SCIENTIFIC WORTHIES.

XXXVI.—SIR WILLIAM CROOKES, F.R.S.

SIR WILLIAM CROOKES has the rare privilege of looking back upon a scientific activity extending already over more than fifty-five years. By numerous papers and by several volumes the results of his experimental researches in different departments of physics and chemistry have been spread all over the world. Though born in 1832, even his advanced age has not diminished his scientific productiveness.

All Sir William Crookes's researches, with the exception of the first, were made in his private laboratory in Kensington Park Gardens. Although the motion of the walls of this laboratory, as seen under the high magnifying power of the horizontal pendulum, gave rise, at first sight, to doubts as to the solidity of its construction (Philosophical Transactions, 1876, Crookes, "On Repulsion, &c.," § 134), it has stood the test of time. The perennial stability, however, of many of the stones joined by Crookes to the edifice of science never was questionable. Most of those who have risen to eminence in physics have done so by giving their exclusive attention to that science, and it is only rarely that the physicist can do pioneer work also in chemistry. Rarer still is the case of Sir William Crookes, whose series of physical papers is frequently interrupted by communications concerning his chemical discoveries.

In the *Philosophical Magazine* of April, 1861, Crookes tells us:

"In the year 1850, Prof. Hofmann placed at my disposal upwards of 10 lb. of the seleniferous deposit from the sulphuric acid manufactory at Tilkerode, in the Hartz Mountains, for the purpose of extracting from it the selenium, which was afterwards employed in an investigation of the selenocyanides."

In the examination, by the spectroscope, of the residue left in the purification of the crude selenium, Crookes's attention was attracted by a bright green line, which he had never met with before. In following up its appearance, he succeeded in isolating a new metal, which he called thallium, after the emerald green line which has become now as familiar to chemists, even if not brought up in a spectroscopic atmosphere, as the lines of sodium and lithium; and the physicist again and again enjoys the homogeneity of thallium light when observing interference for large differences of path, either with his Rowland or his Michelson grating, or with his Fabry and Perot apparatus, or with his Lummer and Gehrcke plate.

The year 1861 brought the first great triumph to Crookes. During the next twelve years he carried out minute investigations of the many properties of the new element, culminating in his determination of its atomic weight—203·642, or when reduced with the now accepted values for the atomic weights of oxygen and nitrogen, 204·04. Extreme care was given to the necessary weighings, and the pains taken to start with pure substances were enormous. The international committee for the atomic weights and other authorities regard Crookes's determination of the atomic weight of thallium as the best we possess, though thirty-four years have elapsed since the date of its publication.

Crookes finished his determination not without tribulation, having been troubled with discouraging irregularities in his weighings. In order to improve his results, the weighings were made in a partial vacuum, but even under these conditions the balance behaved most capriciously. Sometimes the substance appeared to be heavier when cold than when in a heated condition; sometimes the action was opposite. Working further with indefatigable ardour he came to what he then called "repulsion resulting from radiation," and going on he invented in 1875 an apparatus in illustration of the thoroughly novel and striking phenomena he had observed, the radiometer. His researches in this new field, contained in 485 paragraphs, and published in the Philosophical Transactions of 1874, 1875, 1876, 1878, 1879, represent an immense amount of experimental work of the greatest interest and ingenuity.

Under the influence of the dynamical theory of gases the general nature of the perplexing phenomena was recognised and referred to the intervention of the residual gas. The genius of Schuster, Osborne Reynolds, Tait, Dewar, and Maxwell was associated with this explanation, but special mention should here be made of the more personal, yet beautiful and ennobling example of scientific cooperation given by Sir William Crookes and Sir George Stokes, the documents relating to which have just been published. The new and fascinating chapter in the dynamical theory of gases, relating to the stresses in rarefied gases arising from inequalities in temperature, which thus sprang up in connection with Crookes's experimental work, is, notwithstanding the 110 references to the literature of the radiometer in a modern German text-book, still unfinished. We may be sure that quantitative experiments concerning the radiometer actions under entirely new conditions will again prove the importance of the chapter, emblazoned on its cover by Crookes's light-mill.

Crookes thus was brought into touch with the dynamical theory of gases and with experimental work in high vacua, and so came to his experiments concerning the electric discharge in gases. In this province we are indebted to him for some very striking discoveries relating to the now well-known kathode rays, then already associated with the names of Plücker (1859), Hittorf (1869), and Goldstein (1876). His brilliant experiments ("The Trajectory of Molecules," "Molecular Physics in High Vacua," "Phosphorogenic Properties of Molecular Discharge") were published in the Philosophical Transactions for 1879, but became generally known to the world—not to the scientific world alone—by his lecture on "Radiant Matter," delivered on Friday, August 22, 1879, at Sheffield, to the British Association for the Advancement of Science. Even now the reading of this lecture, though the facts in it have become familiar, brings one under its irresistible charm, and Lenard and Tesla, describing in eloquent terms the impression made by it on their young minds, certainly give utterance to a prevalent opinion. In the beautiful volumes on "Ions, Electrons, Corpuscules," for which physicists are indebted to the Société française de Physique, only one lecture has been inserted, that of Sir William.

There exists perhaps only one lecture given on a similar occasion which has become as popular and made on the hearers as deep an impression, both by its contents and its accomplished form; I mean the lecture delivered before the Association of German Naturalists at Stuttgart in 1889 by Hertz, in which his great discoveries were expounded.

All the wonderful and important properties of the constituents of the kathode rays or of radiant matter: its darting in a straight line from the negative pole, the position of the positive electrode being unimportant; its casting of a shadow when intercepted by solid matter; the strong mechanical action radiant matter seems to exert where it strikes; the change of direction by a neighbouring magnet; the heat produced when its motion is arrested; the remarkable power which the molecular rays possess of causing phosphorescence in preparations of calcium sulphide shining with blue-violet, yellow, orange or green light, in diamonds shining with nearly all colours of the rainbow, in rubies glowing with a rich full red; all these results Crookes tried to explain by the hypothesis that the kathode rays, or streams of radiant matter, or of matter in an ultra-gaseous state are particles or molecules negatively charged and projected with great velocity from the negative electrode. The inherent truth of Sir William Crookes's hypothesis concerning the nature of the kathode rays is, after much controversy for a space of nearly twenty years, now established, and the original hypothesis, with finer contents, is now accepted by all physicists.

In Crookes's experiments for the first time the majestic simplicity of the kathode rays became clearly apparent. In the irritating complexity of the other phenomena of the vacuum tube, appearances of great purity had been isolated, so that Crookes could risk the opinion "that we are here brought face to face with Matter in a Fourth state or condition," neither solid, liquid, nor gaseous.

Crookes alone among his contemporaries recognised the essential importance of the kathode rays, and with almost prophetic insight foresaw the part radiant matter would have to play in the development of physical science. In the splendid evolution of electronic theory we are now witnessing, we see how true Crookes's foreshadowing of the *rôle* of radiant matter was.

"In studying this Fourth state of Matter, we seem at length to have within our grasp and obedient to our control the little indivisible particles which, with good warrant, are supposed to constitute the physical basis of the universe. We have seen that in some of its properties Radiant Matter is as material as this table, whilst in other properties it almost assumes the character of Radiant Energy. We have actually touched the border land where Matter and Force seem to merge into one another, the shadowy realm between Known and Unknown, which for me has always had peculiar temptations. I venture to think that the greatest scientific problems of the future will find their solution in this Border Land, and even beyond; here, it seems to me, lie Ultimate realities, subtle, far-reaching, wonderful.

"Yet all these were, when no Man did them know,
Yet have from wisest Ages hidden beene;
And later Times thinges more unknowne shall show.
Why then should witlesse Man so much misweene,
That nothing is, but that which he hath seene?"

All the experiments in this lecture now have become classical, and several of them are repeated every year in every university of the world. The most familiar and representative of the group is perhaps that one with the Maltese cross in the pear-shaped Crookes's tube, in which the black shadow of the cross is projected on the hemispherical phosphorescent end of the tube, in such a manner that a permanent impression on the memory of the student is made.

As an outcome of work recorded in Crookes's various preceding papers, "On Repulsion resulting from Radiation," &c., and, therefore, with paragraphs numbered in continuation of his "Phosphorogenic Properties of Molecular Discharge," Crookes in 1881 published a research on "The Viscosity of Gases at High Exhaustion." Maxwell's great theoretical discovery that the viscosity of a gas is independent of the density, one of the most beautiful proofs for the reality of molecular motion, had already been the starting-point of experiments by Maxwell himself, Kundt and Warburg, using the method of rotating discs.

In Crookes's experiments the method of observation consisted in noticing the subsidence of the vibrations of a delicately suspended lamina oscillating within a bulb containing the gas. By these simple yet adequate means, very careful measurements were made, and the falling off of the viscosity of different gases from atmospheric pressure to very high exhaustions downwards observed, especial attention being paid to the highest vacua and definite measurements made of the degree of exhaustion employed. At these high exhaustions Maxwell's law completely breaks down, as Maxwell himself foresaw. His observations were discussed in a splendid "note" by Sir George Stokes, another example of the cooperation between these physicists.

Crookes's apparatus afforded at the same time many other data and measurements. The apparent attraction by heat was only found in air of greater than one-thousandth part of ordinary density; while there is repulsion when the density is further increased, the repulsion increasing to a maximum, and thence fading away towards zero as the rarefaction is continued.

In 1881 Crookes's paper on radiant matter spectroscopy appeared. An entirely new method of spectrum analysis is given, based on the well-known fact that under the influence of the kathode rays a large number of substances emit phosphorescent light, some faintly and others with great intensity. Most bodies give a faint continuous spectrum, but more rarely the spectrum of the phosphorescent light is discontinuous, and to bodies manifesting it his attention has been specially directed. This characteristic spectrum is given by the group of elements known as the rare earths, especially yttria in some of its compounds; and in the study of this group the method is of very great importance, and has given, in the hands of Sir William Crookes, at an immense amount of trouble and time, very valuable results. To give, however, an adequate survey of these investigations would demand much space, and uncommon chemical knowledge of the rare earths. We mention only that not long ago Crookes isolated from yttria a new earth, characterised by an isolated strong group of lines high up in the ultra-violet, ascribed by Sir William to a new element named by him victorium.

In connection with his work on the photographed spectra of the elements, of which it seems only a small portion has been published, we record one of his smaller papers, relating to "the slit of a spectroscope," that narrow, but extremely important, gate to a large domain. Crookes makes the very ingenious suggestion to use quartz jaws, cut in the same manner as metal ones. The prismatic edges refracting away all the light which falls on them, their transparency offers no objection, while only the light passing between the jaws comes into operation. As the quartz jaws can be worked to a finer edge, they give better definition.

"With a pair of jaws in the spectroscope at present in use, I can take excellent photographs when they are only 0·0001 inch apart. For eye observation the width can easily be less than that."

Another small paper of date 1879 is also characteristic of Crookes's experimental skill, and illustrates at the same time, if I may say so, the purity of his work. The exceedingly small rate of leak of electricity in a high vacuum is illustrated by Crookes's observation that a pair of gold leaves in a vacuum bulb retains an electrical charge for months.

Of Crookes's recent work, we mention his experimental work on radium. In 1900 Crookes first effected the separation from uranium by two distinct chemical methods of the one direct transformation product, called uranium X. He discovered in 1903 that the alpha rays from radium produce, probably by their bombardment, phosphorescence on a target of crystalline zinc sulphide. This wonderful phenomenon, perhaps the most direct proof of the discontinuous structure of matter, was popularised in his spintharoscope.

These examples must suffice to impart an idea of Crookes's work. "The best history," it has been verily said, "is but like the art of Rembrandt; it casts a vivid light on certain selected causes, on those which were best and greatest; it leaves all the rest in shadow and unseen." What is true in the science of history cannot become untrue in the history of science. It would be desirable to follow a similar precept in trying to picture before our mind the origin of the gratitude and admiration physicists feel for a philosopher, who by his experimental skill, his acute observation, and the continuity of his endeavours, combined with his daring intuition, has impressed indelible marks in different branches of physics and chemistry. This involves, however, more than we can attempt here.

Sir William Crookes is a member or corresponding member of a number of scientific societies in his own country and abroad. At one time or another he has occupied the presidential chair of many of the leading learned and scientific societies of Great Britain. The Royal Society awarded him a Royal Medal in 1875, the Davy Medal in 1888, the Copley Medal in 1904; the French Académie des Sciences, a gold medal and a prize in 1880; the Society of Arts, the Albert Medal in 1899; and he was knighted by the late Queen Victoria in 1897.

P. ZEEMAN.

THE SOILS OF IRELAND.

A Description of the Soil-Geology of Ireland, based upon Geological Survey Maps and Records, with Notes on Climate. By J. R. Kilroe. Department of Agriculture and Technical Instruction for Ireland. Pp. xii+300. (Dublin: H.M. Stationery Office, 1907.) Price 6s.

IN his preface the author states that on the completion of the one-inch geological map of Ireland "the opportunity seemed favourable for presenting to the public a succinct account of the geology of the country, prepared chiefly from the standpoint of agriculture," of which opinion the present work is the outcome.

It is certainly a matter of cardinal importance to an agricultural country like Ireland that its Geological Survey officers should have the needs of the farmers before them, and should in the progress of their mapping look at the country-side with something of the farmer's eye, and an appreciation of the kind of information that is likely to be of value to him.

It is perhaps too much as yet to ask that the Geological Survey should give rise to a second department charged with the preparation of soil maps, though in other countries the State is undertaking this service for the agriculturist; but, failing so large a measure, what information of value to the working farmer can the geologist proper put into his maps and memoirs? A good "drift" map must be the basis, a map in which, however, the drift should be differentiated further than it is on our present maps, where the common designation of "boulder clay" is often made to cover in a single district true clays, coarse stony gravels, and deposits that are little more than sand. Of course, the boundaries of such drifts can only be indicated approximately, partly because they grade into one another in some places, and in others thin out insensibly into true "sedentary" soils derived from the underlying "solid" rock. To the farmer, lithological character is the important feature in a drift, not its origin, and we believe the field geologist would find no difficulty in providing the information if he had the requirement before him from the outset. Again, some indication of the thickness of the drift might be given, with notes as to the proximity of valuable soil ameliorators, like beds of marl below peat or chalk below clay. Of course, much chemical analysis cannot be recorded, but we think the map should indicate whether a clay formation is calcareous or deficient in lime; again, some notes on drainage and water supply might be added to the memoir. A farmer, for example, finds a certain field full of springs; a geologist could generally tell him whether this is due to the outcrop of an impermeable band or to a fault (in which case a ditch can be cut to tap the springs), or to general ground water, in which case the field will want tile draining.

Mr. Kilroe, however, has no opportunity in this book of working on such a scale; his object has rather been to do for Ireland what the late Prof. E. Risler did for France in his "Geologie Agricole," to take the formations one by one and show how the nature of the rock is reflected in the physiography and the soil constitution, and in its turn in the agriculture of the district it occupies. To produce such a book is a noble ambition, but we fear that the materials for it hardly exist as yet in the case of Ireland, for throughout Mr. Kilroe's book we are struck by the paucity of data really bearing on the point at issue. The analyses of rocks and soils, even of waters, are rarely of Irish origin; often, indeed, they refer to Continental specimens, and they are of very various dates and values. There is hardly a reference to Irish farming in the book; for instance, barley growing is a very special and localised culture in Ireland, and one which has had considerable attention from the Department of Agriculture, but when we inquire if it is associated with any formation in particular, we find no reference to it, nor, indeed, to the distribution of any other crop, in Mr. Kilroe's book. Instead, Mr. Kilroe gives us too much of his views on agricultural chemistry, generally in the form of extracts from other writers, and these extracts only show how difficult it is for a specialist to preserve a due critical sense when "getting up" another subject. For example, we read:—

"When it is considered that silicate of alumina (clay) in itself furnishes no essential element of plant food . . . it is evident that the stony particles, pebbles, &c., contain the stock supplies of mineral nutrients."

Or again:—

"The waters flowing from the Old Red Sandstone would doubtless be poor in lime for the purpose of irrigation. They, however, probably contain such a proportion of potash as would justify some expense in distributing them over meadow-land or pasturage not being grazed."

We only wish that Mr. Kilroe could have tempered his zeal for imparting information. It is just the same with the section on climate; we have a series of paragraphs on soil and air temperatures, on cyclones and weather forecasts, on clouds and similar generalities, but little or nothing on the Irish climate or its local distribution, which counts for so much in the agriculture of the country.

"Cut the cackle and come to the 'osses" was an old and sound piece of advice, and the "'osses" we hope to get from Mr. Kilroe are Irish—Irish rocks, Irish soils, Irish crops and stock.

A. D. H.

SCHOLARSHIPS AND INDUSTRY.

Dyeing in Germany and America. By Sidney H. Higgins. Pp. xvi+112. (Manchester: University Press, 1907.) Price 1s. net.

THE Gartside scholarships of commerce and industry were established in 1902 for a period of ten years. They are of a special character, the main feature of the scheme under which they are administered being the close manner in which they are linked up with industrial life. The first year of the scholarship is tenable in the University of Manchester, a course of study being adopted which will directly qualify the scholar to investigate some special branch of commerce or industry at home and abroad during the second year. The scheme is a most valuable recognition of the close union which should exist between science and industry, and the late Mr. Gartside has certainly indicated a very useful direction in which others may endow further scholarships. The book now under review represents a report to the electors of the work carried out during the period of the scholarship.

A comparison of the development of the coal-tar colour industry in Germany and this country has been so frequently made to the great disparagement of English enterprise and educational methods, that very properly this branch of the subject was not further investigated by the author, his work being concerned with the application rather than the manufacture of dyes. The fact that in the main we hold our own against all competitors in the dyeing and printing industry is brought out very clearly. In Germany the dye-houses are, with few exceptions, smaller, and the methods less scientific, than in the large centres of the industry in England, such as Manchester and Bradford; and in handicraft skill the English dyer is perhaps unapproachable. The great volume of dyeing done in the United States appears to be chiefly due to the large and rapidly increasing demand made by the home market, and the competition of America in foreign markets is comparatively insignificant in this branch of trade. Moreover, in most of the principal dye-houses in New England the managers and foremen are British. The distribution of trade is, however, a matter of very delicate balance, and the fact that Germany has almost the monopoly of the manufacture of coal-tar dyes may easily result in the transfer to her of the leading position in the dyeing industry.

The coal-tar colour industry is, in fact, one of Germany's greatest industrial assets, and apart from its directly profitable character it has also been of the greatest importance as the mother of many new industries, such as those of synthetic pharmaceutical products, liquid chlorine, anhydrosulphuric acid, &c. The requirements of the industry have also reacted largely on the standard and character of the instruction given in the German universities and colleges, and, most important of all, have been a great object-lesson to the German Government and people with regard to the supreme importance of science in industrial life. This has again reacted in the direction of the more general appreciation and utilisation of technical education in Germany, and has been an important factor in inducing the Government and local authorities to render assistance in fostering the various industries; a condition of things which, unfortunately, is largely absent in this country.

A great feature of the dyeing trade in England has been the establishment of powerful trade combinations, whereas the industry has not developed along these lines in Germany or in America. It is undoubtedly true that when efficiently managed these large associations lead to great economies in such directions as the concentration of work, improvement of equipment, and better conditions for buying and selling. Operations conducted on a large scale can be carried on more cheaply and more profitably than is possible by a large number of smaller producers. Consequently, both workman, employer, and consumer should benefit. On the other hand, the danger of the misuse of great concentration of power is well known, and experience has yet to show whether the condition of an industry controlled in this manner is as stable and permanent as when competition and individual enterprise have freer scope.

Turning to a more definite criticism of the work under review, it undoubtedly forms very interesting reading if not examined too closely as regards technical accuracy. The material is arranged under the following headings:—cop dyeing, sulphur colours and indigo, mercerising, bleaching, the industry in the United States, conditions of life in the industry, efficiency of the industry, colour production. It could not reasonably be expected that the author would be able to show a profound knowledge of present-day practice in all branches, and it would not be fair to criticise the book from this standpoint. It must rather be considered as the statement of an organised series of observations made by a trained mind upon a subject of which the observer has some special knowledge. If read with this in view, the book will be found most interesting and valuable. The author has made excellent use of the great facilities placed at his disposal, and has done much to justify the idea of the founder of these scholarships that they would be of value, not only to the individual, but to the trade of the country. In conclusion it must be said that the literary style and even the grammar and punctuation of the subject-matter are open to much more criticism than is desirable in a book issued with the imprint of a university. The idea that a careless use of the English language is permissible in books dealing with technical subjects is one to which too strong exception cannot be taken.

WALTER M. GARDNER.

PERSONAL HYGIENE.

The Care of the Body. By Dr. Francis Cavanagh. (The New Library of Medicine, edited by Dr. C. W. Saleeby.) Pp. xvi+292. (London: Methuen and Co., n.d.) Price 7s. 6d. net.

THIS book belongs to the excellent "New Library of Medicine" series issued by Messrs. Methuen. In the series, as planned, all the great aspects of "preventive medicine" are dealt with from many standpoints. In "The Care of the Body" Dr. Cavanagh handles in a very popular yet fundamentally scientific way the leading generalities of personal bodily hygiene —sleep, baths, exercise, training, fatigue and massage, clothing, skin, hair, teeth, feet and hands, light, eye, ear, nose. Each of these has a chapter. The volume is completed by chapters on position, habit, and the functions of the physician. The style is breezy and rapid. It is well adapted to the lay reader, who more easily acquires casual than rigidly ordered knowledge. But Dr. Cavanagh indicates in every page an easy familiarity with the latest science at the moment when apparently he is most exuberant in his verbal flow.

The method has its dangers, for it may give currency to vague and inexact doctrines. But here the sparkle of the writing secures the interest without impairing the science. Health is undefined, but the problem of health is mainly how to maintain the fight against malign environment, and "fitness" is largely the capacity to master hostile germs. The discussion of sleep adapts scientific theory to practice, and has many sound hints Of the cold bath it is said, "In general, the value of a cold bath is in inverse proportion to its length" (p. 39). Of exercise, the view is that "all mental processes are based upon a simple unit of action or process, in which some one muscle-fibre is a chief factor" (p. 55). Play is preferred.

The criticism of current superstitions as to exercise and training is pointed and conclusive. The cardinal point is the relation of exercise to diet. Dr. Cavanagh is somewhat dogmatic (p. 60) on the intellectual training of women. He assumes too readily that accepted intellectual standards are a true test of mental capacity even in men. In exercise, walking and running, not any artificial system, are fundamental. "Muscles are not meant to work or be developed individually" (p. 78).

The discussion of fatigue is highly general, but adequate for its purpose. Of clothing a good deal is said in detail, the principle being that "man is homoiothermal," and 98°·4 Fahrenheit is his normal temperature. Clothing is closely criticised from this standpoint. In the other chapters—teeth, eyes, &c.—many hints of experience are embodied, and, though the main facts are well known, every reader will find them set forth in a fresh and stimulating way. The chapters on position and habit are well loaded with good matter. The last chapter points the view that dominates this book and the series it belongs to, namely, that henceforward the physician's true function is to prevent, not to cure, and the profession should be organised accordingly. Altogether, the author succeeds in his effort to be simple, scientific, and vivacious. The aim of the series is to apply scientific medicine to the informing of public opinion, and this volume, within its range, certainly furthers that aim. If looked-for topics are sometimes omitted, they are likely to be found in other volumes.

OUR BOOK SHELF.

Practical Mathematics. By Prof. John Perry, F.R.S. Pp. 183. (London: Wyman and Sons, Ltd., 1907.) Price 9*d*.

THE first edition, a slim little pamphlet price sixpence, was reviewed in these columns about the end of the last century; this new edition begins to show signs of corpulence.

The pamphlet has raised a crowd of imitators, bulky works on engineering and mathematics, workshop arithmetic, and general utilitarian and commercial theory; it would be better, for historical interest, to preserve its original size.

The author has forced the Mathematical Tripos to adopt the Slide Rule for numerical computation; and would do well to follow up by a description of the Hospitalier notation of writing derived units, as ft.^{2} and ft.^{3} for square and cubic feet, lb./ft.^{2} for pressure, and so on; no need then for the mathematical Esperanto suggested some years ago.

The slide-rule hint—"practise with simple numbers"; "ask no one to help you"—should be followed by arithmetical exercises intended to show the learner how to discover the use for himself: such as cube 2, 3, 4, . . . and then extract the cube root; better then to discard all rules, as they can always be re-invented with greater ease than recollected. Considering that the slide rule and logarithm table work to the base 10, the definition of the logarithm in § 8 is $-n = \log N$, if $10^n = N$; not $a^n = N$, which is confusing by its useless generality.

The practical student Prof. Perry has in view is called upon to work and act, but not to write and explain. His geometry is so very easy, consisting in drawing a few lines by instruments. But if required to give an explanation he would find himself compelled to give six lines or more of tedious definition to one line of demonstration; he would become Euclidean without knowing it.

The author enjoys attacking the schoolmaster, who shows certainly many weak points of inherited prejudice. Prof. Perry looks at geometry from the point of view of everyone becoming an engineer in his turn; the schoolmaster deals with very few students of that class, and can make out a very good case for Euclid; Greek in Euclid and Euclid in Greek; and he has an answer ready for the question in the note on p. 8—"Why not say—*delogarize?*"—Because the word is a mongrel.

La Théorie de la Physique chez les Physiciens contemporains. By Abel Rey. Pp. vi+412. (Paris: Félix Alcan, 1907.) Price 7.50 francs.

RECOGNISING the serious discordance between the views of contemporary physicists upon the true meaning and value of physical theories, the author of this interesting book inquires whether this conflict of opinion justifies the contention of the anti-intellectualist philosophers that such theories are purely arbitrary constructions leading, not to completer knowledge of the world, but merely to more effective practical control of its course. M. Rey proceeds by an able cross-examination of actual scientific thinkers, classifying them by reference to their attitude towards the post-Newtonian mathematical physics—which assumed the actuality in detail of the molecular machinery that it invoked to explain phenomena.

In his first group fall Rankine, Mach, Ostwald, and Duhem, who agree in rejecting the ontological pretensions of the mechanical theory and in conceiving the various departments of physics as autonomous sciences connected with one another and with mechanics by the notion of energy. British readers will be gratified by the importance which the author attaches here to the work of our countryman—whom he regards as the father of the critical movement—and will welcome his clear account of the views of the brilliant professor of Bordeaux. Next to these M. Rey places Poincaré as a critic who corrects rather than rejects the traditional doctrine, accepting its belief that the data of observation in physics are the product of the superposition of an infinite number of elementary phenomena to which the differential equations of theory refer, but recognising that its conception of these phenomena as molecules in movement is only a description in one idiom of objective relations that could equally well be rendered in another. Last come the physicists (including most of the British school) who have lost the confidence of the post-Newtonian mechanists rather than their ideals; who still hold that physical phenomena can be explained by the conceptions of mechanics, but no longer profess to be able to describe, detail by detail, the ultimate moving elements and motions that underlie these phenomena.

In the second part of his book the author seeks to show that the salient divergences between the schools simply mask the essential congruity of their views. All physicists admit—in whatever idiom they may describe them—the same ultimate objective data; while even if their hypotheses are only methodological instruments of organisation and discovery, it must be recognised that the science presents in the different schools a real though not obvious unity of development T. P. N.

How to tell the Birds from the Flowers: a Manual of Flornithology for Beginners. Verses and illustrations. By Prof. R. W. Wood. Pp. 28. (San Francisco and New York: Paul Elder and Company, n.d.) Price 50 cents net, or in cat-bird cambric, 75 cents net.

It will come somewhat as a surprise to those of our readers who know Prof. Wood only as a physicist to learn that the present booklet contains nothing but quaint illustrations and jest in verse. The volume is obviously a satire directed against the sentimental nature-study literature which sometimes masquerades as scientific teaching, particularly in the United States.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Winding of Rivers in Plains.

A CURIOUS obsession as to a matter of fact, to which everyone is more or less liable when obfuscated by an erroneous theory, has recently been noticed by me in some geological books, *e.g.* in Le Conte's "A Compend of Geology," and in Tyndall's "Glaciers of the Alps." I noticed it first in my late colleague Prof. Watts's recent little text-book of geology; but, indeed, I have not found any book of the kind quite clear and correct on the subject.

The statement is clearly made and illustrated by a figure that the flow of a bending river is most rapid on the outer side, where its banks are concave; and the well-known scouring or excavating action which a stream exerts on this bank is then attributed to this imaginary more rapid flow.

But the fact is that the flow is most rapid on the inner or sediment-depositing side of the bend, and Prof. James Thomson showed in 1876, in a well-known communication to the Glasgow meeting of the British Association—when he exhibited a model, confirming calculations previously made by himself—that the excavating action of a river is not due to the direct scouring action of the main stream at all. The explanation which he gave was virtually as follows:—

The rapid flow on the inner and strongly curved side of the bend piles up the water on the outer side by centrifugal force, so that near the concave bank it is nearly stationary, but elevated; its energy there is potential, not kinetic. Now if the rapidity of flow were uniform from top to bottom the slope would be in equilibrium; but owing to the retardation of the bed the flow near the bottom is slower, and there is not nearly so much centrifugal force exerted down below; wherefore the piled-up water is continuously returning from upper to lower level, that is, from the concave to the convex bank, as an undercurrent, almost at right angles to the main stream, bringing with it, by its undertow, silt and solid matter, which it deposits near the inner side of the bend; thus constantly increasing its own sinuosity in the well-known way.

The stream itself, combining a progressive with a lateral circulating motion, may be said to *screw* itself like a corkscrew round a bend: and it is the lateral circulation which shifts the bed.

So much for streams, now for glaciers. Prof. Tyndall, as is well known, took careful measurements of the flow of glaciers, and finding that their line of quickest motion was *more* sinuous than the glacier bed, said that this was another analogy to the flow of a river.

There, however, he was in error. The line of most rapid flow of a river is *less* sinuous than the river itself. The water flows round the bend somewhat as it would flow in a vertical columnar vortex; most rapid on the inside, and almost stationary or even retrograding on the outside of some bends. If ice flows otherwise—and I have no reason whatever to doubt Tyndall's measurements—it must be because the rate of change of momentum of so slow a motion, compared with its lateral stiffness, is very small; so that we might certainly anticipate that the laws of its flow would be in many respects different from—though also in some respects singularly like—those of a liquid of but small viscosity. Probably it obeys exactly the laws of an *extremely* viscous liquid the viscosity of which could be specified. The flow cannot be much governed by inertia, as that of water is.

But I know that glacier motion is a thorny subject upon which I have no desire to tread. I would not be understood as making any assertion concerning it, but merely throw out a hint.

As to winding rivers, however, the matter is fairly simple; and the writers of geological and geographical text-books may easily amend some incautious though natural statements as to matters of fact, which they sometimes illustrate by erroneous diagrams.

OLIVER LODGE.

Recalculation of Atomic Weights.

DURING the last few years our knowledge of the accurate atomic weights of the elements silver, sodium, potassium, chlorine, and bromine has been greatly extended by the masterly researches of T. W. Richards and his colleagues. At present, however, there is no really trustworthy value for the ratio of silver to oxygen, and a satisfactory value for nitrogen has only just been obtained by Gray and by Guye.

While reading an account of the determination of the ratio $Ag : AgNO_3$, it occurred to me that this result, together with others previously obtained by Richards, afforded a means of calculating absolutely the atomic weights of the above-mentioned elements in terms of oxygen. The following values are available:—

		Error
(1)	$Ag : KCl = 100 : 69{\cdot}1073$	$0{\cdot}0004 = v$
(2)	$AgCl : KCl = 100 : 52{\cdot}0118$	$0{\cdot}0004 = x$
(3)	$Ag : AgNO_3 = 100 : 157{\cdot}479$	$0{\cdot}001 = w$
(4)	$Ag : AgCl = 100 : 32{\cdot}867$	$0{\cdot}0005 = y$
(5)	$N_2O_5 : K_2O = 100 : 87{\cdot}232$	$0{\cdot}002? = z$

We have thus five simultaneous equations, from four of which the four unknown quantities Ag, K, Cl, and N can be calculated in terms of O. Neglecting 2, and putting $O = 16$, I worked out the atomic weight of N, and was intensely surprised to find the value 13·940.

Now it is a well-known fact that the final results of an "indirect analysis" such as the above may be greatly influenced by a small experimental error, and so I proceeded to estimate the maximum effect which could thus be produced. Putting $(69{\cdot}1073 + v)Ag = 100\,KCl$, where v is the error, instead of the first equation above, and similar expressions for the last three, I obtained the formula

$$N = \frac{2422{\cdot}08 + 600v - 600y - 336w - 287z}{2779{\cdot}94 - 200v + 200y + 174w + 115z} \times 16.$$

From this it is evident that, if v is made positive and the other three quantities negative, the numerator will be increased and the denominator diminished, both these facts tending to raise the value of N. Putting for the symbols their values given in the table of errors, the following result is obtained:—

$$N = \frac{2422{\cdot}08 + 1{\cdot}45}{2779{\cdot}94 - 0{\cdot}58} \times 16 = 13{\cdot}951.$$

In a precisely similar way, but using equation 2 instead of 1, the value 13·937 is obtained, which can be increased to 13·948.

This being the case, the question is, How can this value arise? The experimental work upon which the figures are based seems to have been carried out with every possible precaution, and all the values agreed very closely. The only possible weakness appears to lie in equation 5; the result was deduced from only three experiments, and the agreement was not so good as usual. Assuming for the moment that this value is wrong, it is easy to calculate by how much it is so. Taking N = 14·010, we may say

$$N = 14{\cdot}010 = \frac{2422{\cdot}08 + 6{\cdot}62}{2779{\cdot}94 - 3{\cdot}57} \times 16.$$

If the values of x, w, and y are taken as before, this gives 0·028 as the *minimum* value of z, and it is hardly to be expected that such a large error could have escaped notice. Another possibility is that all the errors are about five times as large as the values given, but even if this were so it would be very improbable that they should all be of such a nature as to raise the atomic weight. Consequently, granted that the discrepancy is due to experimental error, it is almost certain that the analysis of potassium nitrate is at fault. This was carried out by heating with silica, and if the nitrate was not completely decomposed the number 87·232 would be too great. This is the only explanation which seems reasonable; and, moreover, if the ratio obtained in this experiment be changed to 100 : 87·203, all five equations become consistent, and yield frequently accepted values for the atomic weights, silver being 107·883.

Whether this be the true explanation or not, it is obvious that the method outlined above affords an excellent means of checking atomic weight determinations, and is also applicable to finding the absolute weights, since there is no great accumulation of errors.

University College, Gower Street, October 26.

The Fauna of Madagascar.

MADAGASCAR, with certain adjacent islands, has been regarded by some naturalists as forming a distinct "region," the Malagasy, equivalent to the other main regions of the world. On the other hand, Messrs. P. L. and W. L. Sclater ("The Geography of Mammals," London, 1899, p. 108) adhere to the earlier opinion of the first-named of the two authors, as well as of many subsequent writers, and place Madagascar in a subregion only of the Ethiopian region. They remark that "Madagascar appears to contain a sample of the ancient Ethiopian fauna, which has been almost exterminated on the mainland."

The archaic nature of the Madagascar fauna has lately (*Zool. Jahrb.*, 1902) received further confirmation at the hands of Miss A. Carlsson, who found that the peculiar Viverrid genus Eupleres showed likenesses to both the Viverrine and Herpestine sections of the Viverridæ, and was therefore probably an ancient type of Viverrid. Having had lately the opportunity of making some anatomical observations upon another Madagascar genus, viz. Galidictis, I am able still further to support this view. This interesting Viverrid has the external scent glands of the Viverrine section, and a cæcum which is comparatively long, like that of the Herpestinæ. The brain, like that of Eupleres, shows intermediate characters. Finally, the archaic nature of this animal is demonstrated by the completely double uterus, a feature new to the Carnivora, where a bicornuate uterus is at least the rule.

It has been pointed out that Madagascar also shows an unexpected likeness to the neotropical region in its fauna, especially in the group of reptiles. As to mammals, the late Dr. Dobson showed reasons for believing that the alleged close resemblance between the Cuban Soleonodon and the Mascarene Centetes had been exaggerated; but among the Reptilia there are genera which are common to the two regions, *e.g.* the snakes Boa and Corallus. I have been able lately to compare *Corallus madagascariensis* with a South American form, *C. cookii*. In the former the bronchus extends a long way down the larger lung, the liver is prolonged by one lobe nearly to the gall bladder, the umbilical vein of the fœtus does not persist, and the mode of distribution of the intercostal arteries is as in the pythons. In the latter species these characters are as in the Anaconda.

The anatomical differences may possibly seem slight to those not specially acquainted with the structure of serpents; but in the features mentioned there is, if anything, rather a greater difference between the two species of Corallus than between two admittedly distinct genera such as Eryx and Python. It is very desirable that the alleged close resemblance between other forms occurring both in Madagascar and in the neotropical region should be carefully scrutinised.

Zoological Society's Gardens.

The Interpretation of Mendelian Phenomena.

DR. ARCHDALL REID's letter in NATURE of October 3 contains a very positive statement in reference to the relation of Mendelian phenomena to man, which I think should be immediately answered. I delayed supplying an answer because I wished to discuss his statement on a tangible basis. I desired to analyse certain data which I have been collecting, and which throw light upon the problem of segregation in man. This analysis is as yet incomplete, but it is sufficient to show that Dr. Archdall Reid is too confident when he asserts that "there is no segregation in man," and that, "with the exception of eye-colour, and possibly one or two other traits, such as the Mongolian eyelid, human hybrids appear to blend every character as perfectly as skin-colour."

The accounts which I have collected deal with various marriages between Europeans (chiefly Scotch) and the Canadian Red Indians. It is well known that many of the early European settlers in Canada married Red Indian women. The resulting half-breeds in their turn were in some cases intermarried, and in others mated to Europeans.

The Canadian Red Indians can be marked off from Europeans by six definite characters, which concern the nature of the hair, eyes, skin, cheek-bones, nose, and beard. The Indian hair is invariably black, long, glossy, and lank, and cannot be confounded with European hair; the eyes are almost invariably black or, very seldom, dark brown; the skin is tawny brown-yellow (varying from pale olive-yellow to dark brownish yellow); the cheek-bones are high (there is no obliquity to the eyes, thus differing from the Mongol); the nose is very prominent and broad at the base, and is of the *busque* type, that is, the profile is made up of two lines, which diverge widely from the bridge towards the base; and, lastly, there is either no beard or a very scant one of straight hairs on the face of the men. These characters, when well developed, are so different from the corresponding features in Europeans that they cannot easily be confused. No one, for instance, would mistake the long, lank, black hair and black eyes of the Indian for the thick red hair and blue eyes of some of the Scotch persons concerned in the histories now under review.

We may therefore use these six characters as differentiating ones, and may tentatively regard the Indian characters as being allelomorphic to the corresponding European ones. For the sake of brevity I will use symbols, which will have the following significance:—

I = Indian, E = European, H = hair, E = eyes, S = skin, C = cheek-bones, N = nose.

First, then, with regard to the matter of dominance. We must, in this case, be quite sure that the European concerned marries a full-blood Indian. In the cases which I have so far collected, I have only one marriage of such an Indian with a European, and there were only two children of the marriage. The European was a Highland Scot. His complexion was fair, and eyes blue. I have no information of the colour of his hair, since it was white with age when observed, but it was quite thick and not lank. In all the features (with the exception of the beard, of which I have no information) which mark off the Indian from the European, the son and daughter of this marriage were quite Indian.

So far, then, as this one case will take us, these five

Indian characters appear to be dominant over the corresponding allelomorphs of the European. This conclusion, however, receives corroboration from the results of marriages between Europeans and three-quarter blood Indians, when they are traced to the F_2 generation. There is thus no blending, even of colour, but dominance.

We can now deal with the important question of segregation. If segregation occurs in man, and we regard these five characters (the beard is excluded) as allelomorphic pairs, then when a half-breed Indian (that is, the child of a European and Indian marriage) is mated with a European we should expect, *among* others, to find the following types in the offspring:—

(1) Wholly European, EH, EE, ES, EC, EN.
(2) Wholly Indian, IH, IE, IS, IC, IN.
(3) European except in the cheek-bones, EH, EE, ES, IC, EN.
(4) European except in the eyes and cheek-bones, EH, IE, ES, IC, EN.
(5) Indian except in the nose, IH, IE, IS, IC, EN.
(6) Indian except in the hair, EH, IE, IS, IC, IN.
(7) Indian except in the skin and nose, IH, IE, ES, IC, EN.

And all these predicted seven types are to be found in the records of four marriages between an E and $\frac{1}{2}$ I which have been sent to me. A total of seventeen children are considered in this description.

It is perfectly clear that segregation of these five characters is taking place. There is no blending even of the colour of the hair, eyes, or skin. The blue eyes of a Scotchman who was mated to a full-blood Indian, and whose wholly Indian-type hybrid was mated in turn to a Welshman of hazel eyes, came out blue in two members of an offspring of eight children in the F_2 generation. That is clearly enough segregation.

If segregation is really occurring, and if the Indian features are dominant over the European, then it follows that once a pure European type has separated out and is mated with a European, Indian features ought not to appear among their offspring. In the records which I have there are two marriages of this kind, *i.e.* between E and extracted E. From one of these there have resulted five daughters, and from the other a son and a daughter. All seven are European in every trait. The recessive characters have thus far bred true.

These facts, therefore, are not only opposed to Dr. Archdall Reid's statement that there is no segregation in mankind, but they supply him with that instance of an appearance of a "latent" character in a cross between two "natural varieties" as contrasted to "artificial varieties" for which he seeks. For I suppose he will regard (if I may judge from the context of his letter) a cross between an $E \times \frac{1}{2}$ I, followed by a cross of E×extracted E, as crosses between natural varieties. At any rate, they are crosses between human varieties, and he denies rather too emphatically that "latent" characters have ever been revealed in such.

Dr. Archdall Reid is apparently not aware of Farabee's observation on the mating of albino negroes with pigmented negresses. The facts are important, so perhaps I may describe them. An albino negro married a normal negress. They had three children, all pigmented sons. These sons married, and two of them had only normal (pigmented) children; but the third son married twice, and by the first wife had five normal and one albino children, and by the second six normal and three albino children. If we assume that the two negresses which the third son married were themselves carrying albinism recessive (that is, in Dr. Archdall Reid's sense of the word, "latent"), the result is accurately in accordance, as Castle has shown, with Mendelian expectation. For, in the offspring of this third son, coloured individuals and albinoes are expected in the proportion of 3 : 1. There is actually 11 : 4, which is the nearest possible approximation in an offspring of fifteen.

If Dr. Archdall Reid can explain these results, *i.e.* those of the Red Indians and the negroes, on any other theory than Mendelian segregation, or can even show that it is a case of an abnormality of sexual reproduction which occurs under conditions of "artificial selection," it will be of the most entrancing interest.

It may, of course, be objected that the negro case is one of the crossing of artificial and not of natural varieties. To me such an objection presents itself as a play with words. No one, I take it, will deny that if the conditions of the Mississippi region were favourable to albinism and unfavourable to pigmentation, a variety of albino negro would arise as permanent in its characters as any other natural variety of man. Besides, the albino case must be read with that of the Canadian Red Indian, and this is a natural variety as well as the European crossed with it. Both cases lead to the same conclusion.

Dr. Archdall Reid's doubt as to whether Mendelians "are engaged in anything more than the investigation of those abnormalities of sexual reproduction which occur under conditions of artificial selection" therefore becomes an assumption with an inadequate basis.

Geo. P. Mudge.
Biological Laboratory, London Hospital
Medical College, October 21.

I have already (Nature, October 31) dealt with mutations, of which albinism is one. I have no first-hand acquaintance with Red Indian half-breeds. In the case of such characters as skin-colour and shape of nose and cheek-bones, even "when well developed," "the personal equation of the observer and the precision of his categories" have sometimes to be reckoned with. Having regard to the Mendelian doctrine of the independent inheritance of characters, does it not strike Mr. Mudge as singular that in the only example he possesses of marriages between E and extracted E *all* the offspring should be "European in *every* trait"? If his correspondent is correct, the Indian half-breed of the F_1 generation is "quite" indistinguishable from the full-blooded Redskin. I venture to appeal to readers of Nature who have first-hand acquaintance with the facts. The information we need is not whether exceptional half-breeds of the F_1 generation resemble pure-bred Indians, but whether this resemblance is the rule. Personally, I have a fairly large and close acquaintance with the half-breeds of Europeans on the one side, and negroes, Maoris, Kanakas, and several Asiatic races on the other. To my eyes, except in eye-colour, they are clearly distinguishable as half-breeds, though variations occur, and the dark race is sometimes approached rather closely. The case of eye-colour is remarkable. The black persists until one or more infusions of north European blood occur, when the light-coloured eye suddenly appears. So far as I am able to judge, though here I cannot speak with any degree of certainty, the quickness of the re-appearance of the light eye bears a relation to the degree of pigmentation of the dark race; that is, fewer infusions from the light-eyed race are required when it is crossed with the black-eyed European type than when it is crossed with the Asiatic, and more especially the negro. Whatever all this indicates—and I think I know, though lack of space forbids any attempt to entrance Mr. Mudge—very obviously it does not indicate Mendelian segregation. By latent characters I meant those long-lost ancestral traits which re-appear when domesticated races of rabbits, mice, pigeons, and the like are crossed.

G. Archdall Reid.

Newton's Rings in Polarised Light.

In Nature of October 24 (vol. lxxvi., p. 637) Mr. Edser asks whether anyone has tried the experiment of Lloyd's single mirror fringes with polarised light to see whether a change of the character of the fringes would occur on rotating the plane of polarisation of the light. Lloyd tried the experiment himself with light polarised by transmission through tourmaline, and observed no change in the appearance of the fringes (Lloyd, "Papers," p. 156). I have made the same experiment with Lloyd's fringes by internal reflection, and found no effect on rotating a Nicol prism through which the fringes were observed (*Phil. Mag.*, October, p. 507).

The change of phase for grazing incidence is π, whatever be the plane of polarisation of the incident light. The fringes, therefore, are of the same character for light of all kinds.

THE FISHES OF THE NILE.[1]

THESE two handsome volumes are a tribute to the late Dr. John Anderson's zeal in the cause of Egyptian zoology, and a justification of the cordial support which he had from Lord Lister, Dr. Günther, Sir E. Ray Lankester, and Dr. Sclater in prevailing on the Egyptian Government to undertake the inquiry. The author, the collector and the artist are to be congratulated on this important contribution to African ichthyology. Moreover, the region embraced in the description, as shown in the two excellent maps of the Nile system—Upper and Lower—is one of great interest to the general zoologist, for it contains the sole survivors of an order (Polypteridæ) abundantly represented from the Devonian to the Cretaceous, and includes one of the remarkable Dipnoans. It is an area in which the rare electrical fishes Mormyrus and Malapterurus (or, as the author has it, Malopterurus) are mingled with the subtropical and tropical Gymnarchus, the curious Heterotis, the Characinidæ, the Siluridæ, Ophiocephalus, the Anabantidæ, and the Cichlidæ; whilst by way of contrast these are associated with the cosmopolitan *Clupea finta* and *Mugil capito*, with the common *Anguilla vulgaris* and the ubiquitous *Morone labrax*. Yet these do not exhaust the sources of special interest, for not only were fishes, such as the Nile perch, preserved as mummies, their forms inscribed on ancient monuments or perpetuated in bronze models, but in this old-world country the number of fishes which carry and hatch their comparatively large ova and protect their young in the bucco-pharyngeal cavity is remarkable.

The problems connected with the origin and distribution of the fish-fauna are also replete with interest, and though many of these were dealt with by Mr. Boulenger in his valuable address to the zoological section of the British Association in South Africa, much yet remains for future workers both in substantiation and extension.

In the brief introduction the progress of the ichthyology of the Nile is described from 1757, the date of Hasselquist's "Iter Palæstinum," when only thirteen species from the Delta were known. Without going into detail, they had mounted up to eighty-nine in Dr. Günther's account of the fishes of Petherick's expedition, but did not exceed a hundred when the Egyptian Government undertook the present survey. Now the total is 192, and no one has had a greater share in this increase than the author.

An important part of the introduction is the illustrated account given by Mr. Loat, the collector, of the methods of fishing in the Nile, the accumulated skill of many ages having given the native all the practical advantages of his art, so that in this respect he is not inferior to the English, American and Japanese. The throwing- or casting-nets, circle-nets, sweep-nets, modified trammel-nets, long nets like those for sand-eels with a median pocket, push-nets, conical wicker traps, elaborate weirs of stones which closely resemble those at present in use in Japan, besides baited and unbaited hooks, show how varied these methods are. It is not to be supposed, however, that the casting-net is a novelty, for on the coast of Suffolk, for instance, an adept will throw it in a perfect circle. Mr. Loat collected no less than 11,000 specimens, and amongst these were thirty new species. Moreover, just as the Irish use the fatal spurge-root in their rivers, so the Egyptian pulverises the seeds of *Berbera* (or *Mellettia*) *ferruginea*, or "Burberra," for poisoning fishes. In two or three hours thousands, it may be, rise to the surface.

The thorough method in which Mr. Boulenger treats his subject is apparent throughout; elaborate tables of twelve measurements, in addition to nine notes of the number of spines, rays and scales in different parts, accompany each species. He, however, evidently makes too much, at the expense of Rüppell and others, of De Johannis as a pioneer in Egyptian ichthyology, for this author's descriptions and figures have much that is incorrect in them. Moreover, there is a tendency to split species where others group them, and to group them where others split them, the latter being just the fault he himself lately criticised, and with justice, in Smitt. Further, insignificant specific variations between the Nilotic fish-fauna and that of West Africa need not be insisted on too strongly where, as pointed out long ago, the similarity is so great. In looking at the slight diversities between such species as *Marcusenius discorhynchus*, *M. petherici*, *M. budgetti*, and *M. tanganicanus*, the thought involuntarily asserts itself that in the future a different view may be taken of their relationships. Again, there are cases in which the indefatigable author has examined 100 to 200 examples of a fish normally possessing ten to eleven dorsal rays, but he finds that three or four per cent. have seven or eight rays only. It is surely unsatisfactory to describe such a fish as possessing D. 7–10. A more correct method would have been to record it as Dr. Günther has done, viz. D. (7–8) 9–10.

FIG. 1.—Fishing at the mouth of the Sobat. From "The Fishes of the Nile."

One of the most interesting features in the Crossopterygians is the frequent allusion to the labours of the lamented Mr. J. S. Budgett, who contracted a fatal illness whilst pursuing his valuable work on the development of the group in the Niger Delta. Considerable advances have been made in the Dipnoans, that of the Nile (*Protopterus aethiopicus*) differing in habit from *P. annectens* of the West Coast. Of Teleosteans there are nineteen families, and the author gives two classifications, (1) an anatomical, and (2) one based on external characters. Both are valuable. The first family of the Malacopterygians is the generalised Mormyridæ, remarkable for the large size of the brain and the "problematic organ" above it, as well as for their electric organ. Four families, each repre-

[1] "Zoology of Egypt. The Fishes of the Nile." By G. A. Boulenger, F.R.S. Vol. i., text, pp. li+578; vol. ii., plates, pp. xviii+97 plates. (London: Published for the Egyptian Government by Hugh Rees, Ltd., 1907.) Two vols., price 8*l*. 8*s*. net.

sented only by a single species, follow, the last being Cromeria, distinguished from the Galaxiidæ of the Haplomi by the presence of a mesocoracoid (Swinnerton). The family of the Characinidæ (under the Ostariophysi) form a very generalised group confined to the fresh waters of Africa and Central and South America, from which the author thinks they may have migrated by a land connection in Upper Cretaceous times. These supposed precursors of the Cyprinoids number eighteen species in the Nile.

The widely distributed family of the Cyprinidæ comprises the largest number of species within its limts, viz. fifty, and thirty-five of these belong to the genus Barbus, a large proportion, seeing that in Day's "Fishes of India and Neighbouring Regions" there are but seventy. Yet the genus is conspicuous by its absence from the Senegal, the Gambia, and Lake Chad. The author's wealth of material has enabled him to clear up the synonymy of certain species, such as *Lates coubie*, yet it is doubtful if, as in Europe, hybridism may not occur to a greater extent than is at present imagined. The representatives of the genus Barbus, of which there are no fewer than twenty-seven new species in the work, offer a wide field for the features just mentioned, since many are very closely allied, though separable, perhaps, by such points as the proportions of the snout. The tropical or subtropical Silurids are largely represented by fifteen genera and forty-one species, and the habits of some, such as Clarias, are full of interest, for they spend the dry season in burrows in dried-up marshes, which they leave at night in quest of food—both animal and vegetable—using the spines of the pectorals in progression. The name Malapterurus has so long been used that the author's change to Malopterurus jars, and for similar reasons he himself does not follow Starr Jordan in calling the species "*Torpedo*" *electricus*. It is noteworthy that whilst the fresh-water species are all generically distinct from the American, those species which enter the sea on both shores of the Atlantic agree (*e.g.* Arius). The Cichlidæ, a family which presents great difficulties from the close resemblances of many—*e.g.* those of Lake Victoria—have increased, largely by the labours of Mr. Boulenger, during the last few years from twenty species to 210 in Africa, and of these eighteen belong to the Nile. The author considers that the forms inhabiting that great lake (Victoria) sprang from a small number of original (isolated) types, and were modified into a multitude of species according to lines different from those followed by other colonies. Only two or three of these are identical with or very closely related to forms in neighbouring rivers.

FIG. 2.—Throwing-net as used on the Lower Nile. From "The Fishes of the Nile."

Though many interesting facts in regard to reproduction and development are incidentally noted in this fine work on Nile fishes, especially in connection with Mr. Budgett's investigations on Polypterus, Protopterus, and on the breeding of the Mormyridæ, very much yet awaits the observer in this department, and no more fascinating field exists, to judge from the fragmentary knowledge available. Some, like *Hyperopisus bebe*, attach their oval eggs to rootlets of grass, and the larvæ hang in thousands, like amphibians, to the rootlets until the yolk-sac is absorbed. Others have floating nests 2 feet long by 1 foot broad (*Gymnarchus niloticus*) for eggs 10 mm. in diameter, and for larvæ with long gill-filaments. A still larger nest (4 feet in diameter) characterises *Heterotis niloticus*, the larvæ of which also have gill-filaments. The eggs of *Cyprinodon fasciatus* have long filaments, like those of the garfish, which entangle them in masses or suspend them to various objects. The large number of fishes which carry their ova and larvæ in their bucco-pharyngeal cavity is a prominent feature, and Mr. Boulenger has found that it is almost invariably the female which does so, not the male, as in such forms as Arius. In some cases (*Haplochromis strigigena*) the male makes a small cavity in the sand where the eggs are fertilised, the female thereafter taking them into her mouth, and fasting for a fortnight. Yet animals much lower in the scale than fishes do almost the same thing, as in the case of *Asterias Mülleri*, the fertilised eggs and larvæ of which are borne in a mass by the parent over the mouth. The Egyptian fishermen, however, explain the presence of the ova in the mouth of the fishes very simply, viz. by a "reversed method of parturition." The whole subject, from the development of the nuptial tubercles in the males to the post-larval stages of these remarkable Nile fishes, bristles with features of interest. In addition, the field of fish-physiology is inviting. Why is it that *Polypterus bichir* (a fish which dies in tolerably fresh water if prevented from reaching the air) cannot live in brackish water, and that slight salinity kills it? whilst one species of fish in Lake Menzaleh thrives either in fresh or salt water, and another dwells equally in a hot spring at Makulla, in the Persian Gulf, and in salt water all round the Red Sea. The author takes in hand the explanation of the peculiar coloration of *Synodontis batensoda*, in which the ventral aspect of the body is darker than the upper, viz. as a provision in connection with the habit of swimming in a reversed position. Yet this explanation will not avail for the post-larval Callionymus. Again, are the habits of Anabas in Africa similar to those in India?

The able author has brought to the task not only his former experiences of African fishes—north and south, east and west—but the whole resources of the British Museum, and the vast storehouse of information amassed during the lifelong labours of Dr. Günther, and he has accomplished it in a manner creditable to the Egyptian Government, to science, and to himself. His work, indeed, will long form the basis of future labours in the ichthyology of the Nile. The whole of the families are as admirably illustrated as described in the beautiful volume of lifelike lithographs by Messrs. Smit and Green, their work rivalling the exquisite finish of the late G. H. Ford, long *facile princeps* in the department. Finally, if any suggestion may be made in a work so carefully performed, it is that in the index the synonyms might have been printed in italics, and that, in the text, plate xiv. should be substituted on p. 84 for plate xv.

W. C. M.

SOME RECENT PAPERS ON METEORITES.

WE have before us a number of reprints of recent papers descriptive of various meteorites. Several of these are by the late Dr. Henry A. Ward and the late Prof. E. Cohen, two of the most indefatigable workers in this subject, whose loss is much to be deplored. In 1904, two years before his death, Dr. Ward published a "Catalogue of the Ward-Coonley Collection of Meteorites," which is not only a catalogue, but contains, in addition, much useful information, including alphabetical and topographical lists of all known meteorites (about 680 in number). The Ward-Coolney collection, now exhibited in the American Museum of Natural History at New York, is one of the most complete that has ever been made, containing as it does representatives of 603 meteoritic falls; it is further remarkable in that it was brought together in the comparatively short space of time of ten years. Prof. Cohen died in 1905, and a third part of his "Meteoreisenkunde" was published after his death; this, which is the only general work that has yet been attempted on meteorites, unfortunately remains incomplete.

Dr. H. A. Ward (Proc. Rochester Acad. Sci., 1904, vol. iv., pp. 137–148, with 6 plates) gives a description of the Willamette meteorite, which was found in 1902 near the town of Willamette, in Oregon. This mass of metallic nickel-iron measures $10 \times 6\frac{1}{2} \times 4\frac{1}{4}$ feet, and weighs 31,107 lb. (about $15\frac{1}{2}$ tons); it is the third largest meteorite as yet known. Like the largest on record, the Anighito, of $36\frac{1}{2}$ tons, brought by Commander R. E. Peary from Cape York, in Greenland, it is now exhibited in the American Museum of Natural History. The second largest known meteorite is that of Bacubirito, in Mexico, which has an estimated weight of $27\frac{1}{2}$ tons; this mass, though unearthed and described by Dr. Ward in 1902, has not been removed from the place where it was found. The Willamette meteorite is roughly conical in form, and it was found embedded in the ground with the base of the cone uppermost, suggesting that the apex of the cone was to the front of the falling meteor. The mass is remarkable for the deep, rounded, and cylindrical pits, of which several types are distinguished, on the sides and the base of the cone. The deep cavities on the base (Fig. 1) are accounted for by the weathering and rusting action of water standing in pools on the exposed part of the mass as it lay for unknown ages in the soil of the primeval forest of a very moist region. The pittings and groovings on the sides are attributed by the author to the erosive action of the air during the flight of the meteorite; but it seems more likely that they have been produced by weathering in the ground, and that none of the original surface now remains. The nodules and rods of troilite (iron sulphide) enclosed in the metallic iron no doubt formed the centres around which the weathering has proceeded. The Widmanstätten figures on an etched section of the iron show the structure to be octahedral with broad lamellæ. The specific gravity of the iron is 7·7, and it contains $91\frac{1}{2}$ per cent. of iron, 8 per cent. of nickel, and small amounts of cobalt and phosphorus.

Dr. H. A. Ward (*ibid.*, 1905, vol. iv., pp. 193–202) also gives an account of the Bath Furnace aërolite,

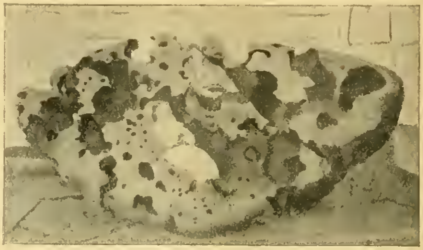

FIG. 1.—Willamette Meteorite. Full view, lower side of meteorite.

which was observed to fall on November 15, 1902, in the vicinity of Bath Furnace in Bath co., Kentucky, the fall being accompanied by a blinding light, loud detonations, and hissing noises. In all, three stones were found; one of them, weighing nearly 13 lb., struck the hard surface of a road, making an east to west furrow about a foot in length and five inches in greatest depth. Another mass of $177\frac{1}{4}$ lb. fell $1\frac{3}{4}$ miles further south; it scarred the trunk of one tree, cut through the roots of another, and buried itself two feet in the ground. A side view (Fig. 2) of this larger

FIG. 2.—Bath Furnace Meteorite. Side view, showing furrows radiating from apex.

stone shows very clearly a system of furrows radiating from the apex, which were produced by the intense erosive action of the air during the flight of the stone. The internal structure of the Bath Furnace meteorite is that of a spheroidal chondrodite like that of the three previously known meteorites (Werchne Tschirskaja, South Russia, 1843; Trenzano, Italy, 1856; and Saline Township, Kansas, 1898), which fell during the November Leonids. Both the Bath Furnace and the Willamette meteorites gave rise to suits at law between the finders and the land owners. In other papers, Dr. Ward describes some new Chilian meteorites, and also gives general notes on the history of meteorites and collections of meteorites, especially as regards the aims of the latter.

Prof. E. Cohen (Ann. S. African Museum, 1906, vol. v., pp. 1–16, with 3 plates), describes the meteoric stone of $30\frac{1}{2}$ lb. which was observed to fall on January 3, 1903, at the mission station of St. Mark's, in Transkei, Cape Colony. The description of the microscopical structure and chemical composition of this stone was completed by Prof. C. Klein, another well-known worker on meteorites, who also died recently (1907).

Mr. L. L. Fermor (Records Geol. Survey India, 1907, vol. xxxv., pp. 79–96, with 12 plates) collects together information respecting the circumstances of the fall of various Indian meteorites, and gives brief notes on their external characters. At greater length (*ibid.*, pp. 68–78, with 3 plates) he describes the fall of stones near Dokachi, in Bengal, on October 22, 1903; here, along a line six miles in length, twenty-four fragments, with a total weight of 3838 grams, were picked up. A list is given of seventy-one meteoritic falls recorded in India since 1798; more records exist in later years, and in the more thickly populated districts, and latterly they have averaged one each year. All, except three, of these Indian meteorites are composed of stony material.

Prof. O. C. Farrington (Field Columbian Museum, Geol. Ser., 1907, vol. iii., pp. 57–110) collects together 360 published analyses of 248 meteoric irons, tabulating them in different classes according to the structure of the iron. It is then seen that there exists a close relationship between chemical composition and structure. All irons with a hexahedral structure are very uniform in composition (94.12 per cent. Fe), whilst in those with an octahedral structure the amount of nickel increases with the fineness of the lamellæ. In the ataxite group, in which the structure is finely granular to compact, there is more variation in composition. The average composition of all meteoric irons is approximately Fe, 90; Ni, 9; Co, 0·9; Cu, 0·02 per cent. The same author also describes in detail in the same journal the siderite of Rodeo, Mexico (found 1852), the siderolite of South Bend, Indiana (found 1893), and the aërolite of Shelburne, Ontario (fell August 13, 1904).

The papers on meteorites noted above are but a few selected at random from the many that have been recently published: except in details, one paper is, however, more or less a repetition of another.

L. J. S.

NOTES.

THE president and council of the Royal Society have recommended the following fellows for election as members of the council for the ensuing year at the anniversary meeting on November 30:—*President*, Lord Rayleigh, O.M.; *treasurer*, Mr. A. B. Kempe; *secretaries*, Prof. J. Larmor, Sir Archibald Geikie, K.C.B.; *foreign secretary*, Prof. J. R. Bradford; *other members of council*, Dr. H. F. Baker, the Right Hon. A. J. Balfour, Sir William Crookes, Mr. Francis Darwin, Sir George Darwin, K.C.B., Prof. J. C. Ewart, Prof. D. Ferrier, Mr. C. T. Heycock, Prof. S. J. Hickson, Prof. J. Joly, the Hon. C. A. Parsons, Dr. A. Scott, Prof. A. C. Seward, Prof. F. T. Trouton, Dr. A. D. Waller, Mr. W. Whitaker.

THE late Dr. Edward Sang's collection of MS. calculations in trigonometry and astronomy has been gifted to the British nation by the Misses Sang, and the president and council of the Royal Society of Edinburgh have been appointed custodiers of the collection, with power to publish such parts as may be judged useful to the scientific world. The society has also been given custody of the duplicate electrotype plates of Dr. Sang's 1871 new seven-place table of logarithms to 200,000, with power to use them for reproducing new editions, or publishing extended tables of seven-place logarithms. At the meeting of the society on November 4, the chairman, Dr. R. H. Traquair, F.R.S., read a statement regarding Dr. Sang's monumental work. The manuscript volumes number forty-seven in all, the contents of thirty-two of which are in transfer duplicate. Vols. i. to iii. contain the details of the steps of the calculations on which the results contained in the next thirty-six volumes are based. Vol. iv. contains the logarithms, calculated to twenty-eight figures, of the prime numbers up to 10,000, and a few beyond. Vols. v. and vi. contain the logarithms to twenty-eight figures of all numbers up to 20,000. From these the succeeding thirty-two volumes are constructed, giving the logarithms to fifteen places of all numbers from 100,000 to 370,000. This colossal work must ever remain of the greatest value to computers of logarithmic tables. It is a great national possession. The other tables in the collection are trigonometrical and astronomical. Of special interest are the tables of sines and tangents calculated according to the centesimal division of the quadrant. It is hoped that ere long some of these tables may be published in such a form as to make them more immediately accessible to computers. They are the foundation of Dr. Sang's published book of seven-place logarithms to 200,000, undoubtedly the most perfect of its kind ever printed. The complete account of the various tables will be printed in the society's Proceedings, and other scientific bodies will have their attention directed to the importance of the collection now in the custody of the society.

THE Huxley memorial medal of the Royal Anthropological Institute was presented to Prof. E. B. Tylor, F.R.S., on Tuesday, November 5, in recognition of his distinguished services to anthropology. On October 2 Prof. Tylor celebrated his seventy-fifth birthday, and the anniversary was made the occasion of the presentation to him of a volume of essays representative of British anthropology. The current volume of the Journal of the Royal Anthropological Institute is dedicated to Prof. Tylor; and the presentation of the Huxley memorial medal is another mark of the esteem in which he is held by anthropologists.

SIR OLIVER LODGE has accepted the invitation of the council of the Faraday Society to succeed the late Sir William Perkin as president of the society.

ON October 20 the Paris newspaper *l'Éclair* liberated 10,000 pilot balloons from a boat on the Seine. One of these balloons was found at mid-day on October 21 at Undermannlaani, near Kausala, which is on the railway mid-way between Helsingfors and Wiborg, in Finland. The distance is 1950 kilometres. The balloon was found twenty hours after the start, and, assuming that it had only just fallen, the average rate was nearly 100 kilometres per hour. The lift of the balloons, including weight of postcard, &c., was supposed to be about 1 gram, but departures from this value must have been frequent, for Mr. Charles J. P. Cave, who witnessed the ascents and sends us these particulars of them, states that the rates of ascent of different balloons varied greatly. The diameter of the balloons was about 35 centimetres. The greatest distance covered by a manned balloon is 1925 kilometres, in the ascent of Count de la Vaulx from Vincennes on October 9, 1900.

THE *Pioneer Mail* states that the Secretary of State for India has sanctioned the establishment of a new bacteriological department on a permanent basis.

IT is reported that the town of Karatagh, in Bokhara, was destroyed by an earthquake on October 21. A message from New Bokhara states that 600 farmsteads have been destroyed, and 200 persons killed.

THE FitzPatrick lectures of the London Royal College of Physicians will be delivered by Dr. Leonard Guthrie on December 3 and December 5, on "Contributions from History and Literature to the Study of Precocity in Children."

IT is reported by *Science* that the observatory of the University of Michigan is being enlarged under the direction of Prof. Hussey. The old instruments are being reconstructed, and a new reflecting telescope added, having an aperture of about 37½ inches.

FROM the *Pioneer Mail* we learn that the Government of India has sanctioned the opening of wireless telegraphic communication between Mergui (Lower Burma) and Victoria Point, with a land line between Victoria Point and Maliwun. An annual guarantee will be given from the provincial revenues of Burma in respect of the combined system. The guarantee will be subject to reconsideration at the end of ten years.

THE opening meeting of the Institution of Electrical Engineers will take place on November 14 at the Institution of Civil Engineers, Great George Street. Lord Kelvin is president for the present session, this making the third time he has occupied the presidential chair. Owing to his absence no presidential address will be given at the opening meeting, but a paper on the dielectric strength of insulating materials and the grading of cables will be read by Mr. A. Russell.

THE council of the Institution of Civil Engineers has made the following awards for the year 1906–7:—the Howard quinquennial prize to Mr. T. E. Vickers, C.B., in recognition of the part he has taken during his career in developing and improving the production of steel for important engineering purposes; Telford gold medals to Mr. Dugald Clerk (London) and Mr. E. J. Way (Johannesburg); Watt gold medals to Mr. J. T. Milton (London), Dr. A. W. Brightmore (Egham), and Mr. C. W. Lloyd-Jones (Secunderabad); George Stephenson gold medals to Mr. G. A. Hobson (London) and Mr. W. C. Copperthwaite (London); Telford premiums to Messrs. C. F. Jenkin (London), W. A. P. Tait (Edinburgh), A. P. Trotter (London), M. Kellow (Penrhyndeudraeth), H. J. S. Heather (Johannesburg), A. M. Robeson (Johannesburg), and J. W. Kitchin (Bristol); a Crampton prize to Mr. R. F. Thorp (London); Manby prizes to Mr. S. A. Frech (London) and Mr. G. D. McGlashan (Blyth); the Miller scholarship and the "James Forrest" medal to Mr. A. C. Anderson (Wolverhampton); Miller prizes to Messrs. R. A. Whitson (Basutoland), C. A. Ablett (Addiscombe), E. H. Heathcote (Henbury, near Macclesfield), G. B. G. Hull (Stockport), H. Stringer (Stoke-on-Trent), G. F. Walton (Edenfield, near Manchester), and A. T. Weston (Woolwich); Bayliss prizes, awarded on the results of the October and February examinations, 1906–7, respectively to Mr. F. C. R. H. Boyd (Luxor, Upper Egypt) and Mr. D. J. Morris (Swansea).

THE inaugural address of the eighty-ninth session of the Institution of Civil Engineers was delivered on Tuesday evening, November 5, by the president, Sir William Matthews, K.C.M.G. In the course of his remarks, the president referred to certain branches of engineering which are associated with the conduct of over-sea traffic, and therefore have an intimate and important bearing on our maritime commerce. In the ships of our mercantile marine we may with certainty look for expansion both with regard to dimensions and numbers. Again, we are fully entitled, in the light of recent events, to anticipate in the immediate future further and possibly great developments in steam propulsion with turbines, either employed alone or associated with reciprocating engines. Then there is the extended use of oil for raising steam, or directly in internal combustion engines. With regard to harbours, docks, and waterways, due and adequate provision must be made for larger and deeper draught ships, in the designs to be prepared for new works, and also where harbours and docks exist of inadequate dimensions for present requirements. As to the actual construction of sea-works, the arrangement of their design so that their execution may entail, so far as possible, repetitions of the same process, with the use of heavy masses and the generous application of suitable plant, may be usually expected to produce satisfactory and economical results, so far as the structures themselves are concerned.

THE awards for the Marseilles International Oceanographic Exhibition, which was held last year, have been issued. Among the recipients we notice the following:—*Grand Prix d'Honneur* to the Admiralty, the British Museum (Natural History), Meteorological Office, Sir John Murray, K.C.B. (president of the British Committee), Fishery Board for Scotland, Department of Agriculture for Ireland. *Grand Prix* to the Scottish National Antarctic Expedition, Challenger Society, Marine Biological Association, Royal Geographical Society, Captain Scott, R.N., Dr. Herbert Fowler (honorary secretary of British Committee), and Mr. W. S. Bruce. In addition, the *Diplôme Commémoratif* has been awarded to about thirty individuals and societies.

THE South Wales Institute of Engineers celebrated its jubilee on October 29. The institute was founded at Merthyr on that date of 1857 by the late Mr. Wm. Menelaus, manager of the Dowlais works. A strong and representative executive was formed, every member of which has now passed away. In 1881 a charter of incorporation was obtained, and in 1894 the institute buildings were opened at Park Place, Cardiff, at a cost of more than 10,000*l*., whilst the new library added last week has cost another 5000*l*. The present membership is 565. Sir W. T. Lewis, who was present at the first meeting of the institute, became in later years its president. The present holder of that office is Mr. T. H. Deakin, and secretary Mr. T. Jones-Price. The library was formally opened by the president on the afternoon of October 29, and a portrait of the founder of the institute (by Mr. Parker Hagarty) was unveiled. Addresses were delivered by Mr. T. Hurry Riches, Mr. Henry Martin, Mr. McMurtrie, and others. The quarterly meeting was then held, and in the evening there was a conversazione, at which there was a crowded attendance. Several lecturettes were delivered by Principal Griffiths, F.R.S., Dr. Hampson, Dr. Perman, and Mr. S. W. Allen. Among other interesting features was an installation of electrophones "laid on" to the London opera and music halls. Sir W. T. Lewis, who was unavoidably absent, sent a congratulatory letter, in which he referred to the fact that the South Wales coal output to-day was nearly seven times its figure at the time of the foundation of the institute.

THE fourth International Fishery Congress will be held at Washington on September 22–26, 1908, on the invitation of the United States Bureau of Fisheries. The first congress was held at Paris in September, 1900, the second was held at St. Petersburg in 1902, and the third at Vienna in 1905. Persons who expect to attend the congress or to submit papers are asked to communicate with the secretary-general as soon as practicable, and the secretaries of institutions and organisations interested in the work of the congress are requested to register their official designation and address so that they may receive further announcements, programmes, invitations, &c. The congress will deliberate on all important affairs concerning fishing and fish culture, and will submit propositions and memorials to Governments and to provincial and local authorities. The subjects to be brought before the congress may be grouped as follows:—(1) commercial fisheries; (2) matters affecting the fishermen and the fishing population; (3) legislation and regulation; (4) international matters affecting the fisheries; (5) aquiculture; (6) acclimatisation; (7) fish-ways and fish-ladders; (8) biological investigation of the waters and their inhabitants; (9) diseases and parasites of fishes, crustaceans, molluscs, and other water animals; (10) angling and sport fishing. In connection with the congress there have been arranged a number of competitive awards for the best or most important investigations, discoveries, inventions, &c., relative to fisheries, aquiculture, ichthyology, fish pathology, and related subjects during the years 1906, 1907, and 1908. The awards will be in the form of money, and aggregate about 440*l.*; and, although the individual amounts are not large, it is hoped that the conferring of the awards by so representative a body as the International Fishery Congress will induce many persons to compete, and will result in much benefit to the fisheries and fish culture. Communications regarding the congress should be addressed to the Secretary-General, International Fishery Congress, Washington, D.C., U.S.A.

A REMARKABLE hailstorm occurred in Cairo on the evening of October 21, preceded by lightning from 6 p.m. to 7.30 p.m. The hailstones measured on an average about 25 mm. in diameter, the largest stones measuring up to 35 mm. The storm was very violent, but only lasted a quarter of an hour. Had it been of longer duration considerable damage would have been inevitable. Such storms are very rare in Egypt. Coming after many hot, rainless months, the sudden downpour of hail caused great excitement amongst the natives. The hailstones fell on the flat-roofed houses with a loud crackling sound resembling that of burning wood-work. Newspapers spread out to catch the falling hail were simply riddled through by the larger stones. Most of the hailstones were spheroidal in shape with white nuclei. After striking the ground they quickly became hemispherical. The temperature in Cairo at the time was 25° C. The weather report issued by the Egyptian Survey Department does not indicate anything exceptional in the general weather conditions before or after the storm. The barometer was nearly normal, with short periodic disturbances between 5 p.m. and 8 p.m. The atmosphere was slightly clouded, and a light wind blowing. The hailstorm was very limited in extent, and apparently the path was N.W. to S.E. The temperature at various altitudes is variable, depending upon meteorological changes, but in ordinary circumstances the rate of change of temperature with altitude amounts to 1° C. for each 100 metres for the first 1500 metres. This would give about 2500 metres as the minimum height for the formation of ice. A systematic exploration of the atmosphere by means of kites and captive balloons with self-recording instruments is now being undertaken by the energetic director of the Helwan Observatory which will greatly extend our knowledge of the upper air over north-east Africa.

WE have received a copy of a paper by Mr. J. F. Bovard, issued as No. 14 of the third volume of the University of California Zoological Publications, on the structure and movements of *Condylostoma patens*, one of the largest of unicellular organisms.

A WRITER in the October number of the *Zoologist* figures a specimen of the "false scorpion," *Chelifer cancroides*, taken last year in a bake-house at Manchester. Up to the year 1892 only four British examples of this creature were known, but since that time the species has been discovered in stables, stores, &c., in various parts of England and Scotland.

"A MONOGRAPH OF THE PETRELS" is the title of a quarto work, by Mr. du Cane Godman, to be published in parts by Messrs. Witherby and Co., of High Holborn. It is to include all the known species of petrels, shearwaters, and albatrosses, and will be illustrated by more than one hundred hand-coloured plates. Mr. Godman's former colleague, the late Mr. Osbert Salvin, contemplated issuing a work of this nature, for which a number of plates were prepared; these will be used in Mr. Godman's volume.

WE have received a copy of a paper, by Mr. H. B. Greene, on the influence of heredity on the diseases and deformities of poultry, issued in connection with the second National Poultry Conference held in July last. From the fact of the isolation of the germ-cells, diseases are not, in the author's opinion, transmissible through the egg, and they must accordingly be regarded as the effects of environment rather than of inheritance. This is distinctly encouraging to the poultry-breeder, as it indicates that much may be done in the way of preventing disease by careful attention to food and sanitation.

AMONG the contents of *Verhandlungen deutsch. zool. Ges.* for 1907, we may refer to a paper by Dr. Steche, of Leipzig, on two luminous fishes, *Photoblepharon palbebratus* and *Heterophthalmus catoptron*, from the Malay Archipelago. Both species are of small size, and belong to the family of horse-mackerels (Carangidæ); they are remarkable among luminiferous fishes in being shallow-water forms, the first-named dwelling among stones at the bottom, while the second is a free-swimmer. Their light-organs, which are situated in the cutis, resemble generally those of deep-water luminous fishes, though they have certain structural peculiarities of their own. The whole upper surface of these fishes appears to be luminiferous.

A LARGE portion of vol. xlix. of the Smithsonian Miscellaneous Collections is occupied by an account of the crabs collected by the North Pacific exploring expedition of 1853–6. Dr. W. Stimpson, it appears, accompanied the expedition as naturalist, and after his return transferred the invertebrate collections to Chicago, where, together with notes and drawings, they were burnt in 1871. After his death in the following year an illustrated report on the crustaceans was discovered, and it is this report which has just been published by the Smithsonian Institute. The only additions to the original MS. are references to Stimpson's preliminary descriptions of species and certain emendations in nomenclature. Among the generic names we may refer to Ptychognathus, which was published in 1858, and therefore antedates and invalidates Owen's use of that term for a South African anomodont reptile.

In a supplemental Bulletin (No. 3) on "leaf-hoppers," recently issued by the Experimental Station of the Hawaiian Sugar Planters' Association at Honolulu, Mr. G. W. Kirkaldy suggests that the Australasian zoological region should be subdivided as follows:—(1) Austro-Malayan, or Papuan, including, in addition to the limits laid down by Wallace, the tropical forests of Queensland, and New Caledonia and the neighbouring islands as far as Fiji; (2) Euronotian, comprising Tasmania and the south-eastern third of Australia; (3) the Maorian, embracing New Zealand and adjacent islands; (4) the Westralian. The Caroline, Marshall, and Marianne groups may be provisionally included in the Austro-Malayan subregion, while the Hawaiian Archipelago forms an unattached subregion of great antiquity. Fiji seems to be related, as regards fauna, to the Papuan Archipelago or to the tropical forest of East Australia, and Wallace's Polynesian subregion should accordingly be abolished. Celebes is perhaps best regarded as an unattached or intermediate subregion.

A list of sedges from Jamaica, compiled by Dr. N. L. Britton from specimens examined in herbaria in New York and London, has been published as a supplement to the fifth volume of the Bulletin of the Department of Agriculture, Jamaica. With regard to previous determinations, Dr. Britton follows in the main the monograph on West Indian Cyperaceæ by the late Mr. C. B. Clarke, published in Urban's "Symbolæ Antillanæ" in 1900, but prefers a broader acceptation of the genus Cyperus. Fifteen genera and about a hundred species are enumerated, of which some require confirmation from additional specimens.

In the October number of the *Trinidad Bulletin* the editor notes, with regard to the species *Theobroma angustifolia* allied to the cacao, that while the fruit is useless for commercial purposes, the tree, being more robust and resistant, is likely to prove useful as grafting stock for cacao plants. Reference is also made to an ornamental grass, *Thysolaena agrostis*, introduced from America, that may be grown in clumps similar to pampas grass. The report by Mr. F. A. Stockdale, mycologist to the Imperial Department of Agriculture in the West Indies, on the palm diseases investigated in Trinidad is published in full. Of the three diseases recorded, the most serious is the root disease caused by a fungus assigned to Botryodiplodia, a genus included in the Sphæropsideæ.

It is reported in the daily papers that Prof. Koch, who is returning home after a long sojourn in the sleeping-sickness districts of Uganda, regards sleeping sickness as an enormous danger to the whole of East Africa. He finds that the tsetse-fly, the *Glossina palpalis*, which conveys the disease, breeds not only on the lake shores, but along the whole length of the rivers. Prof. Koch considers that there is a distinct connection between crocodiles and sleeping sickness. Wherever crocodiles are found the disease may be discovered, but only in places near the water. The blood of crocodiles forms the chief nourishment of the Glossina, which sucks the blood between the plates of the animal's hide. The extermination of the Glossina is impossible, but it is suggested that the same end may be reached by destroying the crocodiles or by the removal of the bushes and undergrowth where the animals lurk.

No one more fully understands the danger of indiscriminately using a *questionnaire* than Dr. J. G. Frazer, who in publishing through the Cambridge University Press his "Questions on the Customs, Beliefs, and Languages of Savages" is careful to point out the true method of utilising them. They are intended, not so much to be put directly to the savage, as to indicate to the inquirer in the field those subjects upon which students at home desire information. Leading questions should be avoided, as they tempt the savage to give answers which he thinks will be acceptable. The savage should be encouraged to talk in his usual vague way on the subject under investigation until he has exhausted his information for the time, when a question judiciously asked may jog his memory. Unexpected information casually offered is the most valuable of all, "first, because not being foreseen by the civilised man it cannot have been consciously or unconsciously suggested by him to the savage; second, because it may put an entirely fresh complexion on a whole series of customs and beliefs about which we had fancied that we knew all that was worth knowing." If used with this much needed caution, this suggestive collection, which is supplementary to the manual issued by the Royal Anthropological Institute, will be of much value to travellers with a taste for investigating the manners and customs of savage or semi-savage races.

Striking evidence of the industrial advantage of the occupation of the Philippines by the United States is afforded by a copiously illustrated article on railway development in the Philippines, by Mr. P. H. Ashmead, in the *Engineering Review* (vol. xxxiii., No. 6). The construction of the railways under Government patronage cannot fail to be of permanent benefit. The vast sums distributed as wages will be spent in the islands. An industrial army of some 30,000 men will have been formed, and such of these as are not required in the working of the railways will be available for other industries, which will receive an impetus by the supply of cheap means of transport.

The Royal Cornwall Polytechnic Society, of which the seventy-fourth annual report has been received, continues to carry on successfully the valuable work in promoting the commercial prosperity of Cornwall and in encouraging mining invention for which it was brought into existence. The annual exhibitions of the society do much to stimulate inventive genius, and from the report on the seventieth exhibition it is seen that in view of the increased mining activity in the county special attention was devoted to life-saving appliances in mines. The papers contributed to the society and published in the report, whilst containing nothing of striking novelty, give much useful information. They include papers on tantalum, by Mr. F. H. Michell; on uranium ores, by Mr. F. J. Stephens; on deep bore-hole surveying, by Mr. W. R. Bawden; on modern mining methods, by Mr. J. H. Collins; and on the bees, wasps, and ants of Cornwall, by Mr. James Clark. The volume concludes with a report on the work of Falmouth Observatory, by Mr. W. L. Fox and Mr. E. Kitto.

In the *American Journal of Mathematics*, xxix., 4, Prof. G. W. Hill shows how the attraction of a homogeneous spherical segment can be evaluated in terms of elliptic integrals.

Writing in the *Popular Science Monthly*, lxxi., 3, under the title of "A Scientific Comedy of Errors," Profs. T. D. A. Cockerell and F. R. B. Hellems present a summary of the early history of the cochineal and allied dye-producing insects. It contains, in particular, an account of a little-known pamphlet by Dr. Friedel (Leipzig, 1701), a man who, as the authors point out, was possessed of the true scientific spirit, but who appears to have corrected the blunders of Leewenhoek only to make lesser blunders of his own.

THE *Rendiconto* of the Bologna Academy for 1905–6 has been recently issued. It contains papers by Prof. Guido Tizzoni and Dr. A. Bongiovanni on the curative action of radium on the virus of rabies, together with a short communication on the same subject by Prof. Ivo Novi, who seems to have arrived at somewhat different conclusions regarding the efficacy of the cure. In addition, Prof. Cesare Arzella discusses in two short notes the conditions of integrability of a series of integrable functions and of partial differential equations respectively.

FROM Captain Lyons's report of the Survey Department of Egypt in 1906, it appears that the two principal features of the work during the year were the completion of the cadastral survey (large-scale plans of the cultivable land of Egypt, on which the individual holdings are indicated), and the publication of about one-quarter of the general map of the Nile valley and the delta on the scale of 1 : 50,000. The work of the meteorological section has greatly increased; among many improvements we may mention that since January, 1906, monthly summaries of the weather have been prepared and published, and that subsequently the area of the Daily Weather Report has been enlarged to include pressure and wind data over the eastern Mediterranean and Nile basin, thus filling up an important gap in the regions for which weather conditions are mapped daily.

THE September part of the Journal of the Institution of Electrical Engineers contains a paper by Mr. E. W. Moss in which, under the title "Electric Valves," short accounts are given of the theory and modes of action of many of the devices used at present for converting alternating into direct currents. Of these, the Norden electrolytic valve and its modifications appear to have proved themselves most capable of dealing with heavy currents, while the glow-lamp valve of Dr. Lee de Forest and Prof. Fleming seems one of the most convenient for the small currents used in wireless telegraphy.

OUR knowledge of the electrical state of the atmosphere should in the near future receive considerable additions from the observations which, according to the June number of *Terrestrial Magnetism and Atmospheric Electricity*, are about to be taken on board the United States magnetic survey yacht *Galilee* during her cruise in the Pacific and by the staff-surgeons on board two of the vessels of the German Royal Navy. The potential gradient, the conductivity of the air, and the radio-activity of air and sea-water are all to be measured regularly during calm weather.

CRYSTALLISED alumina occurs in nature in varying shades of colour, ranging from the colourless sapphire to brown and opaque corundum. The ruby, sapphire, and oriental amethyst are varieties distinguished by their transparency and colour. These colours have been attributed to the presence of traces of salts of iron, manganese, chromium, titanium, and other metals, but the experiments described by M. F. Bordas in the current number of the *Comptes rendus* (No. 18, October 28) would appear to prove that this explanation is insufficient, since by submitting a coloured stone to the action of a highly active radium bromide the colour is modified, passing from red through violet, blue, and green to yellow. Radium bromide of an activity of 1,800,000 was used in these experiments, the time of exposure not being stated. The action could be modified by graduating the activity of the radium salt or by increasing the distance of the stone from the radio-active material. The stones thus treated are not radio-active; they do not light up in the dark under the influence of pure radium bromide, and the coloration is permanent as regards heating.

DR. W. DOBERCK has retired from the position of director of the Hong Kong Observatory, and has been succeeded by Mr. F. G. Figg. He desires it to be known that his permanent address is now "Knowloon," Elgin Road, Sutton, Surrey.

UNDER the title of "A Chronicle of Science," the *Graphic* publishes fortnightly articles which deal attractively and accurately with topics of scientific interest. The issue of October 19 contained an illustrated description of the Percy Sladen Trust Expedition to the Indian Ocean, and the current number (November 2) includes portraits of Sir John Evans and the Rev. W. H. Egerton—the "father" of the Geological Society. Sir John Evans will celebrate his eighty-fourth birthday on November 17, and Mr. Egerton his ninety-sixth on November 13. Mr. Egerton was elected a Fellow of the Geological Society in 1832, and has therefore been on its roll for seventy-five years.

AMONG new books shortly to be issued are to be noted:—"The Functional Inertia of Living Matter," by Dr. D. Fraser Harris; "A Manual of Prescribing," by Dr. C. R. Marshall; and a revision of "Waring's Bazaar Medicines of India," by Lieut.-Colonel C. P. Lukis, I.M.S. Messrs. J. and A. Churchill will publish these three books.

A NEW edition of Mr. Wm. Woods Smyth's "The Bible in the Full Light of Modern Science" has been published by Messrs. Simpkin, Marshall and Co. Much new matter has been added. The price of the book is 1*s*. 6*d*. net.

MR. CARL ZEISS, of Jena (London address, 29 Margaret Street, W.), has published in brochure form full particulars of the field glasses he is prepared to supply. It is convenient to have in this concise form details as to price, linear magnification, and so on of these widely used glasses.

Erratum.—In Prof. Rutherford's letter in NATURE of last week (October 31, p. 661, col. 2, line 23), for "picradium" read "preradium."

OUR ASTRONOMICAL COLUMN.

COMET MELLISH (1907*e*).—Observations of comet 1907*e* made at the Lyons Observatory on October 17 showed that the object had the appearance of a diffused nebulosity of about 35″ diameter, was of about the tenth magnitude, and had a slight central condensation. Observing at the Marseilles Observatory on October 17 and 18, M. Borrelly found the comet to be fairly bright and extended, with a granular appearance (*Comptes rendus*, No. 17, October 21).

Other observations are recorded in No. 4210 of the *Astronomische Nachrichten* (p. 163, October 28), in which Herrn G. van Biesbroeck reports that on October 19, using the 15-inch refractor of the Uccle Observatory with a magnification of 240, he saw the comet as a circular, nebulous object of 1′ diameter and of the tenth magnitude. A central condensation, but no stellar nucleus, was seen.

Prof. Becker, director of the Strassburg Observatory, directs our attention to the fact that the Strassburg observation of this comet, mentioned in these columns last week, was made by Dr. Wirtz.

The following is an abstract from the ephemeris published in No. 4209 of the *Astronomische Nachrichten* (p. 147, October 25) by Dr. M. Ebell:—

Ephemeris 12h. (M.T. Berlin).

1907	α (true) h. m.	δ (true)	Brightness
Nov. 4 ...	6 24·3 ...	+ 8 26·4 ...	2·7
„ 8 ...	5 29·7 ...	+15 0·5 ...	3·0
„ 12 ...	4 24·4 ...	+21 28·1 ...	2·8
„ 16 ...	3 18·3 ...	+25 51·0 ...	2·3

The brightness on October 15, magnitude 9·5, is taken as unity.

From the above it will be seen that the comet is apparently travelling rapidly through Taurus, and will pass some 4° to the north of Aldebaran on November 11. On November 15 it will be less than 1° north of the Pleiades.

