of a delicate rose colour; and *O.* *Servantesi* (the blooms of which last in good condition perhaps longer than those of any other Orchid) is also now well in flower. In addition to these, too, several *Masdevallias* are in bloom, including the curious *M.* *ohimera* and *M.* *Krameriana*; and we also noticed some good examples of *Aerides Fieldingi* and *Vandas*.

## NOTES FROM KEW.

**Hardy Trees and Shrubs.**—Perhaps the most uncommon, as well as the most charming, of the hardy shrubs of the present week is *Rubus deliciosus*, from the Rocky Mountains. This fine garden plant was figured in the "Botanical Magazine" two or three years ago, and, from the letterpress accompanying the illustration, we learn that it was discovered by Dr. James in 1822, but for a period of about forty years from that time it does not seem to have been noticed by any naturalist. To Mr. Isaso Anderson Henry, of Edinburgh, is due the honour of having introduced so fine a shrub to our English gardens; it makes a nice bush about 3 ft. high, and is covered with large, lovely, rose-like, pure white blossoms about 2 in. in diameter. Its original discoverer says it bears a fruit of delicious sweetness and considerable size. Without taking the fruit at all into consideration, it is amply worth cultivating as an ornamental plant. *Genista supina* is one of the showiest of all the Leguminous family at present in flower; its long shoots are bowed down with the weight of their numberless yellow, pea-shaped blooms. *Cytisus ratisbonensis* is somewhat similar to the preceding, though it seems hardly such a free-flowering species. *Amelanchier vulgaris*, the European counterpart of the Service or June Berry, mentioned in last week's notes, is a pretty little tree, the flowers being a beautiful red or pink in bud, and white when fully opened. *Sedum palustre*, or Labrador Tea—so called on account of its use—is a very desirable dwarf Heathwort, conspicuous at the present time on account of its numerous umbels of white flowers. *Ribes aurum* var. *serotinum* is probably the most handsome of the yellow-flowering Currants; the yellow sepals are large, and the short petals are distinctly bordered with red. This is a native of North-West America. *Pothergilla alnifolia* is a dwarf North American deciduous shrub, having spikes of white fragrant flowers. *Staphylea pinnata*, the common Bladder-nut of Central Europe, has pinnate, light green leaves and pendulous racemes of white flowers; grown in pots, this flowers freely and forces readily; the blossoms, too, are a shade purer white than those produced on plants in the open air. *Olestra Gunnii* (on one of the walls) has sprays densely clothed with white *Michauxia* Daisy-like flowers; as a spring-flowering wall plant this can be highly recommended. The double-flowering Cherry (*Prunus Cerasus flore-pleno*) ought to be more frequently seen in our shrubberies, or as single specimens on lawns, &c.; the snow-white double flowers last some time, and are most freely produced.

**Hardy Herbaceous Plants.**—One of the rarest, and also one of the most handsome, of the herbaceous plants now in flower in the Kew collection is *Dracopcephalum heterophyllum*, from the Himalayas; it is a dwarf, neat-habited Labiate, with large, deep blue flowers. A lovely little *Narcissus* is *N. juncifolius*, with rash-like leaves and golden-yellow flowers. A miniature form of this *N. gaditanus*, also from South Europe, may also be seen. *Alyssum montanum* is a splendid little border plant, about 4 in. in height; it is now one carpet of golden-yellow blossom. *Kerneria Boisieri* lasts a long time in bloom; from the compact rosettes of small leaves spring branched panicles of pure white flowers; this plant only attains a height of 3 in. or 4 in. *Paeonia anomala* and *tenifolia* are two exceedingly handsome species from Siberia; the former has finely-cut leaves and crimson flowers, the latter much more finely-cut leaves and dark crimson flowers. A double variety of *P. tenifolia* is also in flower. The eastern *P. decora* is a very showy species, although inferior in that respect to *P. anomala*; the colour of the flower, too, is different, this being a purplish-crimson. *Hemerocallis Kwanos variegata* is a splendid plant with variegated foliage, and has much the appearance, in its present stage, of Variegated Indian Corn. A variegated form of our British Wood Spurge (*Euphorbia amygdaloides*) will also be admired by all who have any leaning towards variegated plants; the variety is not nearly so strong-growing as the type. *Camassia Leichtlinii*, a native of British Columbia, is a very fine Liliaceous plant of recent introduction; it is a noble species with scapes 3 ft. in height, bearing numerous whitish flowers measuring 2 in. across; this certainly ranks first in the genus to which it belongs. Amongst Tulips those worthy of special mention are the yellow-flowered *T. fragrans*, from Algiers; the crimson-scarlet *T. Hageri*, lately introduced from Greece; and *T. retroflexa* and *T. fulgens*, both of garden origin. *T. retroflexa* has large, light yellow flowers with reflexed petals, and, although far below the notice of the Tulip exhibitor, is a very striking and desirable border plant. *T. fulgens* has large, deep crimson, yellow-centred flowers. *Aceranthus diphyllus*—or, as it is now called, *Epidemium diphyllum*—is a pretty plant with pure white flowers. *E. Muschonianum* is another lovely species with whitish flowers. *E. macranthum* has large flowers, with long, curved, tail-like, white petals and broader, purplish sepals. All three are natives of Japan. *Ornithogalum divergens* has umbels of pure white flowers about the size of those of *O. umbellatum* (the Star of Bethlehem).

**Orchids.**—*Epidendrum bicoloratum* from Trinidad is worthy of special mention both on account of its beauty and rarity. Although it has been frequently imported in considerable quantities, the plants have not as a rule survived a couple of seasons, and have rarely produced flowers on growths made in this country. One of the Kew specimens has four and another two large, deliciously scented white flowers, the lips of which are yellow at the base, and dotted with small purplish-crimson spots. During the season of growth this requires much more heat and moisture than are generally found sufficient for most Orchids; supply these conditions and success will not be difficult of attainment. *E. esolobellum* from Guatemala and Honduras is a striking plant, with pleasantly-scented flowers, borne on a long straggling panicle; the sepals and petals, about 1½ in. in length, are greenish at the base and purple upwards; the lip is straw-coloured, bordered with yellow and streaked with rose. *Oncidium sarcoodes* from Brazil has pseudo-bulbs and leaves like those of *O. pubes*, but the flowers, which are produced freely on short, stiff, erect, branched panicles, are large, very bright yellow, blotched with brown-red; this is a most showy and distinct species. *Olotoglossum nebulosum* is a most lovely species, with large pure white flowers, the basal part of the lip being striped and spotted with orange-yellow. *Sobralia macrantha* is a magnificent terrestrial Orchid from Mexico and Guatemala; the slender reed-like stems, about 4 ft. in height, are crowned with rather stiff-lined but very gorgeous, rich purple, aromatic blossoms, above 6 in. in diameter. *Brassia Lawrenceana* is a splendid Brazilian epiphyte with pale golden-yellow flowers, copiously barred and blotched with reddish-brown; the very long, narrow sepals and petals impart a peculiar aspect to the pendulous racemes. *Phalaenopsis Lüddemiana* is represented by a very finely coloured variety, the amethystine tint being very conspicuous; this nicely-scented species was introduced from the Philippines some years ago by Messrs. Low & Co. *Vanda camellata*, also from the Philippines, is hardly showy enough for general cultivation; the flowers, which are produced in long, loose, erect racemes, are pale yellow, streaked with dull pale red. *Aerides affine* var. *roseo-superbum* is a very charming plant, with long drooping spikes of brilliant rosy-pink flowers; it is a native of Sikkim. *Saccolabium curvifolium* is a neat little epiphyte with short, erect spikes of orange-red flowers. *Dendrobium rhodopterygium* is evidently nearly allied to *D. Parishii*, noted some weeks ago, but is altogether, from a gardening point of view, inferior to that species.†

**Tea Roses on North Walls.**—Mr. Taylor grows these very successfully on the north walls of numerous glass houses in the gardens at Longleat, the walls being at the present time covered with the healthy and vigorous growth of these plants. The soil being odd, when beds or borders of loam are prepared for the roots the soil is placed above the level and against the walls of the house. As many as over 900 good blooms of *Gloire de Dijon* have been cut from these walls in one day. Tea Roses in pots are also grown in these gardens, and in a remarkably successful way. They are always grown on their own roots from cuttings struck under a hand-light on a north border.—V.

**Rheum officinale and Genista sulphurea.**—These two useful plants may now be found in several London gardens. The former is rather earlier in the year than usual, established roots of it having already grown into large bushes, consisting of elegant, deeply-cut leaves; few, indeed, would take it for a species of *Rhubarb*, so refined and ornamental is its foliage. The *Genista*, which is in full bloom, is one of the best of the genus for shrubby decoration or for mounds or rockwork. Seedlings of it do not come true to character, but by grafting, good plants of it true to name may be secured. It flowers profusely for several weeks in April and May, and wherever wild gardening is attempted these two plants should be the first amongst large-growing subjects to be planted.—C. S.

**Trifolium uniflorum.**—This old but little known one-flowered Clover is, in my opinion, one of the gems of the *Poa* family, and it is a pity that it is so seldom seen in cultivation. It has a neat trailing habit, and its pink and white flowers, which are borne singly and are larger than those of any of the genus, are studded profusely over the surface of the plant, rendering it a very striking object. It is of the easiest culture, delighting in an exposed position on the rock garden and an open space on which to creep. The other day I observed a plant of it on a rockery at Kew bearing nearly fifty flowers.—W.

**Leucocjum hymalaicum.**—I have this rare and beautiful Snowflake in flower at the present time, but, unlike its congeners, its flowers are pure white, spreading, and nearly 1 in. across. Each bulb has thrown up three or four flower-stalks about 6 in. in height, each bearing two blossoms, which open in succession. It certainly deserves to be better known, and if it flowers in winter, as its specific name would lead one to infer, it would greatly enhance its beauty. I attribute the cause of my plant being in flower now to its being planted rather late last season. A sunny border and a light soil seem to satisfy its requirements.—A.

## TASMANIAN VEGETATION.

BEAUTY, as we know, though always pleasing, may differ in kind, and to those whose eyes are sated with the pervading greenness of English Grass and dense-foliaged Horse Chestnuts and Elms, let us suggest a voyage to this charming island, whose mountains, rivers, lakes, and forests will some day be the haunt of holiday makers seeking refuge from the dust and heat of an Australian summer. The view represented in the engraving may give some idea of the lavish beauty to be seen on the river Derwent, where the Hobart Town Botanic Gardens are situated—a happy spot, where both the gardener and the artist may find his fill of interest. Our point to-day, however, is the gardening; and it is curious to see how instantly the eye is attracted by the light, Grass-green foliage of the Swamp Gum tree that abounds in this neighbourhood, as the popular conception of an Eucalyptus that is exemplified by the well-known Blue Gum (*Eucalyptus globulus*), which, on account of its rapidity of growth and valuable timber, has been largely raised in Europe to the exclusion of other kinds more suited to our climate. The Swamp Gum (*Eucalyptus viminalis*), which is hardly if at all known in this country, is as green as a Weeping Willow when bursting into leaf, and casts no deeper shade than the slenderest Birch tree; it is evergreen, delights in a wet soil, such as we too commonly have to contend against, and therefore deserves trial in this country, where a bright green evergreen tree is a desideratum. In its native country it grows naturally in both colder and moister situations than the Blue Gum, which exists out of doors in England, so there is good reason for hoping that this would thrive in all but the most frost-stricken districts. Mention has already been made of some of the interesting plants in the botanic gardens, so to-day Tasmanian trees deserve their share of attention, from which they have been, it seems to me, unavailingly excluded on account of the tenderness of some. No greater contrast could be imagined than that which the colour and growth of the strange *Casuarina quadrivalvis*, the She or He Oak of colonists, growing on the rocky points that overlook the Derwent, make to the slender and green Swamp Gum. Low and spreading in growth, almost black in colour, its dingy drooping branchlets, hose in hose like a "Mare's-tail," and its clustering brown cones, give the idea of a tree that has been scorched by some bush fire, and exaggerates the green of the first mentioned tree; but it must be confessed that, unless there be a very great hankering after variety, it is a tree which we can leave in its own hemisphere. Other greener and more graceful *Casuarinas* there are, but none that are so likely to stand this climate. Another bend in the river, and a tree that in the distance looks like an Oak deserves remark; it is the *Acacia melanoxylon*, whose wood is much sought after and known by the name of Myall or Violet wood. Apart from its value as timber, it is a most desirable tree, with rather densely tufted spreading branches and evergreen leaves, for any garden in which it may thrive. To a passer-by, without books of reference and unaccustomed to such Austral vegetation, it is hardly necessary to say there are great difficulties in ascertaining the name of anything that he cannot himself

determine; and this is rendered still worse by the misleading names given by the colonists to plants and trees, without rhyme or reason, unless it be that at any cost they determined to retain the names familiar to them before leaving home. The native Honeysuckle (*Banksia australis*) and native Cherry (*Exocarpos cupressiformis*) are well-known instances of this discrepancy between names and things. When trying to master the chief features in such extensive genera as *Eucalyptus* and *Acacia*, there seem to be several misapprehensions also on the botanist's side, and I make this remark the more carefully because in one instance a very beautiful plant is in consequence little known in this country. Of all *Acacias* (here called *Wattles*) none is more beautiful when in flower than that called *A. mollissima*; in early spring it is one cloud of rich yellow sweet-scented blossom; and this is called the Golden Wattle, as well as other later and still deeper coloured kinds. Again, none is less attractive than *Acacia dealbata*, with its scanty pallid blossoms, which appear in summer, not in spring, and with its straggling growth and black bark; this is called the Silver or Black Wattle, in reference, it may be, to flower and bark in turn; therefore it is surprising to find that, botanically speaking, there is no difference between *Acacia mollissima* and *dealbata*. From a gardening point of view,

the two plants are as the poles asunder, for one is ornamental in the extreme, the latter is worthless, so that seed sent from Australia should not be the true *A. dealbata*, but *A. mollissima*. By one of Nature's freaks this beautiful tree is found sufficiently hardy to withstand an ordinary winter in England, but it flowers so early as to require a wall to obtain its lovely blossoms in anything like beauty. No one who has once seen this in perfection will ever, I venture to say, be without it either under glass (where it grows very tall) or in genial situations out of doors. Another tree

View from Botanic Gardens, Hobart Town, Tasmania.

from this part of the world, and that has really proved to be hardy, is the Huon Pine (*Dacrydium Frankii*), which grows in marshy ground towards the mouth of the Huon River; although slow in growth in its own country, it bids fair, from all accounts, to surpass its parents in stature when grown in this country. Like the Huon Pine, *Acacia dealbata* var. *mollissima* grows by the side of watercourses; hence, perhaps, its power of withstanding our damp soil and air. Wandering about day by day, now here, now there, the popular illusion that all Gum trees (*Eucalypti*) are alike vanishes as experience is gained; though the curious and somewhat ungainly habit of branching peculiar to this genus is common to all, yet the diversities of colouring in trunk and leaf, and the varying sizes of leaf and tree, are as great as can well be imagined, and afford endless grounds for admiration. Some trunks are smooth and columnar, without a branch for 150 ft., and in the autumn, when the old bark strips off, are as silver as a Birch; some are dove coloured, and some of a glowing Apricot colour; while in other *Eucalypti*, whose bark is persistent (for all do not lose their bark annually), the trunks are deeply corrugated and as black by nature as even London smoke could paint them. The leaves vary in shape from a perfect round to the slenderest whip-like growth, and in colour may be found of all shades, from the blue *E. globulus* to the brightest green,

or even primrose and red, in young growth, though most kinds are of a dull olive green. Who then can say that all Gum trees are alike? Even among so many there are but few that are really worth trying to grow in a garden, as mere existence can never be ornamental. I would, however, recommend all who wish to reproduce something of antipodean beauty to try at any rate *Eucalyptus amygdalina*, the loftiest and most colossal of Gum trees, which has been measured and found, I am told, to be in one instance 460 ft. in height, and it grows at cold elevations; then there are the Mountain Gum (*Eucalyptus Gunni*), a lofty tree, though rarely reaching more than 100 ft., and the small-growing but large-leaved *Eucalyptus coriacea*, that grows at an elevation where snow falls sometimes in summer (as I saw with my own eyes), both of which are likely to succeed in all parts of England. Then *E. viminalis*, with its green tasselled branches, and *E. obliqua* (stringy bark) come as a trifle less hardy, but as being so distinct as to make them also worth a trial, the first thriving in moist and deep soil, the latter in sandy and rocky positions. One thing seems certain, and that is that where *Eucalyptus globulus* is found to exist all these will thrive and prove ultimately ornamental; while one great attraction they all possess must not be overlooked, namely, that all give out a pleasant and aromatic scent which will add a charm to another sense than that of sight, and recall to those who have had the pleasure of enjoying it the health-giving atmosphere of an Australian or Tasmanian forest. E. H. W.

**Flora of Corfu.**—Bulbous plants form an important item in this flora. Crocus Boryi, out of flower, was extremely abundant on all the higher ground I visited, accompanied by several species of Romleas, but I cannot ascertain that any other species of Crocus occurs on the island, and I think that some error must have crept into Dean Herbert's notes in the "Botanical Register," where he states that seven species, some of them vernal, are indigenous. The four species, *canellatus*, *Boryianus*, *hadriaticus*, and *sativus* (?), known to grow in the neighbouring islands of Santa Maura, Cephalonia, and Zante, are autumn flowering. Narcissi were abundant, but out of flower. The prevailing species seem to be allied to *papyraceus*, but I failed to identify *N. corcyrensis*, figured by Herbert in his *Amarylhidaceae*, which is special to the island. I also found *Iris tuberosa*, and on the flanks of Santa Deka another elegant species, with narrow Grassy leaves and pale blue flowers; several species of Muscari, a *Bellevalia*, *Hyacinthus orientalis*, one or two *Colochicums*, *Ornithogalum exscapum*, and a number of *Orobidhs*. Amongst the other prevalent plants were *Phlomis frutescens*, *Anemone stellata*, *Geranium pyrenaicum*, and a very conspicuous *Saponaria*, allied to *S. calabrica*, but with larger flowers. *Lithospermum purpureo-cœuleum* and several other conspicuous *Boraginaceos* plants.

**Plants Found on Mount Hymettus.**—Athens is environed at a little distance by a series of stony mountain ridges, reaching to about 3500 ft. in height, including Parnes, Corydallus, Pentelions, and Hymettus. The last-named mountain afforded me a most interesting botanical excursion, in which I was accompanied by Professor Ophanides' gardener. From Athens, crossing the classic Illyssa, we drove up the valley of the Eridanus, a small tributary stream, to the Syriani Monastery, whence we ascended the mountain on foot. The prevalent plants were *Arum Draconculas*, *Poterium spinosum*, *Euphorbia spinosa*, *Euphorbia Apios*, *Lloydia græca*, a charming little plant with the habit of a small *Stellaris*, several species of *Thymus*, *Arbutus Andrachne*, a striking shrub, with rich brown smooth bark, and also a smaller species. Crocus Spraneri (*C. canellatus*) and Crocus *levigatus* were most abundant all the way up the mountain. Crocus *sativus* græcos grows on the summit, but this we did not find. A small yellow sweet-scented Tulip occurred sparingly, and on the summit of the lower part of the ridge *Fritillaria græca* was fairly abundant. *Fritillaria tristis* was also indigenous to Hymettus, but I am told has not been recently found.—G. MAW, in "Transactions of Botanical Society of Edinburgh."

**Alyssum saxatile compactum.**—This is somewhat late in coming into full beauty in spring, but it makes up for the delay by a glorious mass of flower such as is not excelled by any yellow-flowered plant in cultivation. Large clumps of it in mixed borders have a striking effect. Cuttings inserted under hand-lights in a shady position in June make useful little tufts for bedding purposes the following year, and if left undisturbed for a few years, form gorgeous masses of flower from the middle of April to the end of May.—J. GROOM, Henham.

## THE FRUIT GARDEN.

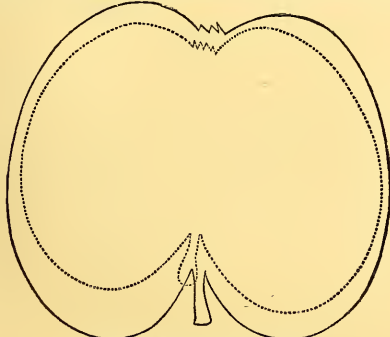

### TAN MULCHINGS FOR STRAWBERRIES.

STRAWBERRIES are to many the great fruit crop of the season, and to all they are a crop much appreciated. Few things mar the pleasure of eating and gathering them more than slugs, snails, and worms. These nestle beneath the leaves or under the mulchings; and just when the fruit begins to ripen and to give forth its luscious odour, out crawl these pests and fasten upon, disfigure, or devour them. It is thus impossible to gather and eat the fruit off the plant—by far the best mode of enjoying it—with pleasure. In any case the disfigurement and destruction of many of the finest fruits become a serious matter, and it may be almost wholly prevented by the following simple expedient: Give the plants at once several overhead dressings of equal parts soot and lime, covering the entire ground between the rows and the plants, and sprinkling freely on and around the crowns. The best time for these dustings and sprinklings is early in the morning or late in the evening. At either season the slugs and snails will be on the move, and caught with the hot, bitter dressing in the most defenceless condition. The first dressing warns off, the second disables, and the third kills them. This is a fair mode of attack; it gives the pests a chance of life. If they have not sufficient sense to take a first warning, they must take the consequences. Twelve or twenty-four hours' grace may be given between the dressings; and the strength of the latter should be cumulative—a slight warning dust at first, then a heavier dose, to be succeeded by a final killing application. For the last dressing double or treble the proportion of soot to lime should be given. Soot is one of the best possible manures for Strawberries, giving that size, substance, and colour to the leaves which is the surest sign of vigour. In about a week after the last dressing, unless rain has fallen in the interval, the plants should receive a heavy overhead drenching. This clears the crowns and leaves and renders the soil uncomfortable for worms, woodlice, earwigs, or other Strawberry-loving creeping insects that may be present. No living thing likes soot or lime, and the mixture is still more nauseous and disagreeable to them. In a few more days, and when the surface gets a little dry, a cleansing dressing of rather fresh tanner's bark may be put on about 1½ in. thick. This is also very distasteful to insects, no snail, slug, or worm remaining in or near it if they can help it. After a few washings it gets so clear of tannin, as not to taint the fruit that lies on it to ripen. The Strawberry plants also seem to thrive under the tan exceedingly, as it keeps the moisture and strength in the soil, though it probably adds but little to the latter. It has another great merit. If it be useful, as it often is during dry weather, to water the plants during their swelling stage, the tan speedily presents a dry surface again for the fruit. This quality of rapid drying and of a rough, hard surface is equally useful during a rainy time through the ripening period. In a word, tanner's bark is one of the cleanest and safest mulchings for Strawberries. Softer materials, such as short Grass litter, waste hay, half rotten straw, &c., yield to the wet and allow the fruit to sink into them, to their sudden and complete destruction, while tan is almost equal to tiles or pebbles in providing a hard, clean bed for the fruit. It is, in a word, one of the cleanest and best dressings for Strawberries, having powerful anti-insect, and also anti-rotting, qualities. D. T. FISH.

### THE AMERICAN NEWTOWN PIPPIN.

AN early March issue of THE GARDEN contains a disparaging paragraph in relation to this famous Apple, which, as an American fruit grower, residing in a favoured locality for its growth and general perfection, I can scarcely allow to pass unnoticed. Not merely from any apt incentive of special fitness do I assume the rôle of its defender in this particular instance, but wholly from a sense of a sort of wounded national pride, and as a simple act of pomological justice; for we certainly are very proud of the Newtown Pippin in America, and feel very bold about it too, as we challenge the world to produce its equal. And I need scarcely add that this peculiar pride has of late been duly respected by a very large number

of appreciative English people, as our increased annual shipments to British ports will fully show. "C. G." and his friends were, he says, greatly disappointed in the flavour of the half-dozen specimens given them by a friend, and he adds that they were considered inferior to several home varieties. I am certainly obliged to him for his care in satisfying himself as to the accuracy of his samples, and, assuming them to have been genuine, can only account for his disappointment by the further assumption of their general imperfection and exceptionally poor quality, arising from unnatural conditions of growth, which is highly probable, from the fact that the past season proved most unfavourable for Apples in this country, and our entire crop was defective and inferior; our Pippins especially so. And, in addition to this, our crop of Pippins being small, and English demands for them being correspondingly greater than usual, our buyers and shippers sorted less closely; "culs" found favour where in former years choicer fruits were tossed aside. From these facts, then, as I know them to be, you can readily deduce ample reasons for the general inferior condition of our Pippins sent you last year; and in the light of these statements your correspondent will, I trust, withhold further censure. This season we hope to send you much better fruits, although you may not pay us so much for them, as our crop will doubtless be larger. For, strange as it may appear, we often do pay the highest price for the poorest quality, and with less murmuring too. I also notice in your

Two forms of Newtown Pippin Apple.

columns other and similar reports of this Apple as received in England last season. They are, of course, not always properly packed for long shipments; and then too many of our sorters and shippers have more guile than conscience, and in various kindred ways English buyers are doubtless cheated and disappointed in the purchase of this American Apple; but, remember, never in a well-grown, genuine Newtown Pippin Apple as it grows here. To enable your readers to identify this fruit on all occasions, I here furnish an outline drawing and an accurate description of it. In size it varies from medium to large. Some of our pomologists were formerly inclined to recognise a sub-variety, but it is now considered as only one, modified by various circumstances of growth. The larger outline is the more common shape; flattish round, angular; stem short; cavity rather deep; smooth, yellow, or greenish-yellow, often with a ruddy red cheek to the sun, shading off to a faint brown. The dotted outline represents another form to which it sometimes approaches in less favourable localities and under poorer culture. The colour is then a brighter green, and the flavour and texture inferior. In well-grown fruit the flesh is fine, very firm, crisp, and juicy, with a rich, sprightly, highly aromatic flavour, quite unapproachable by any other Apple, and a peculiarly fragrant aroma that strongly appeals to the alimentary senses, and courts the favour it deserves. The fragrance arising from an open barrel of this fruit will sufficiently describe what I mean. With us it begins to arrive in fine eating condition in January, and continues thus all through the winter and spring, and even into summer where the conditions of growth and preservation have been favourable. The tree grows slowly and bears shyly while young, but when

greater age is attained it becomes vigorous and very productive under good soil and management. Our bearing trees in the Apple season here on the Hudson are a sight well worth seeing. The bark is rough, shoots thin and flexuous, yet hard and mature, standing our winters perfectly. This Apple was formerly considered quite unreliable, unproductive, and unprofitable, but of late years it has grown better, our orchards are older, and in this district it is now the most profitable Apple we have, always commanding the highest price. Its great firmness and solidity peculiarly fit it for shipping purposes, and it is eagerly sought annually for export purposes. The variety originated in Newtown, Long Island, whence its name, and its greatest perfection is attained in its native locality, and here along the Hudson River. H. HENDRICKS.

Kingston, N. Y., U.S.A.

### INARCHING VINES.

THIS is the best time of the year to inarch Vines. The growths will unite in ten days now, when the generality of wood is tender, green, and full of sap. I inarched some a few weeks ago, and never had them unite quicker or better before. Some who recommend inarching are very particular in their instructions as to making both cuts the same size, in order that the edges and bark may fit exactly, but I have proved this to be unnecessary. In inarching a small Black Hamburg on a Muscat the wood of the former was not a quarter so thick as that of the latter; consequently, it was impossible to make both cuts the same size. The slice of the Muscat wood was some  $\frac{1}{4}$  in. wide or more, while that of the Hamburg was less than  $\frac{1}{4}$  in.; each cut was, however, about 2 in. in length. The cut in the Hamburg was placed against the centre of that of the Muscat. Both were then bound moderately firm together during their whole length with a piece of Raffia Grass, and when this was removed, ten days afterwards, the two were firmly united together. I do not think, however, that this would succeed so well by-and-by when the wood begins to ripen, as then it takes much longer to grow together, and if it be left too late in the season until the sap begins to descend it is difficult to effect a union at all. Hence my reason for calling attention to it at the present time. Perhaps some inexperienced amateur Vine grower may not understand what is meant by "inarching." Let me explain. Inarching is a form of budding, or rather grafting, one kind of Vine on to another, and, when done at the proper time, it is much better than either budding or grafting. The Vines generally inarched are those which are not satisfactory as regards their fruiting qualities, and on which we always put a free-fruited sort. In other cases we try one Vine on another by way of experiment, as some Vines which do well enough on their own roots do still better on the roots of others. The Black Hamburg, for instance, never fails to fruit on any other sort of root, and, provided other things are equal, it may always be fully depended on. For this reason those who have inferior fruiting kinds of Vines will never err in inarching Hamburgs on them. On the other hand, the Black Hamburg is one of the best stocks or roots on which to try all kinds of Vines; and any kind of Vine, new or otherwise, should never be thrown away until it has been tried and found to fail on the Black Hamburg.

As will be understood from what has just been stated, inarching consists in removing a small slice from two Vines shoots between two leaf-joints, and binding the cut surfaces together face to face. The scion should be a plant either raised from an eye or cutting this or last season; it does not make much difference, though the young Vine be a very small one, because as soon as ever it catches hold of the stock on which it is inarched it develops rapidly. I prefer the young Vine to have been rooted from an eye early in spring, and grown on until it is 3 ft. or 4 ft. high, when it is in prime order for inarching. Of course Vines raised like this are grown in pots, and they should be kept in them until the scion has become united to the stock. The part at which the connection is made should be at the first shoot from the ground, or as near this as possible. Sometimes the Vine in the pot can rest on the ground while the scion is being connected with the stock, but where there is nothing convenient on which to rest the pot, a piece of twine or wire may be put round it so as to suspend it

to the trellis. When the inching is accomplished now with soft green wood, the young Vine in the pot may be cut away six weeks after the operation; it should be cut close below the union, and, in case of accident, a piece of soft matting may be kept tied round the joint throughout the season, but this must be looked to frequently to prevent the wood from being tightened or injured thereby.

CAMBRIAN.

#### LIFTING VINES AND OLD FIG TREES.

THE Vines at Wimbledon House, which have, through defective borders and being infested with mealy bug, failed for years to produce satisfactory crops of Grapes, have lately been very successfully lifted and re-planted in fresh borders. In August, after the crop had been out, the roots in the inside borders were lifted, and the longest of them were shortened back. A new border was made, and the roots were re-planted. After this the Vines were kept growing as vigorously as possible until October, after which they ripened their wood and were pruned; they were then thoroughly cleansed, and the houses painted. In November the outside borders were re-made, and the Vines were then started into growth. I should have stated that the old canes, which are inside, were bent down, and that some 2 ft. or 3 ft. of their length were buried in the border, in order to induce them to throw out new roots, and also to leave room at the top of the house for new growth, and to admit light. This operation has proved highly satisfactory, as the buried portions of the stems have emitted abundance of healthy young roots, which no doubt prove a great support to the Vines. This year the latter are carrying a fair crop of fruit, and the laterals are allowed to grow at will. When the fruit is ripe, Mr Ollerhead proposes to remove it, and place the bunches in bottles of water; he then intends to cut down the whole of the Vines close to the ground, and, by taking timely precautions, to prevent them from bleeding so much as to weaken them, it is hoped to get strong canes up this season which will bear a good crop next year. If this operation should prove successful, the whole of the Vineries will be thoroughly renovated, and that without interfering with the crops in any great extent.

Two of the houses in the same garden, which have hitherto been used for plant growing, have been filled with Fig trees. These were lifted from the open ground in December, all roots being cut off to within 2 ft. or 3 ft. of the stem, and planted inside the houses in square holes about 2½ ft. or 3 ft. deep and 4 ft. each way. These holes have been concreted all round the sides, so as to prevent the roots from getting so far as to induce the plants to make growth at the expense of fruit. When lifted, the trees bore a quantity of fruit, which afterwards swelled, but, owing to an accident which befel the heating apparatus, sufficient heat could not be kept up to ripen them thoroughly. The trees themselves, however, have experienced little or no check by the removal; they look perfectly healthy, and, being well set with small fruit, a good crop is anticipated in the autumn. Next season, when the plants have got better established, these will be two of the best Fig houses with which we are acquainted; the trees, indeed, already cover the whole of the circular roof.

C. S.

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**The A Bec Peach.**—In THE GARDEN (see p. 282) Mr. Coleman gives an excellent list of Peaches, classified to suit distinct seasons, and which was doubtless appreciated by many, as, from experience, I know that it is by no means uncommon to find mid-season and late varieties in positions where early sorts would have been far more satisfactory, and *vice versa*. I have looked through many good fruit lists and catalogues, and have failed to find in any of them the variety so highly spoken of under the name of A Bec. Will Mr. Coleman kindly inform us where it is obtainable, as good varieties for early work are not very numerous, and growers would doubtless welcome any really valuable addition to this class?—JAMES GROOM, *Henham*.

**Norfolk Beefing Apple.**—Now that the Apple-room shelves begin to present a somewhat bare appearance, it may be worth while making a note of any sort that may be relied on as fit for kitchen use after May 1, and foremost among these I always find the Norfolk Beefing. We have a few trees of it which are almost certain to carry a fair crop every year, and, as regards keeping, we have some of the fruit now in good condition that were blown off the trees last autumn, and, although bruised, the decayed portion has not spread; in fact, they seem to defy decay, preferring rather to dry up. Where Apples are in request as late as May and June this variety should not be overlooked.—JAMES GROOM, *Henham*.

#### GARDEN BOTANY.

(Continued from p. 424.)

**DEFINITION OF A LEAF.**—A leaf consisting of two distinct parts—a stalk (petiole) and an expanded or flattened part called the blade (fig. 131)—is called a petiolate leaf; when the blade is seated immediately on the stem and devoid of a stalk, the leaf is said to be sessile (figs. 132 and 133).

**DURATION OF LEAVES.**—The leaves of perennial plants—that

Fig. 131.—A branch of *Alnus glauca*; an example of a plant having stalked (petiolate) leaves. Reduced.

is to say, plants whose span of life exceeds one season—are evergreen or deciduous, according as they persist or hang on the plant in a living state during the winter, or fall off in the autumn. All our hardy fruit trees and most of our forest trees, excluding the Pine family, belong to the latter

Fig. 132.—Couch Grass; an example of a plant with stalkless (sessile) leaves.

Fig. 133.—Primrose; another example of sessile leaves.

category. Persistent or evergreen leaves remain attached only till those of the succeeding year are expanded, as in some species of Privet, Enonymus, &c., or for two, three, or more years. In *Arancaria imbricata* they persist a great number of years, and in *Welwitschia mirabilis* they live as long as the plant itself, which may be a period of 100, 200, or more years.

**CONSISTENCE OF LEAVES.**—The substance and texture of leaves afford subsidiary characters useful in distinguishing

species; and some genera and even families are characterised by having leaves of a certain density. For example, the Crassulaceæ (Sedum, Echeveria, and Sempervivum), the genera Mesembryanthemum, Aloe, Haworthia, and many others are remarkable for having almost invariably thick, fleshy leaves. In many of the Cycadææ (Cycas, Zamia, and Encephalartos), they become hard and woody; in Palms they are frequently like parchment (pergamentaceous); and the leaves of the Common Laurel, Rhododendrons, and the India-rubber tree (*Ficus elastica*) are more or less leathery in texture, or what is termed coriaceous, as opposed to membranous (thin and not stiff), as the leaves of a very large proportion of British plants. Several other terms have been employed, but these three—fleshy, coriaceous, and membranous—qualified by adverbs of degree, are sufficient for all, except quite unusual conditions.

**VENATION OF LEAVES.**—The substance of the blade is traversed in various directions by more or less conspicuous lines of tissue of greater density than the intervening tissue, for

these the stout petiole terminates abruptly, and then divides in a radiate manner into relatively slender ribs answering to the folds of the blade. It is characteristic of monocotyledonous plants to have the veins running parallel to the midrib, as in the Gramineæ (Gynerium), Amaryllis, Iris, &c. The Aroideæ (Anthurium, Arum, and Caladium) offer a notable exception to this rule, having usually a distinctly netted venation. The venation of the leaves of dicotyledonous plants generally presents two distinct types, between the extremes of which there exist all intermediate gradations, it is true, but there is seldom any difficulty in assigning a leaf to its respective type. These two types or plans of venation are illustrated by figs. 135 and 136. In the Elm (fig. 135) the principal veins run from the midrib towards the margin, something like the plumelets of a feather; hence this kind of venation is designated pinnate venation. The principal veins in the leaf (fig. 136) radiate from the apex of the petiole, forming a radiate or palmate venation. Sometimes the two types of venation are combined in the same leaf; it is partly so in *Sterculia platanifolia*, and

Fig. 134.—*Ouvirandra fenestralis*, in which the blade of the leaf is almost reduced to the lattice-like venation. About quarter of natural size.

which it forms a kind of framework or support. This network of stronger tissue is spoken of as the venation of the leaf, not, however, because its ramifications or veins have a function analogous to that of the veins of animals. The singular Madagascar water plant, *Ouvirandra fenestralis* (fig. 134), has its leaves almost reduced to the lattice-like venation. Besides what is termed the venation, the blade is commonly crossed longitudinally by a thicker rib continuous with the petiole, when there is one; this is the midrib, which is usually more prominent and thicker than the veins. Sometimes the venation itself is very prominent throughout all its ramifications. The leaves of the great Water Lily, *Victoria regia*, have the veins enormously developed on the under side, forming a remarkable and beautiful framework of great strength. The leaves of most Melastomaceæ (*Cyanophyllum*, *Medinilla*, *Miconia*, &c.) have two, four, six, or more lateral nerves, as they are commonly called, which are often nearly or quite as prominent as the midrib; and the same thing is of frequent occurrence in the genera *Smilax* and *Dioscorea*. Another deviation is offered by the fan-shaped leaves of some Palms. In

very strikingly so in the Horse Chestnut (fig. 137), the primary veins radiating from the petiole, and the secondary ones diverging from the primary.

**SIMPLE AND COMPOUND LEAVES.**—The blade of leaves presents an infinite diversity of forms, all of which may be referred to two principal types, termed simple and compound. A simple leaf may have a blade that is quite undivided and with an unbroken margin, as in fig. 138, or it may be more or less cut or divided, as in fig. 136. A compound leaf consists of separate pieces (leaflets) jointed to the petiole, or midrib, or lateral branches of the latter, as in *Acacia* (fig. 139). Some simple and compound leaves approach each other very closely in external appearance; but if the parts of the blade are not separately jointed (articulated) to the petiole or midrib, as the petiole is to the branch, the leaf is termed simple. Unfortunately, this rule is not strictly followed by botanists, many of whom describe leaves as compound if they are divided to the petiole or midrib, even if the parts are not jointed to the petiole or midrib, and never separate from them.

**FORMS OF SIMPLE LEAVES.**—It is not our intention to attempt

to describe all the varieties possible that leaves present, but rather to direct attention to the principal variations of the two types briefly defined above. A large number of the terms employed to designate the shape, &c., of leaves, petals, &c., retain their generally accepted significations, and are, therefore, intelligible to the reader without illustration or explanation. For example, with regard to the general outline of leaves, petals, &c. (always, be it observed, without reference to indentations or divisions), the terms round, elliptical, oblong, oblique, and triangular belong to this category. And when any two of these or other terms are coupled with a hyphen, as oblong-elliptical and oblong-oblique, the combination either denotes that the shape is midway between that defined by the

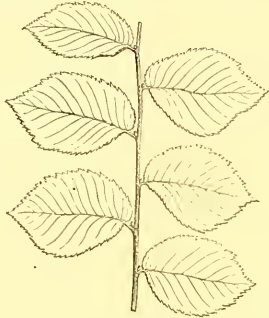

Fig. 135.—Leaves of Elm, with pinnate venation.

terms separately, or that the leaves, or what not, vary between the two extreme shapes indicated. Then, with respect to the apex or tip of a leaf, leaflet, or petal, the terms rounded, blunt (or obtuse), and acute are easily understood. Occasionally a little ambiguity may arise from using the same term to denote a figure and the configuration of a solid. For instance, leaves are described as oblong, and the same term is sometimes applied to a cylindrical seed vessel or leaf, though, of course, only to indicate the outline of its medial plane. On the other hand, there are some Latin and Greek and dog-Latin terms in use

Fig. 136.—Leaf of *Sterculia platanifolia*, with palmate venation.

which require explanation. Most of these terms have been selected or coined to replace cumbersome compounds; they and others have a conventional meaning attached to them. Thus acicular (needle-shaped), cordate (heart-shaped), subulate (awl-shaped), sagittate (the shape of an arrow-head), lanceolate (the shape of a lance-head), reniform (kidney-shaped), &c. In the following paragraphs the applications of these and other useful terms will be explained and illustrated; but it is necessary to remind the reader that mathematical precision, or anything approaching it, is not aimed at in botanical descriptions, either in figure or size, because the parts of all plants are subject to considerable variation in these respects, depending upon the age and vigour of the plant, and the external conditions under which it is growing. Thus the writer has collected perfect flowering plants, growing on a wall, of the

common Poppy (*Papaver Rhoeas*) not more than 2 in. to 4 in. high, whereas under ordinary conditions, as a Cornfield weed this species attains a height of as many feet. Where possible, descriptions of plants are based upon a number of individuals of average size and range of floral and foliage characters;

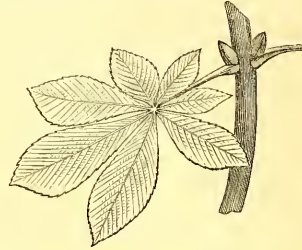

Fig. 137.—Leaf of Horse Chestnut, showing radiate and pinnate venation combined.

extremes, the result of extraordinary conditions, being left out of consideration. The descriptions of a vast number of exotic plants, drawn up often from single dried specimens, are very imperfect; and it is often necessary to compare fresh speci-

Fig. 138.—*Polygonum orientale*; leaves simple.

mens with the types themselves, to determine whether they are of the same species. This being so, the beginner must not be discouraged because he is unable to determine plants

Fig. 139.—*Acacia grandiflora*; leaves compound.

from descriptions alone. After this short explanatory digression we will review some of the principal modifications of the simple leaf. Already mention has been made of scale-leaves, with which some buds are clothed, but there are other

rudimentary leaves, of various degrees of development, which will be noticed under different heads, as phylloides, &c.

**NEEDLE-SHAPED LEAVES.**—One of the most important of the not very highly-developed forms of simple leaf is the acicular, or needle-shaped, like those of many of the Coniferæ (Pines and Firs, &c.), important because characteristic, more especially of this one family, and the antithesis of the flat-leaved plants. The acicular leaves of the Pines are in clusters or bundles of two, three, or five, sheathed by membranous scale-leaves at the base, the number being practically constant for each species. In the Firs, Junipers, &c. (fig. 140), they are clustered or scattered; and through the species of Abies, Podocarpus, Salisburia, &c., we arrive at a kind of leaf differentiated into blade and petiole. In the Cupressineæ, a tribe of the Coniferæ, the leaves are scarcely more than scale-leaves, being very small, closely appressed to the branches, and overlapping each other, or imbricate.

Fig. 140.—Subulate leaves of Juniper.

Fig. 141.—Petate leaf of Tropæolum; the petiole attached within the margin of the blade.

Fig. 142.—Mesembryanthemum acuminiforme, with acicular-shaped sessile leaves.

**LINEAR LEAVES.**—The term linear is applied to leaves, &c., which are many times longer than broad, and nearly the same width throughout the entire length, with the exception of the tip. The leaves of some of the Coniferæ come under this denomination, and it is the characteristic type of leaf of the large orders Gramineæ and Cyperaceæ, the Grass and Sedge families, which abound in nearly all parts of the world. Leaves of this type are usually sessile, and in the families named have a sheathing base. In true Grasses the sheath is split down one side, and at its top there is almost invariably a more or less conspicuous chaff-like scale called the ligule (fig. 143); in Sedges the sheath is closed. When the leaves are somewhat broader and curved, as in Iris and Gladiolus, they are termed ensiform or sword-shaped.

Fig. 143.—Millium multiflorum, showing the ligule at the base of the leaf.

**SUCCULENT LEAVES.**—Fleshy or succulent leaves (fig. 142) are almost endless in variety of form, as in the genus Mesembryanthemum, Crassulaceæ, &c., and some of these forms have special names which we shall not particularise. As already mentioned, the Aloe and Agave type is the most striking among succulent leaves.

**FLAT SIMPLE LEAVES.**—These may be separated primarily into those having entire (unbroken) margins (fig. 144), and those in which the margin is more or less deeply notched or lobed, or the blade deeply divided. When the indentations are only quite shallow in relation to the size of the leaf the latter is said to be toothed. There are three principal kinds of toothing. When the teeth are sharp (acute) and directed outwards the leaf is dentate (fig. 145); when the teeth are acute and directed towards the tip of the leaf, as in the Stinging

Nettle, it is serrate; and when the teeth are rounded, as in fig. 146, it is crenate. Simple, entire, or toothed leaves (or the separate leaflets of compound leaves or petals, &c.) may be referred to one or the other of the forms, or a combination of two or more of them. It will assist in determining the classification of such forms by observing first of all whether they are broadest below the middle, in the middle, or above the middle. The commonest forms broadest below the middle are the lanceolate (leaves of Antirrhinum majus, leaflets of Laburnum), ovate (somewhat the outline of an egg), cordate (leaf of Violet), hastate (Arum maculatum), and sagittate (common

Fig. 144.—Entire leaf of Ducus.

Fig. 145.—Dentate leaf of Saxifraga dentata.

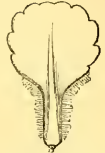

Fig. 146.—Crenate leaf of Saxifraga hirsuta.

Arrow-head). Of those broadest in the middle, it is only necessary to mention the names, as oval, elliptical, rotundate, and orbicular. When broadest above the middle they are, according to their outline, obovate, oblanceolate, obovate, &c.

W. B. HEMSLEY.

**Hoop-petticoat Daffodil** (*Narcissus Bulbocodium*).—The difficulty of flowering this charming little Daffodil in the open air in this country has often been alluded to in your columns. Imported bulbs of it flower freely and ripen seed the first year, but after that they disappear. Such, at least, has been my experience hitherto; but this year a batch of seedlings sown four years ago, raised in a box from home-saved seed and turned out somewhat carelessly in hot weather last June into a sunny border, have flowered freely. This is the more remarkable considering the exceedingly wet summer and winter which preceded this spring. Whether the plants have become sufficiently acclimatised to flower regularly in this climate remains to be seen. The Hoop-petticoat Daffodil is one of the most distinct of the genus, and worthy of some trouble to establish it as a free flowerer.—SALMONICEPS.

**Primroses for Waste Places.**—"A. P.," alluding to remarks made by me on this subject (see p. 407), seems to imply that I made no allusion to what he considers the most important point—the introduction into the places indicated of the garden varieties of the Primrose. Let me assure "A. P." that what he hints at was studiously avoided. My sole aim was to make a popular native more popular still by causing it to be introduced by tens of thousands into districts in which it might be a comparative rarity. I certainly had not the remotest idea of advocating the planting in wild and waste places, perhaps miles from a dwelling, what will barely in many places live in a garden. That a garden plant will thrive in a wilderness I do not doubt, but in such a case design is always apparent, and places must be very secluded indeed where these fine flowers would be allowed to establish themselves. A scarlet Thorn would appear absurd in a hedgerow of the snowy May; and a crimson Primrose in a wood among our national flowers would remind one of the lady "who painted her face and tired her head."—THOMAS WILLIAMS, *Ormskirk*.

**Wallflowers in Paris.**—Amongst the many rural elegancies that make Paris the freshest and brightest of cities, we must give a large place to the Wallflower. We see Wallflowers in plenty in all parts of Europe, and even in London they are not unknown. But really you must go to Paris to see Wallflowers just right, and to learn thereby how cheap is beauty and how universal is the medicine of gladness for the single eye that is full of light. On a sunny day in April you may see in the Parc de Monceaux, and other such places, what at a moderate distance look like beds of crimson Azaleas; but when you reach the spot you find them to be beds of Wallflowers, solid with bloom, quite uniform in height, and, as the gardeners say, "as neat as if turned out of a bandbox." Almost invariably the sorts employed are the deep blood-red and the bluish-purple, all the lacy blues being repudiated, and the best yellows being scarcely anywhere represented. These blood-reds and purples are mixed throughout in equal proportions, and the near view of them is as enjoyable as the distant view is surprising. The odour diffused adds very much to the charm of the golden-green leafage of the trees overhead, for wherever these fiery masses of Wallflowers are to be seen there are also trees enough to make a bower of pleasantness to drive dull care away. How simple and inexpensive are the best pleasures!—"S. H.," in "Gardeners' Magazine."

## PLATE CXXVII.

## TROPÆOLUMS.

(WITH FIGURES OF T. POLYPHYLLUM AND T. SPECIOSUM.)

Drawn by MRS. DUFFIELD.

TROPÆOLUMS are popularly known as Nasturtiums, and this is the reason why: Men first studied the properties of plants and named them accordingly. Thus it came to pass that *Tropæolum minus* was associated with Land Cress (*Lepidium sativum*) and Water Cress (*Nasturtium officinale*) under the generic name of Nasturtium, and the *Tropæolum* was called *Nasturtium indicum*, with the English name of Indian Cress. It is true that *Tropæolums* possess anti-scorbutic properties as well as Water Cress, and it has been observed by a writer on the useful plants of Brazil that *T. pentaphyllum* is one of the very few plants of the excessively rich Brazilian flora that possess this valuable property. The genus *Tropæolum* comprises about forty species, all natives of South America, two or three perhaps extending to Mexico; but this is doubtful, because several species are commonly cultivated either for use or ornament, and may in this way have been introduced north of the Isthmus of Panama. They are almost confined to the mountainous region on the western side of South America, from New Granada to Chili. Three species are natives of Brazil, and one is widely dispersed in Buenos Ayres and Uruguay. Very few of them descend into the tropical zone, and therefore they do not require great heat, which is rather unfavourable to them. On the other hand, the first frost cuts most of them to the ground. They love a half-shaded situation, and all of them will succeed in the open air with us in the summer. It is quite unnecessary to dwell on their merits as ornamental plants, because three or four species and their hybrid varieties are familiar and fully appreciated. We would only call attention to the fact that there are many other species equally, or even more, attractive than those better-known ones. A glance over the following brief descriptions will afford an idea of the richness and variety of the genus, of the brilliant and singular combinations of colour in the flowers, and of the diversity of foliage they present. There are annual and perennial species, and the latter may be sub-divided into two groups, the one with fibrous and the other with tuberous roots. The rapid growth of the annuals, *T. majus*, *minus*, &c., is proverbial, and their hardiness in a temperature above the freezing point, as well as their indifference to the nature and quality of the soil, recommends them where anything unsightly is to be hidden. Some of the tuberous-rooted species are cultivated for their tubers, some of which attain several pounds in weight, and form an important article of food in their native country. They are not all of them of quite so easy culture as the annual species, at least in our climate, and some persons fail altogether, whether owing to their unskillfulness or other causes it is hard to say. The two species represented in the accompanying coloured plate belong to this section, and it is especially concerning them that various persons have communicated to THE GARDEN from time to time the results of their experience, their methods of treatment, &c., to which we may refer the reader desirous of learning something of their culture.

*Annual Species, or Species Treated as Annuals.*

**Small Indian Cress** (*Tropæolum minus*) is a more elegant, but less showy, plant than the large Indian Cress, being smaller in all its parts. Besides the difference in size, it is easily distinguished from the more generally cultivated *T. majus* by its acute, almost bristled-pointed petals, and by the principal veins of the leaf, usually extending beyond the blade in the form of small teeth or soft bristles. It was introduced from the West Indies into Spain soon after the discovery of America, and was in cultivation in this country as long ago as 1596, being one of the few New World plants included in Gerard's catalogue of that date. It is true that Mr. Daydon Jackson, in his reprint of the catalogue, identifies Gerard's plant with *T. majus*, though on what grounds does not appear. The figures in Gerard's "Herbal," and also that in Parkinson's "Paradisi in sole Paradisus Terrestris" (1650), agree with *T. minus*. This plant was a great favourite with both of the writers named. Parkinson says, "It is of so great beauty and sweetness withal, that my Garden of Delight cannot be unfurnished of it." He continues: "The whole flower hath a fine small scent, very pleasing, which, being placed in the

middle of some Carnations or Gillyflowers (for they are in flower at the same time), make a delicate Tussimusie, as they call it, or Nosegay, both for sight and scent." It is widely dispersed in America, where it is at home, and now also in many other warm countries. Doubtless it originally spread from the mountains of the western side of South America. Of trailing habit and annual duration. Figured in the Bot. Mag., t. 98, in the year 1798, when, it is stated, it had been, to a great extent, displaced by the more showy *T. majus*.