The Transit of Mercury.—Astronomers who intend to observe the approaching transit of Mercury, which will take place on November 14 in accordance with the times communicated by Dr. Downing to last week's Nature, will find many interesting notes and suggestions in M. Bigourdan's articles in the *Comptes rendus* (Nos. 16 and 17) for October 14 and 21 respectively. In the former article M. Bigourdan discusses the conditions which are necessary for a transit, the results of earlier observations, and a few of the phenomena which it is advisable to observe. For example, he suggests that an attempt to repeat Langley's observation of Mercury before the first contact in 1878 might be made. In the same year Janssen, using a spectroscope, was able to see the planet projected on a bright prominence before contact with the sun's limb, but this is an unlikely observation at the coming transit, because the contacts take place near the north pole of the sun, where prominences are fewer.

In the second article M. Bigourdan deals with other points of interest, such as the exact measurement of the distances between the edge of the planet and the sun's limbs in order to determine more exactly the times of the contacts, the form of Mercury's disc as seen on the sun, and the possible observation of satellites, which, if they existed, might be seen projected on the bright solar disc; the determination of the planet's diameter and the effects of different apertures in such observations are also discussed. As Mercury will be seen on the sun's disc at midday in Europe, its exact position on the disc may be determined with meridian instruments. M. Bigourdan then discusses the previous observations of both bright and dark rings surrounding the disc of Mercury, and suggests that a spectroscopic examination might reveal special absorption lines, the existence of which would prove the reality of the annuli, and hence the existence of an atmosphere belonging to the planet. Observations of bright points and spots on the planet's disc have been frequently reported during previous transits, but the real existence of such phenomena still requires further confirmation. M. Bigourdan's second paper concludes with a discussion of the methods of observation and the class of instruments it is advisable to employ.

Changes on Saturn's Rings.—A telegram, dated October 28, transmitted by Prof. Pickering to the Kiel Centralstelle, announces that Prof. Campbell observed prominent bright knots, visible during the past week, in Saturn's rings. The knots were symmetrically placed, two being to the east and two to the west (Kiel Circular, No. 101, October 28).

A Bright Meteor.—Mr. Arthur Mee reports that a magnificent meteor was seen by observers at Cardiff and Newport on the evening of October 31. It appeared at exactly 10 o'clock, and fell leisurely from γ Cygni to a point just west of Vega. The head "opened out like a rocket," leaving a train that remained visible for several seconds. Those who saw it are not quite agreed as to the colour of the head, but all testify to its great brilliancy, though the night was by no means a dark one.

THE NEW MUNICIPAL TECHNICAL INSTITUTE, BELFAST.

The formal opening of the new Municipal Technical Institute, Belfast, on October 30, by the Lord Lieutenant of Ireland (the Earl of Aberdeen), may be said to close the first epoch in the history of technical education in that city, and, indeed, in the whole of Ireland. When it is remembered that the Agriculture and Technical Instruction (Ireland) Act became law so recently as 1899, the progress already made is most noteworthy. Within that brief period the annual enrolment of students has risen to 5000, and these are now housed in a building which in beauty of architecture and excellence of equipment may challenge comparison with anything of a similar nature in the United Kingdom.

In the year 1900 the Corporation of Belfast decided to put the Act in force, and appointed a strong committee to carry on the work. The committee chose as its chairman Alderman Sir James Henderson. A happier selection or one more fruitful of good results it is difficult to imagine. A former Dublin University man, a member of the Irish bar, a past Lord Mayor of the City, and the managing director of an old and influential newspaper (the *Belfast News-Letter*), Sir James was admirably fitted to take up the duties of pioneer of technical education in his native city and province. Operations on the site were commenced in February, 1902, but, owing to the peculiar nature of the subsoil, great care was requisite in the formation of a suitable foundation. The site itself is 240 feet by 205 feet in size, and into this area were driven 2756 piles, each 40 feet in length. The heads of these piles were connected to longitudinal timbers, and the whole bonded together in concrete. The formal laying of the foundation-stone was performed on November 24, 1902, by the Earl of Dudley, at that time Lord Lieutenant of Ireland.

A general idea of the external architectural design of the building will be readily grasped from the accompanying reproduction from a photograph; and it will be sufficient to state here that the height of the top of the surmounting balustrade above the pavement is 85 feet; to the top of the domed towers the height is 135 feet. Internally, the building surrounds two courtyards, these courtyards being lined with white glazed bricks and roofed in with glass over the ground floor. The corridors are carried round these areas, and are spacious and well lighted. The floors throughout are of steel and concrete, finished in the laboratories and class-rooms with solid wood blocks, and in the corridors and lavatories with marble terrazzo. Ample gas and water supplies are laid on everywhere, and the building is lighted throughout by electricity. Heating and ventilation are provided by the "Plenum" system. The air, after being washed and screened, enters the heating chamber, where it is passed over tempering coils, and is finally driven throughout the building by a large pair of "Ulster" centrifugal fans. The capacity of these fans is 140,000 cubic feet of air per minute. Arrangements are also made for driving these fans by electricity when heat is not required.

Coming to the question of departmental arrangement, the general idea has been to group together the work of each department in one suite of rooms. The subjects taught are grouped into departments as follows:—mathematics, mechanical engineering, naval architecture, physics and electrical engineering, building trades, textiles, pure and applied chemistry, miscellaneous industries, natural science, commerce, domestic economy, and art.

The department of mechanical engineering includes a total area of 13,000 square feet. On one floor are the lecture rooms, drawing rooms, a photo-printing room, and a mechanical laboratory in which fifty students can work at the same time. The engineering laboratory, workshops, and boiler house are on another floor. The mechanical laboratory is fitted with a large range of appliances of small type all of the newest description. The central idea in providing the equipment has been to keep the application of mechanics to engineering well to the front. A small hydraulics section is attached to this laboratory. The floor of the engineering laboratory is double, and in the intervening space are stored all shafts, belts, pipes, and also the arrangements not directly required for experimental work, thus leaving the floor clear from obstruction. Beneath the lower floor a tank of ten thousand gallons capacity has been built. A wide range of machinery has been installed. The department also comprises a machine shop and a pattern shop.

In the lecture rooms and laboratories of the department of physics and electrical engineering the machinery is of the latest type. Everything has been provided for giving a complete training, theoretical and practical, to the students.

As is to be expected in a city like Belfast, particular attention has been paid to the equipment of the department of textile manufactures, and the result has been to make the new institute almost unique in this respect. Particular emphasis has naturally been laid on the various flax products, and in this connection a very complete range of machines has been installed.

It is unnecessary to examine in detail the equipment of the remaining departments. In every case the expenditure has been equally generous, and the results equally satisfactory. Special mention may be made of the art school, which occupies the entire top storey, and now ranks as one of the best schools in the kingdom. The chemical laboratory is the largest room in the institute, and has been furnished on a complete scale.

Belfast may well be proud of its new institute. Facilities are now provided for the carrying on of the work of technical education such as cannot fail in the immediate future to have an important and beneficial influence on its trade and industries.

In connection with the opening ceremony, a "Souvenir" book has been issued. This contains a number of portraits, views of the institute, a chronological table, salient facts and statistical data, and a historical retrospect of technical instruction in Belfast, whilst the book is finely illustrated with internal and external views of the institute. The book is to be sold at 1*s.*, or by post 1*s.* 3*d.* Copies can be obtained on application to the institute.

The Municipal Technical Institute, Belfast.

LONDON DAY TRAINING COLLEGE FOR TEACHERS.

IN June, 1901, in response to urgent representations from the School Board for London and other important bodies, the late Technical Education Board of the London County Council secured the adoption of a scheme under which the Council undertook to provide and maintain a day training college for men and women teachers in close connection with the newly re-constructed University of London, and a chair of education in the University to be held by the principal of the college.

Work was commenced in October, 1902, under the direction of Prof. John Adams, and has been continued in various temporary premises until the present term, when the college entered into possession of the southern half of the fine block of buildings designed by the Council's architect (Mr. W. E. Riley) to fill a site recently cleared at the Holborn end of Southampton Row. (The northern half of this block will, when finished, be occupied by the L.C.C. Central School of Arts and Crafts.) The celebration of the entrance of the college into its permanent home was the motive of an interesting ceremony conducted by the chairman of the Council (Mr. Percy Harris) on Saturday last, when Lord Rosebery, as Chancellor of the University, formally declared the building open.

The majority of the students of the college are "recognised students" (formerly "King's scholars"), receiving a grant from the Board of Education, who have matriculated, and are thus qualified to enter one of the schools of the University for a three years' course, leading up to the degree in arts or science. Concurrently with their academic studies they take a course of professional instruction at the training college with a view to certification by the Board. In addition to these students, there is a smaller number of graduates who take a one year's course in preparation for the University's diploma in pedagogy, and intend to teach in secondary schools. Since, however, a rapidly increasing proportion of the recognised students enter with a higher qualification than matriculation, and obtain the degree before the conclusion of the three years' course, the work of the college will in a few years become very largely post-graduate, and may be expected to have an important influence upon the standard of teaching in the elementary schools of London.

Since every student is either a graduate or an internal student of the University in arts or science, the equipment of the college has been determined solely by the needs of the professional side of the course of training. Thus the laboratories, which together with the art studio occupy the top floor of the building, are used almost entirely for the demonstration of methods of teaching science subjects. The larger laboratory (55 feet by 30 feet) contains benches of a special design planned for elementary work in chemistry, physics, and mechanics, fume cupboards, a well-equipped demonstration table, and teak tables used chiefly in connection with the instruction in practical mathematics. Between the mathematical and physical benches accommodation is provided for students following the course of a lesson given to a class of children.

The smaller laboratory (30 feet by 20 feet) is devoted to nature-study. In addition to working benches, it is equipped with specimen cases, a dark cupboard, and other fittings. A balance room and a preparation room situated between the two laboratories serve the needs of both. There is also a small room (readily transformable into a photographic dark room) equipped with water, gas, and electric power, and intended to be used for anthropometric work and for researches in pedagogical psychology.

On the roof, within easy access from the laboratories, is a plant house containing a large tank for aquatic plants and animals. The level space around this is utilised as a meteorological observatory in connection with lessons in geography. Finally, on the floor below that already described, is a pedagogical museum, which performs the functions of a geographical laboratory.

Carefully planned and closely correlated courses in mathematics, geography, nature-study, and physical science are taught in these laboratories to the children of the demonstration schools by students under supervision. Most of these students either have already graduated or are about to sit for the B.Sc. degree, and are paying special attention during their last year to the teaching of the scientific subjects of the curriculum.

IMMUNITY TO DISEASE AMONG PLANTS.[1]

THE question of immunity to disease has been so closely studied and so frequently discussed in connection with the diseases of man that it seemed to me that it might be of interest to bring together some of the facts now known to us about the incidence of disease among plants and the theories which have been advanced as to the cause of the immunity which some species and varieties exhibit to various diseases.

The late Prof. Marshall Ward has shown that *Puccinia dispersa*, the brown rust of grasses, seems to exist in several "biologic forms," each of which attacks only one group of nearly related species of Bromus, and the same condition obtains in the Erisipheæ, or mildews, according to Salmon. How is it that these fungi are incapable of infecting such nearly related host plants as are represented by the species within a single genus? The suggestion was originally made that differences in the thickness of the cell walls, fewer or smaller stomata, longer hairs, &c., were the obstacles which repelled the fungi and rendered certain species and genera of plants immune to the attacks of particular fungi. Working with the different species of Brome, Marshall Ward was, however, able to show that there was no relationship between the stomata, hairs, and so forth, and the infectibility of the species. Immunity did not in any way depend upon the anatomical characters of the host plant, but entirely on physiological reactions of the protoplasm of the fungus and of the cells of the host. In other words, infection and resistance to infection depend on the power of the fungus protoplasm to overcome the resistance of the cells of the host by means of enzymes or toxins, and reciprocally on the protoplasm of the cells of the host to form anti-bodies which destroy such enzymes or toxins, just as is the case with resistance of animal organisms to their bacterial foes. Salmon has shown in his experiments that susceptibility in a leaf normally immune to the attacks of the biologic form of a particular mildew may be induced by various mechanical means, such as cutting the leaf or searing it with a red-hot point of a knife, or by exposing the leaf to ether or alcohol vapours, or by exposing it to heat. The resistant vitality is thereby impaired, and the fungus gains the upper hand. Plants, if not immune to a particular disease, may be rendered so to a certain extent by similar methods to those employed in the case of animals. More or less successful injection experiments have been made in the case of fruit trees suffering from chlorosis, and as a result animal parasites have been got rid of as well. Undoubtedly if the general vitality of the tree can be raised some diseases can be thrown off.

Marchal has stated, 1902, that young plants of the lettuce could be rendered immune against *Bremia latucae* by feeding the plants with a solution of copper sulphate (1 in 30,000). This view has received support from Laurent and Massée, but Salmon has not been able to confirm these results. It will be seen that the views are still somewhat conflicting, and too much must not be expected from such methods of treatment.

The hope of the agriculturist lies in another direction. Plants, like animals, are subject, as Darwin has shown, to a considerable amount of variation, and all characters, whether anatomical or physiological, are subject to change or mutation. Immunity to disease, dependent as it is on certain physiological peculiarities, the secretion of antitoxins, rather than on anatomical structure, is similarly a subject of variation. We see this readily illustrated when passing through a field exposed to some epidemic disease, where here and there plants are found which have been either only slightly damaged or not attacked at all. These should be selected for breeding purposes, and thus hardier varieties can be produced. Another method which has shown itself useful for producing resistant forms is by hybridising. It is a well-known fact that hybrids, while partaking of the nature of one or both of the parents in most characters, generally exceed both in vegetative vigour—a characteristic to which the sterility of some hybrids is attributed. But vegetative vigour, as we have seen above, is generally associated with immunity to disease, and hence hybrids are often found to be more resistant. This is not always the case, for in this respect hybrids vary too, but the French horticulturists MM. Bouttes and Guillon have been successful in producing hybrid vines which are more resistant to the mildew than either of the parents.

In the selection of immune varieties one is faced with the unfortunate fact that many of the most resistant forms are the least valuable, producing poorer fruits and seeds than the delicate forms. But by judicious hybridising this defect of the immune race can be largely counteracted. Mr. Lewton Brain has collected a good deal of information on this point. Both in the case of vines and in wheat many disease-resisting forms have been produced.

In connection with cotton crops, it is remarkable how great is the range of variation with regard to the resistance of the plants to the wilt disease (*Neocosmospora vasinfecta*). By selection and suitable hybridising, Rivers has been able to obtain varieties which remained untouched by the disease, while of the neighbouring crops

[1] Abridged from an address delivered at the annual meeting of the British Pharmaceutical Conference at Manchester by Prof. F. E. Weiss.

95 per cent. were destroyed. In the West Indies the Bourbon cane has been given up on account of disease, but very useful and disease-resisting hybrids have been produced by crossing the valuable but easily attacked Tjeribon cane with the resistant Indian Tschan cane.

It will thus be seen that breeders have the power by careful selection to combine disease-resisting powers with relatively great fertility, and therein lies our hope for the future success of agriculture.

THE BED OF THE WESTERN PACIFIC OCEAN.

THE results of surveys carried out by the surveying vessel *Edi* and the cable-ship *Stephan* during 1903 and 1905 in the western and south-western parts of the Pacific Ocean have been published in a paper by Drs. G. Schott and P. Perlewitz, recently issued in the *Archiv der deutschen Seewarte*. An abstract by Dr. Schott appears in the *Annalen der Hydrographie* (1907, p. 108). Taken in conjunction with the work of the American vessel *Nero* (already noticed in these columns) and of the German vessel S.M.S. *Planet* (see *Annalen der Hydrographie*, 1907, pp. 49 and 50, 193 and 194, and 196), these soundings throw a great deal of new light on the configuration of the sea bottom in those regions, disclosing certain characteristic features of great interest in their bearing on the history of the Pacific Ocean and its extension westward at the expense of the Asiatic continent, and also on the general problem of the form of the surface of the lithosphere.

The typical form may be described thus. Along a line running seaward from the coast of Asia the depth is (beyond the continental shelf) about 3000 metres; it diminishes slowly and fairly uniformly at first, then rapidly, until the surface is reached on a cross-line of islands. To seaward of the islands the bottom falls first slowly and then very steeply to a line of "deeps," in which depths of 7000 metres to 9000 metres are reached; then follows a fairly gradual rise to a "Horst" some 4000 metres below the surface. These structures, so far as appears from these observations, occur (1) in the Liu-Kiu Islands and deep; (2) in the Tulur Islands and deep; and (3) in a line following the Pelew Islands, Yap, Guam, and the eastern Ladrones. The soundings of the *Planet* show that the "Tulur" deep (2) is continuous with a long, narrow trough extending northward along the east coast of the Philippines, and it seems not unlikely that the "Liu-Kiu" deep (1) is part of the same depression. The "Guam" deep is identical with the "Caroline" deep discovered by Friederichsen in 1901.

The troughs forming the deeps are usually about ten miles wide (the Guam deep is as much as twenty miles across), and Drs. Schott and Perlewitz are of opinion that they are the result of subsidence occurring on an enormous scale along lines of fracture. It is probable that the disturbances which produced these structures are comparatively recent; geological relations suggest Tertiary times, at least in the case of the Liu-Kiu deep, and there is obviously nothing in the suggestion incompatible with the great antiquity of the Pacific basin as a whole.

HYDROLOGY IN EGYPT.

"THE Rains of the Nile Basin and the Nile Flood of 1906" is the first of a new series of periodical reports which are being published by the Survey Department of Egypt. These departmental papers are intended to comprise results of technical or scientific interest which are obtained in the course of the work of the department.

Captain H. G. Lyons, the director, says that although the increase of rainfall stations in British Central Africa, Uganda, and the Sudan has materially reduced the difficulty of forecasting the flood, the absence of any definite information as to the meteorological conditions of Abyssinia, especially during the rainy season, June to August, is a great drawback, and to overcome this somewhat he intended early in 1907 to send a qualified meteorologist to Addis Abbaba to study the local conditions.

The chapter on the normal distribution of rainfall traces the heavy rains from Zomba and British Central Africa and German East Africa in January and February to Abyssinia and the Sudan in July and August. During these two months these countries receive 60 per cent. of their annual rainfall. In September the rain begins to moderate in Abyssinia, and to retreat southwards.

In discussing the rainfall for 1906, it is shown that most places in the districts under observation had excess rain at the period of normally heavy rains, whilst in their respective dry seasons there was deficiency. In the Nile Basin the rains were somewhat late in commencing.

At the end of October, 1905, it seemed likely that during 1906 the Nile would be low, for the summer rains in Abyssinia had been weak. In November, February, and March some exceptional and heavy rains improved matters, and gave a fairly good supply of water.

At Khartoum the flood commenced on May 27, sixteen days late, and reached its maximum on September 14, ten days late. The volume of the flood estimated from the discharge curve of the Aswan gauge during July, August, September, and October was 0·87 of the mean of thirty-eight years.

During April, 1906, Mr. J. I. Craig made an investigation to determine the amount of seepage through the banks of the river. Using the records of flow at Aswan and Sarras, and special observations of flow made at Kareima, Mr. Craig came to the conclusion that at the period of low water, and on that stretch of the river between Khartoum and Sarras, a distance of 1480 kilometres, water flowed through the banks into the river at the rate of between 140 and 200 cubic metres per second. During the flood water passes out of the river similarly, for then the level of the water-table in the surrounding country is lower than the surface of the river.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Sites Syndicate has had under consideration the most suitable position for the proposed buildings in connection with the school of agriculture. It is of opinion that the most suitable position would be one on the Downing site, to the south of the botany school and parallel with it. The building on this site would be near the departments of botany and geology, and would be accessible from three roads, and it would be well lighted. At the present time the department of agriculture is housed in the basement of the chemical laboratory, but in view of the greatly increasing number of students in agriculture proper provision of laboratories, lecture-room, and museums is urgently needed. Towards the cost of an agricultural school some 13,000*l*. has already been subscribed by friends of agriculture and the University. A suitable building would probably cost some 20,000*l*., and it is further desirable that some provision should be made for maintenance.

Mr. A. E. Shipley has been nominated a manager of the Frederick James Quick fund from January 1, 1908, to December 31, 1913.

The following have been nominated examiners for the Natural Sciences Tripos in 1908:—*Physics*, Mr. J. A. McClelland and Mr. P. V. Bevan; *chemistry*, Dr. Fenton and Mr. K. J. P. Orton; *mineralogy*, Mr. A. Hutchinson and Mr. L. J. Spencer; *human anatomy*, Mr. T. Manners-Smith and Prof. R. Howden; *geology*, Mr. E. J. Garwood and Mr. W. G. Fearnsides; *botany*, Mr. F. W. Oliver and Mr. F. F. Blackman; *zoology*, Dr. Harmer and Mr. R. C. Punnett; *physiology*, Mr. F. G. Hopkins and Dr. M. S. Pembrey.

OXFORD.—The preamble of a statute establishing a professorship of engineering science was passed by Congregation on October 29 by a majority of 152 to 20.

The Burdett-Coutts scholarship in geology has been awarded to R. L. Robinson, Magdalen College; C. H. Dinham, Magdalen College, distinguished himself in the examination.

LORD AVEBURY has been elected without opposition Lord Rector of the University of St. Andrews.

ACCORDING to the *Pioneer Mail*, one lakh of rupees has been added to the Griffith bequest to found a university library attached to the Madras University, and another sum of sixty thousand rupees for university lectureships and research scholarships.

AT a recent meeting of the Senate of the University of London, the following resolution was unanimously adopted:—"That the Senate have received with sincere regret the announcement by Sir Arthur Rücker that he wishes to relinquish office on September 30, 1908, and record their appreciation of the great services he has loyally rendered to the University as principal since its reconstitution."

THE graduate school of applied science at Harvard University recently received the gift of about 2000 acres of valuable timber land as a special adjunct to its instruction in forestry. According to Prof. R. T. Fisher, the forest included in this gift comprises the best body of timber now to be found on an equal area in Massachusetts. Its special advantage is in the arrangement of the age-groups or generations of timber. It so happens that stands of various ages, from the small sapling to the mature tree, are almost equally represented in separate sections of the forest.

THE annual prize distribution and conversazione of the Northampton Polytechnic Institute, Clerkenwell, E.C., will be held on Friday and Saturday, November 29 and 30. The Duke of Connaught has consented to distribute the prizes on November 29, and after the prize distribution the whole of the laboratories, workshops, drawing office, and studios of the institute, both in the main building and in the British Horological Institute adjoining (the technical optics department), will be on view in working order. The conversazione of members and students will be held on the following evening.

THE Board of Education, South Kensington, has issued the following list of candidates successful in this year's competition for the Whitworth scholarships and exhibitions:—(1) Scholarships, 125*l*. a year each, tenable for three years: A. A. Rowse, London; N. J. Perryman, Portsmouth; G. Hudson, Portsmouth; J. Warren, Portsmouth. (2) Exhibitions, 50*l*. a year each, tenable for one year: A. W. Judge, Portsmouth; J. H. Hyde, Leytonstone; E. A. Steed, Devonport; A. J. Begg, Plumstead; M. R. Dewhurst, London; R. D. Given, Edinburgh; F. A. Bumpus, Birmingham; R. J. Iliffe, Liverpool; S. L. Symns, London; F. Morris, Portsmouth; W. P. Johnson, Kelsall Hill, Chester; T. W. Johnstone, Neyland; J. H. Neal, Devonport; H. Mawson, Hunslet, Leeds; E. W. Stedman, Sheerness; F. Morrison, Aberdeen; R. G. Milner, Plumstead; A. Hutchison, Glasgow; H. J. Middleton, Forest Gate; A. T. Phillips, Barking, Essex; W. Macgregor, Greenock; M. J. C. McCarthy, Sheerness; H. T. Wright, London; A. McFadyen, Lasswade, Midlothian; F. G. Rendell, Portsmouth; J. H. Blight, Devonport; F. C. D. Mann, Hayes, Kent; J. E. Collyer, South Woolwich; B. Baker, Southsea; L. C. Brown, Wolverton.

MR. ASQUITH, Chancellor of the Exchequer, visited Aberystwyth on November 1 to open the Edward Davies chemical laboratories, the gift of Mr. David Davies, M.P., and his mother and sisters, to the University College of Wales, Aberystwyth. The new buildings have been erected at a cost of 25,000*l*. In the course of a speech at a great public meeting held subsequently, Mr. Asquith said Aberystwyth has owed little, at all events, until that day to the munificence of the man of wealth, and there are very few other institutions, either in England or in Wales, of which it can be said that it was brought into being and that for many years it was kept in being by the pence of the Welsh people. There are few more interesting or encouraging chapters in the history of democracy than that which recounts what in our time the Welsh people has done for education. In the course of thirty years something very near 120,000*l*. has been subscribed for the purposes of the college, Aberystwyth, and the remarkable feature is that it has been subscribed by 100,000 separate donors. The figures no doubt are equally striking at Bangor and Cardiff. The university system in Wales has been undertaken by the people for the people. During the same period there has been voluntarily subscribed to set on foot a system of intermediate schools something approaching the same sum—80,000*l*. to 100,000*l*. There is still much work to be done, many gaps to be filled; but the Welsh people formed their intermediate system first of all, and now, by the founding of their university colleges, any Welsh child of brains, zeal, and good character, whatever the social surroundings of its parentage, can climb without undue favour or assistance to the very highest position in the pursuits of industry or commerce.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 27.—"Note on the Use of the Radiometer in observing Small Gas Pressures; Application to the Detection of the Gaseous Products produced by Radioactive Bodies." By Sir James **Dewar**, F.R.S.

The experiments described in this paper seem to show that the radiometer may be used as an efficient instrument of research for the detection of small gas pressures and the study of radio-active products. For quantitative measurements the torsion balance or bifilar suspension must be employed. It would be interesting to repeat light repulsion experiments in the highest attainable charcoal vacuum. The author hopes to extend the investigation later.

Entomological Society, October 16.—Mr. C. O. Waterhouse, president, in the chair.—*Exhibits*.—A. H. **Jones**: A series of *Pieris napi*, var. *bryoniae*, from comparatively low altitudes near Budapest, showing a wide range of variation, and a remarkable aberration of *P. napi* (*napaeae*) bearing a strong resemblance on the underside to *P. rapae*.—M. **Burr**: An example of *Apterygida albipennis*, discovered by him near Dover this year; and a ♂ specimen of *D. verrucovirus*, an inhabitant of Scandinavia, from the same locality.—H. **Campion**: *Platycleis roeselii*, Hagenb., ♀, taken September 13 near Herne Bay, of which there are but few well-authenticated British specimens.—E. W. **Campion**: An aberrant specimen of *S. sanguineum*, ♂, from Epping Forest, suggesting relationship with certain Orthoptera, and two *Calopteryx virgo* of his own from the New Forest showing failure in pigment.—W. J. **Kaye**: Specimens of *Callicore aurelia*, Guen., together with a photograph of its larva, showing the remarkable branch-like horns rising out of the head.—Rev. F. D. **Morice**: A normal ♂ specimen of the bee *Anthidium manicatum*, L. (the "hoop-shaver bee" of Gilbert White's "Natural History of Selborne"), and a monstrosity or malformation of the same insect from Argentat, Corrèze, France.—C. O. **Waterhouse**: (1) A living ant, a species of Camponotus, found by Mr. Watson at Kew, in the pseudobulb of an orchis (probably a Bulbophyllum) from the Gold Coast. The bulb was much excavated, but it had no opening by which the ant could have entered; (2) a large wasp (a Salius allied to *dedjax*) with a spider, a Mygale rather larger than itself, but which it had captured and was carrying off.—Lieut.-Colonel Neville **Manders**: A melanic variety of *Hestina nama*, captured near Darjeeling, and a monstrosity of *Papilio krishna*, from Sikkim, in which the wings on the right side were much larger than those on the left.—H. **Main**: The larva of a hymenopterous parasite of *Pygaera bucephala*, of great size comparatively to its host.

Institution of Mining and Metallurgy, October 17.—Prof. William Gowland, president, in the chair.—The origin of the gold in the Rand banket: Prof. J. W. **Gregory**. A carefully reasoned argument in favour of the marine placer theory, as opposed to the infiltration theory. The author quoted the leading authorities both for and against his own conclusions, which are based on a personal visit to the Rand and a subsequent weighing of all available evidence. After a brief historical introduction, the paper was subdivided under the following heads:—theories of the genesis of the Rand gold; the rocks of the Rand goldfield; the arguments against the placer theory; evidence against the infiltration theory; evidence of the microscopic structure of the rocks; comparison with other goldfields; economic bearing of the problem; and, finally, summary of conclusions. The author stated that in his opinion the theory as to the origin of the banket in best agreement with the facts appeared to be that which regarded the banket as a marine placer in which gold and black sand (magnetite with some titaniferous iron) were laid down in a series of shore deposits. Owing to the late hour at which the discussion on this paper terminated, the other paper on the evening's agenda, the deviation of Rand boreholes from the vertical, by Mr. Joseph Kitchin, was held over for discussion at the meeting on November 21.

MANCHESTER.

Literary and Philosophical Society, October 1.—Prof. H. B. Dixon, F.R.S., president, in the chair.—The president delivered an inaugural address, in which he referred shortly to the work on radio-activity, with which is intimately associated the name of Prof. E. Rutherford; the work of Messrs. Barlow and Pope, by which the valency of the chemical atom has been connected in a definite manner with its volume in crystalline structures; the researches of Prof. Perkin on the formation and stability of various carbon rings, more particularly his work on the camphor and terpene series, and at somewhat greater length on the work in which he was most interested personally—the propagation of the explosion wave in gases, the direct determination of the specific heat of CO_2, the temperature of the ignition points of gases, and the re-determination of the atomic weight of chlorine.

October 15.—Prof. H. B. Dixon, F.R.S., president, in the chair.—The relation between the crystalline form and the chemical constitution of simple inorganic substances: Prof. W. J. **Pope** and W. **Barlow**. The authors have applied the methods employed in their paper of October 16, 1906, to the study of the crystalline structure and molecular condition of a number of simple inorganic substances, such as the crystalline elements, binary compounds like silver iodide, potassium chloride, &c., ammonium halogen salts and compounds of the type of rubidium tri-iodide, RbI_3.

PARIS.

Academy of Sciences, October 28.—M. H. Becquerel in the chair.—The disease of the pine in the Jura: MM. **Prillieux** and **Maublanc**. The disease of the pines in the Jura, recently pointed out by M. Bouvier and called by him *rouge*, has been studied in Germany by Hartig, who has shown that the disease is due to the attack of a parasitic fungus, *Phoma abietina*. The same fungus, for which the authors prefer the name *Fusicoccum abietinum*, attacks the pines in the Vosges and the Jura. The disease is not so grave as has been supposed by M. Bouvier, as the trees are rarely killed by it, certain of the branches only being attacked. The rational treatment is the removal of the dead branches and their destruction by incineration; in this way the fructification of the fungus and the dissemination of its spores are avoided; but this treatment may be too costly, and not justified by the actual losses threatened.—The heat of formation of the oxides of lithium: M. **de Forcrand**. A criticism of the data put forward by various authors for the heat of formation of Li_2O, together with experimental data for the heat of formation of LiOH and Li_2O_2.—Observations of the comet 1907*e* (Mellish) made at the Observatory of Besançon with the bent equatorial: P. **Chofardet**. Apparent positions of the comet, and position of the comparison star for the night of October 17. The comet was of the ninth magnitude, of circular form, without a distinct nucleus. Total diameter about 2'.—Observations of the comet 1907*e* made at the Observatory of Algiers with the 31·8 cm. bent equatorial: MM. **Sy** and **Villatte**. Similar sets of observations for October 18 and 20.—Critical transcendental points and inverse functions of integral functions: Pierre **Boutroux**.—Contribution to the synthesis of precious stones of the family of the aluminides: F. **Bordas** (see p. 17).—A new quantitative measuring instrument for the X-rays: H. **Guilleminot**.—Some iodomercurates: A. **Duboin**. The following double iodides have been isolated in a crystalline form and analysed:—

$FeI_2,2HgI_2,6H_2O$; $HgO,2AlI_3,3HgI_2,15H_2O$; and $2AlI_3,5AgI,2AgO,13H_2O$.

—A new method of determining the atomic weights of precision simultaneously for all the elements present in a single chemical reaction: G. D. **Hinrichs**. The author describes a graphical method of reduction to the experimental data for silver, chlorine, thallium, nitrogen, oxygen, and radium, with the result that all the atomic weights are reduced to multiples of 0·5.—A colloidal solution of arsenic: V. **Auger**. A hydrochloric acid solution of arsenious anhydride reduced by hypophosphorous acid at a low temperature in presence of a large amount of alcohol gives a reddish-brown powder, consisting of metallic arsenic, 68·2 per cent.; phosphorus, 0·97 per cent.; alcohol, 2·5 per cent.; and water, 28·4 per cent. This form of arsenic possesses the property of dissolving immediately in a dilute solution of caustic soda, giving a brown colloidal solution, the properties of which are given in detail.—Some causes of error in the estimation of phosphorus in iron, cast iron, and steel: G. **Chesneau**.—The formation of liquid crystals of two new compounds of cholesterin: Paul **Gaubert**. The two compounds are obtained by heating cholesterol with glycollic acid or with glycerol.—The disease of the pine in the forests of the Jura: E. **Henry**. This disease was first observed in the summer of 1906, and up to the present has not caused the death of a single tree.—A new method of reaction of the skin to tuberculosis, and its utilisation in the diagnosis of tuberculosis: J. **Lignières**. A development of the Pirket reaction in which the tuberculin may be replaced by dead tubercle bacilli. The skin need not be broken, as it is sufficient to rub the dead bacilli or pure tuberculin in until the skin is well reddened. Healthy animals give no specific reaction but with tuberculous animals there is a well-marked reaction.—The explanation of the general mechanism of the transformation of glycogen into glucose by the muscles and the animal tissues: F. **Maignon**. The author concludes from his experiments that the muscles possess an amylase capable of effecting the transformation of glycogen into glucose.—The transparency and colour of sea water in the English Channel: M. **Letalle**.

NEW SOUTH WALES.

Royal Society, August 7.—Mr. H. A. Lenehan, vice-president, in the chair.—Note on copper in andesite from near Lautoka, Fiji: H. I. **Jensen**. This paper describes the occurrence of lumps of copper ore weighing from 1 lb. in andesitic matrix. An analysis of a specimen showed that it contained $53\frac{1}{2}$ per cent. Cu, $7\frac{3}{4}$ per cent. Fe, and $21\frac{1}{2}$ per cent. S, the metallic portion being therefore a mixture of bornite and chalcocite. A microscopic examination confirmed the presence of these two minerals. The same minerals were found to occur in many of the normal andesites of the district in smaller quantity. A quantitative estimation revealed 0·034 per cent. of CuO in the normal andesite. It appears from the examination of specimens obtained that either copper ore has segregated out in the consolidation of the lava, or else, in the period of consolidation, magmatic vapours have extracted the copper from portions of the lava and deposited it elsewhere in the mass. The copper distinctly belongs to the andesite magma of the district, and does not constitute a mere xenogenic included product. It is interesting to note that such a differentiation has there taken place in a true volcanic rock.—Analysis of a specimen of sea-water from Coogee, New South Wales: C. J. **White**. Special attention was paid to the specific gravity determinations (for the calculation of which Buchanan's hydrometer No. 6 was used), for this gives the salinity directly, and indirectly gives very valuable indications of the various constituents present (the ratio of dissolved salts to one another being practically constant for all ocean waters).—Notes on some aboriginal tribes: R. H. **Mathews**.—Note on the action of lime on the available soil constituents: F. B. **Guthrie** and L. **Cohen**. The authors have investigated the changes that take place in the amounts of water-soluble and citric-soluble potash and phosphoric acid in limed soils in pots. Three kinds of soil were used, sand, garden loam, and clay. They find that in all cases the amount of mineral plant-food soluble in water had diminished to a considerable extent in the unlimed pots after standing for a month. The effect of liming has been to lessen this loss, but it does not appear to prevent it entirely. There is less water-soluble plant-food in the limed soils after a month than in the original soils, but more than in the untreated soils after a month. The action of lime is largely to increase the amount of nitrogen as nitrites; the nitrate-nitrogen is almost the same in the limed and the unlimed soils, except with the clay soil, where the nitrates are diminished. The total nitrogen as nitrite and nitrate is increased by liming, and the action of lime would appear to be to favour the development of the nitrous organism in particular.

September 4.—Mr. H. A. Lenehan, vice-president, in the chair.—The one-wheeled car: L. **Hargrave**. The paper points out the adaptability of the gyro-engine, a combination of the gyroscope and revolving cylinder engine, for balancing and driving all sorts of vehicles on one wheel over country that would otherwise be impracticable.—The steady deflection method of current measurement with an electrometer: Prof. J. A. **Pollock**. The steady deflection method of measuring currents with an electrometer consists in arranging that the charge on the ordinarily insulated quadrants shall leak to earth at a suitable rate proportional to the potential difference between the two pairs of quadrants. In the paper two ways which have been proposed for carrying out the method are mentioned and discussed.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 7.

ROYAL SOCIETY, at 4.30—The Effect of Pressure upon the Arc Spectra of Metals: W. Geoffrey Duffield.—The Electric Discharge in Monatomic Gases: F. Soddy and T. D. Mackenzie.—The Diurnal Variation of Terrestrial Magnetism: Prof. A. Schuster, F.R.S.—On the Measurement of Temperatures in the Cylinder of a Gas Engine: Prof. H. L. Callendar, F.R.S., and Prof. W. E. Dalby.—Note on the Association of Helium and Thorium in Minerals: Hon. R. J. Strutt, F.R.S.—Further Results of the Experimental Treatment of Trypanosomiasis in Rats (Progress Report of Sleeping Sickness Committee of the Royal Society): H. G. Plimmer and J. D. Thomson.

RÖNTGEN SOCIETY, at 8.15.—The Presidential Address, The Production of High Frequency Oscillations, with Demonstrations: W. Duddell, F.R.S.

LINNEAN SOCIETY, at 8.—The Origin of the Di-trimerous Whorls among Flowers of Dicotyledons: Rev. George Henslow.—Unrecorded Acari from New Zealand: Albert D. Michael.—On *Ænigmatistes africanus*, a new Genus and Species of Diptera: R. Shelford.—*Exhibits*:—A copy of Hudson's "Flora Anglica" 1778, with numerous annotations by the Rev. William Kirby: Alexander Stevenson.—Abnormal Stem of *Eucalyptus salmonophloia*, F. Muell., from West Australia: Dr. A. B. Rendle.

CHEMICAL SOCIETY, at 8.30.—Gaseous Nitrogen Trioxide: H. B. Baker and Mrs. M. Baker.—The Atomic Weight of Tellurium: H. B. Baker and A. H. Bennett.—The Isomerism of the Double Sulphites of Sodium and Potassium: M. H. Godby.—Studies in the Camphane Series, Part xxiv, Camphoryldithiocarbamic Acid and Camphorylthiocarbimide: M. O. Forster and T. Jackson.—The Vapour Pressures of Triethylamine, of *sym*-Trimethylpyridine, and their Mixtures with Water: R. T. Lattey.—Liquid Triethylamine: R. T. Lattey.—The Action of Sulphuretted Hydrogen on Solutions of Sodium Hydrosulphite: F. S. Sinnatt.—The Alkyl Compounds of Gold. Diethylauric Bromide. Preliminary Note: W. J. Pope and C. S. Gibson.—Note on the Constitution of Homoeriodictyol: F. B. Power and F. Tutin.—The Interaction of Methylene Chloride and the Sodium Derivative of Ethyl Malonate: F. Tutin.—Preparation of Aliphatic Nitro-compounds by the Interaction of the Alkyl Iodides and Mercurous Nitrite: P. C. Rây and P. Neogi.—Some Mercury Derivatives of Camphor: J. E. Marsh and R. de J. F. Struthers.—Contribution to the Chemistry of the Terpenes. II. The Oxidation of Limonene with Chromylchloride: G. G. Henderson.—The Synthesis of Acridines and Phenonaphthacridines: Tetra- and Hexa-methylacridines: Dimethylphenonaphthacridines: Dixylylmethylenediamines: A. Senier and A. Compton.

FRIDAY, NOVEMBER 8.

ROYAL ASTRONOMICAL SOCIETY, at 5.—The Nebula H iv. 74 Cygni: Max Wolf.—Note on the Permanency of Some Photo-visual Lenses: W. J. S. Lockyer.—Occultation of the Hyades: Walter Heath.—Disappearance of Saturn's Ring System, 1907 October: R. T. A. Innes.—(1) The Ultraviolet Region in Sun-spot Spectra; (2) The Spectrum of Comet *d* 1907 (Daniel): J. Evershed.—Tables for computing Standard Coordinates on Photographic Plates: A. R. Hinks.

MALACOLOGICAL SOCIETY, at 8.—Description of a New Species of Clathurella, probably from Ceylon: H. B. Preston.—On the Mollusca of Birket-el-Qurun, Egypt: C. A. Smith.—*Turbo granoliratus* (New Guinea); *Sistrum chrysalis, Purpura bougei, Natica bougei* (New Caledonia); *Urosalpinx walkeri, Listra walkeri* (N. W. Australia); *Amalthea coxi* (Port Stephens); *Pitaria elata* (Sierra Leone); all new species: G. B. Sowerby.—Note on the Originals of the Illustrations for E. M. da Costa's "Historia Naturalis Testaceorum Britanniæ," London, 1778: Alex. Reynell.

PHYSICAL SOCIETY, at 8.—Discussion on Mr. Campbell's Paper on the use of Variable Mutual Inductances.—A Graphic Method for Stream-lines and Equipotential Surfaces: L. F. Richardson.—On the Lateral Vibrations of Bars Supported at two Points with one end Overhanging: Dr. J. Morrow.

MONDAY, NOVEMBER 11.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Great Douglas Glacier of New Zealand and its Neighbourhood: J. Mackintosh Bell.

TUESDAY, NOVEMBER 12.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Extension, Widening and Strengthening of Folkestone Pier: H. T. Ker.—The Tranmere Bay Development-Works: S. H. Ellis.

ZOOLOGICAL SOCIETY, at 8.30.—On the Scales of Fish: E. S. Goodrich, F.R.S.—The Rudd Exploration of South Africa. VIII., List of Mammals obtained by Mr. Grant at Beira: Oldfield Thomas, F.R.S., and R. C. Wroughton.—Notes on two African Mammals: R. Lydekker, F.R.S.—Notes on the Feeding of Serpents in Captivity: Dr. P. Chalmers Mitchell, F.R.S., and R. I. Pocock.—Descriptions of new Loricariid Fishes from South America: C. Tate Regan.—Notes on Mayer's Pigeon: Lt.-Col. N. Manders.—On some Points in the Structure of *Galidictis striata*: F. E. Beddard, F.R.S.

SOCIOLOGICAL SOCIETY, at 8.—The Genealogical Method in Anthropological Inquiry: Dr. W. H. R. Rivers.

MINERALOGICAL SOCIETY, at 8.—Anniversary meeting.—On Hopeite and other Zinc Phosphates and Associated Minerals from Rhodesia, Broken Hill Mines: L. J. Spencer.—Notes on Zeolites from Cornwall and Devon: A. Russell.—The Question of a Relation between Isomorphous Miscibility and Parallel Growth of Crystals: T. V. Barker.—On Binnite, Anatase, Brookite and Molybdenite from the Binnenthal: R. H. Solly.—Note on the Crystallisation of Potassium Bichromate: H. A. Miers.

THURSDAY, NOVEMBER 14.

ROYAL SOCIETY, at 4.30.—*Probable Papers*:—On the Cranial and Facial Characters of the Neandertbal Race: Prof. W. J. Sollas, F.R.S.—Some Features in the Hereditary Transmission of the Self-Black and the "Irish" Coat Characters in Rats: G. P. Mudge.—On the Inheritance of Eye-colour in Man: C. C. Hurst.—On the Result of Crossing Round with Wrinkled Peas, with Special Reference to their Starch Grains: A. D. Darbishire.—On the Rate of the Elimination of Chloroform from the Blood after Anæsthesia: G. A. Buckmaster and J. A. Gardner.—Implantation of Actively Proliferating Epithelium: J. O. Wakelin-Barratt.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Dielectric Strength of Insulating Materials and the Grading of Cables: Alexander Russell.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—Election of Council and Officers.—On Hypercomplex Numbers: J. H. Maclagan Wedderburn.—Addendum to a Paper on the Inversion of a Repeated Infinite Integral: T. J. I'A. Bromwich.—Generalisation of a Theorem in the Theory of Divergent Series: G. H. Hardy.—Uniform and Non-uniform Convergence and Divergence of a Series and the Distinction between Right and Left: Dr. W. H. Young.—Application of Quaternions to the Problem of the Infinitesimal Deformation of a Surface: J. E. Campbell.—Nodal Cubics through Eight given Points: J. E. Wright.—The Invariants of a Binary Quintic and the Reality of its Roots: Dr. H. F. Baker.—On a Transformation of Hypergeometric Series: Rev. Dr. E. W. Barnes.—On a Transformation of a Certain Hypergeometric Series: Prof. M. J. M. Hill.—A General Theorem on Integral Functions of Order less than One-half: J. E. Littlewood.

FRIDAY, NOVEMBER 15.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Labour-saving Appliances at the Mines of the New Kleinfontein Co., Transvaal: E. J. Way.

CONTENTS.

PAGE

THURSDAY, NOVEMBER 14, 1907.

A NEW HANDBOOK OF INORGANIC CHEMISTRY.

Handbuch der anorganischen Chemie. Herausgegeben von Dr. R. Abegg. Band ii., Abt. ii. Pp. ix+700. Price 24 marks. Band iii., Abt. i. Pp. x+466. Price 17 marks. Abt. iii. Pp. xiv+876. Price 24 marks. (Leipzig: R. Hirzel, 1905–7.)

A HEARTY welcome may be extended to this valuable work of reference, which does for inorganic chemistry much more than Beilstein's famous handbook has done for organic chemistry. It is no mere guide to the recognition and characterisation of the compounds with which it deals. Its aim is beyond this, and its scope is more general. In a word, the editor endeavours to make use of the vast accumulation of physico-chemical data of the past twenty years, and to incorporate them in the descriptive portion of the work, exercising a critical selection of the material employed and giving at the same time due consideration to theoretical connections and outstanding problems. The periodic system has been adopted as the basis of classification, and the portions of the work already issued deal with the elements of the second, third, and fifth periodic groups respectively. Here it may not be out of place to protest against an aggravating instance of the Teutonic passion for subdivision. The work is to be issued in eight separately paged and indexed volumes, dealing with the eight periodic groups, together with a ninth volume of a general character. One might, therefore, reasonably expect that the numbers of the volumes would correspond to the group numbers of the elements described. Instead of this, we find the elements of the fifth group described in vol. iii., section iii., those of the fourth group presumably in vol. iii., section ii., and so on. Whether the elements of group 6 will be found in vol. iii., section iv., or in vol. iv., section i., remains for the present a subject of agreeable speculation.

Prof. Abegg, in carrying out his scheme, has secured the collaboration of many eminent workers in the domains of inorganic and physical chemistry. Amongst those who contribute to the volumes before us we may mention Marckwald (radium), R. J. Meyer (rare earths), Schenck (phosphorus subgroup), Brauner (atomic weights), and Rohland (technological subjects, *e.g.* mortar, ultramarine).

The account of the metals of the rare earths and their compounds deserves special mention. The subject is introduced by a general section of nearly fifty pages, in which we are presented with a historical survey, an account of the mode of occurrence and general chemical characteristics of the group, an outline of the methods of extraction and separation of the earths, and a discussion of the valency and atomic weights of the elements. Then follows in detail the subgroup of the cerite earths, with a special account of the separation and purification of lanthanum, praseodymium, neodymium, and samarium. The second subgroup is that of the terbium elements, and the third deals with those of the erbium and yttrium families.

Another noteworthy feature of the work is the treatment of the atomic weights of all the elements by the same hand. Prof. Brauner has accomplished his task admirably. He takes Clarke's "Recalculation of the Atomic Weights" as the source of data up to 1896, and thereafter refers to the original papers, using the reports of the International Commission as a guide. Little is said of the older and less exact determinations, but the more modern work is given in considerable detail, and critically discussed in its relationship, not only to the atomic weight of the element directly concerned, but to that of other elements which may be involved in the actual experiments. To give an idea of the scale on which Prof. Brauner has written, it may be stated that the atomic weight of beryllium occupies five and a half pages, and that of nitrogen no less than thirty-two pages. The author freely criticises the tables of the International Commission in the course of his articles, pointing out, for example, that if $N = 14{\cdot}01$ is correct, which he believes to be the case, then Ag cannot be 107·93 as given in the international table, but must lie between 107·88 and 107·89.

Prof. Abegg's "Handbuch" is admirably printed and got up, and must in future form an indispensable item in every properly equipped chemical library.

ITALIAN BIRDS AND NEOGENESIS.

Avifauna Italica. By Enrico Hillyer Giglioli. Secondo resoconto. Pp. xxiv+784. (Firenze: Coi. Tipi dello Stab. Tipografico s. Giuseppe, 1907.)

ITALIAN ornithologists in particular, and students of palæarctic birds in general, will be grateful to Prof. Giglioli for this revised edition of his most valuable work. Herein he now recognises 496 species as entitled to the rank of Italian birds; but this includes species which have only once been obtained within this area, and at least two which many ornithologists will refuse to regard as species at all.

These two exceptions are of more than passing interest, inasmuch as Prof. Giglioli contends that they furnish good examples of "neogenesis": of the birth of new species *per saltum.*

The first of these two cases is that of a redstart obtained by Prof. Giglioli from Sardinia. On data which can only be described as unsatisfactory, the author elects to create a new species—*Ruticilla nigra*—though most of us, on the same evidence, would agree that the examples on which this new species was based were but melanistic specimens of *Ruticilla titys,* the common black redstart. This view he rejects, contending that his own hypothesis is the more reasonable.

Far more importance is to be attached to the second case, which Prof. Giglioli describes at some length, not only in the pages of this work, but also in the

C

Ibis, 1903. Briefly, this concerns an owl which the author then described as a new species—*Athene chiaradia*; in the volume now before us it is accorded still the rank of a species. Though it is scarcely to be expected that ornithologists will recognise this bird as entitled to specific rank, the history which Prof. Giglioli gives of its discovery will never lose its interest.

Within the space at our disposal, it would be impossible to tell the whole story of this most remarkable case. Suffice it to say that the bird upon which Prof. Giglioli founded his new species was a nestling taken from a nest at Pizzocco, in the province of Udine. Though obviously nearly related to the little owl (*Athene noctua*), it differed therefrom, among other things, in having a dark brown instead of a golden-yellow iris—a rather remarkable fact. Naturally, the author at once instituted a search for further examples from this neighbourhood, and two years later this search was rewarded by the discovery of a nest—in close proximity to that from which the original specimen was obtained—containing four nestlings. One of these, be it noted, was a typical *Athene chiaradiae,* while the remaining nestlings were as typically examples of the little owl (*Athene noctua*)! Two other nests containing both dark and yellow-eyed young were later found, and finally a nest with both types of young, together with the parents, was taken. Though these parents were undoubtedly "little owls," they were both somewhat abnormal specimens, both in the matter of size and coloration.

It is to be deplored that no attempt whatever was made to induce any of these birds to breed in confinement; or that the parents were not allowed their freedom in the hope that they might at least go on perpetuating these strange aberrations. Instead, every single bird was killed to furnish specimens for the natural history museum at Florence. Thereby some extremely valuable facts were lost to science for ever! Had Prof. Giglioli endeavoured to breed these birds in confinement, he might have succeeded in establishing his hypothesis of "neogenesis." As it is, both this and the two new species which he founds thereon must be put back to await further evidence.

Though in some matters we may not agree with Prof. Giglioli, we have said enough, perhaps, to show that his book is by no means a dull catalogue of the birds of Italy. W. P. P.

PHYSIOLOGY OF ALIMENTATION.

The Physiology of Alimentation. By Prof. Martin H. Fischer. Pp. viii+348. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1907.) Price 8*s.* 6*d.* net.

THIS is a small but comprehensive account of modern physiological ideas concerning the important subjects of digestion and absorption. The work of physiologists on these questions has of recent years been both laborious and fruitful. Pawlow has devised new methods of examining the secretions and the course of their action on the food-stuffs. The epoch-making work of Emil Fischer has thrown new light on their composition, especially in the case of the proteins. The doctrine that enzymes are catalytic agents has taken firm root. The importance of the chemical stimuli to secretion (secretin and other hormones) has been demonstrated by Starling and Bayliss. The sequence of events in the journey along the alimentary tube has been accurately followed by Cannon's shadow photographs. All these points, and many others, are clearly treated by Prof. Martin Fischer in the very useful little book he has published.

The introduction of new names for the enzymes so long familiar as pepsin, trypsin, rennet, and the like, will, it is to be feared, introduce confusion to the student's mind, although the new nomenclature aims at uniformity. It is interesting, no doubt, to see the actual shadow photographs which Cannon took, but they do not lend themselves well to reproduction, and more diagrammatic pictures would have been instructive.

In a few cases the information given is not up-to-date, or is open to question. For instance, Pawlow's results on the stimulation of the nerves of the pancreas require revision in the light of the discovery of secretin. These results are given in full, and a few pages later Starling's discovery of the pancreatic hormone is described, but no attempt is made to correlate the two, nor is any guidance given to the reader in estimating their relative value.

Again, Weinland's ideas on the "adaptation" of the pancreas are quoted with apparent approval, and the confirmation of his views is wrongly attributed to Vernon. No mention, however, is made of the important work of Plimmer, who has conclusively shown that Weinland's results rest on imperfect methods, and that in the cases investigated no adaptation is discoverable.

The distinction between casein and caseinogen is mentioned, but the former is stated to be produced from the latter by the addition of acid, as well as by the action of caseinase or rennet. This view is justifiable if, as some have recently asserted, the difference between the two proteins is one of state of aggregation only, and not a true chemical difference. But before adopting such a view it is necessary to dispose of all the work which tends in the opposite direction, and to explain how it is the two substances differ in elementary composition.

Prof. Fischer assigns the place of protein synthesis in the body mainly to the absorptive epithelium of the intestine, and quotes Abderhalden as holding the same view. No mention, however, is made of the work of others (*e.g.* Leathes, Howell, and Schryver), which appears to prove that there is no such special seat of synthesis in the wall of the alimentary tract. There are just a few points where adverse criticism appears to be necessary; there always will be differences of opinion between those who interpret the facts of life. Taken as a whole, the book is not only lucid, but correct and instructive.

W. D. H.

SCHOOL ARITHMETIC.

(1) *Arithmetic for Schools.* By the Rev. J. B. Lock. New edition, revised and enlarged with the assistance of V. M. Turnbull. Pp. vii+480. (London: Macmillan and Co., Ltd., 1907.) Price 4*s*. 6*d*.

(2) *Arithmetic, chiefly Examples.* By G. W. Palmer. Pp. x+339+xlii. (London: Macmillan and Co., Ltd., 1907.) Price 3*s*. 6*d*.

(3) *A Modern Arithmetic, with Graphic and Practical Exercises.* By H. Sydney Jones. Part i. Pp. xii+361. (London: Macmillan and Co., Ltd., 1907.) Price 3*s*.

WE are generally accustomed to consider that the teaching of arithmetic has gained its prominent place in all modern educational systems for two reasons, viz., on account of (1) its utilitarian value, and (2) its culture value. The writer of a general text-book on arithmetic, as well as the teacher of arithmetic, should have both these ideas prominently before him, and so far as either of them fails to consider the subject from these two points of view, so far does he fail in its presentation. A little consideration shows that at different points in the study of the subject the relative importance of the two reasons for teaching it varies considerably; but generally, its utility must give way to the culture training.

Until within the last twenty years the tendency of all works on arithmetic was to build up a system which paid no attention to either reason, but treated the subject more as a series of detached methods—the more mechanical the better—of solving problems set by the author, by the teacher, or by the examiner. We had, in fact, a period which reminds us of the paid problem-solvers of the fifteenth century. Since then we have had two parallel movements of reform in arithmetical teaching. The first was chiefly confined to the public elementary schools, where the culture value was considered as the only value. Arithmetic was to be treated as a "series of problems," and inspectors, examiners and teachers went problem-mad. The other movement was found at its height in the evening continuation schools and in the technical schools. In that case, all teaching of arithmetic was considered of importance as it bore on the daily life of the pupils. Fortunately, we now see signs of a combination of these two movements, and provided their relative importance is correctly gauged, the results from the teaching of arithmetic will show a corresponding improvement.

It is interesting to note that each of the three books under review claims to have treated the subject from both points of view, and they all show traces of the two movements referred to above. At the same time they all reveal and will help to promote a weakness in the teaching of arithmetic in the preparatory schools and in the secondary schools. In the public elementary schools of the country the arithmetical education of the pupils until about the age of seven consists of a thorough knowledge of the numbers 1 to 10. This includes the complete analysis and synthesis of each number. Succeeding years are taken up with the extension of these principles to 20, and to 100, and this is followed by the four rules. Such work is also taken up in certain preparatory schools. These books seem to be intended for secondary schools, *i.e.* for pupils from the age of 12 and upwards, and yet they take up the four simple rules. The only satisfactory reason for doing so would be a more rigid and scientific treatment of the subject, with full details as to the development of the processes used. None of the books can be considered satisfactory in this respect, though both Mr. Jones's and Messrs. Lock and Turnbull's books show an advance on previous text-books. It would seem, therefore, that the authors, while recognising that pupils of twelve ought to be ready to take up a more scientific study of arithmetic, are not prepared to look for that improvement in the earlier work which would permit of this step being taken.

All three books show signs of the former school of arithmetic. This is specially seen in the multiplication of money. There is no justification for the retention of the old method of tens which is simply a disguised form of practice. The objection to the direct method usually is that the working has to be roughly done with no definite place in the setting down. That can be easily overcome by setting down the working of each unit directly below that unit. The direct method corresponds closely to the method always used in division. Again, in multiplication and division by decimals, we find one of the many mechanical rules given in each book. These should only be necessary in the case of beginners, and a pupil who thoroughly understands "place values" should not require any of these mechanical aids.

(1) Mr. Lock's arithmetic has now reached its fifth edition, and we can congratulate the author on the improvement of that edition. The omissions from and re-arrangement of the text are all for the benefit of the teaching of elementary mathematics. There are still some traces of the older methods to be found. On p. 67 the old extended method of finding the H.C.F. is given, and alongside is a contracted method (the quotients are not necessary) with the remark, "The work is best arranged thus." On the succeeding page, however, the authors give the working of two examples in the old style. On pp. 96 and 97 we find a series of examples of continued and complex fractions which we hope the authors will remove from the next edition The importance given to vulgar fractions generally takes away from the value of the book as a modern text-book of arithmetic.

(2) Mr. Palmer's book is an example of a type of text-book which has become common during the last few years.

"It is chiefly made up of examples. The explanatory matter consists almost entirely of worked-out examples, except in certain parts of the book where explanation seemed necessary in consequence of some departure having been made from the ordinary method of treatment."

There is no doubt that such a book is the best that one can put in the hands of pupils, but it requires a teacher who is an expert in his subject. We can therefore recommend Mr. Palmer's book with confidence to those teachers who take a special interest in and make a special study of the teaching of arithmetic. They will probably find rules and methods which they do not approve of, but these can be neglected without any loss. The method of dealing with the multiplication of decimals is open to the objection that without any gain a much more difficult method than the direct one is given. The author makes use of rough approximations before and rough checks after working out an example. These are very good, and should be used in all working, but they should not be made the means of finding the decimal point in approximations. The placing of the point should give no difficulty if a logical method has been adopted throughout the study of decimals.

(3) Mr. Jones's book is a laudable attempt to remove the study of arithmetic from its commercial trammels and widen its scope. We are afraid that, in the attempt, he has overburdened his book. Practical work is introduced at all stages of the work, and the numerous explanatory diagrams will be a useful addition to the teaching of the subject. There are one or two things which strike us as being out of place in a book which is intended for a general course in arithmetic. Thus the tables of weights and measures include some units which are not in general use. The introduction of these tends to specialise the work, a thing which Mr. Jones claims, in his preface, that he desires to avoid. We are sorry to see in an arithmetic of this type the instruction to "move the point." It is always difficult for a teacher to keep before young pupils the reason for the step, and he is not aided when the text-book adopts the mechanical method. Mr. Jones has added an index, an example that ought to be followed by all writers of school text-books.

F. L. G.

OUR BOOK SHELF.

Die typischen Geometrien und das Unendliche. By B. Petronievics. Pp. viii+88. (Heidelberg: C. Winter, 1907.) Price 3 marks.

THE author of this curious work asserts (p. 86) that it is impossible to make a one-one correspondence between the points of a linear segment and the elements of the arithmetical continuum (0, 1); in other words, he not only declines to accept the Dedekind-Cantor axiom, but asserts that it is illogical. His attempted proof (p. 85) involves the assumption of actual infinitesimal segments; thus he says "so entspricht dem ersten Punkte, der sich mit dem o-Punkte berührt, gar keine Zahl in der Zahlmenge 0 . . . 1, da das entsprechende Segment unendlich klein ist, und dasselbe wird auch für den zweiten, dritten usw. Punkt gelten."

This idea of immediately adjacent yet different points pervades the whole tract, and leads to wonderful paradoxes; an attempt is made to remove the most obvious difficulties by a distinction between real and unreal points (pp. 9, 10), but this is not satisfactory. There is a continual confusion between the idea of space consisting of points and that of points forming "parts" of space. You cannot eat your cake and then look at it; if in one context "point" means something with extension, it should not be treated elsewhere as having position only. Moreover, no intuition, logic, or metaphysic can get a geometrical thing having extension from two points devoid of it.

Unless something better than this can be said for it, the assumption of actual infinitesimals of different orders in geometry is not likely to be accepted, and the Dedekind-Cantor axiom will probably be retained as the simplest way of connecting geometry with analysis. From the metaphysical side we want something better than a puerile criticism of Cantor's transfinite number-system, vitiated by misunderstandings. Extensional quantities (lengths, volumes, &c.) can be arithmetically defined for figures in an arithmetical space; but no one with an active geometrical imagination can enjoy this way of treating the subject, although he may admire it as a logical feat. Again, take the connectivity of Riemann surfaces, or the classification of knots; here are things with characteristics easily recognised by inspection, but difficult to specify by the arithmetical method; cannot we find some means for testing our intuitions without putting them into this newly invented arithmetical machine? To give a satisfactory answer to the questions arising from the modern aspects of mathematics is a task sufficient to strain the highest philosophical powers; and although Dr. Petronievics has the temerity to declare that Hilbert's "Grundlagen der Geometrie" is logically defective (p. 24, end), he has added little, if anything, which is of value or interest to the discussion.

G. B. M.

Engineering Workshop Practice. By Charles C. Allen. Pp. vii+254. (London: Methuen and Co., n.d.) Price 3*s.* 6*d.*

A BOOK for students on engineering workshop practice is, in many ways, more difficult to write than one addressed to those who, from years of actual practice, have gained an intimate knowledge of the elaborate processes by which engines and other machines are produced. The beginner requires ample explanations of processes, which he has probably never seen carried out, but which to the workman are as familiar as his daily paper.

This book, good as it is, would have been much more useful if no attempt had been made to write for the information of both the beginner and the skilled workman; their needs are so different that the result cannot be satisfactory to either class. A typical instance of the consequences of such an attempt occurs on p. 159, with reference to the cutting of vee threads in a lathe. In a short paragraph the author points out, quite properly, that, in taking a cut over the whole form, there is a great tendency to rip the thread, and then goes on to state that the diagrams indicate the proper method, but offers no further explanation of them. To a skilled workman these diagrams are quite unnecessary; to a student they are merely perplexing. He is left to discover, if he can, that one diagram is intended to indicate that the roughing cut is to be taken on one side of the vee, while in a second diagram a tool, apparently floating in mid-air, lies between two objects, which he may or may not recognise as rake gauges. In other cases where explanations of the diagrams are given they are far from being clear; thus on p. 191, in the instructions for cutting helical gears, we are told that "The cutter used must be selected for the number of teeth there would be in a gear with outside diameter equal to the diameter of a circle determined by the curvature of the gauge in this way." But the author gives no intelligible explanation of what "this way" is.

While it is proper to direct attention to blemishes of this kind, there is no doubt that the author has produced a book of considerable merit, the value of which would be considerably enhanced in future editions if the attempt to deal with the wants of the skilled workman were frankly abandoned.

The text covers most of the elementary operations of the fitting and machine shops, and the graduated exercises are well thought out, and in a well-equipped college workshop under the supervision of a skilled instructor a beginner would no doubt make remarkable progress in the use of tools, and be of real value in a works at the end of the course of instruction.

Steam and other Engines. By J. Duncan. Pp. ix+471. (London: Macmillan and Co., Ltd., 1907.) Price 5*s*.

THE development of municipal technical schools during the last few years has given a great impetus to the production of books written especially for elementary students. Mr. Duncan's book, on steam and other engines, is an admirable little work of this class, which students in the early part of a course on mechanical engineering will greatly appreciate, for it is well and clearly written, and covers a wide range of modern practice.

There is nothing more attractive to young engineering students than the purely mechanical details of engines, and the wealth of illustrations accompanying the descriptive matter will no doubt prove of great interest.

While the illustrations are a prominent feature of this book, the more important elementary principles of heat-engine theory and applied mechanics are also presented in a very skilful manner. Students working through the course of instruction prescribed, especially if they are able to carry out the experiments and take part in the engine and boiler trials, as the author recommends, will obtain quite a considerable knowledge of steam and other heat engines.

There appear to be very few errors or mistakes of any importance, but occasionally the author is not an accurate guide, as, for instance, when dealing with the flow of steam in an expanding nozzle he incidentally says that "In the case of a liquid the problem is simple as the property of expansibility is absent," a statement in direct contradiction to the actual facts, as students of hydraulics are well aware.

The Elements of Mechanics. A Text-Book for Colleges and Technical Schools. By W. S. Franklin and B. Macnutt. Pp. xi+283. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1907.) Price 6*s*. 6*d*. net.

A BOOK on elementary mechanics, which commences by addressing the reader as my young friend, and immediately after, in a lengthy paragraph, draws a comparison between the student and the axolotl, does not seem very promising as a scientific work. This feeling is strengthened when a little further on, in speaking of the laws of motion, one of the authors writes:—

"You, my young friend, must have in some measure my own youthful view, which, to tell the truth, I have never wholly lost, that there is something absurd in the idea of reducing the more complicated phenomena of nature to any orderly system of mechanical law. For to speak of motion is no doubt to call to your mind first of all the phenomena that are associated with the excessively complicated, incessantly changing, turbulent and tumbling motion of wind and water. These phenomena have always had the most insistent appeal to us; they have confronted us everywhere and always, and life is an unending contest with their fortuitous diversity, which rises only too often to irresistible sweeps of destruction in fire and flood, and in calamitous crash of collision and collapse where all things commingle in one dread fluid confusion."

The book does not, happily, continue in this style after the opening chapter, but commences a systematic treatment of elementary mechanics on familiar lines, which, however, does not present any new features worthy of notice, except that inaccuracies and lack of precision in the statement of scientific principles are numerous. A new text-book on mechanics may be justifiable, if the authors can present the subject in a better way than has been presented before, or in a form more adapted to the wants of its readers, but a comparison of this work with any good elementary treatise on the subject cannot fail to show its inferior character. E. G. C.

Die Lösung des Problems der Urzeugung (Archigonia, Generatio spontanea). By Martin Kuckuck. Pp. vii+83; with 34 figs. and one table. (Leipzig: Barth, 1907.) Price 3 marks.

DR. KUCKUCK made a mixture of gelatine, peptone, asparagin, glycerine, and sea-water, boiled it for an hour, put it in a sterilised vessel, and added a little chloride of barium, which brought about ionisation. The outcome was the formation of minute bodies like protozoa, which show "nutrition, growth, reproduction (segmentation), inheritance, movement (rotation), and form cell-groups (cœnobia of Haeckel), which resemble animal morulæ." Barium chloride produces similar morulæ in fresh white of egg and in yolk of egg. Drops of natrium nucleinecum (Merck), allowed to fall on the surface of the gelatine-peptone-asparagin-glycerine-sea-salt mixture, produce rotating corpuscles, which form loose colonies. The author gives very interesting and striking figures, some drawn, some from photographs, of his artificial cells and cell-colonies. The figures drawn from the artificial morulæ would pass muster in a text-book of embryology; the cell-outlines are sharply defined, and each cell has a beautiful nucleus. It seems to us that these and similar experiments would be more interesting, if less were proved.

On this experimental basis, Dr. Kuckuck rears a theoretical superstructure. Mixtures of inorganic and organic substances pass by ionisation into protoplasm. Salts of barium, radium, and nuclein effect this ionisation. The process of organisation is a process of ionisation. It is so now, and it was so in the beginning. The first organisms arose in the sea and were non-nucleated Monera. The nucleated cell arose by the symbiosis of two aniso-electrical non-nucleated cytodes, as is proved by the fertilisation-process, for is not ontogeny a recapitulation of phylogeny? "Everything living has sex (negative and positive ions), and everything is living because it has sex (negative and positive ions): ohne Geschlecht kein Leben." A sort of genealogical tree is given showing the origin of organisms from inorganic substances, so that the Stammbaum is now quite complete, even as to its roots. J. A. T.

The Flora of Columbia, Missouri, and Vicinity. By F. P. Daniels. The University of Missouri Studies. Science Series, vol. i., No. 2. Pp. x+319. (The University of Missouri, 1907.)

As a study of a local flora, this memoir, furnishing a list of the plants and an ecological survey, forms a suitable volume for the science series of the Missouri University publications.

The flora is characterised by a predominance of genera belonging to the orders Compositæ, Gramineæ, and Leguminosæ. The sedges are numerous, since the species of Carex exceed fifty. Desmodium, Mespilus, and Aster are large genera, and Vernonia provides eight new species. The genus Quercus is important both for the number of species and also on account of their dominance in the forests of the area. *Q. alba,* the white oak, *Q. rubra* and *Q. Schneckii,* red oaks, are widely distributed; *Q. macrocarpa, Q. platanoides,* and *Q. palustris* occur on the coal measures; *Q. acuminata* and *Q. tinctoria* are also common.

The ecological survey is detailed, almost too detailed, as it loses conciseness owing to the multifarious subdivisions. The forests, as the prevailing features of the district, receive the most attention; the cliff and marsh associations are also important. The characters of the various formations are carefully delineated, and the text furnishes an estimable addition to the literature of plant distribution, but the area has apparently not been surveyed with the view of plotting on a map, nor are any illustrations provided.

The Evolution of Matter, Life, and Mind. By W. Stewart Duncan. Pp. 250. (Philadelphia: Index Publishing Company, 1907.)

THIS is a *vade mecum* of evolutionism, a sequel to a previous volume in which the author sought to show that feeling and energy are alternate states of matter everywhere. Feeling is given out as energy, and energy is experienced as feeling. Both are spiritual or non-substantial, sister properties or manifestations capable of inhering and co-inhering in one universal substance, the ether. The progress of investigation has enabled the author to make his monism even more definite. Matter is being refined away into a mode of motion in the ether. This ether is "the fountain of all being," "the hitherto unknown God." Prof. Larmor and others are theologians in spite of themselves. Helped by abundant quotations, Mr. Duncan gives a sketch of recent investigations as to the nature of matter, and he points out that he anticipated some of them. In 1893, for instance, he contended that an ordinary ray is a succession of such motions of the ether as beget waves with *longitudinal* as well as transverse elements of vibration, and it was only last year that Prof. J. H. Poynting showed that rays of light do exert energy in the direction of propagation. In the present volume he develops some original speculations, *e.g.* a theory of radiation and gravitation.

The author tells us that we must believe in the spirituality of matter and of the ether. Physical processes are *never* complete chains of sequence. Feeling and energising arise alternately in all matter. Animal matter has sprung from vegetable matter, and the latter from inorganic matter (in the Arctic regions). All that we call "matter" is at least sensitive and capable of feeling. It is so because of what it produces, and it is so because the ether is the fountain of all being, physical and mental. Every receiver of energy passes through two states, which correspond to those of every living personality, a subjective state of feeling which results from influence from without, and an ejective state of energising which results from influence from within. We trust that this is all quite clear.

Mr. Duncan gives an account of the origin of everything—including evil—except the ether, which is a scientific name for God. He traces the evolution of all living creatures and of the human mind, showing that the difficulty of thinking out the long genetic process may be in great measure overcome if we start from a broad enough basis—the psychosis of "matter." In the course of his exposition he quotes the story of a delightful orchid, discovered by Mr. E. A. Suverkrop, of Philadelphia, which sends down a tubular stem into the water when it is thirsty, fills the tip, and coils it up again. "As the last coil is made the water trickles down upon the roots at the other end." When the discoverer touched the leaves, he was "astonished to see the centre stem convulsively coil itself into a spiral like the spring of a watch." Wonders will never cease. Nor is pathos wanting, for on dry ground "it was almost pitiable to see how the tube would work its way over the ground, in search of water that was not."

Ballistic Experiments, from 1864 to 1880. By the Rev. Francis Bashforth. Pp. 33. (Cambridge: University Press, 1907.) Price 1s.

THE pamphlet is interesting reading as an unconscious revelation of the timidity of thought of our military authority. Afraid to trust its opinion, it waited for approbation to come from abroad before expressing a judgment.

Although carried out with our muzzle-loading guns, Mr. Bashforth's experiments were so careful as to require slight modification only to serve for the newest pattern of modern artillery, and the arrangement of his tabular matter for practical use has been adopted universally, and is never likely to be displaced.

Mr. Bashforth is the creator of the science of modern artillery, but our official world considers this a very improper remark to make, at least in his lifetime.

The rapid progress in electromagnetic science has made possible a great improvement in the chronograph, and further experiment is needed urgently if we are to make the best use of manufacture in the production of improved weapons of war.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Origin of Radium.

IN his two interesting letters published in NATURE of September 26 and October 10 respectively, Dr. Boltwood states that he has obtained undoubted proof of the existence of the parent substance of radium, and that he finds it to be allied in chemical properties with thorium. I may be permitted to describe some experiments which afford independent evidence that the parent substance of radium possesses in a chemical sense the properties of thorium, and that it occurs with the latter.

In experiments made with a new intermediate product obtained from thorium to which I have given the name "mesothorium," I was struck by the fact that old preparations of pure thorium contained relatively large quantities of radium. This appeared all the more noteworthy since the monazite sand from which the thorium is prepared contains only a very small quantity of uranium; the radium corresponding to this small amount must consequently have been separated from the thorium during the complicated processes used in extracting the latter.

A few months ago, therefore, I began a systematic investigation of the quantity of radium in samples of thorium salts of different ages. A weighed quantity of the pure nitrate, generally 10 grams, was dissolved in pure water, and the solution boiled and sealed up. After a sufficient interval the radium emanation was collected by boiling the solution, and shortly afterwards, after allowing the thorium emanation to decay, transferred to an electroscope and measured. Samples of thorium nitrate of very different but accurately known ages were placed at my disposal by the firm of Dr. O. Knöfler. It was found as a result that the older the sample the larger was the quantity of radium contained in it. The oldest sample of all, one dating from 1898, contained the greatest amount. In quite a new sample the quantity of radium was very small, 100 grams of the sample being required for its measurement. The radium present in this case was about 1/100 that contained in the sample nine years old.

It was not to be supposed that an insufficient degree of purity was the cause of the large amount of radium in the old sample, nor is it probable that thorium itself slowly decomposes into radium. I therefore considered that in the technical preparation of thorium an active substance is separated with the latter, and in turn decomposes into radium; it is probably the direct parent substance of radium, for which search has been recently made. In order to test this view, an attempt was made to show the increase in the amount of radium in a solution of thorium; 100 grams of freshly prepared thorium nitrate was examined, the quantity of radium being ascertained. The amount of emanation collected after four days was used for calculating the equilibrium amount, which is reached after about a month. On August 17 the flask was sealed, and again tested on October 10; the amount was double as great as in the previous test.

Forty grams of thorium nitrate prepared at the end of April was examined in the same way and left during the vacation. In this case also there was a marked increase in the amount of radium.

Fifty grams of thorium nitrate made in June, 1907, was precipitated from acid solution with oxalic acid. In the filtrate the quantity of radium was determined, the same being also done in October. In each case the same result was obtained. The parent substance of radium had therefore been precipitated with the thorium. By mistake, the precipitated material was mixed with other thorium preparations, and could not, therefore, be further investigated.

About 1 mg. of radio-thorium (activity about 100,000) was freed as far as possible from radium (the small amount retained being determined) and sealed up on August 15. The solution on October 14 gave the same amount of radium emanation as before. The radio-thorium was prepared from thorianite by means of barium sulphate, and should not, therefore, have contained the parent substance of radium, as, indeed, was actually found to be the case.

Knowing the proportion of uranium and thorium in monazite sand, and assuming that all the thorium and the whole of the parent substance of radium are separated during the extraction of thorium, the life of radium can be calculated by determining the quantity of radium in a given weight of thorium of known age. I have assumed the monazite to contain on the average 0·3 per cent. of uranium and about 5 per cent. of thorium oxide. From this it follows that 1 gram of thorium nitrate in equilibrium with radium contains about $2 \cdot 10^{-8}$ gram of radium bromide. From the values I have found with samples of thorium of different age, the period of decay for radium lies between 2000 and 3000 years. Alterations in the proportions of uranium and thorium would naturally cause corresponding deviations in the value of the constant. The values given, therefore, only indicate approximately the order of magnitude of the period of decay, since I am ignorant of the exact composition of the monazite used as a source of the nitrates investigated.

I hope to publish more accurate details shortly in another place. OTTO HAHN.

Chemical Institute, Berlin.

The Victoria Jubilee Technical Institute, Bombay.

I SEE in NATURE of November 7 advertisements for a principal and professor of chemistry for the Victoria Technical College in Bombay. Though I have no connection with the institute, and may be charged with unwarrantable interference, I think that it is only fair to intending competitors that certain facts should be made known.

I wish to point out, in the first place, that the management of this institution is in the hands of a board of trustees, and that the principal is not a member of this board, nor has he the right of communicating with the board except through the medium of the honorary secretary. The title of principal does not even secure to the holder of it the exclusive right of calling meetings of the staff, and, in fact, confers nothing more than the power to enforce discipline. On the occasion of the opening of the new laboratories in February last, I was much impressed by the fact that not only was the principal not among the speakers, but that he and his staff were barely referred to, and that their names only appeared in the descriptive pamphlet which was published for the occasion inside the cover and at the end.

Such were the conditions under which my friend Dr. Mackenzie held the appointment, and it was with no astonishment that I heard on my return from India that he had sent in his resignation. I may add that though Rs. 1000 per mensem with a residence appears to be a good salary, it must be remembered that there is no security of tenure of the appointment, and that the residence offered to Dr. Mackenzie lay between the dustiest road and the busiest railway in the heart of Bombay.

Should any chemist contemplate applying for the "chair" of chemistry with the view of carrying out research in his spare time and ultimately improving his position, I should like to remind him that he will do well to take his library with him. There are no scientific books in Bombay.

Before leaving Bombay I made it clear to some of my friends who are interested in the institute that, in the event of Dr. Mackenzie's resignation being accepted, I should make the facts public, and should warn other scientific men against accepting the appointment upon similar terms. MORRIS W. TRAVERS.

London, November 9.

November Meteors.

THOUGH the general conditions under which the Leonid meteor shower of 1907 takes place are not the most favourable, still a display of moderate intensity may be expected. The shower promises to be most conspicuous on the night of November 16, when moonlight will interfere considerably with observations, especially in the case of the smaller meteors. The following are the times of the various maxima as computed by the writer, the results of these calculations being expressed in Greenwich mean time:—

Leonid epoch, November 15, 9h. The shower, which is of the third order of magnitude, succeeds the epoch, the principal maxima occurring on November 16, 17h., 17h. 30m., and 18h. 30m. There is also a weak secondary epoch on November 17, 10h., the shower in this case preceding the epoch, and having its principal maxima on November 16, 13h. 40m., 18h., and November 17, 2h.

The intensity of the maxima of a meteoric epoch is inversely as the order of magnitude of the shower connected with it. Two showers, though of different intensities, will, as may be seen, take place on the night of November 16.

Scattered through the rest of the month are several interesting minor showers, details of the most remarkable of which will now be given:—

Epoch, November 22, 4h. Shower of tenth order of magnitude. The shower precedes the epoch, the principal maxima occurring on November 20, 8h., November 21, 14h., and November 22, 3h.

Epoch, November 25, 12h. This shower, which is of the ninth order of magnitude, has its principal maxima after the epoch as follows:—November 26, 1h. 50m., November 27, 2h. 30m. and 6h. Of these, the latter two are the heaviest maxima.

Epoch, November 29, 18h. The shower, which is of the fifteenth order of magnitude, follows the epoch, the principal maxima occurring on November 29, 23h., November 30, 18h., and December 1, 4h.

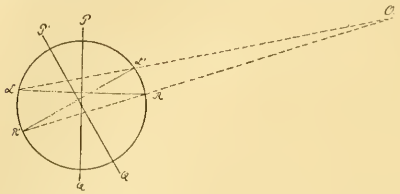
Closely associated with the last shower is another, which occurs early in December, is of the fifth order of magnitude, and has its maxima on December 2, 11h., and December 3, 8h. JOHN R. HENRY.

An Optical Illusion.

THE optical illusion described by Mr. Douglas Carnegie in NATURE of October 18, 1906, may be explained as follows:—

The thaumatrope generally reverses its apparent direction of rotation when the observer shuts one eye, or, better still, both eyes alternately, according to the physiological law that the observation of a motion which is being stopped is in favourable circumstances followed by the perception of that motion in reversed direction.

The accompanying figure shows the card with its plane passing through the observer O. L and R are the intersections of the circumference of the card with an arbitrary horizontal line. Suppose that the card turns round its axis PQ from north to west, the observer will see L removing to the left and R to the right, and from this he can conclude the exact direction of the rotation, provided that he makes sure of L being behind and R before PQ, and not otherwise. For suppose L before PQ in L′ and R behind PQ in R′, the observed removal of these



points respectively to the left and to the right would lead to an apparent opposite direction of rotation—from north to east. Moreover, the axis PQ perpendicular to LR would seem to tilt away from the vertical to P′Q′ perpendicular to L′R′. Hence the illusion depends upon the following condition:—if L and R are seen in the right place with respect to each other, the rotation appears in its true direction, but if, on the contrary, L and R are seen in L′ and R′, so in the wrong place with respect to each other, the card will seem immediately to reverse its direction of rotation, and the axis will seem to tilt away from the vertical.

As an observer, viewing the true direction of the rotating card, will generally be unable to distinguish the right place of the two points when he shuts one of his eyes, the circumstances are favourable for the reversing of the direction of the rotating card.

Utrecht, October 5. L. U. H. C. WERNDLY.

The Interpretation of Mendelian Phenomena.

IF I have read Dr. Archdall Reid's letter in NATURE of October 31 aright, he draws a distinction between the study of heredity in general and the study of the problems of sexual reproduction, now defined as the problem of the function of sex (an expression with which I am perfectly contented). Among the problems of sex he includes the study of the actual transmission of characters as dealt with by Mendelians. The novelty of this classification is certainly attractive; but I find it difficult to understand what branches of knowledge remain to fall under the former head. In what does the study of heredity consist if not in the study of the transmission of characters from parents to offspring?

If by this apparent paradox it is only meant to imply that the Mendelians must confine their study to the transmission of characters by the sexual method, they may seek comfort in the reflection that this is by far the most important of all branches of heredity—it is the only one, for example, which affects the human race. Indeed, the rule that all organisms pass through a sexual cycle at some period of their existence has extremely few exceptions; but I, for one, see no reason for restricting the experimental study of heredity even to this extent. Mendel demonstrated the segregation of the germinal representatives of certain characters in the reproductive cells. What reason is there for doubting that such segregation may take place among the ova of a parthenogenetic individual? There is, in fact, evidence of the actual occurrence of such segregation. More than this, we know of segregation where reproduction is purely vegetative, as in the case of bud sports.

It is the claim of the Mendelians that they have discovered in certain cases some of the fundamental characters of an organism—the units of hereditary transmission, which are represented in the reproductive cells by definite entities known as allelomorphs. Sometimes these characters are identical with those which can be defined by simple inspection previous to experimental analysis, sometimes they are not. Sometimes the apparent character depends upon the simultaneous presence of several allelomorphs, each of which may segregate from its opposite in complete independence of all the others. Mendel himself suggested that this conception, the proof of which he left to his successors, might afford the explanation of certain botanical cases which do not appear to be widely different from that of the mulatto. If Dr. Archdall Reid will produce authenticated pedigrees showing the repeated crossing of the mulatto with pure white blood and pure black blood respectively, together with a detailed account of all the offspring produced, he will make a very substantial contribution to our knowledge of heredity in the human race, and one which will be examined with very great interest by Mendelians. In the absence of such evidence the statement that there is no segregation does not seem to me to be justified, even in this particular instance.

It has been pointed out that Mendel's discovery is leading to a change in our conception of the constitution of an organism comparable with the change which the advent of the atomic theory produced in chemists' conceptions of compound substances. Whatever biological problem we may now discuss, Mendel's facts have to be reckoned with. It is true that the only method so far discovered of studying the constituent characters of organisms consists in the crossing together of individuals in which some of the characters are different. This method is so closely comparable with that by which the chemist studies his compounds that Mendelians have often found a readier appreciation of their views among students of the more precise physical sciences than among biologists. The advantage of introducing exact experiment into the study of heredity ought to be obvious to all, and I fail to see any other objection to the method except its novelty.

If Dr. Archdall Reid desires to grasp this new conception, I can only recommend him to a renewed study of the literature of the subject, beginning with Mendel's own papers. Better still, let him repeat a few of the simpler experiments. There is no royal road to this knowledge; but it is knowledge which is rapidly revolutionising our entire conception of the constitution of a living organism. Dr. Archdall Reid is so far from appreciating this at present that further discussion seems likely to be of very little profit. I will conclude my contribution to this controversy with a word of warning. If Dr. Archdall Reid discards Darwin's opinion, based as it was upon an unequalled experience, that domestic and natural varieties have arisen by essentially the same process, he may find himself landed among a crowd of unsuspected difficulties.

Cambridge, November 2. R. H. LOCK.

Method of Observing the "Subjective Yellow."

A SIMPLE method of obtaining the sensation of yellow produced by the mixture of red and green lights is afforded by a small direct-vision spectroscope of the ordinary kind in which the slit can be rotated to adjust its line perpendicular to the plane of refraction. If the slit is turned slowly from this normal position, the bands of different colours of course take up a sloping direction across the spectrum, like books on a half-filled shelf. As the slope increases, the upper end, for example of the red, closes down on the lower end of the green, and as the two blend the clear yellow tint is produced. Other colour mixtures can be similarly noticed.

It may be added that if the slit is turned thus until its length lies in the plane of refraction, the violet end of the impure spectrum obtained is drawn out and so more easily observed than in the normal method of use, and is still pure enough for most of the purposes for which a simple spectroscope is of use.

University College, Cardiff.

ANTARCTIC ANIMALS.[1]

THE Trustees of the British Museum have published in stately form some of the natural history results of the National Antarctic Expedition (1901-1904), and we cannot but express our satisfaction that the volumes compare so well, both in matter and "get-up," with the similar publications of other European nations, and that they can be placed without reproach on the *Challenger* shelves. As the director of the natural history departments of the British Museum says in the preface to this second volume, "neither trouble nor expense has been spared in order to render the illustration and presentation of the natural history of the expedition worthy of the generous efforts both of Captain Scott and his fellow-explorers and of those who provided funds for that enterprise." Another matter for congratulation is that the results are being published so promptly, and for this thanks are due to the energy and organising ability of Mr. Jeffrey Bell, who has secured the co-operation of specialists, and has acted as sub-editor of the natural history portions of the reports.

The second volume begins with Dr. Edward A. Wilson's report on the mammals, a well-executed piece of work, most beautifully illustrated. The *Discovery* found no traces of the southern right whale (*Balaena australis*), which Sir James Ross reported as abundant in the Ross Sea in the 'forties of the last century, but the rorqual, the Australian whale (*Neobalaena marginata*), a bottle-nose, the killer (which levies toll on the seals and penguins), the dusky dolphin, and two new cetaceans. Dr. Wilson gives a very interesting account of the habits of the seals:—Weddell's seal (*Leptonychotes weddelli*), the sea-leopard (*Stenorhinchus leptonyx*), the crab-eating seal (*Lobodon carcinophagus*), the Ross seal (*Ommatophoca rossi*), the sea-elephant (*Macrorhinus leoninus*), Hooker's sea-lion (*Arctocephalus hookeri*). We should like to give an instance of the author's graphic style:—

"Coming back to the ship by boat from Enderby Island an hour or two after sunset, and on a particularly dark night, with neither stars nor moon, we watched the sinuous and graceful movements of about six large sea-lions that followed our boat apparently out of curiosity. Diving and twisting about beneath us in the pitch-black water, each animal was ablaze with light. Every limb and every movement could be seen, though they moved so rapidly that the eye could scarcely follow them; they played with one another and chased one another and the boat, now coming up to blow, as we could hear, a yard or two astern, and now diving deep down under the boat to appear often close in under the bulwarks; every stroke of the long powerful fore flippers was accurately conveyed to our eyes in the pitchy darkness by the brilliance of the phosphorescence covering them. . . . The sight was a most beautiful one. The animals moved with feints, and twists, and turns, now in curves, now in circles, but always with the sinuous motion of the body like a fish, sunnlemented by powerful strokes of the long fore flippers, and always with

FIG. 1.—Emperor Penguins' Rookery at Cape Crozier. From the "National Antarctic Expedition, 1901-1904."

[1] "National Antarctic Expedition, 1901-1904." Natural History. Vol. ii., Zoology (Vertebrata: Mollusca: Crustacea). Vol. iii., Zoology and Botany (Invertebrata: Marine Algæ, Musci), with numerous plates and illustrations. No continuous pagination. (London: Printed by order of the Trustees of the British Museum, 1907.) Vol. ii., 3*l.*; vol. iii., 2*l.* 10*s.*

the most wonderful rapidity. All this we saw most clearly in the blackest darkness, far more clearly, indeed, than such objects are wont to be seen even under the most favourable conditions, in the daylight."

Of course the memoir is not exactly full of sugarplums of this sort; there are discussions of dental formulæ and plenty of other hard facts, but Dr. Wilson is to be congratulated on bringing not a little of the picturesqueness of reality into his scientific discourse.

In Dr. Wilson's report on the birds, we find abundant details regarding the life and ways of penguins. They are drawn or photographed in every conceivable attitude and situation—walking, "tobogganning," feeding, sleeping, on the nest and "on the run," crowing, piping, dirty and clean, moulting and "ecstatic." The pictures are delightful, and reflect great credit on artists and photographers, and the whole story of the life of the penguins is full of interest. Take the emperor penguin's egg-laying, for instance. The bird chooses the darkest months of the Antarctic winter in which to incubate its egg; it lays it upon sea-ice with no pretence at nesting, but removes it at once to rest upon its feet, where it is held wedged in between the legs closely pressed to a patch of bare skin in the lower abdomen, and covered from exposure by a loose-falling lappet of abdominal skin and feathers. Of course there is no "pouch," only a fold. The incubation requires seven weeks, and one bird cannot undertake this task. A dozen or more stand patiently round waiting for a chance to assist.

"Every adult bird, both male and female, in the whole rookery has a keen desire to 'sit' on something. There is every reason to believe that when the sitting bird feels hungry it hands over its treasure to the nearest neighbour that will undertake the duty of incubation."