**Large Indian Cress, or Nasturtium** (*T. majus*).—Too well known to need description, even in its primitive varieties, and as one of the parents of the beautiful hybrids. Much larger in size, and climbing by means of its leaf-stalks; it likewise differs from the preceding in the broad petals being rounded at the top. From its coarser, *T. Lobbianum*, and co-parent of many garden hybrids, it may at once be distinguished by the absence of hairs on the leaves and outside of the flowers. According to Linneus, this species was introduced into Europe in 1684, and Aiton states that it was introduced into this country by Dr. Lumley Lloyd in 1686. Also an annual and a native of Peru; and one of the earliest plates (23) in the "Botanical Magazine."

**Lobbs's Tropæolum** (*T. Lobbianum*, Bot. Mag., 4097; syn., *T. petiolorum*, Benth.).—This beautiful species was collected about the same time both by Lobbs and Hartweg; but to the former, it appears, belongs the honour of having introduced it into our gardens. It is a native of the mountains of Colombia, where Lobbs detected it in 1843, and sent it home to Mr. Veitch, of Exeter. An annual of vigorous growth and climbing habit with petalate leaves, similar to those of *T. majus*, but hairy. The flowers of the original variety are not so large as those of the later species, and they are hairy outside. Moreover, they also differ in the limb of the three lower petals being toothed and fringed, and not merely the stalk fringed.

**Canary Creeper** (*T. aduncum*, Bot. Reg., t. 718; syn., *T. pergrinum*, Bot. Mag., t. 1351).—Undoubtedly the favourite of the genus, a distinction it fully merits, as it is almost without a rival for window and trellis work where lightness and elegance are required. Indeed, one might say that it is peerless among yellow flowers. The yellow is of the most pleasing shade, having more of the green than the red element in it. Its precise home is uncertain, as it is now spread from Mexico all through the eastern side of South America to Chili; but it has doubtless spread from the Andes. Aiton states that it was originally introduced into this country in 1775, by B. Bewick, Esq.

*Perennial Species.*

**Tricolor Tropæolum** (*T. tricolorum* (Sweet), Brit. Fl. Gard., t. 270).—There seems to be no reason why *T. azureum* should not be as easy to cultivate as this familiar species, which one may see in perfection in almost any garden. Its numerous flowers, which have an almost vermilion-red calyx tipped with purple, and small yellow petals, are exceedingly attractive, associated, as they are, with small, elegant, five-lobed leaves, borne on thread-like stems. This species seems to have been first sent to this country by a Miss White, daughter of the Vice-Consul at Valparaiso, in 1827. It is commonly treated as a greenhouse or window plant, but it will succeed out-of-doors in a warm situation. The first tubers received in this country were sent to Chelsea Botanic Garden, and Sweet records the result of their treatment. Those planted in pots and placed in the hot house did no good, but grew up very weakly and soon dwindled away. Some others planted in a sandy soil by the side of a wall in the open ground grew luxuriantly and ripened abundance of seed. They reached a height of 10 ft., and were covered with a profusion of flowers.

**Blue Tropæolum** (*T. azureum*, Paxt. Mag., ix. 241).—After Mr. Miers published the description of this species in the narrative of his travels in Chili, everybody was anxious to obtain it, to associate with the yellow and red-flowered species; but some time elapsed before lovers of flowers were gratified with a sight of a living flowering plant. William Lobbs met with it near Valparaiso in February, 1842, and sent living plants to Messrs. Veitch, who exhibited a flowering specimen the following September, for which the Royal Horticultural Society awarded them the large silver medal. In spite, however, of the novelty and undoubted beauty of this species, it seems to experience a lingering existence in our gardens, and most persons who see it are disappointed in their expectations of what a Blue Tropæolum would be. Most likely some cultivators have succeeded in developing its full beauty, but I have seen only very weakly plants bearing rather pale blue flowers. To a certain extent this seems to have been the case with the first plants introduced, for Lindley states that this remarkable plant has much deeper-coloured flowers in a wild state than it has yet produced under cultivation. It is by no means so easily cultivated, there can be no doubt,

TWO HARDY TROPAEOLUMS. (T. POLYPHYLLUM AND T. SPECIOSUM.)

as most of its congeners, though it can hardly be beyond the skill of the fraternity. Being a native of the central provinces of Chili, it is not so hardy as most other species, and it is always a slender, delicate plant; therefore, not a gross feeder. It is a very slender, intricately-branched plant, growing 4 ft. or 5 ft. high in its native country, and having small, long-stalked leaves, with the blade deeply divided into four or five variously-shaped, but usually very narrow, lobes. The solitary blue flowers are about 1 in. in diameter, borne on thread-like stalks a little longer than the leaves, and have five equal-spreading, two-lobed petals. Gay describes this as one of the most elegant species of the genus, with flowers of an azure blue.

**Short-spurred Tropæolum** (*T. brachyceras*, Bot. Mag., t. 3851).—A slender climber with the habit and foliage of the Tricolor Tropæolum, and yellow flowers streaked with red, and about  $\frac{3}{4}$  in. in diameter. The petals are almost equal in size and uniform in shape and entire, except a notch at the top. The spur is very short, and hidden from view when the flowers are erect. A native of Chili, introduced by Mr. Cumming in 1840; and it is one of the commonest about Santiago, Valparaiso, &c., climbing over shrubs several feet high. It is called by the natives Flor de Perdiz, or Partridge Flower.

**Sir James Smith's Tropæolum** (*T. Smithi*, Bot. Mag., t. 4385).—A distinct and beautiful species with petalate, deeply five-lobed, glabrous leaves on long stalks, and red and orange flowers of medium size. The lobes of the leaves are broad and distant from each other, and the whole leaf 2 in. to 3 in. in diameter. The calyx is ruby-red, with the exception of the lower half of the spur, which is green; and the finely-fringed petals are orange veined with red. One of the most desirable species, widely dispersed at great altitudes in the mountains of the north-western part of South America. This is another of William Lobb's introductions. How many fine plants this one indefatigable collector sent home, we can form some idea from the number of species of this genus alone with which he enriched the gardens of Europe.

**Violet-flowered Tropæolum** (*T. violacea*, syn. *T. azurea*: Bot. Mag., t. 3985, not of Miers).—Closely allied to *T. azurea*, with which it has been confused, and of which it may possibly be only a variety. It is slender in habit, and the leaves have unequal lobes, differing in this particular from typical *azureum*. The flowers are of a paler hue, and the petals are two-lobed and minutely toothed on the margin, not entire, as in *azureum*. It grows among bushes in half-shady places in 30° to 32° lat. in Chili.

**Moritz's Tropæolum** (*T. Moritzianum*, Bot. Mag., t. 3844; syn. *T. Funchi*).—A very handsome species, of climbing habit, and quite glabrous in all its parts. The large petalate, rotundate, obscurely-lobed leaves attain as much as 5 in. or 6 in. in diameter, and are borne on long stalks. Each of the shallow lobes of the leaf has an orange-coloured callous tip. Flowers medium size, bright red and orange, the petals nearly equal, and very deeply fringed. Certainly one of the most beautiful of greenhouse species. It is a native of New Granada, and was introduced into England about 1840.

**Esculent Tropæolum** (*T. tuberosum*, Bot. Mag., t. 3714).—One of the most ornamental of the hardy tuberous-rooted Tropæolums, but it has proved rather a shy bloomer in many places where it has been tried. It is a tall climber with succulent stems, roundish petalate, lobed leaves about 2 in. or 3 in. across, and rather small red and orange flowers. The lobes of the leaves are broad and almost truncate. The colouration of the flowers is very beautiful, the calyx, with the exception of the green tip of the spur, being a deep red, and the entire petals, which scarcely exceed in length the lobes of the calyx, are of a rich golden yellow, veined with black. This species is, or was, commonly cultivated in Peru at an elevation of between 8000 ft. and 11,000 ft., the tubers being a daily article of food. Mr. McLean introduced it into this country in 1838.

**Elegant Tropæolum** (*T. speciosum*).—This magnificent species is another of the many fine plants introduced by Mr. William Lobb when collecting for Messrs. Veitch, of Exeter. He sent it to England about the year 1846, but it had then long been known in the dried state. It is a native of the southern provinces of Chili, from Concepcion to Chiloe. Although this is constantly being recommended in the gardening papers by the few who succeed in growing it well, it is a plant that one rarely sees, and yet its gorgeous crimson-red flowers are perhaps the showiest of the genus without the gaudiness of many of the garden hybrids. Gay ("*Flora Chilena*") states that in its native country it has numerous slender stems, from 15 ft. to 20 ft. long, climbing over and elegantly interlacing and festooning shrubs and small trees. The long-stalked leaves are divided to the base of the blade into about six oval-oblong lobes, and they are furnished with conspicuous stipules, and the flowers are borne on stalks over-

topping the leaves. The limb of the petals is almost square and slightly bilobed, and borne on a very slender stalk. Instead of the glaucous foliage of *T. polyphyllum*, it is usually more or less hairy.

**Knights's Tropæolum** (*T. polyphyllum*).—The late Mr. Knight, of the Exotic Nursery, King's Road, Chelsea, was the introducer of this fine hairy species, about the year 1842. It varies very much in habit and foliage from different localities, as the dried specimens at Kew testify, the leaves being deeply divided into six to twelve lobes, which in some specimens are very narrow, whereas in others they are broad, as in the commonly cultivated variety. In its native country, according to Gay ("*Flora Chilena*"), the stems grow from 4 ft. to 8 ft. long, and the flowers are always yellow. Growing among shrubs, the stems elongate, and the leaves and flowers are scattered, but in an exposed border it is a plant of compact habit with short, stout, succulent stems, densely clothed with leaves and flowers. It has a wide range in the Andes of South America, ascending to an altitude of 6000 ft. to 7000 ft. as far south as the Cordillera of Santiago, in Chili; and it is, perhaps, the hardiest species of the genus. *T. edule* (Paxt. Mag., ix. 127) is probably a variety of this of more straggling habit.

**White Tropæolum** (*T. albidiflorum*, *Flora des Serres*, iii., pl. 9).—Apparently a variety of *T. polyphyllum*, distinguished by the colour of its flowers, the petals being white inside, passing into deep yellow in the claw, and tinged with pink outside. It was in cultivation in the Brussels Botanic Garden in 1846, but I am not aware that it ever reached this country.

**Notch-petaled Tropæolum** (*T. crenatiflorum*, Bot. Mag., t. 4245).—This has pretty bright yellow flowers, about 1 in. in diameter, and semi-circular, petalate leaves, with rounded, shallow lobes; but the habit of the plant is rather straggling, and the foliage and flowers in the specimens seen are distant. Introduced from Peru by Mr. Lobb about 1845, and, compared with many others, of little ornamental character.

**Planchon's Golden Tropæolum** (*T. chrysanthum*, *Flora des Serres*, x., t. 1005).—A fine, yellow-flowered, climbing (perennial?) species with small, oval, petalate, entire, glandular, hairy leaves. All parts of the medium size flowers are of an almost uniform golden-yellow; the spur relatively short, the two upper petals much smaller than the calyx lobes, and the three lower much larger and toothed on the margin. A very pretty plant; introduced from the temperate parts of New Granada. I have only seen dried specimens and the figure quoted above.

**Wagner's Tropæolum** (*T. Wagnerianum*, *Flora des Serres*, vi., t. 553).—A perennial fibrous-rooted species; in habit and foliage this reminds one of a *Convolvulus* rather than a Tropæolum. It is apparently of twining habit, and it has triangular leaves on rather short petioles. The blade is 2 in. to 3 in. long, and the petiole is inserted just within its margin. Flowers about 2 in., three quarters of which is spur, the latter crimson, except quite at the tip. The lobes of the calyx are green and spreading, and of the same length as the five calyx, very narrow fringed, violet-blue petals. A very curious and beautiful species, of which I have only seen the figure quoted. It is a native of Columbia.

**Decker's Tropæolum** (*T. Deckerianum*, *Flora des Serres*, t. 490).—A very singular species with tricoloured hairy flowers and nudified, hairy, petalate leaves. Roots fibrous; stems climbing to a considerable height, and bearing leaves sometimes as much as 6 in. across. The spur of the flowers is about  $\frac{1}{2}$  in. long, and of a vermilion-red, except at the end where it is green, as well as the calyx lobes; and the petals are small, scarcely exceeding the calyx lobes, azure blue, passing into purple at the base, and very delicately fringed. This beautiful plant is a native of Tovar, in Venezuela, where it was discovered by Moritz and Karsten, who sent it to the Berlin Botanic Garden. There are several other species allied to this, natives of the same region, which are very ornamental. *T. marmoratum* has large, oval, petalate leaves beautifully veined and marbled something in the way of the leaves of *Cissis discolor*. *T. cirrhipes* is another of the same group worth mentioning. The flowers are borne on exceedingly long filiform stalks, which act also as tendrils to support the plant, as also do those of *T. Deckerianum*.

**Two-petaled Tropæolum** (*T. dipetalum*).—A very distinct species, formerly in cultivation on the Continent, if not in this country. It is remarkable in having only two petals, the three lower ones being suppressed. The two petals are large and conspicuous, entire, and oval-oblong, and, as well as the calyx, deep red or crimson. In foliage, too, this is very distinct, the leaves being somewhat pedately lobed with rather broad rounded lobes, and the stalk is inserted just within the margin of the blade. At the base of the long leaf-stalks are large, three-lobed stipules. The whole plant is glabrous, and has quite stout stems. Native of Peru.

**Five-leafleted Tropæolum** (*T. pentaphyllum*, Bot. Mag., t. 3190; syn., *Clymæcarpus pentaphyllum*).—This species agrees with *T. dipetalum* in having only two petals, but there the similarity ceases. It is a tuberous-rooted perennial, with rather slender, reddish stems, well clothed with leaves. The latter are 1 in. or 2 in. across, and palmately divided into five distinct oval or lanceolate leaflets; and the flowers are narrow, about  $\frac{1}{2}$  in. long. The spur is deep red and abruptly hooked near the base, whilst the lobes of the calyx are green, and the two very minute petals red. A very pretty plant, easily distinguished from all other species of the genus by the characters given. It is a native of Bucoes Ayres and Uruguay, where it is very common. Mr. Twœdie, who collected extensively in these countries, introduced it in 1829.

**Cluster-flowered Tropæolum** (*T. umbellatum*, Bot. Mag., t. 4337).—This is at once distinguishable from all other species by the flowers being borne in stalked clusters of four to six or more. It is a tuberous-rooted plant, the tubers, according to Prof. Jameson, weighing from 3 lb. to 5 lb. each. The slender, zigzag stem is well clothed with rather short-stalked, palmately five-lobed leaves 2 in. to 3 in. in diameter; and from the axils of the leaves, and slightly overtopping them, proceed the umbels of flowers. The latter are orange and red, with a green-tipped spur, and little more than 1 in. long, petals small and erect, as well as the lobes of the calyx, so that the flower is very narrow. A native of the lofty mountains of Peru and Ecuador, whence it was introduced by Lobb in 1846.

Among other species in cultivation, or having been cultivated, are: *T. Findeimanni* (Wagner—Regel, Gartenflora, ii. t. 58) is a very slender climber, with membranous, semicircular, indistinctly-lobed leaves, and small vermilion flowers about  $\frac{3}{8}$  in. long. The pointed spur is three times as long as the calyx lobes, and the petals are included. *T. Jarratti* (Paxt. Mag., v. 29), appears to be only a variety of *T. tricolorum*, with rather more yellow in the flowers. *T. sessilifolium* is easily recognised by its very small (about  $\frac{1}{4}$  in. long), almost stalkless, five-lobed leaves. It is a prostrate plant, with slender stems 5 in. or 6 in., or a little longer, bearing a few shortly-stalked red and yellow flowers of moderate size near their extremities. *T. Heyneanum* (Seemann's Jour. Bot., i. t. 5) is a very pretty species, closely allied to the Canary Creeper, but it has smaller orange-coloured flowers, with a straight, not hooked, spur, and the lower petals nearly as large as the upper. Seemann states that it was formerly in cultivation in Germany, and at the date he wrote (1863) Mr. Markham, who mentions this plant in his "Travels in Peru and India," had sent to Peru for a supply of the seeds. What the result was I have not been able to learn.

W. B. HEMSLEY.

[The specimens from which our plate was prepared were grown in Mr. G. F. Wilson's garden at Heatherbank, Weybridge Heath.]

### SAXIFRAGES.

The following are growing beautifully in my garden at Byfleet, Weybridge, and large numbers of them are now in bloom, viz. :—

<i>Saxifraga australis</i>	<i>Saxifraga Inghelsti</i>	<i>Saxifraga lasiophylla</i>	<i>Saxifraga ruparictis</i>
<i>Saxifraga Andrewi</i>	<i>crassifolia ciliaris</i>	<i>longifolia</i>	<i>rosularis</i>
<i>Saxifraga alpine</i>	<i>densa</i>	<i>Sternbergii</i>	<i>rotata</i>
<i>aretoides</i>	<i>elongata</i>	<i>marginata</i>	<i>Rhei</i>
<i>ambigua</i>	<i>Fortunei</i>	<i>marginata</i>	<i>Sternbergii</i>
<i>aromatica</i>	<i>Gaudini</i>	<i>Mollii</i>	<i>serotifolia</i>
<i>aspera</i>	<i>grecolandica</i>	<i>Mawiana</i>	<i>spatulata</i>
<i>Aizoon</i>	<i>Guthrieana</i>	<i>Melvillei</i>	<i>stellaris</i>
	<i>gibraltaria</i>	<i>moschata</i>	<i>Schraderei</i>
	<i>gracilis</i>	<i>nervosa</i>	<i>Stansfeldii</i>
<i>brevisifolia minor</i>	<i>Gauzei birsuta</i>	<i>nivalis</i>	<i>sponheimica</i>
<i>resularis</i>	<i>punctata</i>	<i>nepalensis</i>	<i>komana</i>
<i>compacta</i>	<i>polita</i>	<i>oppositifolia</i>	<i>flavescens</i>
<i>Bursariana</i>	<i>gracilis</i>	<i>pallida</i>	<i>condensata</i>
<i>Bucklandi</i>	<i>hirta</i>	<i>pyrenaica</i>	<i>tazetta</i>
<i>carinthiaca</i>	<i>Havortii</i>	<i>orbicularis</i>	<i>trifurcata</i>
<i>concinata</i>	<i>Hostii</i>	<i>rubra</i>	<i>umbrosa dentata</i>
<i>crisata</i>	<i>hypnoides</i>	<i>peninsylvanica</i>	<i>punctata</i>
<i>capillaria</i>	<i>lurata</i>	<i>pellata</i>	<i>serotifolia</i>
<i>cuneifolia</i>	<i>hybrida</i>	<i>pyrenaica</i>	<i>major</i>
<i>crisata</i>	<i>icelandica</i>	<i>pectinata</i>	<i>fol. var.</i>
<i>Churchilli</i>	<i>irrigua</i>	<i>paniculata</i>	
<i>canaliculata</i>	<i>inacta</i>	<i>pentactyloides</i>	
<i>caespitosa birsuta</i>	<i>incurvisifolia</i>	<i>pyramidalis</i>	<i>serrata</i>
<i>ceratophylla</i>	<i>lanceolata</i>	<i>pyramidalis</i>	<i>valdensis</i>
<i>cesia</i>	<i>lingulata</i>	<i>pyramidalis</i>	<i>Whiteleyi</i>
<i>crisata minor</i>	<i>ligulata</i>	<i>retundifolia</i>	<i>Wilkomiana</i>
<i>cordifolia</i>			

JOSEPH STEVENS.

### RHEUM PALMATUM VAR. TANGUTICUM.\*

BY PROFESSOR BALFOUR.

I HAVE received from Mr. G. P. Regel, Director of the Botanic Garden at St. Petersburg, five young Rhubarb plants, under the name of *Rheum palmatum*, var. *Tanguticum*. The plant was collected by Lieut.-Col. N. Prejevalsky on the north-western range of mountains of Mongolia, in the Tangut country, and in the solitudes of Northern Tibet. It is rare in the environs of Chertintou, but is said to abound near the source of the Tating and Etsina, further to the west. It is known to the Mongols as "Shara-moto," or Yellow tree, and to the Tangutans as "Djumptsa." The leaves of the plant are described as large, sometimes 2 ft. long by 3 ft. broad, and resemble those of *Rheum palmatum*, which has been cultivated in the Botanic Garden since the time of Dr. John Hope, the Professor of Botany in Edinburgh, and who read a paper on the subject to the Royal Society. The leaves, however, differ from those of *R. palmatum*, in being covered with longish and stiff hairs. The flower-stalk is said to attain a height of from 7 ft. to 10 ft., with a thickness of  $\frac{1}{2}$  in. near the ground. It does not branch, as in ordinary Rhubarbs, but is more compact, the flowering branches coming off at a very acute angle and running parallel to the stalk, as shown in the figure in the colonel's book. The root, when fully grown, is said to be about 1 ft. long, and of the same thickness. The flowering time is the end of June or beginning of July, and the seeds ripen towards the end of August. The Tangutans and Chinese dig it up in September and October. It is transported by land in winter and by boats in summer down the Hoang-ho to Pekin, Tientsin, and other ports, where the Europeans buy it, paying six or ten times more than its value at Sining. The plant is quite distinct from *Rheum officinale*, which has lately been introduced into European gardens as the true Rhubarb of commerce. According to Lieut.-Col. Prejevalsky, the plant yields the Kiakhta, or Kian-ao Rhubarb. Professor Maximowitch states that the dried roots (about 36 lbs.) brought home by the colonel, after having been carefully analysed and tested by Russian chemists and physicians, entirely agreed with the best Kiakhta Rhubarb, both in internal structure and in the number of crystals of oxalate of lime, the quantity of extract obtained from the root, and in the medicinal effect of the powder, and other preparations.

**Abronia fragrans**.—This is unquestionably the most remarkable of the genus. It differs from the well-known *A. umbellata* and *A. aromaria* in being usually more or less erect in habit, forming rather large branching tufts, from 1  $\frac{1}{2}$  ft. to 2 ft. in height, and covering when the root is strong, 2 or 3 square ft. of the ground, the stems being decumbent at the base. The flowers are produced in terminal and axillary umbels, and when fully expanded are pure white, diffusing a vanilla-like fragrance for some distance. During the earlier part of the day the limb of the corolla-like calyx is folded inwards, exhibiting only the greenish-white tint of the exterior, but at 4 p.m. the expansion commences, and an interesting transformation takes place. The flowers, which are larger than in any other species, expand several days in succession, and are produced till very late in the season. Plants will flower the first season if seed be sown early, but more strongly in subsequent years. In raising this plant no artificial heat should be employed, but the seed should be allowed to germinate at the temperature of a cool greenhouse, or even a cold frame. Being tap-rooted, the seedlings should be carefully transplanted when about 1 in. high into small pots of light soil, and after one shift may be eventually planted out where they are intended to remain. I have cultivated this fine plant for years past, and it was figured several years ago in the "Botanical Magazine" from specimens furnished by me.—W. THOMPSON, Ipswich.

**Housetop Gardening**.—My garden (says a writer in "Vick's Magazine") is on the roof of my blacksmith shop, two stories high, so you will see I have but little room, and labour under some disadvantages. Still, I had some success. My Balsams were all that could be desired. The *Azaleas* were the first to bloom; others followed soon, like the *Zinnias*, *Verbenas*, *Petunias*, *Portulacas*, *Pansies*, *Ten-week Stocks*, *Cinerarias*, *Asters*, and *Antirrhinums*. The greatest surprise was on the morning of August 5, when a *Datura* plant showed what a plant that behaved well might do by exhibiting forty pure white flowers, with their edges delicately tinged with lavender, fowers trumpet-shaped, from 7 in. to 8  $\frac{1}{2}$  in. long, and from  $\frac{3}{4}$  in. to 5  $\frac{1}{2}$  in. in diameter; every flower was a wonder. My garden on the roof was admired by hundreds of people, it being on view from two streets. Was it not the summer was one long drought, and most of our gardens in the city were quite parched, but ours showed no signs of suffering, unless neglected. If any lovers of flowers without a garden have a house with a flat roof they can grow enough flowers to satisfy any reasonable demand.

\* Read before the Botanical Society of Edinburgh.

## THE INDOOR GARDEN.

### GESNERAS AND THEIR CULTURE.

The species of Gesneras that are generally cultivated are mostly bulbous plants, but some of a deciduous herbaceous character are also grown. The greater portion of them are indigenous to Brazil and the South American continent, consequently they require a considerable amount of warmth in order to grow them successfully. Some, like *G. Cooperi*, bear a profusion of intensely vivid scarlet flowers, which remain long in beauty; others, of which *G. zebrina* may be taken as the type, in addition to their handsome red and yellow flowers, possess the most exquisitely marked leaves, the upper surface of which is clothed with a dense covering of reddish hairs, giving them a beautiful velvet-like appearance. The moderate size which Gesneras attain, and their natural free growth, render them well worth a place amongst the most easily managed of stove plants. The treatment by which *G. Cooperi* can be successfully grown may be taken as suitable for the other bulbous species. It may be propagated at different times of the year, according to the early or later time of its being started into growth; the most satisfactory method is by cuttings made from the young shoots, which spring freely from the crown, much in the way of a *Gloxinia*. Sussupping the plants, after blooming in the summer, to have been gradually dried off, they should, at the beginning of the year, be placed in a moist stove with a temperature of from  $60^{\circ}$  to  $65^{\circ}$  in the night, and a rise of  $10^{\circ}$  by day, giving just as much water as will slightly moisten the soil. So treated, they will soon commence to grow. When the shoots have attained a length of about 2 in., they may be taken off immediately under the first joint, removing the leaves from this; put them in a well-drained pan, in which is placed a little fine sandy soil, and filled up with silver sand. Insert the cuttings sufficiently far apart to prevent crowding, give a little water, and cover with a bell-glass. If bottom-heat can be supplied they will root quicker, but if the night temperature can be kept up to  $70^{\circ}$ , they will do without bottom-heat. As they strike readily, in the course of a few weeks they will have rooted enough to bear moving into small pots, which must be sufficiently drained, and filled with a mixture of sifted loam, to which has been added one-fourth of leaf-mould (also sifted), and as much sand as will give porosity to the whole; water slightly, and again partially cover for a few days with glasses, or put them in a propagating frame, to which admit air gradually, and as soon as they give evidence of making growth, by degrees inure them to the full air of the house. In the course of six or eight weeks they will have made considerable growth, and will require removal into pots 5 in. or 6 in. in diameter, using soil of a similar character to the first potting, only in a rougher, more lumpy condition. Through the summer subject them to an ordinary stove temperature, with sufficient air during the day, keeping them near the glass where they will receive the full volume of light, with a little shade in the middle of the day during bright weather. A neat stick to each will be necessary to support the shoot. I should not advise its being stopped, as the object this first season is to encourage all the leaf growth possible, upon which will depend the size and strength the tubers will attain. From their natural free habit of flowering, the strongest plants will very likely form flower-spikes towards the end of summer; but as the object is to get as much strength as possible into the tubers, I should recommend the bloom being pinched out, as, if allowed to go on, it will considerably restrict the growth of the plants. All through the season they must be attentively watered at the root and syringed overhead in the afternoons at the time of closing the house; keep the soil sufficiently moist so long as they evince a disposition to grow, after which cease syringing, give less shade, but do not allow the soil to become dry so long as the leaves retain their full vitality. When they begin to show signs of going to rest, gradually, not all at once, withhold water until the tops are dead down, at which time the soil should be almost quite dry. The pots should now be placed on a shelf, or in some position at the coolest end of the stove, where they will be secure from drip from the roof or water running from other plants. I mention this, for it is a very common occurrence to see the bulbs of

these and other plants when at rest put under stages or on damp floors, from which they either absorb moisture, or that which drips from above reaches them, by which means the soil, instead of being all but dry, is so wet, that it either causes decay or prematurely starts them into growth; neither must they be subjected to too low a temperature when at rest, or the tubers will rot. From  $50^{\circ}$  to  $55^{\circ}$  at night is as low as they can safely be kept at. Early in the ensuing year they should be shaken out of the old soil and removed to pots proportionate in size to that which the bulbs have attained. Those that have done well will at once bear moving into pots 8 in. in diameter; a size less will do for a smaller root. Drain and fill the pots with soil such as that recommended for the preceding year; the more fibrous material it contains the freer will be the growth of the plants. Always place the potting material before use where it will get a little warm; let it be in rather a dry than a moist state. It often happens with this, and with tubers of a similar character, that they are suddenly transferred from the dry soil in which they have been at rest to new, that contains too much moisture, from which they absorb so much as to cause their destruction. In potting, allow the top of the bulb to remain just above the surface of the soil, pressing the material moderately firm; place them on a shelf in a house or pit where the temperature will be from  $60^{\circ}$  to  $65^{\circ}$  during the night, with a proportionate rise by day. Give enough water to fairly moisten the soil directly they begin to push. It is important that they have sufficient light as soon as shoot-growth commences, as, if their first efforts in this direction be made in a dark situation, the shoots quickly become drawn up weak, a condition that no subsequent treatment for the season can rectify. As solar heat increases, give more warmth both day and night. The time of their blooming will vary with the more or less heat to which they are subjected, but they may be expected to show flower in April or May. When the bloom-spike appears, see that it does not get too much wet by syringing in the after-part of the day, as I have seen the individual unexpanded flowers caused to drop off by it. When the flowers begin to open the plants may be placed in a somewhat cooler situation, such as an intermediate house or a warm conservatory, away from draughts, keeping the soil while in such a position a little drier, but on no account must they be placed where too cold, or they will receive a check that will endanger their health, and cause the blooms to fall off prematurely. If used for decorative purposes in this way, as soon as the flowering is over, they should at once be moved back to the stove and regularly supplied with water until they exhibit signs of going to rest. If, on the other hand, they are not removed during the time of flowering from the stove, plants that are started early in the year, as these were, will generally push up a successional crop of young shoots, much in the way that *Gloxinias* do, which will bloom later in the season. During this second growth weak applications of manure water will materially assist them. Through the autumn give more air, and subject them to a drier atmosphere until the tops have died down; winter them as before. By retarding growth until late in the spring, they may be had in bloom through the autumn, if required. The flowers can be used for cutting, but they are better adapted for decorative purposes on the plant. If carefully managed through the winter, the tubers go on increasing in size, and will last for many years. This class of Gesneras may also be increased by division of the tubers.

The ornamental-leaved kinds, which also produce beautiful flowers, are, as I have previously said, mostly of a herbaceous character, and have scaly, tuberous roots, not unlike the nearly allied plants *Achimenes*. These will strike from cuttings made of the young shoots, either consisting of two or three joints with the top, or a couple, or even a single joint from the lower portion of the shoots, when not got too hard or woody, inserted in silver sand, and covered with a propagating glass, as recommended for those already treated upon; but they are more usually increased by a division of their scale-like tubers, which they form in considerable numbers. These may be either used whole or cut in pieces, according to the scarcity of the kinds or the quantity required; but although a small piece with care will grow, still, as naturally might be supposed, the larger the pieces the stronger the plants will be. For ordinary pur-

poses, the tubers used whole are the best. As this very beautiful section of *Gesneras* is the most useful when had in flower through the early months of the year, it is not wise to start them too soon; if started about March or the beginning of April it will be time enough. The most convenient practice with them I have found is to procure some good-sized propagating pans; drain, and two-thirds fill them with sifted soil made sufficiently light by the addition of a little leaf-mould and sand, and gently press the surface smooth; on this lay the tubers 2 in. apart, covering with  $\frac{1}{2}$  in. of similar material. At once place them in a night temperature of 60° or 65°, keeping the soil only slightly moist until they have begun to grow. As soon as the young shoots have pushed up 1 in. above the surface, move them singly into from 3-in. to 5-in. pots, according to the strength of the roots employed, potting in soil a little coarser than that in which they were started. With this section it is even more important than with the first mentioned to keep them near the light, as the general appearance of the plants is quite as much a matter of consideration as the flowers they ultimately make; for, unless all their leaves are retained in a fresh, healthy condition until the blooming is finished, half their beauty is wanting, and this is not possible if the leaf-development takes place where there is insufficient light. They require shade when the sun is bright, otherwise the leaves do not attain their wonted lustre. Increase the temperature of the house as the days lengthen, apply water to the roots regularly, and syringe overhead in the afternoons. By midsummer the strongest plants may be moved into 8-in. or 9-in. pots, the weaker ones receiving proportionately less room, or two or three of these may be grown in a pot of the larger size, but when sufficiently strong, they look best grown singly. They will need a thin stick to each shoot to keep them in an erect position. As the autumn advances cease shading and the use of the syringe, gradually decreasing the heat, but this should not be reduced lower than that in which they were first started. Their time of blooming will be regulated in a great measure by the heat they are kept in through the winter; in an ordinary stove they will come in through January, February, or the beginning of March, but where wanted so late as the month of March it is well to start a few bulbs after the time advised the preceding spring. After blooming gradually dry them off, storing where they will neither be too cold, nor so warm as to cause them to push before they are required. If room be an object, the tubers may be shaken out of the soil, and placed in paper bags in a little dry sand. Amongst a number of fine kinds, the following are especially deserving of cultivation:—*G. Cooperi*, *G. Barlowi*, *G. Donkelaari*, *G. glloxiniæseflora*, *G. cinnabarina ignea*, *G. exoniensis*, *G. zebрина splendidissima*, and *G. Leopoldi*.

**INSECTS.**—The continuous syringing recommended is generally sufficient to keep down red spider, thrips, and aphides, but should the latter appear, fumigate. They must be carefully guarded from the attacks of mealy bug, for if this insect gain a footing on the fine-leaved kinds, the sponging and brushing necessary for its removal almost always destroys the beauty of the plants.

T. BAINES.

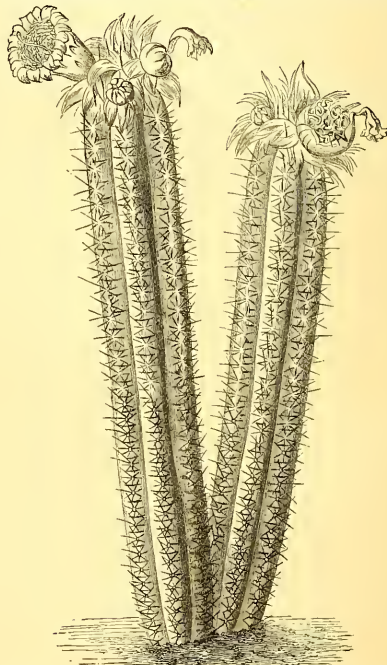

**Continuous Flowering of the Bougainvillea.**—I stated (see p. 79) that I thought too much stress was laid upon the ripening of the wood and the starving process frequently recommended to induce Bougainvilleas to flower, and spoke of a plant which flowered profusely for many months during the year without such treatment. This plant was green and flowering on till nearly last Christmas, when it was pruned. It was started afresh in February, the roots being richly top-dressed and watered, and it is now in flower again, and will soon, to all appearance, be one complete mass of blossom, as the long shoots, now flowering at their extremities, are, I see, breaking back at every joint, every one of which will produce bracts. The plant has been twice top-dressed at the root with rich soil, and I see that the roots are running all over the surface like little quills.—*J. S. W.*

**Utricularia montana.**—There will shortly be a good display of this beautiful and easily-grown plant in Messrs. Veitch's nursery at Chelsea. Some of the plants bear upwards of thirty large branching spikes of blossom, which, when fully expanded, will be most effective amongst the many choice Orchids with which they are associated. This plant may be successfully grown either in pots or pans, but it does best in wooden baskets, in which it spreads rapidly, emitting

fresh crowns out of the sides and bottom so as eventually to form a complete ball of hardy green foliage, and it never fails, under good culture, to produce an abundance of graceful spikes of white blossom. Utricularias must, however, have good drainage and an open compost consisting of fibry peat, broken crocks, and Moss, and, being almost aquatic, too much water can scarcely be given them. In pans placed in a tank in an intermediate house they would grow rapidly and flower freely.—*S.*

#### PILOCEREUS HOULLETTI.

This is a plant which possesses great beauty. It grows from 8 ft. to 10 ft. high; the stem is about 3 in. in diameter, very regular, with sharply-cut angles; the epidermis is coriaceous, spines pale brown, the apex set off with a tuft of soft, white, wool-like hairs about 2 in. long, which vanish with age, leaving hairs only on the head; the

flowers, which are dark brown, are about 2 in. long. Unlike other Cacti, this genus is peculiar in the flower, being composed for the most part of only one set of petals, gradually merging from the sepals. It is known in English collections as *P. glaucescens*. *J. CROUCHER.*

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Todea superba.**—A few weeks ago a correspondent stated (see p. 232) that it is rare to get a stock of this Fern from spores. With a suitable situation there should be no difficulty. In my Filmy house, in which there are several old plants, the walls are lined with *Spbagnum*, and in it they germinate very freely. They are all self-sown. *Todea Wilkesiana*—a much rarer Fern—has also come up from spores. Of this I have some dozens of little plants.—*P. NEILL FRASER, Murrayfield, Edinburgh.*

**Primula amœna alba.**—For growing in fancy earthenware pans or rustic vases, few plants surpass in usefulness this beautiful white-flowered, hardy *Primula*. If old plants of it be parted every year, and a number of the pieces placed in large pans, they produce a mass of blossom that lasts, even in a sitting room, for a considerable length of time; and in a cool, airy conservatory they of course last much longer. When cut the flowers soon shrivel, and they cannot, therefore, be recommended in that state; but no one possessing a cool house should be without a good display of this *Primula* at this season of the year.—*C. S.*

## PROPAGATING.

FUCHSIAS intended for propagation should be pruned well in and got into a house, the temperature of which is about 65°, in Feb. and syringed two or three times a day; under such conditions they will make young growth rapidly. The cutting pots

Fig. 1.

should be the same as those for other soft-wooded plants, and the same treatment should be followed. The cuttings are best made as in fig. 1, as there is no waste, and they strike equally quick as if made with a joint, or, as in fig. 2, by single eyes if a large stock be required of a new or rare sort. The wood

Fig. 2.

should be cut down the centre with a small sharp knife, and the eyes put all round the edge of the cutting pot with the leaves inwards; none should be put in the centre of the pot. Some of the species, such as *F. spectabilis*, *Dominiana*, &c., are best inserted in small thumb-pots—one in a pot, as they

Fig. 3.

take longer to root, and very often one roots after the other at different times. *F. macrantha* will do well from cuttings, but it succeeds best if grafted, as in fig. 3, on *F. syringæflora*, which is a very strong grower. If put in the cutting box and not kept too moist, they will unite in about ten days, when they must be inured to light and air gradually. H. P.

**Grafting Camellias.**—A fair amount of success may doubtless be realised by the method described (see p. 385), but I think that the plan which has been for some years practised at the Chilwell Nurseries is much safer, as it does away with the necessity for bottom-heat, which is injurious to the Camellia. The stocks, which are about three years old, are grafted in the second week in August, and placed in cold frames in the house set apart for growing young Camellias. If plunged in coal-ashes they require very little water until it is time to take them out again, which, if the grafts have taken properly, will be about the second or third week in September, when they may be removed from the frame and placed on a bed covered with ashes, spar, or other cool, moist material. In the middle of February the head of the stock may be cut off and the old tying material removed. It is the safest plan to retie the graft, in order that it may not be loosened by any accident; care must, however, be taken that the worsted, matting, or whatever material is used, does not cut into the bark when the plant begins to grow. By adopting this method we have grafted some hundreds of Camellias at a time, with a loss of only 1 or 2 per cent.—CHAS. E. PEARSON, *Chilwell Nurseries, Notts.*

## GARDENING FOR THE WEEK.

## Indoor Plant Department.

**Cool Orchids.**—In addition to the older species of Orchids that evidently succeed better in comparatively cool quarters than in steaming hot ones, immense numbers have, in recent years, been introduced from the mountainous districts of South America, that not only require this cooler treatment with a view to their flowering satisfactorily, but whose absolute existence depends upon it. Yet amongst those that are now understood as cool orchids there is almost as great a difference in the temperature which they need as between that required by the intermediate section, representing many of the fine Cattleys and *Lælias*, and the occupants of the East Indian department, represented by *Aerides*, *Vandas*, *Saccolabiums*, and others; consequently it becomes a consideration how to treat such Orchids as need different degrees of temperature. This can no doubt be easily enough managed where there are several structures in which to accommodate them, but with many growers they have to be treated collectively in one house, in which case it is necessary to consider how to effect the compromise that thus becomes inevitable. Clearly it cannot be by keeping the house so cold as to just meet the requirements of such plants as those found in the high regions of the Cordilleras of Peru, otherwise the larger number of these cool plants which yet require a little more warmth than the first-named are sure to suffer. I have been led to make these remarks by frequently of late years seeing a number of these plants that were subjected to too cool treatment in bad condition, despite every attention that could be given them in other respects; therefore it is better where there is a mixture of these cool and still cooler plants grown together to keep such portion as do the best in the lowest temperature a few degrees warmer than might be desirable, were it not for inflicting positive injury on the warmer section.

**Root Moisture for Cool Orchids.**—Beginners in the cultivation of Orchids from these high latitudes often err by not giving them sufficient moisture, an abundance of which is indispensable; for, like all other plants that grow naturally in situations where the soil in which their roots are placed is in a perpetually swamp-like state, they are totally incapable of bearing for any length of time, their roots being in a condition even approaching to dryness.

**Dendrobiums.**—Many plants of *D. crassinode* and *D. Wardianum* will have, by this time, done flowering, and will be pushing up their growth freely; these species, though evidently enjoying a fair amount of warmth whilst growing, will yet flower more profusely if subjected to somewhat cooler treatment than they often are; too much warmth simply has the effect of elongating the bulbs with a diminution rather than increase of the blooms produced. The lovely *D. Falconeri* is generally grown much too hot, to which cause may be attributed the meagre production of flowers by which it is too often characterised. It succeeds best on a Sphagnum-covered block hung up close to the glass, in which position it gets dried up every day sufficiently to admit of its being freely syringed, treatment necessary to keep the young unexpanded leaves in the points of the growing shoots clear from yellow thrips, to which it is very subject. *D. devonianum* will, even in the case of such plants as either made their growth the preceding season late, or have been retarded, have their flowers fast advancing at the same time that the young growth will be pushing up freely. The baskets in which they are grown should be steeped in tepid water, so as to get the whole of the material moistened through. It is not advisable to put the plants in anything more than an intermediate house temperature whilst the flower is advancing; the individual blooms, although of unsurpassing beauty both in colour and formation, are yet short-lived, and if at all hurried it will contribute to their shorter duration, and cause their being deficient in the charming purple colouring on the points of the petals and sepals, which adds so much to their appearance. *D. Farnesii* and its many beautiful forms, also the different varieties of *D. densiflorum* and *D. chrysothoux*, will now be swelling up their flower-buds even if kept comparatively cool all through the winter. These, independent of their merits for home decoration, are amongst the finest of exhibition plants, but in the desire to retard them for this purpose they must not be kept too dry, for although moisture given freely at the root very much accelerates the growth of the flowers, yet if water be withheld too long I have often noticed that the flower buds perish.

**Angraecums.**—*A. sequepedale*, with *A. eburneum* and its varieties, will, in most cases, now be out of flower and growing freely. These are from the hot regions of Madagascar, and must have plenty of heat and moisture. They rank among the finest of Orchids, and are deserving of the best position in the house. If the stage on which they are grown is not sufficiently high, elevate them above it so as to get their heads well up to the roof.

**Calanthe veratrifolia.**—The fascination of new plants has been the means of consigning this, one of the very finest white Orchids in existence, to a position of little estimation, yet those who possess a good stock of it have a source from which they can cut the purest of white flowers for months. I have cut button-hole flowers from a single spike of this for twelve weeks in succession. It will now be fast pushing up its spikes, and care must be taken to keep it free from green fly, for, if there is one in the house, it will find it, which will quickly result in a colony of these pests being established, the presence of which spoils the colour of the flowers. Plants of this *Calanthe* that are in a weak state I should advise to cut out of the flower-stems as they make their appearance, as it will worth the sacrifice in order to get them strong, and by removing them before they are far advanced a much longer season of the

best growing period during the summer is permitted for completing its growth. With me it has succeeded much better in pure, good, yellow loam, with a little sand and broken charcoal, than with any addition of peat, but the pots must be well drained and the soil must not be over-watered. Where there are any doubts as to the roots not being in a healthy state, I should recommend the plants being at once taken out, and the decayed portion cut away, as much of the old material removed as can be effected without injuring the living roots, re-potting in fresh soil. The plant does not like too much room proportionate to the quantity of root it possesses. It requires a good amount of heat to grow it well, and shade during bright weather, otherwise its thin, broad leaves get injured; but it will not long remain in a healthy condition if kept too dark, or if the atmosphere is too confined through an insufficient admission of air. There is another form of this plant from Java, differing little in appearance from the Indian species, but so far wanting in purity of colour as to be not worth growing. C. Massee, of which there are two forms, one very much superior to the other, requires to be treated much like the last named species, except that I have found it do better in a little lower temperature. Like *C. varitifolia*, the flowering continues for a very long time, the spikes opening in succession, which, together with its distinct purplish-lilac colour, renders it well worth a place.—T. BAINES.

**Conservatory.**—In order to prolong the flowering season of such plants as are in bloom here, it will now be necessary to attend carefully to shading during the middle of the day in sunny weather. Scrim, a fabric made of flax, is much the best and cheapest shading material in the end. It outlasts considerably any other material I have ever tried. The finest quality of it will break the sun's rays without excluding too much light. Roof climbers will now require regular attention to keep them from becoming an entangled mass. The system of allowing the whole roof to become covered, as is frequently done, is objectionable. It excludes too much light from the plants underneath, especially in dull weather; it also spoils the general effect, which is much enhanced by confining climbers to something like one-fourth of the roof space, and leaving them to hang down gracefully at intervals; yet in this too much uniformity should be avoided by allowing some to hang lower than others. Let every means be employed to keep them free from insects, more especially scale. Azaleas that are brought into bloom in other structures for removal to the conservatory, will be benefited by sprinklings overhead with the syringe every afternoon and their flowers are fully expanded. They should also be shaded, especially the high-coloured varieties. They must likewise be well attended to with water, as during the development of their flowers there is a much greater drain upon the roots than at any other time, and if allowed to become dry the flowers suffer as well as the growth for the ensuing year. Geraniums and Calceolarias that are throwing up flower trusses should be encouraged by means of liquid manure, not too strong, especially in the case of Geraniums, or it causes them to run too much to leaf. Fumigate regularly, and not too severely. To be awake, and not too closely examined, to see that they do not suffer from thrips or red spider, as either quickly spoils them. Cockscobs, Balsams, Achimenes, and Hydrangeas should be well attended to, as these, with the plants previously mentioned, will be the principal things to be depended on during the following two months, when there is a much greater scarcity of flowering plants than during early spring. Chrysanthemums that have filled the small pots they at present occupy should be at once potted into their flowering pots; from 5-in. to 12-in. pots, according to the sizes the plants are required, will be found large enough for general use. If fine flowers are wanted stop the shoots during this month, but not later. A dozen really good blooms on a plant of the large-flowered varieties are preferable to three times the number of stavelings often met with. Plunge them at once in their summer quarters in ashes, which will prevent worms from getting into the pots, and will keep their roots at a much more equable temperature than when not plunged. The effect of rapid change in the temperature of the soil in an ordinary plant pot when not plunged is not sufficiently considered; during bright weather the sun's rays acting upon the soil raise the entire pot to a high heat in an unnatural degree, and therefore the cold chill of even our summer nights causes a corresponding reaction. The first batch of Primulas and Cinerarias will now require potting into thumb-pots, using good loam, well enriched with rotten manure and leaf-mould for the purpose, mixed with a little clean sand. Place the plants in a somewhat close pit or frame; shade them from bright sun and attend to them well with water. Pot off all cuttings struck of Euphorbias, Hydrangeas, and Primulas, placing them in a growing temperature near the glass so as to ensure short, stout growth. *Rhynchospermum jamaicense* is a useful conservatory plant, its fragrant white flowers rendering it a general favourite. It is a plant of easy management, requiring the temperature of a Vinery or intermediate house during its growing season. The different varieties of *Kalosanthes* will now be fast showing flower, and will be benefited by weak manure water. Get them properly tied before the shoots get too heavy. They are useful decorative plants for summer. Now is a good time to propagate them; strike freely in steam or peat, with an admixture of a little sand, giving very little water until they are rooted. Tie out Achimenes as they advance in growth, giving them all the light possible so as to induce a stout, blooming habit. A good number of the oldest plants of scarlet and pink Geraniums should be selected for keeping up the conservatory display during the summer and autumn, and a batch of the scarlet *Pelargonium Vesuvius* should be potted into 6-in. pots and turned out-of-doors, where they will be fully exposed during the summer months. With these I will not size that is required, but a thoroughly matured growth that will ensure their flowering freely when subjected to heat for winter decoration.

**Hard-wooded Plants.**—Azaleas will now be coming into flower without the assistance of fire-heat, and although with the increased temperature of the season they will not last in bloom so long as those that have been forced, yet the much brighter colours which they acquire under more natural conditions will compensate for their shorter duration. The house in which the yellow whist in bloom should be well shaded in order to prolong their flowering as far as possible. Remove all seed-pods from such as have done flowering, after which allow them a fortnight or three weeks to recruit their energies previous to re-potting. Use in the operation good fibrous peat broken into pieces proportionate to the size of the plants; add nothing, except as much silver sand as will not only ensure porosity, but also maintain a sweet, healthy condition of the soil for years, for Azaleas, with anything like fair treatment, are not short liverers. After potting, keep them in a cooler atmosphere than they have been in for a during such time, but give sufficient at top to keep the temperature from getting too high; 80° to 85°, with air, shade, and moisture will do no harm; on the contrary, Azaleas enjoy it. Plants that are vigorous and that push some of their shoots very strong, will be benefited by having the points of such shoots nipped out as soon as they show a disposition to outgrow their neighbours. If done whilst the growth is soft the plants will push several shoots which will set blooms with the rest of the plants. Attend as heretofore to the general stock of hard-wooded plants, and, by close attention, encourage early and vigorous growth.

**Stove.**—Allamandas in pots that have not made a sufficient number of shoots should have their branches wound round the trellis on which they are trained, bringing the points of the shoots downwards towards the top of the pot; this will have the effect of causing them to break freely, which growth will show bloom before it has advanced far. All stove plants that flower from the current season's wood will be benefited by liquid manure as their pots get filled with roots; but in all cases let it not be given too strong, and always in a transparent condition; if applied thick and muddy it closes up the surface of the soil, and does not enter the heart of the plant. We frequently get cold, cutting winds; therefore, where such is the case, never give air at both top and bottom of stoves, as it causes a through current of cold air, which is equally as injurious to vegetable as it is to animal life. We are frequently told that if the openings where the air is admitted are opposite the hot pipes, the air is warmed in its ingress by passing over the heated surface. To some extent it is, but not sufficiently; neither is it sufficiently charged with moisture to be allowed to rush onward on a windy day amongst young tender foliage at this season of the year, towards the autumn, when the object is to keep up late frosts, the case is different. Place *Gloninias*, *Tydeas*, and all soft quick-growing plants near the glass, so as to get all the light possible; otherwise, when they have to be removed for decoration elsewhere, or their flowers are required for cutting, they are so soft and flimsy as to be useless.

**Fern House.**—Plants that have not been re-potted for some time, and where it is not deemed advisable to give them more root room, may be assisted by the application of manure water; but in all cases see that the drainage is effective, otherwise its application will only aggravate the evil. If any plants are out-growing their bounds, either in pots or planted out, it is an easy matter to reduce this over-luxuriance by cutting away, more or less, according to circumstances, their oldest fronds whilst in a green, living state; this will be found to reduce the size of the fronds made afterwards, in proportion to the extent it has been carried out. The different kinds of *Dicksonia*, *Lomaria*, *Cyathea*, &c., that throw up their young fronds in a batch may have, when these are fully developed, the oldest fronds, if unsightly, cut away.