But we must not quote more, strong as the temptation is. Dr. Wilson deals with five species of penguin, two skuas, Wilson's petrel, the Antarctic petrel, the giant petrel, and a score of other birds.

Mr. W. P. Pycraft has made out some very interesting points in his study of nestlings and embryos of the emperor and Adélie penguins. He shows that penguins develop two successive down plumages before assuming the normal definitive feathers. Another remarkable fact is that the feathers are moulted from large areas of the body at once. In their pterylosis the penguins are the most primitive of all Carinatæ. This accomplished osteologist also shows that the embryological evidence confirms what the palæontological evidence hints at, that the penguins are descended from birds which possessed full powers of flight. He gives an interesting discussion of their relationships, and of detailed points of interest such as the sealing up of the nares, which seems to have been a common heritage of all the birds belonging to the great Steganopod branch, except the Colymbi.

The collection of fishes, reported on by Mr. Boulenger, was a very small one, consisting of representatives of ten species, four of which are new.

Dr. W. G. Ridewood deserves congratulation in respect of his fine memoir on the two species of Cephalodiscus obtained by the *Discovery*. He gives a detailed account of *C. hodgsoni*, n.sp., and *C. nigrescens*, Lankester, compares the six species now known, discusses their relations with Rhabdopleura, and clears up a number of obscure details. He proposes to divide the genus into two subgenera—Idiothecia, *e.g. C. nigrescens*, in which the polypides live in separate tubular cavities, and Demiothecia, *e.g. C. hodgsoni*, in which the cavity of the tubarium is continuous. In both the new species obtained by the *Discovery* there are hermaphrodite individuals, with one ovary and one testis, as well as males and females with two ovaries and two testes respectively. Some light is thrown on the development of the buds and of the tubarium, as also on Harmer's "problematical body" (obliquely interlacing cross-striped muscle fibres) and on the peculiar refractive beads in the end bulbs of the plumes of *C. hodgsoni* (material of the tubarium in process of secretion). The seven plates illustrating this valuable memoir are of great excellence.

FIG. 2.—Hooker's Sea Lion. From the "National Antarctic Expedition, 1901–1904."

As to brachiopods, Mr. Edgar A. Smith describes two new species of Magellania, one of which, *M. sulcata*, is remarkable on account of the concentric sulcations and the coarse perforations of the shell. Its marked lines of growth have no analogue among recent forms, but recall the surface ornamentation of *Terebratula sulcifera* from the Lower Chalk.

Turning to molluscs, we find that the *Discovery* obtained only one cephalopod—a larval Histioteuthid—

in regard to which Dr. W. E. Hoyle communicates some notes furnished by Dr. G. Pfeffer. There were also some mandibles, obtained from the stomachs of seals and penguins. Mr. Edgar A. Smith finds twenty-one new species of gastropods in a collection of twenty-six. The most striking forms are *Trophon longstaffi*, and a new genus, Trichoconcha, which has a flexible tough shell, like a chestnut skin, and a beautiful hairy periostracum. The collection does not show any particular resemblance to the Arctic fauna, most of the genera having a world-wide distribution. The almost total absence of colour in nearly every instance is characteristic. Mr. Smith also describes a very remarkable Chiton (*Chaetopleura miranda*, n.sp.), simultaneously reported by Dr. J. Thiele (*Notochiton mirandus*, n.g. et sp.) from Bouvet Island—an instance of wide distribution. The third and seventh valves are stained red, the rest being dirty-whitish. In the collection of fourteen species of lamellibranchs, Mr. Smith found ten that are new, *e.g.* a beautifully sculptured Lima (*Limatula hodgsoni*).

Sir Charles Eliot describes five species of pteropods, and points out at once the distinctness and the relatedness of the northern and southern species of Limacina and Clione. It may be that some once cosmopolitan species have undergone similar but not identical changes in North and South Polar waters. The same authority also reports on the nudibranchs, twelve in all, ten of which are new. He establishes two new genera, Tritoniella and Galvinella, near Tritonia and Galvina respectively, and comes to the conclusion that the Antarctic and Arctic nudibranchs are similar rather than identical.

As to crustaceans, Dr. W. T. Calman describes two species of decapods obtained within the Antarctic Circle, viz., *Chorionus antarcticus* (= *Hippolyte antarctica*, Pfeffer) and *Crangon antarcticus*, Pfeffer, both of which were also collected by the German Polar Commission of 1882–3 at South Georgia. With the exception of the very imperfectly known *Crangon capensis*, Stimpson, *C. antarcticus* is the only southern species of the genus, and is widely separated from all the other species, which are confined to the temperate and (if Sclerocrangon be included) Arctic regions of the Atlantic and Pacific.

No Cumacea have previously been obtained from within the Antarctic Circle, but the *Discovery* collected four species, which Dr. Calman describes. Three are new, and the fourth is a variety of *Campylaspis verrucosa*, known from the north Atlantic and the Mediterranean, though probably with a much wider range.

Mr. A. O. Walker reports on fifty-three species of amphipods (eighteen new) in forty-three genera (four new). As in the Arctic regions, the Lysianassidæ preponderate. It was quite the usual thing to take ten to thirty thousand specimens of *Orchomenopsis rossi* in a single haul. Some of the forms have a wide distribution; thus *Ampelisca macrocephala* is an abundant Arctic species, and the ascidiicolous *Leucothöe spinicarpa* appears to be ubiquitous (the *Discovery's* winter quarters, Ceylon, Maldives, and our own seas). Among the peculiar forms we may notice *Thaumatelson herdmani*, the only known amphipod with its telson in the vertical plane, *Epimeria macrodonta* with long curved and sharp teeth on the body segments, and *Iphimedia hodgsoni*, so densely clothed with fine spines directed backwards that it has a shaggy appearance.

Dr. Johannes Thiele finds that the only leptostracan collected was *Nebalia longicornis magellanica*; Prof. G. Stewardson Brady reports on nine species of ostracods, of which seven are new, including a new cytherid genus Linocheles; Dr. A. Gruvel briefly discusses four cirripedes, including two new species of Scalpellum.

Mr. T. V. Hodgson has had an interesting task in dealing with the large collection of pycnogonids, which evidently have their headquarters in southern seas. He describes three new genera and twenty-three new species, raising the total of Antarctic forms to sixty-three. The new genus Austrodecus, perhaps a close relation of Tanystylum, is a curious little form with a slender and elongated proboscis, like the snout of a weevil beetle, no chelifori, six-jointed palps, and small ovigers; Austroraptus, another new genus, is remarkable for its spurred body and the length of its legs. These two genera, along with the genus Leionymphon, which is re-cast, belong to the family Ammotheidæ, but no true member of the genus Ammothea was found. The most interesting form is, of course, *Pentanymphon australis*, which excited much interest at the time, since it has an extra pair of limbs. It is abundant in circumpolar waters, where also the Scottish Expedition, under Dr. W. S. Bruce, collected a still finer species with the same peculiarity, which turned out to be *Decolopoda australis*, described by Eights some seventy years ago in a forgotten paper. The "bipolarity theory" is affected only by *Colossendeis australis*, for it is, among the numerous species of this genus, nearest to *C. proboscidea*, which occurs at the opposite end of the earth. We may direct attention to the useful device Mr. Hodgson has adopted of giving a brief *résumé* of the most important specific characters at the beginning of each detailed description. The author also contributes an interesting essay at the beginning of the third volume on collecting in Antarctic seas. Dr. E. L. Trouessart describes an Antarctic variety of the Arctic species of halacarid—*Leptospathis alberti*. The two forms hardly differ except in size and proportions, but as the author believes that the species will turn out to be cosmopolitan or subcosmopolitan, he does not attach any importance to its bipolar distribution. As a matter of fact, however, the species is not as yet known except in the two polar seas.

As to "worms," Dr. G. Herbert Fowler reports on three species of Chætognatha. He found the same three and one other in an old *Challenger* collection. He points out that *Krohnia hamata* ranges from 81° 30′ N. to 77° 49′ S., being cosmopolitan and fairly eurythermal; that *Sagitta hexaptera* is cosmopolitan and pantothermal; and that *S. serrato-dentata*, though found in subantarctic as well as north temperate seas, was absent at the colder stations of both *Discovery* and *Challenger*. Dr. O. von Linstow describes *Leptosomatum australe*, n.sp., which is the largest known free nematode, the female attaining a length of almost 50 mm., the male of 37·7 mm. He proposes a new group, Adenophori, for the free nematodes, which will not fit into the three groups Secernentes, Resorbentes, and Pleuromyarii into which he has disposed the parasitic forms. Mr. Arthur E. Shipley describes three species of Dibothriocephalus (two new) which were found living together in the stomach of Ross's seal. It is rather remarkable that the only cestodes brought back by the naturalists of the *Discovery* were got in one rare animal, and that they belong to one genus. The pleurocercoid stages may possibly be found in some cephalopod. We may note the author's enthusiasm; he speaks of *D. wilsoni*, n.sp., as a very attractive little tapeworm of few proglottides.

Turning to Cœlentera, we find, first of all, an interesting memoir by Prof. S. J. Hickson on the Alcyonarians. He finds that *Ceratoisis spicata*, n.sp., is a connecting link between the groups of species formerly separated into the two genera Ceratoisis and Primnoisis. The latter name must now disappear. Another new discovery is *Primnoella divergens*, which links Primnoella and Caligorgia. The collection included another new species of Ceratoisis and five other forms previously described. Prof. Hickson and Mr. F. H. Graveley deal with the hydroid zoophytes, which include some interesting forms, especially *Hydractinia dendritica*, n.sp. Though there is no definitely new generic type, there are ten certainly new species and five more probably new—a very large proportion out of a total of twenty-five. It may be noted that only two of the twenty-five were got outside the limits of McMurdo Bay and the edge of the great ice-barrier, so that we have here a fine representation of the hydroid fauna from the most southerly limit of our knowledge of marine zoology. It is also interesting to find that three of the species are common on British coasts. Dr. John Rennie makes a note on the extraordinarily long tentacles of some unknown siphonophore. They were about as stout as an ordinary bootlace and nearly twenty feet in length. Mr. Hodgson gives a graphic account of the difficulties attending their capture.

Among the sponges, Mr. R. Kirkpatrick found four species of Tetractinellids, forty-three Monaxonellids, twenty-four Calcarea, no Keratosa, and ten species of Hexactinellids. He describes the Hexactinellids, of which three were new genera and eight new species.

The third volume ends with a report on the marine algæ (Pheophyceæ and Florideæ) by Mr. Gepp and Mrs. Gepp, a description of a new coralline by Dr. M. Foslie, and an account of the mosses by M. Jules Cardot. It need hardly be said that with such bulky volumes before us it has not been possible to give more than a hint of the amount of sound and interesting work which they contain.

THE CURE AND PREVENTION OF SLEEPING SICKNESS.

THE sleeping sickness is, and unfortunately continues to be, the most burning problem of European colonisation in equatorial Africa. Like any other medical problem, that of sleeping sickness has two sides, which may be distinguished broadly as prevention and cure. Investigators in all parts of the world have been experimenting actively with the object of finding a drug, or method of treatment, which shall act in sleeping sickness as quinine does in malaria; that is to say, which shall destroy the parasites in the blood, without seriously affecting the health of the patient. Up to the present, the atoxyl treatment has given the best results, but it has often failed to produce more than temporary amelioration, and it is open to doubt if it has produced a complete cure in any case, while, like other arsenical compounds, it may have serious toxic effects. On Thursday last, however, a communication was made to the Royal Society by Drs. H. G. Plimmer and J. D. Thomson, of the Lister Institute, on the effect of certain antimony salts; and, to judge from the preliminary experiments on rats, these compounds appear to be far more efficient in their curative action, and at the same time less toxic in their effects, than atoxyl. The experiments will be extended at once to larger animals and to man, and though it would be premature to say that the long-sought-for cure has been found, the outlook is certainly more full of hope than it has ever been before.

The question of the prevention of sleeping sickness is, of course, bound up with the etiology of the disease. It is known that the disease is caused by the presence of a minute flagellate parasite or "trypanosome," first in the blood, later in the cerebrospinal fluid of the patients; and it is known that the trypanosomes are conveyed from diseased to healthy subjects by the bite of one, possibly more than one, of the species of blood-sucking tsetse-flies. It cannot be too emphatically stated, however, that the tsetse-fly is not, as so often stated, the "cause" of the disease; if the fly be not infected, its bite is harmless, and Koch and others have reported the existence of large areas in which the fly swarms, but in which sleeping sickness does not as yet exist, although the necessary condition for its diffusion is found.

It follows that the problem of prevention may be attacked in two ways; extirpation of the fly, or control of the infection. Considering the vast extent of the range of the species of tsetse-flies in Africa, considering, further, that these flies, being viviparous, have no free larval stages in which they can be destroyed, like mosquitoes, any notion of extirpating tsetse-flies must be considered as frankly utopian. The measures adopted by our Government are wisely directed towards controlling the spread of the infection. Since the fly haunts thick bush on the lake-shore exclusively, the jungle is to be destroyed at all ports, ferries, and landing-places on the lake, where it is unavoidable that human beings should visit the lake-shore; at other points the natives are to be removed from the shore, and persuaded or coerced to live out of the effective range of the fly. Natives known to be diseased are to be segregated, prevented from wandering into the "fly-belts," and placed under treatment. By this means it may be reasonably expected that the spread of the infection may be checked.

There remains, however, the possibility that some wild animal may play a part in spreading the infection, since other animals besides man are known to be susceptible to the trypanosome when inoculated with it in the laboratory. As yet, however, no vertebrate, other than the human species, has been proved to harbour the trypanosome of sleeping sickness in a state of nature. It is well known, however, that other species of trypanosomes, in no way connected with sleeping sickness, are found commonly in wild animals of all classes; and it may be added that the tsetse-flies are quite as willing to suck the blood of a reptile or bird as that of a mammal. Hence there is always the possibility that some species of wild animal may act as a "reservoir" from which the supply of the trypanosome of sleeping sickness may be kept up indefinitely through the agency of tsetse-flies. It is, therefore, of the utmost importance that further researches on the etiology of sleeping sickness should be carried on, with the special object, among others, of discovering any such indigenous source of the disease, for it need hardly be pointed out that it would be of little use to prevent tsetse-flies becoming infected from human beings if they could also obtain the infection from natural sources.

THE POLLUTION OF RIVERS.

ON Thursday, October 31, an influential deputation from the British Science Guild interviewed Mr. Burns, M.P., at the Local Government Board, upon the subject of legislation with respect to the prevention of the pollution of rivers, and the protection of the public against the contamination of shell-fish.

In most directions the tendency to the pollution of our water supplies increases with the demand for pure water, and the area from which such water can be obtained in the neighbourhood of our towns is diminishing. The existing local authorities have conflicting interests when dealing with river pollution, and considerations of guarding the purity of streams are often subordinated to those of refuse disposal and manufacturing requirements. What too often happens is that a sanitary authority, situated toward the head of the stream or upon one of its tributaries, collects its own drinking water from a comparatively pure source, and then adopts the selfish policy of permitting its refuse matter to enter the stream below its own intake, with too little regard for the needs of its neighbour lower down the course of the same river. Perhaps it is hardly to be expected that, of its own initiative, a sanitary authority will face a great deal of extra trouble and expense (beyond what is necessary for its own purposes) in conserving the quality and quantity of water when the entire benefit is to be reaped by other authorities; and this is one of the reasons why a general policy should be adopted and enforced by a central authority.

Although certain river conservancy boards exist and have done good work, and several county councils have done much to reduce the contamination of streams, these bodies are unable to do all that is necessary. The Rivers Pollution Prevention Act of 1876 was not framed so as to render the assistance which such an Act could be made capable of, and most of our larger rivers course through more than one county or between the existing purely arbitrary boundary of counties. The rivers and watersheds of the country are, moreover, generally too extensive to be embraced by any existing sanitary authority.

The case in favour of putting the whole of the watershed areas under one controlling authority is therefore a very strong one. The matter, both in its magnitude and importance, is clearly a national one, and a central authority for the whole country is what is needed. The duty of such an authority would be to maintain a sufficient sanitary supervision and control over authorities whose districts form important catchment areas for our water supplies, with the view of maintaining the purity and volume of the waters at standards sufficient to meet the domestic and trade demands of the country as a whole. Such an authority would also arbitrate and advise upon points in dispute between sanitary authorities, or between sanitary authorities and local industries—in so far as these matters relate to the contamination of water; and the heavy expenditure now entailed by costly and often ill-advised litigation, frequently leading to unsatisfactory results, would more than pay for the expert handling of matters in dispute by the central authority.

There can be no difference of opinion upon the fact that the central authority in this matter should be the Local Government Board; and in the legislation which it is sought to promote certain powers in the above-mentioned direction would be given to that Board, and, in addition, measures are introduced to protect the public health against the pollution of shell-fish.

Mr. Burns received the deputation in a most sympathetic spirit, and expressed the hope of being able to introduce a Bill, dealing with matters referred to by the deputation, in the spring of next year.

SIR JAMES HECTOR, F.R.S.

DEATH has removed the last of the four distinguished geologists, F. von Hochstetter, Sir Julius von Haast, F. W. Hutton and Sir James Hector, who together laid the main foundations of the geology of the Dominion of New Zealand.

Sir James Hector was born in Edinburgh on March 16, 1834, and was the son of Alexander Hector, a Writer to the Signet. He was educated at the Edinburgh Academy and University, where he matriculated in 1852, took his degree of M.D. in 1856, and served as assistant to Edward Forbes and to Sir James Simpson. His knowledge of natural history and medicine, and the influence of Murchison, gained him the post of surgeon and naturalist to Captain Palisser's expedition to the Rocky Mountains of British North America. The expedition was in the field from 1857 to 1860, and its best known result was the discovery of the pass by which the Canadian Pacific Railway now crosses from the Great Plains of Canada to the Pacific coast. At the close of the expedition Hector visited the gold-fields of California and northern Mexico, and he reported upon the coal mines of Vancouver Island. On his return to Scotland he wrote a series of papers on the botany, ethnography and physical geography of the Canadian Rocky Mountains, and a paper, of modest length, "On the Geology of the Country between Lake Superior and the Pacific Ocean (between 48° and 56° N. lat.). . . ."

In the year of his return from America he was appointed geologist to the Government of Otago, and there began the main work of his life. He made extensive and arduous journeys through the province of Otago, which still contains the least known and most difficult country in New Zealand. Some of his results were given in 1863 in a New Zealand Parliamentary Paper on "An Expedition to the North-west Coast of Otago," in which he described the discovery of the pass from Martin's Bay to Lake Wakatipu. His success in Otago soon gained Hector promotion from a provincial to a federal appointment. He was made one of the Commissioners for the New Zealand exhibition at Dunedin in 1865, in preparation for which he made a tour through the colony to report on its economic resources; and in the same year he was appointed director of the Geological Survey of New Zealand and of the New Zealand Colonial Museum at Wellington. There, or in his cottage on the Hutt, a few miles away, he lived for more than forty years. During the first half of this time he issued a long series of important contributions to the natural science of New Zealand; their range was wide, for he was director of the zoological museum, the botanical gardens, the meteorological observatory, and the colonial laboratory, as well as of the Geological Survey. He was also for many years Chancellor of the New Zealand University. He nevertheless found time for extensive original researches. He wrote papers on glacial geology, the origin of the rock basins and the volcanic history of New Zealand; his zoological researches were mainly on the Cetacea, seals, and fish, and he wrote on many groups of New Zealand fossils, notably the moas, and on the discovery of the oldest known penguin, Palæeudyptes. He superintended and edited those valuable series of annual reports issued by the Colonial Museum and by the Geological Survey, beginning in 1867, which are the great storehouse of information on New Zealand geology. In 1868 he married the eldest daughter of the late Sir David Monro, who was then Speaker of the New Zealand Parliament. In 1873 he issued a sketch-map of New Zealand geology, of which the edition issued in 1886, with his "Outlines of New Zealand Geology," is still the best available. In 1879 he compiled an official "Handbook of New Zealand," a work of reference of permanent value, of which a fourth edition was issued in 1886. In that year he also wrote his well-known report on the eruption of Tarawera; he maintained that it was not a normal volcanic, but a hydrothermal eruption, due to a vast explosion of the superheated steam with which the ground around Lake Rotomahana was saturated. This view has not been confirmed for the eruption of Tarawera as a whole, but it is probably correct for the particular explosion which blew up Lake Rotomahana and its famous pink and white terraces.

Hector's work had meanwhile gained world-wide recognition. He had been elected a Fellow of the

Royal Society in 1866; he received the Order of the Golden Cross from the Emperor of Germany in 1874, the decoration of C.M.G. in 1875, and promotion to K.C.M.G. in 1887. He was awarded the Lyell medal of the Geological Society in 1875, and a founder's medal from the Royal Geographical Society in 1891. In the same year Hector was elected the third president of the Australasian Association for the Advancement of Science, and delivered his address on the history of scientific work in New Zealand. But after this period his work became less important. He continued to write short papers; the last which we remember is that on the distribution of the moa in New Zealand, in 1901. But he no longer showed his old energy or success, and the staff of the Geological Survey was transferred to the Mines Department. Hector retained his nominal position as director of the Geological Survey until 1903, but for many years he had no control over the Geological Survey work that was being done in New Zealand. He remained director of the Wellington Museum, the condition of which was often made the subject of severe reproach. Hutton publicly complained in 1899 that the plates that had been prepared years before for the monograph of the fossil Cainozoic mollusca and echinoids of New Zealand were never published, and that the valuable collections of fossils that had been made during the geological survey of the colony were "useless as they now exist in the museum of Wellington." In 1903 Hector resigned his appointments; he had for several years previously exercised little influence on scientific work in New Zealand, but the high value and wide range of his own scientific work, and the inspiring example of the energy and administrative capacity, which for so many years he devoted to the service of his adopted land, will secure him one of the foremost places in the roll of distinguished New Zealand pioneers.

J. W. G.

NOTES.

THE following list of those to whom the Royal Society has this year awarded medals was received a few hours too late for insertion in last week's NATURE. The awards of the Royal medals have received the King's gracious approval:—The Copley medal to Prof. A. A. Michelson, of Chicago, For.Mem.R.S., for his investigations in optics; a Royal medal to Dr. E. W. Hobson, F.R.S., for his investigations in mathematics; a Royal medal to Dr. R. H. Traquair, F.R.S., for his discoveries relating to fossil fishes; the Davy medal to Prof. E. W. Morley, of Cleveland, Ohio, for his contributions to physics and chemistry, and especially for his determinations of the relative atomic weights of hydrogen and oxygen; the Buchanan medal to Mr. W. H. Power, C.B., F.R.S., for his services to sanitary science; the Hughes medal to Prof. Ernest H. Griffiths, F.R.S., for his contributions to exact physical measurement; the Sylvester medal to Prof. W. Wirtinger, of Vienna, for his contributions to the general theory of functions.

THE honours announced on the occasion of the King's birthday on Saturday last are chiefly of political interest. Prof. T. Clifford Allbutt, F.R.S., has been appointed a Knight Commander of the Order of the Bath, but he is the only Fellow of the Royal Society we have been able to find in the list. The new knights include Dr. W. H. Allchin, Dr. W. J. Thompson, and Mr. Charles Whitehead, who is associated with scientific agriculture. Dr. A. Theiler, Government veterinary bacteriologist, Transvaal, has been appointed a Companion of the Order of St. Michael and St. George.

FURTHER particulars have reached us relating to the scientific expedition that will this month visit the Auckland Islands and the Campbell Islands, primarily to extend the magnetic survey of New Zealand to their sub-Antarctic outliers, but also to make zoological, geological, and botanical observations and collections. The expedition, as announced in NATURE of October 24 (vol. lxxvi., p. 644), has been arranged by the Philosophical Institute of Canterbury. The Government S.S. *Hinewoa* will take the expedition on the occasion of her annual trip to visit the depôts placed on the islands for shipwrecked mariners. Of the two dozen members, about half will be left on the Auckland Islands and the rest on the Campbell Islands, to be picked up on the return of the steamer. Among the zoologists will be Profs. Benham and Chilton and Mr. E. Waite; botany is represented by Dr. L. Cockayne and others, geology by Dr. P. Marshall and others, while the magnetic observers will be headed by Dr. Coleridge Farr, who has been engaged for the last few years in carrying out the magnetic survey of New Zealand.

A SMALL expedition will proceed from New Zealand in December to the Kermadec Islands. Five young enthusiastic men have arranged to spend twelve months on these uninhabited islands, collecting, observing, and photographing. The results of the expedition will, it is hoped, be worked out by naturalists in New Zealand.

A CHRISTMAS course of illustrated lectures, adapted to a juvenile auditory, will be delivered at the Royal Institution by Sir David Gill, K.C.B., F.R.S., on "Astronomy Old and New." The dates of the lectures are December 28 (Saturday), 31; January 2, 4, 7, and 9, 1908.

THE administration building of the Mount Weather Meteorological Observatory of the Weather Bureau was, *Science* reports, destroyed by fire on October 23. The loss is said to be 5000*l*., including some valuable instruments.

THE *Times* of November 7 reports that Sir Alfred Jones, president of the Liverpool School of Tropical Medicine, has received a communication from Dr. Kinghorn from Serenje, Zambezi. Dr. Kinghorn records the finding of tsetse-flies, and states that the general opinion throughout the country is that they are rapidly extending. Otherwise the country is singularly free from insect pests. So far, sleeping sickness has not appeared in the district.

A PAPER on disease prevention in the Territorial Army, with a proposed scheme for placing medical officers of health in relation to it, was read on November 8 by Sir Alfred Keogh, Director-General of Army Medical Staff, before the Society of Medical Officers of Health. He explained why an organised military department of sanitation must be called into existence. If in the Territorial Force the work involved is not done in time of war by those who constantly deal with kindred problems in time of peace, it cannot be efficiently done at all. He proposed to ask the medical officers of health of the country to combine in a voluntary organisation, having for its object the preservation of the health of the men who may one day be required to defend the country; to enrol themselves in the Medical Corps of the Territorial Force; to undertake voluntarily the duty of considering the problems to be solved during active operations within their own home area; to be ready to place their knowledge at the disposal of the authorities commanding their divisions of the Territorial Forces. The sanitary department of the Medical Corps would further consist of non-commissioned officers and men detailed to join battalions for the technical duties of water sterilisation, for disinfection, &c.

SOME interesting facts on the continued falling off in the production of natural indigo were given at a recent meeting of the Society of Chemical Industry by Mr. R. J. Friswell, chairman of the society. From Government returns it appears that for the five years ended 1904–5 the total acreage in India devoted to this cultivation was 755,900 acres. In 1905–6 this had fallen to 330,400 acres, or to less than 44 per cent. of its former area. By 1906–7 it had fallen further to 329,800 acres. Meanwhile, the production of synthetic indigo is advancing by leaps and bounds. No statistics are available as to the actual quantity made by foreign factories, but the imports into our own islands may be taken as a fair index. In 1905 synthetic indigo amounting to 32,246 cwt. was imported. In 1906 this increased to 39,042 cwt., an increase of 21 per cent. During the same years the imports of natural indigo were 8201 cwt. and 7641 cwt. respectively, a decrease of 6·8 per cent. Mr. Friswell thinks that natural indigo will for some years to come occupy a place in the world's market. Planters have, therefore, a breathing time to improve their methods, both biologically and chemically—biologically by improving the content of the plant, chemically by improving the methods of winning the indigo and making its quality constant.

THE International Congress on Tuberculosis will be held in Washington, D.C., from September 21 to October 12, 1908. We have received a preliminary announcement from the National Association for the Study and Prevention of Tuberculosis, which has been entrusted with the organisation of the congress. Dr. Frank Billings is the president of the National Association, and Mr. Roosevelt, Mr. Grover Cleveland, and Prof. William Osler are honorary vice-presidents, Dr. John P. C. Foster and Dr. Mazÿck P. Ravenel being the vice-presidents, and Dr. H. B. Jacobs the secretary. The association has appointed a special committee on the International Congress, of which Dr. Lawrence F. Flick, of Philadelphia, is chairman, and Dr. Joseph Walsh, of Philadelphia, secretary. The congress will be divided into seven sections, as follows:—Section i., pathology and bacteriology, president, Dr. William H. Welch, of Baltimore; section ii., clinical study and therapy of tuberculosis—sanatoria, hospitals, and dispensaries, president, Dr. Vincent Y. Bowditch, of Boston; section iii., surgery and orthopedics, president, Dr. Wm. J. Mayo, Rochester, Minn.; section iv., tuberculosis in children, etiology, prevention and treatment, president, Dr. Abraham Jacobi, of New York; section v., hygienic, social, industrial, and economic aspects of tuberculosis, president, Dr. Edward T. Devine, of New York; section vi., State and municipal control of tuberculosis, president, Surgeon-General Walter Wyman, of Washington, D.C.; section vii., tuberculosis in animals and its relations to man, president, Dr. Leonard Pearson, of Philadelphia. The section work of the congress will be carried on in the week September 28 to October 3. During that week there will be two general meetings. A tuberculosis exhibition will be open during the whole time of the congress.

MAYFIELD'S CAVE, Indiana, owing to its short distance (4½ miles) from the University laboratory, was recently selected for systematic exploration, both physiographically and faunistically. The results of this survey form the subject of a paper by Mr. A. M. Banta published by the Carnegie Institution of Washington. In the summary it is pointed out that small caves contain, as a rule, practically the whole cavern-fauna of the district in which they occur, while reference is also made to the probable origin of cave-animals.

OWING to the fact that radical structural differences, constant through large groups, are very few, while minor group-characters, in countless unexpected directions, are extremely numerous and varied, the beetles of the family Tenebrionidæ have always been extremely troublesome to the systematic entomologist. Confronted with this difficulty, Mr. T. L. Casey, in proposing a revised classification of the American representatives of the subfamily Tentyriinæ (Proc. Washington Acad., vol. ix., pp. 276–522), states that he does so with diffidence, although expressing the hope that he is on the right track.

ACCORDING to the report for the year ending on June 30, the Manchester Museum has received a bequest of books and money from the late Mr. Mark Stirrup, many years secretary to the local Geological Society. The interest of the monetary bequest (the first the museum has received) is to be devoted to the improvement of the geological collections. During the year, Prof. Hickson completed his account of the alcyonarian zoophytes obtained during the Antarctic expedition, and likewise identified and described a number of representatives of the same group obtained during the cruise of the *Huxley* in the Bay of Biscay.

OF late years the attention of naturalists interested in the phylogeny of the Insecta has been turned to the Symphyla, a group of arthropods apparently exhibiting to a certain extent characters common to millipedes, centipedes, and thysanurous insects. In the hope of further elucidating the generalised affinities of the Symphyla, Mr. S. R. Williams has therefore investigated the life-history of an American member of the group, *Scutigerella immaculata*, especially in reference to the eggs and the young larvæ, the results of which are published in the Proceedings of the Boston Society of Natural History, vol. xxxiii., pp. 461–485. In possessing seven pair of legs and ten dorsal scales, the larval Scutigerella more nearly resembles the adult than is the case with any diplopod of which the early history is known to the author, and it is therefore regarded as a highly specialised type rather than a generalised ancestral form, such as the hexapod larvæ of other diplopods are generally considered.

A MONOGRAPH of the genus Lepidium, prepared by Dr. A. Thelling, has been published in vol. xli. of the *Neue Denkschriften der schweizerischen naturforschenden Gesellschaft*. It consists of two parts, the first dealing with synonymy and morphology, the second with the classification of the species. The author splits the genus into five sections, differing slightly from the arrangement proposed by Prantl. The sections are distinguished primarily by the character of the fruit, whether winged or plain, and by the relative length and position of the style compared with the wing. Under morphology the variations in the number and position of the stamens and honey glands are noted; among the fruits, the three-valved capsule borne by a variety of *Lepidium sativum* is peculiar. The species are arranged in three geographical groups, comprising species from Europe, Asia and Africa, from America, and from Australia.

A REPORT on the prevention of malaria in British possessions, Egypt, and parts of America, presented by Prof. Ronald Ross to section vii. of the fourteenth International Congress of Hygiene and Demography, held at Berlin in September, has been reprinted from the *Lancet* of September 28 and issued in pamphlet form. In this report Prof. Ross sums up, so far as possible with the imperfect data at his disposal, the results of anti-malaria measures in British possessions. "The ideal procedure for towns in the tropics consists (1) in the removal of mosquito-breeding waters; (2) in the treatment of old cases of malaria with quinine; and (3) in the protection, as an additional safeguard, of hospitals, barracks, jails, and as many houses as possible with wire gauze. To these we must add, as insisted upon by Stephens and Christophers, the principle of segregation of Europeans." The campaign at Ismailia has been the most successful one on record, so that in 1906 the Suez Canal Company officially reported that "toute trace de paludisme a disparu d'Ismailia." In this campaign the result is due to mosquito reduction, and also largely to cinchonisation. This example is all the more conclusive because statistics have existed for many years back. Successful and partially successful results have been obtained from many other districts, notably Klang and Port Swettenham, Hong Kong and Khartoum, and especially at Havana and Panama. Many of these results are hard to estimate on account of the insufficient data. That malaria can be stamped out—given the money—under almost any conditions can hardly be doubted; but for those who have doubts an experiment carefully planned, with all statistics carefully controlled and subject to criticism before, during, and after the experiment, would do much to remove prejudices which still exist.

THE Department of Agriculture in the United States has for some time advocated the sowing of early varieties of cotton in districts where the boll weevil flourishes. Another measure for reducing the pest, recommended in Circular No. 95, prepared by Mr. W. D. Hunter, consists in uprooting the cotton plants in the autumn as soon as the crop is cut off by the weevils; many weevils are thereby prevented from developing, and especially those which pass the winter and attack the next season's crop. It is further recommended that the plants be ploughed up and burnt.

MR. C. A. BARBER has contributed to the Memoirs of the Department of Agriculture in India, vol. i., No. 1, the second part of his investigation of the haustorium of *Santalum album*, the sandal-wood tree. The essential parts of the sucker are the cortical folds with which it grips the host root and the central core by which it penetrates. Vessels are developed around the core and in the upper part of the sucker, but there is discontinuity between them. No true bast is formed in the haustorium. The inter-relation between parasite and host is often remarkable. Sometimes the root is fiercely attacked, as in the case of *Cassia auriculata*; in other cases the parasite is unable to penetrate, as in Zizyphus. The haustorium may even attack another sandal root, when a fusion results, or a great struggle takes place.

THE greater part of the last issue of the *Kew Bulletin* (No. 9) is given up to an interesting account, communicated by Prof. H. H. W. Pearson, of a journey from Walfish Bay to Windhuk. The author distinguishes a botanical area of Walfish Bay where *Nicotiana glauca*, an Argentine colonist, and the native *Tamarix articulata* grow on the flats, and the cucurbitaceous plant *Acanthosicyos horrida* inhabits the sand dunes. The last-named exhibits a marvellous power of absorbing water and storing it in the stems thickly coated with cork. The dunes give place to a tableland, the "Namib," where *Zygophyllum Stapfii* is prominent. This is also the restricted habitat of Welwitschia. Further inland from Usakos to Winterhuk an Acacia park forest occurs. In the same volume the decade of "Diagnoses Africanæ" contains two new genera, Cordeauxia, a leguminous plant from Somaliland, and Peglera, a genus referred doubtfully to the Rhizophoraceæ.

THE Bulletin of the Italian Geographical Society, vol. viii., No. 10, contains a report on the establishment of meteorological stations at the following towns in Asia Minor:—Marash, Urfa, Diarbekir, Mesereh, Calat Scergat, and Babilonia.

FURTHER observations on the anomaly of the recession and progression of Alaskan glaciers are published by Dr. Otto Klotz in the *Geographical Journal* for October (vol. xxx., No. 4). The "Johns Hopkins" glacier has receded nearly seven miles during thirteen years, whereas the adjacent "Grand Pacific" has receded only about three and a half miles during the same period. Dr. Klotz emphasises the need for more observations of the Alaskan glaciers.

THE disputed question of the appearance of icebergs near the Orkney Islands in 1836 has been again raised by Prof. O. Krümmel in the *Zeitschrift der Gesellschaft für Erdkunde*, No. 7, 1907. Assisted by the marine superintendent of the Meteorological Office in London, Dr. Krümmel has published an extract from the log-book of S.M.S. *Cove* which seems to prove conclusively that two large icebergs were actually observed in the vicinity of the Orkney Islands in January, 1836.

AN ingenious instrument, termed a horticultural hygrometer, has been designed by Messrs. Negretti and Zambra. Buchan and Scott have shown that a knowledge of the temperature of the dew point in the late evening would enable gardeners and others to form a fair estimate of the probable minimum temperature to be expected, as it cannot easily fall below the dew point which existed at nightfall. The instrument in question makes use of this knowledge; it consists of dry- and wet-bulb thermometers, and of a cylindrical scale based upon the relation of the dew point to the difference of the readings of the thermometers. By turning the scale to correspond to this difference, it is seen at once from the position of the wet-bulb reading upon it, without the use of tables, whether the dew point is below freezing, and consequently whether frost may be expected. So far, however, as regular meteorological observers are concerned, we presume that they would probably prefer to rely on the use of simple hygrometrical tables.

THE thick fogs which have prevailed over so large a part of the country of late, and have been more than usually dense in London for so early in the season, have given prominence to the question of the dispersion of fog. A scheme invented by M. Demetrius Maggiora, by which a series of atmospheric vibrations are set up by means of explosions of acetylene or other gas in a strong steel cannon about 60 feet high and 6 feet in diameter, has been under the consideration of the Public Control Committee of the London County Council. Before committing themselves to any action on the subject, the director of the Meteorological Office, Dr. W. N. Shaw, F.R.S., has consented to examine and report upon the proposal and its suitability to the atmospheric conditions of London, and a report on the subject is anticipated at an early date.

SOME South African Tardigrada form the subject of a paper by Mr. James Murray in the Journal of the Royal Microscopical Society for October. The material for the paper was received from Mr. W. Milne, of Uitenhage, Cape Colony, in the form of gatherings of moss containing bdelloid rotifers. It yielded eight species of Echiniscus, five of Macrobiotus, and the one known species of Milnesium. Eight of the fourteen species were distinct from any species previously known.

Herbert Spencer's claims as a mathematician form the subject of discussion and criticism at the hands of Dr. J. S. Mackay in the Proceedings of the Edinburgh Mathematical Society (xxv.). The author, referring to the geometrical theorems which Spencer claimed to have discovered, shows that these were well known before Spencer's time, and were not very clearly or lucidly enunciated by Spencer himself. An account of Spencer's views of antipathy towards the metric system and his advocation of the duodecimal system are also given, but his present critic considers that "his outfit of mathematical (or indeed any other) knowledge was both slender and scrappy."

The occurrence of spinel in blast-furnace slags appears to have been first determined in 1880 by Muirhead, who found that highly aluminous slags left a proportion of very intractable residue, varying from 5 per cent. to $17\frac{1}{2}$ per cent. of the whole weight. This when analysed proved to be spinel with about one-third of the magnesia replaced by iron. An interesting instance of the occurrence of spinel in a Hungarian blast-furnace slag is recorded in an abstract of a paper by Mr. J. Krenner in the October issue of the Journal of the Chemical Society. In a white, enamel-like slag obtained on smelting iron ores rich in manganese, very hard brown octahedral crystals were found. The analysis is in accord with the spinel formula; but this spinel contains more manganese than any artificial or natural member of the spinel group hitherto analysed.

Mr. G. H. Gulliver has contributed to the Proceedings of the Institution of Mechanical Engineers (1907, pp. 519–524) a paper on some phenomena of permanent deformation of metals, the object of which is to correct a hypothesis suggested in a previous paper in 1905 to explain the origin of the "contractile cross." It was then suggested that while the somewhat analogous "Lüders' lines" were due to slipping of the elementary crystals within the crystalline grains of the metal, the contractile cross was the result of the slipping of the irregular crystalline grains themselves over each other. It is now established that for aluminium, and probably for other ductile metals, the phenomena of constriction and fracture are due to excessive "slip-band" deformation, and that the contractile cross passes through the crystalline grains of the metal. It is somewhat influenced by the degree of coarseness of the crystalline structure, but is independent of the directions of the boundaries of the crystalline grains.

A comprehensive review of the design, construction, and performance of the Cunard turbine-driven quadruple-screw Atlantic liner *Mauretania* is given in *Engineering* of November 8. The description is accompanied by 186 illustrations, many of which are two-page plates. A similar description was recently published of the *Lusitania*. The *Mauretania* and the *Lusitania* are sister-ships. They are, however, the production of different firms, and differ in numerous details, and particular attention is given in the description to these variations. The *Mauretania*, which has a length over all of 790 feet, a length between perpendiculars of 760 feet, a breadth of 88 feet, a depth, moulded, of 60 feet 6 inches, a gross tonnage of 32,000 tons, and a draught of 33 feet 6 inches, carries 563 first-class passengers, 464 second-class, and 1138 third-class. The average speed on the sea-going trial was 26·03 knots for 1200 miles.

A simple method of generating an alternating current of any desired frequency is described by Dr. Rudenberg in the *Physikalische Zeitschrift* for October 15. It consists in placing a capacity, and if necessary an inductance, in series with a series-wound dynamo, and running the machine in the ordinary way. The frequency of the current produced is determined by the capacity and inductance of the circuit, while the power is derived from the machine, which should have its field magnets laminated. A slight modification of the arrangement converts it into a sensitive receiver for wireless telegraphy.

The *Verhandlungen der deutschen physikalischen Gesellschaft* for September 30 contains an extensive study, by Mr. L. W. Austin, of the conditions which influence the production of rapid electrical oscillations by means of the arc. He finds it possible to generate with carbon, or better with graphite, electrodes currents having frequencies of several hundred thousand per second, which, however, are not sinusoidal. The frequency with a direct-current arc increases with the current strength and with diminution of the arc length, but seems to be independent of the intensity of the oscillations. The effect is greatly increased by running the arc in hydrogen. The author recommends for telegraphic work an arc between silver or copper electrodes in air at about six atmospheres pressure, which possesses many of the properties of a rapid spark discharge, and allows a considerable resistance to be introduced into the shunt circuit.

An important contribution to the study of the chemical changes occurring when air is submitted to the influence of electricity is contained in a paper by E. Warburg and G. Leithäuser in the *Annalen der Physik* (vol. xxiii., p. 210). It is shown that, contrary to the general opinion held hitherto, nitrogen pentoxide is always formed as well as ozone when air is subjected to the so-called "silent" discharge. The action of ozone on nitrogen pentoxide gives a strongly coloured gas "Y" having the same absorption spectrum as the substance supposed by Hautefeuille and Chappuis to be N_2O_6; the amount of "Y" formed is, however, always small in comparison with the quantity of nitrogen pentoxide present, a fact which makes it doubtful whether "Y" really has the composition N_2O_6 as first supposed, when the assumption was made that it was the only oxide of nitrogen produced by the discharge. Measurements are given of the absorption of light by the substance "Y" in the region of the visible spectrum, and also of the absorption by nitrogen pentoxide in the infra-red. The prominence of an absorption band at $5{\cdot}75\ \mu$ in the latter case affords a very delicate means of detecting nitrogen pentoxide when present with other oxides of nitrogen.

The Industrial Society of Mulhouse has issued a programme of prizes to be awarded by the society during the year 1908. The subjects open for competition this year remain practically the same as those for 1906, already summarised in Nature (vol. lxxiii., p. 164), but a few minor alterations have been introduced. The programme can be obtained on application to the secretary at Mulhouse.

Mr. Gustav Fischer, Jena, has just published the fourth revised edition of Prof. W. Kükenthal's "Leitfaden für das zoologische Praktikum." A short section on spiders has been added after the chapter on insects. The character of the work was described in a review of the second edition published in Nature of April 24, 1902 (vol. lxv., p. 581).

The process of transmitting photographs by electricity devised by Prof. Korn, of Munich, and described in Nature of August 29 (vol. lxxvi., p. 445), has been adopted by the *Daily Mirror* for use between London and Paris. A demonstration of the methods and results obtained by this process was given at the offices of that journal on Thursday last, November 7.

A SECOND edition, revised and enlarged, of Prof. Prafulla Chandra Rây's "History of Hindu Chemistry, from the Earliest Times to the Middle of the Sixteenth Century A.D., with Sanskrit Texts, Variants, Translation and Illustrations," has been published by Messrs. Williams and Norgate. The book appeared first in 1902, and was reviewed in the issue of NATURE for May 21, 1903 (vol. lxviii., p. 51). Some material additions have been made to the historical portion of the introduction, throwing further light on the independent origin of the Hindu system of medicine and its priority to that of the Greeks.

THE second volume of the French translation of the third English edition of Mr. W. W. Rouse Ball's "History of Mathematics" has been published by M. A. Hermann, of Paris. The price is 8 francs. The translation is the work of M. L. Freund. The volume has been edited with additions by Dr. R. de Montessus, while M. G. Darboux's paper entitled "Étude sur le Développement des Méthodes géométriques," read at the St. Louis Congress in 1904, is appended. From the same publishers we have received a copy of the second French edition—the work of Mr. J. FitzPatrick—of part iii. of Mr. Rouse Ball's "Mathematical Recreations and Essays"; the translation follows the fourth English edition, and has been enlarged by the inclusion of numerous additions.

MESSRS. GEORGE BELL AND SONS have published a third edition of "A Laboratory Outline of General Chemistry," by Prof. Alexander Smith, professor of chemistry in the University of Chicago, which has been revised in collaboration with Mr. William J. Hale. The first edition of the book was reviewed in our issue for November 9, 1899 (vol. lxi., p. 27). In the preface to the present edition, the authors remark:—"In the effort to make misapprehensions and mistakes as nearly impossible as may be, the directions have been entirely re-written, and in many cases have been amplified, and a number of the experiments have been modified. An entirely new set of figures has also been drawn. To render the exercises more instructive, and still further to discourage mechanical work, a larger number of questions has been inserted."

OUR ASTRONOMICAL COLUMN.

OCCULTATION OF NEPTUNE BY THE MOON.—Dr. Downing directs our attention to an accidental omission from the Nautical Almanac for 1907, of which he publishes particulars in No. 389 (p. 412, November) of the *Observatory*. The data omitted were the particulars of two occultations of Neptune by the moon, due to take place on November 23 and December 20 respectively, and visible at Greenwich; they are as follow:—

Date 1907	Disappearance				Reapp arance			
	Time		Angle from		Time		Angle from	
	Sidereal	Mean	N. point	Vertex	Sidereal	Mean	N. poin	Vertex
	h. m.	h. m.	°	°	h. m.	h. m.	°	°
Nov. 23	1 4	8 57	131	171	1 47	9 40	218	260
Dec. 20	11 14	17 20	180	138	11 23	17 29	195	153

THE IMPROVEMENT OF CELESTIAL PHOTOGRAPHIC IMAGES.—In No. 31 (September 10) of the Lowell Observatory Bulletins, Prof. Lowell describes a method of combining the use of colour screens and isochromatic plates in the photography of Mars, whereby he has succeeded in obtaining much sharper images of the planet's details. In the first instance, it was seen that the colour curve for the 24-inch object-glass was much flatter in the yellow region, about λ 5600, than elsewhere, and further that the inclination of the curve was much greater on the blue than on the red side of the yellow region. To obtain maximum efficiency, then, it seemed necessary to exclude those rays more refrangible than λ 5000, and to bathe the plates so that the orange and red radiations should become more effective. Accordingly, Mr. Wallace was asked to construct screens which would absorb the rays of lower wavelength than λ 5000, and a Seed "23" plate, bathed with pinachrome and pinacyanol, was exposed in conjunction with the screen. This, however, was unsuccessful, and Prof. Lowell then tried Cramer instantaneous isochromatic plates having sharp maxima at λ 4600 and λ 5650. Using the orange screen, which cut out the λ 4600 maximum, very successful photographs were obtained, and Prof. Lowell hopes that during the opposition of Mars in 1909 this method will produce much better photographs than those already obtained. He places on record that one of his plates taken at the recent opposition showed a canal which had hitherto escaped detection, but was seen for the first time on examining the planet next night.

THE GREAT RED SPOT ON JUPITER.—The acceleration of the Great Red Spot on Jupiter is discussed by Mr. Denning in the *Observatory* for November (p. 411, No. 389), who points out that while the acceleration could be accounted for by the passage of the great S. temperate spot when this occurred, as in 1906, some other explanation must be sought for the acceleration during the past summer, when the S. temperate spot was on the opposite side of the disc to the red spot. Mr. Denning hints at the possibility of there being a minor acceleration when the two objects are in opposition, and indicates the necessity for further careful observations. The S. temperate spot has been visible since 1901, and seems likely to continue so for many years; it was in conjunction with the red spot in May, 1906, and will be so again in April-May, 1908.

RED STARS NEAR NOVA VELORUM.—On examining a plate taken with the 24-inch Bruce telescope on June 6, Mrs. Fleming found the spectrum of a new gaseous nebula, which on further examination proved to be the spectrum of Nova Velorum. This plate includes the region

R.A. 10h. 36m. to 11h. 23m., dec. -51° to -57° (1875),

and shows so many interesting spectra characteristic of red stars that Prof. Pickering publishes a list, in Circular No. 131, giving the C.P.D. designation, the position, the magnitude, and the spectral type of some thirty-four of the included objects. The spectrum of Nova Velorum includes seven bright lines at λλ 5013, 4926, 4862, 4643, 4611, 4340, and 4101 respectively, six of which appear to coincide with bright lines in the later spectrum of Nova Persei. The strong helium line at λ 4472, which was bright in Nova Persei (No. 2), is, however, absent from Nova Velorum.

THE SYSTEMATIC ERROR OF LATITUDE OBSERVED WITH A ZENITH TELESCOPE.—From his observations of latitude at Berlin, Herr Battermann found a systematic difference between the latitudes observed by the east-to-west and the west-to-east positions of the zenith telescope. In No. 4207 of the *Astronomische Nachrichten* (p. 97, October 17) Mr. K. Hirayama, of the Tokyo Observatory, discusses this error, basing his conclusions on the results obtained at various stations, and finds that the difference appears to vary with the zenith-distance. As to how the declination of the observed star can affect the reading of the micrometer requires further investigation, but Mr. Hirayama suggests that it may be a physiological effect produced by the varying speed of the star in the field.

INEQUALITIES IN THE MOTION OF THE MOON.[1]

THE most interesting result of Prof. Newcomb's researches on the planetary inequalities in the moon's motion is that he has found $1''\cdot 14$ as the theoretical coefficient of the Jupiter evection term. This term was discovered empirically by Prof. Newcomb in 1876, and Mr. Nevill assigned its origin to Jupiter. Dr. Hill and Radau independently computed its coefficient as $0''\cdot 9$. Two or three years ago it was pointed out that the observations indicated a coefficient $1''\cdot 1$, and now Prof. Newcomb has obtained the same result by theory. This term is now worked out; the subject begins and ends with Prof. Newcomb, and has lasted thirty-one years. No indication is given in the memoir before us as to why Hill and Radau concurred in an imperfect value. It was a curious incident, as we know of no other case where any result of either of these two mathematicians has required revision.

In order to illustrate the methods of the memoir, we briefly indicate the process of calculating the Jupiter evection term.

First Stage.—Using the ordinary notation supplemented by $\alpha = \log a$, Prof. Newcomb starts from Delaunay, vol. ii., pp. 235–6 and 800, and obtains on p. 19 the equations of variation

$$\frac{d}{d(nt)}\alpha = \frac{a}{\mu}\left(\alpha_1\frac{\partial P_1}{\partial l} + \alpha_2\frac{\partial P_1}{\partial \pi} + \alpha_3\frac{\partial P_1}{\partial \theta}\right)$$
$$\frac{d}{d(nt)}e = \frac{a}{\mu}\left(e_1\frac{\partial P_1}{\partial l} + e_2\frac{\partial P_1}{\partial \pi} + e_3\frac{\partial P_1}{\partial \theta}\right)$$
$$\frac{d}{d(nt)}\gamma = \frac{a}{\mu}\left(\gamma_1\frac{\partial P_2}{\partial l} + \gamma_2\frac{\partial P_1}{\partial \pi} + \gamma_3\frac{\partial P_1}{\partial \theta}\right)$$
$$\frac{d}{d(nt)}l_0 = -\frac{a}{\mu}\left(\alpha_1\frac{\partial P_1}{\partial \alpha} + e_1\frac{\partial P_1}{\partial e} + \gamma_1\frac{\partial P_1}{\partial \gamma}\right)$$
$$\frac{d}{d(nt)}\pi_0 = -\frac{a}{\mu}\left(\alpha_2\frac{\partial P_1}{\partial \alpha} + e_2\frac{\partial P_1}{\partial e} + \gamma_2\frac{\partial P_1}{\partial \gamma}\right)$$
$$\frac{d}{d(nt)}\theta_0 = -\frac{a}{\mu}\left(\alpha_3\frac{\partial P_1}{\partial \alpha} + e_3\frac{\partial P_1}{\partial e} + \gamma_3\frac{\partial P_1}{\partial \gamma}\right)$$

P_1 being the potential of the disturbing forces.

He also gives (p. 18) the numerical values of α_1, &c., as follows:—

$$\alpha_1 = +2\cdot 0228 \quad e_1 = \quad 0\cdot 0168 \quad \gamma_1 = -0\cdot 0229$$
$$\alpha_2 = -0\cdot 0301 \quad e_2 = -19\cdot 1534 \quad \gamma_2 = -0\cdot 0200$$
$$\alpha_3 = +0\ 0075 \quad e_3 = +\ 0\cdot 0026 \quad \gamma_3 = -5\cdot 5700$$

Second Stage.—Neglecting certain small terms, we have for the potential of the direct action of a planet

$$\frac{a}{\mu}P_1 = MK\,(\xi^2-\eta^2)\quad \tfrac{1}{2}MC\,(\rho^2-3\zeta^2) + MD2\xi\eta,$$

and a similar form for the potential of the indirect action

$$\frac{a}{\mu}P_1 = -m^2G(\xi^2-\eta^2) - m^2J(\rho^2-3\zeta^2) + m^2I2\xi\eta.$$

For brevity, the sum of the two may be written

$$\frac{a}{\mu}P_1 = 10^{-3}K'(\xi^2-\eta^2) - 10^{-3}C'(\rho^2-3\zeta^2) + 10^{-3}D'2\xi\eta.$$

In the above formulæ, ξ η, ζ, denote the lunar coordinates divided by the moon's mean distance, the axis of ξ being directed towards the mean sun;

$$\rho^2 = \xi^2 + \eta^2 + \zeta^2;$$

and the coefficients MK, MC, MD, m^2G, m^2J, m^2I are known functions of the positions of the earth and the disturbing planet in their orbits. Of these six coefficients, the expansion of the first three in the form

$$\Sigma\,{}^{\cos}_{\sin}\, i(g_4 - g') + jg',$$

i, j being integers, is exceedingly troublesome, and the expansion of the other three assumes that the mutual perturbations of the earth and planet have been calculated.

We are going to illustrate the methods of the memoir by considering as an example the perturbations arising from terms in P_1 with argument

$$2\pi - 2J \text{ or } 2D - 2g + 2g' - 2J.$$

[1] "Investigation of Inequalities in the Motion of the Moon produced by the Action of the Planets." By Simon Newcomb, assisted by Frank E. Ross. Pp. viii+160. (Washington: The Carnegie Institution, 1907).

Such a term may arise in P_1 by combining a lunar argument $2D - 2g + jg'$ with a planetary argument

$$-jg' + 2g' - 2J,$$

j being given any integral value; but we will confine our attention to the case $j = 0$, which gives rise to the only sensible term of the whole number.

We require, therefore, to pick out the planetary terms with argument $2J - 2g' = N_4$, and the lunar terms with argument $2D - 2g = N$.

The following extracts from the memoir cover the first part of the work:—

From p. 85, Table XXII.:—

$$10^3MK = +6''\cdot 119 \cos N_4 + 0''\cdot 006 \sin N_4$$
$$\tfrac{1}{2}10^3MC = -0''\cdot 293 \cos N_4 + 0''\cdot 001 \sin N_4$$
$$10^3MD = -0''\cdot 005 \cos N_4 + 6''\cdot 114 \sin N_4$$

From p. 97, Table XXXIII.:—

$$10^3m^2G = -24\cdot 668 \cos N_4 - 0''.358 \sin N_4$$
$$10^3m^2J = -\ 8\cdot 096 \cos N_4 - 0''\cdot 061 \sin N_4$$
$$10^3m^2I = +\ 0\cdot 363 \cos N_4 - 23''\cdot 488 \sin N_4$$

Hence by addition, p. 145, Table XLV.,

$$K' = +30''\cdot 81 \cos N_4 + (0''\cdot 38 \sin N_4)$$
$$C' = -\ 8''\cdot 39 \cos N_4 - (0''\cdot 06 \sin N_4)$$
$$D' = (+0''\cdot 35 \cos N_4) - 17''\cdot 37 \sin N_4$$

It will soon appear that the six terms of K′, C′, D′ fall into two groups of three; one group of three is indicated by brackets, and will not be proceeded with, as the other and more important group suffices for illustration.

Third Stage.—With the notation (see p. 24)

$$\xi^2 - \eta^2 = 2p \cos N$$
$$\rho^2 - 3\zeta^2 = 2q \cos N$$
$$2\xi\eta = k \sin N$$

we extract from Table XL., p. 112, for this argument $N = -2g + 2\lambda - 2\lambda' = 2D - 2g = 2\pi - 2g'$, the values

$$2p = +0\cdot 007\ 809 \quad 2\frac{\partial p}{\partial \alpha} = +0\cdot 000\ 30 \quad 2\frac{\partial p}{\partial e} = +0\cdot 284\ 09$$
$$2q = +0\cdot 001\ 807 \quad 2\frac{\partial q}{\partial \alpha} = +0\cdot 003\ 73 \quad 2\frac{\partial q}{\partial e} = +0\cdot 065\ 69$$
$$k = +0\cdot 007\ 185 \quad \frac{\partial k}{\partial \alpha} = -0\cdot 000\ 60 \quad \frac{\partial k}{\partial e} = +0\cdot 261\ 69$$

and we note that the differentials with regard to γ are insensible.

These expansions are derived partly from Delaunay's lunar theory and partly from Brown's.

Fourth Stage.—In the differential equations of variation put $\frac{a}{\mu}P_1 = 2p \cos N$.

$$\frac{d}{d(nt)}\alpha = -2p \sin N.\alpha_0 \text{ where } \alpha_0 = \iota\alpha_1 + \iota'\alpha_2 + \iota''\alpha_3$$

(ι ι', ι'', are the coefficients of l, π, θ in N, or $2\pi - 2g'$, so that $\iota' = 2$, $\iota = \iota'' = 0$).

Similarly,

$$\frac{d}{d(nt)}e = -2p \sin N.e_0 \text{ where } e_0 = \iota e_1 + \iota' e_2 + \iota'' e_3.$$

We shall drop the equation for γ, and extract from Table XLVII., p. 146, the values

$$\alpha_0 = -0\cdot 0602 \quad e_0 = -38\cdot 307,$$

as may be easily verified from the values of $2\alpha_2$ and $2e_2$ at the beginning of this article.

From Table XLVIII., p. 147, we extract values of products of $p\ q\ \frac{1}{2}k$ by α_0 and e_0:—

$$\alpha_0 p = -0\cdot 000\ 235 \quad \alpha_0 q = -0\cdot 000\ 054 \quad \tfrac{1}{2}\alpha_0 k = -0\cdot 000\ 216$$
$$e_0 p = -0\cdot 149\ 20 \quad e_0 q = -0\cdot 034\ 28 \quad \tfrac{1}{2}e_0 k = -0\cdot 137\ 90$$

Again, noting that

$$\frac{a}{\mu}\frac{\partial P_1}{\partial \alpha} = \left(2 + \frac{\partial}{\partial \alpha}\right)\left(\frac{a}{\mu}P_1\right)$$

$$-\frac{d}{d(nt)}l_0 = \left\{\alpha_1\left(4p + 2\frac{\partial p}{\partial \alpha}\right) + e_1 2\frac{\partial p}{\partial e} + \gamma_1 2\frac{\partial p}{\partial \gamma}\right\}\cos N = 2L'\cos N$$
$$-\frac{d}{d(nt)}\pi_0 = \left\{\alpha_2\left(4p + 2\frac{\partial p}{\partial \alpha}\right) + e_2 2\frac{\partial p}{\partial e} + \gamma_2 2\frac{\partial p}{\partial \gamma}\right\}\cos N = 2P'\cos N,$$

we shall drop the equation for θ_0, and noting that when q and k respectively replace p, then L′, P′ become in Prof. Newcomb's notation L″, P″ and L_4, P_4.

From Table XLIX., p. 147, we extract :—

$$L' = +0\cdot013\ 67 \quad 2eP' = -0\cdot298\ 75$$
$$L'' = +0\cdot006\ 84 \quad 2eP'' = -0\cdot069\ 08$$
$$L_4 = +0\cdot023\ 51 \quad eP_4 = -0\cdot275\ 19$$

In Prof. Newcomb's value of L′ we think a small error (about 0·00020) has been introduced.

Now putting

$$\begin{aligned} \frac{a}{\mu}P_1 = &\ K_c' \cos N_4\ 2p \cos N \\ & - C_c' \cos N_4\ 2q \cos N \\ & + D_s' \sin N_4\ \ k \sin N \end{aligned}$$

we get

$$\begin{aligned} -\frac{d}{d(nt)} l_0 &= (2K_c'L' - 2C_c'L'' = 2\lambda_1) && \cos N_4 \cos N \\ & \quad + D_s'L_4 && \sin N_4 \sin N \\ -\frac{d}{d(nt)}\pi_0 &= \left(2K_c'P' - 2C_c'P'' = \frac{2\pi_1}{e}\right) && \cos N_4 \cos N \\ & \quad + D_s'P_4 && \sin N_4 \sin N \\ \frac{d}{d(nt)}\alpha &= (-2K_c'\alpha_0 p + 2C_c'\alpha_0 q = 2a_2) && \cos N_4 \sin N \\ & \quad + D_s'\alpha_0 k && \sin N_4 \cos N \\ \frac{d}{d(nt)} e &= (-2K_c'e_0 p + 2C_c'e_0 q = e_2) && \cos N_4 \sin N \\ & \quad + D_s'e_0 k && \sin N_4 \cos N. \end{aligned}$$

At this point we shall reject the terms in $N+N_4$ and write

$$\begin{aligned} -\frac{d}{d(nt)} l_0 &= (\lambda_1 + \tfrac{1}{2}D_s'L_4 = h_{l,c'}) \cos(N - N_4) \\ -e\frac{d}{d(nt)}\pi_0 &= (\pi_1 + \tfrac{1}{2}D_s'eP_4 = eh_{\pi,c'}) \cos(N - N_4) \\ \frac{d}{d(nt)}\alpha &= (a_2 - \tfrac{1}{2}D_s'\alpha_0 k = h_{\alpha,s'}) \sin(N - N_4) \\ \frac{d}{d(nt)} e &= (\tfrac{1}{2}e_2 - \tfrac{1}{2}D_s'e_0 k = h_{e,s'}) \sin(N - N_4). \end{aligned}$$

Putting $\nu' = \dfrac{\text{mean motion of moon}}{\text{mean motion of } N - N_4}$

we obtain on integration

$$2\Delta e = -2\nu' h_{e,s'} \cos(N - N_4) = 2e_c' \cos(N - N_4)$$
$$2e\Delta\pi = -\nu' 2eh_{\pi,c'} \sin(N - N_4) = 2e\pi_s' \sin(N - N_4),$$

and by a double integration, remembering that $\Delta\alpha = -\frac{2}{3}\frac{\Delta n}{n}$,

$$\Delta l = \nu'\left(\frac{3}{2}\nu' h_{\alpha,s} - h_{l,c,}\right) \sin(N - N_4) = l_s' \sin(N - N_4).$$

From p. 153 we extract

$$\nu' = 232\cdot720 \quad l_s' = +0''\cdot256$$
$$2e_c' = -1''\cdot158$$
$$2e\pi_s' = +1''\cdot164.$$

Lastly, if we substitute in

$$\delta v = \delta l + 2\delta e \sin g + 2 \cos g (e\delta l - e\delta\pi)$$

we get

$$\delta v = -1''.15 \sin(g + 2\pi - J).$$

Turning now to the statement of final results on pp. 156–9, we note, with the single exception of the Jupiter evection term, its mainly negative character. Results previously given by Radau and Brown are only very slightly modified, generally by quantities quite insensible to observation. Moreover, no explanation has been reached of the unknown term of long period. Thirty years ago Prof. Newcomb, in what are known as Newcomb's corrections, assigned a coefficient 15″·5 and a period of 273 years with an argument arising from the action of Venus to this unknown term. It is now known that the argument is impossible. The present writer thinks that both the coefficient and the period require some increase. At any rate, Newcomb's empirical term has now ceased to represent the observed motion of the moon. It is not, of course, to be expected that empiricism will predict with any accuracy for any length of time. In the last paragraph of his memoir, Prof. Newcomb recalls his attempt to establish an inequality in the earth's rotation that should simultaneously account for the motion of the moon and the transits of Mercury. About forty years ago there was an impression that planetary astronomy had been worked out by Hansen and Le Verrier. The lunar tables of the one and the planetary tables of the other marked immense advances on those of their predecessors, and the extant observations were not sufficient to sound any note of warning except that it might have been noted that Hansen's tables did not account for the ancient eclipses. We now have new planetary tables and the materials for new tables of the moon, but we cannot share the satisfaction of our predecessors of forty years ago. A very considerable list of residual phenomena has accumulated. Apses and nodes and secular terms do not accord with theory. In the moon some periodic terms are unexplained. In Mars it seems as if a term with one second as coefficient and period about twenty years is required to reconcile theory and observation. In the present memoir Prof. Newcomb has presumably excluded the action of the planets as a possible explanation of the vagaries of the moon.

A word ought to be said as to the excellent form of presentation of the subject by Prof. Newcomb. It illustrates the Roman maxim, so often quoted by the late headmaster of Eton, "Divide et impera"—subdivide into sections, and you will get the grip of it.

NEW FACTS ABOUT THE ARUNTA.

THE Arunta of Central Australia have loomed large of late in ethnological controversy, but we are destined to hear further discussion in the near future. Hitherto our information has been derived first from the observations of Mr. F. J. Gillen in part iv. of "The Report of the Horn Expedition to Central Australia," 1896, and later from the two well-known admirable books by Prof. Baldwin Spencer and Mr. Gillen. In a recent number of *Globus* (Bd. xci., No. 18, p. 285) Herr M. Freiherr v. Leonhardi has an article "On some Religious and Totemic Conceptions of the Aranda and Loritja in Central Australia," based upon information received from Herr C. Strehlow and Herr Reuther, of the Neuen Dettelsaur Mission, who have a mastery over the language of the Arunta, or Aranda. Some of the information thus obtained is so different from that recorded by Spencer and Gillen that it opens a new phase in the discussions concerning these remarkable people. Only the more salient points of Leonhardi's article can be here given; students will have to study it in detail, and they will await with eagerness the promised volume.

The Arunta certainly believe in a supreme, good, heaven-god called Altjira; he is the god of the upper world, and has little to do with men. He has the appearance of a tall man with a red skin and long hair falling over his shoulders, but he has feet like an emu, he eats vegetable food, and the flesh of the emu, which he spears. He is surrounded by beautiful youths and maidens, who are immortal. The stars are his camp-fires, the Milky Way his hunting-ground. Only certain specially conspicuous stars, such as the evening star, the Pleiades, &c., and sun and moon are ancestors of the Arunta, who once lived on earth and had certain totems. From this Altjira, who lives in heaven, and of whom no Tjurunga (Churinga) exists, must be clearly distinguished the ancestors, honoured as gods and endowed with superhuman powers, who lived on earth sometimes as animals, sometimes as men. In three neighbouring groups the supreme God is distinguished from the totem gods in the following way :—Dieri, supreme being, *Mura*, deified ancestors or totem gods, *Mura-Mura*; Arunta, supreme being, *Altjira* (the Uncreated), totem gods, *Altjira-ngamitjina* (the everlasting Uncreated) or *Intrara* (the Undying); Loritcha, supreme being, *Tukura* (the Uncreated), totem gods, *Tukutita* (the eternal Uncreated). Originally Gillen described a great spirit (*Ulthaana*), of whom no mention was made in the subsequent works, but in these "the most important spirit individual in the Arunta tribe is Twanyirika," though we are told he is not regarded "as a supreme being who in any way whatever was supposed to inculcate moral ideas." Neither is Altjira the guardian of cults and morals.

Herr Leonhardi writes:—"Among the most noteworthy of the discoveries of Spencer and Gillen was the idea that each man is the reincarnation of a totemic ancestor, and that after death, each soul returns to its totem centre, where the spirit individuals spend the time between the two incarnations. These child-germs enter the women, conception by means of men being unknown. In the neighbourhood of whichever totem centre a woman first feels pregnant, that becomes the totem of the child. I was not a little astonished when Herr Strehlow wrote that he could not find any reincarnation theory among the blacks, and that it must be a misunderstanding; but Spencer and Gillen are so positive, 'In every tribe without exception the belief in reincarnation is universal.'" Strehlow writes:—"I have made careful inquiries concerning the points raised. I have inquired of different blacks at different times, among others of three witch doctors, who are regarded as guardians of tradition, who grew up in heathendom. They all declare these ideas to be wrong. In different places there are numerous *ratapa* (origins of men, unborn men, who have body and soul, but are invisible). The male origins are in rocks, trees, or in the mistletoe growing on the latter; the female mostly in clefts in rocks. Each *ratapa* belongs to a certain totem, and the *ratapas* of the same totem are collected in one place. This was caused by the totem-ancestors 'getting tired' of their long wandering, and their bodies changed into rocks, trees, &c., and their souls collected in an underground cave. The child-germs are in these rocks and trees, and they go forth thence. If now a woman, who conceives, passes such a mistletoe branch or rock cleft, a *ratapa* enters as a grown youth or girl with body and soul, into her body, causing pains. The *ratapa* grows smaller in the woman's body until later it is born as a child. If an *apma* (snake) *ratapa* enters into a woman, the child belongs to the *apma* totem.

"When a man dies his soul (*etana*) goes, not to the totem centre, but to the island of the dead, where it remains for a time. Eventually it returns to its earlier dwelling place on the earth and says to its former friends, 'Be careful, lest you meet such a fate as mine!' If the dead man has left behind on the earth a small child, his soul enters into it and lives there until the child has grown up and has a beard, when the father's soul departs again, or it enters into his grandson in the same manner. It is finally destroyed by a flash of lightning. Thus one cannot speak of a reincarnation, but only of the temporary dwelling of the soul of the father or grandfather in his son or grandson." Strehlow assures Leonhardi that all the Arunta have the same belief.

"There are other means by which the children enter the women. The *atua ngautja* (souls of totem ancestors dwelling in underground caves) can also enter into the women, if they wish to return to this earth, though their final fate is utter annihilation. A child can enter its mother in animal or plant form. If a woman feels the first intimations of pregnancy immediately after seeing a kangaroo, which runs off and disappears, there is no doubt but that her child will be a kangaroo child.

"Each individual has relationship with two totems, he belongs to the one by birth, or rather by conception, this totem he calls *runga*. The other totem belongs to him, is bound up with him, has communion (*altja*) with him, so he calls it *altjira*. Thus the totem animal or plant of his mother which is forbidden to her to eat is his *altjira*, which belongs to him, of which he can eat as he will. A man named Ebalanga belongs to the iguana totem, so all iguanas are regarded as his friends, or even as his relations, for according to the ideas of the blacks he is himself an iguana. He may kill iguanas but sparingly, and eat only the tail and legs. The wild duck is his mother's totem, this is bound up with him, is his guardian, on whose flesh he feeds." As Leonhardi points out, "the great interest in these new facts is that we have here clearly a totem inherited through the mother. It may be that here is preserved a relic of earlier times, when the totem was inherited directly from the mother, as among so many other Australian tribes, and that the peculiar belief about the conception of children was a later development. As to the primitiveness of the Arunta and their neighbours, there has been much discussion, and the above facts may give new aspects to the controversy."

A word of warning seems desirable. The Arunta investigated by Herr Strehlow appear to have been Christianised, and some of their statements may have been influenced by the new teaching; also there may be slightly different beliefs among various sections of the Arunta. Doubtless these points will be fully discussed in the final publication.

A. C. H.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—At the request of the special board for biology and geology, the general board is proposing to establish a demonstratorship in petrology. This demonstrator will be paid by fees, and not directly by the University.

The same board has also received a communication from the special board for biology and geology requesting that the title "Readership in Animal Morphology" (recently vacated by the election of Mr. Adam Sedgwick as professor of zoology) be changed to "Readership in Zoology." This will widen the subject of the readership so that it will include such subjects as variation and heredity, and will enable the University to provide for the teaching of these subjects, which for the last few years has been given by Mr. Bateson as deputy for the professor of zoology. The general board proposes that the annual stipend attached to the readership should be 100*l*., to be paid from a common university fund, and that the readership be attached to the board for biology and geology.

The Senate has sanctioned an alteration to the Previous Examination of some moment, although it excited no comment and little interest in the University. In future it will be possible for a candidate to take a paper on elementary heat and chemistry as an alternative to the papers on Paley's "Evidences" and elementary logic. In the same part of the examination a single combined paper on arithmetic and algebra will in future be set instead of the separate papers on those subjects.

There was a discussion last week on the proposal of the medical board to institute a third first M.B. Examination (chemistry, physics, and elementary biology) by holding one at the commencement of the October term. The proposal met with little opposition, though it was pointed out that the time of year was rather inconvenient. Supporters of the scheme hope that in time the October examination will largely take the place of the one held at present in December, and that the latter will ultimately disappear.

The electors to the Isaac Newton studentship give notice that the election to a studentship will be held in the Lent term, 1908. The studentships are for the encouragement of research and study in astronomy. Persons eligible are members of the University who have been admitted to the degree of Bachelor of Arts, and who shall be under the age of twenty-five on January 21, 1908. The studentship is usually of the value of 200*l*. per annum.

PROF. W. F. M. GOSS, one of the leading American authorities on railway engineering, has been appointed Dean of the college of engineering of the University of Illinois.

THE Civil Service Commissioners announce, in regard to open competitive examinations for clerkships in the Upper Division of the Civil Service, that, after next year, geography, treated scientifically, will be added to the list of subjects included under the head natural science of which four may be taken up.

A COURSE of eight lectures on the function of the mineral constituents of the soil in the nutrition of plants, by Mr. A. D. Hall, will be given, as part of the advanced lectures in botany of the University of London, in the lecture room of the Chelsea Physic Garden on Mondays and Thursdays, beginning on November 11 at 5 p.m. Dr. O. Rosenheim will give a course of three advanced lectures in physiology on the borderland of animal and vegetable chemistry (proteins, lecithins, pigments, &c.) at King's College on Mondays, beginning on November 25, at 4.30 p.m.

THE Board of Education, South Kensington, has just issued the following list of successful candidates this year for Royal exhibitions, national scholarships, and free studentships (science):—*Royal exhibitions:* W. F. Frew, Plymouth; G. E. Morgan, Portsmouth; E. Grigg, Southsea; E. A. Steed, Devonport; W. E. Curtis, London; H. Carter, Triangle, Halifax; H. W. Turner, Portsmouth. *National scholarships for mechanics (Group A):* A. W. Judge, Portsmouth; A. Regnauld, London; F. R. Rogers, Devonport; C. Bartlett, Plymouth; F. H. G. Marks, Plymouth; J. H. Thomas, Ovenden, Halifax. *Free studentships for mechanics (Group A):* S. Ll. Symns, London; F. A. Bumpus, Birmingham; R. G. M. Frost, Plymouth; E. W. Stedman, Sheerness. *National scholarships for physics (Group B):* A. G. Tarrant, London; J. Hill, Glasgow; J. Macpherson, Manchester; A. Holmes, Gateshead; W. White, Glasgow. *Free studentship for physics (Group B):* W. C. Simmons, Southampton. *National scholarships for chemistry (Group C):* S. R. Illingworth, Shipley; H. Griffiths, Middlesbrough; A. T. Eggington, Ibstock, Leicester; A. Caruth, Birkenhead; L. W. Burridge, London. *Free studentship for chemistry (Group C):* F. A. Knott, London. *National scholarships for biology (Group D):* E. Bateson, Bradford, Yorks; J. Sharpe, Burnley; W. Rushton, Burnley. *National scholarships for geology (Group E):* C. H. Cunnington, London; T. Eastwood, Burnley; E. J. Wayland, London.

MACDONALD COLLEGE, Quebec, established and endowed by Sir William Macdonald, of Montreal, was opened to students on November 7. The object of the founder is the advancement of education, the carrying on of research, the spreading of knowledge likely to benefit rural districts, and the training of teachers for rural schools. From an article in the *Times* of November 9, we learn that the college property comprises 561 acres, and has been divided into the campus of 74 acres, where the buildings are located, with demonstration plots for grasses and flowers; a farm of 100 acres for horticulture and poultry keeping; and a live-stock and grain farm of 387 acres. The buildings have been planned in accordance with the most modern scientific principles. The main building includes departments for nature-study and household science, both with appropriate laboratories. Near the main building are buildings for biology and chemistry, each furnished with laboratories and lecture rooms. The main agricultural building contains greenhouses and laboratories of the live-stock farm, dairy, and horticulture department, the farm machinery hall, and a pavilion for live-stock judging. A poultry building with an annexed brooder house are adjacent to the poultry yards, and in addition there is provision for many other agricultural activities. The cost of the buildings and equipment exceeds 300,000*l.*, and, in addition, Sir William Macdonald has provided a permanent endowment of 400,000*l.* The college is incorporated with McGill University, and Dr. James W. Robertson, C.M.G., is the principal. The college includes a school for teachers, a school of household science, and a school of agriculture. Tuition will be free to residents in the Province of Quebec. There will be a small laboratory fee not exceeding 1*l.* to cover the actual cost of the materials used, and a contingency fee to cover possible breakages, penalties, and other demands. Board, room, and washing will be furnished for 13*s.* per week each, where two students occupy one room, and, in the case of students occupying single rooms, for 14*s.*

AT the Mansion House, London, a meeting was held on November 6 in furtherance of the interests of the permanent buildings fund of the University College of North Wales, Bangor. At the opening of the proceedings Lord Kenyon read a letter from the Prince of Wales, who, as Chancellor of the University of Wales, heartily wished success to the meeting, and pointed out that since the question of higher education in Wales was taken up by the Government twenty-seven years ago, it has been zealously supported by the people of the Principality. They have recognised it as an essential to their progress and prosperity, and this fresh effort should help Wales to render the highest services to the kingdom and Empire. A striking proof of this spirit is to be found in the support received from all classes to the original scheme for the college, when 30,000*l.* was raised by 8000 subscribers, of whom only sixty-eight contributed sums of more than 100*l.* and upwards. This spirit has been equally conspicuous in the case of the present appeal, towards which 30,000*l.* has been collected. During the last twenty-three years the successful and steadily increasing work of the college has been carried on in temporary buildings; but from the outset it was the deliberate policy of the college to provide a first-rate staff, and to postpone the question of buildings until the character of the institution had been determined by their efforts. When the Prince of Wales visited Bangor five years ago, the first step towards providing buildings had just been completed by the munificent gift of a site of the value of 15,000*l.* from the corporation. The laying of the foundation-stone by the King this year has now happily inaugurated the actual work of construction. The present intention is to endeavour to complete the arts and administrative section, but it is hoped that in the near future means may be forthcoming to erect the buildings for the science departments, the work of which must for the present be carried on in the old laboratories. A further contribution of 100*l.* towards the building fund was also received from the Prince of Wales, and announced at the meeting. In addressing the meeting, Lord Kenyon referred to the exhaustion of the resources of North Wales and to the depressed state of the slate trade, in connection with which reference was made to the large amount of support the college had received from the ordinary working quarrymen. Sir Harry Reichel, the principal, gave some interesting statistics showing the same spirit of spontaneous effort in the interests of the Welsh university movement on the part of the middle and working classes of North Wales that was referred to in last week's NATURE in connection with the visit of the Chancellor of the Exchequer to Aberystwyth. It was announced that 11,800*l.* had already been subscribed in London alone. It may be interesting to mention that the progress of the college and its influence on the schools of Wales is shown quite as much in the higher standard of attainment of the students as in the increase in numbers. The unmatriculated students, who used to form a large percentage, have now dwindled down to the vanishing point.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Microscopical Society, October 16.—Dr. J. W. H. Eyre, vice-president, in the chair.—Mr. **Taverner** exhibited a number of stereo-photomicrographs of water mites, taken with a stop behind the objective, as described before a previous meeting. They were taken in their natural colours by the Sanger Shepherd three-colour process.—Ghost images in the secondaries of *Coscinodiscus asteromphalus*, with some remarks on the highest useful ratio of magnifying power to aperture: A. A. C. E. **Merlin.** In an experiment suggested by some remarks of Mr. Nelson, the author was able to distinguish perfectly well-defined ghost images of the condenser stop in many of the cap perforations of *Coscinodiscus asteromphalus*. He used a selected Zeiss 3 mm. apochromat of N.A. 1·42 and a 40 ocular in conjunction with a Powell's dry apochromatic substage condenser. The exact size of the perforations was measured and found to be 1/83,300-inch.—A new prismatic ocular: A. A. C. E. **Merlin.** The author found that prolonged observations with the microscope in an upright position entailed great fatigue to the eye, and it occurred to him that by means of a properly designed prism a comfortable position might be secured. He obtained the assistance of Mr. E. M. Nelson, who computed a prism of the kind required, a diagram of which was drawn on the blackboard. It was constructed for the author by Carl Zeiss, and has proved efficient and satisfactory in use.—A new 1/6-inch semi-apochromatic objective: E. M. **Nelson.** The objective had a working distance of 1 mm.; its N.A. was 0·74, and its initial power 60.—Systematic exposure with transmitted light in photomicrography: A. **Letherby.**

Chemical Society, October 24.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—The constitution of phenol- and quinol-phthalein salts: a contribution to the quinonoid theory of colour: A. G. **Green** and P. E. **King.** The authors have succeeded in preparing the coloured carboxylic esters of the phthaleins and of their mono- and di-methyl esters. These esters are orange to red, are extremely unstable, being readily saponified, not only by weak acids or alkalis, but even by water. The facts observed disclose an exact parallelism between the esters and salts of these phthaleins and those of fluorescein, and place the quinonoid structure of these substances almost beyond question.—Keten: N. T. M. **Wilsmore.** The gaseous substance keten, produced by the action of a hot platinum wire on acetic anhydride, which was discovered by Dr. A. W. Stewart and the author (Nature, 1907, vol. lxxv., p. 510), has been further examined. It has the formula $C_2H_2O_3$, and reacts with primary amines to form the corresponding acetyl derivatives.—Derivatives of the multiple keten group: J. N. **Collie.** The group —CH_2.CO— (which the author proposes to call the "keten" group) can be made to yield by the simplest reactions a very large number of compounds of types largely obtained from plants. Illustrations of this were given from the various published papers of the author.—Production of orcinol compounds by the action of heat on the sodium salt of ethyl acetoacetate: J. N. **Collie** and E. R. **Chrystall.**—A simple gas generator for analytical operations: J. McC. **Sanders.** A simple constant supply apparatus for hydrogen sulphide was described which is suitable for use in schools and in commercial laboratories.—Some double ferrocyanides of calcium, potassium, and ammonium: J. C. **Brown.** *Inter alia*, the conditions for the use of ammonium chloride and potassium ferrocyanide as a qualitative test for calcium were given.—Determination of halogen in organic substances: J. **Moir.** The new method described last year by the author has been improved by adopting the Volhard method of back-titration with standard thiocyanate.—Racemisation by alkali as applied to the resolution of *r*-mandelic acid into its optically active isomerides: A. **McKenzie** and H. A. **Muller.** Various methods of effecting the changes (1) *r*-mandelic acid→*r*-mandelic acid and *l*-mandelic acid, and (2) *r*-mandelic acid→*r*-mandelic acid and *d*-mandelic acid were indicated.—The optical activity of cyclic ammonium compounds: F. **Buckney** and H. O. **Jones.** Out of fourteen compounds of this type examined, only one—allylkairolinium-*d*-bromocamphorsulphonate—gave conclusive evidence of the existence of optical activity.—The action of phosphorus pentachloride on hydroxytrimethylsuccinic ester. 1:2-Dimethyl*cyclo*propane-1:2-dicarboxylic acid (1:2-dimethyltrimethylene-1:2-dicarboxylic acid): H. **Henstock** and Miss B. E. **Woolley.**—The condensation of acetaldehyde and its relation to the biochemical synthesis of fatty acids: H. S. **Raper.** It has been suggested that the formation of fatty acids in animals depends, firstly, on the breakdown of the carbohydrate to acetaldehyde, and, secondly, on the condensation of this with the formation of the higher fatty acids. This hypothesis is confirmed in part, since it has been found that β-hydroxybutyraldehyde, the first product of the condensation of acetaldehyde, on further condensation yields an aldehyde containing eight carbon atoms united in a straight chain.—The influence of solvents on the rotation of optically active compounds, part x., effect of the configuration and degree of saturation of the solvent: T. S. **Patterson,** A. **Henderson,** and F. W. **Fairlie.**—*para*Toluidine monohydrate: J. **Walker** and H. H. **Beveridge.**—Hydrates of some quaternary bases: D. C. **Crichton.**—Two volumetric methods for the determination of chromium: A. W. **Gregory** and J. **McCallum.** The authors describe (1) a modified form of the persulphate method for the estimation of chromium in iron and steel, and (2) a method depending on the oxidation of the chromium with sodium bismuthate.

Faraday Society, October 20.—Mr. N. T. M. Wilsmore in the chair.—The electrolysis of salt solutions in liquefied sulphur dioxide: Dr. Bertram D. **Steele.** Electrodes of various metals were used, and the changes at anode and kathode studied. With platinum and mercury a rapid diminution of current took place, when solutions of sulphur dioxide were electrolysed, possibly due to the formation of sulphur films. With electrodes of silver, copper, and iron of large area, constant currents were maintained. Iodine was liberated at anode, but no metallic potassium was obtained at kathode. The author concludes that sulphur cations exist in solution.—The action of aluminium powder on silica and boric anhydride: F. E. **Weston** and H. Russell **Ellis.** The authors show that it is possible to obtain silicon and boron by reduction of the respective oxides with extremely finely divided aluminium powder, the oxide being also excessively finely powdered. Great difficulty, however, is experienced in removing the alumina from the metalloids.—The reduction of metallic oxides with calcium hydride and calcium: Dr. F. M. **Perkin** and L. **Pratt.** A mixture of copper oxide and calcium hydride reacts with great ease according to the equation $2CuO + CaH_2 = 2Cu + CaO + H_2O$, the ignition taking place by means of a match. Pyrolusite, tinstone, and hæmatite also react readily, but require to be heated in a furnace or the reaction started by means of a fuse. Zinc oxide appears not to be reduced. Wolframite and rutile react only with difficulty. Lead sulphide and antimony sulphide also react vigorously. Boron can also be produced from boric anhydride or borax, and silicon (in small quantities) from silica. Dr. Perkin has already shown the extreme ease with which metallic oxides react with metallic calcium. The authors now show that the reaction with wolframite is particularly energetic, the tungsten being obtained as a fused regulus. Calcium will also replace strontium and barium from their chlorides and hydroxides. It likewise replaces all the alkali metals from their chlorides and hydroxides, the reactions being extremely violent.

Paris.

Academy of Sciences, November 4.—M. H. Becquerel in the chair.—Comparative study of the phenols as parthenogenetic agents: Yves **Delage** and P. **de Beauchamp.** The successful results obtained with tannic acid, described in a previous paper, suggested the trial of other allied substances, the phenols and phenolic acids. Experiments have been made with phenol and the three dihydroxybenzenes, resorcinol being the only active substance of the three latter. Of the trihydroxybenzenes, phloroglucinol is nearly equal in activity to resorcinol, pyrogallol and the unsymmetrical isomer being much inferior. Difficulties of solubility prevented much work being done with the hydroxy-acids. Salicylic and vanillic acids gave poor results, about the same order as phenol; protocatechuic, and especially gallic, acid gave better and more constant results. The suggestion is put forward that the activity of the phenols in parthenogenesis may be proportional to their affinity for oxygen.—Contribution to the therapeutics of trypanosomes: A. **Laveran** and A. **Thiroux.** After reviewing the remedies that have been suggested, arsenious oxide, atoxyl, and mixtures of these with mercury salts, and describing their own experimental results on these substances, the authors propose the injection alternately of atoxyl and arsenic trisulphide. This treatment has given very good results in the cure of rats and guinea-pigs artificially infected with *surra*.—The sugar in the blood plasma: R. **Lepiné** and M. **Boulud.** The authors lay stress on the large errors introduced into the determination of the amount of sugar in the blood plasma by neglecting the glycolysis which goes on during the separation of the blood corpuscles. They detail the methods by which they in part surmount this difficulty, but conclude that the estimation of the sugar in the blood can only give, at the best, a rough approximation to the amount of sugar carried to the tissues.—Observations of the sun made at the Observatory of Lyons during the second quarter of 1907: J. **Guillaume.** Observations were possible on forty-eight days, and the results are expressed in tabular form showing the spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Hyperelliptic surfaces: G. **Bagnera** and M. **de Franchis.**—The adjoint functions of M. Buhl: C. **Popovici.**—Some properties of integral equations: E. **Goursat.**—The free path and number of electrons in metals: L. **Bloch.**—The influence of pressure on the absorption spectra of vapours: A. **Dufour.** An experimental study of the change in the absorption spectrum of bromine vapour under pressures varying from one to twenty atmospheres.—A new element, lutecium, resulting from the splitting of Marignac's ytterbium: G. **Urbain.** The separation was effected by fractional crystallisation of the nitrates from nitric acid of density 1·3. The characteristic lines in the arc spectrum of the new element are given. For the purified ytterbium resulting from the separation the name of neo-ytterbium is proposed.—Bi-secondary butylene chlorohydrin: K. **Krassousky.** An account of this compound, recently described as new by M. Louis Henry, was published by the author in 1902. Further details of its preparation and properties are given.—The alkaline granite *massif* of Dahomey: Henry **Hubert.**—The uralitisation of pyroxene: Louis **Duparc.**—Remarks on the structure of the aleurone grains in the Graminaceæ: A. **Guilliermond.** The author modifies some conclusions drawn by him in previous publications. The aleurone grains in the Graminaceæ offer analogous characters to those of the lupin. They are distinguished only by their smaller content of protein (the latter constituting only a thin layer round the globoids), by the smaller number and larger size of the globoids, and by the insolubility of the protein in potash after fixation by Ladowsky's method or by alcohol.—The experimental production of grapes without pips: Lucien **Daniel.** The production of ripe grapes without pips can be caused by vigorous pruning immediately after the fruit is set, and is produced by overfeeding at the time when the fertilised seed starts developing with great activity.—The evolution of Frenzelina, intestinal parasites of decapod crustacea: L. **Léger** and O. **Duboscq.**—Classification of the Zygopterideæ according to the characters of their leaf impression: Paul **Bertrand.**—Variations of density and amount of oxygen of pools of sea water: R. **Legendre.**—Observation of a discontinuous lightning flash: M. **Luizet.**

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 14.