**Bedding Plants.**—*Pelargoniums* of all sorts, for planting out, should be gradually inured to the weather, and the hardier kinds all but fully exposed. Unless between hedges, under canvas, or beneath the canopy of some densely topped trees, it would be dangerous yet, however, to risk them out of frames or pits. Old stumps of *Fuchsia* may safely be planted out and staked, but those started into growth indoors must be kept there until the weather becomes warmer. *Cineraria maritima*, pricked out of frames or potted, should have the sashes tilted up in front and at back. *Centaurea* now strike freely from cuttings, therefore a stock of them should be secured. Boxes, pans, or pots containing *Gazania splendens* may be arranged out-of-doors along the base of a wall or hedge in a well-sheltered position. Pot off the youngest lot of *Verbena*, *Ageratum*, *Tropaeolum*, *Lobelia*, &c.; keep them in heat for a week or so until they begin to grow again, and then remove them to a cool house or clove frame, and gradually harden them off. Propagating *Dahlia* for ordinary use should now be at an end. Established cuttings and divided roots making growth should be removed to a cold frame, which should be kept close for a time, but eventually thrown open. Keep *Perilla* in a cool frame, and plant out Dell's Crimson Beet where it is to remain. *Alternanthera*, *Iresines*, *Coleuses*, and *Amarantuses* keep rather warm yet, and encourage good stocky growth. To these *Fuchsia Meteor* makes a fine companion, and from early spring-struck cuttings nice plants of it should be had for bedding-out. Sweet Peas, *Propagandium enanthe*, and *Propagandium Nasturtium* may be planted out in boxes in pots or beds in which they were sown; they are sometimes raised in narrow wall borders, and afterwards transplanted. Stocks, *Asters*, *Balsams*, *Tagetes*, African and French *Marigolds*, *Brachyocomeiberidifolia*, and similar plants, if in boxes, should be kept in frames, and the sashes should be tilted up both at back and in front; the *Marigolds* may be pricked out and kept in a warm position for another week or so if necessary. Supply sub-tropical plants freely with water at the root, and syringe them twice a day; a sprinkling of Tobacco-water from the syringe

now and then helps to keep them free from green fly and thrips, and is essentially useful in the case of soft-wooded plants. Gradually reduce the artificial heat where sub-tropical plants are kept.

#### Indoor Fruit Department.

**Vines.**—Pay great attention to the stopping and tying of shoots in late Vineries. Great care is needed in tying down tender shoots; when pressed beyond their strength they are very liable to break off at the base. Lateral growths are quickly produced after the shoots are checked; these should be pinched at the first leaf, and should never be permitted to proceed further than another leaf beyond this. The principal wood of many Vines is frequently suffocated by straggling lateral growths, which preclude air and light, and prevents the ripening of both fruit and wood. The earliest potting amongst young Vines should have made enough roots by this time to feel the benefit of weak applications of liquid manure, which may be given with much benefit at every other watering. Dissolved sheep and cow manure and guano, mixed together or separately, are substantial fertilisers, but it is great waste to give liquid manure when the ball of soil is very dry, as it passes through at the bottom and runs away without doing any good. Dry soil about all plants should first be moistened with clean water, and there is then every chance of the fertilising property of the liquid manure resting about the roots when applied a short time afterwards.

**Pines.**—Where a great number of Queens have been started into fruit simultaneously they will ripen together, unless some of them are retarded, in order that they may come in one after the other. A long succession is best obtained from a batch of this description by removing some of the plants with the fruit attached, when the latter is not quite half ripe, into a shaded house or room, with a temperature of about 50°, and where a circulation of dry air is going on. A fruit which does not become dead-ripe in a close, warm stove in a week will not arrive at that state for more than a month when subjected to this treatment. When it is intended to keep the fruit back for a considerable time, removal should take place shortly after colouring has begun. The flavour is seldom deteriorated much through the ripening being retarded.

#### Flower Garden.

Spring flowers, such as Pansies, bedding Violas, Daisies, Aubrietias, Forget-me-nots, Alyssums, single and double yellow and crimson Wallflowers, Trillium grandiflorum, Trolliuses, Saxifrages, Tulips, &c., are now in perfection, whilst fine-foliaged plants are beginning to be extremely pretty. Edgings of *Echeveria secunda* glauca and others, together with *Sempervivum* of various sorts, should be made at once, for if properly hardened off previously they will stand a slight frost with little harm. Funkias have now begun to grow, and, if necessary, may be lifted, divided, and re-planted. Remove from beds of Cannas, in which the roots were wintered in the open ground, the mulching of leaves, litter, or Grass, which were covered up at the plants last year, and allow to grow, and the beds should be top-dressed with some well-decayed manure and loam. *Spiraea filipendula* makes a fine summer edging for beds, and it may now be transplanted, as may also variegated Grasses, for the same purpose. *Polemonium cœruleum variegatum*, variegated Arabis of different sorts, autumn-sown plants of the golden-leaved Feverfew, Japanese Honeysuckle, and bedding Pansies and Violas. Carnations wintered in pots should now be planted out and staked; also Hollyhocks propagated this spring. The commoner Yuccas wintered in frames may now be consigned to the open borders, as may also Pentstemons, Phloxes, Antirrhinums, and Irises. From the base of clumps of Pampas Grass cut away the most decayed leaves, and administer a thorough soaking of water to the roots. *Campanula carpatia* may be divided and re-planted; this makes a grand edging for a shrubby border, as does also the *Nepeta violacea*, the herbaceous stalks of which should be removed so as to give freedom to the young growth. Sow Polyanthuses and Alpine Auriculas at once on a warm border, and divide and transplant the old ones as soon as they have done flowering in a somewhat shaded border; they thrive best in a good loam mixed with leaf-mould; it is, however, unnecessary to disturb the old stools unless they have become overgrown. Wallflowers may still be sown, but the earlier now the better. Pansy seed may also be sown, cuttings propagated, established plants transplanted, and the seedlings from sowings made early in April in boxes or frames pricked out or planted permanently.

#### Hardy Fruit.

The prospects of all kinds of fruit look not possibly be better, and we may now feel comparatively safe. Unremitting attention will now be required to ward off the attacks of aphides, for, if once these pests get a footing hold upon the trees, all hopes of fruit that is fit either to be seen or eaten are at an end, and the crop of next year is also endangered. Tobacco powder or snuff, applied through a flour dredger, is the best remedy I know till the fruit is set, but afterwards, frequent washing with clear water will keep down all kinds of insects, and prove beneficial in a variety of ways. It should be applied with a certain amount of force, as through a syringe, garden engine, or hose. Keep a sharp look out for grubs on Apricots and caterpillars on Gooseberry bushes, and as there is no remedy so effectual as hand-picking, it should be done at once. Pears, Peaches, and Apricots, that have set their fruit thickly, should be thinned out as soon as it can be seen which fruits are likely to swell best. As to thinning, it is very difficult to give precise directions, for experience alone must teach how thin they ought to be, or how many or much fruit a given tree is capable of bringing to perfection. Quality, rather than quantity, should be aimed at in fruit culture; certainly, one large and well-flavoured

Pear, Peach, or Apricot is preferable to two small ones, and especially with the two latter kinds, the stones of which are a consideration. When thinning, the guiding principle should be to have each fruit clear of its neighbour, evenly distributed over the tree, and fully exposed to sun, air, and light. Young recently-planted trees will require to have the shoots regularly and pinched, trained, or tied into the form they are to assume; in doing which care should be exercised to have the tree equally balanced; that the flow of sap may be alike over all parts. Any shoots that manifest a tendency to grow stronger than the rest may be checked by bending them downwards and keeping the lateral growths closely pinched off; but weak shoots should be allowed to retain all lateral growths made, at least for a considerable period. Canker and gum are the inevitable consequences of too tight ligatures and injury from nails, or bruises in other ways, all of which should be guarded against. Strawberries have made rapid progress during the last few days, and are now throwing up their flower-stems. If it has not yet been done, a mulching of long litter should be applied to them, for the double purpose of keeping the fruit clean at ripening time, and to prevent the too rapid evaporation of moisture.

#### Kitchen Garden.

**Sowing Beet, Planting out Lettuce, &c.**—The principal crop of Beet should now be sown, and, as this is a deep-rooting plant, the ground should be deeply dug and well pulverised. The latter operation is essential for the generality of crops, and for none more so than those that penetrate deeply into the soil and are of a bulbous or tuberous-rooted character. The seeds of this vegetable, not suffering from the attacks of birds or insects, like many others, do not require sowing so thickly; but sufficient seed must be put in to secure a crop without having resort to filling up blanks by planting; for, although Beet will succeed best when thus treated, yet it entails more trouble, and, in dry localities in hot seasons, these plants do not root so freely as some others. Plant out Lettuces that have been sown in the open air as soon as they are large enough to handle; if they are removed to where they are to grow when the leaves are 1½ in. long, they suffer much less than if allowed to get larger before removal. Upon this, in a great measure, depends their ability to stand long without running to seed; much also depends upon their receiving plenty of water until they have taken a firm hold of the soil. Hoe and stick Peas as soon as they are large enough, and keep the soil well drawn up to the stems of Cabbages or Cauliflowers, or they may suffer from the wind, especially in exposed situations. As Potatoes may their appearance aboveground draw the soil well up to them so as to protect them from the slight frosts that are still liable to occur. Potatoes that are planted at the foot of south walls will be much benefited by an occasional soaking with water.

#### Extracts from my Diary.

May 13.—Sowing Sorcerera, Salsafy, Radishes, and Early White Snowball Turnip. Potting late-stalked Coleus and Alternanthera. Pricking off Antirrhinums, German and Ten-Week Stocks. Sticking and earthing up Peas. Dusting Turnips and other seeds just coming up with wood-ashes, to keep off the fly. Looking over Cucumbers and Melons, stopping them, and removing all weak shoots and male blossoms, and fertilising them where required.

May 14.—Sowing Green Curled and White Batavian Endive. Pricking out Lettuce, Cauliflowers, and Asters. Planting out Galeolarias, Pelargoniums, Golden Pyrethrums, and other hardy bedding plants. Thinning out Beet and filling up all failures. Watering newly-planted Cauliflower and Lettuce plants. Digging out Celery trenches and getting manure into them. Looking over Peaches, Nectarines, and Apricots on the walls, nailing in the leading shoots, and disbudbing them where required.

May 15.—Sowing Carters' Giant White Cos and All the Year Round Lettuces. Potting Vegetable Marrows and Ridge Cucumbers. Thinning out Spinach and Turnips. Preparing stakes for Dahlias and Hollyhocks. Watering Cucumbers, Melons, Potatoes, Carrots, and Beans in frames. Looking over Strawberries, and picking off all weak and late blooms. Putting stakes and strings to Broad Beans and earthing them up.

May 16.—Potting on Chilies, Cucumbers, and Pelargoniums. Planting out Vegetable Marrow plants under hand-lights. Fumigating Melons to kill green fly. Looking over Fig trees and stopping all young shoots that require it. Picking the dead leaves off Cauliflowers, and giving them a good earthing. Looking over Vineries, tying down all young shoots, stopping them, and thinning the bunches where required.

May 17.—Sowing Cardoons, Chervil, Thyme, and Mustard and Cress. Potting on small Dracenas and Palms for dinner-table decoration. Planting early Savoy and Brussels Sprouts. Mnlching late Strawberries with long chaff cut from stable litter. Syringing Rose trees with Quassia-chip water to kill green fly. Watering Pines all through, and putting stakes to any that require it. Taking down all wall-rose protections, and storing them away. Hoeing amongst all growing crops.

May 18.—Potting off Balsams, Petunias, and Phloxes. Planting out Lettuces, Cauliflowers, and Tomatoes in the open ground, over the Peach hedges, and tying in the young shoots. Getting all potatoes earthed up as opportunities occur. Thinning out the main crop of Parsnips, Onions, and Carrots. Weeding walks, mowing, and cleaning up the pleasure ground, and rolling down all gravel and turf that require it. Renovating linings for frames. Fruit in use for dessert—Pines and Strawberries.—W. G. P., Dorset.

## TREES AND SHRUBS.

## TREES AND SHRUBS FOR DENSELY POPULATED DISTRICTS.

Those who desire to succeed in planting operations in London, *i.e.*, in the most densely inhabited portions of it, must, without doubt, select their trees and shrubs from a very limited list; nevertheless, it is more satisfactory to plant such as will grow, although few in number, than such as will prove an everlasting eyesore. Let any one take notice of such evergreens as Hollies, Rhododendrons, Laurels, and nearly all the Conifers, and he will at once see how useless it is to plant them in the expectation that they will give satisfaction; so, also, with trees, as, for instance, the Lime, Horse Chestnut, and Sycamore, whose leaves are scorched up by the month of July. I therefore recommend those about to plant such material to pause

before using it too freely. I am aware that occasionally one sees such shrubs and trees in a thriving state, but there is a great difference between those that are well established and were planted when conditions were much more favourable than now and those planted at the present time. One of the very best shrubs, in my opinion, for densely populated districts is the oval-leaved Privet, so justly stated by Mr. Gordon (see p. 410) to be superseding all others for forming hedges. It may fairly rank as a sub-evergreen in London, retaining its leaves in the most exposed situations until new growth occurs, while in sheltered positions it is really evergreen. It is in every respect a noble shrub, whether planted singly or in shrubberies, and for hedges nothing can possibly be better. I can strongly recommend it to those who desire to form a hedge round a churchyard, for instance. It is cheap, transplants well, and is a sure grower. In a few years

it makes fine bushes, well furnished, some 10 ft. in height. The Japanese Privet is also a useful shrub for beds or borders, and one which withstands the smoke. It has fine, broad foliage and a spreading habit—altogether, a most desirable evergreen. The common Privet is likewise useful for hedges or shrubberies, and should find a place in every town garden of moderate extent. The Aucuba, although it makes poor growth, is generally a shrub of good appearance, whilst the berried varieties are decidedly handsome. It should be one of the principal shrubs used for town planting. The *Euonymus* is another excellent subject not sufficiently appreciated. It has a good habit, and whether planted singly in the shrubbery, or trained against walls, it is equally acceptable. The common variety is the only one which succeeds well, the atmosphere of London having but little effect upon its foliage. Box should, on no account, be overlooked; it forms a pretty shrub, and, although it grows slowly, if sheltered by other shrubs it succeeds fairly well. The Gum Cistus, especially when young, is a desirable

addition, its beautiful, but ephemeral, flowers expanding in profusion during the summer months. The common Furze and Broom both thrive well in London, and are extremely gay during spring and summer, as are also the Portuguese and Spanish varieties. For banks, rockeries, and similar places, few shrubs can equal the double-flowering Furze and dwarf *Hypericum*; they withstand smoke, bloom profusely, and soon spread over a large space; the *Hypericum*s are also very useful for carpeting purposes in shady places. The evergreen Honey-suckle is a vigorous-growing shrub; for filling up shrubberies and for placing against walls and fences it will be found useful. The list of deciduous shrubs is far more extensive than that of evergreens. Among the best may be mentioned the Bladder Senna; this has pretty foliage and flowers, followed by singular-looking seed-pods. The Dogwood is useful, on account of the colour of its wood; and *Deutzia scabra* is a good flowering

plant. The varieties of Elder are all vigorous growers, and should not be overlooked in planting large beds and borders; they have dense foliage, and for placing in out-of-the-way situations, or at the back of smaller shrubs, they are unsurpassed; they grow rapidly, and soon occupy spaces under trees where few other plants will grow. *Forsythia suspensa* is another early free-flowering shrub, and one equally well adapted for shrubbery or wall. The Lilacs should, of course, find a place in every garden, and they succeed fairly well in London. In some seasons they flower most profusely, even in the most densely populated districts. The Mock Orange should be grown in every collection for the sake of its fragrant flowers. Too much praise cannot be bestowed on *Ribes sanguineum* as a town shrub; it succeeds admirably, and few plants excel it as regards the beauty of its flowers, which expand early. The broad-leaved Buck-

"A Big Tree." By Van Goyen.

thorn is another of those excellent spreading shrubs which are indispensable on account of their strong-growing and smoke-resisting qualities. Sumach, especially the Stag's-horn and Fern-leaved kinds, form magnificent shrubs, with heavy and beautifully-divided foliage that remains in good condition until late in September. These should be sheltered from sharp cutting winds. Among *Viburnums*, the well-known Snowball is most useful, blooming very freely in favourable seasons. The Weigela, blooming, as it does, early in summer, is an undoubted acquisition. *Yuccas*, too, are suitable for nearly every sheltered position, whether it be in the shrubbery or in the angles of buildings. Nearly every variety succeeds in London, and are very ornamental.

Amongst trees, none that are evergreen are, as far as I know, suitable for town planting. For planting in shrubberies, or singly, or in avenues, the following may be used with advantage, *viz.*, the *Ailantus* and *Catalpa*, two trees that are furnished with magnificent foliage. The double-flowering Peach and Cherry are also really charming trees, flowering, as they

do, early in spring. The Thorns are likewise most desirable, as all of them flower freely and are finely scented; some of them, too, are much admired for their fruit, which is very ornamental; only the deciduous varieties should be used. Of the Planes and Poplars, much is already known; they rank amongst the most useful of trees for permanent planting. Their dense and elegant foliage, continually in a fresh, green condition until October, is a most desirable quality in a London tree. They grow rapidly, forming fair-sized trees in ten years. As regards the Poplars, they are much diversified with respect to character of foliage and growth, as, for instance, the spiræ-like Poplar, the White Poplar, and the Black Italian. Than Willows nothing can be better for moist situations, in which they grow vigorously, and the foliage and habit of some of the varieties are light and elegant, especially the weeping kinds.

Among climbing plants useful for covering walls, fences, or buildings the Ivy and Virginian Creeper occupy the first rank; both being rapid growers, and clinging naturally to walls, they associate well, one being evergreen and the other deciduous. The Pyracantha is an evergreen, and one of the best for fronts of houses; its fruit, which is borne in large bunches, produces a brilliant effect and remains on the branches all the winter. Privets may be trained against walls with good effect, and in such positions they bloom profusely. The Euonymus and Forsythia, as already mentioned, are most useful for this purpose, especially for low walls; they fill up the bare spaces left below larger climbers. Jasminum nudiflorum, producing primrose-coloured flowers freely in winter and spring on its bare green twigs, is a beautiful addition to this class of plants. Nor should the Vine be omitted, as when carefully trained it is a very excellent subject, grows vigorously, and produces an abundance of broad satiny foliage.

This list might be further increased, but I prefer giving the names of tried subjects, and I would recommend those who have planting to carry out in densely populated districts to give the above mentioned trees and shrubs a prominent place whatever else they may choose to try by way of experiment.

Southwark Park.

CHARLES DENNIS.

### "A BIG TREE," BY VAN GOYEN.

HERE we have a fine example of the productions of an early master of the Dutch school, who has been long famed for the air of repose that he managed to give to his landscapes. Van Goyen delighted always in calm waters, reflecting the dark shadows of the trees growing on the bank, and as constantly introduced fishermen drawing their nets in the calm of sunset or of early morn. He was noted for his quickness in painting, a cause, no doubt, of the indifferent preservation of some of his works; and his facility with his pencil was even greater, so that we can picture him as he slowly was journeying down some sluggish stream, immortalising (for our benefit in this instance) some fine old pollard tree that grew by the river's brink. Born at Leyden in 1596, and dying in 1656, he just escaped the stormy times of war, so foreign to his quiet-loving nature, that desolated the Low Countries not long afterwards.

E. H. W.

**Evergreen Hedges.**—My experience is exactly the reverse of that of "W. T." (see p. 400). He says that Thuja Lobbi does not grow so fast as Cupressus Lawsoniana. About five years ago a neighbour of mine planted a hedge of the latter, and at the same time I made one of Thuja Lobbi. My hedge, though considerably more trimmed, is now fully from 1½ ft. to 2 ft. higher than his, both having started about the same size and under equally favourable conditions. Moreover, Thuja Lobbi is better closed and like what a hedge should be, but Cupressus Lawsoniana has the richer colour. If planted in rich soil Yew is by no means a slow grower after the first two or three years; but the densest, most perfect evergreen hedge I have ever seen was one of the Chinese Arbor-vitæ, so dense that apparently a wren could with difficulty have penetrated it.—J. H. W. T., Carlou.

**Eucalyptus globulus.**—This is likely to prove perfectly hardy, at least as far as ordinary winters are concerned. Our plants of it have now passed through a third winter quite uninjured, and are now starting into new growth. W. WILDMATR, Hookfield, Hants.

## THE FLOWER GARDEN.

### YOUNG LILY BULBS INDEPENDENT OF THEIR PARENTS.

At page 252, Mr. Groom says:—"If 'Dunedin' will illustrate the totally distinct character of Lily bulbs in such a manner as to prove that neither directly nor indirectly is the succeeding year's flower-stem affected by cutting down the leaves while they are yet green, he will confer a boon on many cultivators, who, up to the present time, have attached great importance to retaining the foliage in health as long as possible." Without professing to draw any line of distinction between the characteristics of "all other bulbs" and the Lily, I shall endeavour to comply with Mr. Groom's invitation, so far as the Lily itself is concerned.

When the parent Lily bulb has liberated a germ, and as soon as that germ has begun to vegetate, what is it that causes it to adhere to the core or base of the bulb on the spot where it was liberated? Simply microscopic, hair-like, almost transparent rootlets, drawing or absorbing double-refined nutriment, if I may so call it, from the juice of the tender new core on which it is seated. These rootlets begin to be formed before the stem, and are, therefore, the first part of the young plants which protrudes from the seed-bud, the stem not rising until some time after the rootlets have been in action. The core or fleshy substance at the lower part of the bulb may be called the crown of the root and the base of the stem, for here the root and the stem effect a junction or connecting link, the one descending and the other ascending, forming parts of a common axis. The correctness of what I state may be made more apparent if, after a time, the parent bulb be cut in two right down through the centre, as it will then be seen, by the aid of the microscope, that the roots pass down, not simply from the base of the bulb, as some believe, but from the base of the stem itself, through the core. It is here, also, that in some Lilies adventitious buds, or small offsets, occasionally appear on the outside of the edges of the bulb, or where the fleshy scales join the descending axis; but these need never be mistaken for the legitimate central seed-bud. The roots, in their growth, keep pace with the development of the stem, so that, by the time the young stem has grown up near to the apex of the bulb, and before the parent bulb has begun to bloom, the roots of the new bulb will have grown some inches in length; but, being mixed up with the old roots, and having thus become apparently a tangled mass, they escape the notice of the merely superficial observer. When the parent bulb has been in bloom for some time, it then begins to lose strength gradually and to decay. This shows that the object of its growth is accomplished, for it now droops, and, in a short time, the leaves, stem, roots, and scales all perish. In some cases, vitality seems to linger on for a little longer, but the vital spark has fled, and there is now a total and permanent cessation of all the vital functions. The root, stem, and leaves constitute what are called the organs of nutrition or nourishment. Fluid matters are taken up by the cells of the roots from the soil; they are conveyed to the leaves, and there, under the influence of air and light, they are fitted for the purposes of plant life. The functions of the leaves appear to be a combination of those of the lungs and stomach of animals; they not only modify the food brought to them from the roots, so as to fit it for increasing the size of the parent plant, but they also absorb nourishment from the atmosphere, by means of which the vegetative functions are carried on—all tending to the production of the flowers. When the bloom is complete, the leaves cease to perform their functions; and, if not cut down at once, they decay gradually, and remain for a long time as withered unsightly appendages. Nothing can restore them; nor can they, in the slightest degree, aid the new bulb; for that bulb, even when the parent bulb is in full bloom, is wholly independent of any assistance from outside its own immediate organisation. To say, then, that the same identical bulb will ever bloom again is simply a mistake, possibly arising from the fact that the new bulb springs up from the very side, or within less than the hundredth part of an inch of the old flower-stem; which is, I admit, quite enough to mislead any one who only examines the outward or visible appearance of the bulb. To say, also, that either directly or indirectly the

succeeding year's flower-stem is affected by cutting down the leaves of the old plant while they are yet green is another mistake; for the roots of the new bulb have been drawing nourishment from the soil for a length of time before the parent bulb has actually begun to bloom. "Under such circumstances the new bulb must perfect itself solely by the aid of its own roots." There is no doubt of this, for all the sustenance that the old bulb could by any possibility afford has been exhausted in bringing to maturity and in perfecting its own bloom. In such a case we might ask, What is the death of a Lily? I answer that it is the loss of all susceptibility of renewed action; or, in other words, it is a want of the power to vegetate, though the requisites for vegetation are present. Then what is life? Of the nature of life, or the vital principle, science does not profess to be able to give an explanation. In using the term we only mean that power or quality resident in certain structures, by which they are enabled to incorporate with themselves those nutritive particles of matter which they require, and to reproduce structures of their own species or type. The term of vegetable existence, from the period of germination till the final decay of the plant, is extremely various. Nature has ordained that the term of the Lily's existence shall be two years. How can we prove this? By facts which Nature places before us. At the end of March last year I took up six bulbs, and, after dissecting them, sent three of the specimens to the office of THE GARDEN. Last month I also took up six bulbs and dissected them, and they are now lying before me while I write. Now the point is this: there can be no more correct description of those now lying before me than that which was sent with the specimens last year, and which will be found in THE GARDEN of March 31, 1877, page 260. This description has been a true one for thousands of years that have passed, and it will be a true one, year after year, until the chapter on Lilies shall have come to an end. From this the inquirer may learn that in the Lily we have a birth and a death every year, that is, the birth of a young germ and the death of the old bulb, a new fully developed bulb coming forward every year to take its stand between them. Those who assert that the old bulb, for the time being, does not every year decay and die, can know very little correctly of the true organic underground structure of the "Old World Lilies."

At page 357, I am glad to see Mr. Hovey's name once more, but he certainly does puzzle me. In his first letter he says:—"If a plant be broken off in June when 6 in. or 7 in. high, the bulb will die. If cut down in July it will go off into divisions of small bulbs; and if cut down in September the bulbs will only be about half size." He now says:—"It does no more injury to cut away the flower-stem of *L. candidum* when in full bloom than it does to cut off the flower-spike of a Hyacinth. The only safe and sure way to speedily raise good, large, sound, white Lily bulbs is to cut away the flower-stems as soon as they appear aboveground, every inch of growth weakening the bulb." Mr. Hovey tells us this, and he tells us further, that his experience of Lily culture extends over no less than a period of thirty years; he may therefore mean more than he now says, and his next letter may possibly clear it all up. I may now tell him, in return, that my experience goes a little farther back than his. In the Manse garden of my native place in Dumfriesshire, more than forty years ago, I took great delight in the cultivation of all kinds of Lilies that I could procure; and here, since that time, in the neighbourhood of London, I have found it a most pleasing and healthful recreation, after my public duties were over, to devote many of my leisure hours to the study of the Lily, more especially to that portion which includes its underground growth and interior action. In what I have written from time to time I have propounded nothing that I did not think was supported by facts. I trust, therefore, that, however imperfect my communications to THE GARDEN may have been, my time has not been entirely thrown away.

DONEDIN.

**Large Holly Tree.**—The following are the dimensions of a Holly tree growing here: Height, 50 ft.; circumference of stem at 3 ft. from the ground, 3 ft. 6 in. It has few branches, having grown among other trees in a plantation with no room to spread; and it is unfortunately dying, some boys having ripped off a large portion of its bark for bird-lime.—J. H. W. T., *Carlisle*.

## THE KITCHEN GARDEN.

### ASPARAGUS PRIZES.

It was a happy thought to offer the Asparagus prizes, as announced in THE GARDEN of April 20 (see p. 355). Next to Peas, probably Asparagus is the most highly prized vegetable. It is also the one that is often less satisfactory than most others. Even the best way of using it is, as yet, undetermined. Some only eat a mere knob on the point of the shoot; others prefer a good honest 6 in. or more of green stalk. The former is assuredly a most wasteful method of using Asparagus; the major portion of it is as white as ivory and almost as hard, and it is used as a stick to hold on by while the delicious morsel on its crown is duly dipped in butter and devoured. Some information ought to be given in the promised printed instructions as to which of these two forms of Asparagus are to be rewarded; both are recognised and grown even at Argenteuil, the green being called English Asparagus, and the huge timber with edible top on the end the true Argenteuil. Is the latter really a distinct and superior variety, or does the surface and far-apart mode of culture make all the difference? There is much obscurity and mystery about the so-called varieties of Asparagus. The Giant of one place becomes very dwarf indeed, and small and short in another; Conover's, too, seems to become marvellously like the old sort after a few years' cultivation. I have just received two varieties of Asparagus seeds from Argenteuil, the true and the wild, and should like to be further informed of the difference between them. Is not, for example, the English Asparagus, sold under this name in the Parisian markets and eaten with a fork, merely the small of the large stools? Certain it is that locality and soils have more effect on Asparagus than mere difference of sorts, if such there be, or varieties of culture. Hence the importance of requiring the competitors to furnish particulars of the soil and subsoil on which their Asparagus was grown. Soil makes or mars the Asparagus in various ways. Our greatest difficulty here has arisen from a sort of red rust eating into the roots and the crowns. No matter how well the plants start and thrive for a year or two, the fibres get cankered, and the crowns often destroyed by a species of rust that seems fatal to the longevity and vigour of the plants. The finest three or four-year-old plants even get broken down in this way. Complete changes of soil have been tried with little effect. Our loam seems singularly destitute of fibre and considerably impregnated with iron. Various composts and mixtures have been tried with more or less success, but without reaching very satisfactory results. By no previous means has our Asparagus yet reached the best standard of Covent Garden, to say nothing of the tremendously large French Asparagus. I therefore mean to try the plan suggested of planting on a bit of the best kitchen garden ground at wide distances, and without any special preparation. Our kitchen garden is on the chalk, and the latter is within 30 in. of the surface in many places, though some of the Asparagus beds are over 3 ft. deep. Would the proximity of the chalk be likely to originate or spread the root rust? The culture is fairly high, as far as dressing with manure, salt, manure water, &c., is concerned, and it is exactly such as has commanded greater success with far less trouble in other localities. I may add that the average of the neighbourhood is considerably below Cambridge, Ely, Colchester, and Battersea. Colchester is, in fact, famed for its Asparagus, and I believe that it is grown in rich black soil. There is very little such soil about Bury, unless by the side of the river Lark; and in gardens so placed the Asparagus is finer and far healthier. Will any one give their experience of Asparagus culture on loam over the chalk, and near to the latter? Let us trust that substantial improvement in Asparagus culture may be brought about by the handsome prizes to which allusion has just been made.

D. T. FISHER.

[There is, unfortunately, no more erroneous statement than that only the tip of the large imported Asparagus is edible. It is often stale, but even when it has been a week exposed in a shop, besides the time lost in carriage, it is edible to from 4 in. to 5 in. of its length when properly boiled. The shoots are very susceptible to injury from light. We shall only know how delicious it is when such shoots are cooked freshly gathered from our own gardens, in which they may be

grown to perfection. Nobody who has really tried Asparagus in all stages, and who has had the chance of eating this large, partially blanched Asparagus fresh, cares about any other kind, except in soup, or in the various ways cooks use Asparagus in dishes, apart from the best of all ways—that of eating it alone. The kind of Asparagus grown throughout the United Kingdom is often suited for soup and cutting up in small dishes. In France this is obtained for like purposes by close planting occasionally, but usually this kind is obtained from forced plants. These afford the small green shoots desired. The beds for forcing give a good supply of this throughout the winter and spring, and long before large Asparagus is plentiful. In winter and spring this small Grass is the more valued. Asparagus properly grown and cooked is, in our opinion, not second to any vegetable, and is far before Peas. It is frequently grown well in market gardens, though rarely so well as it might be grown, but it is often a complete failure in private gardens; and the reason is quite clear—ten plants where one ought to be. The term English Asparagus has no common acceptation in France, though no doubt it has been used by some one alluding to the shoots cut in England. The question of varieties is an interesting one, and ought to be finally settled. From inquiries made on the spot, we are inclined to think there are at least two good varieties—an early and a late. A trial of 100 plants of these has lately been made by one of our friends, and similar trials ought to be made elsewhere till this most important point is settled. Still, we think sorts are of far less importance than culture; though it is probable that the excellent Argenteuil race is the best and largest. London shops are now full of Asparagus that comes from Toulouse and other distant parts of France that might be grown as well in England, and have the additional advantage of freshness. It was a knowledge of such facts, arising from personal observation of our own old method and that pursued about Argenteuil, that led to the idea of the prizes now offered in the hope of making English culture of Asparagus, imperfect and neglected up to the present time, as good as that pursued in any other country. Some original illustrations are being prepared to illustrate what we intend to publish on the subject; and as soon as these are engraved we shall issue the circular. Meanwhile, the essential point for the present is to plant, and plant thinly. In France, at this season, plants are sent off in great numbers from Argenteuil in a dry state—all healthy one-year seedlings. Mr. Fish's soil is evidently very unsuitable for Asparagus, and we should recommend his going "near the river."] "

#### THINNING ROOT CROPS.

It may be taken as a general fact that far more seeds are sown everywhere than is really necessary, though perhaps, beyond the extra expense incurred in its purchase, no great harm is done if the thinning be commenced early, as, when there are an abundance of plants to select from, there is every probability of securing a better and more even crop. In garden culture, mere size is not so much a consideration as quality. Large coarse vegetables are not looked upon with any favour in good establishments, but rather the reverse; and the fact should be allowed to carry due weight in apportioning the space for each plant to occupy. The most perfect way of thinning vegetables is to begin early, removing the weaker plants first, so that when the thinning is finally completed the best plants only are left at suitable distances. Let anyone take any given number of seeds out of any sample, sow them at equal distances apart, and treat all exactly alike until the crop is fit for use; and yet there will be a considerable variation, even in the best stocks, in both size and quality. Hence, sowing more seeds than is necessary is not all loss, as it enables the cultivator to select the best plants to stand for the crop. Of course, the better the seeds the less need be sown. In thinning root crops, the first operation may be performed with a small, sharp hoe, cutting clear spaces through the rows at small intervals, leaving the plants standing in small isolated patches. In the course of a few days they should be gone over again, and all the weakly plants removed by pulling them up. After another interval of a week or two the plants should be finally singled, leaving, of course, the best. Doing the work tentatively gives a power of selection that, if properly taken advantage of, secures an even, regular crop. If it be desired, the thinning of such crops as Carrots and Onions may be so arranged as to leave the final singling till the plants or roots are large enough for use; but I do

not recommend the plan, as, if the weather be dry, drawing the roots up lets the drought into the land, and a present benefit is obtained at the expense of a future loss. All hoeing is best done when the surface of the land is dry, but the after-thinning and final singling-out should be done, if possible, during a showery time, as then any little disturbance or disarrangement of the soil around the permanent plants will be immediately rectified. As regards the distances that each plant should be allowed to occupy, very good Carrots for table use may be grown 4 in. apart in rows, with from 12 in. to 15 in. separating the drills. Parsnips should have 6 in.; Salsify and Scorzonera the same; Chicory 8 in.; Beet 9 in.; Turnip from 6 in. for the earliest crop to 12 in. or 15 in. for later ones; Onions may be left at distances varying from 2 in. to 6 in., according to the purpose for which they are required. But, of course, the more space given, the larger the bulbs will grow, all other things being equal.

E. HOBDAV.

#### CANKER IN PARSLEY.

"CHEF'S" remarks (see p. 419) on this subject are sound and good. The following hints may be added to them, for Parsley is a most important crop, and not a few have lost good situations and thousands more been made most uncomfortable in them through the failure of Parsley. It grows like a weed when there is plenty, and seems to stand quite still for a month or more together when scarce. Cures for canker in Parsley there seems none. The best preventive is fresh, rich, deep soil and a thin plant. Parsley seems to poison the land like Clover. Not only should no one ever take two crops of Parsley in succession off the same ground, but the longer the intervals between the crops the better are they likely to be. A deep soil is also best for Parsley. It does well on heavy soils if these be lightened a little with burnt earth, ashes, &c.—the refuse of burnt rubbish of any sort. Soot I have found the best manure for Parsley. This may be dug into the ground, applied as a top-dressing, and also employed in a liquid state to flood the crop with during dry weather. I have never found the sun injure Parsley in good soil. Parsley should be sown in rows from 15 in. to 18 in. apart, and the plants thinned to distances of 6 in. to 9 in. from each other. Treated thus, Parsley leaves become highly ornamental, and the produce is finer as well as greater than by the usual mode of crowding the crop. Finally, a loose surface maintained by frequent scarification is of great importance to the free and healthy growth of Parsley. It specially dislikes a hard soil, either above or below, and thrives best on soils at once warm, free, and rich. For winter supply there is no mode so sure and certain as the potting up a dozen or more of 8-in. pots, and placing them in a forcing or other hot-house at a temperature of 60° or so. This treatment produces a magnificent supply of Parsley, at once clean, sweet, tender, and ornamental. Not a few Anthuriums, Ferns, and other plants are grown for their foliage alone that are not one whit more beautiful than will-grown pots of some of the finer and more profusely curled Parsleys. D. T. FISHER.

**How to Lengthen the Asparagus Season.**—Having frequently noticed Mr. Grieve's practice in reference to this matter, as described in last week's GARDEN (see p. 418), it affords me much pleasure in testifying to his great success. His practice differs from that of most people, inasmuch as he forces the whole of his beds every year, which, as he affirms, by no means weakens or exhausts the plants. Few better investments could be made than that in a few hot-water pipes, a simple boiler, and a few frame-lights, as described by Mr. Grieve; and these are really all that is needed to command a supply of this choice vegetable. From Christmas to April or May, the time of cutting in the open air, the advantages of hot water over manure-heat must be shown. It is regular, can be depended upon, and at once applied or withdrawn at pleasure. Manure-heat is most capricious in its action; if at one time burns, at another starves the plants. The heat rises and falls without any regard to the wants of the cultivator, and it takes considerable time to neutralise the evils of excess, or to make up for a deficiency of manure-heat. In the end, too, it is probable that fire-heat is the cheaper of the two, and, as Mr. Grieve says, once the Asparagus is fairly started, very little heat is needed to keep it growing.—D. T. FISHER.

**Carters' Summer Broccoli**—This has yielded me a good supply late in spring, and is altogether an excellent Broccoli for this part of the country.—J. WENFIELD, *Llanstephan*.

**Tomatoes.**—I know of no vegetable that has grown in public favour so much as Tomatoes. We have been gathering them from pots for some time back. When—as is usual—they are planted outside in small pots in May, it is August generally before they are ripe; but this season I have been growing them in 9-in. pots, and have to-day planted out the first batch—full of green fruit, large plants 4 ft. high; I therefore fully expect to have them ripe in June. I find Green Gage to be the earliest and to make the best salad.—R. G.

## ANSWERS TO CORRESPONDENTS.

Questions from correspondents who do not send their names and addresses in full (not necessarily for publication) cannot be answered. The questions are usually submitted to good practitioners in their several departments. Whether questions are answered or asked in this department, we shall be greatly obliged to any readers who bring able to help our correspondents, will kindly furnish answers. Questions cannot always be answered in the same week in which they are received.

**Abnormal Azalea Bloom.**—On the back of one of the petals of an Azalea bloom which I send you may be seen a growth of small stamens. Is this abnormal growth of frequent occurrence?—C. J. L. [No; it shows the close connection that exists between all parts of a flower, and the readiness with which one may take the place of the other.—M.]

**Double Yellow Primroses.**—I send a blossom and leaf of a double yellow Primrose, a seedling from among many that are growing in the gardens here. Is there one of its class as good in the market? It is a very free bloomer.—WILLIAM HOPKINS, Alderholt. [It is, we think, the best by far of any double yellow Primrose we remember to have seen, the colour being very good and the flower large.]

**Orchard Hone Caterpillars.**—I send you some caterpillars which are injuring my fruit trees in pots in a large span-roofed house, 130 ft. by 30 ft.—THOMAS CLARE, Whitley Park. [The small green caterpillars which are injuring your Pear trees are those of a small moth belonging to the family of Looper. These caterpillars draw the young leaves together by a web and can be easily seen and killed. Kindly send us a few more of the caterpillars for breeding purposes.—W.]

**Melons for the Open Air.**—Can you inform me of a kind of Melon hardy enough for open-air planting on the ridge, the plants having been raised under a frame and hardened off?—F. M., JUN. [You might try Manro's Little Heath, Golden Gem, or Suttons' Tom Thumb, all of which are hardy sorts, but we fear the result will not be very satisfactory.—S.]

**Trichomanes reniforme Fringing.**—Can any of your correspondents inform me if this Fern ever fruits in this country? I have two plants—one of them large—but hitherto they have not borne any fertile fronds, and I do not remember to have seen it in fruit anywhere.—F. N. F. [This species of Trichomanes has hitherto seldom produced, under cultivation, fertile fronds. I have not seen them more than two or three times, but they are very beautiful.—W. H. G.]

**Tarred Felt.**—Is this injurious to plants? A Rose tree trained over the roof of a summer house has lost all its shoots—a mishap which I attribute either to frost or the tarred felt. Which is at fault—the frost or the felt? and is there any remedy?—H. M. O. [The tarred felt would not injure your Roses, i.e., if dry before the Roses were trained over it. Of course if the felt has been fresh tarred without removing the Roses, injury would be sure to accrue; but surely you have not done that? Frost is no doubt the delinquent; on them back at once and all will be well.—W. W.]

**New Zealand Flax.**—Are the seeds of this long in coming up? We put some in last spring and again this year, with and without hot-bath, but without success.—R. A. G. [Seeds of this plant do not retain their vitality long enough to withstand the journey from New Zealand to this country. Although they may appear quite plump and fresh they will not grow, and ought never to be either sown or sown. On the other hand, home-saved seed, if sown as soon as gathered, comes up quite freely; but this probably cannot be purchased in seed shops.—T. S.]

**Gum Cistus (Cistus ladaniferus).**—How is this propagated? By cuttings or seeds? If the former, which is the right season for inserting them and how? Also Cistus roseus, C. incanus, and C. salicifolius.—A. M. A. [Cistus ladaniferus is multiplied by cuttings; as are also all the Cistuses and Helianthemums. They likewise grow freely from well-ripened seeds. Berberis fascicularis may be propagated either from seed or layers.—B.]

**Planting Water Lilies.**—I wish to grow the native, large white, Water Lily in a pond joining a river. Can you let me know if I should obtain plants or seed, and how and at what time of year they should be immersed? The depth of the pond varies, but I suppose from 3 ft. to 4 ft. is about the right thing. Who has them for sale?—J. H. W. T., Corlew. [Rootstocks are the best, and they may be planted any time during the winter or spring. In the case you describe they only require to be each tied to a brick or stone, which will keep the rootstocks against the bottom till they have rooted.—A.]

**Roses and the Cloire de Dijon for Panches and Walls.**—Kindly name two or three Roses (not the Cloire de Dijon) best suited to climb over a porch having a N.E. aspect; also two or three climbers best suited for training on the walls of a house having the same aspect (not Virginian Creeper). Will *Fyrus japonica* or *Jasminum nudiflorum* do? The soil is Norwood clay.—R. H. P. [As climbing Roses for a porch having a north-east aspect, I should recommend *Felicite perdue*, *Boursault Amadis*, *Laura Davoust*, *Ruza*, and *Tea Belle de Bordeaux*. Both *Fyrus japonica* and *Jasminum nudiflorum* will succeed against the walls of a house, and to these you may add *Clematis Flammula*, *Lonicera flexosa*, and *Garrya elliptica*.—A. P.]

**The Best Apple Trees for Ornamental Planting.**—I have begun to plant fruit trees for ornament, and having, I think, found out the Pears that form the handsomest trees for town or pleasure grounds, I shall be grateful to any of your readers who will tell me of the kinds of Apples that form the largest and most ornamental trees.—F. L. [The following sorts are free

gro wers, and have handsome blossoms and fruit, viz., Adams' Pearmain, Barrington, Duchess of Oldenburgh, Emperor Alexander, Fearn's Pippin, Flower of Kent, Glory of the West, Golden Noble, Golden Winter Pearmain, Hambleton Deux Ans, Hawthornden, Irish Peach, Kenish Filleback, Early Bough, Lord Suffield, King de Månage, Northern Greening, Reineette de Canada, Wadhurst Pippin, Warner's Mine, White Astrachan, and Yellow Ingestrie.—W. W.]

**Earl Preventive** (see p. 429).—In order to prevent rust, thoroughly scrape and clean the surface of the boiler, and then paint it with red lead or boiled oil. To prevent radiation, cover with Leroy's non-conducting composition for steam boilers.—W. V. M.

**Plants Figured.—A. K.** The plants you name may all be obtained through any of the larger metropolitan nurserymen. Some of them are scarce, but all are obtainable.

**Names of Plants.—P. E. S.** *Hederaea tulipiferum*.—*S. Ritchii*, 1, *Gymnogramma Martensii*; 2, *Adiantum affine*; 3, *Athyrium*, too indistinct and imperfect; 4, *Athyrium filix femina corymbosa*.

**Rose Houses.**—What is the best form of house for the cultivation of Roses—standards, half-standards, climbers—on their own roots? My garden is in such an exposed position that to grow them out-of-doors is attended only with disappointment. In a recent number one of your correspondents objected to side ventilation, and urged that the air should not strike the trees. How can this be avoided, and yet provide sufficient ventilation? My Rose house is about 60 ft. long by 16 ft. wide, and is ventilated by both sides opening, and the ridge rising. What other system can be adopted?—W. C., Newcastle. [The best form of house wherein to cultivate Roses is a span-roof one running north and south, in a fully open situation, where there is nothing to intercept light, and it should be glazed down to within 1 ft. of the ground level. Means of admitting air, both at the sides and roof, is an absolute necessity; but it should never be given at the sides during winter and spring where more or less forcing is carried out; later in the season, when the older foliage becomes matted and the young leaves less tender, air will require to be admitted freely both at top and sides.—T. B.]

**Azaleas after Flowering.**—What is the proper treatment of young Azalea plants after flowering? They are from 12 in. to 15 in. high, and were potted off last autumn into 6-in. pots. Should they be re-potted? If so, into what sized pots? Should they be put out in their fresh pots in the open air, in a shady place, kept well watered, and returned to the house early in autumn (September)? Should the extreme points of the shoots be trimmed off? If so, when?—J. T. [Azaleas potted last autumn, if they have not been kept in a growing temperature through the winter, unless they received a very small shift at the time of being moved, will scarcely require potting this summer. They are said to be 12 in. or 15 in. high, but this conveys an imperfect idea of their size. If the diameter be at all proportionate to the height, and they are in a healthy vigorous condition, they would be better placed at once in 9-in. pots than allowed to remain as they are; but on no account put them out-of-doors whether newly potted or not. Though very common treatment, it is the worst course with these plants that can be followed. They should be kept always wholly under glass during the summer in a growing temperature; if in the north of the kingdom by the aid of a little fire-heat in dull weather; in the south by shutting up early, so as to make use of the sun's warmth; syringing well overhead every afternoon until the flower-buds are fairly visible; then give more air and leave off syringing. Do not keep them too wet at the roots, but water before the soil is ever allowed to become as dry, as is necessary for many hard wooded subjects; pinch out the points of such shoots as are over-strong and taking an undue lead. These also should be tied down, which will tend to equalise the strength.—T. B.]

## Questions.

**Sleep-producing Australian Shrub.**—Can any of the readers of THE GARDEN kindly inform me of the name of an Australian shrub the leaves of which, placed in a basin of water, have the effect of producing refreshing sleep?—A. S. L.

**Shading.**—Is it advisable to white the inside or outside glass of a greenhouse—I mean the roof, and what is the best mixture? Would white lead and turpentine be good? or would it injure such climbers as *Tecoma*, *Tropaeolum*, and others?—W. S.

**Thuja gigantea.**—Is this as hardy as the common American *Arbor-vitae*? Would the *Arbor-vitae* family be generally likely to succeed under tall trees, there being no low branches or undergrowth to interfere with them?—R.

**Green Fly on Orange Trees.**—How can I best get rid of green fly or blight on a large Orange tree in the border of a greenhouse? It appears very healthy, has a large number of Oranges, and is full of blossoms nearly expanded, and which, I fear, will be injured by syringing. Washing and brushing the leaves have been tried, but the blight appears again the next morning.—S. H.

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

MAY 7.

THIS was one of the best meetings as regards exhibits that has been held this year. Orchids, Azaleas, Gloxinias, and Roses formed the principal features, the latter being shown in considerable numbers both in a cut state and in the form of plants.

First-class Certificates were awarded as follows:—

**Rhipidopteris peltata gracillima** (Veitch).—A garden variety, with finely-cut pinnae, previously alluded to in THE GARDEN.

**Azalea Madame Charles Van Eckhaute** (Veitch).—A kind with large semi-double flowers of snowy whiteness, of good substance. Well worth adding to any good collection.

**Coleus George Bunyard** (Veitch).—A distinct kind, having fiery-crimson leaves, broadly margined with bronze and green.

**Adiantum Lawsonianum** (Veitch).—A garden variety, with light, triangular-shaped pinnae. Very distinct, and well worth culture.

**Primula acaulis sulphurea major** (Veitch).—An excellent variety, bearing a profusion of large, double, sulphur-coloured blossoms. Should be grown more or less in every garden, however small.

**Marica pacifica** (Bull).—An Iris-like plant from the South Pacific, bearing curious flowers, with large, white, waxy sepals, blue and white striped recurved petals, edged with brown and yellowish spots.

**Iris Leichtlini** (Elwes).—An hybrid, the result of a cross between *I. asiatica* and *I. iberica*, with unusually large flowers.

**Bomaria Caldasii** (Ellacombe).—A very ornamental variety, bearing large trusses of orange-scarlet, beautifully spotted, funnel-shaped flowers.

**Aquilegia alpina superba** (Dean).—A seedling of a deep bluish-purple colour. Well worth growing.

**Gloxinia Beauty of Anerley** (Willa).—A superb flower of extraordinary size, and of a deep velvet-crimson colour. One of the best Gloxinias of its kind which has been raised for some time.

**Saxifraga calyciflora** (Atkins).—A plant consisting of neat rosettes of glaucous leaves and bearing dull purple flowers on short stalks.

**Coleus Kentish Fire** (Williams).—A brilliant kind, distinct, and well worth attention.

**Camassia Browni**.—A strong-growing Lilywort, bearing very large spikes of beautiful blue blossoms. A great improvement on the well-known *C. esculenta*.

Certificates were also awarded to *Auricula Salvia* (Dean), *Dioscorea retusa* (Veitch), *Anemifidictyon Phyllitidis tessellata* (Williams), and a botanical commendation was awarded to *Androsace sarmentosa* (Atkins), a beautiful rock plant, which, at certain seasons of the year, has leaves which become glaucous. It bears small trusses of pink blossoms.

**Roses**.—A large collection of these came from Messrs. Lane & Son, Great Berkhamsted. The plants were dwarf and remarkably fresh, both as regards foliage and flowers. Among the most noteworthy kinds were well-flowered examples of Paul Neron, John Kaynes, the dark crimson Prince Camille de Rohan, and Julia Touvais. This group was rendered more effective by being edged with neatly-grown plants of Ghent Azalea and the variety *mollis*. Messrs. W. Paul had a group of larger plants, consisting of such kinds as the cream-coloured Madame Hippolyte Jamai, the rose Paul Verdier, Star of Waltham, and the beautiful Tea-scented Madame Margottin. From Messrs. Veitch & Son also came an excellent collection of bushy, well-grown plants, bearing a profusion of fresh, well-formed blossoms, among which we noted remarkably good examples of the delicate Madame Lacharme and the creamy Madame Villermoz, one of the best of pot roses, and one which has been shown so well and often this season. Dupuy-Jamin was well studded with large, rosy-crimson blossoms, and dwarf plants of Marquise de Castellane were unusually fresh and pleasing.

**Orchids**.—A grand collection of these came from Sir Trevor Lawrence. It consisted of remarkably well-flowered plants of *Odontoglossum Cervantesii* and its varieties; *O. aseptum*, bearing magnificent spikes of prettily-marked, chocolate blossoms; *O. vexillarium*

roseum, bearing the largest flowers we have ever seen; the scarlet-orange *Ada aurantiaca*; *Lælia majalis*, bearing large, gorgeous, violet blossoms; and *Dendrobium thyrsiflorum*, furnished with large, pendant clusters of blossom. A large specimen of *Cattleya Skinneri* was very attractive. The group was backed up by *Oncidium Marshallianum*, bearing strong branching flower-spikes from 4 ft. to 5 ft. long, gracefully beset with bright yellow, chocolate-spotted flowers. Mr. Wilm, the Uplands, Birmingham, sent a plant of *Odontoglossum cirrhosum*, bearing a remarkably fine spike of blossom. It was nearly 4 ft. long, branching, and was thickly covered with beautifully-spotted flowers.

**Azaleas**.—These were well shown by Messrs. Veitch & Sons, Chelsea, and Mr. Charles Turner, Slough. The former exhibitors had massive specimens of attractive kinds, which were much admired on account of their profusion of blossom, and their being of a less formal character than is usually the case in specimen Azaleas. We noticed fine examples of the Flag of Truce, still one of the best of the semi-double white kind, the rich orange-scarlet, purple-flushed Stella, and the attractive white violet-striped Madame Mielze. Among newer kinds shown in the shape of small plants, one named Harry Veitch was admired for its distinct rose-coloured blossoms, which reminded one, as regards colour and delicacy, of the beautiful *Odontoglossum vexillarium*. Other good kinds were the semi-double Roi des Belges, Oswald de Kerchove, and the brilliant Flambeau. Mr. Turner's group, which consisted of medium-sized, shapely dwarf standard plants of the choicest kinds, was rendered very attractive by being interspersed with healthy plants of *Cocos Weddelliana* and other Palms, Ferns, and Grasses. Among the most attractive kinds were the beautiful white magnifica and Madame M. Lefebvre, associated with the conspicuous semi-double Juliette, a kind with striking deep rosy-purple imbricated blossoms. The large-flowered grandis and the brilliant orange-scarlet *Non pour le Commerce* showed off to advantage with the attractive *Jean Vervaens*, a kind with rose or salmon-coloured flowers, conspicuously tipped with white.