ROYAL SOCIETY, at 4.30.—On the Cranial and Facial Characters of the Neandertal Race: Prof. W. J. Sollas, F.R.S.—Some Features in the Hereditary Transmission of the Self-Black and the "Irish" Coat Characters in Rats: G. P. Mudge.—On the Inheritance of Eye-colour in Man: C. C. Hurst.—On the Result of Crossing Round with Wrinkled Peas, with Especial Reference to their Starch Grains: A. D. Darbishire.—On the Rate of Elimination of Chloroform from the Blood after Anæsthesia: G. A. Buckmaster and J. A. Gardner.—Implantation of Actively Proliferating Epithelium: Dr. J. O. Wakelin-Barratt.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Dielectric Strength or Insulating Materials and the Grading of Cables: Alexander Russell.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—Election of Council and Officers.—On Hypercomplex Numbers: J. H. Maclagan Wedderburn.—Addendum to a Paper on the Inversion of a Repeated Infinite Integral: T. J. I'A. Bromwich.—Generalisation of a Theorem in the Theory of Divergent Series: G. H. Hardy.—Uniform and Non-uniform Convergence and Divergence of a Series and the Distinction between Right and Left: Dr. W. H. Young.—Application of Quaternions to the Problem of the Infinitesimal Deformation of a Surface: J. E. Campbell.—Nodal Cubics through Eight given Points: J. E. Wright.—The Invariants of a Binary Quintic and the Reality of its Roots: Dr. H. F. Baker.—On a Transformation of Hypergeometric Series: Rev. Dr. E. W. Barnes.—On a Transformation of a Certain Hypergeometric Series: Prof. M. J. M. Hill.—A General Theorem on Integral Functions of Order less than One-half: J. E. Littlewood.

FRIDAY, NOVEMBER 15.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Labour-saving Appliances at the Mines of the New Kleinfontein Co., Transvaal: E. J. Way.

MONDAY, NOVEMBER 18.

SOCIOLOGICAL SOCIETY, at 8.—Mental Defects: Dr. Charles Mercier.

TUESDAY, NOVEMBER 19.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Excavation of a Barrow on Chapel Carne Brea, Cornwall, and other Papers: H. King and B. C. Polkinghorne.—The Wild Tribes of the Ulu Plus: F. W. Knocher.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Discussion*:—The Extension, Widening and Strengthening of Folkestone Pier: H. T. Ker.—*Probable Paper*:—The Tranmere Bay Development Works: S. H. Ellis.

ROYAL STATISTICAL SOCIETY, at 5.—Presidential Address: The Right Hon. Sir Charles W. Dilke, Bart., M.P.

WEDNESDAY, NOVEMBER 20.

GEOLOGICAL SOCIETY, at 8.—Glacial Beds of Cambrian Age in South Australia: Rev. W. Howchin.—On a Formation known as "Glacial Beds of Cambrian Age" in South Australia: H. Basedow and J. D. Iliffe.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—The International Balloon Ascents, July 22 to 27, 1907: Reports by W. H. Dines, F.R.S., J. E. Petavel, F.R.S., W. A. Harwood, Capt. C. H. Ley, R.E., and Prof. W. E. Thrift.—Discussion of the Meteorological Observations made at the British Kite Stations, 1906–7: Miss M. White, T. V. Pring, and J. E. Petavel, F.R.S.

ENTOMOLOGICAL SOCIETY, at 8.

ROYAL MICROSCOPICAL SOCIETY, at 8.—(1) François Watkins' Microscope; (2) A Reply to Prof. Porter's and Mr. Everitt's Criticism upon the Paper, On the Limits of Resolving Power for the Microscope and Telescope: E. M. Nelson.—Mercury Globules as Test Objects for the Microscope: J. W. Gordon.—Light Filters for Photomicrography: E. Moffat.

SOCIETY OF ARTS, at 8.—Inaugural Address by Sir Steuart Colvin Bayley, K.C.S.I.

THURSDAY, NOVEMBER 21.

ROYAL SOCIETY, at 4.30.—*Probable Papers*:—Results of the Interaction of Mercury with Alloys of Other Metals: J. W. Mallet, F.R.S.—Note on the Sensibility of the Ear to the Direction of Explosive Sounds: A. Mallock, F.R.S.—On the Silver Voltameter: Part i., A Comparison of Various Forms of Silver Voltameters: F. E. Smith; and a Determination of the Electrochemical Equivalent of Silver: F. E. Smith and T. Mather, F.R.S.; Part ii., The Chemistry of the Silver Voltameter: F. E. Smith and Dr. T. M. Lowry.—On the Normal Weston Cadmium Cell: F. E. Smith.—On a Method of Depositing Copper upon Glass from Aqueous Solutions in a Thin Brilliantly Reflecting Film, thus Producing a Copper Mirror: Dr. F. D. Chattaway, F.R.S.—On Luminous Efficiency and the Mechanical Equivalent of Light: Dr. C. V. Drysdale.—The Dispersion of Double Refraction in Relation to Crystal Structure: T. H. Havelock.

CHEMICAL SOCIETY, at 8.30.—The Interaction of Metallic Sulphates and Caustic Alkalies: S. P. U. Pickering.—The Chemistry of Bordeaux Mixture: S. P. U. Pickering.—Aromatic Azoimides, Part iii., The Naphthylazoimides and their Nitro-derivatives: M. O. Forster and H. E. Fierz.—Studies of Dynamic Isomerism. Note on the Action of Carbonyl Chloride as an Agent for Arresting Isomeric Change: T. M. Lowry and E. H. Magson.—Emulsions: S. P. U. Pickering.—The Electrometric Measurement of the Hydrolysis of the Salts of Anilinium, Ammonium, Aluminium, Chromium, Thallium, Zinc, Magnesium, Cerium, Thorium, Nickel and Cobalt: H. G. Denham.

INSTITUTION OF MINING AND METALLURGY, at 8.

LINNEAN SOCIETY, at 8.—Abnormal Structures in Leaves, and their Value for Morphology: W. C. Worsdell.—Specimen-preservation in Australian Museums: J. G. Otto Tepper.—Revision of the Genus Illigera, Blume: S. T. Dunn.—*Exhibits*:—Luminous Larva from British Guiana: C. W. Anderson.—Living Specimens of Peripatus, from South Africa: Prof. A. Dendy.—*Linaria arenaria*, and other British Plants: G. C. Druce.

FRIDAY, NOVEMBER 22.

PHYSICAL SOCIETY, at 5.—On Singing Sand from New England: S. Skinner.—Exhibition of a Micromanometer: L. Bairstow.—A Diabolo Experiment: Vernon Boys.—Exhibition of a Gyroscope illustrating Brennan's Monorailway: Prof. H. A. Wilson.

CONTENTS.

THURSDAY, NOVEMBER 21, 1907.

MODERN SCIENCE AND AMERICAN TECHNOLOGY.

The Chemistry of Commerce. A Simple Interpretation of some New Chemistry in its Relation to Modern Industry. By Robert Kennedy Duncan. Pp. x+263. (London and New York: Harper and Brothers, 1907.)

THE author of the book with this alliterative and not very apt title is a teacher of chemical technology in a university of one of the western States of North America. He appears to have spent a year's leave in Europe in making himself more or less familiar with certain manufacturing processes depending upon more or less recondite facts of modern chemistry, and he is constrained to publish what he has learnt in the hope of convincing the American manufacturer, in particular, that modern science is "absolutely applicable" to the economy and progress of his operations. He was the more encouraged to put forth the present attempt for the reason that, as he tells us, a former venture of his received "words of appreciation" from mining engineers in South Africa and school teachers in China, as well as from captains of the navy and captains of industry. From which we may infer that the professor of industrial chemistry at the University of Kansas, of whose literary productions we confess we were hitherto in complete ignorance, is in reality one of the most widely-read authors of his time.

The dozen chapters of which the book is made up are so many detached fragments, and from the fact that they have been copyrighted at different times during the last three years, they would seem to be reprints of magazine or newspaper articles. Their literary style is indeed characteristic of much of Transatlantic journalism. When the author seeks to be convincing he is merely turgid and inflated, and what he strives to gain by emphasis he loses in the effect which might have been secured by sober, accurate, and impartial statement. Perhaps, however, Mr. Duncan is the best judge of the appetite of the class for whom he caters. His own particular world of educated laymen intellectually eager to know of the advance of knowledge, who, we are parenthetically informed, "are not fools," may like to have what he calls their "pabulum" served up to them hot and strong, and with plenty of condiments. But in his attempts to whet that appetite the author at times comes perilously near to the "sensational misinformation" of which we gather "the other fellow" has been occasionally guilty. Whilst regretfully admitting that in his book "there does not inhere the romantic interest attached to radio-activity and the nature of the chemist's atom," he yet claims for it "the glorious interest that attaches to the doing of real things."

These extracts from the author's "foreword" are characteristic of the rest of the work. He has a passion for strong words, and his vocabulary is simply amazing. But unfortunately the words occasionally prove too strong for him; they get beyond his control—carry him off his feet, as it were—and rush him into a labyrinth of phrases where he gets effectually lost.

But to a reader who is not over-fastidious as regards literary style, or whose sensitiveness has been dulled by daily perusal of the journalism of Kansas, there is much in this book to interest and amuse. To begin with, the reader will not be bored by too much theory. Theory, we perceive, is not the author's strong point, and he has little sympathy with it. To him "the doing of real things is the preferred work of the world." He never forgets that he is a professor of technology. Speculations on the why and wherefore are, of course, not wanted in the eager, pushful, strenuous life of young America—at least not in Kansas; and as for the question "Why is gold?" it is, we are told, as insoluble as the question "Why is a hen?"

"No man of science can justifiably make of himself an anchorite." Shades of Cavendish and Cayley! Our author remembers a brilliant young researcher who "told him that he had developed a wholly new chapter in mathematics. 'And the best of it is,' he said with a glow of enthusiasm, 'that it can be of no earthly use, either practical or theoretical!' Had that man passed observingly through the vicious purlieus of the Bowery or through the vast sordid stretches of East London, surely it would have struck home to him that his work was not only not right, that it was a crime."

Oh! Mathematics, Mathematics! What crimes are committed in thy name! Perhaps it is an acute consciousness of this that leads the man of Trinity or the "gentle Johnian" to prefer King's Cross as a mode of entry to London rather than gaze upon the vast sordid stretches through which Liverpool Street is reached, and which a too selfish devotion to "pure" mathematics leaves neglected and unrelieved.

The American manufacturer, we gather, is not over-sensitive. If he were, he would surely wince under what the author calls the "stings and arrows" which are hurled against him in this book. The general character of much of American technology, we are told, is summed up in the phrase, "Save at the spigot and waste at the bung." What pulls the manufacturers through, however, is "expert office management," "efficiency of exclusive control obtained through business intrigue," "huge and lying advertisements," combined with "gross adulteration of manufactured products." This is a fair sample of the author's "pretty way" of expressing himself, but as he is a professor of technology in America he ought to know what he is talking about when he deals with American technology, and we must suppose, therefore, that his strictures are merited. Certainly the evidence he affords of "the utter stupidity and ignorance displayed by glass-makers" (in America) in the chemistry of their manufacture is only less marvellous than the ingenuity they display in the complicated and efficient mechanisms—for the most part of American origin and device—which are to be found in their glass factories. But perhaps, after all, this is only the author's method of adorning his tale and of pointing his moral—to enable him, in fact, to bring out in high relief, and by forcible contrast with this story of confusion and waste, how the science of glass-making is studied and practised at Jena.

"The romantic deportment of the nitrogen atom"—due to a certain "temperamental nervousness" "which sends it flying on the slightest pretext from one atomic community to another," is, he confesses, fascinatingly interesting, and this interest prompts him to follow the vagaries of this "labile element"—this "versatile restless nitrogen"—until it is caught and transformed into what he calls "Kalt-stickstoff," whence it passes into carrots and potatoes. The story, as a story, loses nothing in the telling as told by Mr. Duncan, but the serious student who eagerly desires "to know the significant results of modern knowledge" will be saddened, but not made wiser, by the total lack of accurate statement of ascertained facts in connection with "the problem of the fixation of nitrogen and what man may do when he must," which constitutes the subject-matter of chapter iii.

America has recently grappled with the subject of industrial alcohol, and Mr. Duncan deals with the new departure in characteristic fashion. As regards the alcohols in general, "the one bearing the peculiarly graceful name of *Ethyl* is the flower of the sisterhood and the subject of chapter vii." In beginning to enumerate its properties, "it is embarrassingly plain" that its properties "are not in one bundle"; "it is the most perplexing substance with which man has ever had to deal"—"a perfect femininity of varying and conflicting properties" functioning "ubiquitously and contrariously in the affairs of man." But chequered and dubious as is the reputation of "the flower of the sisterhood"—"the theme of poets, and contrariwise, the rage of publicists," this "angel-demon" is sweetness and purity when compared with "the wine of wood"—methyl alcohol—of which it appears some ten million gallons "have, yearly, been floating about America in various use."

"A not inconsiderable quantity of it is absorbed by the low negro populations of the country, who drink it under the appellation 'white horse' or 'old mule,' or by a pleasing mode of rhetorical transition, and in order, perhaps, to distinguish it from 'Ethyl,' as 'Maude.' Much of it again has appeared in 'witch hazel,' 'bay rum,' 'eau de Cologne,' 'Florida water,' essences, 'Jamaica ginger,' 'extract of lemon,' 'liniments,' patent medicine nostrums, and red ink. Poor and decadent people drink these things, and barring individual idiosyncrasies, whether it be a man in Indian Territory who drinks red ink, or a man in North Dakota who drinks 'Jamaica ginger,' there is apparently a fairly uniform result. Out of ten men who drink four ounces each of pure methyl alcohol in any form whatever, four will probably die, two of them becoming blind before death; the remaining six may recover, but of these two will probably be permanently blind. Even the absorption of its vapour through the lungs, or of the liquid through the skin, may produce permanent blindness. The 'hearings' before the Committee on Ways and Means afford ample confirmation of this in the procession that filed before it of blind wrecks that had once been hat stiffeners, varnishers or shellackers, men who did not drink methyl alcohol, but who merely handled it as a solvent. The harm wrought by the substance has been greatly accentuated in the last few years by its manufacture and sale in a purified form, the so-called 'deodorized' methyl alcohol, whose smell gives no warning of its deadly nature."

Let the sporadic drinkers of methylated spirit in this country now take warning from this fearful recital of the risks they run. Perhaps, too, the users of industrial alcohol among us may congratulate themselves that the revenue authorities now require only half the former quantity of this pernicious substance to be used in "methylation." And perhaps, too, they may see some justification, in the interests of the community, for the maintenance of the present high duty on "potable" methyl alcohol. It was, of course, the relatively low price of this alcohol in America—70 cents as against 2 dollars and 8 cents for the taxed ethyl alcohol, that led to such a widespread substitution of the wood alcohol for the alcohol of fermentation.

What with the "whisky trust" "nobbling" the "wood naphtha trust," and the druggists forcing up the retail price of industrial alcohol to ninety cents a gallon—"a disgrace," says the author, "to commercial decency"—America is only at the beginning of her troubles in this matter, and there are already signs that the present regulations will have to be considerably modified if her manufacturers are to reap the full benefits of untaxed spirits.

The other chapters of the book deal with the industrial applications of catalysis; the use of the rare earths in illumination; the electric furnace, the manufacture of synthetic perfumes and of medicines; opsonins and inoculation, and the applications of cellulose. The last chapter gives an account of a scheme of industrial fellowships to be held in connection with a university which, like that of Kansas, enjoys the advantage of a department of applied chemistry, and the author illustrates its working by its application to the discovery of improvements in the chemistry of laundering, with the object of discovering "how the swift and progressive disintegration of the shirt" in the laundry may be arrested. Considering that the people of America pay a laundry bill of nearly twenty-five million dollars a week, Mr. Duncan thinks that a yearly subsidy of five hundred dollars, payable monthly to the holder of the fellowship for two years, in return for a comprehensive monograph on the chemistry of laundering, is the merest trifle in view of its bearing on the problem of the welfare of shirts. "What more can be desired by a young man at the threshold of his activity, even if it means that he must leave the 'nook merely monastic' of a professor in embryo for a life of industrial alarums and strenuous war?"

But this is only one of the many "exasperating, vitally important" problems which await solution at the hands of him who will combine the practical knowledge of the workshop with the special knowledge that awaits him in the class-rooms at Lawrence, Kansas, U.S.A.

THE PHILOSOPHY OF A BIOLOGIST.

Éléments de Philosophie biologique. By Félix le Dantec. Pp. iii+297. (Paris: F. Alcan, 1907.)

PROGRESS in knowledge takes place by the discovery of facts, and by drawing inferences from the facts discovered. It is commonly supposed that the facts existed before we discovered them; and this hypothesis stands the test of practical utility. But it is not supposed, except by the most careless thinkers, that the inferences which we draw from the facts—our laws and principles—are anything more than conceptual summaries of the facts and sequences of facts within our ken. (We use the word fact, not because in current usage it means that about which there can be no doubt, but because it includes a wider range of phenomena than the word "thing." The fact that 25 per cent. of the peas, produced by breeding from hybrids resulting from the union of a yellow and a green pea, are green can hardly be described as a "thing.") Our inferences may be right or they may be wrong, but they did not exist before we made them. Whether we can draw any sharp distinction between fact and inference; or, to put it in terms of space, whether we can draw a line of demarcation and say where fact ends and where inference begins, is a question which concerns the modern biologist perhaps more vitally than any other; yet it is one which very few have definitely formulated, much less attempted to answer. The cause of the almost universal failure to provide a satisfactory answer is a habit of the mind, encouraged by text-books of logic, which drives it to classify things, often dichotomously, into two mutually exclusive categories. Music affords an example. Some folk hold that the music of certain authors is good, whilst that of others is bad. Others, however, say that taste is a purely relative matter, and that no one has a right to say that the music of a given author is good, or bad, as the case may be.

The real truth is that whilst at one pole there are classes of music which are unquestionably good, that at the other there are types which are equally unquestionably bad; between the two there is a series of intermediate kinds about which it is debatable whether they are good or bad.

It is the same with fact and inference. At one pole there are undoubtedly things which can be classed as facts; at the other, things which cannot be claimed to be more than inference. But between the two there is a whole range of things which some regard as facts, whilst others regard them not only as inferences, but as unwarrantable ones. Biologists are far too much occupied with discovering facts and with drawing inferences to stop to consider the relation between these two processes. It is therefore with particular pleasure that we note the appearance of Prof. le Dantec's book, "Éléments de Philosophie biologique," at the present moment.

The book is divided into two main divisions, of which the first embraces the methods and the second the facts—an arrangement which, at first sight, appears natural, but which, on closer inspection, in our opinion loses this feature. It seems, at first glance, natural that we should first describe the method of quarrying slate, and then dilate on the properties of the material brought to the surface by the machinery we have described. But in our opinion a truer picture of nature is conveyed by displaying the profusion and chaos of her phenomena first, and then tentatively enunciating the general conclusions we have ventured to draw from them afterwards. When we look closer at that part of Prof. le Dantec's book which deals with method, the temporary illusion of naturalness of arrangement completely vanishes; for an array of possibly true but extremely abstruse generalisations meets our eyes. The first chapter deals with the conceptions of "unity" and "diversity," which are surely not part of the equipment by means of which facts are brought to light, but some of the fruits which their discovery has borne.

But we do not wish to convey the impression that in our opinion the book is not a valuable one. It contains some much needed caution on the dangers of an unconscious anthropomorphism in the interpretation of nature, and on the dangers of, what is merely a result of that fallacy, a too premature attempt to analyse phenomena. But perhaps what makes the book more valuable than anything else is Prof. le Dantec's familiarity with the facts with which the science of pathology deals, a range of phenomena which more directly concerns, but is perhaps less heeded by, the student of evolution than any other.

THE HAMBURG EXPEDITION TO SOUTH-WESTERN AUSTRALIA.

Die Fauna Südwest-Australiens. Ergebnisse der Hamburger südwest-australischen Forschungsreise, 1905. Edited by Prof. W. Michaelsen and Dr. R. Hartmeyer. Vol. i., part i. Reisebericht by Prof. W. Michaelsen and Dr. R. Hartmeyer. Pp. viii+116; illustrated. (Jena: Gustav Fischer, 1907.) Price 4 marks.

THE zoological collections of the German South Polar Expedition to South Georgia in 1882–83 are preserved in the Natural History Museum at Hamburg, the staff of which therefrom acquired a special interest in the subantarctic fauna. On the renewal of Antarctic research, the Hamburg zoologists decided they could contribute most usefully to that work by continuing the investigation of the adjacent regions. The marine subantarctic fauna is most accessible on the western coasts of the three great southern continents, where its range is extended northward by cold ocean currents. The Hamburg Museum accordingly arranged zoological expeditions to each of these three areas. The first went to South America, and worked in the Straits of Magellan and along the western coasts of Chilian Patagonia; its collections have been described in a series of monographs issued from 1896 to 1907. The second expedition was led by Dr. Schultze to the coasts of south-western Africa, and the series was completed by the visit of Prof. Michaelsen and Dr. Hartmeyer to Westralia from June to October, 1905. They there made marine collections in Shark's Bay, Champion Bay, Geographe Bay, and King George's Sound; they collected on land, especially around Perth, Geraldton, and Albany, and travelled inland as far eastward as Kalgoorlie. They describe the south-western part of Australia as zoologically "a forgotten corner," for as Westralia is younger and larger and has a smaller population than the Eastern States, it has not been able to organise such extensive studies of its fauna and flora.

The authors regard their expedition as very successful, and their scientific results are to be issued in a series of volumes, of which the part now published is only the general introduction. It describes the authors' journey, and gives a list, with a map of their collecting stations. It consists of two reports, one by Prof. Michaelsen, describing his general observations on the geography of Westralia, including its scenery, physiography, flora and fauna, and the aborigines. Dr. Hartmeyer contributes an account of the sheep-farming, the mining industry at Kalgoorlie, and of the dredging expeditions. Both essays give a pleasant account of the country in spite of sufferings from the ubiquitous Worcester sauce. They gratefully acknowledge the ready help of the officials and people. They remark the "extravagant" width of the Kalgoorlie streets, and the difficulties of railway administration on lines where, as Prof. Michaelsen expresses it, there is no fear of collisions. Their Shark's Bay boatman seems to be a typical Australian; "he speaks not much, but he understands his business, and what he does he does with hand and foot." The report contains interesting comparisons with other faunas. Thus Prof. Michaelsen, who had previously studied the zoology of Lake Baikal, contrasts the fauna of that very ancient, perhaps pre-Devonian, deep lake, with the life of the recent, shallow pools of Western Australia.

The most generally interesting zoological result given is probably Prof. Michaelsen's conclusion as to the relations of eastern and western Australia as indicated by the earthworms (pp. 49–50). He holds that since the appearance of the ancient genus *Plutellus*, south-western Australia has been united by land only to the eastern States. There are no affinities to other lands, which are not also common to eastern Australia. Comparatively few foreign earthworms entered eastern Australia, and they arrived at different dates, and crossed subsequently into south-western Australia. There they developed into distinct though closely allied species, probably at a time when the land extended farther south-westward in separate peninsulas or had been temporarily divided into islands, which gave the worms on them complete though temporary isolation.

As the authors' journey was naturally confined to the best known areas in Westralia, there was not much opportunity for obtaining new geographical information, and the value of the work of the expedition will depend on the technical and biological memoirs which are to follow. This preliminary account gives evidence of such thorough and careful work, that important results may be expected from the work of two such skilled zoological experts. J. W. G.

OUR BOOK SHELF.

Experimental and Theoretical Applications of Thermodynamics to Chemistry. By Dr. Walther Nernst. Pp. x+123. (London: A. Constable and Co., Ltd., 1907.) Price 5s. net.

Technische Anwendungen der physikalischen Chemie. By Dr. Kurt Arndt. Pp. vii+304. (Berlin: Mayer and Müller, 1907.) Price 7 marks.

THE first of the above volumes contains a series of ten lectures delivered by Prof. Nernst at the Yale University in 1906 under the Silliman Foundation. After two introductory chapters, a *résumé* is given of the experimental investigations which have been carried out by the author and his students on chemical equilibria at high temperatures. In a theoretical discussion of the results, the author develops the view that relationships exist between chemical energy and heat other than those expressed by the first and second laws of thermodynamics. From a consideration of the conditions under which the principle of Berthelot comes nearest to expressing the true relation between heat and chemical energy, the conclusion is drawn that the total and free energies are not only exactly equal at absolute zero, but that their values coincide completely in the vicinity of this temperature. In the last three chapters the practical application of the integrated equation of the reaction isochore is illustrated by calculation of the equilibrium in various dissociating systems at high temperatures, such as water vapour, nitric oxide, hydrogen chloride, carbon dioxide, and metal ammonia compounds.

Whether the reader is interested in the fundamental theoretical speculations or the practical application of the derived formulæ, Prof. Nernst's series of lectures cannot be too warmly recommended.

In his "Technische Anwendungen" Dr. Arndt presents an account of certain chapters of physical chemistry and of recent investigations which have an important bearing upon technical processes. The volume does not make any pretence to be a complete treatise on the subject, but carefully chosen examples of the application of physico-chemical principles to industrial processes are discussed in considerable detail. In the first three chapters the formation of nitric oxide from air, the equilibrium in the manufacture of generator and water gas, the manufacture of sulphuric acid by the contact process, the formation of ammonia and of ozone are dealt with, the remaining ten chapters being devoted to a less detailed consideration of catalysts, changes of state, solutions, alloys, dissociation pressures, and the measurement of high temperatures.

The book is distinctly worthy of attention, has many good features, and contains a lot of useful references, although the author—if one may judge from the very small number of references to English chemical literature—does not appear to be very familiar with work carried out in this country. This is an unfortunate circumstance, and detracts not a little from the value of the book. H. M. D.

Die Ausgleichungsrechnung nach der Methode der kleinsten Quadrate. By F. R. Helmert. Second edition. Pp. xviii+578. (Leipzig and Berlin: B. G. Teubner, 1907.) Price 16 marks.

THE principal changes in this new edition consist in the more detailed discussion of errors of observation, instrumental corrections, interpolation problems, and the reduction of triangulations. The last chapter deals with the choice of favourable conditions in various surveying problems. In its present form the work appears to be admirably suited for those who have to make practical use of the theory of errors, especially surveyors and astronomers. The examples are mostly taken from actual observations, and the necessary calculations are given in considerable detail. In the earlier chapters a knowledge of determinants is not assumed, and the explanations given ought to make the method intelligible to readers of quite moderate mathematical ability. For the more difficult and controversial points of the theory, reference is made to the treatise of Czuber; at the same time, a very good example of the unavoidably empirical nature of the whole subject is given by working out the same elementary problem according to each of three different laws of error. Now that the measurements of physics and chemistry are approaching, not to say surpassing, in exactness those of astronomy and geodesy, a practical work of this kind is likely to assist a larger and larger body of experimenters.

Die Purpurbakterien. Eine mikrobiologische Studie. By Prof. Hans Molisch. Pp. 92. (Jena: Gustav Fischer, 1907.) Price 5 marks.

THIS memoir deals with an interesting group of chromogenic microorganisms, viz. those producing brilliant pigments ranging in tint from pink, through rose and deep red to reddish-purple. They are probably more nearly allied to the coloured algæ (Phycochromaceæ) than to the bacteria proper, and one of the earliest descriptions of a member of the group was given by Sir Ray Lankester in 1873 under the title of a "peach-coloured bacterium." The author first discusses the occurrence in nature of these organisms. Sometimes they are met with in great abundance on the sea-coast, in river estuaries, and in hot and sulphur springs. Directions are given for obtaining growths in various organic mixtures, for the preparation of suitable culture media, and for obtaining pure cultures in the latter. The biological and physiological properties are next considered; while light has an inhibitory, or a germicidal, action on most bacteria, the "purple" bacteria develop best in its presence. They are sensitive to all light rays, but in particular to the ultra-violet ones; they do not, however, evolve oxygen in the presence of light, and their need for oxygen varies much, some species being almost anaërobic.

The colouring matter produced by the "purple" bacteria is a mixture of two pigments—a green, "bacteriochlorin," and a red, "bacteriopurpurin." The chemical and other properties of these are described fully.

As regards classification, the organisms are grouped in a special order, the Rhodobacteria. This is divided into two families, distinguished by the presence or absence of sulphur granules, and several new species isolated by the author are described. Altogether the book forms a very useful summary of our knowledge of an interesting and peculiar group of microorganisms. R. T. HEWLETT.

The Case of Existence. By Norman Alliston. Pp. xiii+262. (London: Kegan Paul, Trench, Trübner and Co., Ltd., 1907.) Price 5s. net.

"OF the enigmas of life," says Mr. Alliston in his introduction, "all speak; but nobody acts as if there were an enigma." It is his object to remove this inconsistency by exposing the confusions of thought of those who "want life speculatively to be a mystery." The book has three parts. The first contains a good account of the nature of Explanation and some not ineffective criticisms of Knowledge, Nature, &c., mingled, it must be admitted, with much rather ill-informed dogmatism. The second, in the course of a review of man's "obstinate questionings" about existence, develops the author's peculiar egoistic optimism. The third, in which he draws his ethical corollaries, unfortunately contains some chapters which many readers will find offensive both in matter and in tone. The book contains little to engage the attention of the practised student of philosophy, but, being written with obvious conviction and enthusiasm, may here and there attract a useful recruit to the study of first principles. At a later stage the student may not unprofitably return to these pages to detect and analyse the crudities and ambiguities which abound under a surface of apparent lucidity.

Science German Course. By C. W. P. Moffatt. Pp. xii+228. (London: W. B. Clive.) Price 3s. 6d.

THE portion of this book devoted to grammatical construction and word formation occupies about eighty pages, and is followed by extracts for translation from the German. These selections deal with various scientific subjects, and can be commenced after the student has made himself familiar with the first few pages of the grammar that precedes them. Short vocabularies are given of technical terms in mathematics, physics, chemistry, geology, botany, and zoology. The book thus provides a convenient means of obtaining sufficient acquaintance with the German language to read simple scientific descriptions in it with intelligence.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Wehnelt Kathode in a High Vacuum.

THAT a good vacuum can be made into a good conductor by the use of an incandescent kathode is known since the discovery of the Edison effect, and has been investigated with great thoroughness by O. W. Richardson (Trans. Roy. Soc., 1903, 201 A, 497). Wehnelt has shown (*Ann. d. Physik*, 1904, iv., 14, 425) that if the incandescent kathode is coated with one of the alkaline earths, surprising results can be obtained. From a platinum foil kathode at 1300° C. to 1400° C. coated with lime, two to three amperes per sq. cm. of surface can be passed through a good vacuum, the kathode fall being practically negligible, and the total voltage across the vacuum tube being below 30 volts. This result is so very remarkable that I have repeated it in the following way to test whether, as is commonly supposed, the phenomenon is really independent of the perfection of the vacuum.

In a tube provided with a Wehnelt kathode of about a sq. cm. area was mounted an anode of the metal calcium. I have recently shown (Proc. Roy. Soc., 1907, 78 A, 429) that calcium at its volatilising temperature (700° C. to 800° C.) absorbs practically instantaneously and very perfectly all known gases and vapours except the chemically inert gases of the argon family, and have described a form of vacuum furnace suitable for this operation. The tube was prepared in the usual way by preliminary exhaustion and washing out with oxygen to remove argon, and then subjected to the action of calcium heated in a furnace attached to the apparatus. When a good vacuum had been obtained, current from the 250-volt supply was passed through the tube between the heated Wehnelt kathode and the calcium anode in order to heat the latter.

The gases evolved from the anode and tube under this treatment were absorbed by the calcium in the furnace. The current was regulated by a resistance to about 1·2 amperes, and was interrupted at intervals to give the evolved gases time to flow out of the apparatus. When the gases had been for the most part removed the current was passed continuously, heating the calcium anode up to its volatilising point. Quite suddenly and completely the current through the tube stopped, and at the same moment a copious mirror of calcium was volatilised from the anode. In a little while a very feeble glow started and passed intermittently from time to time, but it was not enough to move the ammeter needle, and was most likely due to a further slow evolution of gas from the still heated surfaces. A current could be passed by a coil from the hot kathode to a third electrode as anode without causing any appreciable resumption of the flow in the 250-volt circuit.

More gas was then generated within the apparatus by heating the third electrode with the coil discharge, and the current in the main circuit resumed its original intensity, again heating up the calcium anode. The original phenomenon was repeated, a sudden cessation of current taking place when the calcium volatilised. Just before stopping, the glow of the tube changed to that characteristic of argon, so probably a trace of air had not been removed. The whole phenomenon could be repeated by admitting oxygen to the apparatus and proceeding as before.

This experiment shows that in a sufficiently high vacuum the Wehnelt electrode ceases to be effective. In the experiments so far recorded the saturation current has increased with the improvement of the vacuum, and the phenomenon has been supposed to be in the first place independent of the residual trace of gas present. Wehnelt (*loc. cit.*, p. 445) remarks :—" Für Drucke unter 0·1 mm. ist die für eine bestimmte Temperatur ausgesandte Zahl von negativen Ionen unabhängig vom Druck," and (p. 456) " die Grenzstromstärken um so höher sein . . . je tiefer die Druck ist." In his description of his modification of the Braun tube (*Phys. Zeit.*, 1905, vi., 732) he says the vacuum in the tube must be as perfect as possible.

Richardson, whose mathematical theory of the general phenomenon has received quantitative experimental confirmation, and has been accepted by Wehnelt in the case of his electrode, regarded the action as purely electronic. Commenting on the magnitude of the current and the smallness of the residual gas—in one experiment 2 amperes per sq. cm. at a measured pressure of 0·0016 mm. from a carbon lamp-filament—he says (*loc. cit.*, p. 546) :— " This (the current) is twenty-five times the maximum value obtained by supposing each molecule to produce one ion ; so that it is highly improbable that any considerable part of the conductivity investigated is due to ions produced in this way. . . . Both these points of view lead to the conclusion that the corpuscles are not produced by a dynamical action between the molecules of the surrounding gas and the surface of the metal. In fact, all the experimental results seem to point to the view that the corpuscles are produced from the metal by a process similar to evaporation."

These isolated quotations, of course, may not fairly express the opinions of the authors about what is a very complex phenomenon ; but the general impression their results has conveyed, I think, has been that the large currents dealt with were wholly conveyed by the expelled electrons, and therefore should pass through any vacuum, however perfect. I do not think the electronic emission can account for more than a negligible fraction of the total current, which is carried almost wholly by the residual gas.

The results here given bear out the general view I have from time to time advocated since my experience with the use of calcium, that degrees of vacuum are in practice apt to be overrated, and really high degrees of vacuum are not so readily obtained as is commonly supposed.

FREDERICK SODDY.

Physical Chemistry Laboratory, The University, Glasgow.

The Interpretation of Mendelian Phenomena.

I AM strongly inclined to agree with Dr. Archdall Reid that Mendelian investigations throw no light on many of the most important problems of biology, such as the causes of variation, the evolution of adaptations, and many others. On the other hand, it is difficult to understand what Dr. Archdall Reid means by the statement that Mendelism is the investigation of sex. In one of his letters he describes Mendelian phenomena as " abnormalities of sexual reproduction which occur under conditions of artificial selection." If this means peculiarities of heredity in sexual reproduction observed in cultivated varieties, it may be allowed to pass ; but in an appendix to the second edition of his " Principles of Heredity," Dr. Reid states that the inheritance of Mendelian characters is probably sexual. He proceeds as follows :—" Nature has evolved alternative inheritance to create and perpetuate sexual differentiation, but, just as blending of sexual characters sometimes occurs, so on the other hand the inheritance of non-sexual characters is sometimes alternative. As we have seen, whenever the latter happens, the non-sexual differences are, like the sexual differences, usually considerable. Nature makes the mistake, so to speak, of treating them as sexual. Of course, however, the alternative inheritance of large non-sexual differences is not certain, not so ' clean ' as that of sexual differences, the alternative inheritance of which has been established by a long course of selection."

According to this, the alternative inheritance of non-sexual characters is of the same nature as sexual dimorphism. It seems to me that Dr. Reid has not sufficiently studied the inheritance of secondary sexual characters. It is admitted by almost all evolutionists from Darwin himself downwards that selection cannot have been the cause of the alternative inheritance of sexual differences. The female in selecting a particular male cannot prevent the transmission of his peculiarities to her daughters. The male characters must be limited to the male sex from their first origin as variations, because otherwise the selection of the individual male would merely ensure their transmission to both sexes.

The essential peculiarity of secondary sexual characters is their physiological connection with the primary, *i.e.* with the male or female gonads. It is not merely a question of alternative inheritance ; both male and female characters are inherited by each individual, but normally only one set is developed. When, however, the male gonads are removed, the male characters are usually not normally developed, but suppressed. In Mendelian cases the development of alternative characters is usually entirely independent, both in theory and fact, of the sex or condition of the gonads.

The contrast of male and female corresponds to alternative dominance in a heterozygote ; male characters are dominant in male, female in female, but either can and does transmit both. In Mendelian cases alternative inheritance is segregative ; a recessive transmits only recessive characters, a pure dominant only the dominant. In other passages which I could quote Dr. Reid has shown that he has failed to appreciate this fundamental distinction between dominance and segregation, between the heterozygote and the homozygote, between the first generation of a Mendelian cross and the second.

Excepting parthenogenesis, the heredity of all characters is sexual in that it is connected with fertilisation, but I do not see that Mendelian characters are sexual in any other sense. The theory that the inheritance of sexual characters is Mendelian is one which has a definite meaning and can be investigated. Dr. Archdall Reid's statement that Mendelian inheritance is sexual is in one sense a truism, in another seems to me to have no real meaning at all, for to say that nature has evolved alternative inheritance to perpetuate sexual differentiation explains nothing.

J. T. CUNNINGHAM.

Highgate, November 3.

I AM very willing, and, like most people with theories, I believe I am able to maintain the correctness of the views to which Mr. Cunningham refers ; but to discuss my speculations now would be to confuse the issue. I may say, however, that the appendix to the second edition of my work, from which Mr. Cunningham quotes, is a mere sketch hastily thrown together to meet the objections of critics who had advised the lay and scientific public that a book, which I fondly hoped contained a little that was new, and which certainly contained more than a little of which Mendelians seem profoundly unaware, was antiquated and worthless, not because there were no new facts or inferences in it, nor because its facts and inferences were invalid, but simply and solely because I had not adopted " the new method " nor accepted the "new views," nor limited myself to matters which came within the range of the "new science." The criterion of merit struck me as highly remarkable and certainly very new, and indicative of a degree of toleration which, if not altogether new, is at least unusual amongst men of science. The passage quoted by Mr. Cunningham demonstrates that I expressed myself very badly. Soon, however, I shall have an opportunity of trying to do better, and I suggest that until then Mr. Cunningham shall suspend judgment.

In previous communications to NATURE I have admitted that Mendelism may conceivably shed a light on the function of sex, but I challenged its exponents to mention a single other problem on which it has the remotest bearing. No one has as yet mentioned another problem, and Mr. Cunningham denies, apparently, that it has a bearing on that of sex. Must we assume, then, that it sheds no light on anything at all?

IF, instead of dwelling on the dangers incurred by those who venture to differ from Darwin, Mr. Lock (November 14) demonstrated my errors, he would be more convincing; and, since he is probably the only human being who doubts the blending of the black and white races in Mulattoes and their descendants, it would be well if he, rather than I, undertook the collection of pedigrees. He would feel himself on the track of a great discovery which would enlighten even Mulattoes, whereas I should feel I was wasting time. I do not know what I can gain from the renewed study which he is good enough to suggest. I am well aware of the three principal Mendelian doctrines—segregation of units, independent inheritance of characters, Mendel's law is the greatest of biological discoveries—and the more I see and read the more thoroughly I am convinced that they are all demonstrably erroneous, and that nothing but the restricted area covered by Mendelian studies has prevented a recognition of that fact by Mendelians themselves.

According to selectionists blending is the function, or at least the effect of conjugation. According to Mendelians, not blending, but segregation, occurs. Taken by itself, this doctrine assigns no function to conjugation; it merely controverts the theory of blending. Taken in conjunction with the Mendelian hypothesis of the independent inheritance of characters, it assigns to conjugation the function of effecting an exchange of units between the paternal and maternal sets of allelomorphs. That much the Mendelian doctrines imply—that much and no more. Clearly, then, Mendelism is concerned solely with the function of sex. At any rate, I can conceive of nothing else, and, judging from their spoken and written communications, Mendelians have been so rapt in contemplation of the grandeur of the discovery that they have given no further thought to the matter.

"But everybody said," quoth he,
"That 'twas a famous victory."

Mr. Lock declares that, since conjugation is nearly universal, all, or nearly all, the questions of heredity are problems of the function of sex. He might as reasonably argue that, since assimilation and death are universal, all problems of heredity are problems of assimilation and death. The looseness of thought which pervades Mendelism is well illustrated by his remarks on parthenogenesis and bud-variation. Mendelian segregation implies the separation of allelomorphs which, through the union of two gametes, have previously met in a zygote. There can be no meeting, and therefore no separation when reproduction is parthenogenetic. Mr. Lock, in fact, enunciates the surprising doctrine that all variation is Mendelian segregation. I hope he will forgive the bluntness of the expression, but he trifles with established terms.

Southsea, November 17. G. ARCHDALL REID.

The Winding of Rivers in Plains.

SIR OLIVER LODGE's letter in NATURE of November 7 is itself an illustration of his comment on the way in which misunderstanding of cause may lead to misrepresentation of fact. The statements quoted by him are, as is often the case in text-books, inaccurate in so far as they are incomplete, but, nevertheless, in closer accordance with the facts of nature, viewed from the geological point of view, than he supposes.

We are not dependent on the calculations of mathematicians for our knowledge of the behaviour of rivers; at one time I had a goodly collection of notes of observations made and published by others, but having unfortunately lost this, I shall write only of what I have seen myself, having had many opportunities of observing the behaviour of rivers which are subject to large variations of flow. In the dry season, when the water is low and the stream flows quietly in a channel of more than sufficient size to carry the discharge, I have noticed that the current is often perceptibly more rapid over the shallow water on the inner side of the bend than in the deep channel on the outer. The line of maximum velocity of flow would, consequently, lie nearer the inner than the outer side of the bend, and be less sinuous than the general course of the river, in accordance with the investigation quoted by Sir Oliver Lodge; but at these times the geological activity of the stream is so small as to be almost negligible. When, on the other hand, the same stream is in flood, and a day's work is more than that of a decade or a century of the placid flow, another state of things prevails; then the current sweeps rapidly round the outer side of the curve, and on the inner side is comparatively slack water. The line of maximum velocity must, therefore, become more sinuous than the river itself, and not only is this result to be reached by deduction, but in some cases it has been visibly perceptible. Further, the undertow on the outer edge of the curve has not been visibly distinguishable in any case that I have seen; if existing, its effect must have been insignificant in comparison with that of the horizontal movement of the stream, and often it certainly does not exist. At times, and in certain circumstances, sand and even pebbles may be thrown up to the surface of the water near the outer bank of the stream, and where the waters have overflowed the banks pebbles may be found lying on the dry ground after the flood has passed away; these facts show that there must, in some cases at least, be an upward, not a downward, current along the bed on the outer side of the bend of a stream.

Do not let me be misunderstood. So far as Sir Oliver Lodge is pleading for accuracy in text-books we are all with him, but when he states, as a positive fact, that the line of maximum velocity of current in a river is less sinuous than the river itself, and that the current along the outer bank of a curve is more rapid than along the inner, then I must join issue with him and maintain that these statements are only sometimes true. This is no question of the accuracy of Prof. James Thomson's calculations, but they evidently cover only that part of the problem which is least important from a geological point of view. R. D. OLDHAM.

"Magic Mirror" Effects.

I HAD occasion recently to coat with collodion a silver surface mirror on patent plate 2 millimetres thick. During the operation the mirror was held with one of the rubber pneumatic holders frequently used by photographers when coating or varnishing plates. As the film of collodion set, a series of interference colours disposed in concentric circles appeared immediately over the region of the suction disc of the holder. I could scarcely bring myself to encourage the idea which at once occurred to me, viz. that the slight suction of the pneumatic holder was actually deforming so thick a plate of glass and producing an appreciable concavity in its vicinity.

But this seems really to have been the case. For when the beam of light from a lantern (placed with its back to the screen) was reflected back on to the screen by the mirror held with the pneumatic holder, there appeared in the rectangular patch of light determined by the size and shape of the mirror a much brighter internal circular patch which changed its position conformably with any alteration of the position of the pneumatic holder.

I have never seen any reference made to deformations produced in this way; yet such deformations might be found to have a practical significance in critical coating operations where absolute uniformity in the thickness of the coating is desired. DOUGLAS CARNEGIE.

NOTES ON ANCIENT BRITISH MONUMENTS.

I.

SINCE the publication of my book "Stonehenge" some months ago I have received so much valuable information, so many suggestions and promises of work, that I feel it will be convenient if I refer to some of the points which have been thus raised. They refer to many sides of the inquiry, and indicate how very many questions susceptible of local study are raised by the idea of the possible astronomical use of the monuments.

It is only right, however, that I should state *in limine* that the reviews of the book have been almost entirely condemnatory. I am consoled, however, by the fact that there is evidence that the volume had not been read, and that the reviewers have taken so little trouble to inform themselves that they confound the changes brought about in the places of stars by the precession of the equinoxes with those produced in the case of the sun in consequence of the gradual lessening of the obliquity of the ecliptic.

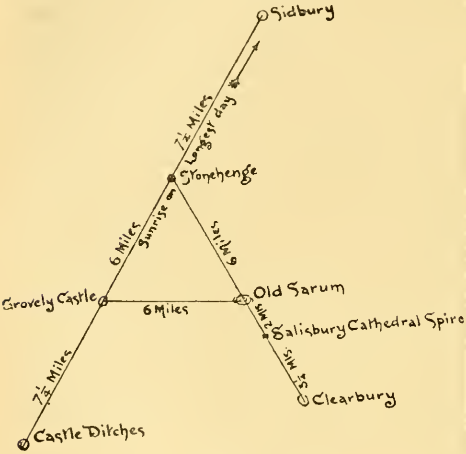

FIG. 1.

Ignoring all the new observations the statement of which was the object of the book, they condemn what they are pleased to call my *theory*, as if a theory were anything but an attempt—even if only a feeble one—to group facts together so that they may be properly understood, and rigid tests applied to it by further work. It is a supreme satisfaction to me to know that further work is going on. Societies for the "Astronomical Study of Ancient Monuments" have been started in Cornwall and Wales, and local inquiries of great value are being made. I am glad to say that these efforts are being sympathetically aided by the existing archæological societies, which, I think, have much to gain by the constant companionship of the spade and theodolite. I also have spent some holiday time in Cornwall, Wales, and Aberdeenshire, adding a special study of cromlechs to the inquiry. What I have previously written concerning the May-year is greatly strengthened by the fact that most of the cromlechs I have examined were constructed so that the sunrise in May or November could be watched from the priests' quarters inside the cromlech through the narrow opening necessary for their protection. I shall give the details of these observations later.

The Inter-relation of Monuments.

In my "Notes on Stonehenge" (NATURE, vol. lxxi., p. 391) I referred to some remarkable relations between Stonehenge and the surrounding localities which had been communicated to me by Colonel Johnston, the late director-general of the Ordnance Survey. These are rendered manifest by the accompanying diagrams which I reproduce.

Fig. 1 shows that Stonehenge is (1) on the same straight line which contains Sidbury, Grovely Castle and Castle Ditches; (2) at the apex of an equilateral triangle of *exactly six miles in the side*; (3) that Salisbury, *i.e.* *Sol*isbury Cathedral, from its name an old solar temple, was on the same straight line which contained Stonehenge and Old Sarum.

Fig. 2 shows that the oldest cross-roads on Salisbury Plain exactly occupy the centre of the triangle referred to.

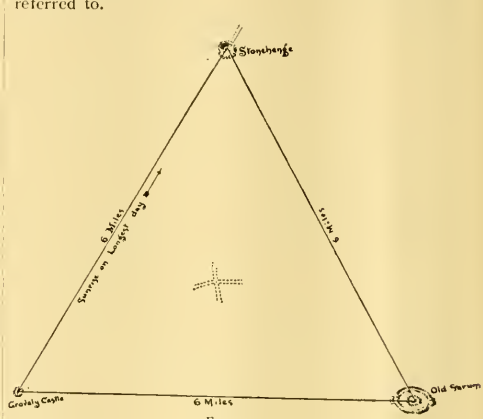

FIG. 2.

Such relations as the above, but on a smaller scale, are often to be noticed, in some cases between monuments, in others between monuments and decided natural features on the sky line as seen from them. I give some examples from Cornwall.

At Trevethy is one of the most famous cromlechs in that county, and it has not been *restored*, so that we need not hesitate to measure it to try to determine its meaning. Close by, at St. Cleer, is a renowned holy well, and a little further away King Doniert's stone.

The accompanying photographic reduction of the Ordnance map shows the strict relation of these monuments. The entrance of the cromlech is directed towards the November sunrise, az. S. 63° E.; looking in the opposite direction it commands the May sunset. I shall refer to this later. As seen from the holy well the cromlech marks the azimuth of the May sunrise. The monolith, King Doniert's stone, is true west from the cromlech, and so marks the equinoctial sunsets.

In the Bodmin district are two famous circles, the Stripple stones and Trippet stones, some half-mile apart.

The following table shows the relation of the latter to the former, and also to the surrounding hill-tops, as I believe was first noticed by Mr. A. L. Lewis.

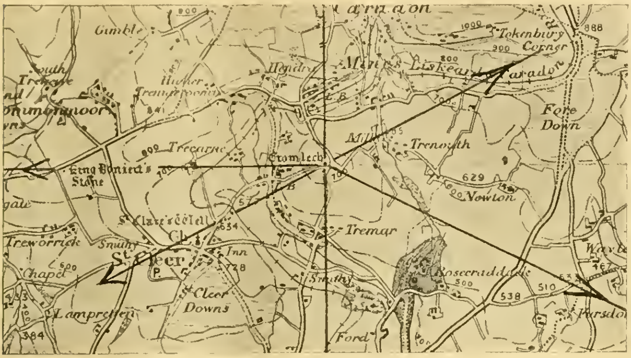

FIG. 3.—The inter-relation of the monuments near Liskeard.

We indeed learn why the circle was erected on the precise spot it occupies.

Trippet Stones, Blisland, lat. 50° 33′ *N.*

	Az.	Hill	Dec.	Star	Date
To Stripple Stones.	N. 81° 30′ E.	2°	N. 6° 42′	Pleiades	1720 B.C.
,, Rough Tor ..	N. 15° E.	1½°	N. 39° 1′	Arcturus	1700 B.C.
,, Brown Willy ...	N. 31° E.	1½°	N. 34° 5′	Capella	1420 B.C.
,, Hawks Tor ...	N. 63° E.	2½°	N. 18° 34′	May Sun	May 14.
,, Barrow	S. 63° E.	1½° assumed	S. 19° 31′	Nov. Sun	Nov. 21.

My wife and I visited the Trippet stones in April, 1907, in the company of Mr. Horton Bolitho and Mr. Collings. A hail-storm made observations difficult, and this may explain the departure of the May and November days from the normal. The coincidence of the dates of the possible observations of Arcturus and Capella suggests that we have then the true date of the erecting of the circle, Brown Willy being subsequently used with Capella when the old alignment of Arcturus on Rough Tor became useless in consequence of the precessional movement.

I shall have more to say on the inter-relation of monuments and double and multiple circles on a future occasion.

Ancient Connection between Stonehenge and Grovely.

Figs. 1 and 2 suffice to show the old association between Stonehenge and Grovely. Canon Wordsworth, in a paper on "Grovely Customs," communicated to the annual meeting of the Wiltshire Archæological Society held in July, 1906, at Wilton, has brought together some additional particulars touching this association.

Some of the new information refers to the gathering of wood in the valleys near Stonehenge; this, I think, may be accepted as strengthening the evidence that the plain at Stonehenge was not wooded, contrary to the opinions of many that the monument was built in a sacred grove of oaks. My argument against this view was that if the monuments had any astronomical use at Stonehenge, Dartmoor, or elsewhere, they would not have been erected among trees, which would have spoiled the observations which were always made on the horizon.

Next, in support of my view that Stonehenge was initially a May-year temple, the celebrations referred to by Canon Wordsworth occur in May. He recalled an extract from a paper written by Mr. J. N. Powell, on "South Wilts in Romano-British Times," in which the writer approached the subject from the point of view of the folklorist and student of primitive religion. Mr. Powell said:—"At Wishford an oak bush is cut annually, formerly at Whitsuntide, but since the Restoration on May 29, and hauled down into the village. It is then decked with ribbons and hung from the church tower, and the day is kept as a revel." Canon Wordsworth said that, if he rightly understood his drift, he supposed that that symbol of the villagers' right to gather wood, and in olden times also to pasture cattle in Grovely Forest, was associated with, or found its expression in, a ceremony of prehistoric cult or nature-worship. He then read a number of extracts from documents lent by the Rector of Wishford, the Rev. F. W. Macdonald, amongst which were the following:—"The aforesaid lords, freeholders and tenants of Barford St. Martin, have had, or should time out of mind have, yearly brought unto them against every Whit Sunday by the Ranger or his assigns, one fat Buck, the one half to

FIG. 4.—The Trevethy Cromlech.

Wishford and the other to Barford, to make merry withal amongst the neighbours. And the Ranger is to have from each of the Manors of Wishford and Barford one white loaf and one gallon of beer and a pair of gloves, or twelve pence in money for the whole, and if the Ranger do not bring nor send the fat Buck then the inhabitants of any of the said Manors or any of them, after that day may go into the said forest and kill and bring away a Buck for each of the said parishes at their pleasure, and then the Ranger is not to have anything." "The custom is and ever time out of mind hath been, that the lords and freeholders of Wishford Magna, and Barford St. Martin, and their tenants, by themselves, their servants and assigns, may take and fetch in the woods of Grovely, speeke rods (probably spicks or spars for use in thatching) and breeding rods, for their houses standing in the said manors of Wishford and Barford, and also fould shoars (stakes for supporting hurdles) and wreethrs (long rods for turning into hurdles) to be employed within the said manors at all times without controulment, and every one of the said lords and tenants that do use to fetch such ought to give the Ranger one hen yearly if he require and send for the same." "The ancient custom is that at all Courts holden for Grovely the Jury and Homage for the said forest hath ever been made, and in Right ought still to be made, of the freeholders, tenants, or inhabitants of Wishford Magna, or Barford St. Martin aforesaid and of none other."

Among the entries in the Rector's book is the following: "Whereas the lord of the manor and parishioners of the parish of Wishford aforesaid did time immemorial use and enjoy laudable custom yearly in the month of May to cut down and carry away boughs of trees growing in the Chase of Grovely in the said county of Wilts (being part of the estate of the Earls of Pembroke) therewith to adorne the said Church of Wishford, and whereas the right honourable Philip, late Earl of Pembroke (probably seventh Earl, 1647–83), finding that the said usage and entry on the said Chase in the said month of May was a prejudice to his deer in that Chase, it being about fawning time, Did come to an agreement with the said Richard Howe, lord of the said manor of Wishford, and the parishioners of the said parish, and did grant to the said parishioners an annual rent charge in fee simple of six pounds a year issuing out of a meadow called Burdenball Meadow in the parish of Wilton in the said county of Wilts. And whereas the said rent of six pounds has been much in arrear and the right honourable Thomas, now Earl of Pembroke (Thomas Herbert, 8th Earl of Pembroke 1683–1733, Lord High Admiral 1702–1708, Lieut. of Ireland 1707), hath agreed with the said lord of the said manor and parishioners to give them the sum of 260*l*. of lawful money of Great Britain, in case they would release their right of the said rent of six pounds of the arrears."

Here we see how dates are changed, and we get a new reason for the abolition of an ancient custom. But this is not all. There is a suggestion of the old stone worship at Salisbury, the spire of which, as we have seen, is exactly in the line Stonehenge-Old Sarum prolonged.

"The lords, freeholders, tenants and inhabitants of the Manor of Great Wishford, or so many of them as would, in ancient time have used to go in a dance to the Cathedral Church of our Blessed Lady in the city of New Sarum on Whit-Tuesday in the said County of Wilts and there made their Claim to their custom in the forest of Grovely in these words, 'Grovely! Grovely!! and All Grovely!!!'" With reference to the last extract, Canon Wordsworth remarked that the dance to the Mother Church of Salisbury might have been connected with the procession to pay chimney-money, "smoke-farthings," or Pentecostal oblations. But after the Restoration of Church and King in 1660 the date was changed to May 29 in connection with the annual thanksgiving then instituted. The custom was kept up until the beginning of the nineteenth century. The last survivor who took part in it died in 1891, in her eighty-eighth year, and she described it to Mr. Hill (the rector in 1885) as a regular revel, with booths and shows erected in the Close. It was therefore suppressed, but still two women, as a deputation from the bough-bearers, went in with oak branches, which they reverently laid on the altar of the Cathedral Church. The last person who performed this ceremony died so lately as 1853. The people taking part in the procession used to dress in white, and they assembled first at Townsend's Tree, at the south end of the village street. They still in 1885 carried oak boughs in procession, but only as far as the Rectory, and performed their dance there.

Cheap and Handy Instruments.

Undoubtedly for final observations at any monument a theodolite must be employed, using the sun or Polaris in order to avoid all magnetic difficulties, and reversing the telescope to secure the correct altitude of the horizon.

But for rapid surveys there are many handy forms of instrument by means of which preliminary informa-

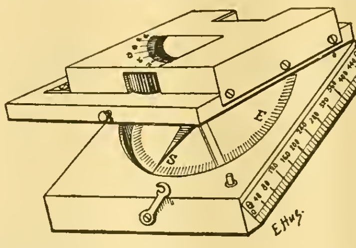

FIG. 5.—M. Hue's combined compass and clinometer.

tion can be gathered, both with regard to azimuth and, what is equally important, the angular height of the horizon. In a reconnaissance lately among the Aberdeen circles I employed a clino-compass of Barker's pattern; this weighs only a few ounces and is carried in a sling over the shoulders; even a tripod can be dispensed with, though it is much better to have one; the lightest form is that used by the Kodak Company for their cameras. In the clino-compass, as the name implies, both azimuths and altitudes are measured by the same instrument, the level being replaced by a pendulum; in this form, especially in the case of the altitudes, the mean of several observations should be taken. In my opinion, a desideratum for such work is a simple small instrument with level and reversible telescope for small altitudes only—a miniature dumpy level, fitting on to the same tripod which carries the azimuth compass.

We learn from the "Manual of Prehistoric Researches" published by the Société préhistorique de France that the French archæologists are much more thorough and philosophical in their inquiries than their British brethren. It is not a question of the spade *versus* the theodolite, but of the spade *and* the theodolite, and as full instructions are given about one as about the other.

It is quite refreshing to read the chapter "Indications pour faire un levé de Terrain à la Boussole," and then the instructions given relating to subsequent work with the large-scale maps published by the French Government.

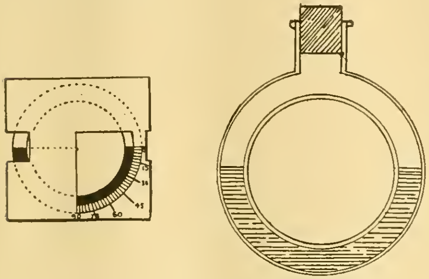

FIG. 6.—Details of the water-level clinometer.

For the angular measurement of elevation, including, therefore, the angular height of the horizon as seen from any monument, the archæologist is recommended to use a very simple and convenient addition to the compass devised by M. Hue. The method employed can be readily gathered from the accompanying woodcuts, obligingly sent to me by the publishers of the "Manual."

It would be a good thing if some one of our many archæological societies would prepare an edition of this excellent French manual for the use of British workers.

NORMAN LOCKYER.

PLAGUE AND FLEAS.

IT is a matter of dispute as to where in ancient literature the first definite mention of rats and plague is to be found, and where such mention does occur it is again uncertain what the author intended to convey. It can hardly be doubted, however, that Avicenna, who flourished about the year 1000, clearly refers to this relationship when he says, "Et de eis quae significant illud (the approach of plague) est ut videas mures et animalia quae habitant sub terra fugere ad superficiem terrae et 'pate sedar" id est commoveri hinc inde sicut ebria."

It is noteworthy, however, that Avicenna does not state that the rats died. Passing over many other records of more or less definiteness we come to the important statement of the Byzantine historian Nicephorus Gregoras, who wrote of the plague in Constantinople in 1347, "Nec vero homines solos morbus ille usque flagellabat; sed et si quae alia animalia cum hominibus plerumque degerent et habitarent; canes inquam et equos et cujusque modi avium genera; ipsos etiam mures, si qui forte in domorum parietibus latitabant." Orraeus also, in the plague of Moscow in 1771, mentions rats, but no special stress is laid on the fact, and other animals, as by many other authors, are included. He says, "De avibus a plurimis narrabatur quod minores cantatrices caveis detentae in domibus infectis emorerentur, immo quod mures et glires quantumvis antea copiosi disparuerint; sed de his fides apud relatores esto."

In modern times the death of rats during or before epidemics of human plague was first noticed in India, viz. in Kumaon, 1833–35, by Gowan, in the Pali plague; 1836–8, by Forbes White; and in Kumaon, 1853, by Francis and Planck. Renny states that during the epidemic of 1851 in Kumaon, in two huts occupied by sixteen men (twelve of whom died of plague) a large number of dead rats was found, but that the cattle, thirty in number, escaped. Rocher, in 1878, in Gun-nam, Baker and Lovry in China, state that the rats were first attacked. Yersin, studying the great epidemic of 1894 in China, states that the rats found dead contained the plague bacillus in abundance, and many of them presented true buboes. Many other observations of a similar kind might be quoted. Not always, however, is the relationship manifest, for Hankin states that despite the most careful inquiries no evidence could be obtained of the existence of an outbreak among rats during or after the outbreak among human beings in Hurdwar. Nor, again, in the epidemic of Glasgow could the relationship be established, though it was proved in the outbreak in 1901–2. Further research will show whether these exceptions are real, or due to insufficient observation.

Not only rats, but other animals have in recent years been found to suffer from plague. Thus there exists in Mongolia a peculiar form of plague known as tarbagan plague. The tarbagan is a marmot-like rodent (*Artomys bobac*).

Almost every year an epidemic disease breaks out among these marmots, and a marmot that is affected always dies. The natives of the Baikal districts avoid handling any animal that has axillary and inguinal buboes, though dogs and wolves are said to eat them with impunity. In the skinning and handling of these marmots the peasants contract the disease, and epidemics of this origin are reported throughout the whole of the east Asiatic plateau of Siberia and Mongolia to Tibet. The disease is almost undoubtedly plague, though bacteriological proof is not yet forthcoming.

It has been noted, further, that palm squirrels (*Sciurus palmarum*) die of plague in great numbers in certain parts of India. Further, among the Carnivora, dogs and cats may develop plague. In certain parts of India cats have been found in abundance with suppurating buboes in the neck, the position of the bubo, it is interesting to note, suggesting its origin in ingested food (rats). Finally, monkeys have died of plague in several places in India.

Rats and Fleas.—Ogata, in 1897, succeeded in giving a mouse plague by means of bacilli got from fleas taken from rats dead of plague. Simond, in 1898, attributed the infection of man to the fleas which had left the bodies of rats dead from plague.

"It is usually in the morning that the carcass of a rat which has died in the night is fatal to him who touches it. We were unable to discover a single case of a rat whose death had occurred twenty-four hours previously having communicated the plague. Simond also made the following experiment. He placed twenty fleas (obtained from a cat) in a bell jar, with a rat dying of plague. He then placed a healthy rat in a cage into the bell jar, but also allowed the cadaver of the first rat to remain thirty-six hours in the vessel. The second rat died on the fifth day of plague. The experiment was repeated, but not always with success" (Quoted from Nuttall, "Insects, Arachnids, and Myriapods as Carriers of Bacterial and Parasitic Diseases," pp. 9–20).

Simond believed that infection from man to man takes places, but in an insignificant number of cases as compared to those where fleas carry the infection from rat to man. He regards rats as the main cause in the spread of plague among human subjects.

Loir affirmed that the fleas of rats are the main agents through which the disease is transmitted to man. Kolle and Nuttall, however, obtained negative results in this direction. The Indian Plague Commission (1899) came to the conclusion that Simond's proposition that suctorial insects play an important part in the transmission of plague from sick to healthy animals is so weak as to be hardly deserving of consideration.

In 1902 Gauthier and Raybaud, at Marseilles, carried out further experiments, and got positive results. "Recueillant en bloc un certain nombre de puces sur des rats capturés sains, nous avons parasité artificiellement à leur asile des animaux de laboratoire préalablement inoculés de cultures pures. Nous avons cherché ensuite à produire infestation parasitaire et l'infection consécutive d'animaux neufs. Les résultats absolument concordants de cette série d'experiences (five experiments) nous permettent de conclure que les puces des rats sont capables d'une façon constante de transmettre la peste d'animal à animal rat ou souris."

Further, they showed that rat fleas could bite man.

Ashburton Thompson, studying the plague epidemics in Sydney from the epidemiological standpoint, came to the conclusion that Simond's hypothesis of the flea best explains the phenomena of the epidemic plague as seen at Sydney. He further states that the laboratory proof has been given by Raybaud and Gauthier, and by Dr. J. S. C. Elkington at Bombay, "whose observations are affirmatory of Simond's original experiments made in India."

Elkington [1] describes his own results in the following words:—"The technical difficulties were considerable . . . and a great deal of experiment was required before a satisfactory means was obtained of insuring the captivity of such a small and active insect whilst feeding. This was finally effected by confining them in a test tube of which the mouth was covered with very fine gauze through which the insect could thrust its proboscis when the gauze was applied to the skin of the feeder-animal. Fleas were then fed on experimentally infected rats. . . . The fleas were then kept in a dark drawer still in the feeding tube for varying periods, after which they were again fed on healthy young rats selected for their vigour and health. The results were most successful, and I have records of four instances in which I was able to carry out this method of infection. Captain Liston also was successful in several cases. Attempts were then made to convey the disease from human beings to rats. Two instances were successful, the period from the first feeding being eight hours. . . . Both rats died of plague, one on the fourth, the other on the sixth day."

Much attention was now given to the question as to what species of fleas those found on rats belong.

Tidswell, in 1903, working at Sydney, found that 81 per cent. of the fleas on rats were *P. pallidus* (*i.e.* *P. cheopis*). Tiraboschi found that 40 per cent. of fleas on ship rats belonged to the same species. Liston, 1905, found that while other species were found on European rats in India, 99 per cent. of the fleas were *P. cheopis*. Though unable himself to get positive results in the transmission, yet he says, "To sum up, then, rat fleas (*P. cheopis*) can always be found in (plague) infected houses; these fleas will take to an animal which is not their normal host." Finally we have the experiments of the Plague Commission of 1905 working in Bombay. These elaborate and very carefully conducted experiments have conclusively established the fact of the conveyance of plague from the infected to the healthy rat by means of the plague flea. We still require light on the exact method by which the bacilli are conveyed; why so many other investigators have failed in similar experiments, and whether rats transmit the disease in any other way, and, indeed, whether this is the most important way. In discoveries of this kind we are apt to give the credit at the time to the person who forges the last link of the chain which stretches across the gap of unknown causes. Credit is, however, also due to those who forge the intermediate links; indeed, perhaps most of all to him who forged the first link, without which the chain would not have been begun.

THE INTERNATIONAL ASSOCIATION OF SEISMOLOGY.

THE first general meeting of the International Association of Seismology was held at The Hague on September 24 and 25, and was preceded on September 21 and 23 by a meeting of the permanent committee, which is the body charged with carrying out the decisions of the general assembly.

The following countries (in alphabetical order according to their French names) now form part of the association:—Germany, Austria, Belgium, Bulgaria, Canada, Chili, Congo, Spain, United States, Great Britain, Greece, Hungary, Japan, Italy, Mexico, Norway, the Colonies of the Netherlands, Portugal, Roumania, Russia, Servia, and Switzerland. It was understood that the French Government was prepared to join, but as the necessary money grant had not been submitted to the Chamber of Deputies, the adhesion has not yet been formally made. Nevertheless, the French delegates were requested to take part in the proceedings on the same footing as those of the other countries.

The budget for the forthcoming year was submitted to the permanent committee, and was carefully discussed. The income of the association is now about 1900*l*. The secretary, Prof. Kövesligethy, of Budapest, on whom a great part of the labour of the association falls, receives 200*l*.; 460*l*. is spent in other salaries, including those of a type-writer, mechanic, and in connection with the Central Bureau at Strassburg; office expenses amount to about 150*l*.

In addition to the above salaries, two scientific assistants, Mr. Rosenthal, of Pulkowa, and Mr. Oddone, of Rome, were during last year paid out of the funds of the association, and were engaged in preparing separate catalogues of microseismic and macroseismic disturbances. The question how far scientific assistants of this kind should during the next two years be maintained by the association was left to the decision of the executive committee, which consists of the president, vice-president, and secretary. There is no question, however, that the formation of the catalogues will always form one of the great objects of the association, and its publication will absorb a material fraction of its funds.

One of the subjects discussed at the meetings was the study and origin of small periodic disturbances, some of which have short periods of 6 to 11 seconds, or the somewhat longer period of 30 seconds. The latter seem to occur when strong winds sweep over a country, but no connection of the former with meteorological occurrences has been proved, and the only suggestion of a rational explanation is that due to Prof. Wiechert, who believes them to be due to the impact of ocean waves on the shores. A small committee was appointed to investigate the question, and a sum of 50*l.* was placed at its disposal. Prof. Omori, who had independently expressed the wish to investigate this matter, was also granted a sum of 50*l.* to carry out his investigations.

Another committee was appointed to report on the question of preparing a complete annual index of the literature of the subject. The committee was instructed to enter into communication with the International Catalogue and the "Office international de Bibliographie," in order to ascertain whether one of the existing organisations may be utilised for the purpose.

According to a resolution arrived at in Rome in October, 1906, the president of the association vacates his office on April 1 following the general meetings, which, as a rule, take place every four years. The permanent committee had therefore to elect a new president; Prof. Palazzo, who has held the office during the last year, not being re-eligible, a ballot was taken, and Prof. Arthur Schuster received the majority of votes. In thanking the meeting for the honour bestowed upon him, and accepting the office, Prof. Schuster said that he was not an expert on seismological questions, but considered it to be his duty to accept the position, as he considered that it was intended as a recognition of the services rendered by Great Britain, and notably by Prof. Milne, not only in originating the scientific study of earthquakes, but also in first organising combined observations on an international basis. Prof. Forel, of Lausanne, who is well known through his work on seiches, was elected vice-president.

The general meeting was opened on the morning of September 24 by a speech of the Minister of the Colonies, and the two succeeding days were taken up in great part by addresses on various subjects connected with seismology. Of special interest were the account given by Prince Galitzin of his seismometric studies, and a paper by Prof. Wiechert on the utilisation of seismic records towards the investigation of the physical properties of the earth.

It was the duty of the general meeting to fix the locality of the central bureau, and it was resolved to retain Strassburg for the next period of four years.

The delegates were most hospitably entertained; an evening entertainment, as well as a dinner, was given by the Minister of the Colonies on behalf of the Government of Her Majesty the Queen, and the meeting concluded with an excursion by boat through some of the characteristic canals and inland lakes of the country. Prof. van der Stok, the vice-president, and his able assistants, Dr. Hartmann, Dr. Romeijn, Mr. Levoir, and Baron van Voorst tot Voorst, must be congratulated on the perfection of the organisation, which more than anything else allowed the meeting to do its work smoothly and effectively. The permanent committee will come together in 1909 at some place in Switzerland not yet determined, and the place for the next general meeting in 1911 will then have to be fixed. It was too soon to come to any definite decision, but an informal expression that the meeting might appropriately take place in England seemed to meet with a very general approval.

SIR F. L. McCLINTOCK, K.C.B., F.R.S.

ADMIRAL SIR FRANCIS LEOPOLD McCLINTOCK, whose death on Sunday last, at eighty-eight years of age, we regret to announce, will be remembered so long as the story of polar exploration has any interest for the human race. Fifty years have passed since the *Fox*, with Sir Leopold (then Captain) McClintock in command, sailed in search of the Franklin expedition, and the fiftieth anniversary of this memorable event was appropriately marked on June 30 last by a letter of congratulation sent to him from the Royal Geographical Society.

Sir Leopold McClintock's Arctic service began in 1848, when he accompanied Sir James Clark Ross as second lieutenant on board H.M.S. *Enterprise*, in the expedition sent out by the Admiralty. Returning unsuccessful in November, 1849, McClintock joined a second expedition sent out early in 1850 as senior lieutenant of H.M.S. *Assistance*, with Sir Erasmus Ommanney. It was his fortune in August, 1850, to see, at Cape Riley, the first traces of the missing Franklin expedition. In the following spring, whilst frozen up at Griffith Island, he signalised himself by a remarkable sledge journey of 80 days and 760 geographical miles, reaching the most westerly point which had been attained from the east in the Arctic regions. Upon the return of this expedition to England in October, 1851, he was promoted to the rank of commander; and in the following spring he proceeded to the Arctic regions in command of H.M.S. *Intrepid*, one of five vessels composing the third searching expedition, under Sir Edward Belcher's command. In accordance with instructions from the Admiralty, the *Intrepid*, in company with the *Resolute*, Captain Kellett, wintered at Melville Island, in order to search for Captain McClure and his companions; and, fortunately, they were discovered and rescued, after their three years' imprisonment in the ice. McClintock again distinguished himself by his sledge journey of 105 days and 1210 geographical miles into the hitherto unexplored region northward of Melville Island. The advances which Arctic sledge-travelling has made are almost entirely due to the improvements effected by him. Abandoning four out of the five ships imbedded in the ice, and also McClure's ship, the *Investigator*, the *personnel* of this expedition, with McClure and his companions, returned to England in October, 1854, in the depôt ship *North Star*, and two relief ships, freshly arrived out, under Captain Inglefield.

In 1857 McClintock accepted the command of the search expedition fitted out mostly at Lady Franklin's expense. He selected and equipped the steam-yacht *Fox*, of 177 tons, and with twenty-four companions sailed on July 1, 1857. He returned on September 20, 1859, having discovered, upon the north-west shore of King William's Island, a record announcing the death of Sir John Franklin and the abandonment of the *Erebus* and *Terror*. He brought home intelligence of their discoveries and the fate of their crews, and many relics of the expedition. The story of this voyage was fully related by McClintock himself in "The Voyage of the *Fox* in the Arctic Seas: a Narrative of the Discovery of the Fate of Sir John Franklin and his Companions," a work which ran through many editions, and is a classic story of geographical achievement. In recognition of his services McClintock was knighted, and in 1865 was elected a Fellow of the Royal Society. He was appointed a K.C.B. in 1891.

NOTES.

In consequence of numerous reports as to the occurrence of a very serious disease among bees in the Isle of Wight, known locally as "paralysis," the Board of Agriculture and Fisheries instructed Mr. A. D. Imms to undertake an inquiry into the nature and cause of the disease; his report on the result of his investigations has now been issued by the Board in pamphlet form. Fortunately, the geographical distribution of the disease is confined apparently to the Isle of Wight, so that with due precaution there should be little or no fear of its spreading to the mainland apiaries. "The disease is eminently one of the digestive system, and might be described as being a condition of enlargement of the hind intestine." Smears made from the contents of the colon showed large numbers of bacteria, and it is possible that there may be some connection between this disease and the well-known form of "dysentery" in bees. The symptoms are complete loss of flight, crawling aimlessly over the ground or up grass stems and the supports of the hive.

The cablegrams from America in Monday's papers announced the tragic death of Prof. L. M. Underwood, of Columbia University, New York. His mind had been unhinged by the recent financial crisis, and he committed suicide after killing his wife and attempting to kill his daughter. He was born in New York State in 1853, and became professor of botany in Columbia University in 1896. His published works included "Descriptive Catalogue of North American Hepaticæ," "Moulds, Mildews and Mushrooms," "Our Native Ferns and their Allies," and "Our Native Ferns and How to Study Them."

At the unanimous invitation of the executive committee of the Yorkshire Naturalists' Union, Dr. Wheelton Hind has accepted the presidency of the union for the forthcoming year. Dr. Hind is well known throughout the country for his successful work amongst Carboniferous rocks, and in Yorkshire he has been unusually successful in identifying and tracing various zones in the Carboniferous limestone. His work in Yorkshire makes the selection of him as president of the county society very appropriate, and will doubtless result in increased attention being paid to the geological problems of the Carboniferous period by the members of the union.

The gold medal of the Institution of Mining and Metallurgy has been awarded to Sir Archibald Geikie, K.C.B., F.R.S., in recognition of his services to geological science. The Consolidated Gold Fields of South Africa gold medal and premium has been awarded to Dr. T. K. Rose for his researches on the metallurgy of gold.

The programme of the arrangements for the new session of the Society of Arts which has just been issued includes a series of six lectures on industrial hygiene by different experts, who will deal with such subjects as dust in factories and in mines, lead and mercury poisoning in pottery and match-making, work in compressed air, and child labour. A course of lectures on the "Navigation of the Air" is to be given under the Shaw trust by Dr. Hele Shaw, F.R.S. Four courses of Cantor lectures are announced, the first on the microscope, by Mr. Conrad Beck. There is a very full list of papers for the ordinary and sectional meetings, and at Christmas Mr. Martin Duncan will lecture to a juvenile audience on the kinematograph.

Dr. Koch, who returned to Berlin early this month after an absence of eighteen months in German East Africa, has been promoted to the rank of Wirklicher Geheimer Rath, with the title of Excellency, in recognition of his researches into the causes of the sleeping sickness.

At the meeting of the London Mathematical Society on November 14, the council and officers for the ensuing session were elected as follows:—*President*, Prof. W. Burnside; *vice-presidents*, Prof. A. R. Forsyth and Prof. H. M. Macdonald; *treasurer*, Prof. J. Larmor; *secretaries*, Prof. A. E. H. Love and Mr. J. H. Grace; *other members of the council*, Dr. H. F. Baker, Mr. A. Berry, Mr. T. J. I'A. Bromwich, Mr. A. L. Dixon, Prof. E. B. Elliott, Mr. G. H. Hardy, Dr. E. W. Hobson, Sir W. D. Niven, Mr. H. W. Richmond, and Mr. A. E. Western.

The *Times* correspondent at Paris gives in the issue of November 14 particulars of an improvement of wireless telegraphy apparatus on board French warships which has enabled communication to be made with facility at a distance of 750 kilometres (466 miles), while the previous *maximum* distance was 300 kilometres (186 miles). According to a telegram from Algiers, the cruiser *République*, on leaving Toulon, proceeded to Ajaccio, a port chosen in order to increase the difficulties of transmission to the *Jules Ferry*, anchored at Toulon, Ajaccio being situated in a hollow of the mountains. Communication was maintained without interruption between the two ships while the *République* was *en route*. It is also stated that the *République* has been able to communicate with the Eiffel Tower in Paris from the Golfe de Jouan, in the Alpes Maritimes Department, a distance of 800 kilometres (500 miles), the ship not merely receiving messages from the tower, but communicating with it in reply.

A promising career has been cut short by the death, on November 12, of Dr. A. M. Pirrie, at the early age of twenty-eight. Dr. Pirrie went to the Sudan in 1906 as anthropologist to the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum. Under the direction of Dr. Balfour, the director of the laboratories, he made his first expedition up the Nile to the southern limits of the Sudan, and penetrated to remote parts of the Bahr-el-Ghazal. A second expedition took him to the borders of Abyssinia. On both occasions he was engaged on anthropological and physiological researches into tropical diseases; but unfortunately he contracted fever, and was compelled to return to England. Dr. Pirrie brought back a valuable collection of objects of anthropological and other scientific interest, and at intervals during his illness he was engaged on his report to the Carnegie Institution and the Wellcome Research Laboratories, Khartoum, for which institutions he acted jointly in the work he carried out in the Sudan.

The sixth annual meeting of the South African Association for the Advancement of Science will be held at Grahamstown during the week ending July 11, 1908, under the presidency of the Hon. Sir Walter Hely-Hutchinson, G.C.M.G. The presidents of the sections are as follows:—Section A, mathematics, physics, astronomy, meteorology, geodesy, and geography, Prof. Alexander Ogg, of Rhodes University College, Grahamstown; Sections B and C chemistry, metallurgy, mineralogy and geology, engineer ing, mining and architecture, Prof. E. H. L. Schwarz, of Rhodes University College, Grahamstown; Section D, botany, zoology, agriculture and forestry, bacteriology, physiology, hygiene, Dr. S. Schönland; Section E, education, philology, psychology, history and archæology, Mr. W. G. Bennie; Section F, economics and statistics, sociology, anthropology and ethnology, Mr. W. Hammond Tooke. The local honorary secretary at Grahamstown is Prof. J. E. Duerden, of the Rhodes University College.

THE Paris correspondent of the *Times* states that, according to a telegram from Montpellier, a mass of earth, having a volume of about 400,000 cubic metres, and forming one whole slope, as it were, of Mont Bringuez, near Lodève, in the Department of the Hérault, has become detached and has moved over a distance of about 1200 feet, carrying with it the tilled soil, fields, woods, and meadows, and obliterating all the ordinary landmarks, bridges, roads, &c., on its passage. A large chestnut grove has thus been moved about 500 feet without, apparently, suffering any damage, but numerous lakes have been formed in the vicinity, and the spectacle is said to resemble that of a region devastated by an earthquake.

AN appeal to the charitable public on behalf of the underfed children attending elementary schools has reached us from the London County Council. For many years past various associations have rendered valuable assistance in collecting and distributing funds. With these associations the Council is in close connection, and every effort is being made to bring the Council, the associations, and the schools into such relationship as will result in a highly efficient organisation for relieving distress. In order to meet the needs of the coming winter, the Council is anxious that at least 15,000*l.* should be raised. If, however, the response is not adequate this winter, there will probably be no alternative in the winter of 1908–9 but to resort to the rates. The Council has voted a sum for equipment and appliances, and will place every convenience at the disposal of the associations. Contributions may be sent to any of the other associations cooperating with the Council, or to Mr. H. Percy Harris, chairman of the London County Council, 98 Gloucester Terrace, Hyde Park, W.; Mr. John T. Taylor, chairman of the Education Committee, 19 Woodchurch Road, Hampstead, N.W.; or Mr. E. A. H. Joy, chairman of the Subcommittee on Underfed Children, Tower House, Woolwich.

A MEETING of representatives of sanitary committees of county and borough councils and port sanitary authorities of England and Wales was held at Caxton Hall, Westminster, on November 15. The object in view was to consider the establishment of a permanent union of such authorities to secure uniformity of action in the administration of matters relating to public health. Mr. H. W. Newton, chairman of the sanitary committee of the Newcastle Corporation, who presided, moved the following resolution, which, after considerable discussion, was adopted by a large majority. The resolution approved of the establishment of a union of the sanitary authorities of England and Wales for the purpose of promoting the public-health interests of the nation. The union is to have for its immediate objects:—(1) to secure, so far as may be practicable, harmony of interest and uniformity of action among sanitary authorities in general on matters relating to the public health; (2) to stimulate and concentrate effort for the purpose of effecting necessary sanitary reforms, whether for the public weal or the benefit of individual sanitary districts; (3) to encourage and promote the study of practical hygiene, and to educate opinion with respect to the national as well as the local importance of public-health work in general; (4) to consider the different conditions and circumstances, general or local, whereby disease is liable to be caused to man, and, so far as may be, to obtain their removal. Other resolutions were also adopted empowering the chairman and Dr. H. E. Armstrong, of Newcastle, as a provisional committee, to draw up a constitution to be discussed afterwards, and to communicate with sanitary authorities asking their adhesion to the union under the name of "National Union of Public Health Authorities."

THE October issue of the *Museums Journal* is illustrated with a portrait of the late Mr. John Maclauchlan, president of the Museums Association, 1906–7. Mr. Maclauchlan presided at the July meeting of the association in Dundee, when he appeared to be in excellent health, but in September he was prostrated by the acute development of a mortal disease with which he had been afflicted for some time, and on October 1 the attack had a fatal termination.

IN the August number of the *Philippine Journal of Science* (ii., No. 4), Lieut. Clarence Cole records the frequent occurrence of the parasitic worm *Necator americanus* in natives of the Philippine Islands; Mr. Harry Marshall gives a good summary of the trend of recent research in immunity; and Dr. Musgrave and Mr. Richmond discuss the relation of infant feeding and infant mortality in the Philippines.

WE have received No. 8 of vol. i. of the Bulletin of the Committee for the Study of Special Diseases, Cambridge. It contains an inquiry into the value of the opsonic index by Messrs. FitzGerald, Whiteman, and Strangeways. As the result of an enormous amount of work, the conclusion is arrived at that, unless at least 1000 cells are counted, the percentage error may be so great as to render the method worthless. In view of the concordant experience of a number of different observers on the value of the method, this conclusion cannot be accepted as final, though it is difficult to detect any fallacy in the experimental details.

To the sixth number of *British Birds* Mr. H. S. Gladstone communicates some interesting particulars with regard to the Irish nesting-colony of red-necked phalaropes, the one place in the United Kingdom where the species is known to breed. Although not reported until 1903, it appears that a few pairs of the birds had established themselves three years previously. In 1902 seventeen birds, mostly females, were seen; two years later Mr. Gladstone estimated the number at thirty pairs, while in 1905, when the nesting-area had become considerably enlarged, he considered there were nearly fifty couples. Unfortunately, the original tenant, who did all he could to protect the birds, has left the farm, and there are ugly reports of a big egging-raid having taken place during the past season.

A REMARKABLE new dipterid larva, *Acanthomera tetratruncum*, from Paraguay, is described by Mr. Karl Fiebrig in the *Zeitschrift für wissenschaftliche Insectenbiologie*, ser. 2, vol. ii., pp. 316–323 and 344–347. The larva, it appears, is a wood-borer, and has the mouth-parts modified into a powerful boring organ. The terminal segment of the body forms an extremely hard, chitinous shield, beneath which is a "mouth-like" chamber for the reception of the posterior stigmata, these being thereby completely protected from contact with foreign bodies. There is, moreover, a finger-shaped tracheal organ in this region which may act as a kind of "gill-stigma." The adaptation of the larva to its peculiar mode of existence is thus very marked. The larval stage seems to be unusually prolonged, an apparently almost full-grown larva observed at the end of July not having developed into the imago until the following January. As it was observed to be still active a short time before the final transformation the pupa-stage is inferred to be brief. An enlarged figure of the adult fly is given in the second part of the paper.

Two papers in the October number of the *Journal of Anatomy and Physiology* relating to Australian natives are of more than ordinary interest. In the first, Dr. W. L. H. Duckworth describes several brains, pointing out that these afford evidence of the low grade of the aborigines. They frequently show, for example, features very rarely met with in the white races, which are, however, normal in apes. Such simian features are, nevertheless, by no means restricted to Australians, whose brains are in other respects essentially human. In the second paper Dr. Ramsay Smith, after describing the results of an investigation into the mode of development of the teeth of Australians, discusses the bearing of this on tooth-development generally. He finds that simple cuspidate teeth, like canines and incisors, are developed from a single tube of dentine, tipped or capped with enamel, and also that this development takes place by constriction. This being so, he urges that in the case of complex teeth, such as molars, in place of any fusion or absorption of cusps, development has taken place by plication or constriction of an original primitive, single, simple tube, according to the method revealed by his observations. Hence the theory of the origin of "heterodont" teeth from fused primitive cones, as well as the theory of the aggregation of cusps, so far at least as it involves the origin of roots, must be re-considered.

On the subject of school gardens, attention is directed in the editorial of *Irish Gardening* to the absence of these in Ireland, although it is an essentially agricultural country, while in most European countries they have been extensively provided. Mr. W. Johnston contributes a practical article on raspberry cultivation, and Mr. P. Brock writes on the propagation of chrysanthemums; special articles are also concerned with the development and classes of carnations, and the culture of Cape heaths.

Miss A. G. Stokey has contributed to the July number of the *Botanical Gazette* a description of the roots of *Lycopodium pithyoides*, a subtropical plant in which every stem is a potential sporophyll. The stem is characterised by the large number of roots that run through the cortex, amounting to more than fifty in one instance. The roots arise within a few millimetres of the apex of apparently mature stems. The vascular strand in the root shows in transverse section a crescent-shaped mass of xylem, with phlœm lying between the horns of the crescent. At the apex of the root four distinct initial regions can be distinguished.

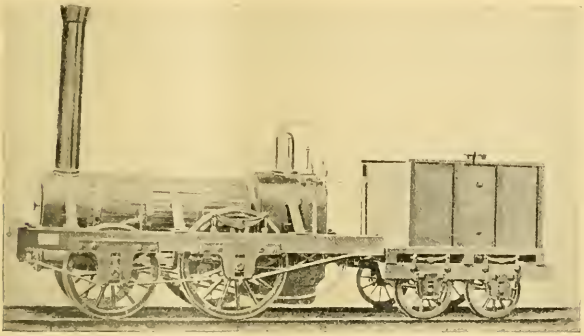
With the object of disseminating the information locally and for others interested, Dr. W. L. Bray has prepared an account, published as Bulletin No. 82 of the University of Texas, of the distribution and adaptation of the vegetation in that State. The factors that control the various plant zones are discussed upon the principles laid down in Schimper's "Pflanzen-Geographie." In connection with water supply, the author distinguishes primarily a moisture-demanding vegetation in east Texas and a dry-climate vegetation in west Texas. Mesophytic types of woodland, notably long- and short-leaf pine and mixed forests, are characteristic of the east, whereas in the west, xerophytic formations abound, such as the "chaparal" scrub, grassy plains, and the "sotol" country inhabited by succulents and dwarf shrubs. There is also a wide range of temperature, from the semi-tropical region where the culture of tropical plants is only prevented by occasional forests, to a cold zone where the Douglas spruce is dominant. Between these lie the "cotton-belt" and the "corn-belt."

In the September number of the Cape of Good Hope *Agricultural Journal*, Mr. Robertson describes his investigations on a local cattle disease he considers to be identical with Nocard and Leclinche's "pasteurellose." He isolated from the affected tissues a bacillus which produces all the symptoms of the disease when inoculated into healthy sheep or cattle. Dr. Nobbs also gives an account of the work proposed to be done at the experiment stations at Knysna, on the wet "sour veld," and at Robertson, in the semi-arid "Karroo" district. These two widely different types of country are fairly common in Cape Colony. "Sour veld" is known by its vegetation; much of it is, or was, forest, but a good deal is covered with scrubby bushes 2 feet to 10 feet high, and reeds, sedges, bracken, and the sugar-bush family (Proteaceæ) are numerous. There is abundant rainfall. The land is being brought into cultivation, but is found to be very sterile in spite of being virgin soil of excellent mechanical condition. Cropping, manuring, and tillage experiments are in progress. On the fertile "Karroo" land the conditions are altogether different; the rainfall is only 10 inches or 12 inches, and as this comes chiefly in winter, recourse must be had to irrigation and special cultivation methods during summer. The experiments at Robertson are in these directions.

The Bulletin of the American Geographical Society, Nos. 7, 8, contains a paper by Miss E. C. Semple on geographical boundaries. After dwelling on the indefinite character of most natural boundaries, Miss Semple gives an account of the conditions generally existing in the border zone between two races or states, illustrations being afforded by the early history of the United States and the wide frontier between Russia and the East. The system of maintaining a waste boundary strip for protective purposes has been superseded in modern States by a fixed political boundary, which, however, does not prevent the existence of a frontier district, the inhabitants of which are generally a mixed race of the two contiguous elements. By means of a map showing the races of Central Europe, the migrations of Slav and Teuton over the political boundary are strikingly illustrated. Attention is also directed to the tendency of border zones to become inhabited by undesirable refugees from both sides.

In compliance with a request made by the Solar Commission of the Meteorological Congress at Innsbruck in 1905, the Weather Bureau of the Philippines has published a useful statement of the rainfall of that archipelago, in the preparation of which all the available data at the disposal of the Manila Observatory have been revised by the Rev. M. S. Masó, S.J., under the direction of the Rev. Father Algué. The rainfall differs considerably, owing to the extension of the archipelago in the N.–S. direction; the annual average amount is about 87 inches, the extreme values being 35·5 inches and about 157 inches. Three different climates are distinguished; the first and worst has two well-defined seasons, wet and dry, in which more than 80 per cent. of the annual fall occurs during the summer months. The second climate consists of eight or nine rainy months, the percentage being high in both summer and winter. The third and best climate has a fairly even distribution of rainfall over the whole year. Reference should be made to the paper in question for particulars as to the location of these districts; tables are given showing the monthly and annual rainfall at all stations.

THE Journal of the Franklin Institute (vol. clxiv., No. 4) contains an interesting report on the development of the American locomotive as exemplified in the Baldwin Locomotive Works of Philadelphia. Founded in 1831, the works in 1832 completed one locomotive and employed thirty men. In 1906 they built 2652 locomotives and employed 17,432 men. Illustrations are given of seventeen locomotives of different types made by the company, the most interesting being the famous "Old Ironsides," completed and tried on November 23, 1832. In these early days mechanics were few, and suitable tools could hardly be obtained. Cylinders had to be bored with a chisel fastened in a block of wood, whilst blacksmiths who could weld bars of iron exceeding $1\frac{1}{4}$ inch square were not to be had. Mathias Baldwin, therefore, had to do most of the work himself in order to educate the men who assisted him to fashion the necessary tools for the various processes.



"Old Ironsides" Locomotive.

IN view of the large number of ancient coins and medals that have been preserved, it is surprising that so little is known regarding the dies used. Some important contributions to the knowledge of the subject are made by Prof. C. Zenghelis in the *Chemiker Zeitung* of November 9. In 1904 a die used for coinage was found by a native at Tel El Athrib, Egypt, and was subsequently presented to the museum at Athens. It dates from 430 B.C. to 322 B.C., and is probably the only genuine antique die preserved. It consists of bronze, and is 6 cm. high and weighs 164·12 grams. On the base is engraved the owl exhibited by the Athenian tetradrachma pieces. The surface was covered partly with a patina of copper carbonate and partly with red cuprous oxide. On analysis it was found that the die consisted of a bronze with 22·51 per cent. of tin and 69·85 per cent. of copper. The remaining 7·64 per cent. undoubtedly consisted of oxygen, as careful tests failed to show the presence of other elements. Some cuprous oxide was mixed with the material for analysis, and as in such alloys the tin oxidises more rapidly than the copper, it may safely be assumed that the mean composition of the alloy was 75 per cent. of copper and 25 per cent. of tin. The strikingly large proportion of tin in the alloy is quite unusual for bronzes of that period, which usually contain 90 per cent. of copper and 10 per cent. of tin, and the oldest bronzes of all are still poorer in tin. The die affords remarkable evidence of the metallurgical skill of the ancients. The extreme hardness required for a die was secured by increasing the proportion of tin, whilst the requisite malleability was secured by carefully using in the preparation of the alloy the purest copper and tin, absolutely free from lead or zinc, which would have made it softer, and from antimony and arsenic, which would have made it brittle.

MADAME CURIE announces in the October number of *Le Radium* the result of her re-determination of the atomic weight of radium under conditions much more favourable to accuracy than those which existed in 1902, when she had only 9 centigrams of chloride of radium on which to work. The present determination has been made with 4 decigrams by the method used in the former case, and gives as the result 226·2, if the atomic weight of silver be taken as 107·8. Madame Curie estimates the possible error of the determination as less than half a unit.

THE Munich *Medizinische Wochenschrift* for October 15 contains a description of an induction coil for Röntgen-ray work, constructed by Dr. J. Rosenthal, which is capable of producing a photograph of a man's thorax in two seconds with the tube 50 centimetres away. This certainly brings us nearer to the much desired Röntgen-ray kinematograph of the action of important organs like the heart, and it is to be hoped that Dr. Rosenthal will succeed in still further reducing the time of exposure. One feature of his coil is the division of both primary and secondary into two or more parts, which can be placed in series or in parallel with each other without stopping the coil.

THE August Bulletin of the Bureau of Standards of Washington contains an article on the melting points of the elements of the iron group by Mr. G. H. Burgess. The determinations were made by placing minute quantities (0·001 milligram) of the elements on a platinum strip heated by the passage of an electric current through it. The temperature of the strip was measured by an optical pyrometer standardised by reference to the melting points of zinc, 419° C.; antimony, 630°·5 C.; copper, 1084° C.; and platinum, 1753° C. The results are as follows:— iron, 1505° C.; chromium, 1489° C.; cobalt, 1464° C.; nickel, 1435° C.; manganese, 1207° C.

THE report of the director and librarian to the Warrington Museum Committee for the year ending June 30 provides evidence that good work in the direction of encouraging scientific observation is being done at Warrington with the aid of the museum and its staff. Among other arrangements made at the museum to interest students and young pupils in natural history may be mentioned the wild-flower table, which appears to be visited regularly by students and by teachers preparing object-lessons. With the assistance of voluntary helpers, the staff provided for the table during the year more than 2500 specimens of freshly gathered wild-flowers, the greatest number on a single day being 168, on July 23.

THE Proceedings of the council of the Institute of Chemistry from July to October of the present year show that the council has directed the attention of the Local Government Board to the desirability of making the condition of appointment of public analysts attractive to candidates with the highest qualifications, and has also urged that the tenure of offices held by men of such ability and experience should be made more secure. Approval is expressed of the action of the County Council of East Suffolk, which has lately set an example by empowering the county coroner to order an analysis by a properly qualified analyst in any case of suspected poison, not being one of alleged foul play. The council has deemed it desirable to advise fellows or associates of the institute who may be seeking appointments in India to make sure they are gazetted as officers, and recognised as such in the regulations of the department under which they are seeking appointment, so that they may not find themselves in a position inferior to that to which they have a right, both officially and socially.

THE annual report of the Smithsonian Institution for the year ending June 30, 1906, has been received. Of its 546 pages, ninety-one refer to administrative matters, and include the reports of the executive committee of the Board of Regents and the acting secretary, Mr. Richard Rathbun, together with the Acts and Resolutions of Congress relative to the Smithsonian Institution adopted during the year. The appendix is again the most extensive and interesting part of the publication. Among other important contributions to this part of the volume we notice the translations of Madame Curie's opening lecture at the Sorbonne on November 5, 1906, on modern theories of electricity and matter; Prof. Himstedt's essay on radio-activity; M. H. Radau's account of astronomy on Mont Blanc; an abstract of M. A. Lacroix's description of Vesuvius in eruption in April, 1906; M. E. Bugnion's contribution to polyembryony and the determination of sex; Herr E. Pfizenmayer's contribution to the morphology of the mammoth; M. L. Cuénot's lecture on heredity; M. A. Yermoloff's description of the bisons of the Caucasus; Dr. Jakob Huber's account of the founding of colonies by Atta Sexdens; M. Hugues Obermaier's description of Quaternary human remains in central Europe; Prof. R. Blanchard's lecture on zoology and medicine; and M. Eugène Lemaire's account of the *rôle* of chemistry in paintings. Among original contributions to the appendix are those of Mr. C. G. Abbot on recent progress in astronomical research, and Mr. C. J. Blanchard on the national reclamation of arid lands. Royal Institution discourses reprinted include those of Mr. Marconi on recent advances in wireless telegraphy, and Prof. Schuster on international science. As usual, the appendix contains a profusion of beautiful illustrations.

A THIRD impression of Dr. David Nabarro's "Laws of Health" has been published by Mr. Edward Arnold. The book provides a simply worded description of the organs of the human body, and much sensible advice as to how to ensure their health and general well-being. The author has acquainted himself with the needs of schools, and his book should be of service to teachers in the preparation of lessons on elementary hygiene.

THE third volume of the "Index of Economic Material in Documents of the States of the United States" has been received. The index is being prepared for the department of economics and sociology of the Carnegie Institution of Washington, and is being published by the institution. The present instalment is by Adelaide R. Hasse, and is concerned wholly with the documents of Vermont, and deals with the years 1789–1904. The index is confined to printed reports of administrative officers, legislative committees, and special commissions of the States, and to governors' messages. It does not refer particularly to constitutions, laws and legislative proceedings, or to court decisions.

OUR ASTRONOMICAL COLUMN.

A LARGE SOLAR PROMINENCE.—Dr. A. A. Rambaut, F.R.S., sends us particulars of a large solar prominence observed by him on Friday last, November 15, at the Radcliffe Observatory, Oxford. Using a slit tangential to the sun's limb, a prominence having the form of two smooth rounded hills was observed at 11h. 45m., and it quickly increased in height until it filled the slit. A few minutes later the whole aperture in the brass plate to which the jaws of the slit were attached on the collimator was not large enough to contain the whole of the outburst. The prominence was in position-angle 273° on the sun's disc measured in the usual way from the north point through east. A sun-spot of fair size, surrounded by masses of bright faculæ, was visible in nearly the same position-angle and near the limb. In the interval between 11h. 56m. and 12h. 10m., that is, in fourteen minutes, the height of the prominence increased 140,000 miles, so the rate of increase was 10,000 miles per minute, or 167 miles per second. The height attained was 324,600 miles.

MELLISH'S COMET, 1907*e*.—A new set of elements, calculated from places observed on October 15 and 19 and November 2, and a daily ephemeris for comet 1907*e*, are published by Herr M. Ebell in No. 4212 (p. 195, November 7) of the *Astronomische Nachrichten.* The following is an abstract from the ephemeris:—

Ephemeris 12h. (M.T. Berlin).

1907	α (app.) h. m.	δ (app.) ° ′	log r	log Δ	Brightness
Nov. 20	2 14·3	+28 8·4	0·1720	9·7179	1·66
,, 24	1 32·0	+28 33·1	0·1855	9·7865	1·14
,, 28	1 1·9	+28 19·9	0·1987	9·8541	0·78
Dec. 2	0 40·5	+27 55·1	0·2116	9·9172	0·55
,, 6	0 25·3	+27 29·7	0·2243	9·9748	0·40

At the time of unit brightness (October 15) the comet's magnitude was about 9·5.

On November 23 the comet will pass about 40′ S. of α Trianguli, and on November 28 it will be $6\frac{3}{4}$° S. of β Andromedæ, crossing the meridian at about 8.30 p.m.

MARS AS THE ABODE OF LIFE.—The *Century Magazine* for November (No. 1, vol. lxxv., p. 113) contains the first of a series of articles on the possibility of Mars being inhabitable, in which Prof. Lowell discusses, as an introduction, the possible origin and evolution of planets. He commences with a description of meteorites, and traces out the various steps of the meteoritic hypothesis, and then defines six stages through which the cooling celestial mass passes in its progress from a self-luminous sun to a cold dead body. Discussing the present aspects of the planets, he shows that these are in accord with the stages defined, and points out that the crumpling which produces landscape variations is essentially an effect of cooling. The relative roughness of the surfaces of the earth, of Mars, and of the moon is then discussed, and the comparatively abnormal mountainous character of the last-named explained by its initial temperature being the temperature of the combined earth and moon masses, and therefore sufficient to produce, in the cooling of so small a mass, the huge lunar mountains with which we are familiar; the non-mountainous character of the Martian landscape is also explained. This first paper concludes with a discussion of the formation and distribution of continental and oceanic areas.

SATURN'S RINGS.—Several recent observations of Saturn's rings are reported in No. 4213 (p. 219, November 10) of the *Astronomische Nachrichten*. Dr. Ristenpart reports that on November 5 he was able to see the ring distinctly, as a ghost-like fine line, with the 12-inch equatorial of the Urania Observatory at Berlin.

Prof. Hartwig, observing at Bamberg on November 7, was surprised to find that the ring on both sides appeared of a reddish-brown colour. The shadow of the rings on the surface of the planet was very distinct, and broader than it was four weeks previously. A telegram from Cambridge (Mass.) reports that Prof. Lowell confirms the observation of the symmetrical knots in Saturn's rings made by Prof. Campbell.

In the same journal Herr Paul Guthnick places on record the results of observations of Saturn's rings and satellites made at the Royal Observatory, Berlin, during part of the week referred to by Prof. Campbell.

ELEMENTS AND EPHEMERIS FOR THE MINOR PLANET PATROCLUS.—A set of elements and an ephemeris, covering the period October 31 to November 16, for Patroclus (1906 VY), one of the three Jovian asteroids, are given in No. 4212 (p. 193, November 7) of the *Astronomische Nachrichten* by Herr V. Heinrich. The opposition will take place on November 30, the magnitude of the minor planet being 14·5.

COMPARISONS OF THE PLACES OF MARS FOR THE OPPOSITIONS OF 1907 AND 1909.—In a paper communicated to the Royal Astronomical Society (Monthly Notices, vol. lxvii., No. 9, p. 575) Dr. Downing compares the places of Mars calculated from Newcomb's tables with the places calculated from Le Verrier's tables near the times of opposition in 1907 and 1909. The results are tabulated for every eight days from May 26 to August 14, 1907, and from August 14 to November 2, 1909. On September 23, 1909 (near the time of opposition), the correction to Le Verrier's place is $-10·5$ seconds of arc in R.A. and $-5''·5$ in declination, to his heliocentric longitude of Mars $-4''·1$, and to the longitude of the sun $-0''·9$; the distance of Mars from the earth will be 0·39.

SCIENCE AT THE FRANCO-BRITISH EXHIBITION OF 1908.

IT has been announced in various newspapers that there will be a Franco-British Exhibition next year. Those who have passed near Uxbridge Road will have also noticed that a large area of ground is being covered rapidly with exhibition buildings.

According to its prospectus, it is to be an exhibition of science, arts, and industries, and it is a matter of concern to all English men of science to see that in such an exhibition science is given its proper place.

Up to the present time no accounts of any attempt to represent science at this exhibition have been made public; we give, therefore, a short sketch of the efforts which are being made to have a pure science section as a part of the exhibition. Such a section is a novelty in exhibitions, and that there will be a science section is due to the action of the British Science Guild. That body approached the executive committee of the exhibition, suggesting that a section should be set apart for pure science, dealing mainly with original research as carried on both in the laboratory and in factories.

The executive committee accepted the suggestion, and a committee was formed which has been at work since June last.

It is hoped that the French side of the exhibition will deal with French science in a similar way.

The committee is constituted as follows:—Sir Norman Lockyer, K.C.B., F.R.S., chairman; Prof. John Perry, F.R.S., vice-chairman; Sir Alexander Pedler, C.I.E., F.R.S., hon. secretary. Members: Captain Sir Wm. de W. Abney, K.C.B., F.R.S., Prof. J. O. Arnold, Major B. F. S. Baden-Powell, Dr. F. A. Bather, Prof. C. V. Boys, F.R.S., Prof. Callendar, F.R.S., Major Close, R.E., Captain Ettrick W. Creak, R.N., C.B., F.R.S., Mr. Horace Darwin, F.R.S., Prof. J. A. Ewing, F.R.S., Prof. Farmer, F.R.S., Rear-Admiral Field, F.R.S., Mr. L. Fletcher, F.R.S., Mr. G. H. Fowler, Sir Archibald Geikie, K.C.B., F.R.S., Sir David Gill, K.C.B., F.R.S., Dr. R. T. Glazebrook, F.R.S., Prof. Gotch, F.R.S., Mr. Walter Rosenhain, Colonel Hellard, R.E.; Colonel Sir Thomas Holdich, K.C.M.G., K.C.I.E., C.B., Sir E. Ray Lankester, F.R.S., Dr. W. J. Lockyer, Prof. R. Meldola, F.R.S., Prof. H. A. Miers, F.R.S., Dr. H. R. Mill, Prof. Milne, F.R.S., Prof. Poulton, F.R.S., Lieut.-Colonel D. Prain, C.I.E., F.R.S., Sir William H. Preece, K.C.B., F.R.S., Sir William Ramsay, K.C.B., F.R.S., Dr. Ridewood, Mr. Frederick Rudler, I.S.O., Prof. Rutherford, F.R.S., Dr. W. N. Shaw, F.R.S., Mr. A. E. Shipley, F.R.S., Mr. L. J. Spencer, Dr. J. J. H. Teall, F.R.S., Prof. Silvanus Thompson, F.R.S., Prof. T. E. Thorpe, C.B., F.R.S., Prof. Trouton, F.R.S., Colonel Sir Charles M. Watson, R.E., K.C.M.G., C.B., Sir H. Trueman Wood.

The exhibits are for convenience subdivided into three sections:—

(*a*) Historical apparatus which has been used by eminent scientific discoverers, or has been the means of elucidating important truths.

(*b*) Instruments and methods used in experiments and observations, including those used in laboratory and works research.

(*c*) Instruments and methods used in and results obtained from the exploration of (1) the land; (2) the sea; (3) the air; (4) the heavens.

The various subjects are dealt with as follows:—

Division 1: arithmetic and mathematical science, geometry, measurement, molecular physics, and sound. Subcommittee, Prof. Perry, Prof. C. V. Boys, and Mr. Horace Darwin; convener, Prof. Perry.

Division 2: light and photography. Subcommittee, Captain Sir Wm. de W. Abney and Sir H. T. Wood; convener, Sir H. T. Wood.

Division 3: invisible radiations. Subcommittee, Prof. S. P. Thompson, Prof. Rutherford, and Hon. R. J. Strutt; convener, Prof. Rutherford.

Division 4: heat. Subcommittee, Prof. Callendar and Mr. Horace Darwin; convener, Prof. Callendar.

Division 5: magnetism and electricity. Subcommittee, Prof. S. P. Thompson, Prof. Trouton, and Sir Wm. H. Preece; convener, Prof. Trouton.

Division 6: chemistry. Subcommittee, Prof. Thorpe, Prof. Meldola, Sir Wm. Ramsay, and Sir Alex. Pedler; convener, ——.

Division 7: mineralogy and crystallography. Subcommittee, Prof. Miers, Dr. Fletcher, and Mr. L. J. Spencer; convener, Prof. Miers.

Division 8: animal biology. Subcommittee, Sir E. Ray Lankester, Prof. Gotch, Mr. A. E. Shipley, Prof. Poulton, and Dr. Ridewood; convener, Prof. Gotch.

Division 9: vegetable biology. Subcommittee, Lieut.-Colonel D. Prain and Prof. Farmer; convener, Prof. Farmer.

(1) *Exploration of the Land.*

Division 10: geography. Subcommittee, Sir D. Gill, General Sir T. Holdich, Prof. J. Milne, Colonel Sir Charles M. Watson, Colonel Hellard, and Major Close; convener, Colonel Sir C. M. Watson.

Division 11: geology. Subcommittee, Sir Archibald Geikie, Dr. J. J. H. Teall, Mr. F. Rudler, and Dr. F. A. Bather; convener, Mr. F. Rudler.

(2) *Exploration of the Sea.*

Division 12: oceanography and hydrography. Subcommittee, Rear-Admiral Field, Captain Creak, Mr. G. H. Fowler, and Mr. D. J. Matthew; convener, Captain Creak.

(3) *Exploration of the Air.*

Division 13: meteorology. Subcommittee, Dr. Shaw, Dr. Mill, and Major Baden-Powell; convener, Dr. Shaw.

(4) *Exploration of the Heavens.*

Division 14: astronomy. Subcommittee, Sir D. Gill, Sir Norman Lockyer, and Dr. Lockyer; convener, Dr. Lockyer.

Division 15: geodesy. Subcommittee, Committees 10 and 14 sitting together; convener, Major Close.

Division 16: metallography. This additional subsection has only lately been formed, and should have been included between subsections 6 and 7 (chemistry and mineralogy and crystallography). Subcommittee, Prof. Arnold, Prof. J. A. Ewing, Mr. Walter Rosenhain, and Mr. J. E. Stead; convener, Mr. Walter Rosenhain.

It is hoped that everyone interested in the welfare of science will materially assist the committee, the work of which is a labour of love. Such help, in the form of the loan of objects, photographs, &c., of scientific interest which they may possess, will add greatly to the value of the sections. The conveners of each section will gladly communicate with such intending exhibitors if applications be made to them through the main office (56 Victoria Street, S.W.).

THE EXTINCT VERTEBRATE FAUNA OF PATAGONIA.[1]

If eccentric originality stand for genius, and refusal to follow the beaten track, even when compass-bearings indicate that it is the right one, be deemed merit, then, unquestionably, the author of the work before us is entitled to stand in the first rank of scientific men. If, on the other hand—but perhaps it will be better to leave our readers to complete this sentence as their own judgment dictates after the perusal of the following remarks and criticisms.

Dr. Ameghino was, it seems, engaged on a monograph on Patagonian fossil fishes, when the appearance of an article by Mr. O. Wilckens on the Cretaceous and Tertiary strata of Patagonia led him to direct his attention to the task of confuting the (to him) heterodox views therein expressed. The result is the present bulky volume, which comprises within its purview a survey of the whole of the vertebrate-bearing strata of Patagonia, together with a summary of the author's views with regard to their geological ages and the relationships and phylogenies of their faunas.

So far as vertebrate palæontology is concerned, Dr. Ameghino has long been imbued with the idea that the Argentine Republic (like Boston in another sense) is the "hub of the universe." In previous works he has demonstrated to his own satisfaction that South America was the birth-place of every mammalian group save that typified by man. He now goes one better, and claims that even *Homo sapiens* himself traces his ancestry to the great South American birthplace and nursery of creation, where he was represented by "*Homo pampeanus*" in the reputed Lower Pliocene strata of Mar del Plata.

There was, however, we are told, a yet earlier forerunner of the human race in Patagonia, to wit, the still apparently unknown Homosimius of the Lower Miocene or Oligocene, and it was this hypothetical creature which passed from South America by a land-bridge across the Atlantic, in company with Cercopithecidæ, to colonise the Old World, where the more bestial man-like apes made their appearance at a later date as a lateral offshoot from the human stock. Finally, to go still further back, the whole order of the Primates (not to mention other mammalian groups) traces its descent to the Argentine Microbiotherium, which the prosaic palæontologists of other countries persist in regarding as neither more nor less than an aberrant type of opossum. We have thus the direct descent of man from marsupials, in defiance of the accepted view that marsupials and placentals are not in the same line.

The above is merely one example from among many elaborate mammalian phylogenies to be met with in this volume; all, if we may say so, evolved from the author's fertile imagination rather than based on any tangible foundation of fact—or, at least, upon any that is apparent to ourselves.

To put the matter briefly, it may be said that whereas most palæontologists of repute who have practical acquaintance with the country or its fossils, or with both together, see in the Patagonian sequence a series of Cretaceous strata with dinosaurian remains followed, after an interval, by others containing one or two mammalian faunas of apparently Miocene age, Dr. Ameghino recognises in the lower beds a mingled mammalian and dinosaurian Cretaceous fauna, succeeded by several distinct mammalian faunas extending from the Eocene upwards. Nor is this all, for while those who do not accept his views consider that the exclusively Patagonian extinct mammalian fauna (and more especially the Ungulate) is *sui generis* and strictly local, the author is of opinion that the various faunas recognised by himself present numerous ramifying affinities with practically all the other Tertiary faunas of the globe, of which, indeed, he regards the former as the *fons et origo*.

It is, however, only fair to add that at the commencement of the volume Dr. Ameghino puts these two irreconcilable views candidly before his readers, and if he elects, in opposition to, practically, the united opinion of the rest of the palæontological world, to adhere to the second alternative, he has, of course, a perfect right to do so. To attempt to refute his views by summarising and criticising the evidence would manifestly be impossible within the limits of a single short article, and it must accordingly suffice to reiterate emphatically that they are not endorsed by even a respectable minority of expert opinion elsewhere.

It may, however, be well to refer to a couple of instances (in addition to those already cited) of what we venture to call Dr. Ameghino's idiosyncrasies in the matter of classification and phylogeny. European palæontologists, after very careful study, have arrived at the conclusion that the remarkable Eocene Egyptian ungulate Arsinöitherium either represents a special group of the order by itself or that it is an aberrant hyrax. Our author scouts both these opinions, and without any apparent reason refers the genus to the Ancylopoda, as typified by the European Chalicotherium (Macrotherium). Again, if there is one apparently well-established fact in palæontology it is that the Egyptian Mœritherium is on the direct ancestral line of the modern Proboscidea. In this, according to our author, palæontologists are, however, altogether wrong, and instead of Africa having been the birthplace of the elephants, we are to look for this in South America, whence, by some unexplained magic, various (shall we say imaginary?) genera with almost unpronounceable names blossomed on the one hand into Palæomastodon and the elephants, and on the other into the forlorn and childless Mœritherium.

To enter into further details would be mere waste of space, and it must suffice to add, in conclusion, that, while fully appreciating the great industry Dr. Ameghino has displayed in collecting and describing the palæontological marvels of Patagonia, we sincerely regret our inability to accord him that encomium on the results of his labours which it would have been a real pleasure to bestow.

R. L.

HYDROLOGY IN THE UNITED STATES.

We have been favoured by the Department of the United States Geological Survey with seven[1] more papers on the geology and water resources of various States. Most of these, although containing valuable information on such subjects as underground water supplies, rainfall and stream flow, pollution and its relation to typhoid fever, weir experiments as to the measurement of running water, are principally of local interest.

Paper No. 194, on the pollution of the Illinois and Mississippi Rivers by Chicago sewage, by Marshall O.

[1] "The Geology and Water Resources of the Western Portion of the Panhandle of Texas." By C. Gould. Water Supply and Irrigation Paper, No. 191.
"The Water Supply of Nome Region, Seward Peninsula." By J. C. Holt and F. Henshaw. Paper No. 196.
"Underground Waters of the Costal Plain of Texas." By T. U. Taylor. Paper No. 190.
"Potomac River Basin." By Parker, Willis, Bolster and Marsh. Paper No. 192.
"The Quality of Surface Waters in Minnesota." By Wesbrook. Paper No. 193.
"Weir Experiments, Coefficients and Formulas." By R. E. Horton. Paper No. 200. (Washington: Government Printing Office, 1907.)

Leighton, is of much wider interest, containing the particulars of a most searching investigation as to what distance it is possible for the typhoid bacillus to travel in a running stream, and so convey disease from one place to another.

It is well known that the city of Chicago, in order to preserve the purity of the water in Lake Michigan, from which it derives its water supply, diverted the sewage from the lake into a canal thirty miles long for conveying it into the Desplaines river, which connects with the Illinois River, and so with the Mississippi, on which is situated the town of St. Louis. The law authorising the construction of the canal required that the sewage was to be diluted with 20,000 cubic feet of water from the lake per minute for each 1000 inhabitants of the sanitary district.

An epidemic of typhoid fever having broken out in St. Louis, the sanitary authorities were advised that this could be traced to germs transported from Chicago, where a large number of typhoid-fever cases had prevailed. The State of Missouri, in which St. Louis is situated, therefore commenced proceedings in the Law Courts against the State of Illinois and the sanitary district of Chicago for an injunction to prevent further pollution of the Mississippi water. The evidence taken "comprises the best symposium on river pollution, its biological and chemical aspects, and general and special sanitary significance that has ever been assembled." The contentions of both parties were supported by all the most qualified chemists, biologists, and sanitary experts in the United States, no less than forty-one expert witnesses having been called. The record of the evidence occupies 8000 printed pages. The paper now under notice contains a digest of this evidence and the finding of the court.

The distance between the two cities is 322 miles, and there are on the main stream and its tributaries between these two points a population of $1\frac{1}{2}$ million inhabitants. The quantity of sewage discharged from Chicago at the time of the trial was given as 1500 tons daily, and the volume of fresh water sent down with this 300,000 cubic feet a minute. By means of float experiments, most carefully carried out, it was shown that it took nearly eleven days for the water to travel from Chicago to St. Louis.

It was also shown that typhoid fever had prevailed more or less every year for the previous ten years in the towns on the banks of the Mississippi and its tributaries, the number of cases in 1902 amounting to more than 1200, of which 800 occurred in the Chicago district.

One of the most interesting of the experiments made to determine how long a typhoid bacillus would live in a running stream was the discharge into the Mississippi River, just below the junction with the Illinois, of several millions of *Bacillus prodigiosus*, an organism of the same type as the typhoid bacillus, but which had never been found in the Mississippi water. This bacterium was subsequently found in samples collected at different places between the Illinois outfall and the intake of the St. Louis water supply. It was shown that this particular bacillus could live in running water for periods extending from thirty to fifty days, and was still alive when the experiments ceased. Dr. Ravold, who conducted these experiments, testified that it was highly probable that a typhoid bacillus can be carried in a virulent condition a distance equal to that between Chicago and St. Louis. It was admitted that sunlight was detrimental to the life of "bacteria," but the effect depends on the turbidity of the running water and the depth to which it will admit the sun's rays. In the Illinois River the effect of the sun was dissipated in a depth of less than a foot. The factors which cause the disappearance of bacteria are aëration, dilution, sunlight, sedimentation, and absence of food supply.

Cases were brought forward in which it was shown that typhoid fever germs had travelled along a river upwards of fifty-seven miles, and caused infection in water supplies; in another outbreak of typhoid which had been investigated, the distance over which the typhoid germ had been traced as having travelled was 175 miles, and in another 113 miles. It was shown that although the dilution of the Chicago sewage by the clean water from the lake would render it less injurious, yet this would not destroy the typhoid bacillus or hinder it from travelling down the river.

On the other side it was contended that it had never yet been satisfactorily proved how long the typhoid bacillus will live in the sewage-contaminated water of a stream, but, according to laboratory experiments, the time might be stated as varying between weeks and months. It was held by some experts that typhoid bacilli disappeared when water bacteria became active. As an illustration of this was quoted the fact that the water of the river Spree, which passed through Berlin and received the city sewage, after the course of a few miles widens out into a quiescent body of water. The sewage water entering the lake became so purified that when leaving it was practically as pure as it was above Berlin before it became polluted. The same result happened to the river Limmat, which flows into Lake Zurich.

It was stated also that the river Seine, after receiving the sewage of Paris, purified itself within a distance of forty-three miles.

An elaborate series of experiments was made to determine the longevity of the typhoid bacillus under natural conditions in the water of the drainage canal and other places. The bacilli were placed in parchment sacks suspended in the water by floats, through which substances in solution could pass, but which did not permit the bacilli to pass out. These sacks were suspended in a light cage, and into them was introduced a quantity of sewage, together with a strong culture of typhoid bacilli. The results of these experiments, closely simulating those in nature, indicated that the typhoid bacillus does not survive for a period longer than four days in water similar to that discharged from Chicago.

Experiments made by the witnesses for Chicago as to the survival of the *B. prodigiosus* failed to confirm those of the complainants, and their evidence was to the effect that it was improbable that the organisms reported to have been found at the intake of the St. Louis water were the same as those placed in the drainage canal. It was also stated that, although the typhoid bacillus may remain alive in the human body for many months, and in wet soil some weeks and possibly months, yet in water it dies out quickly, the length of time depending on the character of the water, being longer in pure water than in that which is polluted, where it has to fight for its existence with other bacteria.

The judgment of the Supreme Court of the United States was given in February, 1906, to the following effect:—that the case as presented to the court fell so far below the allegations that it was not brought within the principles heretofore established, and the Bill was therefore dismissed.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The thanks of the University are to be given to the Rev. Dr. Bonney, who has presented to the Sedgwick Museum the whole of his collection of rock slices, consisting of two thousand seven hundred specimens, of which the British examples number about thirteen hundred. The latter represent especially the rocks of Cornwall, Charnwood, the Wrekin, the Bunter pebbles, north Wales, Scotland, and the Channel Islands. The European collection contains some four hundred and fifty specimens collected from different parts of the Alps, Brittany, and the Ardennes. There is also a large collection of specimens from the Himalayas, Novaia Zemlya, Ararat, Canada (Eozoon, &c.), Rocky Mountains, Andes, Ecuador, Bolivia, Aconcagua district, Socotra, and the diamantiferous district of South Africa.

Dr. Myers has been appointed university lecturer in experimental psychology until Michaelmas, 1912, and Dr. W. H. R. Rivers university lecturer in the physiology of the senses until the same date.

Mr. A. Hutchinson has been appointed chairman of the examiners for the natural sciences tripos.

The Walsingham medal for 1907 has been awarded to E. Mellanby, formerly research student at Emmanuel College, for his essay on the metabolism of creatinin and creatin. The Walsingham medal for 1908 will be awarded for a monograph or essay giving evidence of original research on any botanical, geological, or zoological subject, zoology being understood to include animal morphology and physiology.

GLASGOW.—Dr. Charles E. Fawsitt has been appointed to the newly instituted Graham Young lectureship in metallurgical chemistry, and Dr. T. S. Patterson to the Waltonian lectureship in organic chemistry. The endowments for the new lectureships have been provided in part by Mr. Graham Young's trustees, in part by the Carnegie trust, and in part by the old Waltonian foundation.

Mr. F. H. Downie and Mr. F. R. Stewart have been appointed demonstrators in engineering, and Dr. G. H. Clark Muirhead demonstrator in physiology.

The University Court has instituted a new lectureship in psychology, general and experimental. The lecturer will be charged with the equipment and conduct of the laboratory of experimental psychology, for which provision is made in the new buildings of the physiology department, and will also give instruction in educational psychology to teachers in training. The first appointment will be made on December 12. Applicants are referred to the secretary of the University Court for further information.

The following regulations for the final examination for the degree of B.Sc. (pure science), proposed by the faculty of science, were adopted by the Senate on November 7:—(*a*) one of the subjects taken by each candidate shall be chosen by him to be the principal subject in his examination, and the remaining two or more shall be considered to be subsidiary subjects; (*b*) the subsidiary subjects must be, in part at least, cognate to the principal subject, and the examination in them shall also be upon an honours standard, but shall have special regard to those parts of the subjects which are cognate to the principal subject; (*c*) candidates shall be required to state at the time they enter for the final examination in each subject whether they desire it to be regarded as their principal subject or as a subsidiary subject, and in the event of the latter being the case they shall be required to state which subject they propose to take as their principal subject; (*d*) in estimating the attainments of the various candidates in any subject, the examiners may take into account the duly attested records of their practical work.

LONDON.—The question of the establishment at South Kensington of an institute for preliminary and intermediate medical studies is being vigorously discussed. For the vacancy on the Senate caused by the resignation of Dr. Lauriston Shaw, three candidates have been nominated, the constituency being the faculty of medicine, composed of teachers of medical subjects who are recognised by the University, to the number of nearly 400. Those candidates are Prof. Starling, of University College; Dr. Norman Moore, of St. Bartholomew's; and Mr. F. C. Wallis, of Charing Cross. The concentration of the teaching of preliminary medical subjects is the principal question now before the electors. It will be remembered that Dr. J. K. Fowler and Prof. Rose Bradford, who formerly represented the faculty of medicine on the Senate, lost their seats on the Senate in a recent election owing to their advocacy of concentration, their places being taken by Dr. Caley and Mr. Leonard Hill.

MANCHESTER.—During the last two years the University has collaborated in the work of the International Committee for the investigation of the meteorological conditions of the upper atmosphere. A kite station has been erected on the Derbyshire moors near Glossop, and the results, which have been supplemented by records obtained with free balloons, have proved most encouraging. Prof. Schuster has now intimated his intention of presenting 500*l.* to the University in order to make it possible to pursue this work actively. An observer will be permanently stationed on the moor, and, commencing on January 1, 1908, it is intended to send up meteorological instruments daily by means of kites and balloons. The work is to be continued, in the first instance, during one year.

DR. R. T. GLAZEBROOK, F.R.S., will distribute the prizes and certificates and deliver an address at the Sir John Cass Technical Institute on Tuesday, December 3. The chair will be taken by Sir Owen Roberts, chairman of the governing body. There will be an exhibition of students' work and apparatus in the laboratories, workshops, and other rooms of the institute.

THE aggregate number of students at German technical colleges amounted last winter term to 12,000, of whom 2700 were foreigners—that is, about 22 per cent. At the colleges at Dresden, Darmstadt, and Karlsruhe more than one-third of the students were foreigners, and of these 80 per cent. were Russians.

WE have received from Prof. V. Karapetoff, of Cornell University, a copy of an interesting paper read by him before the American Institute of Electrical Engineers on the concentric method of teaching electrical engineering. The method he advocates is based on the principle of passing from practice to theory instead of from theory to practice, as is now usual. The study of engineering should, he considers, begin in the freshman year, and be carried throughout four years. Engineering education should be taken up first with a bird's-eye view of actual practice, and not with theory. Auxiliary sciences (mathematics, mechanics, physics, and chemistry) should not be required further than is necessary for the understanding of engineering, and should be given later in the course. Each year of study should be, so far as possible, self-contained, the mental horizon of the student being gradually and concentrically widened. The same author also delivered an address before the New York Electrical Society on the human side of the engineering profession. He argues that the true purpose and value of engineering activity lie in providing better and easier ways for satisfying ordinary human needs. This provides more leisure and opens new possibilities for a higher intellectual development of humanity. The engineer's personal satisfaction consists in knowing this high purpose of his vocation, and in giving his service at maximum efficiency. The other compensation is a result, and not the purpose.

THE final report of the National Association for the Promotion of Technical and Secondary Education has now been published. In accordance with a resolution of its executive committee, adopted at a meeting on March 20 last, the association was wound up on June 30 of this year. The final report takes the form of a brief historical review of the work of the association, and incidentally serves to show the substantial progress which has been made in our national education during the last twenty years. The inaugural meeting was held on July 1, 1887, when the president, the Duke of Devonshire, who served in that capacity throughout the society's existence, took the chair. The association certainly had an excellent record of service. Largely as the results of its activities were passed the Technical Instruction Act and the Welsh Intermediate Education Act in 1889, the Local Taxation (Custom and Excise) Act in 1890, the Technical Instruction (Amendment) Act in 1891, and the Schools for Science and Art Act in 1891, and many administrative improvements were also secured. Several of the association's publications, too, did much to educate public opinion, and among these may be mentioned "Studies in Secondary Education," "A Manual to the Intermediate Education (Wales) Act, 1889, and the Technical Instruction Act, 1889," and the quarterly issues of the *Record of Technical and Secondary Education*. As was only natural, many prominent men of science were from its inauguration closely identified with the association. It will suffice to refer, among many others, to the late Prof. Huxley, to Lord Avebury, Sir William Abney, Sir William Mather, and Sir Henry Roscoe. It is greatly to be hoped that the work so successfully accomplished by the association will be carried on by existing societies of a kindred nature, for, as the Duke of Devonshire remarked at the last annual meeting, a great deal more still remains to be done. The library of the association has been purchased by Sir William Mather, and presented to the Manchester Free Library, and the balance of its funds, amounting to nearly 250*l.*, has been voted to the late secretary, Mr. Frederick Oldman, as an acknowledgment of his services.

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 7.—"Observations on the Life-history of Leucocytes. Part II. On the Origin of the Granules." By C. E. **Walker**. Communicated by Prof. C. S. Sherrington, F.R.S.

The granules that are so frequently found in leucocytes generally seem to lie scattered quite irregularly in the cytoplasm of the cells in which they occur. In the bone marrow, however, where the leucocytes containing granules are often extremely numerous, a section of properly preserved material will show that the granules are arranged in a more or less definite manner. The granules in these are, as a rule, oval in shape, and seem to lie in sequence close to each other, so that a line drawn through their long axes would appear as a thread or wire coiled up irregularly in the cytoplasm of the cell. There are many gradations in the regularity of this arrangement of the granules. It varies from a mere suggestion of some of them having been strung together, to a very definite order, and the joining of several end to end. There are again other cells in which a large number of granules join together, forming in places a thick, deeply staining thread, the axis of which is continuous with the axis of the strings of separate granules. From these it is possible to pass by almost insensible gradations to cells where there are no granules, but only a thick thread coiled round the nucleus. From this stage it is again possible to pass to cells where the coiled-up thread occupies a space slightly larger than, or equal to the nucleus, until we arrive at some where it seems to be about the same size in proportion to the nucleus as is the archoplasm in the case of the spermatid. Though it has not been possible as yet to trace the origin of this thread farther, it is strongly suggested that it arises in the archoplasm, which is often seen to be connected with it. During the whole of its existence the thread stains very deeply, and always with the basic in preference to the acid stain. When it has entirely broken up, the granules formed from it still stain in the same manner, but as they begin to lose their regular arrangement so they begin to lose their affinity for the basic stain. These phenomena have only been met with among the cells of the bone marrow. It has been seen that the staining reaction in some at any rate of the granular cells changes from basic to acid; the presence, therefore, of cells containing acidophile and basiphile granules in various proportions is just what one would expect, and is no argument against a common origin of both from the thread here described as occurring in the cells of the bone marrow. The opportunity is taken of pointing out the relationship between the structures which arise from the true archoplasm. Among such structures are the archoplasmic vesicles found in the cells of the testis, which develop into the cephalic cap of the spermatozoon, the similar structures (Plimmer's bodies) which appear in some of the cells in malignant growths, and the granules in leucocytes.

June 27.—"Observations on the Life-history of Leucocytes. Part III." By C. E. **Walker**. Communicated by Prof. J. B. Farmer, F.R.S.

The author in a previous communication described the occurrence of the meiotic phase and of a number of post-meiotic generations among the leucocytes in vertebrate animals. The number of chromosomes in such cells must, if this occurs, be reduced to one-half of that found in the somatic cells. Such leucocytes will, in fact, have passed through that change which appears to be a necessary prelude to conjugation throughout the animal and vegetable kingdoms. The present paper describes certain phenomena as occurring in leucocytes, and claims that these are most probably to be interpreted as a process of conjugation between individual leucocytes that have passed through the meiotic phase. This conjugation is said to be accomplished in a somewhat complicated manner. The nucleus of one leucocyte sends out a process which penetrates the cytoplasm belonging to itself and to that of the partner in conjugation. This process is in the form of a tube, and through it the linin and chromatin of the one nucleus are drawn into that of the other. The absorption of one cell by another is a well-known phenomenon, but is a comparatively simple affair. The absorbed cell is taken into the cytoplasm of the absorbing cell, and is there digested. No nuclear change takes place, and the absorption is apparently carried out in the cytoplasm without the nucleus being directly involved.

It is claimed that the appearance of a special and complex apparatus with no apparent result but the transference of the contents of one nucleus to the other without exposing the contents so transferred to the action of the cytoplasm, shows that some process other than mere absorption of one cell by another is taking place, and that fertilisation is the probable explanation. It is also suggested that this may be a form of fertilisation not hitherto observed in unicellular forms, and that its occurrence among leucocytes is a case of phylogenetic reversion.

Physical Society, October 25.—Prof. J. Perry, F.R.S., president, in the chair.—Magnetic oscillators as radiators in wireless telegraphy: Dr. J. A. **Fleming**. The paper describes experiments made with flat square coils of various sizes used as magnetic oscillators in the quadrangle of University College, London. In one circuit undamped oscillations were set up by means of a Poulsen arc, and the induced oscillations created in the other circuit at a distance were detected and measured by means of the author's oscillation valve or glow-lamp detector. The distance separating the two circuits was varied from about 50 feet to 250 feet. Curves were obtained showing how the secondary current varied with the distance of the circuits apart and with their relative position. It was shown that the inductive effect was greatest when the flat coils were in a horizontal position and at a certain distance above the earth. The law of variation with distance proved to be something between the inverse cube and the inverse square of the distance. It was then shown that increase in size of the coils had a very marked action in increasing the inductive effect, and also that for equal power the use of the spark method, creating intermittent oscillations in the primary, gave better effects than the use of the arc or undamped oscillations. It was also shown that for the coils used the true radiation of energy was very small, and therefore that the distance effects obtained were almost entirely due to magnetic or Faradaic induction. Suggestions were then made for increasing the efficacy of the ordinary inductive type of wireless telegraphy by the use of high-frequency oscillations in the primary circuit, and a suitable detector such as the author's oscillation valve combined with a telephone as a receiver in the secondary circuit. Such a method would have a far greater reach than the ordinary low-frequency alternating current inductive telegraphy, and not be open to the objection of disturbing commercial telephonic circuits.—The use of variable mutual inductances: A. **Campbell**. In connection with wireless telegraphy, the measurement of small inductances and capacities is of importance; one of the methods described has special reference to small self-inductances. Mutual inductances can be more easily dealt with than self-inductances, for the former can be (1) more accurately calculated from dimensions; (2) are less affected by change of frequency; and (3) when variable can be made to pass through zero value. A convenient form of variable mutual inductance consists of a continuously variable part and a series of steps. The first consists of two equal parallel coils with a third coil moving parallel to their planes round an axis eccentric to the fixed coils. The scale thus obtained is very open near zero (which is an advantage), and the graduation is done by experiment, a theoretical discussion being given in an appendix. The steps are obtained by means of another fixed coil of stranded wire, each strand giving an equal subdivision. The model shown had two ranges, from 0·01 up to 200 and 2000 microhenries.

Entomological Society, November 6.—Mr. E. Saunders, F.R.S., vice-president, in the chair.—*Exhibits.*—A. H. **Jones**: A specimen of the longicorn beetle *Acanthocinus aedilis*, L., a Rannoch species, found in Gray's Inn Road.—Dr. F. A. **Dixey**: ♂ and ♀ specimens of a new Pinacopteryx, discovered by Mr. S. A. Neave in northern Rhodesia. The ♀ resembled that of *P. rubrobasalis*, but the ♂ was quite distinct. Both sexes of *P. rubrobasalis* and the female sex of Mr. Neave's species were mimics of *Mylothris agathina.*—W. G. **Sheldon**: A series of *Limenitis populi* and ab. *tremulae* with intermediate forms taken this year near Laon, and a series of *Chrysophanus hippothoë* from the same region, the females displaying a wide range of variation for so restricted a locality as that in which they were captured.—G. C. **Champion**: A fully developed example of *Mesovelia furcata*, M. and R., from Slapton, south Devon, and *Thamnotrizon cinereus* from Lynmouth, north Devon.—A. **Harrison** and Hugh **Main**: A case of *Aplecta nebulosa*, arranged to show the great range of variation of this species in Delamere Forest, with series from Epping Forest, north Cornwall, and the New Forest for comparison.—R. S. **Mitford**: (1) Two ♂ specimens of *Cryptocephalus bipunctatus*, taken by him at Niton, in the Isle of Wight, in July, these being two forms of varieties well known on the Continent, but hitherto found in Britain; (2) *Paracymus aeneus*, captured on the north Essex coast in June, 1898, thus establishing the claim of *P. aeneus* to be regarded as a British beetle; (3) an example of the very rare *Lathrobium rufipenne*, taken at Niton, Isle of Wight, in July, 1906, a specimen of the rare *Ceuthorrhynchus viduatus*, taken by him at Brading, Isle of Wight, in July, 1907, and a specimen of *Cis dentatus*, taken at Sandown, Isle of Wight, in July, 1906; this species, although well known on the Continent, had never before been recorded in Britain.—*Papers.*—A large series of Nycteribiidæ (parasitic Diptera) from Ceylon: J. E. **Collin.**—(1) Some butterflies taken in Jamaica; (2) some butterflies of Tobago: Dr. G. B. **Longstaff.**

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section) contains the following memoirs communicated to the society:—

March 9.—The uniformisation of real algebraic curves: P. **Koebe.**

May 11.—The uniformisation of given analytic curves: P. **Koebe.**—The radio-activity of the air over the open sea: C. **Runge.**—Researches from the Göttingen University chemical laboratory, xvii.:—(1) on oxygenated derivatives of sylvestrene; (2) on nopinone; (3) on the synthesis of higher homologues of terpin and of higher homologous terpenes: O. **Wallach.**—Contribution to the theory of undamped electric oscillations in gas discharges: E. **Riecke.**—Numerical survey of the near and remote earthquakes registered at the Samoa Observatory during 1906: F. **Linke.**

July 6.—The effect of light upon the formation of sulphuric acid: A. **Coehn.**—The class enumeration of the *Körper* of complex multiplication: R. **Fueter.**

July 7.—The boundary values in the case of the differential equation $\Delta\Delta U = 0$: A. **Haar.**

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 21.

ROYAL SOCIETY, at 4.30.—Results of the Interaction of Mercury with Alloys of Other Metals: Dr. J. W. Mallet, F.R.S.—Note on the Sensibility of the Ear to the Direction of Explosive Sounds: A. Mallock, F.R.S.—On the Silver Voltameter: Part i., A Comparison of Various Forms of Silver Voltameters: F. E. Smith; and a Determination of the Electrochemical Equivalent of Silver: F. E. Smith and T. Mather, F.R.S.; Part ii., The Chemistry of the Silver Voltameter: F. E. Smith and Dr. T. M. Lowry.—On the Normal Weston Cadmium Cell: F. E. Smith.—On a Method of Depositing Copper upon Glass from Aqueous Solutions in a Thin Brilliantly Reflecting Film, and thus Producing a Copper Mirror: Dr. F. D. Chattaway, F.R.S.—On Luminous Efficiency and the Mechanical Equivalent of Light: Dr. C. V. Drysdale.—The Dispersion of Double Refraction in Relation to Crystal Structure: Dr. T. H. Havelock.

CHEMICAL SOCIETY, at 8.30.—The Interaction of Metallic Sulphates and Caustic Alkalies: S. P. U. Pickering.—The Chemistry of Bordeaux Mixture: S. P. U. Pickering.—Aromatic Azoimides, Part iii., The Naphthylazoimides and their Nitro-derivatives: M. O. Forster and H. E. Fierz.—Studies of Dynamic Isomerism. Note on the Action of Carbonyl Chloride as an Agent for Arresting Isomeric Change: T. M. Lowry and E. H. Magson.—Emulsions: S. P. U. Pickering.—The Electrometric Measurement of the Hydrolysis of the Salts of Anilinium, Ammonium, Aluminium, Chromium, Thallium, Zinc, Magnesium, Cerium, Thorium, Nickel and Cobalt: H. G. Denham.

INSTITUTION OF MINING AND METALLURGY, at 8.

LINNEAN SOCIETY, at 8.—Abnormal Structures in Leaves, and their Value for Morphology: W. C. Worsdell.—Specimen-preservation in Australian Museums: J. G. Otto Tepper.—Revision of the Genus Illigera, Blume: S. T. Dunn.—*Exhibits*:—Luminous Larva from British Guiana: C. W. Anderson.—Living Specimens of Peripatus, from South Africa: Prof. A. Dendy.—*Linaria arenaria*, and other British Plants: G. C. Druce.

FRIDAY, NOVEMBER 22.

PHYSICAL SOCIETY, at 5.—On Singing Sand from New England: S. Skinner.—Exhibition of a Micromanometer: L. Bairstow.—A Diabolo Experiment: Vernon Boys.—Exhibition of a Gyroscope illustrating Brennan's Monorailway: Prof. H. A. Wilson.

MONDAY, NOVEMBER 25.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Exploration of the Nun-Kun Mountain Group and its Glaciers: Dr. W. Hunter Workman.

SOCIOLOGICAL SOCIETY, at 8.—The Psychological Origin of Religion: Prof. J. H. Leuba.

SOCIETY OF ARTS, at 8.—The Theory of the Microscope: Conrad Beck.

INSTITUTE OF ACTUARIES, at 5.—On the Valuation of Staff Pension Funds, Part ii., Widows' and Children's Pensions (continued): H. W. Manly, with Tables by W. A. Workman.—A Pension Fund Problem; with some Remarks on the Deduction of Salary-scales: J. Bacon.

TUESDAY, NOVEMBER 26.

ZOOLOGICAL SOCIETY, at 8.30.—On some New and Little-known Araneidea: Rev. O. Pickard-Cambridge, F.R.S.—Descriptions of New Species of South-American Cryptocephalini; M. Jacoby.—A Monograph of the Chiropteran Genera Uroderma, Enchisthenes, and Artibeus: Dr. K. Andersen.—Environmental Studies on the Limpet: E. S. Russell.—Contributions to the Knowledge of the Anatomy of the Batrachian Family Pelobatidæ: F. E. Beddard, F.R.S.—On the Microlepidoptera of Tenerife: Lord Walsingham, F.R.S.—Dates of Publication of the Separate Parts of Gmelin's Edition (thirteenth) of the "Systema Naturæ" of Linnæus: J. Hopkinson.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Tranmere Bay Development Works: S. H. Ellis.

WEDNESDAY, NOVEMBER 27.

BRITISH ASTRONOMICAL ASSOCIATION, at 5.—Address by Sir David Gill, K.C.B., F.R.S.

SOCIETY OF ARTS, at 8.—The Franco-British Exhibition, 1908: Sir John A. Cockburn, K.C.M.G.

THURSDAY, NOVEMBER 28.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Development of Turbo-Generators: Dr. Robert Pohl.

FRIDAY, NOVEMBER 20.

SOCIETY OF ARTS, at 8.—The Hygiene of Work in Compressed Air (Diving, Caisson Work, Sub-aqueous Tunnelling, &c.): Dr. J. S. Haldane, F.R.S.

THURSDAY, NOVEMBER 28, 1907.

THE VERTEBRATE NERVOUS SYSTEM.

The Nervous System of Vertebrates. By Prof. J. B. Johnston. Pp. 370. (London: J. Murray, 1907.) Price 15*s*. net.

THE author's aim has been "to produce a text-book of comparative neurology, giving an account of the nervous system as a whole, to trace its phylogenetic history, and to show the factors which have determined the course of evolution." He states (in the preface) that the functional point of view is the chief characteristic of the present work, but that (p. 10), as an introduction to the study of the nervous system, it deals chiefly with structure.

The work starts with a brief, though clear, summary of the various methods used in the investigation of the nervous system, and then proceeds to a very useful description of the general morphology of the same, more particularly as found in the Cyclostoma, Selachians, and Amphibia. Then follows a lucid account of the main features and processes in the development of the nervous system, especially as seen in the lower vertebrates, and valuable light is thrown on the evolution of those parts of the nervous system associated more directly with the visceral arches, spiracular and branchial clefts, and of the lateral line structures. We note the author, without hesitation, ascribes taste, or gustatory, functions to structures distributed more or less widely on the outside of the head, and in extreme cases, as in some bony fishes, on the fins and over almost the entire body, yet the true and specific function of these organs remains still to be determined.

In a brief description of the nerve elements and their functions the formulation of the neurone theory is ascribed (p. 10) to Waldeyer, in 1891, whereas this distinguished savant did little more than suggest the term "neurone" for structures the conceptions of which in this connection had been gathering strength since the days of Schleiden and Schwann, some fifty years earlier.

In discussing nerve degeneration and regeneration the author *inter alia* states (p. 90) that the proximal portion of a divided peripheral nerve remains in a healthy condition. This may be true for some of the lower vertebrates, but is incorrect for many of the higher forms, as v. Gehuchten and others have proved.

In chapters v. to xii. the author discusses with much originality and lucidity the four kinds of nervous activity, viz., the somatic afferent, somatic efferent, visceral afferent, and visceral efferent, and these chapters, together with that on the evolution of the cerebral hemispheres, may be accounted some of the most valuable in the book. The description of the neuromasts is especially useful, and though on debateable and obscure ground the whole matter is suggestively and clearly treated. However, the author not infrequently falls into the common error of confusing or using indiscriminately the term "afferent" and "sensory," and throughout the work seems more at home with the subject as it concerns the lower than with that of the higher vertebrates, especially in connection with recent work.

Perhaps, too, reference may be made to the following assertions:—On p. 110 it is stated that "sensory cutaneous fibres emit collaterals which cross directly to the opposite side of the spinal cord." These crossing fibres have never yet been shown degenerated in a mammal, and the statement is incorrect for at least the majority of the higher vertebrates. Again, on p. 115 it is stated that "a part of the secondary neurones of the V. nerve ascend on the same side of the body," whereas recent work tends to show the contrary, at least in mammals.

In the description of the cerebellum several statements call for modification. Thus it is stated, p. 240, that "all three peduncles of the cerebellum carry both incoming and outgoing fibres," whereas many recent workers on higher vertebrates have shown the inferior cerebellar peduncle to contain only afferent fibres. Again, on p. 243, it is stated that "primary somatic sensory fibres from *spinal* roots enter the cerebellum directly." On p. 245 that "the direct cerebellar tract from Clarke's column ends, according to most observers, in the deep grey nuclei of the cerebellum" (instead of in the cortex of the vermis); and on the same page that "the axones of the Purkinje cells pass to the spinal cord and inferior olive," and that "the fibres passing to the Nucleus Dentatus seem to include fibres from the posterior column nuclei." With all of these statements we are in disagreement, and naturally, therefore, with deductions drawn therefrom. Moreover, we regret in the account of the cerebellum the absence of reference to the views of Hughlings Jackson, or to the recent work by Sherrington, whilst the general conception that the cerebellar cortex is a large recipient surface for afferent impulses from all parts of the body; that this gives off its efferent impulses along the fibres to the cerebellar nuclei, and these gain efferent impulses to the bodily structures as advocated more particularly by Clarke and Horsley, Déjerine, Thomas, Klimoff, &c., seems insufficiently emphasised.

The last chapter offers briefly a review of the more important facts concerning the neopallium, and would have been more useful had it in the discussion of the sensori-motor areas treated of such sub-divisions as the audito-sensory, audito-psychic, visuo-sensory, and visuo-psychic, which are not mentioned; and had the motor area not been depicted as involving the post-central gyrus which Grünbaum and Sherrington disproved for Anthropoids, and many surgeons have disproved in man.

On the whole, the book gives the impression of having been written by an able zoologist interested in neurology, rather than by a pure neurologist, and therein lies a good deal of its value. No more abstruse problem has ever been presented to man than that of the vertebrate nervous system, and in the present work the author presents a very readable and succinct account of his subject, which forms a valuable and welcome addition to the literature relating to it.

W. PAGE MAY.

ELECTRIC POWER AND TRACTION.

Electric Power and Traction. By F. H. Davies. Pp. vi+293. (London: A. Constable and Co., Ltd., 1907.) Price 6s. net.

ELECTRIC power and traction is such an immense subject that it is rather a bold undertaking to deal with it in a small volume of 293 pages, even if the reader is supposed to know the elementary laws of electrical engineering. The book, however, does not pretend to be a regular text-book, but it is evidently intended for those whose knowledge of electrical engineering is limited, and to these as well as students it can be recommended.

Four chapters deal with the generation and distribution of power. The various systems of direct and alternating current are briefly discussed, and descriptions of typical installations are given. As the author briefly touches upon the subject of direct-current high-tension transmission, it is rather surprising that no mention is made of the Thury system, which has come into prominence during the last few years.

Two chapters are devoted to D.C. and A.C. motors, and their principles are expounded. In directing attention to the starting-up of induction motors, the author omits to mention the important method of changing from "star" to "delta" on the stator, which is used for most squirrel-cage motors up to 20 horse-power.

The chapters on the application of electric power are the best in the book, and the advantages of electric driving are clearly brought out. On p. 124 there appears a statement which shows that, in the author's opinion, the time is not far distant when the voltage for lighting ships will be raised to 200 or 240, but this prediction will not command universal assent. The modern tendency even on shore is to return to 110 volts, especially since the introduction of metallic filament lamps, and it seems more probable that 100 or 110 volts will remain the standard voltage for marine work.

The last ten chapters of the book are devoted to electric traction, and although one may find in them a few statements which are open to criticism, they contain a good deal of practical information. The conduit and surface-contact systems are dealt with, and the advantages of electric traction are briefly set out. Full details are given of the direct-current system in use on the Metropolitan, District and London tube railways. The benefits of "multiple-unit control systems" are briefly touched upon. In view of the prominence given to the Westinghouse control system, it is surprising that no mention is made of the British Thomson-Houston system, the more so as the latter is in use on nearly all the London tubes and underground railways.

In his remarks on substations the author, in dealing with motor-generators, has omitted to mention Bruce Peebles' motor-converters, which in recent years have come largely into use, notably on the Great Western Railway, where it is the standard equipment for all substations.

On p. 240 the novel statement appears that the middle rail on the Metropolitan and District railways is not protected, "because it is practically at earth potential." Perhaps if the author would try it, by touching it, he might change his opinion.

The exposition of the *pros* and *cons.* of three-phase, single-phase, and D.C. systems is not absolutely convincing, because, to judge from the disproportionately numerous descriptions of single-phase locomotives, it would almost seem that the author has an unduly high opinion of this system. It might have been of interest if particulars had been given of the New York Central locomotives, as they represent the most recent practice in D.C. traction, and surpass anything that has been done, so far, with the single-phase system. The book is well printed, and illustrated by excellent photographs. It contains a good deal of sound practical information, and can be recommended to the class of readers for whom it is intended. Systematic Practical Organic Chemistry. By G. M. Norman. Pp. viii+98. (London: W. B. Clive, University Tutorial Press, Ltd., 1907.) Price 1s. 6d.

A Course of Practical Organic Chemistry. By T. Slater Price and D. F. Twiss. Pp. xiii+239. (London: Longmans, Green and Co., 1907.) Price 3s. 6d.

A Scheme for the Detection of the More Common Classes of Carbon Compounds. By F. E. Weston. New edition. Pp. viii+95. (London: Longmans, Green and Co., 1907.) Price 2s. 6d.

MR. OLDHAM'S book provides a complete course of instruction for schools. He has had in view the London matriculation and the Army entrance examination, but has added important sections not included in either syllabus, which he says with a touch of irony "should be taught wherever a teacher is free from the trammels of an examination syllabus and need think only of giving sound instruction."

Judging from a general survey of the book, we are inclined to think that the syllabuses above mentioned were not altogether present in the author's mind when he wrote it, for sound instruction is certainly the keynote of his method.

Part i. especially is excellently arranged, clearly written, and admirably illustrated. If the school time admitted of it one could not devise a better course for the beginner in chemistry; but the standard eventually reached is far beyond that of any matriculation candidate, and one is doubtful if even three school years would suffice to cover the ground mapped out, unless, indeed, the experimental part were performed for, instead of by, the student, which would be a misfortune. The programme is an ambitious one; but we believe it is thoroughly sound, and if it could be begun at school and carried to the end of part i. slowly and methodically, it would form an excellent groundwork for a subsequent college course.

There is little to criticise. Attention should be directed to one omission which is not uncommon in elementary text-books. It states on p. 40 that "you have found out that hydrogen is contained in acids." It is quite true that hydrogen is described as being obtained by the action of acids on metals, but there is no suggestion as to where the gas comes from, and, so far as any information to the contrary goes, it might just as well come from the metal. Some explanation or comment is called for, because a few pages further on the action of acids on carbonates is described, and in this case the process appears to be reversed, the gas coming from the solid and not from the acid.

We should like to see electrolysis entirely banished from elementary books. The decomposition of water by the current is a mysterious and unconvincing experiment. It is difficult to understand why the gases appear at the ends of two different platinum wires, and why the volumes which collect should represent the true composition of the liquid. The union of the two gases to form water by means of the electric spark only serves to heighten the mystery. A careful drilling in these two operations gives the schoolboy an agent which in his imagination will produce or decompose every compound gas that ever existed, and he uses this knowledge, as we all know, with a reckless facility. It is a satisfaction to find that Lavoisier did not, as we are generally told, institute experiments to prove the conservation of matter, but, as the author states, did several experiments which showed it. Lavoisier simply took the principle for granted, as most chemists had done before him, from Boyle onward. Dalton, by the way, was not exactly a schoolmaster in Manchester, though he served in that capacity at Kendal.

The attractive appearance, substantial get-up, and exquisitely drawn diagrams of Dr. Martin's book command at once a careful perusal. It differs essentially from the foregoing in confining itself to the practical, or, perhaps more strictly, to the manipulative side of chemistry. Each experiment stands alone, and has no necessary connection with the one that precedes or follows it, minute directions being given for its performance. It is also for Army and matriculation candidates, and will no doubt prove very useful to both candidate and teacher as a laboratory *vade mecum*.

Mr. G. M. Norman's "Systematic Practical Organic Chemistry" is one of the organised science series, and is intended to meet the requirements of stages i. and ii. of the Board of Education examination. It contains a description of a series of simple preparations and a variety of useful tests. It is satisfactory to find that the Board of Education now requires evidence that the candidate has carried out a number of preparations before presenting himself. It is to be hoped that before long the Board of Education will take the further step of requiring the evidence without the candidate. No kind of chemistry lends itself to a two or three hours' practical examination, organic chemistry perhaps least of all, and the evidence of knowledge elicited by the sort of experiment set at these examinations has very little value. That, however, does not impair the usefulness of the book under review, which may be safely commended both for the purpose it is intended to fulfil and also as an introduction to practical organic chemistry.

Messrs. Price and Twiss's "Practical Organic Chemistry," like the preceding volume, owes its origin to the new syllabus of the Board of Education, and is intended to meet to some extent the requirements of stage iii. (theoretical organic), as well as to prepare for stages i. and ii. (practical organic) of the Board's examination. The treatment of the subject is full and comprehensive. It contains the usual series of simple preparations, an account of the qualitative and quantitative examination of organic compounds, molecular-weight estimations, and useful schemes of analysis. Without introducing any specially novel features, it presents a fairly complete programme of practical study which if carefully carried out should form a sound basis for subsequent research in organic chemistry. The descriptions are clear and concise, and the illustrations, though not numerous, are probably sufficient for the purpose. It may be recommended as a thoroughly safe book for the laboratory.

Mr. Weston's book on the detection of organic compounds deals, as it states, with qualitative methods only. That such a book should have reached a second edition and should serve the needs of the final B.Sc. of the London University and of the honours stage of the Board of Education is a hopeful sign of the times, if we must have this kind of test. Such defects as the book possesses, and they are not numerous, are to be attributed to the fact that it is written to meet the requirements of a practical examination where time is an important factor.

The author confines his attention to the study of pure organic substances only, giving directions which, if carefully followed, should lead to their detection, and at the same time to the acquisition of much useful information and manipulative skill on the part of the student.

This is all thoroughly sound and satisfactory so long as it is recognised that it is an introduction to analysis, and that the real laboratory problems involve such things as the separation of mixtures and the purification of impure products. It appears from a general perusal of the book that some of the directions need amplifying. This refers more particularly to the means of ascertaining the presence of oxygen, upon which the grouping of the compounds is based, to the identification of aromatic hydrocarbons (p. 12), to Fenton's oxidation method for detecting ketohexoses (p. 47), and to Fischer's benzaldehyde green reaction for aldehydes (p. 40). We would also suggest the following additions or modifications in a future edition:—the use of bromo- and nitro-phenylhydrazine, methyl sulphate and semicarbazide as useful reagents and of Tollens' reagent (the name, by the way, is spelt with an "s") for pentoses, also the consistent use of the modern system of nomenclature and a good index.

J. B. C.

OUR BOOK SHELF.

Vergleichende Morphologie der Pflanzen. I. Theil, mit 200 i.d. Text gedr. Abbild. u. zwei lith. Doppeltafeln. By Dr. Jos. Velenovský. Pp. 277+plates. (Prag: Fr. Rivnác, 1905.)

Dr. Velenovský has written the earlier portion of a work which will be found of no small interest to botanists, not only because the author has brought together a number of new observations of his own, but because he deals with the whole mass of facts from a definite point of view. Probably, as he himself hints in the preface, his views may not command general acceptance, and we confess to experiencing a certain sense of disappointment after reading the book. The point of view which the author adopts is, it seems to us, too rigid and formal. Morphology has really outgrown the stage of pure formalism. We have come to recognise that the task of trying to understand why and how development has followed on the lines one can actually trace, is overshadowing the purely formal abstractions which used to constitute morphology.

Twenty years ago it was the fashion to divorce physiological notions from morphological concepts. At the present time, probably most botanists have an inkling, if not a conviction, that morphological "laws" really do resemble those of the Medes and Persians. The "laws" in both cases last just so long as they can continue to be tolerated. With increased knowledge the bonds of the old laws are loosened, and fresh working theories become needed to comprehend the increased range of intellectual vision.

But it must not be thought that the foregoing remarks are intended to depreciate the value of the book before us, for it appears to us to be one that can be read with considerable interest and profit. Much of the author's railing against certain practices which are not uncommon at the present time is justifiable, although he is apt perhaps to overstate the case. "In modern times hardly anything but a monograph is appreciated; each author is acquainted with his own particular genus, or it may be, family, and he cares for nothing else. . . ."

But when Dr. Velenovský leaves generalities and comes to closer quarters with his subject-matter, he is on ground where he will meet with less opposition, albeit his methods may awaken some surprise. In these days laborious description of anatomical detail too often replaces an attempt to give a comprehensive account of the plants themselves. The author, however, scarcely devotes any space at all to internal structure, and finds room thereby to give a more complete account of the range of external variation within the cryptogamic groups to which this volume is devoted; and it is not impossible that some of his readers may experience a kind of mild shock at finding many unfamiliar forms included in a group which they have hitherto only known through one or two laboratory "types."

The book contains many new illustrations, and it is not unlikely to meet with a better reception than its author seems to think it will obtain. J. B. F.

De Vormen der Aardkorst: Inleiding tot de Studie der Physiographie. By J. van Baren. Pp. viii+232. (Groningen: J. B. Wolters, 1907.)

This little book attempts, in the course of 207 pages, to cover the whole ground of physical geology, and to give an account of the most important observations and discoveries made in this branch of science up to the year 1905. It is necessarily, therefore, somewhat sketchy, but ample compensation for this will be found in the freshness of its information, whether conveyed by illustrations or letterpress. The illustrations are particularly good, and the only one which strikes us as distinctly old-fashioned is the diagram showing the distribution of seismic areas.

In the opening pages the student is introduced to the meaning of elementary technical terms, with their equivalents given in English, French, and German. These would be more useful if they were more exact; the English for "Streichen" is not "direction," but "strike," and an "overthrust" is not identical with either an inclined or a recumbent fold. It is singular that many Continental geologists, notwithstanding their apparent familiarity with the structure of north-western Sutherland, should still seem to find a difficulty in grasping the real significance of our "overthrust."

The author does not attempt to found any system of his own, and in disputed questions generally contents himself with summarising the opinions of others; hence, in treating of the internal state of the earth, the important bearing of recent seismological observations is overlooked, for if distortional waves do really traverse the whole mass of the planet, we need no longer give serious attention to theories which involve a gaseous interior.

The origin of coral atolls is briefly discussed, and the boring in Funafuti is referred to as furnishing a proof that in certain cases Darwin's theory holds good; on the other hand, it is asserted that this theory will not apply to the atoll-like reefs of the West Indies. This latter statement would seem to show that the author cannot have read Darwin's "Coral Reefs" with sufficient care, for Darwin himself expressly excluded these reefs from his explanation. In this oversight, however, the author by no means stands alone.

To the general reader, whose interest is restricted to results, this work will provide a useful epitome, nor is it without a claim upon the advanced student; it brings together many new facts hitherto scattered and disconnected, and builds them into the edifice of his science.

Nests and Eggs of Birds found Breeding in Australia and Tasmania. By A. J. North. Vol. ii., part ii. (Australian Museum, 1907.)

This part of the second volume of the new edition of Mr. North's excellent work on the nests and eggs of the birds found breeding in Australia and Tasmania describes the greater portion of the large and important family Meliphagidæ, commenced towards the latter end of the preceding part, and the families Nectariniidæ, Zosteropidæ, Dicædæ, and Pardalotidæ. The figures of the eggs, which are of the natural size, were reproduced by heliotype process at the Government Printing Office from photographs of specimens. The letterpress contains descriptions of the birds, their nests and eggs, and a general account of their life-history. The excellent detailed description of the birds, the copious field notes, and the beauty of the illustrations all call for notice. This important and most interesting work is a publication of the Australian museum, beautifully produced, and at a very low price. In the present part we have 138 pages of letterpress (large 4to), three plates (one showing the nest of Lewin's honey eater *in situ*, and the other two comprising sixty-six figures of eggs), besides illustrations in the text of birds, nests, and breeding haunts, for 7*s*. 6*d*.

Grundzüge der Tierkunde für hohere Lehranstalten. By Prof. Karl Smalian. Pp. 304; illustrated. (Leipzig: G. Freytag; Vienna: E. Tempsky, 1907.) Price 4 marks.

This work, which is intended as a companion to the author's "Grundzügen der Pflanzenkunde," is more attractive than the generality of school text-books on account of being illustrated by thirty coloured plates, which are excellent examples of the three-colour process. Not only are they for the most part good pictures of the animals they purport to represent, but they also show in most cases the natural surroundings of the respective species, so far as these can be reproduced with fidelity to nature. Unfortunately, in one instance that has come under our notice the wrong species has been depicted. We refer to the plate of giraffes and zebras facing p. 42, where the animal purporting to be the true or mountain zebra (*Equus zebra*) is the northern race of the bontequagga, or Burchell's zebra (*Equus burchelli granti*). Had the true zebra been depicted, the plate would then have been wrong, as showing a mountain animal on the open plains. The text includes a brief but well-compiled survey of the whole animal kingdom, from Primates to Protozoa, including sporatozoans, with some mention of extinct forms, and the work as a whole appears thoroughly suited to its purpose.

R. L.

Précis des Caractères génériques des Insectes, disposés dans un Ordre naturel par le Citoyen Latreille. A Paris, chez Prévôt, Libraire, Quai des Augustins, et à Brive, chez F. Bourdeaux, Imprimeur Libraire. A Brive, de l'Impriméric de F. Bourdeaux, an 5 de la R. [1796]. Pp. xiv+208. (Imprime à 200 Exemplaires par A. Hermann, n.d.) Price 7 francs.

THIS is a reprint of a very rare book, which is seldom to be found even in the best entomological libraries. It commences with a table of the fourteen classes into which the author divides insects (understanding by that term Arachnida, Crustacea, and Myriopoda, as well as Hexapoda), followed by systematic characters for 351 genera recognised by Latreille, one or two others, described by other authors, being passed over as at present unknown to him. Several very familiar genera, such as Ypsolophus and Adela, are characterised in this book for the first time, but without indication of types, for which reference must be made to Latreille's later works. It is always unsatisfactory to entomological authors to be in doubt respecting the actual contents of a book they only know at second-hand, and we are glad that this scarce book has now been rendered accessible to them in a complete (and, we hope, accurate) reprint.

The Metric and British Systems of Weights, Measures and Coinage. By Dr. F. Mollwo Perkin. Pp. 83; with 17 diagrams. (London: Whittaker and Co., 1907.) Price 1s. 6d.

DR. PERKIN here provides a simply written and clearly expressed account of metric measures of length, area, volume and weight, and, in addition, treats of specific gravities, temperature measurements, and money. As Lord Kelvin has said, "our weights and measures are time-wasting and brain-wearing," and all attempts to familiarise British boys with the simplicity and convenience of the decimal system deserve encouragement. This small volume should prove useful in both day and evening schools, and all engaged in manufacture and commerce would derive advantage from its study.

The Story of Scraggles (A Sparrow). By George W. James. Illustrated from drawings by Sears Gallagher and from photographs. Pp. 88. (London: Chatto and Windus, 1907.) Price 2s. 6d.

THE greater part of this booklet is in the form of the autobiography of an ailing song-sparrow, which could not fly, and was kept in a house for three months. The story, which purports to represent the bird's thoughts and feelings, will probably appeal to little girls, and encourage them to be kind to animals.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither con he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Specific Stability and Mutation.

MR. R. H. LOCK at the close of his letter in NATURE of October 17 (vol. lxxvi., p. 616) makes a remark which, after some consideration, still perplexes me. The question involved is so interesting and, indeed, important, that I feel sure that many of your readers would be glad to know the grounds, doubtless not without weight, which led him to it. I quote the passage:—"that natural conditions lead to the obliteration of a host of mutations is as fair a deduction from the fact that such mutations appear under cultivation as the current deduction that the conditions of cultivation actually cause the occurrence of this kind of variation. We have the testimony of de Vries and others that the former process actually takes place. That the latter process does so is an assumption which still lacks the support of facts."

It contains two propositions:—(1) mutations appear under cultivation; (2) that the conditions of cultivation actually cause the occurrence of this kind of variation . . . is an assumption which still lacks the support of facts. It is the latter on which I think some discussion would probably be illuminating. At first sight the two propositions look contradictory. It is possible, however, that Mr. Lock is using "cause" in a very technical sense. But as Mill remarks, "in practice that particular condition is usually styled the cause, whose share in the matter is superficially the most conspicuous." Now, our knowledge of mutations is almost exclusively drawn from cultivated plants. In such cases cultural conditions are obviously an inseparable antecedent to mutations. What I do not understand is why it is an "assumption" to state that there is a causal nexus between the effect and the conditions.

To avoid ambiguity, I may explain that by "variation" I mean insensible and continuous organic change; by "mutation," that which is large, palpable, and discontinuous.

I believe that in nature variation never ceases, and yet "species" do not perceptibly vary. I pointed out some years ago, in a discussion at the Royal Society, the explanation of this seeming paradox. What we mean by a species is an abstraction which has no concrete existence. It is the mean or average of a host of varying individuals. It will be hardly contested nowadays that, so long as the conditions remain constant, the species remains unchanged. As has been frequently pointed out, the Egyptian flora furnishes a remarkable illustration of the fact over a long period of time. Plant remains from tombs believed to be 4000 years old differ in no respect from the species now living to which they belong, and the mere fact of their preservation shows that the physical conditions have undergone no change. To this persistence under constant surroundings I have given the name of "specific stability."

That mutations occur and exist is obvious to everyone. But that they are of frequent occurrence under purely natural conditions is, I think, unsupported by evidence, and, if they do occur, I agree with Darwin that it may be doubted if they "are ever permanently propagated in a state of nature" ("Origin," fifth edition, p. 49). The reason is that an organism is so nicely adjusted to its surroundings that it is in the highest degree improbable that a sudden and extreme structural change would fit in with them.

If species arise in nature by discontinuous variation or mutation, one would expect to see some evidence of their doing so; but in the British flora I can only call to mind a very few instances. There is a form of *Chelidonium majus* with laciniate leaves and petals. It is said to have first appeared at Heidelberg in 1590; according to Hooker it is only known in cultivation. There are two striking mutations of *Plantago major*, one with a paniculate inflorescence, the other with leafy bracts, which reappear from time to time independently, but always, I think, in cultivated ground. There is a tendency in maples to revert to a ternary symmetry, as is shown by the occasional production of three carpels instead of two. The sycamore often produces seedlings with three cotyledons. I grew some of these, and they had for a time leaves in whorls of threes, but soon reverted to pairs. I have only heard of one case of an adult wild maple with leaves three in a whorl.

There are some singular mutations which occur in the broad-leaved trees of temperate countries, but probably always under somewhat artificial conditions. They seem to be merely correlated with habit, and are quite independent of affinity. The normal angles at which the branches are set on either become very acute or very obtuse; in the one case we get pyramidal forms like the Lombardy poplar, in the other weeping forms. Or the cell-sap is deeply coloured red, masking the green of the chlorophyll corpuscles (copper-beech). In other cases the leaves lose their normal circumscription, and are deeply divided (fern-leaved beech). Apparently all these mutations are in some degree perpetuated by seed, but they do not hold their own in nature, and owe their preservation to planting in gardens and elsewhere. It is not easy to speculate as to the cause of these singular mutations. One may infer from the fact that they are related to habit, and not to affinity, that they are not due to reversion.

While specific stability under constant conditions appears to be the rule in nature, it is widely different in cultivation. When a plant is brought under cultural conditions it maintains its type for some time unaltered, then gives way and becomes practically plastic. From my experience at Kew, where I saw the process continually going on, I hazarded the generalisation that any species, annually reproduced from seed, could be broken down in about five years. During that period specific stability, though menaced, tends to maintain itself. Darwin was well aware of this, and as for the moment his books seem to be little studied, I will quote the passage :—

"We have good grounds for believing that the influence of changed conditions accumulates, so that no effect is produced on a species until it has been exposed during several generations to continual cultivation or domestication. Universal experience shows us that when new flowers are first introduced into our gardens they do not vary; but ultimately all, with the rarest exceptions, vary to a greater or less extent" ("Animals and Plants," ii., p. 261).

He quotes in support the testimony of well-known experts. Thus Salter, the great raiser of chrysanthemums, states :—"Everyone knows that the chief difficulty is in breaking through the original colour and form of the species." Vilmorin, the most distinguished French horticulturist of his time, maintained that "the first step is to get the plant to vary in any manner whatever; for the fixed character of the species being once broken, the desired variation will sooner or later appear."

Abundant illustrations of the fact which has been stated are furnished by the history of individual species. Thus Sabine says of the first dahlia plants introduced into Europe :—"At Madrid they were a long time in the Royal Garden without any indications of change." The history of the Zinnia and of the Swan River daisy is the same. A few years ago Mr. Watson, the curator of Kew, gave me notes of cases which had come under his own observation. *Primula japonica* was introduced in 1871 as "a new crimson primrose." In 1877 it produced rose-coloured as well as various shades of magenta flowers. *Anthurium scherzerianum*, introduced in 1862, had in 1874 produced enormously developed spathes, and in 1880 a form with two spathes to each spadix. In 1874 it was crossed with a white variety, and that called *rothschildianum*, with mottled spathes, was the result. It is interesting to note that "the seedlings are nearly all mottled like the parent." *Impatiens Sultani* was introduced at Kew from Zanzibar in 1881. For several years it did not vary. It now exhibits half-a-dozen distinct shades of red in the flowers. The fine Cape orchid, *Disa grandiflora*, has long been in cultivation in this country; varieties were unknown until it was raised from seed by Dr. Moore at Glasnevin.

I may add two cases which have more particularly come under my own notice. *Nemesia strumosa*, a rather local South African plant, was introduced about 1892. It now shows indications of breaking up into two distinct races, with the greatest variety in the coloration of the flowers.

The most remarkable, however, is that of *Primula obconica*, introduced in 1882. For many years it was perfectly stable, but within the last few has exhibited the most surprising variation both in the number, form, and colour of the flowers.

In all these cases I think we may safely infer from the persistent specific stability at the commencement of cultivation that the changes which subsequently occur would not have occurred in nature. We cannot regard the one state as in any way a continuation of the other. The changes which occur under cultural conditions are, in fact, something *sui generis*. We may say, of course, if we like, that the potentiality of such changes was latent in the species in nature; but, as a matter of fact, if so, it was suppressed, and there is no evidence of its being called into activity.

The evidence, on the other hand, that such changes follow cultural conditions as a result is simply overwhelming, and I do not suppose that Mr. Lock denies it to be the case. The only question can be as to how they operate. Now there is one point in connection with plants under cultivation the importance of which I have not seen referred to. It is this: in nature we deal with a host of individuals; in cultivation with a very limited number. In my view specific stability is maintained partly by the weeding out of unfavourable variations, partly by wide interbreeding. Now it is obvious that under cultivation the latter agency is inoperative, and cultural conditions bring other influences to bear, especially as regards nutrition; but these I have no space to discuss.

I take it that the species in nature has two weapons in reserve for self-preservation. Of these, variation is the most effective if given time, as it will act automatically. Mutation, on the other hand, though it might now and again hit the mark, is likely in most cases to overshoot it, and is therefore seldom called into play or utilised; and observation seems to confirm this.

In the development of a plant under cultivation the horticulturist takes advantage of both variation and mutation. In the case of the Cyclamen, I have shown that the fine forms now existing are almost entirely the result of accumulated variation. As with the garden Cineraria there has been mutation in floral coloration; but the small amount of variation in the foliage proves, I think conclusively, that in other respects the latter has gradually been evolved from the wild *Cineraria cruenta*, though Darwin, from second-hand information with which I supplied him, stated otherwise.

The case of the Chinese primrose is extremely interesting. When introduced in 1820 it had probably already undergone some cultural development at the hands of the Chinese. It was slowly developed in Europe for a long period without manifesting any striking structural change, until it bore little superficial resemblance to the wild stock. This was discovered in the gorge of the Yangtse, and when introduced into this country proved very intractable of cultivation; in fact, I doubt if at the moment it is to be found in our gardens. Within about the last quarter of a century the cultivated form has exhibited two very remarkable mutations, and it is interesting to observe that these appear to recur independently. The first was the so-called "fern-leaved form." I do not know if this was ever fixed, but, if so, it did not take the public taste, and was not preserved; but fern-leaved individuals appear to occur casually in batches of seedlings of quite distinct races with the ordinary foliage. The transition from the palmatifid to the pinnatifid form of leaf is theoretically interesting. Nothing can well look more different than a fan-palm and a feather-palm, but we can see an intermediate stage in an Australian Livistona. The second mutation, the "ivy-leaved form," is much rarer, and in every way more remarkable. It is apparently accompanied by more or less floral abortion, and it has not been found possible to perpetuate it. The fern-leaved form is, it can hardly be doubted, a reversion to an ancestral type which has been perpetuated in other species, and this may also be the case with the ivy-leaved form, though this is more obscure.

The races of Œnothera which De Vries has raised are nothing more than what a horticulturist would expect; and it may be conceded that if such races could hold their own in nature, distinct species might originate in this way. But there is no evidence that they do; and the probability of their being able to do so is against them. Œnotheras are pretty prolific where they occur, and so far as my experience goes they keep true to type.

Cultural mutations seem, as a matter of fact, to have little, if any, capacity for holding their own in the struggle for existence. I cannot call to mind a single instance of one which has been successful, and even in cultivation there is some reason to think that they are short-lived; but this is a point on which we are in urgent need of carefully ascertained facts. One is told, for example, that new varieties of the potato mostly cease to give satisfactory results after a few years. This is, however, a case of purely vegetative reproduction, and similar statements are made about the sugar-cane, which it is now hoped to regenerate by seminal reproduction. I can remember when potato-fields were covered with flowers and subsequently with fruit. I suppose it was thought antagonistic to tuber-production, as it probably was, and sterile races were selected accordingly. Prof. Hildebrand came to this country to study the subject, and I was able to supply him with information which I had collected for another purpose.

There is practically nothing to add to what has been said on the subject by Asa Gray ("Darwiniana," pp. 338–347). It is notoriously difficult to get hold of old cultivated strains of garden plants, and change of fashion hardly seems sufficient to account for the difficulty. Gray points out "that with high feeding and artificial appliances comes vastly increased liability to disease, which may practically annihilate the race." This has all but happened to the hollyhock, and, left to itself, the Phylloxera would have exterminated the vine in Europe. The existence of a species in nature implies a complicated adjustment to the surroundings. It is not sufficient to launch upon them a new form; in order that it may hold its own, the adjustment must be provided as well. It is by no means always an easy thing to transfer a species from one part of the earth's surface to another. The seed of the Kerguelen cabbage brought back by the *Challenger* germinated freely at Kew, but not a single plant was raised from the seedlings, which all succumbed to a ubiquitous Peronospora.

De Vries has done good service in directing attention to the study of mutations, the nature and origin of which deserve the most attentive study. They graduate into monstrosities which are even more mysterious. It is worth while directing the attention of those who are interested in mutations to the material which exists in Japanese horticultural books. Japanese taste in such matters is widely different from European. In the case of the garden convolvulus (Ipomœa), which is pretty stable with us, the Japanese have figured an extraordinary range of variations which no one else would dream of preserving.

W. T. THISELTON-DYER.

Witcombe, November 9.

The Winding of Rivers in Plains.

BEFORE writing to NATURE on the theory of winding rivers, it would have been wiser for me to have had some observations made as to the conditions of actual flow in the field in different circumstances. It is possible that the more complicated conditions which obtain in some places render the simple theory only partially applicable. My letter was immediately applicable rather to the flow in Prof. James Thomson's simplified model, where the artificial stream had a wooden bed, and the tendency to silt was indicated by short pieces of cotton pinned by one end to the bottom. It may be that the deposit of drift on the inner side of some streams retards their flow by an unexpected amount; and probably there are other causes which prevent the James Thomson theory from being the last word on the subject. I do not pretend to be a field naturalist in any sense, and my cautionary note concerning the flow of glaciers I would ask readers to apply to the flow of rivers also, and to interpret the whole of my letter as a hint and exposition of theory rather than as an assertion and statement of fact.

OLIVER LODGE.

November 20.

SIR OLIVER LODGE's letter in NATURE of November 7 on the winding of rivers in plains has induced me to measure the velocity of flow in different parts of a bend in the river Wey near here. A short line—17 feet—was measured on the bank at the bend, and marks set up at right angles to it, and the time taken by blocks of wood to move between the marks measured with a stop-watch. The distances of the blocks from the inner bank were estimated in terms of the breadth of the river, with the following results:—

Distance from inner bank	Velocity in feet per second
0·3	0·30
0·5	0·45
0·6	0·55
0·8	0·71

This does not bear out his statement that "the flow is most rapid on the inner or sediment-depositing side of the bend," and that the water near the concave bank is nearly stationary, but upholds the common opinion of boating men and others.

The numbers refer to the surface flow only, and it is quite probable that there may be the undercurrent across the bed of the river; in fact, the sudden shelving so often noticed in rivers, and harbour channels where there is a strong tide, has led me to suspect for a long time such cross-currents.

The surface flow-lines are neither parallel nor straight. For this reason a short base line was used, and the velocities obtained are only approximate, but are certainly not far from the above values.

At the end of the experiments two blocks of wood were simultaneously floated down the stream, one near the inner, the other near the outer bank, and the latter won the race by twelve seconds.

However, I noticed that close to the outer bank (within 2 or 3 feet of it) there were back eddies forming a set of feeble whirlpools, and these may play an important part in the scouring.

The Occurrence of Copper and Lithium in Radium-bearing Minerals.

IT is possible that the remarkable action of radium emanation on copper, as recently announced by Sir William Ramsay (NATURE, July 18, vol. lxxvi., p. 269), may not be confined to solutions, but may also occur in the solid state. If so, it should be found that those minerals which contain both radium and copper contain lithium also.

In connection with another investigation, I had separated a sample of pitchblende, from Gilpin County, Colorado, into its principal constituents. The amount of copper in the sample was considerable. The final filtrate, remaining after the separation of the various analytical groups, contained only ammonium and alkali salts. After the evaporation of a portion of this solution, representing about 3 grams of the mineral, and the volatilisation of the ammonium salts, a small residue was left which, when examined spectroscopically, gave a very bright lithium line. This result led me to examine four other samples of uranium-radium minerals. These samples comprised a second specimen of pitchblende from the same locality as the first; carnotite from Montrose County, Colorado; gummite from North Carolina; and pitchblende from Bohemia. All the minerals, with the exception of the gummite, contained both copper and lithium in easily recognisable amounts. The qualitative analysis of 1 gram of the gummite showed no copper, but did show the presence of lithium in small amount.

The discovery of lithium and copper in uranium-radium minerals does not necessarily indicate the change of copper into lithium, since the presence of lithium may have been fortuitous; but assuming the accuracy of Prof. Ramsay's observation, the presence of lithium in uranium-radium-copper minerals is precisely what one should expect. The presence of lithium and absence of copper in the sample of gummite may be explained by the assumption that the change of copper into lithium has been completed. It may be added that even if further investigation should reveal the absence of lithium in any uranium-radium-copper mineral, the result would not constitute a valid argument against Prof. Ramsay's hypothesis, since the latter referred to copper in solution and not in the solid state. HERBERT N. MCCOY.

A Convenient Formula in Thermodynamics.

IT is possible that many teachers of thermodynamics may not have noticed that the characteristic equation for 1 kilogram of air takes the easily rememberable form $pv = T/10$, when p is measured in standard atmospheres, v in cubic feet, and T in thermodynamic centigrade degrees, the accuracy of the even integer being fully as great as that of the gas law itself. These units are, of course, a curious mixture of the English and Continental systems, but this seldom makes much difference in actual problems, and the convenience of the formula for rough mental computations is sometimes very great.