**Cut Flowers**.—Mr. Elwes, Preston House, Cirencester, sent a very attractive collection of hardy flowers, consisting of bright-looking Tulips (species), the beautiful blue *Phlox divarica* (from North America), splendid spikes of the British *Orchis mascula*, the North American *Lady's-slipper* (*Cypripedium pubescens* and *C. parviflorum*), bright in colour, and good in form and size. In this group were also several very attractive *Sparaxis*, *Cycolobotras*, and a beautiful branching spike of the New Zealand *Arthropodium paniculatum*, bearing white, starry flowers. *Fritillarias*, *Leucocoma*, and *Trillium* were also all represented, also several beautiful *Irids*. Messrs. Paul & Son, the Old Nurseries, Chestnut, sent excellent stands of cut Roses, among which we noted bright and well-formed blossoms of *alba rosea*, Prince Camille de Rohan, bright scarlet *Duc de Rohan*, Charles Lefebvre, and Captain Christy; also the beautiful rich creamy-yellow *Belle Lyonnaise*, fine blooms of *Souvenir d'un Ami*, and Madame Villermoz, associating effectively with the deep pink *Annie Laxton*, *Mrs. Raby*, and other valuable kinds. A large collection of cut blooms of *Rhododendrons* came from Messrs. Veitch & Sons, also *Magnolias*, Ghent *Azaleas*, *Viburnum Lantana*, and *Wistaria japonica alba*, a kind seldom seen, but one which would be of great value for associating with the blue-flowered kind. Mr. Parker, Tooting, sent a collection of herbaceous plants, consisting of *Scilla campanulata* and its varieties, and *S. nutans* and its varieties, the latter bearing unusually large and brightly-coloured flowers; also *Iris obliquens*, *Iris alba lutea*, *Iris biflora*, a beautiful *Iberia* named *Tenoreana*, and a purple *Viola* named *Delabordei*. Mr. J. H. Goodacre, The Gardens, Elvaston Castle, Derby, sent fine cut spikes of *Stephanotis* and *Bougainvillea*. Messrs. William Paul & Son also had a large collection of cut *Roses*, among which we noticed large blooms of *Star of Waltham*, bright blooms of *Madame Charles Wood*, and good examples of *Magna Charta* and *Louis Van Houtte*. Mr. Cannell, Swanley, sent magnificent blooms of seedling *Mimulus*; also blooms of white and salmon *Vesuvius Pelargoniums*. A good collection of blooms of *Maréchal Niel* was shown by Mr. Mayo, Oxford. Cut blooms of *Rose La France*, from Mr. Iggleden, were admired on account of their bright colour. Mr. Wheble, Bulmarsh Court, Reading, exhibited blooms of *Rhododendron Russellianum*, cut from a plant in the open air fifty years old, 15 ft. high, which this year bears five hundred blossoms. Messrs. Barr & Sugden sent a collection of *Daffodils*, *Anemones*, *Scillas*, *Sparaxis*, and other hardy flowers. Mr. R. Dean sent cut blooms of *Cheiranthus Alleni* and *C. Marshallii*; both kinds possess the same habit of growth, but the flowers of the former are much darker than the latter. A beautiful variety of *Primula amœna* named *laciniata* was also shown; its flowers are of a bright rose, and the petals deeply cut and very ornamental.

**Miscellaneous Subjects**.—Messrs. Veitch & Son exhibited an attractive group of new plants, consisting of *Erythrina marmorata*,

a beautiful variegated form of a well-known wall plant, and likely to be largely grown on account of its showy green and cream-coloured foliage. Finely-coloured plants of *Phyllanthus roseo-pictus* were also shown; also *Acalypha Maceana*, *Tillandsia zebrina* major, bearing a large, sword-like, brilliant scarlet flower-spike. Well-flowered plants of *Hemanthus cinnabarinus* were shown in good condition; also a garden variety of *Todea*, named *plumosa*, a small-growing kind, with graceful, and somewhat finely cut pinnae. Mr. B. S. Williams, Holloway, sent a very attractive collection of plants, consisting of finely-flowered specimens of *Franciscosa calycina*, *Azalea*, *Boronia*, &c.; also neat, one-shaped plants of *Erica ventricosa coccinea minor*, and *Genetyllis talipifera*. Several choice *Orchidee* were also noticeable in this group, among which may be mentioned finely-flowered plants of *Dendrobium Falconeri* and *D. Devonianum*. Panfuls of *Primaula amoena alba* were very attractive, as were also fine healthy specimens of the new *Dracuna Bausei*. Messrs. Rollison & Sons, Tooting, showed an extensive collection of *Azaleas*, *Heaths*, *Palms*, *Orchids*, and other attractive subjects, edged with small *Ferns*, *Colerases*, &c. The same firm also sent a large basket of plants of *Primaula cortusoides amoena*, which made an attractive feature; also a well-flowered plant of *Iris iberica*; and Mr. Aldous, South Kensington, sent a group of decorative plants, consisting of *Lily of the Valley*, *Ericas*, *Ferns*, *Fuchsias*, &c. Mr. Turner, Slough, sent a basket of plants of a single *Petunia*, *Mont Beauty*, a strong-growing kind with very large purple flowers with white centre, and well adapted for covering pillars, stones, or roots; from Messrs. Paul & Son, the Old Nurseries, Chesham, came a basket of plants of the golden *Philadelphus coronarius folius aureus*. Messrs. Osborn & Sons, Fulham, sent a group of healthy *Palms*, *Crotons*, *Yuccas*, and other useful plants; also baskets of plants of *Harrison's Musk* (*Mimulus moschatus Harrisoni*) and *Gentiana acutilis*, to show their attractive character when grown in masses. Large groups of named *Gloxinias* were shown from the Royal Horticultural Society's gardens, Chiswick; and from Mr. Wills' nursery, Anerley, came a large collection of seedling kinds, well flowered and of great merit. Mr. Wills also contributed an artistically-arranged group of *Orchids*, *Ferns*, *Gloxinias*, *Palms*, &c., which attracted much attention.

**Fruit and Vegetables.**—Mr. Iggulden, gardener to R. Baker, Esq., Orsett Hall, Romford, sent a basket of fruit consisting of black and white Grapes and a Melon, all of which were creditable for the season. Mr. Miles, The Gardens, Wycombe Abbey, sent excellent fruit of the Black Circassian and Elton Cherries, and Mr. L. Killick, Langley, Maidstone, sent Apples, Gooseberry Pippin, Sturmer Pippin, Kingswood Crab, and Wellington in good condition. Mr. Gilbert, Burchley, showed good examples of Foster's Seedling Grapes, Early Beatrice Peaches, Hathaway, Excelsior, and Carters' Green Gate Tomato; also beautiful examples of Myatt's Prolific Kidney Potato.

In the afternoon twenty-five new members were elected, after which Mr. Elwes delivered an interesting lecture on the Tulip, giving the history and distribution of nearly all the known species of that plant, many of which have been in cultivation for upwards of 300 years. Some of the best kinds the lecturer had before him in flower, and others were illustrated by coloured plates in old books. Though some species are found nearly all over Europe and Asia, the most appear to come from Turkey, Hindostan, and Asia Minor. There are very few species found in Japan, *Tulipa stellata*, which is the smallest as well as the earliest, being perhaps the only one. This kind blooms in January or February, unless cut off by frost. The lecturer, whilst fully recognising the importance of the garden Tulips, which are imported from Holland every year in such large quantities, was of opinion that more interest and enjoyment were to be derived from the many different wild species than from any of the florists' kinds; he also generously offered to give any one desirous of cultivating the species any information that laid in his power, as well as help them to secure bulbs. From experience, Mr. Elwes found that the best way to keep choice Tulips was to cover them during the winter months with hand-glasses, or to take them up and store them away every year, and especially was this necessary in wet soils and districts. Many good kinds had been almost lost to cultivation through neglecting this precaution.

#### SQUILLS FOR THE WILD GARDEN.

THESE must always play an important part in the wild garden. Their variations in colour are endless, ranging, as they do, from the most intense purple-blue to a delicate sky-blue, and with markings varying from the richest blue to the deepest purple. Of reds there is almost every shade, and many of the whites vie with the *Lily of the Valley* in elegance and density of bell. To Aiton's typical form of *Scilla campanulata* we have to add *S. campanulata minor*, *S. campanulata minor purpurea striata*, and *S. campanulata aperta* with its

conspicuous spreading flowers of rich blue. The emperor and empress of the family are, however, *S. c. maxima cœrulea* and *S. c. m. atra cœrulea*. *S. patula*, which may be said to be half way between *S. campanulata* and *S. nutans*, and its large-flowered variety *S. p. grandiflora*, next deserve attention. Following these come *S. nutans belgica* and our own native *Bluebell Squill* (*S. nutans*). The *campanulata* section is represented by pinks of various hues and whites of various sizes, and to the *patula* section also belong whites and pinks, while *nutans* has also great variations in shades of pink and white. *S. nutans lilacina* is a charming kind, its white colour being faintly tinged with lilac. I am indebted to Major Trevor Clarke for this beautiful little variety. Before closing our list we must not omit *S. cœrulea*, the latest to flower, though not the least decorative, a variety which is only represented in pink. These constitute only a portion of the varieties of Squills which I cultivate. I have at least fifty so-called varieties in my collection, all more or less distinct, which have been gathered together from many sources both in this country and on the Continent, but as neither science nor horticulture would be benefited by the rest as many forms, I purpose fixing upon twenty of the best and using the same as mixtures. P. BARR.

**Romneya Coulteri and Genetyllis Hookeri in the Isle of Wight.**—*Romneya Coulteri* has proved itself to be quite hardy in the Isle of Wight. A plant of it which I had from America of very small size about a year ago is now doing well, and will be a fine sight in the summer. It has been in the open ground for more than a year. The plant, however, which has surprised me most in point of endurance is *Genetyllis Hookeri*. Sir W. Hutt planted it out last year in the open border in his garden at Appley Towers, and it is in splendid condition now, and quite a mass of bloom. This may well lead to other experiments with the same class of plants in the south of England.—H. EWELANK, *St. John's, Ryde*.

**Sparaxis and Ixias.**—It will doubtless be interesting to know that at the present time I have *Sparaxis* in full flower in the open ground. They were planted in January, 1877, and were protected last winter with a straw mat rolled over them at night and unrolled during the daytime. The bulbs themselves are perfectly hardy; what they require is a little protection for the foliage, which, when the bulbs are left in the ground, is shot up early in winter. Were they, like Daffodils, to throw up their foliage in spring, they would remain in all parts of this country unharmed. In a few days I shall have *Ixias* in bloom under similar conditions.—P. BARR.

**Fruit Prospects in Hants.**—Notwithstanding our fears, fruit prospects are now most cheering, and the puzzle is, how comes it that so little injury has been done by the late severe weather? Peaches are a better crop than they have been for years past. Apricots are marvellously plentiful; every blossom seems to have set; but perhaps I ought to add that our trees were well protected. Plums are magnificent; Cherries the same; Pears have not bloomed so thickly, but all are set and swelling freely; Apples are now in full flower, and look extra vigorous; Goosecherries have suffered somewhat, but Currants will be a full crop. Altogether, fruit prospects in this district are encouraging.—W. WILDSMITH, *Heckfield, Hants*.

**Fruit Crops in North Notts.**—We have not had such a genial beginning of May as has occurred this season for many years back, for up to this date (the 6th) the temperature has been above the average, and with a rainfall of 71 parts of an inch; vegetation has therefore grown amazingly. The show of fruit-tree blossoms, such as Apples, Pears, Plums, and Cherries, is abundant, and the fruit will be sure to set well, should no cold east winds set in. The keen frost on the morning of April 1 has somewhat thinned the crops of Apricots, where the trees were not protected, as well as Peaches and Nectarines, and some of the earliest opened Pear blossoms on the walls, but this only on exposed aspects. On the glass-covered wall here the fruit on the above kinds of trees has set thicker than usual, causing much thinning already. Small hardy bush fruits, such as Goosecherries, will be good crops, although injured a little on the tops of the bushes by the frosts in the beginning of April. Currants and Raspberries are now in full flower, and Strawberries show well for a good crop. I never had early Pears so forward as they are at this date in May; Ringlender is in pod, and, owing to the rows being protected from sparrows in the winter months with wire protectors, the foliage has not been nipped so much as usual. The earliest planted Potatoes have yet had no check from frosts, and some of the American early sort named Alpha will be ready for lifting in two or three weeks, where grown at the bottom of a south wall.—WILLIAM TILLERY, *Welbeck, Worksop*.

The Maiden-hair Tree from Cuttings.—Mr. G. Berry increases *Salsiburia adiantifolia* freely from cuttings in the nursery at Longlat. The cuttings are put in in lines in autumn.—V.

"This is an art  
Which does mend Nature: change it rather: but  
THE ART ITSELF IS NATURE."—Shakespeare.

### SNOWDROPS AND SNOWFLAKES FOR WASTE PLACES.

It may seem strange to say anything about Snowdrops, especially at Midsummer; but then there is the summer Snowflake, which, although not a Snowdrop, is commonly looked upon as the summer representative of that universal favourite. Though Snowdrops are gone, however, it is just the time to prepare for a spring display of these ever welcome flowers by planting them by the bushel, or, in other words, sowing them broadcast. Whoever has seen the Snowdrop at home, in the copses and thickets of many parts of England, must have felt a pleasure totally different from that of seeing it in gardens and shrubberies. About a mile from where I live is a fine wood, with a green drive up the centre of it, and a stony-bedded brook crosses a portion of it and runs through a park. In one of the wildest parts of this wood are a few clumps of Snowdrops, and although I have as many of these plants as most people, I always go every year to see these Snowdrops in the wood. Now there are hundreds of miles of woodland walks and drives in the kingdom where one simply walks among trees. How interesting such places might be made by planting them with Snowdrops and similar plants. We have all heard of the Lily of the Valley woods at Woburn, and how jealously they are guarded. But plant such things in

abundance, and they need not be guarded at all. The fact is, there is too much conservatism as regards these sorts of flowers. Some imagine that flowers of this or any other class never ought to be out of a garden. They may as well imagine that a bird never looks well except in a cage. If all surplus stock of Snowdrops, Crocuses, and even Hyacinths were distributed in the woods and copses, and by path sides in gentlemen's grounds, a feature would be added to many of them which they do not at present possess. The great fault to be found with most of the places in England is, that no matter how great their capabilities may be, gardening only begins at the garden gate. What I have said in reference to the Snowdrop also applies to the summer Snowflake (*Leucojum aestivum*). This has some claim to be considered indigenous. It is a very hardy, somewhat stately-looking plant (that is, compared with the Snowdrop), and its introduction into damp spots in woods and groves would be charming. The seed-pods of this plant are very handsome, large, and pendulous. I may add that for all places, especially those that are wild, the single kind is infinitely superior to the double sort. THOMAS WILLIAMS.

*Ormskirck.*

### TREATMENT OF IMPORTED LILIES.

"DUNEDIN," whose close reasoning and admirable method have carried to my mind a conviction of his accuracy, would confer on me, and probably on others, an obligation if he will so far descend from the level of physiological investigation to the region of practical horticulture, as to say whether or not he confirms the deduction I draw from his last letter (p. 385). He says, as to imported bulbs of *Lilium auratum*, planted in spring, that they flower so late that the new bulb, which at the time the old bulb flowers, should liberate the germ of the third bulb, cannot do so for want of heat. I propose, therefore, to

grow on my imported bulbs, of which I planted a good number this spring, as fast as I can, this summer and autumn, in heat, so as to make them flower as early as possible. If at and after the time of flowering, which will probably be late in the autumn, I put them in a hot-house, I should infer, from what "Dunedin" says, that the new germ will be liberated, and will vegetate and flower the year after next, after which it will be safe. If this be correct, the buyers of imported bulbs may take comfort, and the wholesale loss of these bulbs, spoken of by several of your correspondents, will be arrested, simply by growing them for two or three years under glass. It is clear that, if planted previously in the open ground, they will be lost. I fear, however, that even if the third year's germ be thus preserved, by substituting artificial heat at the flowering time late in autumn for natural heat at the flowering time in July, the germ, coming into birth several months later, will itself flower late, and its offspring again will be late, and so on *in perpetuum*; so that not for many years, at any rate, will they be got to bloom early enough to be grown in the open ground. If a germ, liberated in July, will flower in July two years afterwards, a germ liberated in, say, October will not flower till October two years afterwards. The remedy for this would be to promote quick growth, so as to make the plant flower a little earlier each year, until at last it was got to flower early enough to be planted in the open ground while the weather was still hot enough for the germ to vegetate. May I ask for a little further information as to the effect of cutting down the flower-stems of *Lilium candidum*? Mr. Hovey says (p. 387) that to produce good bulbs speedily the flower-stem should be cut down when it appears above the ground. Does he mean that the plant should be prevented that year from flowering at all? If so, I presume that he recommends it only in the case of young bulbs or offsets, not of those which are already of flowering size. Will he also kindly say to what other sorts of Lily the same plan applies? I recollect that one of your recent correspondents said he always cut down *L. longiflorum*. Mr. Hovey speaks of this as an old piece of knowledge; but to learn, one must not be ashamed of asking questions, even at the risk of being put down as an ignoramus.

E. HARVEY.

**Sikkim Rhododendrons**—I have sent you three sorts of Rhododendrons cut from the open ground. The darkest is, I believe, Thomsoni, which has been beautifully in bloom for these five or six weeks past, and it was used in quantity for church decoration at Easter. The plant is 9 ft. high, and about as much through. Owing to the rough wet weather which we have had, I am unable to send you a good specimen, but you will see that there is from five to seven flowers in each truss. *R. cinnabarinum*, which is 8 ft. high, is now covered with flowers, and, from the specimen sent, you will see how profuse they are. It is, I consider, as regards beauty, second to no other hardy shrub. *R. Dalhousie*, also sent, was planted out in the spring of last year, and therefore its hardiness has not been proved, like that of the others which have been out-of-doors for many years. *R. niveum* is another distinct hardy early-flowering and beautiful variety, but this year its flowers were injured by frost in the beginning of April. They are planted on high sheltered situations.—J. GARLAND, Killerton, Eweter. [The specimens sent are magnificent, the cream-coloured flowers of *R. Dalhousie* being unusually large and beautiful. The gem of the collection is, however, *R. cinnabarinum*, with its drooping clusters of brilliant, orange-scarlet blossoms, each not unlike, as regards form, of our largest-flowered Fuchsias. As Mr. Garland truly says, this is second to no hardy flowering shrub, and it is one which should be in every garden in which it will succeed.]

**Rodgersia podophylla**.—This is undoubtedly one of the most striking novelties that has ever been added to our list of hardy, fine-foliated perennials. It is a member of the Saxifrage family, though in the absence of flowers remarkably unlike one. The chief point of interest is its leaves, which are developed direct from the roots. The leaf-stalk rises quite vertically to a height, it is said, of from 3 ft. to 4 ft.; but in the specimen which I had examined at Kew it is but 15 in. in height. The blade of the leaf consists of five wedge-shaped divisions, each 1 ft. in length and 9 in. in breadth at the widest part, radiating with almost mathematical precision from the apex of the leaf-stalk, and spreading horizontally. Each division is again divided into three or six pointed lobes with toothed margins and the whole leaf shines with a metallic lustre. Its flowers are borne on branching spikes, which also spring from the roots, but are inconspicuous and of a whitish-green colour, much resembling those of

the Hieracium-leaved Saxifrage (*S. hieracifolia*). Altogether, it is unlike any plant I know of, of the nearest approach to it in habit being some of the species of *Amorphanthales*. Should it prove of easy propagation, I predict for it a brilliant future, as I feel assured by the rate of growth in the Kew specimen, which I observed last year was but a small one, that, with special culture, it would soon attain the height of 3 ft. to 4 ft., as asserted, and that the blade of the leaf would be also developed in proportion, say to 3 ft. or even 4 ft. in diameter. What a grand acquisition, therefore, would this not be in producing a sub-tropical effect! It is a native of North Japan, and was first introduced to cultivation a few years since at the St. Petersburg Botanic Garden.—W.

**Choice Rhododendrons Hardy at Edinburgh.**—We find *R. lepidotum* to be perfectly hardy, and to bloom very freely even in a small state. Many of our plants of it had two or three flowers on them when they were not more than 1 in. high. Along with the seeds from which we raised *R. lepidotum* came some of what proves to be an exceedingly dwarf form of *R. glaucum*. It also flowers freely with us when only 2 in. high, and forms a pretty dwarf tufted bush, very distinct from the usual form. Most of the Indian Rhododendrons are hardy here. We have Thomson's now in glorious bloom. The following are growing out-of-doors without protection and have flowered with us, viz., *ellipticum*, *Fortunei*, *fulgens*, *Hodgsoni*, *Falconeri*, *longifolium*, *Blandfordianum*, *virgatum*, *cinabarinum*, *c. majus* (a very fine form), *barbatum*, *argenteum*, *eruginosum*, *camptocarpum*, and *Wallichi*. *R. fulgens* is one of the finest; the colour more vivid than any sort which has yet bloomed here.—W. W. JOHNSON, *The Lawson Company's Nursery, Edinburgh*.

**Rainfall in May at Bury St. Edmunds.**—We have just experienced the most continuous fall of rain that has occurred in this neighbourhood for many years. It commenced to fall about 5 a.m. on Tuesday, the 7th, and continued until 10 p.m. on Wednesday, the 8th, being forty-one hours, and amounted to 2.63 in., or more than 2½ in., a considerable item in a district where the mean annual rainfall barely exceeds 25 in. The wind was from east and north-east.—P. GRIEVE, *Culford*.

**Boronia Drummondii.**—This, one of the most showy and beautiful of the genus, has flowers of a bright pink colour set off to advantage by golden anthers. Even in a small state this *Boronia*, under good culture, never fails to produce abundance of bloom on every small shoot, and, if kept in a light airy house, its flowers will last for several months in good condition. A quantity of plants of it now in bloom in Messrs. Rollison's nursery at Tooting make a very attractive display. Wherever hard-wooded plants are grown this *Boronia* should find a prominent place. There is also a white-flowered variety of it which is equally worth culture.

**Dendrobium thyrsiflorum.**—The best example of this attractive Dendrobe which we have seen for a long time is now in bloom in Messrs. Veitch's nursery at Chelsea. It bears four drooping spikes as uniformly furnished with flowers as the stem of a massive Hyacinth. Each spike bears no fewer than sixty large flowers, with rich golden labellum and pure white petals. The showy character, as well as the free-flowering qualities and easy culture of this plant, make it one of the most valuable of Orchids.

**Speckled Gloxinias.**—Among the many seedling Gloxinias now in flower in Messrs. Veitch's nursery none are more striking and distinct in character than what may be termed a new race, with speckled flowers, resembling in appearance some of the newer kinds of Tydes. Their colours vary from pale blue to bright crimson; the flowers are upright in habit, and are in every way well worth adding to any collection, however small.

**Anemone palmata alba.**—This beautiful white-flowered variety of the Cyclamen-leaved Anemone is now blooming freely in the Hale Farm Nursery at Tottenham. Its flowers are very showy, the under sides of the petals being slightly tinted (with yellowish-green and violet, whilst the inner side, which is as white as snow, is set off to advantage by a bright golden centre. It succeeds best on warm borders or on rockwork.

**Auricula Silvia.**—The progress made in all sections of Auriculas during the past few years is remarkable, and it is satisfactory to find that new and improved kinds continue still to be raised. The beautiful Alpine variety shown under the above name by Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, at a recent meeting at South Kensington, at which it received a first-class certificate, fully confirms these remarks, the substance, form, and colour of its flowers being all a step in advance in the right direction. It is a large, maroon flower, with a smooth, yellow paste, and one which will no doubt become a favourite with Auricula growers.

## THE FRUIT GARDEN.

**An Ornamental Fruit Wall.**—In carrying out some alterations lately it became necessary to build a wall across the end of our ground, and as fruit is a desideratum, and the wall having a due south aspect, it was deemed necessary to utilize it for fruit trees. Now fruit walls in dressed grounds, as one usually sees them, are not very ornamental, and in order to remedy this, I put a glass coping along the top 3 ft. wide, and, to further add to the appearance, placed, at 10 ft. intervals, a light 1½ in. column to support the front, up which I purpose training the lightest and most graceful climbers, which I think will not materially interfere with the fruit trees. The whole is arranged thus—Border, or rather terrace, 2 ft. wide, 3 ft. high; front edge, 5 ft. of turf; 4½ ft. walk; 5 ft. turf; and 6½ ft. from edge of turf to wall. These two strips of turf are made to correspond, containing, as they do, alternately small specimen shrubs and 3 ft. circles of Roses, at 8 ft. intervals; that part of the border between the edge of turf and the foot of the columns will be planted with low-growing flowering plants in a pretty manner. Altogether, it has an appearance quite different from that of ordinary fruit borders, and might be very well tolerated in the most select dressed grounds.—T. SMITH, *Newry*.

**Fruit Crops in the Midlands.**—I am happy to bear testimony to the good accounts given of our fruit crops (see p. 375) by Mr. Tillery, of Welbeck. Now fruits of all kinds promise to be abundant. Pear blossom was this, but, every bloom appears to have set, and the growth of the young fruit is most satisfactory. All vegetable crops are looking admirably. Peas sown in November are podding, which is at least three weeks in advance of former years. I never remember seeing Asparagus grow so thickly and abundantly; in fact, our whole garden is like one vast hotbed, and I anticipate a year of plenty.—R. GILBERT, *Burghley*.

**Fruit Prospects.**—Cherries and Plums have passed through the ordeal of the spring bravely and well. I never saw such a fine set on that best of all Plums in any situation—the Jefferson. It is, however, on a north wall. Golden Drops, on an east wall, were rather forward to escape the severe frosts which culminated on April 1. The lekworth Imperatrice, on the same wall, was later, and with protection, has set freely. As a rule, this most useful of all late Plums, sets shyly. This season the set is thick indeed. But Plums are capricious about the crop they finally elect to carry, and not seldom shed the major portion of their fruit when about the size of small Cherries. The Victoria Plum is, as usual, clustered thick with fruit. Cherries promise well, and the floods which we have had will ensure a heavy crop of Strawberries, which are just coming into flower.—D. T. FISII.