The data upon which this computation of the gas constant is based are the statements in the third (1905) edition of Landolt and Boernstein, that 1 litre of air under standard conditions weighs 1·2928 grams, and that an English yard is 0·91438 metre, and the value $T_0 = 273°{\cdot}13$ given by Buckingham in the Bulletin of the Bureau of Standards for May. The value $R = 0{\cdot}1$ is consistent with these assumptions within less than one-fiftieth of 1 per cent.

The corresponding values of C_p and C_v, reduced from the mean of the results of Regnault (1862), Wiedemann (1876), and Witkowski (1896), are $C_p = 0{\cdot}3467$ and $C_v = 0{\cdot}2467$ cubic-foot-atmospheres.

Cambridge, Mass. HARVEY N. DAVIS.

A Miocene Wasp.

IN NATURE of June 13, 1901 (vol. lxiv., p. 158), I described a curious variation in a bee (Epeolus), the second transverso-cubital nervure of the wings having its lower half absent. This aberration was evidently an example of "discontinuous variation," and from its occurrence in several specimens captured at the same place, it seemed that it must be inherited. There is a genus of Scoliid wasps, Paratiphia, in which the absence of the lower part of the first transverso-cubital nervure is normal. The species, found principally in the southern and western parts of North America, are quite numerous; and the broken nervure, looking exactly like the aberration described in the bee, is a good generic character. Nothing has hitherto been recorded concerning the past history of this genus, but I have before me a well-preserved Paratiphia from the Miocene shales of Florissant, Colorado, collected by Mr. S. A. Rohwer at station 14 in 1907. This insect, which I shall call *Paratiphia praefracta*, is black, with the thorax large and robust (about 4 mm. long and $3\frac{1}{4}$ mm. broad); the head rather small (slightly more than 2 mm. diameter); the antennæ thickened; the abdomen constricted between the first and second segments, and parallel sided beyond; the hind tibiæ dentate on the outer side; the wings clear hyaline, anterior wing about 7 mm. long, with the large stigma very dark, the nervures light ferruginous. The specimen is a male. The venation is perfectly normal for Paratiphia in every respect, including the broken transverso-cubital vein.

It is certainly an interesting fact that a character like that of an imperfect vein, which can arise suddenly as a mere aberration, should persist from Miocene times (at least) to the present, and characterise a whole genus. From observations on bees and other Hymenoptera, it is evident that this modification has occurred many thousands of times without becoming permanent; that it has become so in the case of Paratiphia is therefore all the more remarkable. T. D. A. COCKERELL.

The Eggs of the Platypus.

SINCE writing the notice of Mr. le Souef's book on Australian wild life in NATURE for October 24 (vol. lxxvi., p. 635), I have been making inquiries as to the existence in collections of any examples of platypus egg definitely known to have been taken from the nest after extrusion. It has been suggested to me that Mr. Caldwell and Dr. Semon might possess such specimens. The former gentleman told me, however, some years ago that he never found an extruded specimen, and I learn from Dr. Semon that he was equally unsuccessful in this respect. In his letter he writes that "I have never found extruded eggs of Ornithorhynchus, but only intra-uterine specimens. To obtain the former, it would be necessary to open a very large number of burrows."

In the central hall of the British Museum is shown an egg-shell of a platypus sent from Queensland by Mr. G. P. Hill in 1902, but this, like Mr. le Soeuf's specimens, was doubtless found in its present broken condition.

Such broken shells might, apparently, be extruded from the uterus with the fœtus; and, so far as I can find, there still appears to be no definite evidence that the eggs are really laid entire. THE REVIEWER.

November 15.

Literature relating to Australian Aborigines.

IN NATURE of May 9 (vol. lxxvi., p. 32) I observed a communication from Mr. R. H. Mathews in which he makes certain statements imputing to me, by insinuation, what amounts to literary dishonesty. Will you kindly permit me to express my views on the subject?

Mr. Mathews says that I have "ignored" certain statements made by him in communications to scientific societies, and which were published before the appearance of my "Native Tribes of South-East Australia" in 1904, in which I record the same facts.

Mr. Mathews speaks of my account of the Dora ceremony, and makes the following insinuation:—"Dr. Howitt 'ignores' that I described that rite in January, 1900. If he did not avail himself of my work, which appeared four years earlier than his, then there is a wondrous agreement in our details."

My account of the Dora ceremony was given to me by Mr. Harry E. Aldridge in 1882. It was from his own experiences at the ceremonies on more than one occasion, and he had a knowledge of the tribal language.

Mr. Mathews also says that I "ignore" a map which he published in 1900, and which is substantially the same as one at p. 44 of my work. He adds the following sentence:—"In comparing the two maps and the explanatory letterpress accompanying mine, we observe a marvellous coincidence. Many other examples could be cited."

The map showing the native tribes of South Australia at p. 44 of my work was compiled from data supplied by the Rev. Otto Siebert, who obtained them by careful and protracted inquiries from persons knowing the several localities, as well as from personal knowledge. Practically the details as to the tribes of the Lake Eyre district and of the Flinders Range are substantially the same as those given in a sketch-map which accompanied one of my pioneer papers entitled "The Dieri and other Kindred Tribes of Central Australia," which appeared in the Journal of the Anthropological Institute of August, 1890. This was the result of investigations made from 1871 to that date. In this instance, if I were to follow Mr. Mathews's example, I might suggest that he has "ignored" this pioneer work, and express something similar to his "wondrous agreement in our details." There is, however, nothing to wonder at in the agreement of two investigations of the same subject. My statements are based upon independent investigations, made in some cases many years ago, when the results were recorded for future publications. If Mr. Mathews finds instances in which his information has a "wondrous" agreement with mine, he may rest assured that his conclusions are correct.

My information as to the Yantruwunta class-names Tiniwa and Kulpuru was received from my correspondent the Rev. Otto Siebert, and was based on his personal knowledge, in 1897.

I learn from Mr. Mathews's letter that he has sent "more than one hundred contributions to various scientific societies." I have only met with two of them, neither of which recommended itself to me by its accuracy. It is therefore difficult to understand how I can have "ignored" statements of which I am ignorant.

It will be evident that there is no foundation for Mr. Mathews's injurious insinuations, which, I regret to say, bear upon them evidence of a personal animus. The case is one of *Honi soit qui mal y pense.*

A. W. Howitt.

Metung, Victoria, July 8.

In the foregoing remarks Dr. A. W. Howitt states that at the time his book appeared, in 1904, he was not aware that I had published a description of the Toara (Dora) ceremony, and also a map of South Australia, four years previously. It seems incredible that he did not make himself acquainted with the current literature bearing upon the Australian aborigines up to the time he published his book.

If Mr. Howitt obtained his account of the Dora from Mr. Aldridge in 1882, it is remarkable that he did not publish it until twenty-two years afterwards, especially as he was very prompt in publishing his report of the Kuringal ceremony in 1884 and the Jeraeil in 1885. He does not, however, appear to have had much confidence in Mr. Aldridge's account of the laws of marriage and descent in vogue among the same tribes who practised the Dora ceremony. He says that Mr. Aldridge sent him "a number of tables of marriages and descents, which differed considerably amongst themselves; so much so that the correctness of some of them seemed doubtful."[1] Mr. Howitt did not run the risk of printing more than one table out of them all, but even that one is erroneous, as I have demonstrated elsewhere.

Mr. Howitt refers to a "sketch-map" published by him in 1890.[2] In that map he showed the Urapuna (my Arrabunna) tribe as being located away to the north of the Awmani (my Ahminnie). Not content with this inaccuracy, he increased its magnitude by placing another tribe, which he called the Wongkurapuna, on the east of the Urapuna and Awmani. He was, apparently, not at that time aware that the two names, Urapuna and Wongkurapuna, represent the same people, the prefix *wonk* merely meaning "speech."

Again, the Kuyani (my Kooyeeunna), which I place on the southern end of Lake Eyre, is shown on Mr. Howitt's "sketch-map" as occupying the country I have correctly allocated to the Kutchnamootha tribe. His map is altogether a blank as to the numerous tribes occupying the country from south Lake Eyre to Port Lincoln and Fowler's Bay. Even Mr. Howitt himself did not reproduce *his own map* in his book of 1904, but preferred to utilise one which is identical with mine. Spencer and Gillen were apparently misled by the worthless map of 1890. In referring to the Urabunna tribe, they speak of "the Dieri, whose territory adjoins the Urabunna on the south."[1] My map shows the Urabunna on the western or opposite side of Lake Eyre to that on which the Dieri is situated.

Mr. Howitt states that he got the phratry names Tiniwa and Kulpuru independently. Even if so, he should have made himself acquainted with and referred to my prior reports of 1899 and 1900. He shirks my statement that he "had never heard of the Blood divisions," and he also passes over my claim to priority in reporting certain important facts in the sociology of the Wiradjuri tribes.

It is asserted by Mr. Howitt that he has only seen *two* of my articles on the Australian blacks. I contributed five articles to the Royal Society of Victoria, of which Mr. Howitt was a member, and I was told that he took part in the discussions upon some of them. They were all printed in the Proceedings of that society, vols. vii., ix., and x., and these volumes were issued to Mr. Howitt in virtue of his membership.

Numerous articles of mine have been published by the anthropological societies of the following places:—London, Berlin, Washington, Paris, and Vienna, as well as by other societies. I presented forty separate copies (reprints) of various papers written by me on the aborigines to the public library in Melbourne in 1899. A bibliography of nearly all the articles published by me is printed in the Journal of the Royal Society of New South Wales, vol. xxxviii., pp. 376–381. The whole of my works are therefore within reach of any man who wishes to consult them.

As I am about to make a strong assertion, I will confine myself to five articles published in the Proceedings of the Royal Society of Victoria and twelve in the Journal of the Anthropological Institute. If Mr. Howitt still maintains that he has not seen these seventeen articles, I cannot believe him.

In regard to Mr. Howitt's remark that where I find "instances" in which my information agrees with his I may rest assured that my "conclusions are correct," I may briefly mention that on one occasion, in 1894, I did rely on Mr. Howitt's assertion that descent in the Kaiabara tribe is in the male line. From personal inquiries among the blacks in 1898 I was able to correct my former statement, and to show that descent is in the female line.[2] Mr. Howitt, however, repeats his former error in his book at p. 229, where he says that "descent [in the Kaiabara] is in the male line."

Mr. Howitt accuses me of "personal animus." There cannot be any question about the "personal animus" which prompted him to ignore my prior work, which had the effect of temporarily misleading an English reviewer. Nor can there be any mistake about the animus evinced in the statement that he has "only met with two of my papers, neither of which recommended itself to him by its accuracy." His object in both cases is manifestly to make little of my work. Even now, while he tells us that he ignored my prior work in "ignorance," he does not express any regret, but attempts to justify the course he adopted.

In the present case both authors reside in the same country and are known to each other as workers among the same tribes. I cannot help repeating that it is both "marvellous" and "wondrous" if they did not make themselves acquainted with each other's publications, especially as there were intervals of four, five, and eight years in which to do so. Mr. Howitt's experiences should be a warning to others to avoid the pitfall of claiming originality for work which has already been published some years in scientific journals of undoubted repute.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

II.—*The Cornish Cromlechs.*

FROM the point of view of orientation, the interest in barrows, tumuli, chambered cairns, dolmens and cromlechs lies in the assumption that they were built for live men to dwell in. That they all represent different stages of the same structure—stages depending upon decay due to the action of rain, or wanton destruction in the interests of agriculture—can be gathered from a complete study of the whole evidence.

Borlase, in his "Dolmens of Ireland" (p. 426), refers to some of it. Mr. John Bell, of Dundalk, a famous antiquary, disinterred no less than sixty cromlechs from cairns or barrows in Ulster. Many "cairns," indeed, on the early Ordnance maps are marked dolmens in subsequent editions, the interior stone framework being the only thing remaining after the covering of soil had been re-distributed over the fields, an ordinary "agricultural" operation.

Borlase insists upon the fact that large tumuli were not essential; "all that was necessary was that the walls of the cell or crypt should be impervious to the elements and to wild animals" (p. 427). As a corollary to this, "in distinction from the cist, it was the intention and object of the builders that access should be had to it [the cell or crypt] from without."

It was this intention which has provided us with "creeps," "fougous," "allées ouvertes," and "allées couvertes," and these, as I shall show, are of as high importance as the cell itself from the orientation point of view. They all constituted, not only entrances, but "outlooks" for the man inside; and it matters not whether the cell was as extensive, as complicated, as carefully built, and the creep as long, as at Maeshowe, or whether we deal with a cell of the simplest and rudest form, with a bare entrance and outlook, such as the creephole in one of the stones at Trevethy.

Archæologists, as a rule, though not, I think, universally, consider the whole series of structures we are now dealing with as having originally, whatever their present stage, been constructed for tombs.

For them there is little difference between such a cell with an entrance such as the barrows and cromlechs reveal; and a cist, which is simply a rude small coffin built up of five or six stones, in which there is only room for the body, and to which there is no entrance at all. The evidence on which they rely is that certain things have been found in these cells, which they consider can only have been associated with burials.

[1] Continued from p. 59.

Photo. by Lady Lockyer.

FIG. 7.—Cromlech on Lesquoit Farm, near Bodmin. The upright stone on the right is oriented to the May sunrise.

The argument against this view does not only depend upon the details of structure, such as revealed in Maeshowe, perhaps the most perfect cell now remaining, but upon their association with other stone monuments, especially with stone circles; so that as the Gorsedd we see to-day is but a survival of the ancient stone circle which was associated with living men, the cromlechs must, in all probability, have been also associated with living men. They are not merely tombs. I hold that they were never meant for tombs, and to argue that they were built for sepulchral purposes because people have since been buried in them is to deny that a church was built for the worship of God because we find corpses in it.

If we consider frankly and fairly the position of the first priests and leaders of the people who controlled the worship and the daily life of the early inhabitants of Britain, we can arrive at a quite plausible theory concerning these cromlechs.

The circle builders had to look after the welfare of the surrounding population, and see what they could do to help them in every way; and when we consider that, I think much of the mystery surrounding the cromlech is at once cleared away. In the first place, there is no doubt in my mind that these people, who had command of the sea, and came over here and built the circles and cromlechs along our shores, and cared very little for going inland where they could not be supported by their constantly returning ships, were Semitic in their origin, or familiar with the Semitic peoples. In any case they must have lived somewhere, and with some kind of shelter.

Now we know from Robertson Smith that Semitic worship was carried on in caves, and one reason for this might have been that the priests really lived in caves.

Now the cromlech was really an improvement upon the natural or artificial cave, and, further, if there were no caves, some shelter must have been provided. The easiest way to protect the priests and priestcraft from the elements and from animals was by erecting such a structure as stones would enable them to do, and then covering it with earth which could not fall upon them, and I look upon the stones of the cromlech as the skeletons of the barrows which were thus built to protect the people living in them.

One of the first things that they wanted to be protected from was damp. It was important to keep out the rain, because they had their fires to look after, not merely for cooking purposes, but for sacred purposes, and if they did not keep their sacred fires going, as Mr. Baring-Gould believes they did, they must have been, at all events, sure of a supply of dry wood. That is one reason why they should try to keep out the damp. Britain was then much richer in wild animals than it is now, and measures had to be taken to protect the priests, both in the day and during the night, from the incursions of animals by keeping them out in some way or other. I think this is a point which archæologists have not sufficiently considered. There were no carpenters in those days. They could not cut down a tree. They could not make a door. When we consider the matter carefully, we find that the only way to protect themselves was by constructing, however large the chamber, an entrance to it which should be very small, because it must have been closed by a small stone, capable of being handled by one or two men, the only way they had of sealing it.

Photo. by Lady Lockyer.

FIG. 8.—Druid's Altar at Pawton, near Bodmin, looking to May sunrise.

Then these people had to drink, and it was only natural that they should have a water supply in these cromlechs. May that not be the real origin of all the crockery, large or small, and the horn spoons, that one finds in these places?

They must have required food as well as drink, and they must have cooked their food, or have eaten it raw; the evidence of bones and ashes shows that they cooked it. Considerations of this kind suggest that many of the things, including structure and contents, that archæologists have associated with death may as reasonably and probably have been associated with the life conditions possible to the early inhabitants of our islands.

The above-stated view that men really lived in the cromlechs, which we know to have been associated geographically with the circles, would be strengthened if we could show that the construction of the cromlechs was such that they were associated with circles in other ways, and in such ways as would require the presence of the same men in both.

I have recently commenced the study of the cromlechs from this point of view, using the orientation theory as my guide. The work at the circles has shown conclusively—to my mind at all events—that they were used, among other things, as calendars or almanacks, to watch the sun's course throughout the year and so locate the various festivals which are all older than Christianity; and as night-dials to determine the lapse of time during the night and the rising of the morning star, so that the morning fire-sacrifice could be made at the moment of sunrise.

Photo. by Lady Lockyer.

FIG. 9.—Druid's Altar, looking towards November sunset.

Now all this would require a staff, and both the staff and the fire would require some shelter. I have assumed the cromlech to be this shelter, and this assumption enables us to go a step further. A convenient arrangement would be that much or most of the watching during the night—it was all night work if in the term night we include the dawn—could be done in the shelter itself, and this could be managed if the entrance to it was aligned on the part of the horizon to be chiefly watched.

Now what were those points? The circles supply the information. They were chiefly, as the May-year was then paramount, the sunrise place in May and August, when the sun's declination is 16° 20′ N., and that in November and February, when the sun's declination is 16° 20′ S., these two sunrise places marking off the quarters of the year and the chief festivals. Next came the rising place of the clock-star, and later the place of sunrise on the longest and shortest days—the solstices.

The question to be settled, then, is, Do the entrances to the cromlechs point in these directions? Could the priests have done their night work under shelter?

Some of the data used in the attempt to answer this question I have obtained myself from the monuments; in other cases I have endeavoured to get the required information from the so-called plans or surveys to be found in archæological records. The great majority of these, however, I have found to be utterly useless for my purpose. A brilliant exception, however, is found in the carefully oriented work of Lukis on the Cornish monuments, so I will begin with Cornwall and the May-year sunrises.

The following table gives the theoretical values of the azimuths of the sunrise places. It has been previously shown in my book, "Stonehenge," that the circles conform to them.

Cornwall. Lat. 50°.

Conditions	True Azimuths	
	May and August sunrise	November and February sunrise
	° ′	° ′
Sea horizon, refraction, semi-diameter	N. 62 58 E.	S. 64 32 E.
½° hill ,, ,,	N. 63 44 E.	S. 64 22 E.
1° ,, ,, ,,	N. 64 30 E.	S. 63 34 E.
1½° ,, ,, ,,	N. 65 16 E.	S. 62 50 E.
2° ,, ,, ,,	N. 66 E.	S. 62 5 E.

Following this table I give another, showing the azimuths of most of the chief Cornish cromlechs.

Orientation of Cornish Cromlechs.

Name	Remarks	Azimuths (true)
SERIES 1		
Lesquoit Farm	My own observations, April, 1907, near Bodmin. Hill, 1½°	N. 64° E.
Druid's Altar ...	My own observations, April, 1907, at Pawton. Hill, 1½°	N. 64 E.
Lanyon Quoit...	This was "re-erected" before Lukis's time, so I have taken Borlase ("Antiquities of Cornwall," plate xxi), assuming his N. is N. true ...	N. 66 E.
Mulfra Quoit ...	Lukis, plate xix	N. 63 E.
Chywoone Quoit	,, ,, xx	N. 64 E.
Zennor Quoit ...	,, ,, xxi	N. 64 E.
Three Brothers of Grugith ...	,, ,, xxiii	N. 64 E.
SERIES 2		
Trewethy ...	My own observations, April, 1907, near St. Cleer... ...	S. 62 E.
Caerwynen ...	Lukis, plate xxiv	S. 65 E.
Pennance ...	,, ,, xxix	S. 64 E.

We see, then, that many of the chief Cornish cromlechs are aligned on the May and August or the November and February sunrises as carefully as are the outstanding stones connected with the associated circles.

The true azimuths have been determined from magnetic observations made by Lukis and myself by subtracting 20° 30′, the west variation in Lukis's time, and 18° at the present in the case of my own observations; it will be seen that they agree closely with the theoretical values given above.

The above list, however, does not exhaust all the cromlechs in Lukis's work perfect enough to allow of their orientation to be determined. We have:—

Name	Remarks	Azimuths (true)
Tregiffian ...	Lukis, plate xv...	N. 52° E.
Barrow near Tregaseal circles	Lukis, plate xvii, reproducing Trounson...	S. 50 E.

These are solstitial alignments. The variation of 1° or 2° in this and the preceding table no doubt arises from the fact that the height of the horizon varies from place to place, and no information on this head is given by Lukis.

NORMAN LOCKYER.

THE PRESERVATION OF EGGS.

FEW people not directly connected with the trade have any adequate idea of the extent to which the egg of the domestic fowl is imported into this country. Whether the volume of this trade ought to be an unmixed source of satisfaction to us is another question, for there can be little doubt that if some of the energy, enterprise, and organising power which have been turned to such excellent account in Denmark, for example, were applied to the production of eggs in this country, we should be less dependent than we are on foreign supplies. Intimately bound up with this question of egg production is that of their preservation, but although much has been written on the value of particular methods, no systematic investigation of the conditions under which eggs must be kept to maintain and ensure their quality as food has hitherto been attempted, nor has any proper comparison been made as to the relative merits of the various methods which are practised. Those who are interested in this important subject will therefore welcome the appearance of a paper by Mr. Fr. Prall in a recent number of the *Zeitschrift für Untersuchung der Nahrungs- und Genussmittel* (No. 7, vol. xiv., October 1, 1907, p. 445), in which the question is treated both observationally and experimentally with all the precision and care which should characterise a scientific inquiry.

The adequate solution of this problem demands that the eggs when preserved shall maintain their normal appearance, smell and taste; in other words, they must in nowise differ in chemical and physical characters, or in behaviour on cooking, from fresh eggs. The chemical and physical changes to which eggs are naturally subject are largely dependent on the temperature and relative humidity of the air, and on the presence in it of moulds and germs. In an absolutely sterile atmosphere at a sufficiently low temperature and of a proper degree of humidity, eggs will preserve their "freshness" for very long periods of time, if not indefinitely; and all successful methods of keeping eggs imply a practical recognition of these conditions.

Of the various methods of distinguishing old and bad eggs from fresh eggs, one of the simplest is to make a hole of about the size and shape of an egg in a wooden or tin box, and hold the egg in the inside of this box against the light behind the hole. Good sound eggs are thus seen to be perfectly transparent without striations or spots, and the bubble of air within is not wider in diameter than a sixpence.

Eggs selected for preserving should be those of well-fed fowls—preferably from those of which corn is the chief diet. The eggs should be quite clean; if dirty they should be washed with a little dilute alcohol (50 per cent.), and carefully dried.

In what may be called "dry conservation," the main thing is to keep the surrounding air as clean as possible, and free from smell. The temperature should be low, but should not sink much below 32° F., otherwise freezing might cause the eggs to burst. The relative humidity should be from 60 to 80. The best plan is to stand the eggs on an egg-rack in a cool, light cellar, and preferably in an ice closet, or, on the large scale, in cold-air stores, with their points downwards, so that the air can circulate freely round them. Nothing is gained by turning the eggs at short intervals, say weekly, as recommended by some; or by packing them in salt, sawdust, powdered coal, or charcoal, wood ashes, sand, &c. Some of these things are found to "taint" the eggs; others are apt to become damp and set up the action of moulds.

It is occasionally recommended that the egg should be protected from the outer air by covering the shells with fat, vaseline, paraffin wax, collodion, &c., or that the shell should be treated with salicylic, boracic, or hydrofluosilicic acid, or even sulphuric acid, whereby the calcareous material is chemically altered and made less pervious. Immersing the egg in Condy's fluid or a solution of potassium permanganate has also been suggested. Eggs so treated in no case were found to keep better than by cold storage in pure air.

Eggs which cannot be kept in cold stores or in an ice-chest may be preserved by Hanika's method. This consists in first putting the clean eggs into recently-boiled water at a temperature of about 110°, and then dipping them into boiling water for 10 seconds, after which they are to be immediately put into cold water. By this treatment all organisms are killed, and a hard coating is formed between the shell and the "white." The shells are finally washed with a little strong alcohol, dried, and placed in clean, dry saw-dust. Eggs so treated were found to be in perfect condition after the lapse of nine months.

Attempts are frequently made to preserve eggs by immersing them in solutions of various salts, or of substances which are known to act as antiseptics. Few of these solutions give a wholly satisfactory result; indeed, many of them, as, for example, salt, salicylic acid, borax, and glycerin, penetrate the shell, and either harden the yolk or impair the flavour. Of these liquids lime-water has been most frequently used, but by long immersion in this solution the yolk is apt to mix with the white, and the shell is rendered so fragile that it is very liable to be broken on boiling. The white of an egg which has been kept in lime-water is difficult to "whip." Much better results are obtained by the use of a 10 per cent. solution of water-glass, especially if the shells are smeared with fat or vaseline, whereby the slight taste of the alkali which the eggs are otherwise apt to acquire may be obviated.

Mr. Prall's paper, which contains the results of many hundreds of experiments and carefully made observations, arranged in tabular form and set out in detail, is a valuable contribution to the economics of an important food problem, and merits careful study by those who are interested in the subject.

NOTES.

ON Thursday last, November 21, the Lord Mayor of Liverpool presided over an influential gathering of Welshmen from that city and from the Principality, and the following resolution was carried unanimously:—"That this meeting believes that the time has come for the early history of Wales to receive full and systematic investigation by all the means at the disposal of modern archæological science." The Oxford professor of Celtic (Sir John Rhys) supported this at some length, pointing out that sporadic excavations were not enough in themselves, and that a systematic survey should also be made of all the antiquities of Wales and the Marches. This would entail, not only the digging over of barrows and graves, but the orientation of stone circles, cromlechs, and camps. The theodolite as well as the shovel should be called into requisition; in fact, no means should be neglected which might tend to increase the value of the investigation. Two other motions were passed, and a committee, which includes Dr. Arthur J. Evans and Prof. Haverfield among its members, was appointed for the carrying out of the work. The weight of the undertaking will fall on the University of Liverpool, which, however, is to receive assistance from the Welsh colleges. Our readers need not be reminded that Liverpool University lays special stress on the study of archæology, and includes among its staff Prof. Bosanquet and Prof. John Garstang. We have every confidence that any work undertaken by Liverpool will be done well and thoroughly. The organising secretary is Mr. Owen Rhoscomyl, 38 Bedford Street, Liverpool.

THE Wilde medal for 1908 of the Manchester Literary and Philosophical Society has been awarded to Prof. J. Larmor, F.R.S., and will be presented to him on March 3 next. Prof. Larmor will on that date deliver the Wilde lecture on "The Physical Aspect of the Atomic Theory," and will be entertained afterwards at a dinner in his honour.

THE Physical Society announces that the third annual exhibition of electrical, optical, and other physical apparatus will be held at the Royal College of Science, South Kensington, on Friday evening, December 13, from seven to ten o'clock.

THE executive committee of the National Physical Laboratory has appointed Mr. G. W. Walker, official assistant to the professor of natural philosophy in the University of Glasgow, as superintendent of the Eskdalemuir Observatory. Mr. Guy Barr, of Christ's College, Cambridge, has been appointed to an assistantship in the metallurgical and chemical department of the National Physical Laboratory.

THE death is announced, at the age of sixty-nine, of Prof. T. Barker, professor of mathematics at Owens College, Manchester, from 1865 to 1885.

AN international exhibition of applications of electricity will be opened at Marseilles on April 19, 1908, under the patronage of the Government of the French Republic, and with the cooperation of the local authorities, municipal council, general council, Board of Trade, and other bodies. Particulars can be obtained at the office of the Commissariat-General, Boulevard Louis Salvator, 52, Marseilles, and at the Secretariat-General, 63 Boulevard Haussmann, Paris.

THE *Times* correspondent at Cape Town reports on November 23 that the Chief Justice, presiding at a meeting of the National Preservation Society, urged the need of stronger measures to preserve rare flora and fauna from extinction. The gnu, gemsbok, mountain zebra, eland, and giraffe were all nearly extinct. He said he remembered, when a barrister on circuit, seeing great herds where there are now railway stations.

AT a meeting of the Royal Society of Edinburgh, held on November 4, the following were elected honorary fellows:—(1) *as British Honorary Fellows*, Sir A. B. W. Kennedy, F.R.S., Sir E. Ray Lankester, K.C.B., F.R.S., Dr. J. A. H. Murray, Prof. C. S. Sherrington, F.R.S.; (2) *as Foreign Honorary Fellows*, Prof. Emil Fischer, Berlin; Dr. G. W. Hill, New York; Prof. F. W. G. Kohlrausch, Charlottenburg; Prof. H. F. Osborn, New York; Prof. I. P. Pavlov, St. Petersburg; Prof. G. Retzius, Stockholm; Prof. A. Righi, Bologna; Prof. L. J. Troost, Paris.

THE meeting of the second International Conference on the Sleeping Sickness, which was to have assembled at the Foreign Office on November 1, has been postponed in order that the delegates may have before them the results obtained by Prof. Koch, who has lately been carrying out an exhaustive inquiry into the subject on the spot, and is now engaged in the preparation of his report. The conference will probably not meet before the middle of February. The British delegation will consist of Lord Fitzmaurice, Sir Walter Foster, M.P., Mr. A. Walrond Clarke, Mr. H. J. Read, Sir Patrick Manson, K.C.M.G., Colonel David Bruce, C.B., F.R.S., Dr. J. Rose Bradford, F.R.S., and Sir Rubert Boyce, F.R.S.

A COMMITTEE having for its object the collection of information dealing with sleeping sickness, the stimulation of research into the cause, method of transference, and cure of the disease, and the publication from time to time of communications with reference to it, has been formed at Liverpool. The committee comprises Sir Alfred Jones (chairman), the Lord Mayor of Liverpool, Prof. Moore, Prof. Salvin-Moore, Prof. Annett, Prof. Sherrington, F.R.S., Dr. Stephens, Dr. Anton Breinl, Dr. Prout, C.M.G., Dr. A. Evans, Dr. M. Nierenstein, Mr. J. W. Garrett, and Dr. J. L. Todd. Sir Rubert Boyce, F.R.S., and Mr. A. H. Milne are the corresponding secretaries.

A DESPATCH recently received at Washington from Lieut. B. H. Camden, commanding a revenue cutter in Alaska, reports the entire disappearance of McCulloch Peak, Bogoslof Island (which rose from the sea in 1796), as the result of volcanic disturbances. The explosion which destroyed this peak has been followed by remarkable changes in the profiles of Mount Makush and neighbouring mountains, which are now softened to a general symmetry by a padding of lava dust that has almost disguised them beyond recognition. A vast quantity of this material, hundreds of feet in depth, has been deposited over the entire island.

IT is announced in *Science* that the Field Museum of Natural History, Chicago, has profited by a decision of the Chicago Probate Court to the extent of 86,000*l*. The money was paid by the late Mr. Marshall Field to the trustees of the museum prior to the date of his will, which contained a bequest of 1,600,000*l*. to the institution. A suit was brought by the trustees against the executors of the will to determine whether the bequest was intended to be exclusive of the amount previously donated. The judge decided the suit in favour of the museum. From the same source we learn that about four acres of ground have been set apart in the block adjoining Washington Park and the Midway Plaisance to serve as a botanic garden for the University of Chicago. The garden will be easily accessible from the Hull Botanical Laboratory, and is to be strictly a laboratory garden, which will add greatly to the facilities for experimental work. The area, it is hoped, will be largely increased later.

THE Home Secretary has appointed a departmental committee to inquire into the subject of artificial humidity in cotton-weaving factories. The members of the committee are Sir Hamilton Freer-Smith (chairman), Mr. J. Cross, Mr. H. Higson, Mr. T. Roberts, Mr. D. J. Shackleton, M.P., and Prof. J. L. Smith. The terms of reference to the committee are to inquire and report:—(1) what temperature and humidity are necessary in each case for the manufacture of different classes of cotton fabrics; (2) at what degrees of temperature and humidity combined definite bodily discomfort arises under the conditions of the work carried on by the operatives, and what, if any, danger to health is involved by continuous work at those degrees; (3) what means of cooling humid sheds (where necessary) exist, whether combined with the means of humidifying or otherwise, which are both efficient and practicable, having regard to the conditions required for the manufacture of the several classes of goods; (4) what special arrangements, if any, are necessary in order to admit of the proper ventilation of dry weaving sheds without prejudice to the process of manufacture. The secretary to the committee is Mr. D. R. Wilson, to whom correspondence may be addressed at the Factory Department, Home Office.

ONE of the most famous establishments for the distribution of new and rare plants in this country is that of James Veitch and Sons, Ltd., Chelsea, the late managing director of which company died on November 13 at Exeter at the age of thirty-nine years. Mr. James Herbert Veitch was a son of John Gould Veitch, who died in 1870. The son was admitted to the firm whilst still young, and when he was twenty-three years of age was sent on a botanical tour to Australia, New Zealand, India, Corea, and Japan, a tour which occupied a period of two years. After his return, Mr. Veitch published in "A Traveller's Notes" some impressions he had obtained in regard to the public and private gardening and botanical establishments he had visited for the purpose of studying the cultivated plants in those countries, and obtaining information as to the possibility of introducing new species to English gardens. After the lapse of several years he was appointed managing director of the Chelsea business, and continued to discharge the responsibilities of that position until last year, when failing health compelled him to retire from business. During the time he was managing director, a special representative was dispatched to the western portion of China, approaching to Tibet, for the purpose of collecting new species of plants suitable for cultivation in English gardens. The collector, Mr. E. H. Wilson, visited China twice, the two visits occupying a period of four years, and, as a result, a large number of new species of decorative trees and shrubs, conifers, perennial herbaceous flowering plants, and some biennials were secured. One species that has already become common in gardens is the Tibetan poppy (*Meconopsis integrifolia*), and others that have been distributed include species of Senecio, Vitis, Davidia, Berberis, Buddleia, Clematis, Corydalis, Cypripedium, Deutzia, Jasminum, Primula, Rubus, and many other genera. Mr. Veitch rendered a good service to botanical and horticultural literature by publishing last year the "Hortus Veitchii," which contains short descriptions and references to publication of most of the exotic plants introduced to British gardens by the firm of Veitch during a period of more than fifty years.

IN the introduction to a paper on parasites of Bermuda fishes, published in the Proceedings of the U.S. National Museum (No. 1560), Mr. Edwin Linton observes that fishes from the inner reefs appear to be freer from encysted parasites than those living on the outer reefs and in deep water outside. This he explains by the fact that, owing to the exceeding clearness of the water, sharks, which are the great dispersers of cestode ova, do not frequent the shoal-water. In contrast to the comparative immunity enjoyed by the shallow-water forms is the strong infestation of the deep-water species, the large "groupers" and rock-fish, living at a depth of about fourteen fathoms, harbouring numerous encysted cestodes on the viscera, more especially the walls of the stomach.

THE young stages of two fresh-water American crayfishes form the subject of an elaborate memoir by Prof. E. A. Andrews, of the Johns Hopkins University, published in the Smithsonian Contributions to Knowledge (vol. xxxv., No. 1718). Of the two genera, Cambarus is limited to North America east of the Rocky Mountains, while Astacus is common to the Pacific slope of the northern half of the American continent and the two great northern continents of the Old World. As the former is the more specialised form of the two—more especially as regards the adaptation of the young for a life of association with the female parent—it is a reasonable hypothesis that the group reached the New World by way of what is now Bering Strait, while the evolution of Cambarus from Astacus-like ancestors took place in the region of Mexico. In regard to the latter part of this theory, it might, we think, be stated that the evolution took place from Astacus itself, seeing that this genus is common to both hemispheres. The larval stages of the two genera are found to differ in a number of important particulars, and other results of the investigation furnish a basis for practical application to the problems of the artificial cultivation of crayfishes and the introduction of new species.

IN the October issue of the *Emu* Mr. A. H. Mattingley gives some harrowing details of the results of the visit of a party of "osprey"-plume hunters to a colony of egrets. The writer had visited the site some months previously, when all was well, but on re-visiting the place at Christmas it soon became evident that mischief had been done. "As we drew nearer, what a spectacle met our gaze—a sight that fairly made my blood boil with indignation. There, strewn on the floating water-weed, and also on adjacent logs, were at least fifty carcases of large white and smaller plumed egrets—nearly one-third of the colony, perhaps more—the birds having been shot off their nests containing young. . . . There were fifty birds ruthlessly destroyed, besides their young (about 200) left to die of starvation! This last fact was betokened by at least seventy carcases of nestlings . . . which had fallen from the nests into the water and been drowned; while in the trees above the remainder of the nestlings could be seen staggering in the nests." Some of these unfortunates fell from time to time into the water, others died of inanition as they sat, while yet others stretched out their necks in the vain attempt to attract the attention of others of their own kind as they flew by with food in their beaks.

ACCORDING to the report for October, the additions to the Zoological Society's menagerie during that month were 214 in number, of which 107 were acquired by presentation and three by purchase, while ninety-two were received on deposit, ten by exchange, and two were born in the gardens. Special attention is directed by the secretary to the following:—two chinchillas (*Chinchilla lanigera*), presented by the Countess De Grey; five viscachas (*Lagostomus trichodactylus*), three presented by the Countess De Grey and two deposited; a spotted cuscus (*Phalanger maculatus*), a species new to the collection, purchased; and a naked-throated bell-bird (*Chasmorhynchus nudicollis*), a ground-hornbill (*Bucorvus abyssinicus*), and two Arizona poisonous lizards (*Heloderma suspectum*), deposited.

THE University of California continues its useful series of publications on the religion, sociology, and languages of the Indian population of the State. The most valuable of those recently issued is a monograph, by Mr. A. L. Kroeber, on the religion of the Indians of California. This is a form of Animism; but its distinguishing characteristic is the strong belief in Shamanism, generally in connection with disease and death. Dancing, always accompanied by singing, is a conspicuous element in all tribal ceremonials. In one tribe the dance is performed by the women, who stand up to their hips in water. The author gives full details of the mode in which the Shaman or medicine-man is initiated. The profession, though lucrative, can hardly be said to be desirable. Among some tribes, if he loses several patients in succession, he is held responsible by the relatives; in another, murder seems to be his normal end; in a third, if he fails to cure, he is obliged to return his fee. The author also gives a most interesting account of the rites of initiation for girls and boys, of the domestic and tribal celebrations, and of the mythology and popular beliefs. In a second paper he furnishes an elaborate analysis of the Washo language of east central California and Nevada. It is satisfactory to learn that the University has acquired the large MS. collections on the North American Indians made during a long service among them by the late distinguished scholar, Dr. Washington Matthews. These are now being published, the first instalment being a collection of Navaho myths, prayers, and songs, with the text and a translation.

THE importance of algal growth in the colonisation of new ground is well recognised, but there are few records of detailed examination, so that the paper contributed by Dr. F. E. Fritsch to the *Geographical Journal* (November), embodying primarily the results of observation in the tropical climate of Ceylon, furnishes valuable data for reference and for extended inquiry. The blue-green algæ, by reason of their colour and sheaths, are peculiarly protected against insolation and desiccation, and therefore comprise the bulk of aërial algal colonies in Ceylon. Dr. Fritsch distinguishes four methods of growth, which he calls *adhesive, tangled, tufted,* and *stratified*. The adhesive is the earliest and simplest type; tangled and tufted colonies, being better adapted as regards respiration and water absorption, proceed from the adhesive; the stratified form is a special modification determined by light or possibly by moisture conditions.

THROUGHOUT Germany the moors form an important feature of the vegetation, and on this account have engaged the attention of botanists, who have investigated their origin and formation. With the view of providing ocular demonstration of their development, Dr. C. A. Weber has designed two attractive coloured plates indicating in section elevation the different strata that have formed successive stages in the production of a moor. The diagram of the low-moor pictures the various zones from a mineral substratum through rush-turf to coniferous forest. The plate illustrating the high-moor decked with cotton grass shows additional layers, notably sphagnum-zones superposed. The plates, measuring 110 cm. by 150 cm., are published by Gebrüder Borntraeger at the price of twenty shillings, or mounted on linen thirty-two shillings, a pair. The same firm is also publishing a set of plates illustrating pharmaceutical products at a subscription price of twenty-five shillings for five plates. A specimen plate of *Lignum Guaiacum* bears figures of wood and cortex as seen in different sections, also of the broken elements. The plates have been drawn by Mr. J. Pohl under the direction of Dr. E. Gilg.

THE latest Bulletin (No. 26) issued by the Geological Survey of Western Australia contains a series of miscellaneous reports which in themselves are not of sufficient length to warrant issue as separate publications. The volume covers eighty-seven pages, and contains fourteen illustrations and six maps. Mr. A. Gibb Maitland contributes papers on the occurrence of artesian water in the Northampton and Geraldine district, on the geology of Princess Royal Harbour, with special reference to the occurrence of petroleum, and on recent advances in the knowledge of the geology of Western Australia. Mr. H. P. Woodward gives an account of the geology of the country between the Ashburton and Minilya rivers. Mr. W. D. Campbell describes the phosphatic deposits near Dandaraga. The discovery is one of great value to the State. The deposit occurs in a series of beds which have been followed for twenty-two miles, one bed of fossil bone and coprolite rock, 7 feet in thickness, containing 15·32 per cent. to 39·34 per cent. of phosphoric acid. Mr. W. D. Campbell also contributes some notes on a geological map of the Greenough River district. Mr. E. S. Simpson describes a small meteorite, a siderite of the octahedrite type weighing 120·2 grams, from the Nuleri district of Western Australia. He also contributes a valuable report on the prevention of the external corrosion of goldfields' water-supply pipes. The Survey is to be congratulated upon the issue of these reports in a collective form, as they cannot fail to help to make known the varied mineral resources of Western Australia.

A THOROUGH change has occurred in the type of the weather during the past week, and more wintry conditions than at any time this season have been experienced. Night frosts have occurred in many parts of the country, and heavy snow has fallen over the northern portion of England. Cyclonic disturbances continue to arrive from the Atlantic with considerable frequency, and at times these are accompanied by winds of gale force. On Monday a whirlwind was experienced in the neighbourhood of Deal, and some farm buildings sustained considerable damage. The autumn has, on the whole, been exceptionally mild, the day and night temperatures being generally at least 5° above the average.

WE have received the fourteenth annual report of meteorology in Mysore, being the results of observations at Bangalore, Mysore, Hassan, and Chitaldrug for 1906. To the present report the daily means for the twelve years 1893–1904 have been added for each of those important stations. The director (Mr. J. Cook) states that, in accordance with the recent action of the Government of India, which has reduced the majority of its second-class observatories to third-class ones, the last two of the above-mentioned stations will hereafter be of the third class. For this reason the twelve-year means now published for those places will be valuable as climatic standards of reference.

AN important article by Captain Tancredi in the *Rivista Coloniale* on the climate of the Italian colony of Eritrea, from observations at fourteen stations, is summarised in the Quarterly Journal of the Royal Meteorological Society for October. The observations at Massaua extend over ten years, and these, so far as regards temperature, rainfall, and humidity, have also been discussed with others extending (with small interruptions) over eighteen years (1885–1902) by Drs. Eredia and Memmo in the Bulletin of the Italian Geographical Society. The lowest of the mean monthly minima, 72°·3, occurs in January, and the mean maximum, 103°·1, in July; the mean yearly temperature is 86°·0. The year may be divided into two periods; from May to October the monthly means are above, and from November to April below, the mean value. The average annual rainfall is small, being only 7·19 inches, of which 6·04 inches fall between October and March; none falls in June. Malaria depends especially upon the altitude; places above 6000 feet are practically free from it, while in the low-lying regions it is endemic, and assumes an epidemic character in some months, apparently depending upon the *régime* of the rainfall in the locality.

THE Smithsonian Institution has published ("Miscellaneous Collections," xlix.) a memorial of the late Prof. S. P. Langley, accompanied by a bibliography of his published writings. It contains addresses by Dr. Andrew D. White, dealing with biographical details; by Prof. E. C. Pickering, dealing with Prof. Langley's contributions to astronomy and astrophysics; and by Mr. Octave Chanute, dealing with his contributions to aërodynamics. The last-named address is of considerable interest in consequence of the conflicting statements which appeared in the Press at the time in reference to the alleged success or failure of Langley's experiments on aëroplane flight. The facts of the case as chronicled by Mr. Chanute will now become a matter of history.

IN the Proceedings of the Edinburgh Mathematical Society (xxv.), Mr. R. F. Muirhead directs attention to a simple method of calculating first and second moments of certain elementary figures. By "second moments" are meant the same as "moments of inertia," the term being preferred, as it does not imply that we are concerned with masses. The method in question, or one very similar to it, was known at Cambridge many years ago, but does not seem hitherto to have been much discussed in print. As applied to the triangle, this method consists essentially in dividing a triangle into four smaller triangles by joining the middle points of the sides, and applying Huyghens's principle of parallel axes to obtain a relation between the moments of the original triangle and the four smaller ones.

AN interesting account of the Amalgamated Radio-Telegraph Company's new Transatlantic wireless station at Knockroe appears in the *Electrician* of November 15. The station is nearly completed, and when finished an Atlantic shipping service will be started, while as soon as the Canadian station is opened a Transatlantic service will be commenced. Three masts, 350 feet high, carry the insulated ends of some 300 wires, which descend in a cone to nine short masts, 70 feet high, erected in a circle about the taller ones. The Poulsen system of wireless telegraphy by undamped waves is employed, and it will be interesting to compare the Marconi and the Poulsen systems in a Transatlantic service. Possibly in this station a higher voltage than that usually employed in the Poulsen system—400 to 500 volts—may be found necessary, but otherwise the apparatus installed does not differ very considerably from that at other stations. A great many improvements have been made in the different parts of the apparatus since Mr. Poulsen gave a demonstration of his system at the Queen's Hall, a full account of which appeared in these columns at the time (NATURE, vol. lxxv., pp. 105, 106), and the transmitter at Knockroe station has been designed to transmit waves 3000 to 5000 metres long, and capable of giving the desired wave-length without any variation. The company has also a new thermoelectric detector with which it expects to print Transatlantic messages, and in consequence to be independent of telephonic reception. The Poulsen-Pedersen "ticker" method of reception also has been adapted to working a relay and a Morse inker. This "ticker" receiver has been greatly improved upon, and the latest form recently established a long-distance record, receiving a ship signal at a distance of 2060 miles.

THE theory of the formation of the rainbow has been worked out more completely than hitherto by Prof. T. Tanakadate in the August number of the Proceedings of the Tokyo Mathematico-Physical Society. Taking account of the loss of light on reflection and refraction, and of the effect of polarisation, the author follows Airy's treatment, and obtains an expression for the intensity of light of each of the four bows due to drops of a particular size, in a form suitable for numerical calculation.

IN the *Physical Review* for October Prof. W. S. Franklin and Mr. L. A. Freudenberger describe an arrangement they have found very satisfactory for measuring the resistance of electrolytes without the use of electrodes. The electrolyte is placed in an annular glass tank which encircles the iron of a small transformer the primary of which forms one arm of a resistance bridge. In the corresponding arm of the bridge a similar transformer is placed, and the resistance of its secondary adjusted until the bridge is balanced, when an alternating current is supplied to it. The apparatus is so simple and the results are so good that electrodeless methods should replace some of those at present in use.

THE *Physikalische Zeitschrift* for October 24 contains abstracts of many of the papers read at the Versammlung deutscher Naturforscher und Aerzte in Dresden in September. The meeting, owing largely to the exertions of Prof. Hallwachs, was very successful. Of many papers of great interest, two may be mentioned. Drs. E. Gehrcke and O. Reichenheim have measured the change of wave-length of the light of the anode rays when they are seen end on, and have shown that when the anode is of sodium, lithium, or strontium the rays consist of molecules of these metals thrown off from the anode. Drs. Scheel and Heuse have measured the expansion of platinum between $-183°$ C. and $+16°$ C., and find as the mean result of three determinations by the two-microscope method and by Fizeau's method 1602×10^{-4} cm. per centimetre.

ARRANGEMENTS are being made by which the Proceedings of the London Mathematical Society may be subscribed for by the public at a uniform price per volume, the volumes to be supplied either in parts, as issued, or in volumes at the option of the subscriber. The arrangement will begin to take effect with the next volume, the first part of which will probably be published early in January, 1908.

THE *Anglo-German Courier* of November 23, published by the *African World*, is entirely devoted to an illustrated description in German and English of the recent visit of the German Emperor and Empress to London. This is the final number of that periodical, which was started to promote friendly feelings between the people of Great Britain and Germany—a mission that may now be regarded as accomplished.

Two well-illustrated and conveniently arranged catalogues have been received from Messrs. Casella and Co. One deals with self-recording instruments for scientific, engineering, and industrial purposes, and the other provides descriptions of anemometers, air meters, and wind-direction instruments. The catalogues deserve the attention of meteorologists, teachers of geography, and other observers.

A SECOND English edition, which has been re-written, of Prof. A. F. Hollemann's "Text-book of Organic Chemistry," has been published in this country by Messrs. Chapman and Hall, Ltd., and by Messrs. John Wiley and Sons in New York. The first English edition was reviewed in NATURE of June 18, 1903 (vol. lxviii., p. 149), and it will suffice to say that the present volume is, like the former, the translation of Dr. A. Jamieson Walker, and is from the third Dutch edition. The translator has had the cooperation of the author and the assistance of Dr. Owen E. Mott.

MESSRS. J. M. DENT AND CO. have published the first number of the *New Quarterly*, a review of science and literature, edited by Mr. Desmond MacCarthy. The price of each issue is 2*s.* 6*d.* net. If science is to receive the same amount of attention in subsequent numbers, the review should become popular in the scientific world. Of the nine articles included in the present issue, four deal with various departments of scientific work. Lord Rayleigh, P.R.S., discusses the question, "How do we perceive the direction of sound?" The Hon. Bertrand Russell writes on the study of mathematics; the Hon. R. J. Strutt, F.R.S., deals with the question, Can we detect our drift through space? and Mr. G. A. Paley contributes an article on biology and politics.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN DECEMBER:—

Dec. 1. 2h. Mercury at greatest western elongation (20° 20′).
3. 18h. 30m. Mercury 4° W. from the Moon.
7. 11h. 42m. Minimum of Algol (β Persei).
10–13. Epoch of the Geminid meteoric shower.
10. 17h. Mars in conjunction with Moon. (Mars 3° 25′ S.).
10. 8h. 31m. Minimum of Algol (β Persei).
11. 22h. Venus in conjunction with Uranus (Venus 0° 59′ S.).
12. 3h. 35m. to 4h. 28m. Moon occults 30 Piscium (mag. 4·7).
,, 5h. 28m. to 6h. 42m. Moon occults 33 Piscium (mag. 4·6).
13. 5h. 20m. Minimum of Algol (β Persei).
,, 3h. 54m. to 4h. 44m. Moon occults 20 Ceti (mag. 4·9).
15. 2h. 55m. to 3h. 47m. Moon occults ξ^2 Ceti (mag. 4·3).
17. 12h. 53m. to 13h. 18m. Moon occults δ^1 Tauri (mag. 3·9).
,, 14h. 9m. to 15h. 18m. Moon occults δ^3 Tauri (mag. 4·2).
20. 22h. Vesta in conjunction with the Moon. (Vesta 0° 59′ S.).
22. 12h. Sun enters Capricornus. Winter commences.
23. 2h. 6m. Jupiter in conjunction with Moon (Jupiter 1° 53′ S.).
30. 10h. 14m. Minimum of Algol (β Persei).
31. 3h. Mars in conjunction with Saturn. (Mars 1° 50′ N.).

SATURN'S RINGS.—Further observations of the invisibility of Saturn's rings during the recent passage of the earth through the plane containing them are recorded in No 4215 (p. 249, November 17) of the *Astronomische Nachrichten.* According to the calculations of Prof. B. Peter, of Leipzig, the second disappearance should have taken place on October 4. M. Schaer, of Geneva, saw the rings as a luminous line without any difficulty on October 2, using a reflector of 140 mm. aperture. On October 3 the weather was unfavourable, but the rings were still visible, with a reflector of 100 mm. aperture, at 6h. 45m. on October 4. At 7h. 30m., however, the last trace of the bright line had disappeared. Continuing the observations with a refractor of 34 cm. aperture, at 7h. 45m. the rings could be seen momentarily, but were totally invisible at 8h. Bands of a brownish tint were several times seen on each side of the trace of the rings.

Dr. Hassenstein made observations with the 13-inch refractor at Königsberg on October 1 and 3. At 8h. (G.M.T.) on the former date the rings were undoubtedly visible, but at 5h. (G.M.T.) on October 3 they were invisible; at 10h. the rings could not be seen, but dark streaks and the shadow of the rings were visible. Dr. Hassenstein concludes that the passage of the earth through the plane of the rings took place at 0h. (G.M.T.) on October 3.

PHOTOGRAPHS OF JUPITER.—The November number of the *Bulletin de la Société astronomique de France* (p. 481) contains a reproduction from a photograph of Jupiter taken by M. Quénisset at the Juvisy Observatory on March 2. The instrument employed was the Viennet objective of 0·16 m. (6·3 inches) aperture and 2·9 m. (114 inches) focal length, and about 100 exposures were made. The resulting images show many details, and some of them are remarkably well defined, presenting nearly all the details seen with the 240 mm. equatorial at the same time. On some of the photographs the Great Red Spot is even more apparent than in the visual observation. A reproduction from a drawing made forty minutes earlier shows how well the details are registered on the photograph.

The same journal contains reproductinns from Prof. Lowell's photographs of Mars taken on July 11 and 28 respectively.

FINAL DESIGNATIONS OF RECENTLY DISCOVERED VARIABLES.—No. 4212 of the *Astronomische Nachrichten* (p. 181, November 7) contains a table giving the final designations of recently discovered variable stars allotted by the commission of the A.G. catalogue for variable stars. The list gives the provisional and final designations, the position for 1900, the precession, the chart place, and the range of magnitude for each variable, and includes twenty-four variable stars of long period, eleven irregular and twenty-five short-period objects, and thirteen variables of the Algol type.

A LARGE ERUPTIVE PROMINENCE.—Four excellent photographs of a large eruptive prominence, taken by Mr. Fox on May 21 with the Rumford spectroheliograph of the Yerkes Observatory, are reproduced in No. 3, vol. xxvi., of the *Astrophysical Journal* (October, p. 155). On the first photograph the prominence was seen strongly attached to the sun's limb, but on the succeeding plates it is shown as greatly altered in form and considerably weakened in its lower parts. Thirteen plates were exposed, using the H line, between 4h. 2m. and 5h. 59m., and during that period the height of the prominence, as measured on the photographs, varied as shown in the following table:—

G.M.T.	Height			G.M.T.	Height		
h. m.	"	kms.	miles	h. m.	"	kms.	miles
4 2	228·6	167,800	103,200	5 44	370·4	271,900	168,850
5 1	280·5	205,800	126,800	5 55	423·3	310,700	192,950
5 43	431·8	316,900	196,800	5 59	412·7	303,000	188,150

SURVEYS OF NEBULÆ.—Future workers on the possible changes in nebulæ or in the stars involved in such masses will find the exhaustive surveys of the Andromeda, the ξ Persei, and the 12 Monocerotis nebulæ, recently carried out at the Astrophysical Institute, Königstuhl-Heidelberg, of invaluable assistance.

The results of these surveys are published at length in the *Publikationen* of the institute, No. 1, vol. iii., containing those obtained by Herr P. Gotz from his researches on the Andromeda nebula, and No. 11, vol. ii., embodying Herr Lohnert's results concerning the star-densities of the nebulæ near ξ Persei and 12 Monocerotis respectively. The former treats of 1259 stars involved in the great spiral nebulæ, and gives the position and magnitude of each star for the equinox of 1900; then follows a catalogue of fifty-four recognisable points in the nebula which have been measured, and of which the positions (1900) are given. The treatise concludes with a detailed description of the nebula, a discussion of the relation of the star-density to the form and brightness of the gaseous mass in various parts, and the results of a statistical investigation of the distribution of the stars. Among other results, Herr Gotz finds that all the stars concerned are fainter than the ninth, whilst sixty-four are fainter than the sixteenth, magnitude. The greatest number, taken in magnitudes, are between magnitude 14·0 and 15·0, there being 316 of this class.

Herr Lohnert's work deals similarly with the distribution of the stars in the other two nebulæ named, the results being given in tables and also shown diagrammatically, as are those appertaining to the Andromeda research.

NEW GEOLOGICAL SURVEY MAPS AND MEMOIRS.[1]

(1) THE Geological Survey is making rapid progress in the publication of its re-survey of Cornwall; the memoir on the geology of Falmouth and Truro (Sheet 352) has already been reviewed in NATURE, and that on the Newquay district was described in the issue for May 16. Now we have the Penzance sheet of the map (adjoining that of Falmouth), and an explanation thereof.

This area includes not only the "Land's End district," including Penzance and St. Ives, but also the neck of land which unites it to the rest of Cornwall. The district possesses several interesting physical features, for the granite areas up to a height of about 420 feet above the sea exhibit smooth and undulating contours, the ground forming a dissected plateau and rising gently to the foot of a well-marked bluff, which is an ancient sea-cliff. The age of this plateau cannot be fixed for certain, and though Mr. Reid seems inclined to refer it to early Pliocene time, he admits that it may be much older (? Eocene), and may only have been re-modelled and graded in Pliocene times. The low-lying neck of land which lies between Mounts Bay and St. Ives Bay has also an interesting history; originally it may have been part of an Eocene river-valley, but in Pliocene times it was a strait, and the Land's End district was then an island.

The most important rock-masses delineated on the colour-printed map and described in the memoir are:—(1) the three members of the Lower Palæozoic system, which are probably of Ordovician age, but have received local names in Cornwall—the Mylor series, the Falmouth series, and the Portscatho series; (2) the masses of intrusive igneous rock—granite and greenstone—which have been thrust through these ancient strata.

The contact-alterations produced by these successive intrusions are fully explained. The greenstones (diabasic rocks) are earlier than the granite, and their effects are different from those produced by the latter. Each area of granite is surrounded by an *aureole* or belt of altered rock, and the border of the granite itself has been converted into schorl-rock (quartz and tourmaline). It is in these altered belts and in the adjacent parts of the granite that the principal mineral wealth of the country has been found.

There is a chapter on the elvans or dykes of quartz-

[1] (1) "The Geology of the Lands End District." By Clement Reid, F.R.S., and Dr. J. S. Flett, with contributions by Messrs. Wilkinson, Dixon, Pollard, and MacAlister. Pp. viii+158; with six plates. (London: H.M Stationery Office, 1907.) Price of memoir 3*s.* 6*d.*, of map 2*s.* 6*d.*

(2) "The Geology of the Country around Hungerford and Newbury." By H. J. Osborne White. Pp iv+150; illustrated. (London: H. M. Stationery Office, 1907.) Price of memoir 2*s.* 6*d.*, of map 1*s.* 6*d.*

porphyry which traverse the district, and are of slightly later date than the granite. Fifty-seven pages are devoted to economic geology and mining, much information being given about the mineral lodes and the mines, some of which are now being re-opened.

Brief accounts are given of the Pliocene deposits of St. Erth and of the later Pleistocene accumulations.

The photographic views are clear and well reproduced, as may be seen from the example here given. The map is well printed on good thick paper, and the only fault we have to find with the colouring is that the tints indicating Pliocene and Valley Gravel are barely distinguishable from one another.

(2) The second memoir deals with an area which includes parts of Berkshire, Wiltshire, and Hampshire, the larger portion being in Berkshire and traversed by the valley of the Kennet. Nothing older than the Selbornian (Upper Greensand) reaches the surface, and the greater part is occupied by Chalk, Eocene beds, and Clay-with-flints. The colouring of the map is clear, and the paper on which it is printed is thicker than that of sheets issued in previous years.

It is some time since this area was surveyed, and in the meantime Mr. Osborne White has made a detailed study of the Chalk and its zones in Berkshire, as well as of the superficial deposits of this and neighbouring districts, so that the preparation of the memoir could not have been put into better hands.

Of the Cretaceous rocks described, the chief interest centres in the Upper Chalk, which is dealt with zone by zone; two of these, the zone of *Marsupites testudinarius* and that of *Actinocamax quadratus*, have only been proved to exist in Berkshire within the last three years. The former has a continuous outcrop from the western border as far east as Newbury, and this outcrop is indicated on a sketch-map in the memoir; but the higher zone is only found in two small outliers, which are due to shallow synclinal flexures.

By aid of this zonal work Mr. White is able to show the exact nature and extent of the unconformity between the Chalk and the Eocene. This proves to be a gradual overstep, the Eocene passing transgressively on to older and older beds in a northerly direction. Hence it would seem that, prior to the Eocene sedimentation, the whole area had a continuous slope from north to south, and that the Kingsclere-Pewsey anticline is entirely of post-Eocene date.

Chapters are devoted to the Reading beds, the London Clay, the Lower Bagshot beds, the Clay-with-Flints, the Plateau Gravel, the valley gravels, alluvium, and economics. There are also appendices on the Mollusca of the alluvium of the Kennet by Messrs. A. S. Kennard and B. B. Woodward, and on the insoluble matter in samples of Upper Chalk by Dr. W. Pollard and Mr. H. H. Thomas. Finally, the memoir is furnished with a bibliography and a good index.

View of the south side of the Land's End. From "The Geology of the Land's End District."

RECENT PUBLICATIONS OF THE U.S. MUSEUM.[1]

THE subjoined list (which is exclusive of a large number of minor publications) affords a striking example of the energy with which scientific research is being pushed in America, a noteworthy fact being that,

[1] (1) "The Birds of North and Middle America." Part iv. By R. Ridgway. Bull. U.S. Nat. Museum, No. 50. Pp. xxii+973.
(2) "Catalogue of the Type and Figured Specimens of Fossils, Minerals, Rocks, and Ores in the Department of Geology, U.S. Mus." Part ii. By J. P Merrill. *Op. cit.*, No. 53. Pp. v+370.
(3) "The Families and Genera of Bats." By G. S. Miller. *Op. ci* No. 57. Pp. xvii+282.
(4) "Herpetology of Japan and Adjacent Territory." By L. Stejneger *Op. cit.*, No. 58. Pp. xx+577.
(5) "Report on the Diatoms of the *Albatross* Voyages in the Pacific Ocean, 1888-1904" By Albert Mann. Contr. U.S. Nat. Herbarium, vol. x., part v. Pp. v+221-424.

out of the five memoirs, only two are devoted solely to American biological subjects. Since all five are by well-known experts, the following brief remarks may in the main take the form of commendation rather than of criticism.

As regards No. 1, Mr. Ridgway is to be congratulated on having got through rather more than half his heavy task, the present part bringing him nearly to the conclusion of the perching birds, of which no less than 1675 species and races are recorded in the first four parts. As in the previous volumes, generic terms are employed in the modern restricted sense, and the "keys" to the various family and generic groups are all that can be desired in the way of lucidity and comprehensiveness.

The catalogue standing as No. 2 in our list is a work exclusively for the benefit of specialists, to whom it will no doubt prove invaluable. The invertebrates having been completed in the first part, the present issue is devoted to fossil vertebrates, fossil plants, and minerals, rocks, and ores, which are severally arranged in three main sections. In the vertebrate section the specimens are referred to their respective classes, in which they are catalogued according to the alphabetical order of their names. This seems, on the whole, the most satisfactory arrangement; but we venture to think that the author has carried the alphabetical plan a little too far in making it extend to the class-divisions, the sequence of birds, fishes, mammals, and reptiles being, in our opinion, decidedly unsatisfactory. The system of cross-references in cases where a specimen has been referred to more than one genus is well planned, but the addition of a species index to each section or class would have considerably added to the value of the catalogue as a work of reference.

With No. 3 we come to a work of prime importance, which cannot fail to be of the highest value to systematists. No complete revision of the families and genera of bats has, we believe, been published since the issue of Dobson's invaluable catalogue, and as great progress in our knowledge of the group has been made since that date, such a revision was urgently wanted. For this task few zoologists are better equipped than Mr. Miller, who for some years past has devoted much attention to the order, and has studied the chief collection on both sides of the Atlantic. Perhaps the most important divergences from the Dobsonian classification are the wide sundering of the Emballonuridæ and Vespertilionidæ, and the transference of the mastiff-bats from the former group to a separate family following the latter; the second change being a further development of one inaugurated by Winge and endorsed by Max Weber.

Dr. Stejneger's work on the reptiles of Japan, the Liu Kiu and neighbouring islands, and a considerable proportion of the mainland of the Far East, will take rank as a valuable systematic monograph, in which special attention is devoted to geographical distribution.

In his memoir on the Pacific diatoms collected by the *Albatross*, standing last on our list, the author directs attention to the importance of collecting these organisms on account of their value in determining difficult questions connected with the extent and volume of ocean currents, and the origin of the materials deposited on the bed of the sea. Now that this has been pointed out, there is little doubt that the authorities will see their way to the collection of diatoms in a much more careful and systematic manner than has hitherto been attempted in America.

R. L.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The board of anthropological studies has put forward a proposal to establish a diploma in anthropology. The board believes that the interests of anthropology will be best served by the encouragement of research, and that the proposed diploma in anthropology should be granted for an original dissertation, and not by examination.

On the recommendation of the general board of studies the readership in animal morphology is to be transferred to the more general subject of zoology. It is proposed that the board be authorised to appoint a reader in zoology with the annual stipend of 100*l*., to be paid from the common university fund. The board also proposes that a demonstrator in petrology be appointed.

Mr. W. Welsh has been appointed chairman of the examiners for part i. of the mathematical tripos, 1908 (new regulations).

Prof. Ridgeway, the Disney professor, gives notice that he will maintain the thesis "that Sergi's theory of 'the Mediterranean race' is untenable," on Wednesday, December 4, at 5 p.m., in the archæological lecture-room.

LONDON.—At the meeting of the Senate on November 20 a report was received from the committee specially appointed to advise the Senate on the question of the establishment of the proposed Institute of Medical Sciences at South Kensington. The committee found that the financial support offered for the original scheme was inadequate, and that, apart from the money difficulty, the scheme had become impracticable on account of the opposition of the medical faculty. The Senate therefore decided that the donors to the fund should be informed that the money paid was at their disposal.

Prof. Starling, F.R.S., has been elected by the medical faculty a member of the Senate, in succession to Dr. Lauriston Shaw, resigned.

MANCHESTER.—A deputation from the University, supported by the members of Parliament and municipal authorities of Lancashire and the surrounding counties, waited upon the Chancellor of the Exchequer on November 20 in reference to the proposed reduction of the Government grant to the University from 12,000*l*. to 10,000*l*. per annum. Throughout this district numerous public bodies interested in higher education have passed resolutions expressing disappointment at the recommendation of the advisory committee, and requesting the Government to continue its full support. The Vice-Chancellor gave evidence to show that this reduction in the grant will seriously hamper the steps which have been taken to develop in various directions the higher branches of the work of the University. The Chancellor of the Exchequer emphasised the determination of the Government not to reduce the total grant of 100,000*l*. devoted to higher education, but, whilst admitting that there was no suggestion that the work of the University had been slackened in any of its departments, pointed out that the advisory committee was unbiased and free from pressure from any quarter. Further consideration of the case was promised. Quite apart from its local effect, the "principle of a maximum" is regarded here as one of great danger to the advance of higher education. The *Manchester Guardian* remarks:—"In our own opinion the committee has not only incidentally done serious damage to the University, but it has done violence to a principle much more important than the one it has introduced. That principle is, that while there are many valid reasons why the amount spent by the State on educational institutions should be increased, there is only one valid reason for its ever being reduced—their inefficiency. It is right to penalise a college or a school because it does not come up to standard, but it is contrary to justice and to public policy to penalise one of which nothing but praise is uttered."

OXFORD.—A grant of 300*l*. having been made from the University chest to the professor of pathology for the provision of a lecturer and a demonstrator in his department, the professor has nominated Dr. E. W. Ainley Walker as lecturer in pathology.

SHEFFIELD.—Mr. Haldane visited the University on November 20, and inspected various departments and addressed a large gathering of the students, staff, and others, presided over by Sir Charles Eliot, the Vice-Chancellor. Mr. Haldane spoke of the developments of recent times which have brought universities into contact with industrial life. The closest connection of science and industry may be made to the lasting advantage of both, and without damage to either. It is becoming truer every day that no man can hope to control a great university who has not at his disposal resources which science alone can give. The laboratory and the professor have inspired some of the greatest industrial movements of the time, and all indications are that that will continue to be so more and more. It is sometimes said that the only source of wealth is labour. This was true in old days, when science was little applied to industry, and there were capitalists and labourers and little else, but conditions have since then been changed. There is an abundance of labour, but also a greater abundance of capital. It is becoming apparent that labour undirected, labour without knowledge and without scientific ability to direct it, is incapable of serving the purpose of those who wish to develop the resources of nature. The real source of wealth is the direction of labour and capital to the right points of application. Knowledge is the source of wealth—scientific knowledge, business knowledge—the capacity of the trained man; and the men with that capacity, the men of brain and of science, are emerging more and more as those who have the power of controlling the resources of the earth, and labour and capital are becoming more and more instruments in their hands.

GIFTS and legacies to the funds of Yale University amounted to more than 100,000*l*. during the fiscal year recently completed. Gifts amounting to 70,000*l*. were received by the New York University during the past fiscal year. The value of this University's property is more than 1,000,000*l*.

PROF. BEDSON last June completed his twenty-fifth year as professor of chemistry at the Armstrong College, Newcastle-upon-Tyne. The event was the occasion of many congratulations and suitable presentations. In addition to the celebration arranged last summer, we notice from the report of the principal of the college that the council has "deemed it only fitting to mark the occasion, and its profound appreciation of Prof. Bedson's exceptional services to the college, by unanimously voting him a 'jubilee' vacation of six months, to take effect in the course of the coming year, together with a sum of 200*l*." We congratulate Prof. Bedson, and commend the course of action adopted by the Newcastle authorities to the notice of other college councils.

THE fifth annual report of the Manchester Education Committee deals with the year 1906–7, and provides much information concerning the successful attempts made in the city to coordinate educational effort and to prevent overlapping and waste. Full particulars are given as to the work during the session of the Municipal School of Technology. There was for some reason a decrease of 164 in the total number of individual day and evening students enrolled, which, however, reached 5149. The total volume of work of the evening departments, computed in student hours, that is, by multiplying the number of students enrolled by the total number of hours of instruction, was 444,827 student hours, whilst the actual volume of work, namely, the total number of hours of instruction multiplied by the actual attendances, was 290,046, or 65 per cent. of the total volume of work.

THE inaugural address delivered by Prof. Willis G. Tucker at the opening of the present session of the Albany Medical College has been reprinted from the Albany Medical Annals of the present month. The address dealt with educational democracy, and in it Prof. Tucker indicated several directions in which, unless care is taken, danger may result to American higher education from the large private benefactions of recent years. Quoting from a speech of Chancellor MacCracken at New York University, Prof. Tucker urged that, as a result of the gifts of millions of dollars from great American financiers, the universities are in danger of being reckoned the purchased servants of a narrow caste. He went on to insist that in a country like the United States "higher education should be in no way dependent upon the variable and perhaps ill-directed impulses of individuals, however generous and philanthropic they may be." He maintained that it is the duty of the State to provide technical and higher education for the people, enumerated the reasons for his belief, and indicated some of the directions in which he thought the necessary funds might be raised.

THE report of the council of University College, Bristol, presented to the governors at their annual meeting on November 20, is a record of steady progress as regards number of students and results of original investigations. For a college with limited means and indifferent local support, the amount of research carried on is particularly noteworthy. A department in economic biology has been formed with the object of rendering assistance to those engaged in agriculture and kindred pursuits. By carrying out investigations and experiments, and by suggesting preventive or remedial measures where crops and fruit trees have been threatened or attacked by insect or other pests, it is hoped that the department will meet a real need. The committee of the Bristol Museum has consented to form collections illustrative of economic biology. Though the college is a centre of intellectual life and interest in the city of Bristol and neighbourhood, it derives only a meagre income of about 500*l*. a year from the sustentation fund. If this may be taken as an index of public support to higher education in the west of England, the prospects of a university do not seem very promising. It is hoped, however, that the King will visit the city to open the Avonmouth Docks next year, and that the promoters of the scheme for a university will be justified by that time in asking for a charter.

THE report for the session 1906–7 of the department of technology of the City and Guilds of London Institute has now been published. During the session, 3311 classes in technological subjects were registered at 376 centres, in 286 towns. These classes were attended by 46,048 students, being 1580 more than in 1905–6; 21,728 candidates were presented in technology from 439 centres in the United Kingdom, and of these 13,054 passed. By including the candidates from India and the colonies, and those for teachers' certificates in manual training and domestic economy, the total number of examinees was 23,572. These figures show an increase on those of any previous year. Members of the institute's staff for the examination, inspection, or organisation of classes visited ninety-two centres during the year. The report points out two main causes which impede progress in the technical instruction of artisans and prevent the results of the teaching from being as satisfactory as might be desired. They are, first, the difficulty of finding competent teachers, and, secondly, the unduly large proportion of artisan students who enter technical classes without the preliminary knowledge necessary to take full advantage of the instruction they receive. It is fully recognised in the report that the teaching of technology has improved greatly during the past decade, but it is noted that the examiners have still to direct attention repeatedly to the insufficient knowledge that candidates possess of the principles of the subjects, and to point out that the fluctuating quality of answers in different groups of papers indicates faulty teaching as the source. As regards the preliminary training of the students, it is desirable, the report says, that more encouragement should be given to the further attendance of pupils at a school in which provision is made for manual training, English, and practical science teaching, before commencing the distinctly technical part of their course of training.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, November 7.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—Gaseous nitrogen trioxide: H. B. **Baker** and Mrs. **Baker**. Liquid nitrogen trioxide can be converted into the gaseous state if it is dried completely. The liquid is green at the ordinary temperature, but becomes blue below -2°. In liquid air it solidifies to a mass of dark blue crystals.—The atomic weight of tellurium: H. B. **Baker** and A. H. **Bennett**. During the last thirteen years the authors have investigated tellurium, and the possibility of its containing a second element, but so far all the evidence obtained points to the homogeneity of the element.—The isomerism of the double sulphites of sodium and potassium: M. H. **Godby**. No evidence of the existence of the two isomeric salts $KO.SO_2Na$ and $NaO.SO_2K$ could be obtained.—Studies in the camphane series, part xxiv., camphoryldithiocarbamic acid and camphorylthiocarbimide: M. O. **Forster** and T. **Jackson**. Descriptions of both these compounds are given.—The vapour pressures of triethylamine, of 2 : 4 : 6-trimethylpyridine, and of their mixtures with water: R. T. **Lattey**. The total pressure curves obtained experimentally for these mixtures conform to the type expected theoretically. The partial pressure curves can be calculated by a form of the Duhem-Margules equation.—Liquid triethylamine: R. T. **Lattey**. Evidence is brought forward to show that the amine is a unimolecular liquid. Note on the constitution of homoeriodictyol: F. B. **Power** and F. **Tutin**. It is shown that in so far as the observations of Mossler (*Sitz. K. Acad. Wiss. Wien*, June) with regard to this compound are accurate, they can be explained by the formula previously suggested by the authors (Trans. Chem. Soc., xci., 889).—The alkyl compounds of gold. Diethylauric bromide, preliminary note: W. J. **Pope** and C. S. **Gibson**. This colourless crystalline substance, the first alkyl compound of gold described, is obtained by the action of auric bromide on magnesium ethyl bromide in ether.—The interaction of methylene chloride and the sodium derivative of ethyl malonate. A correction: F. **Tutin**. The yellow sodium salt previously described (*ibid.*, xci., 1141) is the sodium derivative of ethyl dicarboxyglutaconate, formed by the action of chloroform present as an impurity in the methylene chloride.—Preparation of aliphatic nitro-compounds: P. C. **Rây** and P. **Neogi**. The nature and quantities of the nitrites and nitro-compounds obtained by interaction of various alkyl iodides with mercurous nitrite are given.—Some mercury derivatives of camphor: J. E. **Marsh** and R. de J. F. **Struthers**. A description of the compounds obtained by heating camphor with alkaline mercuric iodide.—Contributions to the chemistry of the terpenes, part ii.: G. G. **Henderson**. The addition product of chromyl chloride and limonene is described, as well as the decomposition products obtained from this.—The synthesis of acridines and phenonaphthacridines, tetra- and hexa-methylacridines, dimethylphenonaphthacridines, dixylylmethylenediamines: A. **Senior** and A. **Compton**.—The root and leaves of *Morinda longiflora*: M. **Barrowcliff** and F. **Tutin**. These materials are reputed in Sierra Leone to possess valuable medicinal properties, but the products obtained from them, viz. (*a*) hydroxymethoxymethylanthraquinone, (*b*) morindanol, $C_{38}H_{61}O_3.OH$, m.p. 278, (*c*) a phytosterol, (*d*) hentriacontane, (*e*) a mixture of lower fatty acids and citric acid, and (*f*) resins and other amorphous products, possess no pronounced physiological activity. A small amount of the alizarin monomethyl ether, which occurs in "Chay" root, was also obtained.—Ethyl α-cyano-γ-phenylacetoacetate: A. R. **Smith** and J. F. **Thorpe**.—Aromatic amides and imides of camphoric acid: W. O. **Wootton**.—The melting point of *d*-phenylglucosazone: F. **Tutin**. The phenylosazones of sugars occurring naturally in a number of plants have been prepared, and found to melt at temperatures varying from 205° to 219°. On re-crystallisation from pyridine they melted at 215° to 218°, which is the melting point of *d*-phenylglucosazone, similarly re-crystallised from pyridine.—The interaction of cyanodihydrocarvone, amyl nitrite, and sodium ethoxide: A. **Lapworth** and E. **Wechsler**.

Royal Anthropological Institute, November 5.—Prof. D. J. Cunningham, F.R.S., president, in the chair.—A new method of ascertaining the stature and making other measurements of the living person: Prof. D. J. **Cunningham**. The apparatus consists of a large bed of slate placed against a wall and divided into centimetre squares. The subject is placed against the slate, and by the aid of a carpenter's square the height and other measurements can be read off.—A series of so-called "grave stones" and other objects of a similar nature from the west of New South Wales: N. W. **Thomas**. The objects, most of which are apparently manufactured of a mixture of gypsum and sand, are in many cases marked with parallel grooves and signs resembling broad arrows. Some of them are long, banana-shaped objects with a cup-shaped hollow in the base. These are said to be found in sandhills associated with implements and other remains of old camps. As to the meaning of these there is absolutely no information. Others, which are shorter, thicker, and sometimes helmet-shaped, are certainly placed upon graves, but the precise object is uncertain.

Royal Astronomical Society, November 8.—Mr. Newall, president, in the chair.—Pogson's Observations of Variable Stars, edited by C. L. Brook and H. H. Turner: Prof. **Turner**.—Note on the ancient solar eclipses discussed by Mr. Cowell: A. C. D. **Crommelin**. The author had made an independent calculation of the six most important ancient eclipses, and obtained results practically identical with those of Mr. Cowell. Further reasons were given for supposing that the eclipse of −1062 was witnessed from Babylon itself, and a brief statement was given of the point at issue between Mr. Cowell and Prof. Newcomb and Mr. Nevill.—Disappearance of Saturn's ring system, October 3: R. T. A. **Innes**. The ring was easily seen with the 9-inch refractor of the Johannesburg Observatory at 4.45, in twilight, but became invisible by 10.30 the same evening, so the earth must have passed through the plane of the ring soon after invisibility.—The ultra-violet region in sun-spot spectra, and spectrum of comet *d*1907: J. **Evershed**. The papers were read by Dr. Michie Smith, who showed a series of sun-spot spectra taken at Kodaikánal Observatory, and also a photograph of the comet spectrum showing several lines extending into the tail, and a pair of very bright lines confined to the nucleus, which were identified with the lines of cyanogen.—Photograph of comet *d*1907 taken at the Royal Observatory, Greenwich: A. S. **Eddington**. The tail of the comet appeared to consist of a number of fine straight rays spreading from the nucleus.—Note on the permanency of some photovisual lenses: Dr. W. J. S. **Lockyer**. Six of these lenses, of apertures of 3 inches to 12 inches, have been in use at the Solar Physics Observatory, and in periods of from twenty-three to eighty-three months they have all developed curious markings on one or more of their inner surfaces. The markings appeared on the inner surfaces of one or both of the outside lenses, and not on the inner lens, as had been expected. A series of photographs was shown, the markings being crystalline formations, sometimes covering the entire lens. It was concluded that the formation was due to the absorption of water vapour by the glass, setting free its alkaline components to form carbonates, which are deposited as crystals. Further particulars were given in a note by Mr. Dennis Taylor, appended to Dr. Lockyer's paper.—Spectroscopic observations of cyanogen in the solar atmosphere and in interplanetary space: H. F. **Newall**. The author had found by the method of Cornu that cyanogen was present in the solar atmosphere, but it also appeared to exist in space, and the suggestion was made that the presence of cyanogen in comets, as shown by their spectra, might be due to the latter circumstance rather than to its existence in comets themselves.—A series of spectroheliograph photographs of solar faculæ and prominences taken at the Kodaikánal Observatory, India: Dr. Michie **Smith**.

Mathematical Society, November 14.—Prof. W. Burnside, president, in the chair.—Hyper-complex numbers: J. H. Maclagan **Wedderburn**. The object of the paper is to develop a treatment of hyper-complex number-systems by aid of the calculus introduced by Frobenius, and applied by him to the theory of groups.—The invariants of a binary quintic and the reality of its roots: Dr. H. F. **Baker**. It is usual to express the invariants of a quintic in terms of a set of four, which are connected by a syzygy. In the paper three rational functions of the four are introduced, each of them an invariant, and two of them absolute invariants, in terms of which each of the four, and any other invariant, can be expressed rationally, and the explicit expressions of the four original invariants in terms of the three new invariants are given. When the two new absolute invariants, denoted by X, Y, are regarded as coordinates of a point in a plane, the conditions that the quintic, with real coefficients, may have one, three, or five real roots are determined by the division of the plane into four regions by means of a certain quartic curve, corresponding to the vanishing of the discriminant, and an arc of a certain cubic curve which touches this quartic. The number of real roots is determined without any ambiguity by the situation of (X, Y), whether it is in one of these regions or on a bounding line.—The application of quaternions to the problem of the infinitesimal deformation of a surface: J. E. **Campbell.** Weingarten's characteristic function in this problem can be interpreted kinematically as the normal component of the rotation, which an element of surface undergoes in the course of the deformation. The direct application of the method of moving axes, to obtain the characteristic equation, can be simplified very much by the use of quaternions.—Addendum to a paper on the inversion of a repeated infinite integral: T. J. I'A. **Bromwich.**—Generalisation of a theorem in the theory of divergent series: G. H. **Hardy.**—Uniform and non-uniform convergence and divergence of a series, and the distinction between right and left: Dr. W. H. **Young.** Nodal cubics through eight given points: J. E. **Wright.**—A transformation of hypergeometric series: Dr. E. W. **Barnes.**—A transformation of a certain hypergeometric series: Prof. M. J. M. **Hill.** A general theorem on integral functions of order less than one-half: J. E. **Littlewood.**

PARIS.

Academy of Sciences, November 11.—M. A. Chauveau in the chair.—A new mineral species, arising from the Athenian plumbiferous scoria of Laurium: A. **Lacroix** and A. **de Schulten.** This is one of a series of minerals arising from the action of sea water upon scoria rich in metallic lead and galena. Its composition corresponds to the formula $Pb_3(AsO_4)_2,3PbCl_2$. The crystallographic measurements are given, and the hardness (3·5) and density (7·1) measured. The name georgiadesite is proposed for the mineral.—The influence of feeding on the course of experimental tuberculosis: MM. **Lannelongue, Achard,** and **Gaillard.** In sixty strictly comparative experiments, in three classes of diet in which fat, carbohydrate, and nitrogenous food respectively predominated, the animals with the fatty food died in forty days; with sugar, eighty-seven days; and with gluten, 371 days. This confirms the result of the authors' early work, clearly demonstrating the superiority of a strongly nitrogenous diet in fighting tuberculosis. Continued algebraic fractions: Edmond **Maillet.**—The periodic solutions of the equation

$$\Delta u + \lambda a(x, y, z)u = 0:$$

A. **Myller.**—The method of colour photography of MM. A. and L. Lumière: Adrien **Guébhard.** A discussion of the phenomena attending the reversal of the image in this process.—The measurement of the anomalous dispersion in crystals at different temperatures, and on some theoretical consequences: Jean **Becquerel.** It is shown that the large increase of intensity observed for the majority of the absorption bands of tysonite when the crystal is plunged into liquid air is not entirely due to the contraction of the bands, but is also caused by an increase in the total energy absorbed, corresponding to the increase in the dielectric coefficient of the electrons.—A comparison of the effects of the X-rays and radium upon the plant cell. Value of the unit M in plant physiology: H. **Guilleminot.**—The action of radium bromide on precious stone of the alumina family: F. **Bordas.** A modification of the method described in a previous paper. Colourless corundum has been transformed into topaz, the depth of colour of natural topazes increased, and a similar effect produced with faintly coloured rubies. Colourless fused alumina, submitted to the action of radium bromide, became first rose-coloured and then reddish yellow. Since this action takes place equally well at −200°, the conclusion is drawn that the phenomenon of coloration is not due to oxidation.—The diastatic function of colloids: J. **Duclaux.** From a quantitative study of the catalysis of hydrogen peroxide solutions by colloidal solutions of ferric hydrate, the author concludes that the hydrolysed part of the salt does not intervene in the catalysis, and that it is the undecomposed ferric chloride which effects the change.—The action of gold on the dioxide of sodium and barium: Fernand **Meyer.** Precipitated gold reacts with fused sodium dioxide, yielding sodium aurate, and barium dioxide attacks gold similarly, although the reaction is less complete. From these substances auric acid can be prepared by the action of sulphuric acid. Auric acid, dried in a vacuum in the dark, has the composition $Au_2O_3,3H_2O$ or $Au(OH)_3$. The preparation of the pure aurates of sodium, potassium, barium, strontium, and calcium from this acid is described. These aurates are decomposed by heat or light, the insoluble residue being Au_2O, and not gold as supposed by Fremy.—The preparation of some iodides *in vacuo*: Marcel **Guichard.** The preparation of the anhydrous iodides of iron, nickel, silicon, and aluminium is described.—The action of amorphous arsenic on the alkyl halides: V. **Auger.** Amorphous arsenic, prepared by the reduction of a hydrochloric acid solution of arsenious anhydride with stannous chloride or a hypophosphite, is very active. It reacts with methyl iodide at the ordinary temperature, and at higher temperatures in sealed tubes with CCl_4, $CHCl_3$, $C_2H_4Br_2$, $C_2H_4I_2$, CHI_3, and various alkyl iodides.—The iodohydrins and alkyliodohydrins derived from styrolene: Marc **Tiffeneau.**—The action of urea, thiourea, urethane, and some amides on xanthydrol: R. **Fosse.**—The application of the Hoffmann reaction to sparteine: Charles **Moureu** and Amand **Valeur.**—The estimation of fat in skimmed milk: R. **Lezé.** Three litres of the milk are mixed with ammonia and caustic soda, and the whole passed through a centrifugal separator.—The coloration of certain precious stones under radio-active influences: Daniel **Berthelot.**—The products of the volcano Monte Ferru, Sardinia: M. **Deprat.**—The influence of high altitude on the loss of water by the organism: H. **Guillemard** and Aug. **Moog.** The effect of high altitude is not to increase the rate of loss of moisture from the body, but, on the contrary, to reduce it. The experiments leading to this conclusion were conducted at Paris, Chamonix (1050 metres), Grands-Mulets (3050 metres), and the summit of Mt. Blanc (4810 metres).—The development of the energy of the voice: M. **Marage.** A description, with diagrams, of a set of exercises to increase the volume of air expelled from the lungs.—The visibility of night signals at sea: André **Broca** and M. **Polack.** The practical conclusions drawn from this investigation are as follows. If a signal of doubtful colour is better seen by direct vision than by indirect vision, it is red. In the contrary case the light is blue or colourless.—A new method of determining the accelerating power of neutral potassium and sodium salts on the coagulation of milk by vegetable ferments: C. **Gerber.**—The mitosis of cells containing *Bacillus cuenoti*: L. **Mercier.**—The experimental study of medicines stimulating the movement of the stomach by the aid of fluoroscopy: G. **Carrière.**—A new Myxomycetum, an endoparasite of insects: Louis **Léger.**

November 18.—M. Henri Becquerel in the chair.—The transit of Mercury across the sun of November 13 and 14, 1907. Observations made at the Observatory of Nice: M. **Bassot.**—Observations of the Daniel comet, 1907*d*, and a general plan of organisation for the complete physical study of comets: H. **Deslandres.** The transit of Mercury of November 14, 1907, at the Observatory of Lyons: Ch. **André.**—Observations made at the Observatory of Toulouse of the transit of Mercury of November 13–14: B. **Baillaud.**—Similar observations made at the Observatory of Marseilles: E. **Stephan.**—Similar observations from the Observatory of Bordeaux: L. **Picart** and E. **Esclangon.**—Similar observations from the Observatory of Bourges: Th. **Moreux.**—The occultation of the satellites of Jupiter: G. **Le Cadet.**—The observation of the transit of Mercury across the sun, November 13–14, 1907: A. de la Baume **Pluvinel.**—Remarks on the relation between the solar activity and magnetic perturbations: MM. **Cirera** and **Balcelli.**—The transit of Mercury, November 13–14, at the Observatory of Besançon: MM. **Bruck, Chofardet,** and **Pernet.**—The correction of the astigmatism of doubly refracting prisms: C. **Tissot** and Félix **Pellin.** The astigmatism can be corrected by the use of an appropriate cylindrical lens.—The propagation of telephone currents on subterranean lines: Henri **Abraham** and M. **Devaux-Charbonnel.**—The magnetic double refraction of organic liquids: A. **Cotton,** H. **Mouton,** and P. **Weiss.**—The multiplicity of sounds emitted by tuning forks: G. **Sizes** and G. **Massol.**—The action of the Röntgen rays upon crystallised alumina: F. **Bordas.** The author has described in previous papers the alteration of colour produced in various forms of crystallised alumina by the action of the rays from radium bromide. From the fact that the radium salt acts from the inside of a glass tube, the α rays are excluded from the action. Since similar colouring effects are now shown to be produced by the Röntgen rays, it is probable that the effects observed are due to the γ rays.—The presence of *p*-methoxycinnamic aldehyde in essence of estragon, and on some derivatives of estragol: Maurice **Daufreme.** The aldehyde was isolated from the essence by repeated fractional distillation under reduced pressure, and by its reactions and analysis identified with *p*-methoxycinnamic aldehyde. Since, however, the constants did not agree with those of the same aldehyde, as described by Scholtz and Wiedemann, a synthetical sample was prepared, and found to be identical with that from the essence.—The artificial reproduction of heavy spar, celestine, and anglesite, and on isomorphous mixtures of these substances: Paul **Gaubert.** The method used is the re-crystallisation of the precipitated sulphate from sulphuric acid at, or slightly below, its boiling point.—The influence of the concentration of sugar solutions on the development of the spikes of *Ulex europaeus*: Marin **Molliard.**—Floral anomalies due to mechanical action: M. **Ducamp.**—The use of heat for the treatment of coffee plants against the attacks of the Indian borer (*Xylotrechus quadrupes*): Louis **Boutan.** To have any practical results it is necessary that all parts of the plant affected should be raised to a temperature of 50° C. This cannot be done by the direct action of a burner, and the author has designed a special stove for this purpose.—The possibility of establishing the diagnosis of death by radiography: Charles **Vaillant.** In a radiograph of a living person the stomach and intestines are not visible. Owing to their stationary condition after death, and possibly owing also to the development of gases which reinforce the action of the rays, these organs are clearly shown immediately after death in the radiograph, and the clearness increases with lapse of time after death. —The study of the epiploïc sero-appendices: R. **Robinson.** —The north Pyrenees and pre-Pyrenees sheets of *charriage* to the east of the Neste: Léon **Bertrand.**—An ancient bed of the Pliocene Loire: E. **Chaput.**—The relation between the radio-activity of subterranean waters and their hydrology: F. **Dienert** and E. **Bouquet.**

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 28.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Development of Turbo-Generators: Dr. Robert Pohl.

FRIDAY, NOVEMBER 29.

SOCIETY OF ARTS, at 8.—The Hygiene of Work in Compressed Air. (Diving, Caisson Work, Sub-aqueous Tunnelling, &c.): Dr. J. S. Haldane, F.R.S.

SATURDAY, NOVEMBER 30.

ESSEX FIELD CLUB (at Essex Museum of Natural History, Stratford), at 6 p.m.—Notes on an Ancient Human Skeleton found at Foxearth, Essex: J. M. Wood.—A History of the Mineral Waters and Mineral Springs of Essex: Miller Christy and (Miss) May May Thresh.

THURSDAY, DECEMBER 5, 1907.

A TEXT-BOOK OF PLANT PHYSIOLOGY.

Lectures on Plant Physiology. By Prof. Ludwig Jost. Authorised English translation by Prof. Harvey Gibson. Pp. xiv+564; illustrated. (Oxford: Clarendon Press, 1907.) Price 21*s*. net.

PROF. JOST'S lectures appeared in German in 1904, and were soon appreciatively reviewed in the columns of NATURE. It was twenty years since a book had appeared so admirably adapted for the use of students of the physiology of plants, and an English translation was eagerly awaited by teachers of the subject. Now that it is to hand we find that it contains several hundred mistranslations; quotation of a short series of these will show how greatly the English rendering lacks accuracy. On p. 44, and elsewhere, "succulent plants" become "oily plants." On p. 114, by mistranslation, all Brown and Morris's work on the carbohydrates of foliage leaves is transferred to another investigator.

On p. 128, the fact that in Engelmann's micro-spectral investigations by the bacterial method the assimilating cells are lighted from *below* is ignored, and the significance of a table of data is destroyed in translation by the illuminated side being styled the *upper* side. On p. 229, Pflüger's hypothesis that respiration always involves direct oxidation of the actual substance of the protoplasm itself is stated in one sentence, and yet the next says that if it could be shown that nitro-bacteria only oxidise ammonia in their respiration, this theory would be *established*. The German says the exact opposite—that the theory would thus be *disproved*. On p. 230 we find the statement that small doses of sugar and organic food *accelerate* the development of nitrifying organisms, whereas the *inhibiting* action of such "nutriments" upon these special organisms is one of the outstanding wonders of protoplasmic mutability. On p. 265 it is stated that certain "cells exhibited growth at their ends" instead of "the cell-growth came to an end."

On p. 278, dealing with the forms of the plant-body, we read:—

"There are quite a number of plants which form only one axis, on which no lateral members save leaves are produced. In a second series may be placed the numerous coniferæ which *develop lateral branches only*. The majority of higher plants, however, form both lateral buds and leaves."

Consultation of the German shows that the three contrasted series really are:—main axes bearing (1) leaves only; (2) leaves and occasional lateral branches; and (3) leaves and as many lateral buds as there are leaves. On p. 334 the process of "budding" is described under the title of "grafting," and that of "grafting" under "budding." On p. 335 "leaf-trace" is translated by "leaf-spur," while on p. 331 it appears as "leaf-base." On p. 339, discussing the range of adaptation to habitat, we read:—

"Although amphibious plants can live in water as well as on land, there is usually in the long run a certain minimum and a certain maximum degree of dampness which may not be exceeded; in other words, amphibious plants cannot on the one hand become aquatics nor on the other xerophytes."

It is hard for the English student to divine that what the author says is that amphibious plants on land generally need a fair amount of moisture; they cannot range from an aquatic habit all the way to a xerophytic habit.

On p. 400 one sentence says that the raising of the temperature of the arum spadix above that of its environment by respiration is scarcely appreciable during *intra-molecular* respiration, while the next says that the organ is hotter in intra-molecular respiration than in normal respiration. On p. 407 we find that Askenasy observed certain capillary phenomena on wetting "deposits on cover-glasses"; this should be on wetting "a pile of cover-glasses": on the same page it is stated that the possibility of gelatine having, in its substance, microscopically fine capillary spaces containing air is disproved by its "impermeability to air"; the German says by its "transparence."

On p. 543 there occurs the following incomprehensibility as a rendering of the Weber-Fechner law as exemplified in human perception of differences of weight:—

"A weight of 1 mg. must be increased one-third, a weight of 10 mg. must be increased ten-thirds before we can appreciate a difference between them."

In some ten or more places the expression "presentation time," in reference to a stimulus, is rendered by "latent period" to the complete confounding of the sense.

Finally, the headings of the chapters are not always correctly rendered. Chapter xxxii. deals with movements due to "Kohäsion des Füllwassers," which means the cohesion of the water-contents filling the cells. Yet in the title and throughout the chapter *Füllwasser* is translated by "imbibition-water," which is quite a different phenomenon.

To these faults of commission are yet to be added those of omission. In the bibliographies at the ends of the chapters all the titles of English works still remain in the German language. Is the student to take no pride in his heritage in the work of Darwin, Hales, Knight, and others? Further, all the many works translated from the German by the Oxford Press are quoted in German without reference to the fact that there are English translations available for students. Even the references to Pfeffer's "Physiology" are all to the pages and volumes of the German edition.

When provided with a list of essential corrections of the text, this text-book will be a very valuable addition to the distinguished series of German handbooks prepared for English students by the Clarendon Press.

In conclusion we may express our high esteem for Prof. Jost's lectures. The exposition is extremely lucid, and just what is needed for students taking up the advanced study of physiology. The author pays well-merited tribute to Pfeffer's classical handbook.

with which the present work does not compete in fulness of treatment, the different parts of the subject being elaborated only so far as will be assimilable by students. In dealing with matters that are still unsettled, the author shows considerable judgment, but he has perhaps a tendency to over-refine the division and classification of phenomena, as, for example, in discussing symbiosis, parasitism, and fermentation.

Short passages, in square brackets, have been interpolated by the author here and there in this issue with the intention of bringing the text up-to-date. Special details may be thus indicated, but broader advances can hardly be dealt with in this way; nevertheless, the work is the most modern exposition of the physiology of plants available in any language.

F. F. B.

LIQUID AND GASEOUS FUELS.

Liquid and Gaseous Fuels, and the Part They Play in Modern Power Production. By Prof. V. B. Lewes. Pp. xiv+334. (London: A. Constable and Co., Ltd., 1907.) Price 6*s*. net.

WITH the multiplication of institutions where the teaching of applied science is made a leading feature, there has sprung into existence quite a number of text-books which specially appeal to students of this kind. Some of these works are both interesting and useful, but it must be confessed that they one and all seem rather to appeal to the type of mind which is disinclined to attack any really difficult problems. Text-books such as were published twenty years ago, by men such as Rankin and Cotterill, which endeavoured to get at the scientific principles underlying the applications of applied science, seem, with very few exceptions, to have gone out of date and to have become replaced with more interesting and better written books, dealing more or less with the descriptive part of the subject which they treat. Prof. Lewes very modestly states that he does not wish to produce a work that shall, to any extent, enter into detail, and his book is professedly a sketch of the subject. This is to be regretted, as we feel sure that a chemist of such eminence could have produced a work which would have been of great value, not only to the students, but to that large class of engineers who wish to get information on some of the difficult points in connection with both liquid and gaseous fuels.

The chapters on combustion deal wholly with burning at ordinary pressures, and are both clear and accurate. It is unfortunate that the scope of the work does not allow Prof. Lewes to allude to some of the phenomena of burning under pressure, a subject of enormous importance, and one of which very little is known.

The description of the various forms of solid fuels, together with the determination of their calorimetric values, is well done, but we should have expected to find something said about the discrepancy which almost always occurs when using the Junker calorimeter with gas and air, which has not been completely saturated, as this affects the quantity of condensed water that has to be measured in order to obtain the lower value.

There is a great deal of useful information on the subject of liquid fuels; the arrangement of the hydrocarbons contained in these fuels is very well brought out, and no student can read through this chapter without acquiring a good idea of the various forms of liquid fuels derived from a common base..

The manufacture of coal-gas is, of course, of very considerable interest. There is nothing very novel, nor, should we say, of much service to the average student, unless, indeed, he is proposing to become a gas engineer.

There is an excellent description of the various methods of making water-gas, which at one time it was anticipated would play a very considerable part in the application of cheap gas for both heating and power purposes, and is very largely used for certain work. The large percentage of carbon monoxide which it contains has caused it to be looked upon with suspicion, except for the purpose of carburetted water-gas for use in coal-gas mains, and it is probable that very little water-gas is used for any other purpose, although, probably, this gas would be very much more used if it were possible to obtain a reduction in the standard now insisted upon as regards the illuminating value of gas.

The description of the producers proper is not so full as the merits of these producers would entitle them to. The suction producer is alluded to, but not described to any great length, and in considering the bituminous producers Prof. Lewes appears to consider that it is essential in bituminous plants to recover the ammonia. This is, of course, a mistake. There are a large number of bituminous plants running which do not recover the ammonia, and which are perfectly satisfactory. Indeed, it is doubtful whether in the method of using excess steam in order to prevent the destruction of ammonia the value of the bituminous plant is not brought down, as a much better gas can be made when the steam is cut down to the lowest amount which can be used to prevent clinkering.

The last chapter, which deals with the fuel of the future, is certainly the most interesting of the whole work, and it points out very clearly that when the existing supplies of fuel become limited, we shall have to fall back upon alcohol, produced from vegetation of some sort or another, which may be made almost inexhaustible. There is no doubt that this is quite correct, and it is very much to be regretted that at present no experiments on alcohol on any scale can be made, owing to the restrictions which our fiscal conditions impose, and we presume that owing to this, the work will be carried out in some other country where the Government is more sympathetic towards scientific research.

There is one point which Prof. Lewes appears to have overlooked. He considers that the alcohol will be either manufactured from potato starch or sawdust. There seems no reason to doubt that when the question becomes urgent some highly-specialised plant will have been brought into existence for the sole purpose of absorbing the maximum amount of carbon dioxide from the air, and in this manner it may be possible enormously to increase the amount of carbon which a given area of land will pick up. This may sound fanciful, but the wonderful improvements which hybridisation has effected in the past make it quite possible that in the future still greater improvements may be looked for.

A PRACTICAL HANDBOOK ON RUBBER.

Rubber Cultivation in the British Empire. By Herbert Wright. Pp. vi+100. (London: Maclaren and Sons, 1907.) Price 2s. 6d.

THIS is one of the most interesting and useful little books yet published on rubber cultivation, and should be in the hands of every planter. It is a reprint of a lecture delivered before the Society of Arts. The book is not only of great value to those interested in plantation rubber, but also to those interested in the development of wild rubber. Mr. Herbert Wright, who was at one time controller of the Government experimental station in Ceylon, is now the editor of the *India Rubber Journal.* He is also the author of one of our best standard works on rubber, viz. "Hevea Brasiliensis," which is a scientific treatise on the botany of rubber. The present publication is more in the form of a useful and practical handbook, and deals with the great potentialities of the rubber industry, and its importance from "the producer's standpoint, especially in British possessions."

The gradually increasing demand for raw rubber, and the remunerative prices obtained, have produced enormous developments in the past few years on Eastern plantations. At the present the most important centre for rubber collection is tropical America, which supplies about 60 per cent. of the world's output. Africa comes next with 30 per cent. to 35 per cent., but tropical Asia last year only contributed 3 per cent. Borneo, New Guinea, Fiji, New Caledonia, and the Seychelles are also commencing to develop a strong interest in rubber-producing plants.

"It may be safely stated," writes Mr. Wright, "that to-day there are no less than 14,000,000*l.* of English money represented as paid up capital in companies directly or indirectly concerned with rubber growing. Furthermore, it may be estimated that approximately 30,000,000*l.* worth of rubber may be consumed during the present year."

The natural order which supplies the greater part of the world's rubber is the Euphorbiaceæ, the most valuable species being the Hevea, which produces the well-known Para rubber which has been planted so extensively in Ceylon, Federated Malay States, Straits Settlements, and Sumatra.

Mr. Wright speaks with considerable authority and experience on plantation Para rubber, and he thinks that it will sooner or later obtain a prominent, if not the commanding, position as a source of future rubber; but this will not be for many years, for in speaking of wild rubber he says:—

"Should the supply from wild sources become scarce—an improbable occurrence—it would be impossible for the plantations to supply the balance for many years to come, as the producing capacity of the land now alienated for rubber in the East will only be in 1912 or 1913 some 12,500 to 25,000 tons per year. The rubber manufacturers have hitherto been dependent, almost entirely, on wild rubber; and it seems illogical to suggest that the rubber forests on which so much new capital and enterprise have been recently expended, and in which prominent scientific and business men are concerned, will be unable to satisfy the increased demand expected in the next few years. It may confidently be regarded as the principal source of rubber for the next half score of years, for the simple reason that plantations in the proper sense do not exist to produce what will be required."

At the end of the lecture there is an instructive discussion, in which Lieut.-Col. Prain, Mr. Gray, Mr. Fritz Zorn, and Mr. S. Figgis took part.

L. C. B.

OUR BOOK SHELF.

School Hygiene; a Handbook for Teachers of all Grades, School Managers, &c. By Herbert Jones. Pp. x+151. Dent's Mathematical and Scientific Text-books for Schools. (London: Dent and Co., 1907.) Price 2s.

THIS is one of the many books that the great movement towards school hygiene has thrown up. The book, or rather booklet, contains practically nothing that is new, but the selection of topics is done with judgment and care; every main subject of environmental hygiene is touched on with sufficient fulness to meet the needs of immediate practice or to provoke to further reading, and the illustrations are profuse and good. The author has succeeded in treating "the subject as simply as possible." The work of Dr. Kerr at the London County Council is largely drawn upon. As in Dr. Newsholme's "School Hygiene," the book is allocated half to the school and half to the scholar. In criticism, it may be said that rather much space is given to matters, *e.g.* site, building construction, and sanitary appliances, &c., that the teacher cannot alter or affect, and rather little space to what he can affect. But with this qualification the booklet forms a good introduction to the subject. The writing is well adapted to the intended readers.

Regeneration and Transplantation. By Prof. E. Korschelt. Pp. 286; 144 figures. (Jena: G. Fischer, 1907.) Price 7 marks.

OF recent years there has been much experimenting and not a little theorising regarding regeneration and grafting. The results of the experiments have sometimes been very remarkable and full of theoretical suggestiveness, and they are now so numerous that a general survey of their import is very welcome. We have already a volume on regeneration by Prof. T. H. Morgan which has been of great service; we have now an analogous volume by Prof. Korschelt. He traces the phenomena of regeneration through the world of organisms, in unicellulars and multicellulars, in plants and in animals, in young forms and full-grown forms, showing the varied distribution of the regenerative capacity and its varied expressions, and always returning to the central question, How has it come about, and by what precise processes does it come about, that a lost part is re-grown and the intactness of the creature restored? Special sections of the book are devoted to a discussion of such subjects as the following:—autotomy, often-repeated regeneration, restitutions and regulations, heteromorphosis, atavism in regeneration, imperfect and superfluous regeneration, the relation of the nervous system to regeneration, the relation of regeneration to nutrition, to reproduction, to age, and to environmental conditions. The author's exposition is lucid, and there is an illustration on every second page. In the second part of the book we find an account of grafting or transplantation in plants and in animals, with strange figures of grafted polyps and worms, pupæ and tadpoles, frogs and newts—an altogether quaint assemblage. At the end of the book there is an exhaustive bibliography, certainly amazing in its dimensions, very usefully subdivided into sections relating to different aspects of the subject. As to the general theory of regeneration, Prof. Korschelt seems to incline to a compromise between the views of Weismann and Morgan, admitting that there is a great deal to be said on both sides. He seems—for he is anything but dogmatic—to believe that the regenerative capacity is a primary quality of living matter, which, along certain lines of evolution, has been accentuated and specialised by natural selection. Thus the regenerative capacity is, in general, a primary quality, but in particular cases an adaptive character.

Organische Zweckmässigkeit, Entwicklung und Vererbung von Standpunkte der Physiologie. By Dr. Paul Jensen. Pp. xiii+251. (Jena: Gustav Fischer, 1907.) Price 5 marks.

Prof. Jensen has produced a book which attempts to deal in a philosophical manner with some of the most difficult problems that confront the biologist. The reader will perhaps be inclined to deprecate an attitude of "cock-sureness" that rather pervades the whole, but he will at the same time recognise that in many places the author is stimulating and suggestive.

A great part of the whole volume is devoted to the examination of the various explanations that have been put forward to account for adaptation in the organic world, as well as of those which have attempted to deal with the meaning and the method of evolution.

After a somewhat lengthy discussion of these topics, the author puts forward the analogies shown by various cosmic mechanisms to assume positions of relative or absolute stability, and he regards them as useful in throwing light on the problems of evolution. The whole of the constructive part of the book strikes us as very speculative, and though of undoubted interest, it may be doubted whether the point of view as advocated by Jensen will find much sympathy amongst working biologists. The title of the work indicates that it is written from the standpoint of physiology, but we have searched its pages in vain to find any serious physiology, as ordinarily understood, discussed in it at all. There is much philosophy of a sort, and much acute destructive criticism of many ideas and notions that are widely current. But it does not appear that in grappling with the problems he has set himself to face and to solve, the author has expressed himself so clearly as did Herbert Spencer many years ago. There is much in the work before us that recalls the "Principles of Biology," though there is a great difference between the lucid expression of Herbert Spencer and that of our author. The following passage, relating to the causes of extinction of species and genera in the past, will furnish a fair sample of the method of treatment:—"According to our theory of development, a *natural* extinction of species is to be anticipated as the expression of a general law. Organisms that are dying out in this way fall into the same category as those systems which, after enduring through a long period in a stationary condition, pass finally, as the result of slowly advancing changes, into a relatively stable state (death); a destiny that . . . in time will overtake many existing organisms, in spite of the 'rejuvenating' effects of amphimixis" (p. 237). LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

The Windings of Rivers.

At the meeting of the British Association at Edinburgh in 1892 I read a paper on the subject of the winding of rivers before the geographical section. It was illustrated by a large number of diagrams, but, as these could not be included in the report of the meeting, only the title of the paper appeared. It may not be out of place to give a short account of it, as the subject is now attracting some attention.

In Fig. 1 the courses of three streams are shown. These are distinguished by the letters A, B, C, without indication of their identity or of the scale on which they are drawn. If anyone were to try to select the one which represents the largest or the smallest of these streams he might do so correctly, but he would not be surprised if he were told that he had guessed wrongly, for it could only be a guess. The length of each tracing is the same. In nature it represents in A nine English miles, in B two hundred and sixteen miles, and in C one and a half miles.

Tracing B represents the part of the Mississippi between the mouth of the Arkansas River and that of the Red River. Tracing A represents the Devon Water, a tributary of the Forth, and tracing C represents a quite insignificant brook called the Catter Burn, a tributary of the Endrick, one of the principal affluents of Loch Lomond. These tracings, and indeed the maps of all countries, show clearly the great family likeness exhibited by rivers in all parts of the world. This likeness rests on the fact that in all rivers the relation between the length of an arc or bow and that of its chord is nearly the same. It is an organic rather than a family likeness, and resembles that which exists between dogs of different breeds or builds.

The following table shows, for a selection of well-known rivers, the degree in which the above relation holds good:—

River on the stretch		Length of stretch		Ratio	Number of bows	Average length of bows
From	To	Direct	Along windings			
Mississippi		Miles	Miles			Miles
Columbus	Memphis	124	204	1·65	23	8·87
Memphis	Natchez	270	490	1·83	62	8·10
Natchez	Baton Rouge	88	133	1·51	18	7·39
Baton Rouge	Carrolton	72	124	1·72	20	6·20
Columbus	Carrolton	554	955	1·72	122	7·83
Thames						
Marlow	Walton	18·7	30·0	1·61		
Teddington	Isle of Dogs	16·8	26·5	1·58	11	2·4
Danube	Near mouth	11·4	22·5	1·97	13	1·73
Rhine		kilom.	kilom.			kilom.
Germersheim	Mannheim	34·1	69·2	2·03	11	6·3
Main		114	144	1·27	44	3·27
Neckar						
Heilbronn	Mannheim	80	112	1·40	26	4·30
Lahn						
O. Lahnstein	Limburg	17·2	29·7	1·73		
Mosel	Nr. Coblentz	7·0	10·0	1·43		
Ahr						
Altenahr	Ahrweiler	4·6	9 6	2·09		

From the table it will be seen that over a length of nearly one thousand miles of the Mississippi the average length of stream, following the windings, is 1·72 times greater than the direct distance. In the Lahn we find almost the same factor. The Lower Danube, the Rhine, and the Ahr show a factor approximating to 2. The Main, Mosel, Neckar, and Thames have lower factors. The mean of all the factors is 1·68. For a certain number of the rivers the number of "bows" is given with their average length. The size of the bows stands in some relation to the volume of the river. What that relation exactly is I am not able to state. To arrive at it will require a careful study of the flood waters of the river in connection with the form of its bed. It is the flood waters which form the bed. When the river falls to low-water

FIG. 1.

level we often see it cutting out a secondary bed on a much smaller scale, which is obliterated by the next following flood.

It may be taken that the mean track of a stream traces the line of lowest level in the valley. Consequently, the ground must rise on both sides of it. The cross-section of the valley through the river resembles that through the middle of a watch glass, rising at first very slightly on both sides of the stream, then more rapidly as the confines of the valley are approached. It is evident that water displaced to one side of the river will, in returning to it, tend to pass to the other side, and to oscillate about the lowest point.

If the bed of a stream flowing through alluvial ground were rectified so as to direct the water along a straight trough cut in the material, it might preserve a straight course for a time, but a stream following such a course specification until some were obtained which resembled the courses of actual rivers. Fig. 2 shows one specimen out of many which were exhibited at the meeting of the British Association.

It is assumed that the rhythmic motion set up in a mass of water which is disturbed in its uniform rectilineal motion will be reducible to two reciprocating motions, one in the direction of the fall of the stream and the other at right angles to it. When the gradient of the stream is very steep and the nature of the bed homogeneous, as it is in the case of water flowing down the front of a glacier, the longitudinal oscillation is swamped by the powerful and continuous action of gravity, which does not affect the transverse component. In these circumstances we often meet with small streams which describe an almost perfect simple harmonic curve.

In the ordinary stream of the meandering type the gradient is very small, in the case of the Mississippi from 2 inches to 4 inches per mile, so that the longitudinal pulse can produce its full effect. When the two oscillations are simple pendulum motions and have the same period they produce an ellipse, which, when combined with the steady onward flow due to gravity, produces sinuosities unlike those of actual streams. When the period of the transverse oscillation is twice that of the longitudinal one, their combination produces a figure of eight (8). When a figure of eight is combined with steady forward motion so that both are travelled over in the direction of the arrows in the figure, then it does delineate a curve which may resemble the course of an actual stream. This is illustrated in Fig. 2. In it the sinuous curve falls into three parts, each consisting of a double bow, corresponding to a complete excursion of the tracing point round one of the figures of eight. The horizontal line indicates the path of undisturbed flow of the stream running from left to right in the direction of the arrows. It is divided into seventy-two equal spaces, each of which represents the distance which would be covered by the undisturbed stream in the interval of time in which the circle which generates the transverse reciprocating motion describes one twenty-fourth of a revolution, so that the undisturbed stream passes over twenty-four spaces in the time that the tracing point passes once round the figure

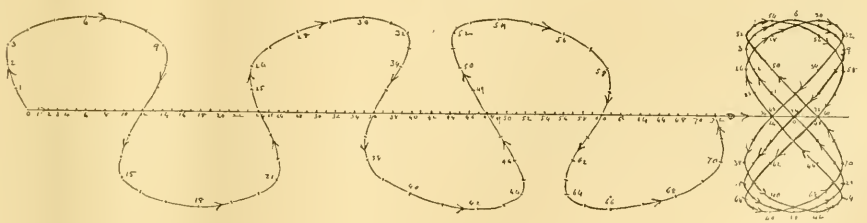

FIG. 2.

is in a state of unstable equilibrium. The smallest accident or obstruction disturbs the uniform rectilinear motion of the water, and tends to induce oscillations, both longitudinal and transverse. These begin immediately to cut into the banks, if they are yielding, and take larger and larger dimensions until they reach a limit when they have produced a course of the sinuosity which corresponds to the laws of the harmonic motion of its waters.

No attempt was made to arrive at these laws *a priori*. The method of investigation used was purely empirical. Curves were traced according to all kinds of harmonic

of eight. The resultant path of the tracing point is the sinuous curve, which cuts the horizontal line at 12 and 24 when the symmetrical 8 is used, and in 36, 48, or 60, 72 when one of the other two figures is used. It is an essential condition that the tracing point shall go round the 8 in the direction of the arrows, so that it shall be moving in the same sense as the undisturbed water when it traverses the outside parts of the figure which are approximately parallel to the path of undisturbed flow. In describing the sinuous line it is convenient to draw the figure of eight on tracing paper. Then, when the centre of the 8 is placed over any mark on the horizontal line numbered, say, 9, the point on the periphery of the 8 numbered 9 must be superposed on the point on the sinuous curve also numbered 9.

The description of the sinuous line is a simple case of mechanical drawing, and presents no difficulty. By varying the harmonic composition of the figure of eight and the rate of undisturbed flow of the water, an infinite number of different individual curves can be produced which are all covered by the same generic specification. It is an interesting occupation, in leisure moments, to compose curves of this kind and to compare them with those traced by actual rivers on the face of the earth.

J. Y. BUCHANAN.

IT is not difficult to show the character of the flow at the bottom of a small river. For several years I have taken my students along the course of the river Fender near Birkenhead, and we have conducted experiments which confirm the laws of bottom flow first pointed out by Thomson. At first we put down tubes containing coloured liquids, and the stream-line motion was very clearly shown by lines of colour. Later, I have employed lump sugar soaked in a strong alcoholic solution of magenta. On placing one of these cubes at the outer bend of a curve—the "turnpool"—it is found that the water there is almost stagnant. Gradually an aureole of coloured water forms round the sugar as it dissolves, and this slowly creeps across the stream towards the inner bend. The advantage of this method is that the coloured sugar is several minutes in dissolving, and it is very easily carried about.

For surface flow I have found mahogany sawdust to be the best, as it approaches water in density, and the fine particles are not influenced by air currents.

Although in measuring the surface flow the line of maximum velocity is usually more eccentric than the middle line of the stream, there are cases where the quickest flow is near the inner bend.

In a small experimental river in my laboratory I can produce both effects at will. A river is always tending towards a definite adjustment of its parts to correspond with the characteristics of its flow. The floor becomes graded by the filling of hollows and the removal of obstacles, and the swings become regular and rhythmic like the swings of a pendulum. This condition is seldom found except in the flood plains, and I presume this is the special case referred to by Sir Oliver Lodge.

In the ungraded part many exceptional and interfering circumstances come into play. I have noticed in experimenting with my laboratory river that when the stream has become perfectly adjusted the line of maximum flow is towards the outer curves, but if any disturbing cause is introduced, such as an increase or decrease in the quantity of water flowing in the channel, a variation in the slope of the bed giving a more rapid or gentler fall, or the introduction of an obstacle to form narrows, the normal characteristics of the flow are disturbed, and the maximum flow may be on the inner curve or more violently bent to the outer curve. This is determined by the changed conditions and the tendency of the stream to readjust itself. Prof. Thomson's model, not dealing with graded conditions, may easily have produced the abnormal effects he describes.

A comparison of the flow of a river with that of a glacier shows more points of similarity than most people suppose. In a curved glacier such as the Findelen, the surface at the outer bend is higher than at the inner bend, and the inner bend is always marked by a "toe-cap" moraine like the shallows on the inner curve of a river. It is only reasonable to suppose that this is the result of a cross current under the glacier, such as can be demonstrated in rivers. Moreover, we have in glaciers the phenomena of whirlpools and eddies where tributaries join the main stream.

The phenomena of flow are practically the same whether the medium is solid, liquid, or gaseous. The essential feature of flow is *shearing*. In a stream the surface layers shear over the lower, the mid-stream portion shears through the lateral parts, and in a meandering course momentum impels the water towards the outer bends and shears it round the slower moving water in the inner bend. So in glaciers and even in solid rocks flowing under earth stresses the same laws apply. The only difference lies in the unit of shear. In the case of liquids and gases this is extremely small, whereas in glaciers it is usually the "Kugel" which gives rise to the corn structure in glacial ice. In rocks the unit varies from masses of gigantic size to others of very small dimensions. This, perhaps, may be regarded as a very crude conception of the meaning of flow, but I have found it useful in giving students a graphic idea of the complicated movements in rivers and glaciers.

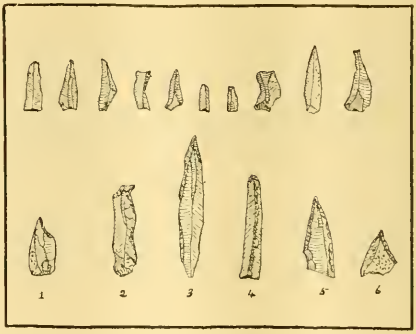
Small Flint Implements from Bungay.

THE small flint implements figured in the accompanying drawing were found in a sandy hollow about 2 feet deep at Bungay, in Suffolk. The sand in this hole was littered with minute flakes; in a few minutes I picked up between fifty and sixty, of which the figured ones are typical examples. I hesitate to describe the implements as "pigmy flints," because their fine secondary chipping is not confined to the thicker edge or "back" of the flakes, but, judging from photographs I have seen, they closely resemble some pigmies found recently near Brighton by Mr. H. S. Toms. So far as the untrimmed flakes are concerned, it is impossible to distinguish them from typical



Small flint flakes and implements from Bungay. Two-thirds actual size.

pigmy flakes, while the trimming of implements 3 and 5 is identical with that of the pigmies.

In consequence of nearly all the English pigmies having been found on the surface of the ground, it has been impossible to say with any confidence whether they belong to the Neolithic, Bronze, or Early Iron period. In view of this, it is interesting to know that the small flakes and implements from Bungay were found in association with a polished axe of grey flint, a black flint lance-head of very delicate workmanship, one of the rare and finely chipped triangular "knives," and some small convex scrapers showing very delicate secondary chipping. These implements were found in the same sandy hole when the small implements were discovered, and from an examination of the sides of the hollow it was evident that they all came from what might be called a "Neolithic floor" about 18 inches from the surface of the ground. Nowhere on the surface of the surrounding ground could I find a single flake or implement, and if the ground had not been disturbed in order that a small quantity of sand might be carted away, not one of the implements would have been brought to light. As it happened, they were all found within an area of about six square yards. Some small bones found on the same site have been identified as those of a girl or a small woman.

The makers of the small flint implements evidently had their home or their "workshop" on a sandy knoll only a few feet above the level of the marshes of the Waveney Valley. On this knoll and a neighbouring one there are some saucer-shaped depressions in the ground very suggestive of hut-circles. W. A. DUTT.

Lowestoft.

Graphical Interpolation.

SIR GEORGE DARWIN has directed attention (*Mess. of Math.*, 1877; Phil. Trans., A, 1891; "Collected Works," vol. i., p. 319) to the problem of interpolating values of a function at points each half-way between two consecutive points of an equidistant set, *e.g.* for determining probable half-hourly values when the hourly ones are found from observations. Let q', Q', Q, q be four points (Fig. 1) with equidistant ordinates u', U', U, u. It is required to find P where the graph through these four points cuts the ordinate half-way between Q and Q'. By taking the origin on the half-way ordinate and writing the function as

$$y=a+bx+cx^2+dx^3+\ .\ .,$$

we find that if we neglect terms beyond x^3, then

$$a=\frac{U'+U}{2}+\frac{1}{8}\left(\frac{U'+U}{2}-\frac{u'+u}{2}\right).$$

A rule for determining the point P is accordingly:—join QQ', qq' and let them cut the central ordinate in V, v respectively, then P lies in vV produced, and $PV=\frac{1}{8}Vv$. This rule, although theoretically identical, is simpler in form than that discovered by Sir George Darwin, and seems to be safer, especially near a point of inflexion. It may be worth noticing that in the special case where QQ' and qq' are parallel, the cubic reduces to a parabola, and the rule for finding P is involved in the relation $PV:Pv=QV^2:qv^2=1:9$. At the beginning and end of the series the rule breaks down, but it can be adapted by assuming the parabolic form for the first and last arcs. In the latter case q is indeterminate, and $q'v$ must be drawn parallel to $Q'Q$ (Fig. 2).

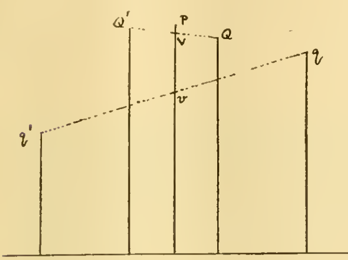


FIG. 1.

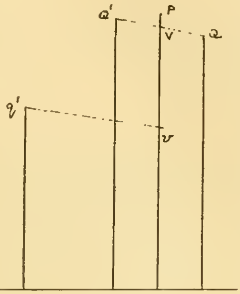

FIG. 2.

In the diagram (Fig. 3) the rule is applied to an example in which the assumption that the function can be expressed as a power series is scarcely justifiable, but it will be seen that it makes it easy to draw a smooth curve through the points Q. F. J. W. WHIPPLE.

Merchant Taylors' School, E.C.

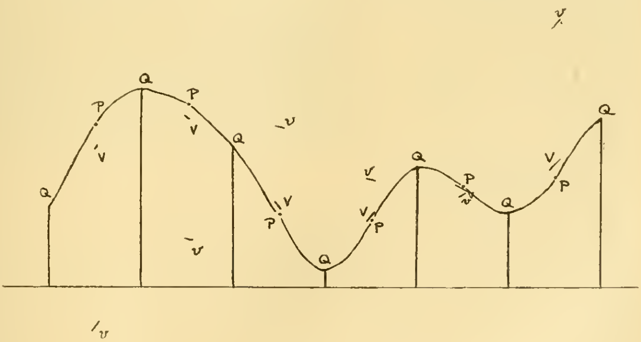

FIG. 3.

Reflection of Polarised Light.

SOME recent correspondence (vol. lxxvi., p. 637) having directed attention to an error in Preston's "Theory of Light," I venture to send notice of another error in the same work (see article 158). The same error will be found in Prof. Tait's article on light (see p. 611, vol. xiv., of the "Encyclopædia Britannica"), and is repeated in his text-book on light (article 271).

I sent word of the error to the late Sir George Stokes, who expressed himself astonished at it, and said he would look into the matter; but I did not hear from him again, as his letter to me (dated September 19, 1902) was written only five months before his death.

Let the planes of two thin plates of ordinary glass, A and B, be parallel, so that light, which has been completely plane-polarised by reflection from A, falls at the polarising angle upon B. Preston states that this light will be wholly reflected from B, whilst Tait states that this light will be reflected, almost without loss, from B.

As a matter of fact, if we represent by unity the intensity of the polarised beam incident upon B, then the intensity of the light reflected from B will be represented by about $\frac{2}{7}$, and this takes into account both surfaces of B. The remainder of the beam, about $\frac{5}{7}$, is transmitted. To reflect the whole of the incident beam an infinite number of plates would be required, and the glass would have to be perfectly transparent.

Both authors state correctly that, when the plane of reflection of B is perpendicular to that of A, and the polarised light from A falls at the polarising angle on B, then practically none of this light will be reflected from B.

I therefore think that the mistake arose from accidentally supposing that the total want of reflection in the second case should be balanced, as it were, by a complete reflection in the first case. C. T. WHITMELL.

Invermay, Hyde Park, Leeds.

THE TOTAL SOLAR ECLIPSE OF JANUARY 3, 1908.

ON the third day of the approaching new year, according to Greenwich mean time, a total eclipse of the sun will take place, the line of totality passing from a point in the Pacific, about east longitude 155° and north latitude 12°, in a curved path through Polynesia and terminating in Mexico.

Unfortunately for astronomers and others who go far afield to make observations on these occasions, the eclipse is mostly restricted to the ocean, and the only two portions of land from which totality can be seen are two Pacific islands, namely, Hull Island, in the Phœnix group, and Flint Island, to the north of Tahiti.

The accompanying map, Fig. 1, gives a general idea of the path of the line of totality. It is taken from the "Nautical Almanac" for the year 1908, but has here been considerably reduced, and several lines which were not required for this article have been omitted, and the land areas more shaded.

The positions of the two islands to which reference above has been made are denoted by two small circles on the central line. Even these observing stations do not offer those facilities with regard to anchorage, landing, shelter, &c., which make eclipsing easy, as the following particulars, gathered from Dr. Downing's paper in the Monthly Notices of the Royal Astronomical Society, will show.

Hull Island has a lagoon and a little fresh water, and cocoa-nut trees 50 feet high grow on it. The island is surrounded by a coral reef, which makes landing very difficult except by entering the lagoon by means of the boat passages on the north-west side. There is also no anchorage.

Even Flint Island does not offer more enticing facilities. It is 13 feet high, and covered with brushwood and trees, and is $2\frac{1}{2}$ miles long and half a mile broad. Fringing it is a steep coral reef, which at low water is dry and extends seaward about half a cable. At the northern end of the island this reef extends seaward $4\frac{1}{2}$ cables, and at the southern end $2\frac{1}{2}$ cables. Two small lagoons of brackish water are situated in the interior. Landing also is described as very bad even for surf boats, and there is either bad anchorage or none at all.

So far as is known at present, no one intends going to Hull Island, but as Flint Island will be occupied the following data regarding the particulars of totality, gathered from the above-mentioned source, may be of interest. As the island is situated in longitude 151° 48′ W. and latitude 11° 26′ S., the duration of totality is 4 minutes. Such a long eclipse will be specially suitable for the study of some problems, and more especially for those connected with the corona. This station is also very favourable in another respect, because the sun at eclipse time has an altitude of 74 degrees, or only 16 degrees from the zenith.

The following table shows the times of the four contacts of the moon with the sun in both Greenwich and local mean time.

Mean Solar Time.

	Greenwich	d.	h.	m.	s.	Local	d.	h.	m.	s.
(1)	January	3	7	52	51	January	2	21	45	39
(2)	,,	3	9	22	44	,,	2	23	15	32
(3)	,,	3	9	26	44	,,	2	23	19	32
(4)	,,	3	11	2	59	,,	3	0	55	47

While the accessibility of the station and the weather conditions are not all that could be wished for, the length of totality, the great altitude of the sun, and the importance of continuity of observation of eclipses are sufficiently tantalising to tempt astronomers to journey to this far-off land.

There is another reason which makes the observation of this eclipse of great importance.

The last eclipse from which successful results were obtained was that which occurred in 1905, the eclipse of 1907 not having been seen in consequence of unfavourable weather conditions. The next after 1908 will be the eclipse of 1912, which will be visible from South America for one minute. The other eclipses which will take place in this interval are as follows:—

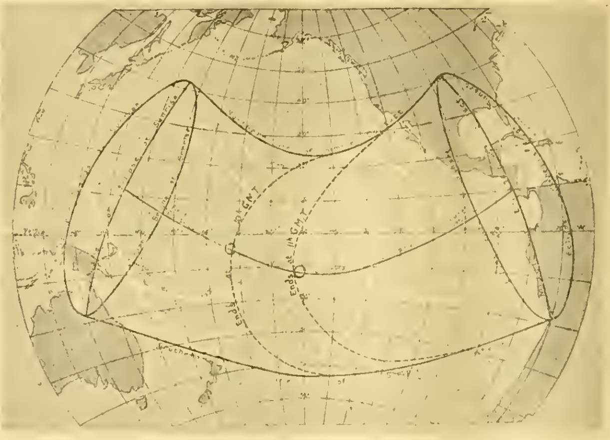

FIG. 1.—The track of the total solar eclipse of January 3, 1908. The small circles on the central line denote the positions of the two islands from which totality can be observed.

The Greenland and Siberian eclipse of 1909 is an annular one, and therefore not of any importance for physical astronomers.

An eclipse will occur in Tasmania in 1910, but as totality will commence at 4h. 3·5m. and end at 4h. 6·4m., and as the sun will set at 4h. 53m. Hobart mean time, the sun will probably be too low for any extensive series of observations.

In 1911 an eclipse track will begin in the south-eastern portion of Australia, pass across the Pacific Ocean, and finish by skirting the coast of Florida.

It may be that some islands lie in the track, in which case this eclipse can be utilised, but at the Australian end of the line the sun will probably have too small an altitude to warrant the sending of expeditions from great distances.

In April of 1912 there will be an eclipse visible in Spain, but until the calculations are published it is not certain whether it will be "total" or "annular." This uncertainty is due to the fact that the apparent diameters of the sun and moon on that occasion will be so very nearly equal that it will depend on the value of the moon's diameter employed in the computations whether the sun will be totally eclipsed or not. Should it prove, however, to be total, the time of duration will probably be very short. Such an eclipse would most probably be a very valuable one from the point of view of the spectroscopic study of the chromosphere.

It will thus be seen that we shall most probably have to wait until October, 1912, for a favourable eclipse following that of 1908, so it is hoped that the approaching event in the Pacific will be satisfactorily observed.

The accompanying map of the world (Fig. 2) shows the tracks of all the eclipses to which reference above has been made, with the exception of that of April, 1912. This chart is taken from Mrs. Todd's excellent little book, entitled "Total Eclipses of the Sun" (1894), but all those tracks which were not required have been deleted, and the year of occurrence of each eclipse has been printed in larger type.

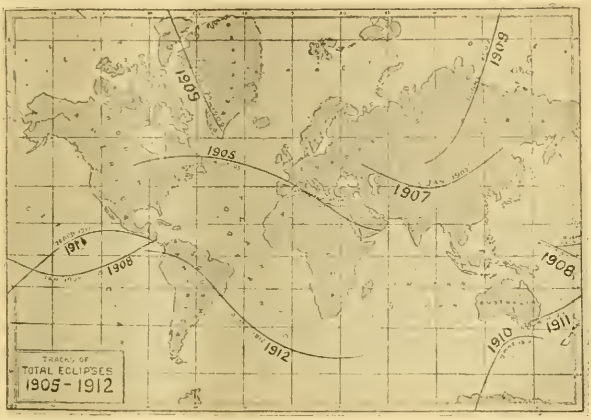

FIG. 2.—Chart showing the tracks of all the total solar eclipses from 1895 to 1912. The 1909 annular eclipse is included also, but the uncertain total eclipse of April, 1912, which might be seen from Spain, is excluded.

It is interesting further to point out that the eclipse of 1905 occurred at the time of greatest solar activity as indicated by the sun-spots, while that of 1912 will take place about the epoch of minimum sun-spots.

The eclipse of 1908, occurring in an intermediate year, will therefore be a useful connecting link between the two, and renders it important even from this point of view alone.

The only official expedition which, so far as is known, has made preparations to view this eclipse is the one from the Lick Observatory in America, under the direction of Prof. W. W. Campbell. Flint Island will be the observing station, and Mr. William H. Crocker, of San Francisco, who has defrayed the expenses of five previous expeditions, has again offered to finance this one. The Navy Department of the United States has come forward and provided a war vessel to transport the expedition from Tahiti to Flint Island and back. The ship put on this special duty is the *Annapolis*, and she will be under the personal command of His Excellency Governor Moore, U.S.N., of the Island of Tuituila, Samoa.

No doubt the officers and men of the *Annapolis* will prove most valuable assistants to Prof. Campbell, as they were found useful in the eclipse of 1905. On that occasion, it may be remembered, the United States Navy Department sent a "special eclipse squadron" of three vessels to Europe, under the command of Rear-Admiral C. M. Chester, U.S.N., the result of which was a complete series of observations only the preliminary results of which have as yet been published.

To describe briefly the scientific staff and instruments which will be conveyed by the *Annapolis*, reference has been made to the contents of an article which recently appeared in the Journal of the Royal Astronomical Society of Canada (vol. i., No. 4, p. 254) from the pen of Mr. C. A. Chant.

It is there stated that the party will probably consist of Prof. Campbell, with Messrs. Aitken, Perrine, and Albrecht, of the Lick Observatory; Prof. Lewis, of the University of California; Prof. Abbot and his assistant, and possibly one or two other assistants. They will all sail from San Francisco on November 22, arriving at Tahiti on December 4. The party will then join the *Annapolis* and sail for Flint Island.

With regard to the instrumental equipment, corona pictures on a large and small scale will be secured by a 40-feet focal length coronagraph pointed straight at the sun, and by a 5-inch objective of 70 inches focal length respectively. For the purpose of searching for intra-Mercurial planets, two groups of four cameras each will be pointed towards the east and west equatorial regions of the sun's surroundings. Objective-prism spectrographs, or prismatic cameras as they are often called, will be employed for obtaining photographs of the spectrum of the chromosphere. In one of these "running" plates will be used to record the sequences of changes in the spectrum of the sun's limb about the times of second and third contact.

This method was, so far as I am aware, first employed at Sir Norman Lockyer's suggestion in the prismatic camera in my charge at the eclipse of 1896 in Lapland. Unfortunately, clouds prevented any photographs at all being secured. Prof. Campbell successfully applied the method to the eclipses of 1898, 1900, and 1905, and therefore proposes to continue the series.

Other spectrographs included in the programme are one of low dispersion for recording the general structure of the corona, another for the determination of the wave-length of the green coronal line, and a third for studying the form of the gaseous envelope responsible for the green line. For the ultra-violet spectrum of the corona, Prof. Lewis is taking out a large quartz spectrograph. Polariscopic photographs will be undertaken, and a study of the brightness of the corona as a whole will be attempted.

From the above brief sketch it will be gathered that Prof. Campbell's party is equipped with a fine set of instruments, and that it is prepared to cover a wide field of research.

Although the above will be the only official expedition to the island, an enthusiastic amateur in the person of Mr. F. K. McClean is already wending his way there. Mr. McClean is the son of the late Mr. Frank McClean, F.R.S., who, it will be remembered, besides completing a valuable spectroscopic survey of the brighter stars in both hemispheres, made valuable endowments both to the Cape Observatory and the Cambridge University.

At the eclipse of 1905 Mr. F. K. McClean accompanied the Solar Physics Observatory's expedition to Majorca as volunteer assistant. On that occasion he was in charge of a large coronagraph of 16 feet focal length, which he manipulated successfully, so he is not a novice at eclipse work.

For the coming eclipse he is taking out a fine 22-inch siderostat, one coronagraph, and a small grating spectrograph. The coronagraph consists of a $4\frac{3}{8}$-inch De la Rue objective of 8 feet focal length, which has been used on numerous occasions during eclipses by the Solar Physics Observatory expeditions.

The optical parts of the grating spectrograph consist of a 4-inch Voigtländer of 42 inches focal length, and a Thorp's transparent replica of a Rowland diffraction grating having 14,500 lines to the inch and a ruled surface of 3×2 inches. In the eclipse of 1905 this instrument gave such satisfactory results that Mr. McClean wished to employ it again under, it is hoped, better weather conditions.

Mr. McClean has so arranged his programme that, failing any assistance at the station, he can make exposures in both the instruments. There is little doubt, however, that Prof. Campbell will be able to render him help should he require it.

It may be mentioned that if the *Annapolis* had been able to accommodate more than twelve of the eclipse party Mr. McClean would have been invited to join the Lick expedition. To reach Flint Island he has therefore gone to Auckland *viâ* Australia, and has chartered a special steamer to take him and his equipment to the island and back. From later information I find that, by arrangement with Prof. Campbell, he will pick up at Tahiti Mr. C. J. Mersfield, of the Royal Society of Sydney, and Mr. Moors, of the Sydney University, both of whom have volunteered to act as Prof. Campbell's assistants, and will convey them to Flint Island and back to Tahiti.

Let us hope that eclipse day will be fine, and that all will return with results which will add to our knowledge of the sun.

A cablegram, dated November 25, from Mr. McClean, at Auckland, states that Mr. Mersfield has joined him and will be attached to the Lick party. He further informs me that Mr. Raymond, of the Sydney Observatory, and Mr. Short, photographer to that observatory, together with the Rev. Mr. Walker, an amateur astronomer at Auckland, are going out with him and will form his party.

WILLIAM J. S. LOCKYER.

NEW AËROPLANES.

AN account of the successful aëroplane flights by which Mr. Henry Farman has succeeded in breaking the record hitherto held by M. Santos Dumont (in the absence of trustworthy information concerning the experiments of the Wright brothers) has probably been seen by most readers of NATURE in the daily papers. We are indebted to an article by M. René Doncière in *La Nature* for the further details regarding the machine and its performances which form the subject of the present notice.

Mr. Farman's machine has been constructed in the works of Messrs. Voisin Brothers, and is of the well-known cellular form, as shown in the accompanying illustration. The front pair of planes measure 12×2 metres, the height between them being 2 metres. This pair is connected by a framework $4\frac{1}{2}$ metres long with the rear pair of planes, which only measures 6 metres transversely. The vertical rudder is situated between the latter planes, while a horizontal rudder is fixed right in front of the machine. The motors and tanks of petrol are contained in a spindle-shaped case in front, into which is let the seat for the operator.

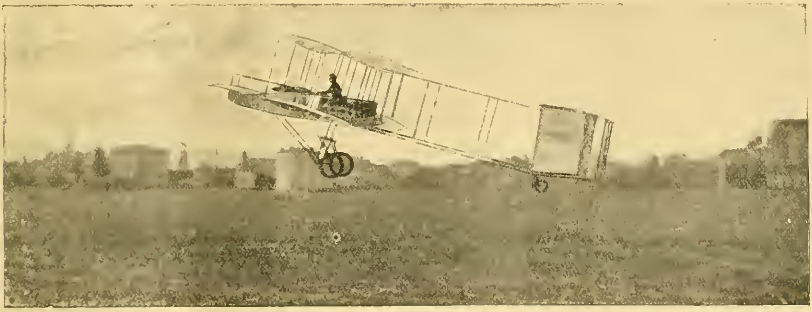
The motive power is furnished by an eight-cylinder "Antoinette" motor of 40–50 (metric) horse-power, and operates on a propeller the two vanes of which are 2·10 metres across and 1·10 metres in pitch. The whole apparatus rests on four wheels when on the ground. The total wing surface is 52 square metres and the weight 500 kilograms; the length of the machine is 10 metres. At present—or at any rate at the time of M. Doncière's account—the machine has a tendency to take an upward direction on leaving the ground, but while this prevented Mr. Farman from making extended trips, he has nevertheless succeeded in covering 771 to 800 metres at a height of 6 metres above the ground. These records, performed on and after October 26, following after flights of 303 and 350 metres, represented the maximum course obtainable within the limits of the field on which the experiments were made.

In regard to what the average Englishman would call the "practical" aspect of these experiments with reference to the possibilities of aëroplane machines coming into general use, reference is made to the great skill needed in controlling the machine. The operator has to manipulate or observe at the same moment the vertical and the horizontal rudder, the carburettor, the sparking, the pressure gauges of the petrol and water, to listen to the throbbing of the motor, to balance the machine laterally, taking account of the effects of wind, and finally to avoid coming into collision with the crowd of spectators.

Later news states that Mr. Farman has again made several attempts to win the Deutsch Archdeacon prize, but has failed to do so owing to the wheels of his machine grazing the ground, especially in the neighbourhood of the turning points.

Another aëroplane which is also attracting considerable attention at Paris is the "monoplane" of M. Robert Esnault Pelterie. This, unlike most recent types, has only a single transverse supporting surface, which in one machine measured 9·6 metres from tip to tip with a superficial area of 18 square metres; in a more recent machine these dimensions have been reduced to 8·6 metres and 16 square metres respectively. The surface is somewhat concave in form. In addition there is a single horizontal rudder placed at the rear, while the motor and propeller are in the front of the machine. The motor consists of seven cylinders arranged round a circle, and it gives 25 to 30 horse-power with a weight of 44 kilograms. The total weight of the machine and its rider amount to 240 kilograms. For running along the ground the monoplane has two wheels, arranged bicycle-fashion, attached to the body, and two other wheels are attached to the tips of the wings. The recorded performances, which commenced on October 22, include straight flights of about 100 metres and 147 metres, and a path stated to be a semicircle of radius about 1640 feet, which, if correct, represents a flight of, roughly, 1600 metres. But at the end of the flight of 147 metres the machine fell vertically on the ground, and was damaged.

An aëroplane constructed on the other side of the Atlantic is described in the *Scientific American* for November 16 as "a heavier than air flying machine which lacks the faults of former similar devices according to its inventor, J. W. Roshon, of Harrisburg, Pa. . . ." This machine, which has not yet been tried, is characterised by its complexity to much the same extent that the monoplane is characterised by its simplicity. It has three principal supporting planes, the bottom and middle plane measuring 24 feet transversely by 8 feet longitudinally, while the top plane has only a transverse measurement of 12 feet. Between these three planes, which are placed one above the other, giving a total height of 17 feet, there are 26 narrow flat planes placed transversely at the front and rear of the larger planes. The total wing surface is 900 square feet, say 80 square metres, and the weight with an operator is estimated at 600lb., say 270 kilograms. To launch this large machine into the air an inclined plane has been specially constructed curving up at the bottom in order to start the machine with its rider skyward, but for the first test a bag of sand is to take the place of the latter.



Mr. Farman's aëroplane in full flight. From *La Nature*.

A further departure from the present fashion of machine is the gyroplane of Messrs. Breguet, which revives interest in the attempt to overcome gravity by vertical screw propellers. As at present designed, it is supported by four propellers placed at the corners of a square, each propeller having four revolving vanes, and each vane carrying a pair of superposed planes. The machine, which with its operator would weigh 540 kilograms, was found to hover successfully in the air at a height of a few feet for a minute, this representing the limit of the experiment, and the machine being held down to prevent any accident. It is thus claimed that aërial navigation by vertical screws is possible.

It is interesting to record the fact that the *Scientific American* estimates Mr. Farman's longest flight on October 26 as 2529·52 feet, and his longest measured flight on November 7 as 2624·66 feet. The French records are 771 and 800 metres respectively. Thus, by the use of English units, the American correspondent would appear to claim, if the results are correct, to have estimated these long-distance flights to within an eighth of an inch. But unless the figures represent the results of actual exact measurements (and of this no evidence is given), their accuracy cannot be admitted.

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

THE anniversary meeting of the Royal Society was held on Saturday, November 30, St. Andrew's Day. Lord Rayleigh, the president, was in the chair. Among the subjects referred to in the report of the council are the publication of the National Antarctic Expedition results, the International Catalogue of Scientific Literature, Royal Society's Catalogue of Scientific Papers, International Association of Academies, sleeping sickness, and Malta fever. The following statement, drawn up by the council, was presented to the Royal Commission on Vivisection in March last:—

The Royal Society, from its age and the position accorded to it among scientific institutions, feels its responsibility as a guardian of the general interests of science in this country. Founded as it was for the promotion of natural knowledge, whenever from time to time legislative changes have been proposed which might seem likely to affect the advancement of that knowledge, the society has desired to make its voice heard on behalf of scientific progress. The recent appointment of a Royal Commission on the subject of experiments on animals has been deemed by the president and council of the Royal Society to be an occasion when they may ask to be allowed to lay before that Commission a statement of their views on the broad scientific bearings of the question.

There can be no doubt that the main cause of the remarkable development of science in modern times has been the adoption of the experimental method of investigating nature. In every department of research this method has led to the most important advances, both in questions of theory and in practical applications to the useful purposes of life. From the beginning of its history the Royal Society has fostered the prosecution of experiment, not only in physical and chemical, but in biological inquiry, and its publications are full of records of the discoveries which have consequently been made.

In no branches of investigation have the theoretical and practical successes of experimental work been more conspicuous in recent years than in physiology and its practical applications in medicine and surgery. In medicine, the careful and patient testing of the effects of drugs on the lower animals has not only led to an accurate knowledge, not otherwise attainable, of these effects as produced on the human body, but has greatly increased the number of substances now available to the physician in the treatment of disease. Without this method of investigation the progress of pharmacology, in recent years so astonishing and beneficent, would be arrested, and diseases, which may in time be successfully combated, would continue their ravages unchecked. In modern surgery the application of similar experimental work has been attended with brilliant success. Most delicate and fundamental operations on the human body have been made possible by the knowledge obtained from the treatment of animals.

The president and council of the Royal Society claim that since the continued advancement of science in every department depends so largely upon the use of the experimental method, the utmost caution should be observed in any proposals for legislation whereby the prosecution of the method might be unduly limited. So much has already been gained from the application of experiments on animals, both for the progress of physiology and for the alleviation of human suffering, and so much more may be confidently expected in the future, that the president and council trust that nothing will be done that would hamper the legitimate employment of the method.

While precautions should undoubtedly be taken against improper use of experiment on living animals, it is not the province of the society to suggest what safeguards should be adopted. It is, however, the bounden duty of the president and council to urge that those safeguards should be so framed as not unnecessarily to interfere with that advancement of knowledge to promote which the society exists.

Such restriction would not only cripple or arrest the growth in this country of an important branch of biological science, but in so doing would reduce the efficiency of both physician and surgeon to mitigate or cure disease. It might then become no longer possible to maintain the high position which this country has gained in researches necessary for the advancement of knowledge and for the guidance of medical practice, and the investigators to whose devotion and skill the progress of medical science owes so much might be compelled to seek in foreign universities and scientific organisations the opportunities for research which they could no longer find at home.

This statement is not founded on general knowledge alone. The cooperation of the Royal Society has often been sought by the Government of this country in taking measures to arrest the spread of deadly disease, and to improve the conditions of health in distant parts of the British Empire. Without the ungrudging services of physiologists and pathologists, many of whom the society is proud to count among its fellows, the services thus solicited could not have been given. The president and council gladly avail themselves of this opportunity of testifying to the laborious and unselfish devotion, often in most dangerous conditions, with which the necessary experimental researches have been carried on, and to the value of these researches, not only in enlarging our biological conceptions, but in alleviating the sufferings of mankind.

A further sum of 350*l*. has been voted by the council from the Government grant towards a fund of 2000*l*. which Sir David Gill is endeavouring to raise for the purpose of extending the work of measuring the great African geodetic arc. The grant was voted conditionally upon the 2000*l*. referred to being obtained.

The main part of Lord Rayleigh's presidential address is reprinted below.

An important feature in the work of the Royal Society consists of various inquiries, undertaken for different departments of Government, in regard to diseases which affect the tropical portions of our foreign possessions and dependencies. Among these diseases the attention of the civilised world has been for some years directed to the malady known as sleeping sickness. The first concerted action for the study and combating of this appalling scourge arose out of a representation made by the Royal Society to the Foreign Office in the spring of 1902, in consequence of which, at the request of the Treasury, the society's Malaria Committee organised and dispatched a small scientific commission to Uganda. In the course of a short time the source of the disease was traced by this Commission to the presence of a trypanosome in the blood and cerebro-spinal fluid of the victims, and the further discovery was also made by the same Commission that the trypanosomes are carried by a species of biting tsetse-fly. These important revelations were followed up by detailed studies of the character and distribution both of the disease and of the fly. Besides sending out a succession of observers to prosecute the investigations of its Commission at Entebbe, the Royal Society urged upon the Colonial Office the necessity of organising, and under an increased medical staff, a more comprehensive inquiry into the local conditions under which the disease is propagated. This recommendation was carried out, and some valuable information on the subject has been obtained. Meanwhile, though various drugs had been tried with at best only temporary success, no lasting remedy had been found for the malady, which has continued to be fatal and to spread steadily over Central and East Africa.

The various European Governments which have possessions in those regions have at last determined to make a united effort to cope with sleeping sickness through the instrumentality of an International Conference having a separate bureau in each country concerned and a central bureau in London. The object of this cooperation will be to collect information bearing on the disease, to devise and carry out such scientific researches as may seem to be necessary, and to concert measures for dealing with the disease and the populations affected or likely to be affected by it. The Royal Society, having led the way in this subject, has been invited to give the proposed combined international action its support. The society welcomes the proposal, and will be prepared to render every assistance in its power. In the meantime, our Tropical Diseases Committee is continuously and actively engaged in the endeavour to discover a drug that may prove effective in the treatment of the disease. Their investigations have been directed to the study of trypanosomiasis in rats, and the latest results obtained are such as to encourage the hope that at least in this direction their labours have been successful.

During the present year three parts of the reports of the society's Mediterranean Fever Commission have been published, embodying the final observations and conclusions in this important inquiry, which was undertaken at the joint request of the Admiralty, War Office, and Colonial Office. The members of the Commission have shown how the scourge of fever, which has been so long rife in Malta, and has so seriously reduced the strength of our garrison there, may be eventually banished from the island. Already their recommendations, so far as they have been followed, have reduced the amount of fever to trifling proportions. It now remains for the authorities to adopt the further precautions pointed out to them, which will probably banish the disease altogether.

Progress has been made with the National Physical Laboratory's buildings at Eskdale Muir, some of which are now ready for occupation. It was hoped that the work might have begun this summer, and the Treasury has provided a sum of 750*l*. for the expenses during three-quarters of the current financial year. Owing to the bad weather in the early summer this anticipation has not been realised, but a start will be made very shortly. The buildings are admirably adapted for their purpose, and will render possible the study of terrestrial magnetism under the undisturbed conditions which used to exist at Kew.

The completion of the work on the electrical units will be satisfactory to those who have been interested in this question. At the time of my own researches, about twenty-five years ago, the ohm and the ampere were uncertain to 2 per cent. or 3 per cent., and I then scarcely hoped to get nearer than one part in a thousand. The recent work carried on at Bushey would seem to indicate that an accuracy of one part in ten thousand may have been attained. The possibility of such a refinement depends largely upon the use in the instruments of coils composed of a single layer of wire, the position of every turn of which is open to exact determination. The importance of this feature was insisted upon by the late Prof. Jones.

Accuracy of measurement appeals less to the lay and scientific public than discoveries promising to open up new fields; but though its importance at any particular stage may be overrated, it promotes a much needed consolidation and security in the scientific edifice. A remarkable example of enhanced accuracy is afforded by modern measurements of luminous wave-lengths, for which we are mainly indebted to our Copley medallist. Not only did he introduce the vacuum tube charged with mercury or cadmium as the best source of homogeneous light, but by a most able use of an ingenious method he determined, with the highest precision, the values of the cadmium red, green, and blue wave-lengths in terms of one another, and of the metre. His work has been skilfully followed up by Fabry and Perot, and numerous wave-lengths are now known with a relative accuracy of one millionth part. When we reflect upon the almost ultra-microscopic magnitude of a wave-length of light, the possibility of such an achievement may well excite our astonishment.

For the advancement of science the main requirement is, of course, original work of a high standard, adequately explained and published; but this is not enough. The advances so made must be secured, and this can hardly be unless they are appreciated by the scientific public.

In all the principal countries of the world we have now a body of men professionally connected with science in its various departments. No doubt the attention of many of these is so engrossed by teaching that it would be hard to expect much more from them, though we must remember that teaching itself takes on a new life when touched with the spirit of original inquiry; but in the older universities, at any rate, the advancement of science is one of the first duties of professors. Actual additions to knowledge occupy here the first place; but there must be many who, from advancing years or for other reasons, find themselves unable to do much more work of this kind. It is these I would exhort that they may fulfil their function in another way. If each man would mark out for himself a field—it need not be more than a small one—and make it his business to be thoroughly conversant with all things, new and old, that fall within it, the danger of which I have spoken would be largely obviated. A short paper, a letter to a scientific newspaper, or even conversation with friends and pupils, would rescue from oblivion writings that had been temporarily overlooked, thereby advancing knowledge generally, and sometimes saving from discouragement an unknown worker capable of further achievements. Another service such experts might render would be to furnish advice to younger men desirous of pursuing their special subject.

A movement is on foot, and has already received valuable support, to promote the publication of standard scientific works in embossed type suitable for the use of the blind. Mr. H. M. Taylor tells me that in the course of the last twelve months he has written out the whole of Mr. C. Smith's "Elementary Algebra" in Braille type, has afterwards read the copy with his fingers, and again, later, read the whole in proof. There can be no doubt that books in embossed type on such subjects as mechanics, physics, astronomy, geology, not to mention the various biological sciences, would be an immense boon to many blind readers. I commend the proposal heartily to your notice.

Another remedy for the confusion into which scientific literature is liable to fall may lie in the direction of restricting the amount of unessential detail that is sometimes prevalent in the publication of scientific results. In comparing the outputs of the present time and of, say, thirty years ago, the most striking feature that appears is doubtless the increase of bulk, in recent years coming especially from young workers stimulated by the healthy encouragement of direct research as a part of scientific education. But I think it may also be observed, and not alone in the case of such early dissertations, that there is, on the whole, less care taken for the concise presentation of results, and that the main principles are often submerged under a flood of experimental detail. When the author himself has not taken the trouble to digest his material or to prepare it properly for the press, the reader may be tempted to judge of the care taken in the work from the pains taken in its presentation. The tendency in some subjects to submit for immediate publication the undigested contents of note-books is one that we hear much of at the present time. It is a matter that is difficult for publishing bodies to deal with, except by simple refusal of imperfectly prepared material, with its danger of giving offence to authors of recognised standing, but it seems not unlikely that at present public scientific opinion would endorse such a course of action. A related difficulty, and one that contributes to this trouble, is the tendency, noticeable in some public scientific organisations, to imagine that their activity is estimated by the number of pages of printed matter they can produce in the year. Probably no consideration is further removed than this from the minds of the educated public, whose judgment is alone worth considering.

Copley Medal.

The Copley medal is awarded to Prof. Albert Abraham Michelson, For.Mem.R.S., on the ground of his experimental investigations in optics.

In 1879 Michelson brought out a determination of the velocity of light by an improved method, based on Foucault's, which gave 299,980 kilometres per second. Three years later, by means of a modification of the method, capable of even greater precision, he found for this constant, of fundamental importance for electric as well as optical science, the value of 299,853 kilometres.

Michelson has been a pioneer in the construction of interferometers, which are now indispensable in optics and metrology. With his new instrument, at Paris, he determined the absolute wave-lengths of the red, green, and blue lines of cadmium by counting the number of fringes (twice the number of wave-lengths) corresponding to the length of the standard metre of the Bureau International des Poids et Mesures. He found the metre to be 1,553,164 times the wave-length of the red line of cadmium, a result which is almost in exact agreement with the re-determination last year by Perot and Fabry. Michelson thus proved the feasibility of an absolute standard of length, in wave-lengths, of such accuracy, that if the standard metre were lost or destroyed it could be replaced by duplicates which could not be distinguished from the original.

He had the greatest share in the elaboration of precise experiments on the relative motion of ether and matter. He repeated in an improved form Fresnel's experiment of the speed of light in moving media, using water and sulphide of carbon. He found that the fraction of the velocity of the water by which the velocity of light is increased is 0·434, with a possible error of $\pm 0{\cdot}02$. The fact that the speed is less in water than in air shows experimentally that the corpuscular theory is erroneous; but his results, moreover, established the correctness of Fresnel's formula for the effect, the theory of which has since become well understood.

In conjunction with E. W. Morley, he devised and carried out a very remarkable method by which, on the assumption of ether at rest, an effect depending on quantities of the order $(v/V)^2$ would appear to be appreciable. No displacement of the fringes was found. Of this result the simplest explanation would be that the ether near the earth partakes fully in its orbital motion; but modern electric and optical science appears to demand a quiescent ether, and the existence of this and similar null results is fundamental for its theory.

He has shown the possible application of the interferometer method to astronomy, by himself measuring the diameters of the four satellites of Jupiter, which are only about one second of arc. He suggests the further application of the instrument to such of the fixed stars as may not subtend less than one-hundredth of a second of arc.

In 1898 Michelson constructed a spectroscope which enables us to make use of the great resolving powers of the very high orders of spectra which are absent in the use of the ordinary grating, and with the added advantage of having most of the light in one spectrum. The echelon consists of a pile of glass plates of precisely equal thickness, which overlap by an equal amount; with it spectral lines which appear single with the most powerful gratings can be resolved into components. This instrument has been especially useful for the direct observation of the important, because definite, influence of magnetism on light, discovered by Zeeman. With thirty plates, and using the 25,000th spectrum, the echelon has a resolving power of 750,000, while the most powerful gratings do not exceed 100,000.

In connection with the analysis of radiations, he has constructed and used various machines for the analysis of periodic motions. For example, in conjunction with

Stratton, he perfected a remarkable machine which is based on the equilibrium of a rigid body under the action of springs.

Prof. Michelson has also investigated by his interferometer the important subject, both theoretically and practically, of the breadth and the structure of spectral lines, including the effect of a magnetic field, and in various other ways his genius has opened up new ground in experimental optics.

Royal Medals.

One of the Royal medals has been awarded, with the approval of His Majesty, to Dr. Ernest William Hobson, F.R.S.

During the last twenty years Dr. E. W. Hobson has been distinguished for the fundamental character of his contributions to mathematics and mathematical physics. His earlier published work, from 1888 onwards, deals largely with the so-called harmonic analysis, which embraces many topics having for their common aim the solution of the potential equation in forms suitable for application to the problems of physics. The exhaustive examination of the general types of harmonic functions contained in his paper in the Phil. Trans., 1896, has been found to be of high utility for this application. He was led by these researches, and particularly by the difficulty of describing in general terms the characteristics of a function capable of being represented by Fourier's series, to take part in the revision of the logical basis of differential and integral calculus which is now in progress; his presidential address to the London Mathematical Society in 1902 on the questions here arising aroused general interest among mathematicians, and he has recently (1907) published an extensive volume dealing with the whole matter and its applications to the theory of Fourier's series, which is of great importance for the history and development of mathematics.

His Majesty has also approved the award of a Royal medal to Dr. Ramsay H. Traquair, F.R.S. Dr. Traquair is honoured on the ground of his long-continued researches on the fossil fishes of Palæozoic strata, which have culminated, within the past ten years, in his discovery of new groups of Silurian and Devonian fishes, and in his complete exposition of the structure of Drepanaspis, Phlyctenaspis, and other remarkable forms.

For nearly forty years Dr. Traquair has been busy with the description of fossil fishes, mostly from the Palæozoic rocks of Scotland, and he is deservedly held to be one of the most eminent palæontologists of the day. He has been highly successful in the interpretation of the often very obscure and fragmentary remains which he has had to elucidate, and his restorations of fishes have won such credit as to appear in all modern text-books of palæontology. It may be said that his work, notwithstanding the great difficulties of the subject, has well stood the test of time.

Dr. Traquair has done much to advance our knowledge of the osteology of fishes generally. His earliest memoirs on the asymmetrical skull of flat-fishes and on the skull of Polypterus remain models of exactness. His acquaintance with osteology enabled him to show how former superficial examination of the Palæozoic fishes had led to wrong interpretations. He demonstrated that Chirolepis was not an Acanthodian, as previously supposed, but a true Palæoniscid. In 1877 he satisfactorily defined the Palæoniscidæ and their genera for the first time, and conclusively proved them to be more nearly related to the sturgeons than to any of the other modern ganoids with which they had been associated. He thus made an entirely new departure in the interpretation of extinct fishes, replacing an artificial classification by one based on phylogenetic relationship. His later memoir on the Platysomidæ was equally fundamental and of the same nature.

All subsequent discoveries, many made by Traquair himself, have confirmed these conclusions, which are now universally accepted.

In 1878 Dr. Traquair demonstrated the dipneustan nature of the Devonian Dipterus, and somewhat later he began the detailed study of the Devonian fishes. His latest researches on the Upper Silurian fishes of Scotland are equally important, and provide a mass of new knowledge for which we are indebted to his exceptional skill and judgment in unravelling the mysteries of early vertebrate life.

Davy Medal.

The Davy medal is awarded to Prof. Edward Williams Morley. Prof. Edward W. Morley is well known both to chemists and to physicists for his work in the application of optical interferences and other physical phenomena to increase the accuracy of measurement. Numerous valuable papers have appeared, either in collaboration with Prof. Michelson and others, or in his own name, on such subjects. Special reference may be made to his experiments, in conjunction with Prof. Michelson, on the fundamental question of the absence of effect of translatory motion of material bodies on luminous phenomena.

His claim to the Davy medal rests on grounds closely related to these researches, for he has combined thorough mastery of accurate measurement with an intimate knowledge of modern chemistry, and has utilised them in his attempt to solve one of the most difficult and fundamental problems of chemical science. The special problem to which he has consecrated many years of his life is the determination of the relative atomic weights of hydrogen and oxygen; it has been attacked by him with rare insight and skill, and with indomitable perseverance, and he seems to have settled it for many years to come, if not permanently. All the recent work devoted to this problem, and there has been much, has tended to establish more firmly the ratio arrived at by Prof. Morley.

His determinations of the absolute weights of a litre of hydrogen and of oxygen, and his investigations of the amounts of moisture retained by gases dried by various desiccating agents, are of the very greatest importance for scientific progress.

Sylvester Medal.

Prof. Wilhelm Wirtinger, of Vienna, is the recipient of the Sylvester medal. He is distinguished for the importance and wide scope of his contributions to the general theory of functions. Our knowledge of the general properties and characteristics of functions of any number of independent variables, and our ideas for the further investigation of such functions, are, for the most part, at present bound up with the theory of multiply-periodic functions, and this theory is of as great importance for general solid geometry as the ideas of Abel have proved to be for the theory of plane curves. Prof. Wirtinger has applied himself for many years to the study of the general problems here involved. A general summary of his researches is given by him in the Abel centenary volume (xxvi., 1902) of the "Acta Mathematica." Two of his papers may be particularly referred to, both of 1895. One of these deals with the reduction of the theory and general multiply-periodic functions to the theory of algebraic functions, with a view to their expression by Theta functions; this was one of the life problems of Weierstrass, who did not, however, during his lifetime, publish anything more than several brief indications of a method of solution. Prof. Wirtinger's memoir obtains a solution, and is, moreover, characterised throughout by most stimulating depth and grasp of general principles. This paper was followed by two others, one continuing the matter in detail, the other making an application of its principles to the general theory of automorphic functions. Another extensive paper, which obtained the Beneke prize of the Royal Society of Göttingen, deals with the general theory of Theta functions. In it he obtained results of far-reaching importance, for geometry as well as for the theory of functions, the full development of which will require many years of work.

Hughes Medal.

The Hughes medal is awarded to Principal Ernest Howard Griffiths. Principal Griffiths has conferred great benefit on physical science by his series of measurements of fundamental constants, mainly in the domain of thermal and electric energy. At a time when the equivalent of the thermal unit in mechanical energy stood urgently in need of revision, he devoted himself to the problem with all the refinements and patient manipulation that could be devised, the result being a value for Joule's equivalent which at once acquired authority in the light of the evidence produced, and largely confirmed the corrections already advanced by Rowland and others. A main cause of discrepancy had been found to be the variation of the thermal capacity of water with the temperature; and by an investigation in which this variation was determined, Griffiths elucidated and correlated fundamentally the work of previous observers, from Joule onward. Of special importance also, in the domain of chemical physics, was an investigation of the depression of the freezing point of water by very dilute admixture of dissolved substances, wherein he verified, with all the refinement of absolute physical determinations, that the change of freezing point ran exactly parallel to the electric conductivity when the dilution of the electrolysable salt was comparable to that of gases, being twice as much per molecule as the standard value of the depression for non-electrolytes.

Buchanan Medal.

The Buchanan medal is awarded to Mr. William Henry Power, C.B., F.R.S. Mr. Power's services to hygienic science and practice have extended over a period of more than thirty years, and have been of the most distinguished kind. He has himself personally conducted successful inquiries into the causes of the spread of various diseases, and has obtained results which have proved of the greatest benefit to mankind. Moreover, in his long connection with the medical department of the Local Government Board he has planned and directed numerous general and local investigations whereby our knowledge of disease, and of the methods of coping with it, have been greatly increased. The medical reports issued by the Local Government Board, which are universally regarded as among the most important contributions of our time to this subject, have for many years past been either written by him or owe much to his editorial criticism and supervision. It is not too much to say that no living man in this country has advanced the cause of scientific hygiene more than Mr. Power, nr is more worthy of the distinction of the Buchanan medal.

In the evening of the anniversary meeting, the fellows of the society and their guests dined together at the Whitehall Rooms of the Hôtel Métropole. Lord Rayleigh was in the chair, and responded to the toast of the Royal Society proposed by Lord Dunedin. Speeches were also made by several of the medallists, and by Lord Fitzmaurice and the Dean of Westminster.

NOTES.

In proposing the toast of "The Royal Society" at the anniversary dinner on Saturday last, Lord Dunedin referred to the popularisation of science as one of the functions of a society which exists for the promotion of natural knowledge. This remark provides the subject of a letter by an anonymous correspondent in Tuesday's *Times*. The writer urges that the neglect of science in this country is largely due to the indifference shown by scientific men to the intellectual interests of the average reader. Few men of science make any attempt to describe their investigations in language which can be understood by men of culture without special scientific knowledge, and it is scarcely too much to say that most investigators are so closely absorbed in their particular researches that whether the world in general knows anything of the results or not is regarded as no concern of theirs. This spirit, and the obscure and diffuse manner in which scientific investigations are often described are to be deplored. Lord Rayleigh, in the presidential address which appears elsewhere in this issue, directs attention to the undigested material often presented as papers to scientific societies; and it seems as if the zeal for research is rarely accompanied by the aspiration for simplicity of expression. Prof. M. E. Sadler suggests in Wednesday's *Times* that the neglect of the teaching of the mother tongue in our schools provides a reason "why so many Englishmen of learning and high scientific attainment are unable to express themselves in a lucid and stimulating way." It may be pointed out, however, that though rhetoric receives more attention in the United States than it does in this country, the style of scientific papers and other works from America is not superior to that of our own scientific literature. But whatever the explanation may be, there can be only one opinion as to the advantage of increasing interest in scientific work by making the results as widely known as possible.

The formation of the Royal Society of Medicine has already been the subject of a congratulatory note in these columns. The inaugural dinner of the society, held on Tuesday last, December 3, was a remarkable testimony to the successful establishment of what Sir Ray Lankester described on that occasion as the National Academy of Medicine. The society consists of thirteen federated sections, representing fifteen pre-existing societies, and it is hoped that other sections will be included before long, so that no branch of medical knowledge will be unrepresented in the society. The number of fellows is upwards of 1800, and of members above 600, and there is every reason to anticipate that these numbers will be considerably increased now that the society is in full working order. The library, which has been strengthened by the inclusion of those of the Odontological and Obstetrical Societies with that of the Royal Medical and Chirurgical, now consists of upwards of 70,000 volumes, and in the reading-room of the society no fewer than eighty-nine British and 180 foreign periodicals can be consulted. Sir W. Church, president of the society, who presided at the dinner on Tuesday, bore testimony to the manner in which the various bodies now forming the Royal Society of Medicine have been willing to sacrifice somewhat of their independence and individual prestige for the common good. Never in the history of medicine has there been a time in which so wide a field has engaged the attention of medical men as the present. In every department of medicine, science has placed at the disposal of medical men new methods and fresh means, not only for the investigation, but also for the treatment of disease, and the ground to be covered in each branch of medicine must as time goes on necessarily increase. To provide every facility for diffusing the increased knowledge which is being gained and enable the profession to keep in touch with what is going on is perhaps at the present time the main object of the society; but the time will come, and that soon, when the Royal Society of Medicine will be in a position, not only to discuss the value of the researches brought to its notice, but also, through the appointment of scientific committees, to add to knowledge.

The Lalande medal has been awarded by the Paris Academy of Sciences to Mr. Thomas Lewis, of the Greenwich Observatory, and secretary of the Royal Astronomical Society.

Sir W. H. Bennett, K.C.V.O., has been elected president of the Incorporated Institute of Hygiene in succession to the late Sir W. H. Broadbent, F.R.S.

An experiment in the breeding of Maine lobsters in the Pacific Ocean is about to be tried by the U.S. Commission of Sea and Shore Fisheries. A car-load of seed lobsters has already been dispatched by a fast express from the Government hatchery at Boothbay to the western coast.

By the death of Mr. M. Walton Brown, which occurred on November 22, the Institution of Mining Engineers loses an indefatigable secretary and the profession of coal mining one of its most useful representatives. Mr. Walton Brown was the author of numerous papers on mining engineering, and was the recognised authority in this country on the scientific principles of colliery ventilation.

A DISCUSSION on the subject of "Rivers Pollution from the Naturalist's Point of View" will be introduced by Prof. R. Meldola, F.R.S., at a conference meeting to be held, under the auspices of the Essex Field Club, on Saturday, December 14, at 6 p.m., in the physical lecture theatre of the Municipal Technical Institition, Romford Road, Stratford, Essex.

AT the meeting of the Cardiff City Observatory Committee on November 30 it was announced that arrangements are busily proceeding for the installation of a seismograph at the observatory on Penylan Hill. The seismograph is being provided by the Cardiff Naturalists' Society, its upkeep being undertaken by the city council. It is hoped that the instrument may be installed early in the new year, and that Prof. Milne will be able to attend the opening. Prof. Milne has urged the establishment of a seismograph at Cardiff, which will form a triangle with the existing stations at Birmingham and Shide.

WE are pleased to learn that Mr. Haffkine has accepted an appointment to a post at Calcutta offered to him by the Secretary of State for India. It will be remembered that Mr. Haffkine was held responsible for an unfortunate accident that occurred in the Punjab in connection with plague inoculation, an accident for which a large body of scientific opinion has pronounced him to be in no way to blame. So far the Secretary of State has recognised the strength of that opinion, but we could have wished that the recognition had taken a form more complete and more in accordance with the true circumstances of the case.

THE Paris correspondent of the *Times* reports that Dr. Jean Charcot, who conducted a successful expedition to the South Polar regions two years ago, is now engaged in the preparation of another expedition to the Antarctic circle. The State has made a credit grant of 24,000*l.* toward the cost, but at least 6000*l.* more will be required. Dr. Charcot intends to start next July. He will proceed by way of Buenos Ayres and Cape Horn to the Antarctic region which he discovered and named "Terre Loubet." The Marquis de Dion has offered Dr. Charcot some motor sledges, so that dogs will not be needed.

THE annual conversazione and exhibition of new apparatus, heretofore held under the auspices of the late British Electro-Therapeutic Society, but now under the electro-therapeutical section of the Royal Society of Medicine, will be held in the Queen's (small) Hall on Friday, December 13. The leading makers of electro-medical and X-ray apparatus are taking part, and many new designs will be shown, so far as possible under working conditions. Communications regarding cards of admission or other matters must be addressed to Dr. Reginald Morton, hon. secretary, 22 Queen Anne Street, Cavendish Square, London, W.

THE American Association for the Advancement of Science will meet at Chicago on December 28. The business meetings commence on December 30, in the morning of which the first general session will be held, and the new president, Prof. E. L. Nichols, will be introduced by Dr. W. H. Welch, the retiring president. In the afternoon addresses will be given by some of the presidents of sections. Prof. Edward Kasner will speak on "Geometry and Mechanics" to the section of mathematics and astronomy; Mr. Richardson will address the section of chemistry on "A Plea for the Broader Education of the Engineer," and Prof. Conklin will deliver his address to the section of zoology. In the evening of the same day the retiring president will deliver his address. On December 31 Prof. W. C. Sabine will address the section of physics on the "Origin of the Musical Scale"; Mr. Conant the section of social and economic science on the "Influence of Friction in Economics"; and Dr. Flexner the section of physiology and experimental medicine on "Recent Advances and Present Tendencies in Pathology." Messrs. MacDougal, Warner, and Brown will respectively address the sections of botany, mechanical engineering, and education on subjects to be announced later. Mr. Charles L. Hutchinson is the chairman of the local committee, and Mr. J. Paul Goode is the local secretary.

THE following are among the lecture arrangements at the Royal Institution before Easter:—Sir David Gill, a Christmas course of six illustrated lectures on "Astronomy, Old and New," adapted to a juvenile auditory; Dr. A. A. Gray, two lectures on the internal ear of different animals; Prof. W. Stirling, six lectures on membranes, their structure, uses, and products; Dr. E. A. Wallis Budge, three lectures on the Egyptian Sudan, its history, monuments and peoples, past and present; Prof. W. W. Watts, two lectures on (1) the building of Britain, (2) recent light on ancient physiographies; Prof. W. Somerville, two lectures on wood, its botanical and technical aspects; Sir John Rhys, two lectures on Celtic; Dr. R. T. Glazebrook, two lectures on physics; Mr. R. Lydekker, two lectures on (1) the animals of Africa, (2) the animals of South America; Prof. Gisbert Kapp, the electrification of railways; and Prof. J. J. Thomson, six lectures on electric discharges through gases. The Friday evening meetings will commence on January 17, when Prof. T. E. Thorpe will deliver a discourse on the centenary of Davy's discovery of the metals of the alkalis. Succeeding discourses will probably be given by Colonel David Bruce, Prof. E. Rutherford, Dr. C. W. Saleeby, Sir Oliver Lodge, Prof. W. A. Bone, Prof. J. Milne, Prof. A. E. H. Love, the Hon. R. J. Strutt, and Prof. J. J. Thomson.

BY the death (which was announced in the *Times* of November 28) of Dr. Carl Bovallius, late professor of zoology at the University of Upsala, Sweden has lost one of her most eminent ethnologists, naturalists, and scientific explorers. A graduate of Upsala, Bovallius took the degree of Ph.D. in 1875, and from some time after that date held the chair of zoology until 1897. In zoology his main subjects were Mollusca and Crustacea, especially the amphipod group of the latter, and the Swedish representatives of both groups. "Contributions to a Monograph of the Amphipoda Hyperidea" is the title of one of his works, the first part (in two numbers) of which was published at Stockholm, 1887–9. It is only by this single part, which appears to be all that was issued, that his name is represented in the catalogue of the Zoological Society's library. Forestry was another of his specialities, and from reports furnished by him as the results of investigations undertaken between 1889 and 1895 the present forest laws of Sweden were based. As an explorer and surveyor he travelled much in Central America from 1881 to 1883, returning again to Nicaragua in 1900, while in 1898–9 he visited southern Venezuela and the Amazons. From these countries he brought extensive zoological and ethnographical collections. In the obituary notice in the *Times* of November 29 he is reported to have made important contributions to the natural history departments of the British Museum, but his name does not appear as a donor in the recently published volumes on the "History of the

Collections" in those departments; and his donations appear to be limited to a few river crustaceans. Dr. Bovallius was the recipient of several decorations from his own and foreign sovereigns, among these being the Grand Cross of the Order of Isabella Catholica and the knighthood of the Danish Order of the Dannebrog, and of the Portuguese Order of St. Iago.

The ascidians collected on the coast of California by the U.S. Fisheries steamer *Albatross* during the summer of 1904 include a number of new species, which are described by Mr. W. E. Ritter in the Zoological Publications of California University, vol. iv., No. 1.

The greater portion of the October issue of the *American Naturalist* is occupied by a paper by Mr. A. W. Grabau on orthogenetic variation (*i.e.* variation along definite lines) in the shells of gastropod molluscs. Among the points discussed are the mode of arrangement and development of ribs and spines on the shell.

To Messrs. Witherby and Co. we are indebted for a copy of an illustrated pamphlet entitled "Gilbert White of Selborne." The text formed the subject of a lecture delivered before the Hastings and St. Leonards Natural History Society in June last by Mr. W. H. Mullens. The illustrations include several views of Selborne village, and one of the interior of the church. A good summary of the chief features of White's career will be found in this well-got-up pamphlet, of which the price is half-a-crown.

In No. 1567 (vol. xxxiii., pp. 197–228) of the Proceedings of the U.S. National Museum, Lord Walsingham describes a number of new North American moths of the tineid group, with the addition of a list of genera of the family Blastobasidæ. The specimens on which the determinations are based were in part supplied by the U.S. Museum and U.S. Department of Agriculture, and in part contained in the author's own collection. Types of most of the new species are now in the U.S. Museum. Soft river-tortoises (Trionychidæ) from various Tertiary horizons in the United States form the subject of a paper by Mr. O. P. Hay published in the Bulletin of the American Museum of Natural History, vol. xxxii., pp. 847–863.

To the November issue of the *Zoologist* Mr. W. L. Distant, the editor, contributes the second and concluding part of his article on the extermination of animals, dealing in this instance with the destruction dealt by man. After referring to the destruction of African antelopes and quaggas for the sake of their hides, the author quotes a statement to the effect that in the twenty years from 1856 to 1876 Africa supplied Europe with an annual average of 1,500,000 lb. of ivory, in addition to 250,000 lb. exported to India and about 150,000 lb. to America, this representing the destruction of about 51,000 elephants. Another item which bulks very large is the toll of alligators killed in Florida for their hides, this being estimated at no less than two and a half millions. In Australia, again, we find a flock-owner boasting that in the course of eighteen months he had killed, on his own estate, 64,000 of the smaller marsupials, such as wallabies and kangaroo-rats, in addition to several thousand kangaroos. As the author well remarks, no species can stand such wastage long, and kangaroos and their kin must apparently be exterminated as wild animals at no very distant date.

To vol. xvi. of the *Anales* of the National Museum of Buenos Aires Dr. F. Ameghino contributes no less than 135 pages of "preliminary notes" on an atlas vertebra and imperfect femur (which, so far as we see, may or may not be associated) from the later Tertiary deposits of Monte Hermosa. On these two specimens, coupled with certain alleged evidence of the existence of an intelligent being at the time the Monte Hermoso strata were deposited, he considers himself justified in naming a new genus and species—*Tetraprothomo argentinus*—of the family Hominidæ. Nor is this all, for in the latter part of the paper he publishes a series of phylogenies in which the Ungulata and Primates, together with the Patagonian extinct Carnivora, are derived from a single South American ancestral type, the Microbiotheriidæ, a group which most palæontologists now regard as inseparable from the opossums. On a later page we are furnished with the names of a number of non-existent connecting links between "Tetraprothomo" and man and gibbons on the one hand, and earlier forms on the other. It may be added that in one of the hypothetical genera is included the Neanderthal man under the name of *Prothomo neanderthalensis*.

The fifth annual report of the Horniman Museum and Library, Forest Hill, S.E., dealing with the work of the year 1906, has been issued. The museum is intended to be a teaching institution where the general public, students, and school children may be able to inspect properly labelled specimens exhibited in related series. Saturday morning lectures for teachers and afternoon lectures for the general public have been held with much success. The report contains illustrations of some of the models made by the museum naturalist to illustrate natural phenomena. Among these are diagrammatic models of coral reefs designed to illustrate the manner in which they are built up and the effects of currents on the growth of the reefs. Useful though these models are, their scientific value would have been increased had they been modelled to a true scale, and some indication of the scale given.

The Bulletin of the Johns Hopkins Hospital for November (xviii., No. 200) contains an interesting paper by Dr. Arthur Meyer on the physician and surgeon in Shakespeare.