**Frost and Unexpanded Blooms.**—We have hitherto considered fruit tree blossoms to be safe from frost, so long as they remained in the bud or unexpanded state, but this year much of the bloom was certainly "nipped in the bud" by the frosts which occurred in the last week in March, and more especially on the morning of April 1. I quite agree with Mr. Fish (see p. 408) that the petals are much harder than the stamens and pistils, as the fine weather that succeeded April 1 brought out the petals in abundance, but only, in many cases, to raise false hopes of fruit crops, as those of the early Plums, Pears, and Gooseberries that were in a forward bud state have expanded and dropped off, although the flowering season was the most propitious we have had for years during the rest of April and early in May. Late fruits have, on that account, expanded and set their crops rapidly and satisfactorily.—J. GROOM, *Henham*.

**The Gooseberry at Longlet.**—Seldom does the poor Gooseberry get due honour. We ourselves prefer them to Grapes, but many wonder at this, and we do not expect disciples. At Longlet, however, the merits of the Goose berry seem known, as there is a border and wall securely covered with wire netting, so as to form a Gooseberry house nearly 300 ft. long and 12 ft. wide. This is for the long preservation of the keeping kinds from the attacks of birds, and we have never seen such good provision to this end. With this plan the Gooseberry may be eaten in good condition for a long time.

**The A Bec Peach.**—Allow me to inform Mr. Groom (see p. 438) that this fine early Peach can be obtained true from Messrs. Veitch of Chelsea, to whom I have supplied buds from my original tree. If Mr. Groom will turn to the "Florist and Pomologist" for January and March, he will there find it figured and fully described. Having grown this Peach for a number of years, I can strongly recommend it as a variety suitable either for open walls or for growing under glass, where it ripens about twelve days later than the Early Grosse Mignonne. It is said to have originated at Beilly, near Lyons, and to belong to the group that produce leaves with round glands and flowers of the largest size.—W. COLEMAN, *Easton*.

## NOTES OF THE WEEK.

**A Blue Bush in May.**—*Solanum crispum* appears to be hardy in Ireland, and an old specimen of it, in flower now in the Botanic Gardens at Glasnevin, is about 12 ft. through and over 7 ft. high. It is in full flower—one sheet of lovely light blue blossoms. It looks as if a field of Blush Potato blooms were gathered together into one huge nosegay. It is the more valuable from the scarcity at this season of blue-flowered shrubs. Indeed, we do not remember at any time to have seen a shrub of the same order of beauty and colour. It is a plant to be noted by all having gardens in mild or seashore districts. One does not visit the Botanic Gardens at Glasnevin at any season without experiencing pleasant surprises of this sort. It is a garden which, while doing excellent work as a botanic garden, and being stored with a wealth of beautiful hardy flowers and tree life, of great value to all horticulturalists, does not make the word "science" ridiculous by using it to justify narrow-minded and most unscientific exclusiveness.

**New and Rare Irises.**—The following Irises are now in flower in the Kew collection, viz., *Iris balkana*, a handsome species of the bearded section, bearing large flowers of a bright claret-purple colour; in habit and form of flower it resembles *I. Chamairis*; it is a native of Northern Thrace. *I. rubro-marginata* is also a new species, but very inferior in point of beauty to the preceding, though distinct in foliage, the leaves being bordered with a reddish-purple line, as its specific name implies; its flowers are about the size of *I. pumila*, but of a dull purple colour, and very fugitive. It is a very dwarf plant, not more than 5 in. in height, and is found in the neighbourhood of Scutari. *I. Rédoutéana*, although not new, is far from being common. Mr. Baker puts it as a variety of *I. lurida*, but it is a taller and more slender plant, and its flowers are very much darker in colour. *I. Douglasiana*, one of the bearded section, is also an uncommon plant, which has, however, much to recommend it; its foliage is very distinct, presenting, as it does, a ribbed surface; and the base, and also the flower-stalks, are tinted with a dark red colour; its blossoms are light purple, streaked with white, and very handsome. It is a native of California, and was introduced to gardens about five years ago by Messrs. Veitch.—A.

**Double Scarlet Geum.**—This Geum, which has been in existence for some years, is not nearly so often met with in gardens as it should be. It is perfectly hardy, easily increased by division of the root, thrives well in any good garden mould, and from early in April until the end of September established plants of it yield abundance of bright orange-scarlet double blossoms, which in a cut state are quite equal, or even superior to those of the double scarlet *Pelargonium*. They last in good condition for some time after being cut; and when it is considered that a good supply of them can be had with little or no trouble for six months in the year, no garden, however small, should, one would think, be without this plant. Good established roots of it lifted late in the autumn, and wintered in a house or pit, would, if kept close to the glass, and given plenty of air and water, and a little heat after Christmas, no doubt produce good flowering plants for the cool conservatory full of flower in February, or even earlier. We lately saw large beds of it in flower in the Hale Farm Nurseries, where they form an attractive feature.

**Plants in Flower in the Botanic Gardens at Glasnevin.**—Among many interesting plants in flower here, and noted during a hurried visit, are a very remarkable hybrid *Sarcocolla*, exactly intermediate between *S. flava* and *S. rubra*, and having large red flowers of singular beauty; *Eurya Gunniata*, a handsome evergreen bush in the open garden, with flowers like a showy *Michaelmas Daisy*; the Winter's Bark Tree; *Veronica Hulkeana*, very pretty against walls in the open air; *Crinum ornatum*, very large, and handsome, flowering since the beginning of May in borders in front of hothouses, and in a well-sheltered position; *Gypsophila cerastioides*, a gem of the genus, and a showy and neat Alpine plant from India; *Erigeron multiradiatum*, also a handsome dwarf Indian Alpine plant.

**Orchids at Chelsea.**—Amongst the many fine Orchids now in bloom in Messrs. Veitch's nursery we noted the largest-flowered variety of *Lælia purpurata* we have yet seen. Its petals and sepals are of ivory whiteness and of remarkable substance, and the lip is richly coloured. *Cattleya Mendellii*, in the same house, is blooming freely; its flowers are unusually large and gorgeous, having broad, imbricated petals of transparent whiteness, the lip being delicately tipped with violet. *C. Mossii aurea* is likewise very attractive, its rich golden-purple-tipped lip setting off to advantage its massive violet petals. *C. lobata*, too, a variety not often seen in flower, is here blooming freely, as is also a fine plant of *Vanda téres* growing round a thick stick, which it clothes with healthy green leaves. This Orchid is seldom seen flowering freely, but the one in question being

subjected to cool treatment, and kept dry at the roots during winter, now bears several spikes of curiously-formed, waxy, red and yellow-tipped blossoms. *Masdevallias* will soon be in full flower, as will also large plants of the rare *Vanda Parishii*. *Oncidium crispum* is furnished with masses of rich chocolate blossoms, one plant of it just coming into flower bearing six unusually strong spikes. A large-flowered and highly-coloured variety of *Vanda Fieldingii* is bearing long, drooping spikes of sweetly-scented blossoms, and *Aerides Veitchii* and *Saccolabium vittatum* are also at present equally attractive.

**A "Weeping Willow" for the Conservatory.**—*Grevillea Mangleyi*, now in flower in a cool house at Glasnevin, is even more graceful in habit than the Weeping Willow, the cord-like shoots falling vertically and densely, and the foliage being peculiar and graceful. It is a valuable plant for those having a large winter garden or conservatory. The flowers are very slender, of ivory whiteness, and produced towards the apex of the falling twigs.

**Caladium La Perle.**—One of the most distinct forms of this useful decorative plant which has come under our notice for some time may now be found in several of the principal London nurseries under this name. Its leaves, which are produced on stalks about 1½ ft. or 2 ft. long, are transparent, reminding one of silver tissue paper. They are traversed with light green veins, and are partially suffused with delicate pink or violet. Whether or not the plant will retain this character remains to be seen, but should such be the case this variety will assuredly stand in the foremost rank amongst *Caladiums*.

**Azaleas at Clapton.**—A fine display of Indian *Azaleas* may now be seen in Messrs. Lowe's nursery at Clapton. The plants, numbering some 60,000, are of home growth, and, as far as can be judged from appearance, they are superior to imported plants. It is only during the past few years that growing Indian *Azaleas* in quantity in England has been tried, but it is now found to succeed satisfactorily. The two kinds most largely grown in this nursery are the rose and white varieties of Bernard André.

**Seedling Pansies.**—We have received from Mr. Caudwell, of Wanage, blooms of seedling Pansies, all excellent in their way, and showing what, with a little attention, can be obtained by means of careful cross-breeding and selection. The blooms in question vary from cream-colour to crimson, and there are also many beautiful striped and blue kinds. A bed or border planted with such Pansies, irrespective of height or colour, would doubtless prove a continual source of interest.

**Hardy Plants in the College Gardens.**—Among interesting subjects now in flower in the College Botanic Gardens at Dublin are *Edwardsia grandiflora*, a very fine specimen on a wall, with numerous flowers; *Anemone palmata*, very fine as a border plant; *Iris susiana*, in fine flower in the open border; and *Rhododendron chamaecistus*. *Sparmannia africana* has survived the winter in the open air in this garden. The variegated New Zealand Flax thrives well in the borders, and *Selinum decipiens* is remarkable for its fine foliage, even among the many fine-folaged plants in the Order to which it belongs.

**Seedling Columbes.**—We noticed in Mr. Ware's nursery at Tottenham the other day some seedling Columbes, many of which are distinct and beautiful. Some of their flowers were of a delicate violet, others were cream-coloured, pale yellow, blue, and white; some being of large size and of fine form. No particular attention had been paid to cross fertilisation, but, nevertheless, some of them are quite equal to many named hybrids sometimes found in gardens.

**Double Striped Vesuvius.**—Sports from this *Pelargonium* seem to be endless. One of its sports striped with white has been named *New Life*, and another with a double scarlet flower has been called *Wonderful*. There are also single white and salmon sports from it, and now we have received from Mr. Knight, of Batle, a striped form of *Wonderful*, or it might be called a double *New Life*.

**The Flamingo Plant.**—There is now a fine display of various forms of the scarlet-spathed *Anthurium Sobczermanianum* in Messrs. Veitch's nursery at Chelsea. The variety called *Wardi*, a coloured plate of which was given in THE GARDEN (see p. 12), is conspicuous for its broad, brilliant scarlet spathes, and for growing in the form of large specimens it is doubtless the best variety; but, associated with it, are forms with smaller spathes, which are equally desirable for general decorative purposes, and their flowers, moreover, are much more eligible for cutting. A kind named *Palmeri* is a very desirable one, and makes a fine feature. Its spathes, which are produced in great abundance on long stalks, are much narrower than those of any other variety, and taper to a sharp point, many of them measuring from 4 in. to 6 in. in length. Associated with Palms and similar plants in one of the glass corridors, these *Anthuriums*, which are represented by plants of all sizes, are exceedingly effective.

## NOTES FROM KEW.

**Hardy Trees and Shrubs.**—*Jamesia americana*, from the Rocky Mountains, a Saxifragaceae shrub closely allied to *Hydrangea*, is now in flower; in a wild state it is a very rare and local plant, and was originally found on Alpine ridges in Colorado territory by Dr. James, the discoverer of *Rubus deliciosus*. The white blossoms, nearly  $\frac{1}{2}$  in. in diameter, are borne freely on terminal cymes. This species first produced flowers in this country in the collection of the Rev. H. N. Ellacombe. *Mespilus grandiflorus* is a fine little tree with glossy green leaves and large, pure white flowers; as a single specimen or to plant in the mixed shrubbery it is equally desirable. *Cytisus ramentaceus*, a native of Dalmatia, has hairy leaves and upright racemes of large yellow flowers; this is sometimes seen under the name of *Petteria ramentacea*. *Colletia spinosa* is a very peculiar South American member of the *Buckthorn* family, and the leaves are sometimes altogether suppressed; this much-branched, extremely spinose shrub is now covered with its bell-shaped, whitish flowers. *Kerria japonica*, or rather the double form of that plant, ought not to be passed by without notice; its numerous bright yellow blossoms show up well in the mixed shrubbery border. The leafless branches of the Judas Tree (*Cercis siliquastrum*) are now gay with thousands of small purple flowers; this tree attains a considerable size if allowed time and room. Many readers of THE GARDEN must be familiar with the fine avenue of this tree in the Paris Jardin des Plantes.

**Hardy Herbaceous Plants.**—Two distinct and well-marked forms of *Trollius asiaticus*, named respectively *Fortunei* and *japonicus*, are very fine; both have flowers of a somewhat deeper orange colour than those of the type. *Aethionum jucunda* is a rather rare and very handsome Crucifer; it forms a compact, cushion-like mass of pleasing, pale purplish flowers. *Iberis Tomerensis*, from Italy, is a very free-flowering and desirable plant, the blooms of which are at first white, though afterwards they gradually assume a purple tint. *Romanzovia unalascensis* requires little care; it is a pretty, low-growing annual with white flowers and light green round leaves. *Tiarella cordifolia* is a charming Saxifragaceae perennial with upright racemes of pure white flowers borne on scapes about 6 in. or 9 in. in height; this is found in a wild state from Canada to Virginia, and is prettier than perhaps any of the cultivated species of the allied genera *Mitella* and *Heuchera*. *Raoumouia pyrenaica*, a peculiar little Pyrenean herb, has rough leaves and a short scape bearing several purplish flowers. *Honstonia cœrulea* is a lovely little rock plant, which seems to do well at Kew; at any rate better specimens may be seen there than the one to which a cultural commendation was given at the Royal Horticultural Society's show of May 7. The lovely blue-blue flowers of this beautiful North American rock plant are produced in great profusion. *Cortusa Matthioli* and *C. pubens* are blooming side by side; the former has bright red flowers, whilst the latter has light rose-coloured ones. *Phlox divaricata*, a North American species with lavender-blue flowers, is a striking border plant; it was amongst the cut flowers exhibited by Mr. Elwes last week. *Craspedia Ritchei* is a very peculiar Australian Composite with Gnaphalium-like leaves, and flower-stems 1 ft. in height, crowned with dense, globular heads of yellow flowers. *Globularia trichosanthes* is a little Eastern species with heads of blue flowers. A most uncommon looking plant is *Mertensia maritima*, a native of the northern seacoasts of Britain; the pretty flowers, which are pink on opening, change to blue-purple, and contrast beautifully with the very glaucous, rather fleshy leaves; many a garden could be made bright with the British flora alone. *Euphorbia pilosa* var. *trigona*, carpa makes a fine show with its tall stems (3 ft. or more in height), surmounted by numerous heads of yellow-green bracts and flowers. *Iris balkana*, from Turkey, is a very charming species of dwarf habit, and has dull, claret-coloured flowers. *Polygonatum rosemum* is peculiar (in a genus where perhaps all the other species have white or whitish-green flowers) on account of its pretty little rose-coloured blossoms; it is a native of Siberia, and grows about 6 in. or 8 in. high. *Helonias bullata* is a North American bog plant, with a rosette of oblong leaves and a stout scape about 18 in. high terminated by a dense raceme of purplish flowers. The Californian *Calochortus elegans*, although not so handsome as some of its congeners, is well worth growing; the very hairy petals are white above and dark purple below. The Oriental *Ornithogalum latifolium*, with its large leaves and tall stout scape bearing a raceme of large, long-stalked, fine white flowers, is very showy.

**Greenhouse Plants.**—A most conspicuous and elegant plant for the decoration of the greenhouse and cool conservatory is the New Zealand *Veronica Huilkeana*; the large, much-branched panicles bear numberless flowers of a delicate mauve colour. *Gompholobium polymorphum superbum*, one of the most handsome of the Australian Leguminosae, has small leaves, borne on thin twining stems, and large, pea-shaped crimson flowers. *Boronia elatior* is a lovely species,

with small, pinnated leaves and drooping, bell-shaped, rosy-pink blossoms; this, as might be expected from its name, grows to a greater height than most of the other species of this very beautiful genus. *Viburnum plicatum*, although in reality a hardy shrub, flowers well in pots and makes an excellent greenhouse plant; it is a native of North China, and, like the *Gaulther Rose* (*V. Opulus*), has globular heads of snowy-white, neutral flowers; it differs, however, from *V. Opulus* in the oblong, plaited, serrated leaves. The short, dark green, Acanthus-like leaves and purplish flowers of *Grevillea acanthifolia* make an extremely pretty combination; this species is well worth growing, if only on account of its neat habit and handsome foliage. *Phylidrum glaberrimum*, recently introduced from the South Pacific by Mr. W. Bull, is a useful decorative plant; the leathery, dull green, sword-shaped leaves are about 2 ft. in length and 1 in. in breadth, and from the centres of the tufts of leaves spring the flower-stems, which overtop them by 1 ft.; the flowers on the erect panicle, as well as the bracts and panicle branches, are white, the anthers orange-red. *Orchis foliosa* is a lovely terrestrial Orchid from Madeira, which attains a height of 2 ft. or more; the noble, glossy green leaves set off beautifully the large spike of purple flowers. Altogether, this is a very striking plant. *Fabians imbricata*, with its Heath-like leaves and lovely, trumpet-shaped, pure white blossoms, is a charming Chilean shrub; this does well in the open air if a sufficiently sheltered position be chosen for it.

**Stove Plants.**—Foremost in rarity, and perhaps also in beauty, is the tropical African *Adenium speciosum*. This peculiar member of the Dogbane family has gouty stems and branches, and brilliant, rosy-crimson, Allamanda-like flowers. *Billbergia Middendorffiana*, from tropical America, though possessing flowers in themselves quite inconspicuous, makes a fine show; the lower half of the central leaves are a brilliant reddish-crimson, and amply compensate for lack of beauty in the flowers.

**Orchids.**—The North Indian *Cœlogyne ochracea* is a charming plant; the sweetly-scented flowers, which are borne in upright racemes, are pure white, with the exception of the lip, the lower half of which is orange-yellow. Similar in size and habit is *C. elegans*, but in this the orange is nearly suppressed. *Dendrobium cariniferum* has hairy stems and leaves and thick, wax-like flowers, whitish, except the lip, which is marked and lined with deep orange. *Madevalla coriacea*, from New Granada, has greenish flowers, spotted and lined with purple. Another New Granadian species, *M. Trochilus*, has a very tall, angled scape; the long, tawny-yellow tails and the dull reddish-brown of the remaining parts of the flower impart a peculiar aspect to this species. *Odontoglossum spectrum* is a very pleasing and showy plant, the flowers being of a uniform light yellow, copiously spotted and blotched with cinnamon-brown, and the lip being nicely fringed. †

**Caccinia glauca.**—I have no wish to refute the statement made by Mr. Thompson in THE GARDEN (see p. 274) in reference to this plant, as I suspect the description to have been drawn from a specimen in a depauperated condition; but if he could see it as now growing in the herbaceous ground at Kew, he would, I think, modify his remarks. It is apparently in a rich soil, and has made stems about 2 ft. in length, and rises to nearly the same height; moreover, the flowers are over 1 in. in diameter and last a long time in good condition; they are, as Mr. Thompson says, of a pinkish colour when first expanding, but they afterwards change to blue. This, together with the distinctive character of the foliage, which is very glaucous and beset with short prickles, renders it a really handsome plant quite equal to any of the *Borage* family at present in flower.—A.

**Continuous Blooming of Bougainvilleas.**—I have read with interest the remarks of "Chet" (see p. 79) and of "J. S. W." (see p. 446) concerning the blooming of *Bougainvilleas*, and I wish to ask whether spectabilis was found to bloom as freely as glabra under the same treatment. I have found the treatment recommended to suit glabra admirably, but not spectabilis. That variety flowers on the previous year's growth, while glabra flowers on that of the current year; therefore the more vigorous the growth, the more abundant the bloom. I have seen spectabilis grown in various ways and under various kinds of treatment, but the way under which I have seen it flower best is where the roots were restricted in an intermediate house fully exposed to the sun, and where it was pruned as one does a Peach tree. The roots were never allowed to get very dry at any time. I saw lately the best bloomed plants of this variety that it has ever been my good fortune to see. They were growing in a small stove with little or no fire heat, and they were one mass of bloom. They had been grown in the same sized pots for these last ten years, with a little top-dressing now and then when the roots got washed bare. These never got pruned, but were allowed to grow at will, the longest shoots being not more than 15 in. in length when the growth was completed. W. W., Eaglehurst.

## LANDSCAPE BY HOBBEEMA.

Any one who has visited Grenoble, in its fair valley, hemmed in by snow-capped Alps, and examined its museum, will at once recognise in this print a friend that only needs to be seen to be admired. Hobbema, a Dutchman, born about 1629, and brought up amid the flat expanse of Holland's ditch-divided plains at a time when Dutch art was at its best, learnt from his master, Solomon Ruysdael, to seek always for pictorial effect in carefully arranged masses of light, and shade, and sunny atmospheres rather than in bold mountainous outlines unknown to him in his own country. With a Dutchman's characteristic love of home, yet with a true artist's spirit, he has known how to paint his own country's quiet landscapes when seen to the greatest advantage. From the first, Hobbema rose to notice through the truth and beauty of his skies and clouds, which are best seen in a flat country, such as

Landscape by Hobbema.

Holland; and that, combined with his fidelity to his subject, has given him a fame that is green and fresh even after the lapse of two centuries. E. H. W.

**Training Clematises.**—When Clematises are grown for covering large spaces on walls or any unsightly objects, the wood should be well thinned out at the winter pruning, the healthy vigorous shoots only being retained, which should be securely fastened at regular intervals apart, and as the young growth progresses, which it will do rapidly in April and May, it should be trained carefully over the space to be covered until the plants commence to flower, when they should be allowed to grow as they please; but if allowed to do so at first, the shoots become so entwined as to form a tangled mass, from which it is impossible again to separate them without breaking; and as they mostly flower at the extremities of the current year's growth, great care should be taken to retain them intact, or the quantity of flower will be greatly diminished.—J. G.

**Chestnut Hybrid Tea Rose.**—"R. H. P." asked (see p. 454) for names of Roses suitable for a north-east porch. I do not see included in the list given him the Chestnut Hybrid. In my garden on a wall where all the other Tea-scented sorts and Noisettes (including Gloire de Dijon) show but too plainly the severity of our March frosts, the Chestnut Hybrid is covered with vigorous blossom buds, the foliage is good, and there is no sign of aphid or leaf-roller, a good proof that the vascular system of the plant is uninjured. This Rose is not, in my opinion, appreciated as it deserves. Perhaps the attempts of growers to push it into the front rank as an exhibition Rose have placed it under a cloud, where its true merits are obscured. I look forward to the time when, in company with that universal favourite Gloire de Dijon, it will be one of the chief ornaments of walls and gardens throughout the land.—P. *Frome*.

**Papaver umbrosum.**—This is a strikingly brilliant plant, which takes up and perpetuates the waning glory of Anemone fulgens. Plants of it raised from seeds sown last spring are now in flower here, and are decidedly the most brilliant blooms in a garden full of blossom.—H. M., *Bromsgrove*.

## THE FLOWER GARDEN.

## LOBELIA PUMILA GRANDIFLORA AND VIOLA BLUE PERFECTION.

SINCE the introduction of *Lobelia pumila*, a few years ago, its popularity has become universal, and, grown in suitable soils, it is a perfect gem; but, unfortunately, its beauty is comparatively short-lived. From its early habit of flowering and sturdy, compact growth, it is necessarily a favourite wherever an early display is required; its demise, therefore, so early in the season detracts from its general utility, and doubtless militates against its popularity with those who do not take proper steps to prolong its season of flowering, or who do not endeavour to find a suitable substitute for it. The *Viola Blue Perfection* is the plant of all others for this purpose, and is especially adapted to low-lying, damp localities for autumn flowering. In order to be successful, there ought, however, to be something like concert in relation to the time and mode of propagating the two sets of plants. The best way in which to secure a stock of *Lobelia pumila* is by cutting a few of the old plants down early in autumn before they have exhausted themselves with flowering; or, what is still better, to keep a few plants in reserve, either in pots or boxes, behind a north wall, or some partially shaded place, where there would be less tendency to flowering than if they were kept in an open situation. The pots or boxes should be filled with 1 in. or 2 in. of any rough material, such as the riddings of leaf-mould, immediately over the crocks, filling up the remainder with any light rich soil that can best be spared, the object being to produce a non-flowering state of growth, a condition to be recommended in all cases for stock plants. Towards the middle of September the plants will require a shift to a more exposed situation, in order to harden them before winter weather sets in; and they should be housed early in some airy position barely affording protection from frost. This *Lobelia* is very impatient of much moisture during the short, dull days of winter, and it succeeds best on a shelf, near the glass, in a warm greenhouse, where it can get plenty of air and light. In starting the plants in spring the change to a warmer climate should be brought about gradually, avoiding a saturated atmosphere till the plants are in a free-growing state; after that, heat and moisture are conditions essential to their health and well-being.

This *Lobelia* is propagated by division or by cuttings, if any one likes to take that trouble. If there be a good stock in hand propagating may be deferred till late in March, as plants raised earlier in the season are likely to come into flower before the proper time; indeed, before other subjects furnish anything like a combined effect. Where the stock is limited, or where large quantities are required, there is, of course, no other alternative than to begin propagating early, in which case the best plan to adopt is to keep pulling the first batches to pieces, and to continue the practice in rotation to the end of the propagating season. A short time ago we pulled our earliest batch to pieces and re-planted the detached portions in boxes, removing all flowering points at the same time. This improves the vigour of the plants and prolongs their season of flowering fully a fortnight later than would otherwise be the case. The chief aim in the cultivation of this *Lobelia* should be to avoid premature flowering according to the time when a display is expected, making allowance for climate and locality. Another good way of prolonging the flowering season is to cut the plants over with a pair of hedge shears early in August. When that can be done they invariably break away and flower profusely a second time, but no plan equals that of having a stock of the *Blue Perfection Viola* at hand to plant out on the first favourable opportunity after the *Lobelias* are past their best.

The *Violas* are easily propagated, and are unsurpassed as autumn-flowering plants. They luxuriate in a moist climate if the soil be not of a too tenacious character, but they require somewhat special treatment to come in as a succession to the *Lobelias*. They may be readily propagated out-of-doors with the assistance of a glass frame or hand-light early in July. The cuttings should be inserted in a mixture of leaf-mould and sand, run through a fine riddle, and kept moist by means of a fine-rosed watering-pot or syringe. When the cuttings are

well rooted, choose a cloudy moist day for planting them out on a sheltered dry border for the winter; they may remain till the following April or beginning of May, when means should be taken to keep them from flowering before they are required in August. This is done by removing them to a north or west aspect, and planting them out in leaf-mould only, in order that they will lift with good balls, and receive no check in the course of being transferred to their autumn quarters. The point of each plant should also be pinched out, and by the time they are required to take the place of the *Lobelias* they will be well furnished and coming into full flower.

W. HINDS.

### SUMMER FLOWER GARDENING.