The pages of the *Journal of Hygiene* for October (vii., No. 5) are mainly occupied with two papers on ship beri-beri and scurvy by Prof. Holst and Dr. Frölich. It is stated that ship beri-beri is closely connected with food, and shows a marked congruence with scurvy. By keeping animals on certain diets, conditions were produced simulating human scurvy very closely. The etiology of tropical beri-beri is considered to be outside the field of these investigations.

The reports of the Board of Health, New South Wales, on the outbreaks of plague at Sydney are important contributions to the epidemiology of this disease, and show conclusively the interdependence of the rat and plague. The latest report, by Dr. Ashburton Thompson, deals with the sixth outbreak, which occurred in 1906. A continuous outlook is kept for infection in rats, large numbers of which are caught and examined. In the fifth outbreak, in 1905, the last case of plague in man occurred on July 12, and the last plague-infected rat was identified on December 5. In 1906, the first plague-rat was identified on January 23, the first case in man occurred on March 12, the last on December 22, and the last plague-rat was identified on December 29. From December 6, 1905, to January 22, 1906, 3225 rats and mice were examined and found to be plague-free. During the epizootic period, January 23 to December 29, 1906, 27,731 rats and mice were examined, among which plague was identified in

174 rats and mice. It is again shown, therefore, that the plague epidemic is preceded by an epizootic among the rats and mice. Notes are given on the species of rodents affected, and on the clinical details of the cases.

THE Bulletin of the Department of Agriculture, Jamaica (August and September), contains articles on the subject of curing vanilla pods for market and on the vanilla industry, also on bastard logwood and cacao cultivation.

WE have received from Messrs. A. E. Staley, of Thavies Inn, London, a list of Bausch and Lomb's new microscope models fitted with an improved form of fine adjustment, also a brochure on the use and care of the microscope.

THE development of the pollen grain in the gymnospermous genus Dacrydium is interesting because, according to the account contributed by Miss M. S. Young to the *Botanical Gazette* (September), a number of cells are formed in what is technically known as the microgametophyte. The spore passes out of the single-cell stage when a small prothallial cell is cut off; by another division of the vegetative nucleus a second prothallial cell is formed, and in a similar way a third, the generative cell, is produced. The generative cell gives rise to a sterile and a so-called body cell, the progenitor of the sperm cells. As the second prothallial cell not infrequently divides, the mature pollen grain may show as many as seven nuclei.

IN the *Engineering Magazine* (vol. xxxiv., No. 2) a new mineral industry, the manufacture of radium, is described by Mr. Jacques Boyer. He gives illustrations of the works lately installed at Nogent-sur-Marne, where waggon-loads of various minerals (pitchblende, autunite, chalcolite, carnotite, and thorianite) are treated for an ultimate production consisting of a few minute particles of radium salts.

THE Institution of Engineers and Shipbuilders in Scotland has reached its jubilee year, and in his presidential address Mr. John Ward gave an able retrospect of the events connected with the work of the institution, a subject especially suitable in view of the fact that it is also the centenary of marine engineering as applied successfully to ocean navigation. To the address, which is printed in the Transactions (vol. li., No. 1), is appended a useful chronology of events in the evolution of the marine steam engine.

THE problem of peat utilisation, so often pronounced hopeless, may now be considered as practically solved. The Mond Power-Gas Corporation is building a large peat-generator gas-plant near Herne, in Westphalia; Messrs. Crossley Brothers are projecting plants on the basis of their long-continued experiments at Openshaw; and Martin Ziegler has made peat-coke and obtained the chemical by-products, at Oldenburg and at other places, ever since 1897. The Ziegler plant at Beuerberg, in Upper Bavaria, which was opened in 1906, is described in detail in *Engineering* of November 15. The results obtained have been eminently satisfactory, and suggest the possibility of manufacturing at a profit peat-coke and chemicals in Ireland, where from 16 feet to 40 feet of peat can be worked over large areas.

MR. GUSTAVE CANET, past-president of the French Society of Civil Engineers, has honoured the Junior Institution of Engineers by accepting the presidency, and in his inaugural address, which was delivered on November 18, he frankly and critically compared English and French practice in connection with the design and manufacture of artillery. The conditions under which gun-makers work in the two countries are, he pointed out, essentially different. The whole tendency of French policy has been adverse to the interests of private manufacturers. In Great Britain, on the other hand, there has never been any restriction placed upon manufacturers with regard to the supply, during peace time, of war material to foreign Powers. Hence works of private manufacturers have developed and have acquired vast experience that is a valuable national asset, for they can place all their resources at the disposal of the Government in case of need.

STRIKING evidence of the reduction in working costs and in the number of unskilled coloured labourers effected by the installation of labour-saving appliances in the Transvaal mines is afforded in the paper on the equipment of the New Kleinfontein mine read by Mr. E. J. Way before the Institution of Mechanical Engineers on November 15. A branch line was constructed from the nearest railway station up to the mine, and the surface plant was equipped with a complete system of conveyors and elevators for handling all coal, ash, ore, waste rock, and residue sands, whilst the stopes underground have been provided with swinging conveyors specially designed to permit the rapid and easy dismantling and re-erection necessitated by blasting requirements and by the constant shifting of the working faces of the stopes. The actual annual reduction in the working costs due to the installation of labour-saving appliances is equivalent to a saving of nearly 3*s*. per ton milled.

THE Institution of Mining and Metallurgy has drawn up a series of standard weights and measures with the object of securing uniformity in scientific papers. The word "ton" shall, it is decided, represent a weight of 2000 lb. avoirdupois; the word "gallon" shall represent the Imperial gallon measure of 10 lb. of water. Temperatures shall be expressed in degrees centigrade. Returns of gold and silver shall be expressed in terms of fine gold and fine silver respectively, not as "bullion." Gold contents of ores, determined by assay, shall be expressed in money values as well as in weights; and in this connection the value shall be taken (as a convenient constant) at 85*s*. per troy ounce of fine gold. The adoption of these definitions in assay returns will doubtless obviate much of the existing confusion, but it is to be feared that the use of the new ton of 2000 lb. would, in the case of statistics of mineral production, not be so convenient as the statute ton of 2240 lb. or the metric ton of 2204 lb., both of which may legally be employed.

IN the Transactions of the Institution of Engineers and Shipbuilders in Scotland, Dr. Victor Cremieu describes his proposed apparatus for extinguishing the rolling of ships, some references to which have appeared in the daily Press. One method involves the use of a heavy sphere rolling in viscous liquid in a curved tube at the bottom of the ship; in the second form the moving weight takes the form of a pendulum swinging in a chamber in the form of a sector of a circle, again filled with viscous liquid. The paper contains no reference to what would happen in the event of the weight striking the boundaries of the chamber in a heavy sea or in a disaster.

IN the *Rendiconto* of the Naples Academy (Mathematical and Physical Section), xiii., 3 and 4, Profs. F. Bassani and C. Chistoni direct attention to a recently formed orifice in the Solfatara of Pozzuoli. This opening was first seen on February 2, and the authors consider that it affords an excellent opportunity for the study of geophysical problems connected with the changes of level of the well-known temple of Serapis. They propose that a series of observations should be undertaken at once under the control of the department of geophysics of the University of Naples pending the formation of the geophysical institution which is to be established at Pozzuoli, and that Government assistance should be asked for the necessary means of carrying on the temporary researches rendered urgent by the present eruption. Prof. Bassani, in conjunction with Dr. A. Galdieri, describes further observations on the windows broken at Ottajano during the eruption of Vesuvius of 1906, and maintains their view, which has been doubted by other writers, that the damage was done by lapilli driven against the windows by the action of wind.

"The Climate of Abbassia, near Cairo," is the title of No. 3 of the useful Survey Department papers now being issued by the Egyptian Ministry of Finance. The observatory at Abbassia was founded by the Khedive Ismail Pasha in 1868, and was removed to Helwan in 1903. Summaries of the observations have been issued from time to time, except for the five years before the removal; the present report contains a careful discussion, by Mr. B. F. E. Keeling, of the results of those five years and summaries of the mean values for the whole thirty-five years. The mean annual temperature was 70°·2; January, 54°·1; July, 83°·5; the absolute extremes, 117°·1 (August, 1881) and 28°·4 (February, 1880). Rainfall is very small; the mean for seventeen years was only 1·18 inches; from June to September, inclusive, no rain falls. There are about 3100 hours of bright sunshine annually, not far from double the average amount in the south of England. Series of charts show the mean annual and daily curves for each of the principal elements.

We have recently had an opportunity of inspecting and testing the binocular diffraction spectroscope patented and sold by Dr. Marshall Watts, and have found it to be a remarkably efficient instrument for the spectroscopic investigation of light-sources of definite form, such as vacuum tubes. It consists of an ordinary good field-glass having attached in front of each object-glass a transparent diffraction grating mounted on optically worked plane glass. In examining a luminous vacuum tube we found that the bright lines apparently stood out in relief, whilst the illumination, even in the second and third orders, was very satisfactory. The first-order spectrum of Capella, on by no means a perfect night, was seen as quite a bright colour band. For the examination of broader light-sources, such as flames or arcs, a metal or ebonite plate with a slit in it may be usefully employed in order to obtain a purer spectrum. The price of the binocular spectroscope is 3*l*. 3*s*., and further details of the instrument may be obtained from Dr. Watts, "Shirley," Venner Road, Sydenham.

The fortieth anniversary of the existence of the German Chemical Society was celebrated recently in Berlin. We learn from the *Times* that the meeting was devoted to retrospective addresses on important achievements of chemistry during the last forty years. Prof. Nernst delivered an address on physical chemistry; Prof. Landolt spoke on the development of inorganic chemistry; Prof. Graebe described the successes of the chemistry of the carbon compounds by the process of synthetical combinations; and Prof. Otto N. Witt, who discussed the development of technical chemistry, remarked that technical chemistry has brought about a revolution in productive industry mainly by the aid of electrotechnical science. Prof. Witt directed attention to the manufacture of cellulose from wood leading to the changed methods in the production of paper, to the employment of nitro-cellulose for the preparation of silk-like substances for weaving, to the synthetic production of indigo and alizarin, and to the fixation of atmospheric nitrogen.

The current number of the *Oxford and Cambridge Review*, the second issue, contains two articles dealing with scientific subjects. Mr. J. Butler Burke contributes an article on "Haeckel and Haeckelism," and the headmaster of Eton College, under the title "More about Biometry," tells of the introduction of the system of anthropometric measurement of the boys at Eton, and refers to this movement as "a united act of faith in the desirability of knowledge for its own sake."

A second edition, which has been revised and enlarged, of "The Practice of Soft Cheesemaking: a Guide to the Manufacture of Soft Cheese and Preparation of Cream for Market," by Messrs. C. W. Walker-Tisdale and Theodore R. Robinson, has been published by Mr. John North at the office of the *Dairy World and British Dairy Farmer*. The characteristics of the book were described in a review of the first edition which appeared in Nature for June 9, 1904 (vol. lxx., p. 137). The practice of making soft cheese is increasing in this country, and this new edition of a useful book should assist small holders endeavouring to gain a livelihood from the land.

OUR ASTRONOMICAL COLUMN.

Mercury as a Morning Star.—Although the present elongation of Mercury—the planet was at greatest western elongation (20° 20′) at 2h. on Sunday last—is not so favourable for the naked-eye observation of the planet as those which took place in February and August respectively, there is a possibility that during the next day or two observers may be able to pick up this elusive object near the eastern horizon just before dawn. On December 6 the planet will rise at 5h. 57m. a.m., the sun at 7h. 51m., whilst on December 8 the respective times will be 6h. 4m. and 7h. 54m.

At this season of the year an object near the horizon is not easy to find, and the would-be observer would do well to learn beforehand the exact rising point, and then

Relative positions of Mercury and bright stars at 6 a.m. December 6; observer facing due east.

to get into such a position that the horizon thereabouts is quite free. The planet rises a little less than 30° S. of E., and this direction may be noted, and in some way marked, on the previous evening, by observing the rise of Sirius, which takes place in the same azimuth at about 9 p.m. β Libræ rises about an hour before Mercury at a point some 15° nearer the east point.

The accompanying rough sketch-map may assist the observer to locate the planet. It is intended to show the approximate position of the stars, with the observer facing due east, at the time that Mercury rises, the stars being shown here as projected on to a plane parallel to the plane of the meridian.

A Bright Meteor.—An exceptionally bright meteor was observed by Mr. T. F. Connolly, at South Kensington, at

11h. 30m. p.m. on November 27. The commencement of the flight was estimated to lie half-way between α Cygni and ζ Ursæ Majoris, and after pursuing a vertical path the meteor died away before reaching the horizon. The colour of the object was yellow, its shape that of a pear, a round head followed by a tapering tail. The meteor travelled slowly, and no persistent trail was observed.

Saturn's Rings.—A communication from Prof. Pickering to the *Astronomische Nachrichten* (No. 4216, p. 267, November 26) contains the following messages received from Prof. Lowell:—"Condensations in Saturn's rings confirmed here and measured repeatedly. They are visible symmetric and permanent. Outer situated near the outer edge, ansa *b*, inner at middle of ansa *c*. A conspicuous relative gap also detected and measured at 1·56 radius from the centre of the planet. Ring easily seen. Placed further south from shadow at west than east." This message was dated November 7, and the following was dated November 22:—"Ring shadow on Saturn bisected, black medial line, phenomenon explicable by extra-plane particles only."

The Recent Transit of Mercury.—No. 21 of the Paris *Comptes rendus* (November 18) contains a number of communications regarding the observations of the transit of Mercury which took place on November 13.

At the Nice Observatory the times of the contacts were observed with several different instruments, and micrometer measurements of the polar and equatorial diameters were made. For several seconds "before" the second contact black ligaments were seen by MM. Javelle and Simonin, and before third contact; the black disc of the planet was seen to be surrounded by a whitish or yellowish appearance. The measurements of the diameters are not consistent for different observers, but they all agree in making the polar diameter the shorter. M. Charlois saw very distinctly the black ligament after the second and before the third contacts, its thickness being less than the diameter of the planet. The unsteadiness of the image rendered the proposed astrophysical observations almost impossible.

At the Lyons Observatory observations of the times of contact and measurements of the diameters were also made, and none of the three observers was able to see any peculiar feature on the planet's disc.

M. Bourget, at Toulouse, found the planetary disc distinctly blacker than the nuclei of the neighbouring sunspots, and, at intervals, suspected that it was surrounded by a slight, pale yellow border.

At Marseilles, where a number of observations of contacts and of diameters were made, M. Borrelly noted that the disc was of a dark violet colour, and appeared to be surrounded by a nebulous greyish ring of light nearly as thick as the diameter of the planet. The same observer believes he saw Mercury as a small dark disc surrounded by a violet annulus about an hour before first contact. Paying special attention to the matter, M. Esmiol was unable to discern the slightest deformation of the horns of the planet as it crossed the sun's limb at entry, but saw a sharply defined ring, of about three seconds in thickness, around the dark disc of the planet during the whole of the transit.

With the smaller magnifications at the Bourges Observatory, both the yellowish aureole and the luminous spot were seen, but Abbé Th. Moreux believes both of them to be subjective phenomena. At the beginning of the observations the bright spot was to the east of the centre, but at the end it appeared to be to the west. With a magnification of 325 it always appeared central.

Comte de la Baume Pluvinel, who had set up special spectroscopic apparatus at the Nice Observatory, was unable to find any modification of the solar spectrum near the planet's limb, although he especially examined the absorption bands of oxygen and water vapour, both visually and photographically.

Arrangements were made for observing the possible spectroscopic phenomena, visually and photographically, at the Solar Physics Observatory, South Kensington, but clouds prevented the observations being made. The planet was only seen for a few seconds some little time after the commencement of the transit, and appeared as a well-defined black disc.

SOME RECENT WORK IN PALÆONTOLOGY.

Among palæontological papers sent to us, the following have a faunistic bearing:—

Mr. F. R. Cowper Reed ("Memoirs of the Geological Survey of India," "Palæontologia Indica," new series, vol. ii., mem. 3, 1906) describes the lower Palæozoic fossils of the northern Shan States, Burma, and points out that we know very few fossils from pre-Devonian rocks in southern Asia. The rich finds in Burma, which have mainly become revealed through the survey by Mr. T. D. La Touche, are consequently very welcome. Dr. Bather has furnished thirty-four pages on the cystideans, and Miss Elles has assisted in the description of the graptolites, which are represented by three species of Monograptus (p. 90). The critical remarks on genera by Dr. Bather and Mr. Reed render the memoir of general importance. The Naungkangyi beds, which doubtless include more than one stage (p. 83), are shown to have affinities with the Lower Ordovician of northern Europe. La Touche believes the Nyaungbaw beds to be Upper Ordovician; but the fossil evidence is scanty. The Namhsim Sandstones (p. 152) are correlated with the European Wenlock. The Zebingyi beds, which contain abundant *Tentaculites elegans*, side by side with Monograptus, are of later age, and the fauna verges on that of the Lower Devonian of Europe; but the presence of Monograptus leads Mr. Reed to regard these Burmese strata as uppermost Silurian, the fauna heralding that which afterwards spread into the Mediterranean or south European province. The fine plates in the memoir are from drawings by Mr. T. A. Brock.

Dr. Carl Diener deals with the fauna of the Tropites-limestone of Byans, on the south-west flank of the Himalayas, adjoining Tibet and Nepal (*ibid.*, ser. xv., vol. v., mem. 1, 1906). The author visited the sections in 1892, and extensive collections have since been made by the Indian Geological Survey in 1899 and 1900. The cephalopod-fauna includes Atractites, Orthoceras, and a fine series of ammonites, these last furnishing 155 species out of 168 forms of all kinds known from this horizon (p. 188). This fauna is now well illustrated. We have already referred (Nature, vol. lxxiv., p. 530) to the conclusion that in Byans, in one limestone band 3 feet in thickness, the dissimilar Carnic and Noric faunas of the Alps are both represented. Transitional types of ammonites are not, however, discoverable, and the apparent mingling of the faunas is held to be due to lack of sedimentation, whereby a thin stratum represents a prolonged epoch of Triassic time.

In the succeeding memoir (*ibid.*, mem. 2) Dr. Diener describes "the fauna of the Himalayan Muschelkalk." The beds are mainly of Upper Muschelkalk age, yielding numerous cephalopods. India is no longer inferior to Europe in the number of species known from this stage. Ten species of cephalopods, and three common species of brachiopods (p. 135), are identical with those of Europe.

Mr. H. Woods, working, like Mr. Cowper Reed, in Cambridge, describes the Cretaceous fauna of Pondoland for the Geological Survey of Cape Colony ("Annals of the South African Museum," vol. iv., part vii., 1906). He has also had the advantage of examining Mr. Griesbach's collection in the Hamburg Museum. The whole deposit in Pondoland is regarded by Mr. Woods as Upper Senonian. Mr. Brock must again be congratulated on the beautiful plates accompanying the memoir.

Mr. S. Tokunaga (Journ. Coll. of Science, Univ. of Tokyo, vol. xxi., article 2, 1906), in a paper on fossils from the environs of Tokyo, has made good use of material close to the city itself, in beds hitherto regarded as Pliocene. The fauna is almost entirely molluscan, but the author has secured from it a few remains of *Elephas antiquus*. Carefully comparing his results with those of his predecessor Brauns, who wrote in 1881, he is persuaded that the affinities with the European Crag beds have been overstated; and he brings the deposits round Tokyo forward into post-Pliocene or "Diluvial" times. The new species, and many already recorded, are figured on five large plates.

We may perhaps refer here to Mr. Schuchert's discussion of the Carboniferous and Permian beds of Russia, India, and America (*American Journal of Science*, vol. xxii., 1906, pp. 29 and 143), since the treatment is mainly palæontological. The conclusion arrived at is that as yet we cannot determine whether the Permian is an independent system; but hopes are expressed that the unbroken section of 9000 feet in south-western Texas, opening in Carboniferous strata, may throw important light on the true Permian sequence. The Permian faunas usually known to us are detached members of an obviously larger system, which may prove after all to be the Carboniferous.

We have received also a number of papers dealing with special divisions of fossil organic remains:—

In the Transactions of the Geological Society of South Africa, vol. ix., 1906, p. 125, Messrs. Mellor and Leslie describe the fossil forest exposed, during an unusually dry season, in the bed of the Vaal near Vereeniging. The river had etched out, as it were, the roots of trees, bedded below in coal, and a picture of a land-surface lay revealed, probably of Permian age. The authors believe that the roots and associated stems belong to Nœggerathiopsis. Photographs are given of this interesting exposure, which may not again become visible for many years.

Fusulina, like Nummulites, has an interest for all geologists, apart from the fact that it is a handsome representative of the Foraminifera. Mr. H. Yabe (Journ. Coll. Science, Univ. of Tokyo, vol. xxi., article 5, 1906), in describing a Fusulina-limestone from Korea, discusses the genus in general, and adds a new subgenus, Neoschwagerina, to the three proposed by Schellwien, viz. Fusulina s.s., Schwagerina, and Doliolina. He corrects (p. 17) a reference to Fusulina-limestone in Borneo, originating in the *Geological Magazine* in 1875, and points out that Sumatra was the locality referred to. A useful summary of the distribution of such limestones is provided, and Brazil, Persia, Turkestan, and the Salt Range are grouped together as regions on the coast of the Carboniferous "Mediterranean Ocean" (p. 24). Our knowledge of Fusulina-limestone in Asia is still extending (see the recent discoveries in Burma, "Records Geol. Surv. of India," vol. xxxv., 1907, p. 52), and stratigraphers may well read Yabe's paper in connection with Schuchert's faunistic review, to which attention has been directed above. A Japanese author who writes in such good English may perhaps be excused for using "foraminifera" throughout as a singular noun.

An important criticism on the views of Prof. J. E. Duerden as to the primary hexameral character of rugose corals appears from Mr. T. C. Brown in the *American Journal of Science* for April. Brown selects *Streptelasma rectum*, one of the Devonian corals examined by Duerden, as a type, and discovers in its earliest stage a primary set of four septa, two forming a bar across the calicle, the other two (alar septa) being set obliquely on the cardinal one. In the next stage a secondary septum appears in each of the comparatively large cardinal spaces, and joins the alar septum obliquely. Here, then, a pseudo-hexameral effect is temporarily produced. The author comments on Mr. R. C. Carruthers's recent paper in the *Annals and Magazine of Natural History*, which describes a similar succession of septa, but which puts forward a different view as to the mode of development of the first pair of secondary septa. We may feel sure that Prof. Duerden's work will be further stimulated by the parallel and critical investigations to which it has given rise.

Mr. Frank Springer uses the discovery of the disc of Onychocrinus as a basis for a complete review and a new analysis of the genera of *Crinoidea flexibilia* (*Journ. of Geology*, vol. xiv., 1906, p. 467). Drawings were made from Angelin's specimens by Mr. G. Liljevall, of Stockholm, who discovered, in the course of his work, that Ichthyocrinus has an extra (primitive radianal) plate in the right posterior ray. Springer thereupon examined numerous specimens of this genus from other localities, and states (p. 478) that the Silurian ones agree with those drawn by Liljevall, while the Carboniferous ones have no radianal. For the latter, which are regarded as showing an evolutionary elimination of a primitive character, the genus Metichthyocrinus is now proposed. A comparison is instituted (p. 504) between the progressive variation in position and the final removal of the radianal in time, and the similar events that affect the anal plate during the life-history of Antedon. The six figures illustrating the disc of Onychocrinus are unfortunately not numbered, and some ingenuity is required before they can be fitted in with their descriptions.

The characters of certain labyrinthodont footprints have led the Rev. Longinos Navás, S.J. (*Boletín de la Sociedad Aragonesa de Ciencias naturales*, tomo v., 1906, p. 208), to form a new species, *Chirosaurus ibericus* or *Cheirotherium ibericum*; but surely the reference of the beds at El Moncayo, in which the specimen occurs, to the Silurian (p. 212) rests on far too little evidence. Footprints of Chirosaurus from Lower Triassic strata are, moreover, already known in Aragon, and are cited by our author. The fact that he is not startled by his own conclusion shows that, in his zoological studies, the succession of vertebrate forms has not as yet attracted him.

Mr. G. R. Wieland (*Science*, vol. xxiii., 1906, p. 819, and vol. xxv., 1907, p. 66) brings together good evidence on "Dinosaurian gastroliths." The surface of such stones, even when they are flints, shows "a higher polish than wind or water ever produces." The deinosaurs are, moreover, credited with a selective taste for brightly coloured pebbles.

In a paper on the origin of the Wasatch deposits of the Big Basin (*American Journal of Science*, vol. xxiii., 1907, p. 356), Mr. F. B. Loomis describes (p. 363) a new species of Lambdotherium, and one of Glyptosaurus, a terrestrial lizard. The fauna, which includes Eohippus, Phenacodus, Coryphodon, Crocodilus, aquatic turtles, and a few fishes, is explained as having accumulated in flood-plains, and not in a lake-basin, as has been generally asserted.

The Rev. T. Gardner, S.J., describes and illustrates several types of small stone implements formed by primitive man in Rhodesia ("Zambesi Mission Record," vol. iii., 1906, p. 149). The author points out that many of the specimens now found upon the surface may have been once deeply buried, and were washed out during the sudden bursts of rain. We are already familiar with the argument as to the antiquity of such implements in Africa, based on their occurrence in the river-gravels cut through by the Zambesi gorge. In Father Gardner's paper we are brought into touch with some of the first discoverers of these interesting forms, including the observant author and the scholars of St. George's School in Bulawayo.

Finally, fossil man receives a whole-hearted greeting from the Positivists, represented by Dr. Cancalon, in an essay on "Le Progrès aux Temps paléolithiques" (*Revue positiviste internationale*, 1907). The proofs of this paper have not been very carefully corrected; but its acceptance of long ages of mental progress in man, as not incompatible with Comte's conception of human nature, will no doubt be of service in certain quarters, where science has hitherto seemed fraught with pessimism rather than with a guiding inspiration.

G. A. J. C.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Dr. Barclay-Smith has been appointed university lecturer in advanced human anatomy as from Michaelmas, 1907, until Michaelmas, 1912.

Prof. H. S. Carslaw has been approved for the degree of doctor in science.

The degree committee of the special board for mathematics is of opinion that the work submitted by J. B. Hubrecht, of Christ's College, entitled "An Attempt at a Spectroscopic Investigation of the Solar Rotation," is of distinction as a record of original research.

WE learn from the *Revue scientifique* that the University of Lyons has accepted a gift from M. Théodore Vautier of 4000*l*., the income from which is to be devoted to research work in experimental physics.

SIR EDWARD H. CARSON, P.C., M.P., will distribute the prizes and certificates at the Borough Polytechnic Institute on Thursday, December 12. Mr. J. Leonard Spicer, chairman of the governing body, will take the chair at 8 p.m.

COPIES of the general and departmental reports on the work of Bradford Technical College for the session 1906–7 presented to the Higher Education Subcommittee of the city have been received. The principal of the college appeals to employers of labour in the city to recognise the efforts made by those in their employ who desire to obtain instruction in evening classes, and urges masters to make arrangements to liberate students during the time the classes meet. The work of the department of textile industries is exerting a beneficial influence on the trade of Bradford. The demand for students trained in the department, and the increasing tendency of combers, spinners, and manufacturers to appeal to the college in cases of difficulty, have been very marked during the session. The reports contain other indications that the college is assisting the various industries in its neighbourhood.

AT the recent annual convocation of the University of Allahabad for conferring degrees, the Vice-Chancellor, Rai Sunder Lal Bahadur, delivered an address on the need for higher technical education in the United Provinces. Referring to the conference which sat in August last at Naini Tal to consider important questions in connection with technical education, the Vice-Chancellor said, we learn from the *Pioneer Mail*, that "among the matters which engaged the attention of the conference was the suggestion for the establishment of a high-class technological institute for research and instruction, where students could receive instruction in chemical technology, mechanical engineering, and other kindred subjects. The cost of maintaining an institution like this will be large. According to Sir Norman Lockyer," continued the Vice-Chancellor, "for the up-keep of seven out of twenty-two universities, the annual sum found in Germany chiefly by the State comes up to 271,000*l*. When these figures are borne in mind, the cost of the proposed institute ought not to stand in the way of its establishment. Its advantages will abundantly repay the outlay. It will provide an opening for graduates in science, and will divert many of them to the useful paths of industry and research. In such an institution graduates, who have studied the general principles of science in colleges, will be able to master the various methods of the practical application of science to the needs of the present day. They will there learn with what extraordinary skill, in other and more advanced countries, men are 'harnessing science in the service of business and the other tasks of modern life.'"

THE Earl of Crewe, chairman of the governing body of the Imperial College of Science and Technology, has authorised the publication of the following communication:—The governing body of the Imperial College of Science and Technology has appointed three standing committees, a finance committee (chairman, Sir Francis Mowatt), an education committee (chairman, Mr. Arthur Acland), and a general purposes committee (chairman, Lord Halsbury). In addition, two temporary committees have been appointed, namely, a transfer committee (chairman, Mr. Arthur Acland), and an organisation committee (chairman, Mr. Gerald Balfour; vice-chairman, Sir William White). Matters relating to the transfer to the Imperial College of the constituent institutions, which it has been arranged shall take effect as from January 1 next, and to the transfer of land from the Exhibition Commissioners, have been referred to the transfer committee. The organisation committee, to which have been referred matters relating to the future organisation of the Imperial College, has appointed four subcommittees to consider questions arising under this head in relation to the following sciences or groups of sciences, viz.:—(1) mining and metallurgy (chairman of the subcommittee, Sir Julius Wernher); (2) other branches of engineering (chairman, Sir John Wolfe-Barry); (3) biological sciences (chairman, Sir Archibald Geikie); and (4) other pure and applied sciences (chairman, Sir Arthur Rücker). The governing body has authorised the appointment of persons not members of the governing body who are specially conversant with the sciences in question or with their industrial applications as additional members of these subcommittees, which are now engaged in considering the questions referred to them. The governing body has also approved in principle the appointment of a principal officer of the Imperial College, and has referred the question of his title and functions to the organisation committee.

SOCIETIES AND ACADEMIES.

LONDON.

Society of Chemical Industry, November 4.—Mr. R. J. Friswell in the chair.—The determination of indigotin in indigo-yielding plants: Cyril **Bergtheil** and R. V. **Briggs**. The accurate determination of indigotin in the indigo plant is of considerable importance, since a correct estimate of the efficiency of the process of indigo manufacture depends thereon. A method of precipitating indigotin from an extract of the plant in boiling water by means of ammonium persulphate, proposed by Rawson in 1904 and modified by the present authors, has been shown to give correct results by comparison with those obtained by fermentation of the extract by means of the indigo enzyme (Journ. Soc. Chem. Industry, 1906, xxv., 729). This method has been criticised by Orchardson, Wood and Bloxam, and two alternative methods proposed, one of which, depending on the same principle, is said to give results identical with those obtained by the authors' method, whilst the other, depending on the precipitation of indirubin by the action of isatin in acid solution, indicates a considerably higher potential yield of indigotin in the plant extract used (Journ. Soc. Chem. Industry, xxvi., 4). The authors' original method is now verified, and some minor modifications are recommended. The conclusion that the isatin method may in certain circumstances indicate a higher indican content in a given extract than the persulphate method is not borne out by the authors' experiments.—Analysis of indigo (part iii.) and of the dried leaves of *Indigofera arrecta* and *I. Sumatrana*: R. **Gaunt**, F. **Thomas**, and W. P. **Bloxam**. A summary is first given of the results of the work on indigo carried out for the Government of India at the University of Leeds during the years 1905–7. In the present paper the exact conditions were prescribed for the preparation of pure indigotin to serve as the standard on which the tetrasulphonate process for the estimation of indigotin is based. A reply was made to certain criticisms on the tetrasulphonate process; the defects complained of were shown to be due to want of proper precaution on the part of the operators. The methods in use for the estimation of indigotin in the leaf were described. The persulphate method was found altogether faulty, as the results obtained by it were too low. The new "isatin" method was found to give much higher results, and, moreover, the method is quantitative, as proved by its action on the glucoside indican, which has recently been isolated in quantity by Messrs. A. G. Perkin and W. P. Bloxam. As a result of employing the isatin process, the indigo leaf is demonstrated to be capable of yielding more indigotin than had previously been supposed. Again, the percentage of leaf present in the green plant has been underestimated in India. It is insisted that these facts are in favour of the survival of the Indian indigo industry. Finally, it was submitted that the work on the indigo ferment or enzyme had not been properly followed out, and that the present reports on the Indian manufacture are eminently unsatisfactory, for (1) the colour-giving value of the raw materials was seriously underestimated, whilst (2) the indigotin value of the manufactured cake was overestimated, and this owing to the persistent use of unsatisfactory methods of analysis in lieu of adopting the tetrasulphonate process.

Physical Society, November 8.—Dr. C. Chree, F.R.S., vice-president, in the chair.—A freehand graphic way of determining stream surfaces and equipotentials: L. F. **Richardson**. Where an accuracy of 1 per cent. to 3 per cent. of the range is sufficient, solutions of the equation

$$\frac{\partial^2 V}{\partial x^2}+\frac{\partial^2 V}{\partial y^2}+\frac{\partial^2 V}{\partial z^2}=0$$

may be obtained by drawing equipotentials and sections of stream surfaces, and amending them freehand until the chequers which they form take the appropriate shape at each point of the field. The method can only be applied in cert.'n types of symmetry, as where V is constant along each line of one or other of the following families of lines:—(1) parallel straight lines; (2) circles with their centres on a common axis and their planes normal to this axis; (3) radii from a point; (4) the normals common to the two surfaces of a thin shell of any shape; and (5) a certain family of screw-threads. It is doubtful whether there are any other possible types. Within these five types of symmetry the freehand method far surpasses analytical methods in its adaptability to boundaries and boundary conditions of almost any shape which can be drawn on paper. It can no doubt be extended to deal with conductivity which depends on position, on the potential, or on the force.—The lateral vibration of bars supported at two points with one end overhanging: Dr. J. **Morrow.** When a bar, supported at one end and at some other point in its length, vibrates under its own mass only, the expression from which the frequency can be determined is of considerable complexity. When different values are assumed for the ratio of the overhanging length to the distance between the supports, the expression reduces to a customary form with a coefficient depending on this ratio. This coefficient is given here to six figures for different ratios from zero to unity. The results show that Dunkerley's approximate values cannot be relied on to more than two figures, and that Chree's simple formula gives remarkable accuracy for cases in which the overhanging length is less than half the span.

Zoological Society, November 12.—Dr. F. DuCane Godman, F.R.S., vice-president, in the chair.—Mammals collected at Beira by Mr. C. H. B. Grant, being No. 8 of the series of papers on the Rudd exploration of South Africa: Oldfield **Thomas** and R. C. **Wroughton.** Twenty-eight species were included in the collection, represented by 127 specimens, all, as before, presented to the National Museum by Mr. C. D. Rudd. The region not having been previously worked, the series was of much interest from a geographical point of view.—The feeding of serpents in captivity: Dr. P. C. **Mitchell** and R. I. **Pocock.** The different habits of python-like, non-poisonous and poisonous colubrine and viperine snakes were described, and it was stated that no evidence was found as to the existence of a specific fear of snakes in the case of any vertebrates except Primates, and that, amongst Primates, lemurs were distinguished from true monkeys by their complete indifference to snakes.—Descriptions of some new loricariid fishes, viz. five species of Plecostomus and an Otocinclus from eastern Brazil, and two species of Arges from Colombia: C. Tate **Regan.**—Notes on Mayer's pigeon: Lieut.-Colonel N. **Manders.** The habits of this nearly extinct bird were described.—Observations on the structure of the rare Madagascar mammal, *Galidictis striata*: F. E. **Beddard.**

Institution of Mining and Metallurgy, November 21.—Prof. W. Gowland, president, in the chair.—The deviation of Rand bore-holes from the vertical: J. **Kitchin.** Although there are altogether 235 bore-holes sunk in the Witwatersrand area, of which forty-five have reached a depth of 3000 feet or more, the author has contented himself with a review of twenty-two only, in respect to which results sufficiently full for tabulation are available. As regards these, the general characteristics were such that he has tabulated the following ascertained effects:—(1) the bore-holes almost invariably deviate in a northerly direction; (2) they almost invariably deviate against the strata; (3) the deviation tends to be greatest when the dip is least; (4) the deviation is not confined to any particular spot or spots in the bore-holes, but seems in most cases to be more or less general throughout; and (5) there is no appreciable deviation in the case of the flat-lying surface dolomite and any amygdaloidal diabase underlying it, or in the case apparently of surface igneous rock, but in all other instances the deviation is usually marked, and its rate of increase comparatively uniform. In other words, deviation is not observed except where the rocks passed through are bedded and have a dip. The average horizontal displacement of the twenty-two bore-holes specially submitted for analysis was 440 feet at a depth of 2000 feet, the minimum being 160 feet in a bore-hole 2000 feet deep, and the maximum 2370 feet in a bore-hole 4200 feet deep. As an appendix, the author gave particulars of a further twenty bore-holes, data of which were less detailed.—The separation of tin-oxide from wolfram: A. **Treloar** and G. **Johnson.** A record of experiments made by the authors in Cornwall upon "tinny-wolfram" with the view of saving the tin left in the product of the magnetic separator. The most successful results were obtained by taking the separated product in a dry state and boiling it in dilute sulphuric acid, which in a fairly large-scale experiment gave an extraction of 20 per cent. of tin-oxide. Hitherto, since the introduction of magnetic separation for Cornish ores, large quantities of tin-oxide have been given away in the parcels of wolfram sold, owing to a lack of means to effect this further separation from the tinny-wolfram.

PARIS.

Academy of Sciences, November 23.—M. Henri Becquerel in the chair.—Remarks concerning the nitrous isomerisation of isobutyl alcohol: Louis **Henry.** The conversion of the hydrochlorides of the fatty amines into alcohols by sodium nitrite results in the simple replacement of the (NH_2) group by (OH) for methylamine and ethylamine. Higher members of the series undergo a more complicated change, isomeric alcohols being produced. Isobutylamine gives isobutyl alcohol,

$$(CH_3)_2.CH.CH_2.OH,$$

and trimethylcarbinol, $(CH_3)_3.C.(OH)$, the proportion of the latter (about three-quarters) being determined by converting it into tertiary butyl chloride.—The determination of the solar elements and the masses of Mars and Jupiter by meridian observations of Vesta: G. **Leveau.** The whole of the observations made at Greenwich and Paris between the years 1807 and 1904, and numbering 5440, are utilised, and the results compared with those of Le Verrier and Newcomb.—Observation of the passage of Mercury across the sun's disc made with the Gautier equatorial (40 cm.) at the National Observatory of Athens: D. **Eginitis.** The atmospheric conditions at Athens were bad, and accurate measurements, in consequence, were impossible. The brilliant ring round the disc of Mercury observed in the transit of 1891 was not seen on this occasion.—The order of the function $D(\lambda)$ of Fredholm: T. **Lalesco.**—Some points in the theory of fundamental functions relating to certain integral equations: Bryon **Heywood.**—The irregular points of convergent series of analytical functions: P. **Montel.**—Some properties of integrals passing through a singular point of a differential equation: H. **Dulac.**—The rotatory magnetic dispersion of crystals in the neighbourhood of absorption bands: Jean **Becquerel.**—Influence of the reaction of the medium on the size of the colloidal granules: André **Mayer,** G. **Schæffer,** and E. **Terroine.** Numerous examples are given showing that the addition of traces of acid to negative colloidal solutions, or of alkalies to positive solutions, has the effect of increasing the size of the colloidal granules.—A new compound of uranium, the tetra-iodide: Marcel **Guichard.** Metallic uranium and iodine are sealed up in a vacuous tube, the iodine being heated to 180° C. and the uranium to 500° C.; the iodide UI_4 is thus formed. It is unstable, and readily acted upon by moisture or oxygen.—The synthesis of ammonia by catalysis starting from its elements: Léon **Brunel** and Paul **Woog.**—A method for estimating very small quantities of zinc: Gabriel **Bertrand** and Maurice **Javillier.** The method is based upon the insolubility of calcium zincate, and allows of the separation of 0·1 mg. of zinc from three litres of solution, a dilution of 1 in 30,000,000.—Lupeol: P. **van Romburgh.** A comparison of the lupeol obtained from *bresk* (the juice of *Dyera Lowii*) with that extracted as cinnamate from the gutta-percha of *Palaquium Treubii.*—Two isomeric methylsparteines: Charles **Moureu** and Amand **Valeur.** An account of two isomeric bases obtained by the decomposition of α-methylsparteinium hydrate.—Experiments on the synthesis of β-campholene lactone and on the lactone of 2:4-dimethyl*cyclo*pentanol-2-acetic acid: G. **Blanc.**—The primitive form of the male fig: Leclerc **du Sablon.**—The signification of the reddening ("maladie du Rouge") of the fir: L. **Mangin.**—A remarkable case of autotomy of the floral peduncle of the tobacco plant, caused by traumatism of the corolla: Paul **Becquerel.**—Contribution to the anatomical study of some textile Cyperaceæ of Madagascar: P. **Claverie.**—Contribution to the chemical study of mistletoe, *Viscum album*: M. **Leprince.** An account of the method of isolating an alkaloid from this plant, 25 kilograms of the dried material giving 1·6 grams of the chlorohydrate of the base, $(C_8H_{11}N)HCl$.—The physiological action of the mistletoe, *Viscum album*: Réne **Gaultier** and J. **Chevalier.**—A new sign of true death: E. de Bourgade **de la Dardye.** Referring to a communication by M. Vaillant in the last number of the *Comptes rendus*, the author refers to a communication of his on the same subject published in 1898, in which the immobility of the heart, diaphragm, and intestines after death showed up clearly in radiographs.—Artificial parthenogenesis: Jacques **Loeb.** Criticisms of the work of M. Delage on the same subject.—The comparative morphology of *Pachydavularia erecta* and *Suavopsis elegans*: Louis **Roule.**—The diagnosis of tuberculosis in animals, especially in cattle, by the simultaneous use of the ophthalmo- and cutidermo-reaction: J. **Lignières.**—The comparison of the secretions of the two kidneys in hydruric diabetes: C. **Fleig** and E. **Jeanbrau.**—Tuberculosis cultures *in vivo* and antituberculous vaccination: M. **Moussu.**—The sterilisation of the human ovary by the X-rays: Foveau **de Courmelles.**—The individualisation, graduation, and methodical localisation of the altitude cure applied to the treatment of tuberculosis: Christian **Beck.** The author proposes to send the patients up in groups attached to captive balloons.—The systematic position of the fossil stems known as Psaronius, Psaroniocaulon, Caulopteris: Fernand **Pelourde.**

AN UPPER CRETACEOUS FLORA.

The Cretaceous Flora of Southern New York and New England. By Arthur Hollick. Pp. 219, including 40 plates. (Washington: Government Printing Office, 1906.)

THE Cretaceous flora is of extreme interest to botanists, for it was during this period that the great, and, as it appears, sudden, change took place from the ancient type of Mesozoic vegetation, with its predominant Cycadophyta and Conifers, to a flora of an essentially modern *facies,* with the Angiosperms already supreme. The recent remarkable work of Dr. Wieland (NATURE, vol. lxxv., p. 329; vol. lxxvi., p. 113) has intensified the interest of this transformation from the old into the new, by showing that the Cycadophyta of the earlier Mesozoic had themselves evolved a floral organisation comparable to that of an Angiosperm, indicating that the dominant groups of the two floras, different as they appear, may yet prove to have been genetically related.

Dr. Hollick's monograph relates entirely to an Upper Cretaceous flora in which Angiosperms, or at least Dicotyledons, have completely assumed the leading *rôle,* and little trace of their cycad-like predecessors remains. The beds yielding the fossil plants belong to the "Island Series" of Dr. Lester Ward, who thus described their distribution:—

"From Morgan (New Jersey), . . . the formation may be traced northward across Staten Island and the northern shore of Long Island, and it re-appears on Martha's Vineyard in the celebrated cliffs of Gay Head" (p. 13).

The horizon of the beds is mainly that of our Upper Chalk (Senonian), and possibly as old, in some cases, as late Cenomanian, but it is doubtful whether the intermediate Turonian is represented (p. 119). An interesting feature of the deposits is that the concretions containing the plant-remains almost always occur in glacial moraine, or in Cretaceous beds more or less disturbed by glacial action, and scarcely ever in their original positions (p. 26).

Of the 222 species to which a systematic position is assigned, six are referred to the Pteridophyta, 27 to the Gymnosperms, four to the Monocotyledons, and no less than 185 to the Dicotyledons. In spite of the many elements of doubt involved in all determinations of more or less fragmentary impressions, these figures probably give a fair though rough idea of the true proportions, and though further investigation may somewhat add to the relative importance of the Gymnosperms, there can be no doubt that the Dicotyledons had already completely gained the upper hand in the short interval, geologically speaking, since Lower Cretaceous times. The Cycadales, the characteristic plants of the earlier period, are represented by a few doubtful fragments. The fossils referred to Williamsonia by the author are, as he says, of uncertain affinity, and it has been suggested that they may rather be attributed to Magnoliaceæ, an order which, on leaf-evidence, was largely represented in the flora.

The insignificance of the Monocotyledons is another striking point—the four fossils referred to them all seem somewhat dubious. The geological evidence, here and elsewhere, certainly weighs heavily on the side of the opinion, now widely held, that the Dicotyledons constitute the original angiospermous stock, from which the Monocotyledons have diverged.

The author's determinations are, at the present stage of investigation, necessarily based almost wholly on impressions of leaves, for such remains of flowers and fruits as have been found seldom seem to have helped materially in the identification. The botanist can rarely feel confidence in conclusions as to affinity derived from leaf-characters alone, and it is to be regretted that so many of the fossils are referred to recent genera, the evidence for such attribution being scarcely ever adequate. The author's object has apparently been to identify his specimens, generically or specifically, with those described by previous palæobotanists, rather than to determine their botanical affinities for himself. As an ample record of a rich flora the monograph has great value, especially from a stratigraphical point of view; but, as is usually the case with work on Upper Cretaceous or Tertiary plants, the data will need a far more critical treatment before any accurate botanical conclusions can be drawn.

In speaking of the coniferous remains, the author directs attention to the wide and interesting field open for future investigation in the examination of the internal structure of certain specimens. That the structure should so often be preserved is a most hopeful circumstance, and the work already done on some of this invaluable material by Prof. Jeffrey, of Harvard, partly in conjunction with the present author, shows how much may be looked for when the internal, as well as the superficial, characters of these interesting relics have been more widely investigated.

PAPER MILL-WORKERS AND TECHNOLOGY.

Chapters on Paper-making. Vol. iii., Comprising a Short Practical Treatise in which Boiling, Bleaching, Loading, Colouring, and Similar Questions are discussed. Pp. viii + 134; price 5*s.* net. Vol. iv., Containing Discussions upon Water Supplies and the Management of the Paper Machine, and its Influence upon the Qualities of Papers. Pp. vii + 156; price 5*s.* net. By Clayton Beadle. (London: Crosby Lockwood and Son, 1907.)

THE author is one of a group of workers who aim at a progressive elevation of the standard of technological education and practice in this still very important branch of our productive industry. The paper-maker in this country has weighty reasons for preferring the "practical man" to, or before, the student of the theoretical basis of his practice. It is not the weighty reasons, however, which determine his attitude. It is the feminine quality or defect of pure prejudice; the argument is introduced *post hoc*

 G

for its justification. The author, aware of this rule of prejudice, but encouraged by distinguished exceptions, adopts the plan of "pegging away." These volumes are the records of a scheme of higher education by correspondence. Questions directed to the elucidation of typical problems arising in the ordinary routine of the mill are set and distributed through the medium of the technical Press amongst the workers, who are invited to transmit their solutions of the problems to be criticised and corrected. A further object is to assist the workers in preparing for the more formal examination test of the City and Guilds Institute. At the same time, the questions propounded are judiciously chosen outside the formal or text-book range of the examinations syllabus of that excellent institution. We give a selection of subjects dealt with :—*Beating*, with sections on the size and speed of beater rolls, the efficiency of refining engines and edge runners; *Sizing, Colouring and Loading*, with special problems; the *Paper Machine*, with sectional treatment of dandy rolls, wire and suction boxes; the *Qualities of Papers* in relation to use, involving practical problems in "bulk," transparency, tenacity and stretch, special printing surfaces and the like.

The chapters follow one another without any attempt at a logical sequence, and each chapter comprises a selection of students' answers, also without any attempt at classification. The author's critical remarks alternate with the matter in inverted commas, and these criticisms are quite as unequal as his students' efforts. The reader is consequently confronted on each page with a species of pictorial puzzle, with the accompanying challenge to "find the policeman."

We say "policeman" taking the accepted symbol of law and order, and the student of technology is of course seeking instruction in these fundamental regulating factors of industrial processes. This defect of form, or want of form, necessarily limits the usefulness of these volumes. As a "causerie" on mill practice they will be found interesting and suggestive, but as a guide to technological instruction the matter should have been much more carefully ordered and edited. An important function of the teacher is to teach his subjects on positive, didactic lines, and the author abdicates this position in not prefacing each chapter with his own model answer to the questions propounded.

These "Chapters on Paper-making" notwithstanding constitute a most useful appeal to the latent intelligence of our mill workers.

Paper-mills are often so situated as to cut them off from tuition classes, and, further, it must not be forgotten that most workers are on night-shifts in alternate weeks, and this is a serious impediment to instruction by classes or lectures.

The author's educational work is therefore particularly deserving of encouragement, and with a little more conviction on his own part as to its solid value, he will probably see fit so to improve the form and style of subsequent "chapters" as more efficiently to supplement and complement the work of the technological institutions.

LOCAL ORNITHOLOGY.

(1) *Bird-Life of the Borders, on Moorland and Sea, with Faunal Notes extending over Forty Years.* By Abel Chapman. Pp. xii+458; map and illustrations. (London: Gurney and Jackson, 1907.) Price 14*s.* net.

(2) *The Birds of Kent.* By William J. Davis. Pp. vi+304; plate and map. (Dartford: J. and W. Davis, 1907.) Price 6*s.* net.

(3) *Notes on the Birds of Rutland.* By C. Reginald Haines. Pp. xlvii+175; 8 plates and map. (London: R. H. Porter, 1907.) Price 7*s.* 6*d.* net.

(1) IN preparing the second edition of his pleasant and valuable account of the birds of the borders, Mr. Chapman has practically re-written on a broader basis the first section of the book, *i.e.* that relating to the Cheviots and the moorlands of the borders. The second part, which treats of the north-eastern sea-board, and, to some extent, may be considered as a treatise on the wild-fowling to be had on that coast, as well as an account of the wild-fowl to be met with there, has been merely revised.

The borderland stretching from Cheviot to the Solway comprises an area of hundreds of square miles of mountain and moor. The author defines the region covered by his observations as that mountain land which remains as it was created, unaltered by the hand of man, bounded by the line where the shepherd's crook supplants the plough; where heather and bracken, whinstone and black-faced sheep repel corn and cultivation; where grouse and blackcock yet retain their ancient domain, excluding partridge and pheasant; and where the ring-ouzel dispossesses the blackbird.

"A region largely of peat as distinguished from soil, of flowe, moss, and crag; of tumbling burns and lonely moorland, glorious in all its primeval beauty."

As on the higher fell-ranges of the borders it takes two to four acres to support each sheep; the hill country is very thinly inhabited. In this edition the author has slightly extended his purview so as to include the subjacent country, namely, the foothills which slope downwards from the higher range, "and which zone might perhaps be termed the sub-alpine region." This is the fringe of the moorland, yet it lies beyond the range of the plough, and its faunal character may be exemplified by the substitution of the blackcock, peewit, and whinchat for the red grouse, golden plover, and wheat-ear of the higher land. Here we come within the outer limit of many of the lowland woodland forms.

Beginning with the earlier months, the bird-life of the moorlands is traced in a succession of chapters throughout the year. The author having had forty years' experience of the district to which he is devotedly attached, and the book being preeminently one of personal observations, and of statements of facts, as seen by him, supplemented and expanded to some extent by theories which he felt justified in founding upon these observations, it follows that in these articles we have a very complete account of the avifauna of a district which is little known and visited.

The bird-life of the borders is constantly changing throughout the year, save, perhaps, just during the heart of the breeding season; and among all the 200 species of birds which may roughly be estimated to form its feathered population, the author finds that only fourteen are absolutely stationary.

Interspersed among the regular sequence of the chapters detailing the bird-life at different seasons, we have accounts of the game-fish, migration, grouse-shooting, and grouse-disease; and a chapter of specific bird studies dealing chiefly with some of the rarer birds met with in, or which have recently extended their range to, the district. Among the many bits of stray information there are some very pertinent remarks on the important question of heather burning and the effect upon heather of black-faced sheep, which manage, when forced by sheer necessity, to retain life in them by grubbing down into its roots.

The chapter on the process of migration advances some rather novel ideas. The author suggests, in the first place, that no one has ever seen the process of migration in actual operation, and that migratory birds seen at lightships, &c., are not in the process of migration, but at its termination, making good their landfall; and further, that the few birds one sees at sea are merely waifs and strays. He disbelieves that the journeys which small birds of little wing-power perform are accomplished in the way that is ordinarily accepted, *i.e.* by hard, straightaway flying. He says that birds can reach, high in the air, regions and conditions quite beyond human knowledge; can sustain life in rarefied atmospheres where mammals could not; and may there be able to rest without exertion, or find meteorological or atmospheric forces that mitigate or abolish the labours of ordinary flight, or possibly assist its progress. All this is very suggestive, and facts are brought forward in support of these views; but much of it must remain conjectural, of course, and extreme cold, and the stormy conditions supposed to prevail at high altitudes, would, we think, have to be considered.

In the latter part of the book the wild-fowl of the north-eastern coast, their haunts and habits, and the way to get at them with a big gun, are fully dealt with; but, unfortunately, the impracticable or inaccessible nature of their chosen haunts has left inquirers much in the dark as regards the specific distribution of the grey geese on those shores. As an account of the local habits and distribution of the border birds, this book is chiefly valuable—for the habits and the nature of the haunts of birds differ in different districts. To give one instance of this, speaking (and doubtless drawing on his observations of the bird somewhere or other) of the black-tailed godwit as a former breeding species in Britain, the author says of this country, "Nowadays there are no fens; consequently no godwits." But this is not a necessary consequence. On the Continent, this godwit is known to breed in good drained grass marshes, and its nest has been found in a dry, sandy bean-field in reclaimed lands.

The author holds strong opinions, and perhaps some of his conclusions will not be universally accepted; possibly all the less so from his criticism of others, and a slight reluctance to accept the observations of some others as facts when they clash with his preconceived notions; and his distrust of what has not been seen by himself. But we have no more readable bird-book on our shelves, and the new edition will be welcome to those who have for years been unable to obtain the original one. Some of the author's drawings and pen-and-ink sketches are very pleasing and life-like. But with regard to the plate (not by the author) supposed to represent a coot and two Sclavonian grebes in full winter dress at midsummer, we should certainly say that the heads of the grebes as drawn—the shape and size of the beak, and the white passing over and behind the eye—resemble more closely those of crested grebes in winter plumage. There is a map of the district, and a good index.

(2) Mr. Davis points out that hitherto no book dealing with the birds of the entire county of Kent has been published, although the works of Messrs. Dowker on east Kent, Prentis on the Rainham district, and the present author on Dartford and the north-west, have paved the way for a complete county avifauna. The information to be derived from these sources has now been brought together and supplemented by various records in the periodicals and notes which have been furnished by observers in various parts of the county. A short description of the eggs and nests has been given in most cases, and something about the habits of the birds which are resident in or regular visitors to the county. Unfortunately, the author's personal experience relates only to portions of the county, and the information respecting many of the birds can hardly be said to have been brought down to date.

Kent has given a name to no less than three birds on the British list, and we naturally turn to them in expectation of finding a full account of their history and present status in the county. It is therefore disappointing to find that the account of the Kentish plover consists of little more than a reprint of Mr. Farren's article in *Country Life* (most excellent in itself) on the breeding habits of this little plover; while of the Sandwich tern, discovered at the place of that name in 1784, we are merely informed that "no doubt they still breed on the Kentish coast." As to the Dartford warbler, a perusal of the four and a half pages devoted to this species, "probably more interesting to the inhabitants of the town of Dartford than any other bird," leaves us in doubt whether it is still an inhabitant of Kent or not. Half a page is filled with a quotation as to the discovery of a nest and eggs of this bird in Yorkshire; but this might well have been omitted, since the Yorkshire authorities consider the record is open to the gravest doubt, and refuse to enrol the Dartford warbler on the Yorkshire list.

We can only consider this little book as a further instalment towards the adequate avifauna of Kent which we still await. Iceland, where the chough is said to breed, must be a misprint for Ireland. The appendix includes a useful list of birds observed in east Kent during the past twenty years by Mr. H. S. D. Byron, received by the author too late for incorporation in the text. A full index and a large map make reference to the species and localities easy.

(3) One by one the English counties are getting their bird-books, and the latest to acquire this distinction is Rutland, by far the smallest of them all. Pre-eminently an agricultural county, its natural features present nothing striking, and do not show any great diversity. Of its 100,000 acres, permanent pasture absorbs more than half; not a hundred acres are waste land or heath, and not 200 acres are water. But Mr. Haines is surely far below the mark when he states that there are scarcely 400 acres of woodland. In these circumstances he has done well in being able to give so large a list as 200 of birds which have occurred in this fruitful and profitable little bit of land, Besides the natural disabilities of Rutland as a bird resort, the historian of its ornithology has to contend with a further drawback in the almost total lack of notes bearing on the subject which date back more than a hundred years.

The one exception is to be found in the notes by Thomas Barker, of Lyndon Hall, Gilbert White's brother-in-law, and two of the earliest of these are initialed by the historian of Selborne. But the notes do not amount to much, and refer chiefly to the arrival and departure, and the opening of song of less than a score of species. The most interesting of them is the wood-lark—a very rare bird now in Rutland. A slip is made in describing the gentleman who brought these notes to light as a *descendant* of Gilbert White! The later printed authorities are very few, and although a work published in 1889 is entitled "The Vertebrates of Leicestershire and Rutland," the Rutland birds are very inadequately treated therein. So that there was quite room for a new and complete work on the subject, in the preparation of which the present author has had the assistance of a large number of observers.

The general condition and character of the avifauna of the county is treated in a lucid and interesting manner in the concluding portion of the introduction, and lists are given of the species which have increased or decreased in recent years. Lists, too, are given of the resident species which are subject to some migration, and of the whole of the species actually enumerated as Rutland birds, showing their status in the county. The references made to the habits and life-histories of birds in the body of the work have been drawn from observations made in Rutland itself. The facts of most importance for British ornithologists in general to be gleaned from the pages of this handy little volume are: the eighth instance of the occurrence of Bonaparte's gull; the unique nesting of the bee-eater; the addition of Rutland to the counties where the pied flycatcher has been seen; the recent appearance of the bearded tit in the county; the acquisition of the redshank as a nesting species; the very early return of the wryneck; and the early nesting of the corncrake and partridge. The author himself seems to feel a little doubtful about the identification of the Bonaparte's gull, and ornithologists in general will be still more so; while as for the nesting of the bee-eater, we cannot help thinking that some mistake or confusion of specimens occurred; the confusion in which the authority for the record seemed to be about the smaller grebes (p. 163) inclines us more strongly to this view.

The plates are pleasing, though they have not all of them much to do with Rutland especially. But there is one which will puzzle most people. As the jack snipe, the principal figure in it, is cut all to pieces by the shot which has apparently been fired, and is obviously dead in the air, we cannot see why the picture should be called "A Narrow Escape"; unless the title refers to the dog, which does not appear to have been hit! We have, however, seen a plate in another book which has a striking resemblance to this one, but there it has another and more appropriate title. A good index and a map complete this nicely got up little volume.

ELECTRICAL ENGINEERING.

(1) *A Text-book of Electrical Engineering.* By Dr. Adolf Thomälen; translated from the German by G. W. O. Howe. Pp. viii+456. (London: Edward Arnold, 1907.) Price 15*s.* net.

(2) *The Elements of Electrical Engineering.* By Profs. W. S. Franklin and Wm. Esty. Vol. i. Direct-Current Machines, Electric Distribution and Lighting. Pp. xiii+517. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1906.) Price 18*s.* 6*d.* net.

(1) THIS book is an English translation of the second edition of the "Kurze Lehrbuch der Elektrotechnik," and includes some additional matter which will be introduced into the third edition. It is intended to meet the needs of electrical engineering students who have passed the most elementary stages and are taking a second- and third-year course at the technical colleges.

It is not easy to give a satisfactory definition of electrical engineering, but in default of a better it may be suggested that the subject should comprise the generation, distribution and utilisation of electric energy. This may be interpreted narrowly or broadly according to the judgment of the individual. If this be accepted as a reasonable definition, the book before us is by no means comprehensive enough to be justly called "a text-book of electrical engineering"; it should rather be called "an introduction to the theory of dynamo design." Distribution of electric energy is not considered at all, and its utilisation only in so far as the theories of motors, direct and alternating current, are concerned. The theories of direct-current feeders, of switchgear for controlling generators and motors, of electric traction apparatus, are not abstruse, and a knowledge of these matters is likely to be more useful to the average engineer than the theory of dynamo machinery.

Recognising, however, the limitations of the subject-matter, the book may be safely recommended for what it contains, although it is surprising that there should have been much difficulty in finding books already in existence covering the same range, as stated in the preface. As a brief indication of the contents it may be stated that the first five chapters deal with fundamental principles of electricity and magnetism, the next four with the theory of direct-current dynamos and motors; these are followed by a single chapter on alternating-current theory, a chapter on transformers, four chapters on alternating-current generators and synchronous motors, and four chapters on induction motors. The book concludes with a few pages devoted to rotary converters, and an appendix on the symbolic method of treating vectors.

The matter is well arranged and clearly set forth. Considerable space is taken up by the various types of direct-current armature windings, illustrated by several good diagrams, and the important question of sparking receives proper attention.

The treatment of alternating-current generators is good, but it seems questionable whether students should be taught to look upon the magnetising current in the field windings of an alternator as a vector quantity. With this exception the section devoted to the behaviour of such machines on loads with various power factors is excellent, and the discussion of parallel running is particularly clear. Induction motors are considered in the light of the semicircle diagram with a good deal of theoretical elaboration, and single-phase commutator motors are mentioned briefly.

Taken as a whole, the book will probably strike electrical engineers as being somewhat too theoretical. It does not claim to go beyond the principles of the subject, leaving aside altogether constructional details. There are, however, many items of information which could be given without any trouble, and which would give a greater reality to the student's ideas. Thus, for instance, it seems a pity that a budding electrical engineer should arrive at the end of the book without ever having been told that electrical apparatus must satisfy the requirements of a temperature specification. There should be no need for a man to go through a course of dynamo design to learn this elementary but important fact.

A word of praise may be given to the translator, who has done his work with marked success; it is sufficient to say that the book does not read like a translation form the German, and all who have done such work will agree that this is high praise.

(2) This is another book for the use of students, but it is intended not only for those taking a special electrical course, but also for others studying general engineering. With this object in view, the authors have endeavoured to differentiate between the two classes of readers, by giving in appendices and in several special sections in small type what they call the more elaborate developments of the subject. This seems a good plan, and it is well carried out.

The authors are professors in Lehigh University, and the book, in consequence, caters especially for the American engineer. Apart from this, the present volume may be thoroughly recommended to students in this country, on account of the practical nature of the information contained therein. For example, the authors are not content with tracing through the preliminary theory of the direct-current generator and then leaving the subject at that point, as so many English text-books do, but they go on to discuss what limits the output of a generator in actual practice, and give a chapter on ratings and guarantees. As a whole, the book is far more in touch with practical conditions than the usual examples of this class of literature.

The present volume is confined to the study of direct currents, their generation, distribution, and utilisation for lighting. The first part is devoted to elementary theory, the theory of dynamo machines, the practical aspect of such machinery, including its rating and performance guarantees, its control by switchgear, and its operation alone and in conjunction with storage batteries. The second half contains chapters on distribution and wiring, on photometry and electric lighting, and four appendices on the magnetisation of iron, on characteristic curves, on armature windings, and on problems illustrating the contents of the whole volume.

The book will no doubt serve its particular purpose admirably, but so far as this country is concerned it is unfortunate that the slight differences between English and American practice are sufficient to deter many students from purchasing a book of considerable value in its own country.

OUR BOOK SHELF.

Modern Lithology, illustrated and defined, for the use of University, Technical, and Civil-Service Students. By E. H. Adye. Pp. 128. (Edinburgh and London: W. and A. K. Johnston, Ltd., 1907.) Price 10s. net.

The excellent microscopic drawings of rock-sections previously issued by Mr. Adye (see Nature, vol. lxxi., p. 341), in a work entitled "The Twentieth Century Atlas of Petrography," prepare us for the present series of sixteen smaller plates. With four coloured figures on each, some of them subdivided into two semicircles, we have a wide range of rocks accurately and artistically represented. The drawing and description of thin sections is not strictly "lithology," however "modern" it may be; but Mr. Adye deals with the illustrations clearly in the accompanying text. He also gives a glossary of petrographic terms, which contains many useful references to original papers.

The definitions of the crystallographic systems are, as often happens in elementary books, far too limited, and would exclude copper pyrites, for example, from the tetragonal system, and hemimorphite from the orthorhombic. If, moreover, rhombohedral and hexagonal are to be taken as synonymous, as stated on p. 97, there is no place under the definition given for such common minerals as quartz and calcite. A crystallographic "pyramid" (p. 111) cannot nowadays be regarded as a closed form. The glossary, as a whole, however, is a mine of information, and every geologist may read it with advantage. "Tachylite," here and on p. 18, should be "tachylyte"; but this correction has been made again and again without result in geological literature. Few misprints occur; we notice "Jannetez," "Bôricky," "Radanthal," and *Galionella*.

There is no strict arrangement in the subjects on the plates, and, as we have hinted, no attempt has been made at writing on lithology in the broad sense. But the book, with its complete index, is a really good companion for those who require guidance in studying the characters presented by thin sections. No small work has hitherto given us so effective a series of coloured petrographic illustrations. We are thus not quite sure about the description of the pyroxene-andesite from Bohemia on plate v., because the drawing so closely resembles the rock of Tichlowitz, with its brown hornblende in the groundmass, its monoclinic pyroxene, and its patches of zeolites as the only pale constituents. Again and again we could name the locality of the rock selected from the accurate details of the illustration; and when we turn to the descriptive text, we find very little room for criticism. G. A. J. C.

Inflammation. An Introduction to the Study of Pathology. Being the reprint (revised and enlarged) of an article in Prof. Allbutt's "System of Medicine." By Prof. J. George Adami. Pp. xvi+240. (London: Macmillan and Co., Ltd., 1907.) Price 5*s*. net.

Reprints in book form of articles appearing in larger volumes are not always desirable, but in the present instance so much has been added to the matter as virtually to constitute a new work. We congratulate Prof. Adami heartily on the successful issue of an arduous task; no one knows how difficult until he attempts to write on inflammation. The subject of inflammation, forming, as it does, the fundamental basis of pathology, and it might be said also of the science and practice of medicine, is beset with difficulties. The literature on it is voluminous and bewildering, and pathologists owe a debt of gratitude to Prof. Adami for having the courage to attack it. The matter is divided into sections; the first gives a general survey of the inflammatory process, the second deals with the various factors of the process—the part played by the leucocytes, the exudate, the blood-vessels, the nervous system, cells of the part, and the temperature changes; the third section deals with general considerations, and includes a chapter on the principles of treatment of the inflammatory state. Every statement made is based on published work, to which the reference is appended (and the book therefore forms a valuable bibliograohy on the subject of inflammation), and critical additions and summaries are liberally interspersed. The book is well and sufficiently illustrated, and no student of pathology can do without it. R. T. Hewlett.

Notes on Maritime Meteorology. By Commander M. W. Campbell Hepworth, C.B. Pp. viii+90; 7 plates. (London: George Philip and Son, Ltd., 1907.) Price 2*s*. 6*d*. net.

This work consists of papers contributed to societies and institutions between 1883 and 1900, compiled while the author was on active service afloat. Two of them, occupying nearly half the book, are of a more general nature than the rest, and deal with meteorology as a factor in naval warfare and with the value of meteorological observations at sea. The author contends that, given two opposing fleets equal in all respects, "the victory in a series of engagements shall be to the fleet in the direction of whose movements meteorology shall have given the greatest aid," and some striking instances are cited of the value of weather knowledge. The other papers are of a more special character, and relate chiefly to the navigation of the Indian and Pacific oceans. Taken in connection with the useful charts dealing with the marine meteorology of those oceans published by the Admiralty and the Meteorological Office, the results of investigations by so experienced a seaman and so keen an observer as the author of the work in question will be of great interest and value to those now afloat.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Mulattos.

Mr. H. G. Wells, in his interesting book "The Future in America" (1906), tells (pp. 269–270) a story at second-hand which apparently, however, he accepts as accurate in perfect good faith. I transcribe the facts as they were given to him:—

"A few years ago a young fellow came to Boston from New Orleans. Looked all right. Dark—but he explained that by an Italian grandmother. Touch of French in him too. Popular. Well, he made advances to a Boston girl—good family. Gave a fairly straight account of himself. Married."

The offspring of the marriage was a son:—

"Black as your hat. Absolutely negroid. Projecting jaw, thick lips, frizzy hair, flat nose—everything."

In this case Mr. Wells observes:—"The taint in the blood surges up so powerfully as to blacken the child at birth beyond even the habit of the pure-blooded negro."

This is, at any rate, ultra-Mendelian. Such a story would hardly be told and repeated unless it corresponded to popular belief. What one would like to have is precise evidence that such cases actually occur. If verifiable, it would be of great importance both on scientific and political grounds. I find, however, nothing resembling it in such authorities as I am able to consult. No such case is mentioned by either Darwin or Delage, though neither would have been likely to pass over such a striking instance of reversion had it been known to him. Sir William Lawrence, in his "Lectures on Physiology, Zoology, and the Natural History of Man" (1822), a book still worth consulting, has industriously collected (pp. 472–484) all the facts available at the time about mulattos, but has no instance of the kind.

The problem involved is thus stated by Galton ("Natural Inheritance," p. 13):—"A solitary peculiarity that blended freely with the characteristics of the parent stock, would disappear in hereditary transmission." He then discusses the case of a European mating in a black population:—"If the whiteness refused to blend with the blackness, some of the offspring of the white man would be wholly white and the rest wholly black. The same event would occur in the grandchildren, mostly, but not exclusively, in the children of the white offspring, and so on in subsequent generations. Therefore, unless the white stock became wholly extinct, some undiluted specimens of it would make their appearance during an indefinite time, giving it repeated chances of holding its own in the struggle for existence." *Mutatis mutandis*, the same law would hold for a black mating in a white population.

Lawrence quotes a single case (p. 279) in which a refusal to blend certainly existed:—"A negress had twins by an Englishman: one was perfectly black, with short, woolly curled hair; the other was light, with long hair." He also points out that in "mixed breeds" "children may be seen like their grandsires, and unlike the father and mother," a fact observed by Lucretius.

"Fit quoque, ut interdum similes existere avorum
Possint, et referant proavorum sæpe figuras."

On the other hand, according to Lawrence, there was a legal process in the Spanish colonies of South America by which a mulatto could claim a declaration that he was, at any rate politically, free from any taint of black blood. Of Quinterons, who were one-sixteenth black, he says:—"It is not credible that any trace of mixed origin can remain in this case," and even of Tercerons, who were one-quarter black, "in colour and habit of body they cannot be distinguished from their European progenitors." He says (p. 274) that Jamaica Quadroons "are not to be distinguished from whites." But "there is still a contamination of dark blood, although no longer visible. It is said to betray itself sometimes in a relic of the peculiar strong smell of the great-grandmother." If these statements can be relied upon, Galton's hypothetical law does not appear to apply to mulattos, and some doubt is thrown on the case cited by Wells. On the other hand, Lawrence quotes from the Philosophical Transactions ("v., 55") a case of two negroes who had a white child, the paternal grandfather being white. This seems purely Mendelian.

November 25. W. T. THISELTON-DYER.

Specific Stability and Mutation.

THE desire to be as brief as possible has led, I fear, to some obscurity in the sentences quoted by Sir William Thiselton-Dyer (p. 77) from my letter of October 17. The meaning will perhaps be clearer if I explain the precise significance which I attached to the words "appear" and "occurrence."

By the occurrence of a mutation in one of the higher plants I meant the production of a seed capable of germination and containing an embryo with definitely different potentialities from those of its parent. The appearance of a mutation, on the other hand, implies that such a seed has germinated and given rise to a plant recognisably different from other members of the species. My contention is that the conditions of cultivation are such as to allow of the safe germination and growth of plants which would have no chance of survival under natural conditions. It is therefore possible that mutations may *occur* as frequently under natural conditions as under cultivation. This being so, it does not appear to me to be an abuse of language to state that the assumption that cultivation causes the occurrence of mutations is one which requires proof. In support of this assumption Sir William Thiselton-Dyer brings forward certain evidence. With much of this evidence I was already familiar, but it did not appear to me to amount to satisfactory proof of the current position. The authority of eminent breeders is quoted for the fact that, as soon as one new variety of a cultivated species has been obtained, a host of others immediately follow. But the explanation of this may be that the breeder, as soon as he has obtained a single novelty, immediately crosses it—deliberately or by accident—with the original type, thus giving rise to endless new combinations. R. H. LOCK.

Botany School, Cambridge, December 2.

THAT mutations inevitably appear sooner or later under cultural conditions is not an assumption, but a fact. That they do so only casually under natural conditions, and usually fail to perpetuate themselves, equally seems to me not an assumption, but a fact. If, as Mr. Lock seems to argue, there is an equal chance of their *occurrence* in either case, then their *appearance* should be more frequent in nature than in cultivation, because the former has a larger population to work with. But it is not so. I therefore conclude with Darwin that cultivation introduces some provocative condition which is lacking (or latent) in nature. What that condition is seems to me a very important subject for research.

December 5. W. T. THISELTON-DYER.

The Winding of Rivers.

WITH your permission I would like to make a few remarks on the winding of rivers, which is at present being discussed in your pages. My observations were made while fishing, and my remarks refer to the rivers of our own country, and may not apply to rivers of greater volume. But first I would like to point out an objection to Prof. J. Thomson's experiments. In Prof. Thomson's paper in the report of the British Association for 1876 no details of the conditions of the experiment are given, but Sir Oliver Lodge in his letter (NATURE, November 28) says Prof. Thomson's model had a wooden bed. Now it is very evident that we must be careful in drawing conclusions from experiments made under these conditions. That wooden bed, however carefully made, would not be of the shape that nature would have given it, and any deviation from nature's shape would cause unnatural currents. It, however, does seem probable that something of the nature of Prof. Thomson's diagonal under-tow will exist even in river-shaped beds.

The whole question of the flow of water in river beds is extremely complicated. This is evidenced by the contrary results of the observations of your correspondents. But little consideration is sufficient to show that this must be so; the variables are so many. We have, for instance, variations in the curvature of the bend, in the velocity of the water, and in the formation of the bed of the river, which we must remember is dug out and shaped by flood water for flood water, and is but little altered as the river falls in volume. Take, for instance, the case supposed to be represented by Prof. Thomson's model. Here, with a certain curvature and a certain velocity of flow, we can easily imagine the formation of the diagonal under-tow. But if we were to increase the velocity of the flow this cross under-current would decrease and ultimately cease, and when a certain relation of velocity to curvature was arrived at we would get the conditions referred to in Mr. R. D. Oldham's letter in NATURE of November 21, where he says:—"Sand and even pebbles may be thrown up to the surface of the water near the outer bank of the stream, and where the waters have overflowed the banks pebbles may be found lying on the dry ground after the flood has passed away."

In most of the rivers I know which flow in gravel beds, where they are constantly cutting away their banks, the main flow is more sinuous at low level than when in flood. At low level the main stream runs into the pools at the bends on the deep or concave bank, and as the deep sides of the successive pools are on opposite banks of the river, the stream has to cross its bed between the successive pools. While in flood the swiftest flowing part, on the surface at least, is near midstream, but the formation of the bed at the place and the flow above and below may alter this in some cases. After the flood has fallen, the river bed it has shaped has an infinite variety of forms at different places, and the flow of the water at any part must be studied with reference to that particular part, and to the part above which has determined the cross-section and velocity of the water coming to it, and also to the formation of the part below which determines its escape.

There is one very common type of flow which frequently presents itself in varying forms in rivers which alter considerably in volume from time to time. After the flood has fallen the river becomes, so to speak, divided into streams and pools. Over the shallows the water runs rapidly, while in the pools it moves slowly and somewhat irregularly. The streams coming into the pools flow next the concave banks, and come into the pools with some velocity, which is soon lost in the slower movements in the pools. The streams thus lose their kinetic energy, which is converted into potential energy, raising the level of the water at the place where the stream loses its velocity. From this part of the pool, in addition to the stream flowing down the pool, a reverse current is started which flows back on the inner side of the pool, flowing to the upper end of it, where it curves round and flows downwards alongside the main stream. Part of the back current is no doubt due to the inflowing main current causing an induced current, but it seems to be mainly due to the loss of kinetic energy of the stream, causing a rise of the level of the water where its velocity is destroyed.

As to the cutting and wearing away of the banks of rivers, that is mainly the result of eddies formed by the flowing water meeting with obstructions, such as stones, tree roots and stems, inequalities in the banks, &c., or even by water impinging on water. One of the deepest pools in a river I observed was entirely dug out of its gravel bed by eddies produced by the main river meeting a large tributary stream at right angles and mingling their waters in turbulent eddies; and it seems probable that the excavation of the deep pools generally found at the foot of waterfalls have been greatly aided by the eddies formed by the falling water meeting the quieter water of the pools.

The common practice in this country of protecting the banks of rivers by means of little piers or "tooks" to throw the water off them, and into the middle of the bed of the stream, generally results in failure, because the piers cause eddies, and deep pools endangering the banks are frequently dug out by these eddies; and while these piers tend to throw the water to the other side of the channel, yet the sloping bed throws it back and causes it to strike the bank below the pier, thus in some cases making matters worse. The only place I know of where a knowledge of the bad effects of eddies on river banks has been put in practice is in the river Adda, which drains Lake Como, Italy. There the irregularities of the banks seem to have been smoothed to some extent, and then simply paved with small cobble stones a few inches in diameter. Over this the water flows without eddies, and the banks, so far as one could see, gave little trouble, though one would imagine that if a break in this rather weak surface took place destruction might be rapid.

JOHN AITKEN.

Ardenlea, Falkirk, December 3.

May Gorsedds.

IN my communication to NATURE, May 2 (vol. lxxvi., p. 9), I stated that there was another plan of a Gorsedd among the Iolo MSS. at Llanover. The important difference between it and the plan published in that number is the omission of the solstitial stones. It is a May-November Gorsedd pure and simple, based on the equinox, and for that reason very interesting. Both plans are truer to ancient tradition than the present plan favoured by the bards. The present orientation is exclusively solstitial, against the best traditions in point. In the older plans the May-year is given the preeminence in one, and is the only year given in the other. In both the older plans the circle consists of nineteen stones, leaving open a splayed avenue on the east, the breadth of which corresponds to the sun's course from August to November and from February to May. Though the present plan of a circle of twelve stones at equal distance from each other is antiquarianly sound, one may regard the older plans as still sounder. I have elsewhere shown that the exclusively solstitial arrangement of the stones in the present plan is about the only point in connection with the bardic Gorsedd of doubtful antiquity.

The accompanying tracing (Fig. 1), for which I am indebted to Mr. T. H. Thomas, shows how the original plan was rather carelessly drawn, just the kind of diagram which an old bard would draw to accompany a written description, as in this case, for the benefit probably of an engraver.

In the formal and authentic bardic records very little is said about the significance of the various features of the Gorsedd circle. There is no dabbling in archæology.

FIG. 1.—Iolo's May Gorsedd.

It is enough for the bard to be able to say that everything he records is sanctioned by immemorial custom.

In the second quarter of the last century a bard arose who claimed also to be a chief bard or archdruid, having the bardic name "Myvyr Morgannwg." He attempted a scientific and philosophical interpretation of the Gorsedd. He insisted upon the absolute identity of the bardic institution with the circles of the Stone age. He made several successful hits at the truth about the Gorsedd, but wild speculations and irrelevant matter have made his various writings hardly readable.

The accompanying diagram (Fig. 2) represents Myvyr's idea of the "most essential elements of the Gorsedd," and is reproduced from one of his controversial pamphlets. It describes a May-November Gorsedd, but with the solstitial signs, except that Virgo is fixed at the equinox. The diagram is true to the best type, but the interpretation is a misfit. It is a forcible illustration of the disturbing effect of a solstitial cult upon sound May-year tradition.

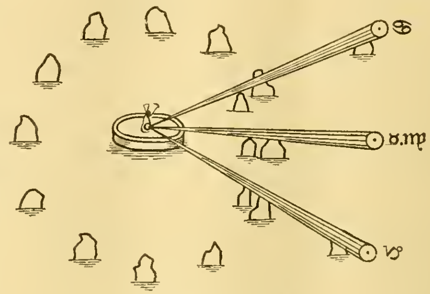

FIG. 2.—Myvyr's May Gorsedd.

Myvyr has also brought his fancy to play on the central stone. A mannikin, holding up something like a bow and arrow, occupies the place of the chief bard, and the three rays look very much like three clubs. Myvyr has nothing to say about the only valuable feature of his Gorsedd, namely, the May-November alignments.

JOHN GRIFFITH.

A FISHING TRIP TO THE GULF OF MEXICO.[1]

MR. AFLALO describes a journey to Florida *viâ* New York, a fortnight's tarpon and other fishing in Florida, and the journey home by way of sundry Central American and West Indian ports. The account given by the author of his outward journey differs in no material respect from numerous extant accounts of similar journeys, but is somewhat marred by a style rather reminiscent of that of the traveller who has perforce to provide his daily or weekly quota of copy for some periodical publication. Such sentences as "In the middle of the ship soft-voiced stewardesses gently raise thick curtains and say that dinner will be up in a minute. It usually is. Fore and aft there is neither curtain nor stewardess, but one sufferer leans across a neighbour of a different race and obeys the irresistible. Everything comes up, even the moon at last . . ." are hardly worthy of a serious volume. There are, however, interesting if slight allusions to and photographs of the Bronx Park Zoological Gardens and New York Aquarium, and a good account of a typical American health and pleasure resort in North Carolina.

Coming as it does from so well-known an authority on sea-fishing as Mr. Aflalo, the second section of the book is naturally by far the most interesting. The account given of tarpon fishing as pursued at Boca Grande is both full and lucid; a sufficiency of detail as to gear, methods of using it, and expenses is given without any needless discursiveness or undue brevity. The whole circumstances of the sport are brought clearly before the reader; the string of boats, each with its armchair fixed athwartships for the angler, towed out to the fishing grounds by a launch in the morning; the fish gaffed long ere they are played to a finish in the fisherman's eagerness to get back to the grounds and kill a larger one; the annoyance resulting

[1] "Sunshine and Sport in Florida and the West Indies." By F. G. Aflalo. Pp. xv + 272. (London: T. Werner Laurie, n.d.).

from hooking anything that is not a tarpon, and the homeward journey to the scales, where the fish are weighed and wasted, for, unlike its Asiatic congener, the tarpon is never used for food. Notwithstanding that we are told that luck and brute force count for far more than skill in tarpon fishing, it is curious what a fascination the sport has for its votaries; there is something beyond the surroundings and beyond the huge size and strength of the fish itself (for these latter, great as they are, become insignificant when compared with the power and bulk of the great serranids and sharks, which are but "vermin" to the tarpon fisher) that lends a glamour to the sport. It is curious to find the same author between the same covers dazzled by this glamour, and yet talking of "the semi-artificial sport of deer 'forests' (*sic*)," setting the armchair and brute force of the tarpon fisher higher than the rough hillsides, patience, and skill of the deer-stalker.

Transformation of an old fort into the New York Aquarium. From "Sunshine and Sport in Florida and the West Indies."

A chapter in this otherwise interesting section of the book devoted to speculations upon the early life-history of the tarpon is marred by the author's preliminary assumption that Megalops is a "herring," an assumption the more surprising when it appears from other passages in the book that he is well acquainted with one, if not both, of its real allies, Elops and Albula. Perhaps, however, in the case of one who does not claim to write as a scientific ichthyologist, such an assumption may be pardoned, as may his want of knowledge of Gill's paper (Smithsonian Miscellaneous Collections, 1905) dealing with the early histories of Megalops and its allies, and epitomising our existing knowledge of the singular metamorphosis passed through by the young of these fishes.

The concluding section of the book contains some useful suggestions for the sea-fisherman who may wish to visit the West Indies, and holds out some hope that Jamaica may hereafter find prosperity as a resort for British tourists.

It only remains to add that the printing and appearance of the book are good, and that an excellent index is provided. The book is well illustrated from photographs, and we are enabled by the kindness of the publisher to reproduce an illustration of the New York Aquarium, showing how an old fort has been adapted for this use; the open tanks built into the floor for the reception of large fishes are well shown in the picture, and present a feature which would seem worthy of imitation on this side of the Atlantic.

L. W. B.

GREEK ARCHÆOLOGY.[1]

THE articles in the latest volume of the "Annual of the British School at Athens" which are of most importance are those by Mr. R. C. Bosanquet, the late director of the School, and his assistants, which describe their excavations in the temple and precinct of the goddess Artemis Orthia at Sparta. Thus, for the first time for some years, the main interest of the School's work is transferred from things "Mycenæan" or "Minoan" to antiquities of the "classical" period. The excavations of the School at Palaíkastro, in Crete, which have produced so many interesting monuments of the older civilisation of Greece, have been brought to an end (Mr. Dawkins describes the last flicker of this work last year in the present volume), and a new scene of labour, amid totally different surroundings, and productive of totally different results, has been wisely chosen. This is as it should be. Eventually the present phase of the school's work will also exhaust itself, and then, all in good time, the attention of the school will no doubt again be turned towards Mycenæan matters. Dr. Arthur Evans will by that time have published his great book on Knossos, the Italian results will also be published, and we can start afresh with renewed interest and increased knowledge, derived from the complete study of the results of the previous period of excavation. Then the school will, it is to be hoped, complete the great

[1] "The Annual of the British School at Athens," xii. Pp. xi+523; 12 plates; and illustrations in text. (London: Macmillan and Co., Ltd., 1905-6.) Price 25s. net.

work of excavation at Phylakopi, in Melos, which remains unfinished. Meanwhile, the Mycenæologues can discuss the results of the energetic exploring work of the last decade, and books such as Prof. Burrows's recently published "Discoveries in Crete," or articles like that of Dr Mackenzie on "Cretan Palaces and the Ægean Civilisation," which appears in this volume, will help us to understand these results better.

Dr. Mackenzie's article continues his discussion of the contingent results of the excavations at Knossos and Phaistos, which commenced in last year's "Annual." In the continuation he passes from architectural evidence to a discussion of various theories as to the origins of Ægean culture, in which

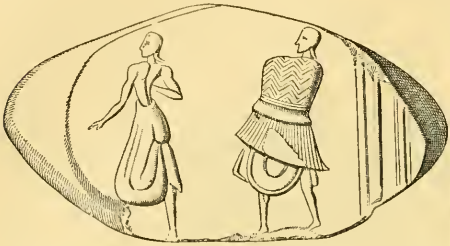

FIG. 1.—Cretan seal-impression, showing Minoan civil and military costume; waistcloth and armour. From the "Annual of the British School at Athens."

he rightly criticises and dismisses the revived Carian theory of Dr. Dörpfeld, and urges his own view and that of Dr. Evans, which is shared by many others, apparently by Prof. Burrows, and certainly by myself (see King and Hall, "Egypt and Western Asia in the Light of Recent Discovery," p. 128), that the Ægean civilisation came from Africa, and was akin in origin to that of Egypt. I mention that this view is held by me, because Dr. Mackenzie credits me in his article with believing rather that Ægean culture came from Asia. He says:—"The designations 'kleinasiatisch' and Asianic, as well as other statements in the passage cited (*Journ. Hell.*

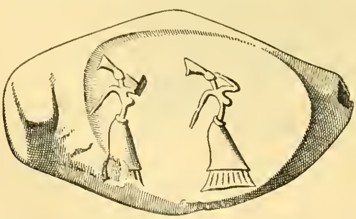

FIG. 2.—Cretan seal-impression, showing Minoan female costume; skirt developed from waistcloth. From the "Annual of the British School at Athens."

Stud., xxv., 323) would seem to indicate an underlying belief on Mr. Hall's part that the primary movement of the Ægeo-Pelasgian people was from an initial centre of departure somewhere in Asia." But, as a matter of fact, I agree entirely with Dr. Mackenzie. The words "kleinasiatisch" and Asianic have been used by me in reference to the pre-Hellenic languages of the Ægean merely because they are so used by the philologists Kretschmer and Fick; and their sole reason for using such terms is that the only later representatives of these languages which are at all well known were spoken in Asia Minor. Prof. Fick may regard these tongues as being of Asiatic origin. Dr. Mackenzie says:—"Even Fick continues to behold one last vestige of the same oriental mirage. The initial racial movement which led to the Ægeo-Pelasgian culture would, according to Fick, have to be assigned a starting-point at some centre in Asia beyond the Hittite country." But I do not, and I think I may reasonably protest against having non-existent "underlying beliefs" assigned to me, in view of the following passage in the same article that Dr. Mackenzie quotes (*J.H.S.*, xxv., p. 337), the meaning of which seems to me perfectly clear:—"If we were to suppose that the prehistoric Greek and the Egyptian civilisations had a common origin back in the darkness of the Age of Stone, that they were twin cultures of the same Mediterranean stock, the one having developed, however, amid the diverse isles and changing seas and skies of the Ægean, the other on the monotonous banks of the Nile, we can see how

FIG. 3.—The Excavations at Sparta; piers of the Roman theatre built in the court of the sanctuary of Artemis Orthia. From the "Annual of the British School at Athens."

the northern culture would naturally show greater freedom and variety, often running off into mere bizarrerie, but as often exhibiting something of that spirit which we, knowing it in the renascent Aryanised civilisation of the later day, call 'Greek.'"

From this I think it is clear that I do not believe in an Asiatic origin for the Ægean culture, and that I do believe in an African origin for it is shown by the passage, already referred to, in Mr. King's and my book (originally published in 1905 as the final volume of an American series), in which I say:—". . . We are gradually being led to perceive the possibility that the Minoan culture of Greece was in its origin an offshoot from that of primeval Egypt, probably in early Neolithic times." One of the things that has always disposed both others and me to believe an African origin for it is the scanty costume worn by the Mycenæans, which has a decidedly southern appearance. Dr. Mackenzie is perhaps the first to direct attention to this point in print, and rightly insists upon its importance, elaborating it at length in this article. On the other hand, we must not forget that such a south-to-north migration, from a warmer to a colder climate, is an unusual proceeding in the history of mankind.

Returning to the excavations at Sparta, we see from the articles dealing with them how important this phase of the school's work is proving to be. The identification of the site and discovery of the remains of the temple of Artemis Orthia, where the well-known Spartan flagellation of the boys took place in honour of the goddess, is a great feather in the caps of Prof. Bosanquet, Mr. Dawkins, and their assistants. The discovery of a regular stratum of early votive offerings, chiefly archaic bronzes of the Olympia type, but in some ways more interesting than those, is an important event, as it adds considerably to our knowledge of archaic Greek art, especially in that peculiarly inartistic and philistine place, Sparta; and the many inscriptions of Roman date throw light, not only on the flagellation ceremony, but generally on the course of life in Roman Sparta. In publishing these inscriptions, Mr. H. J. W. Tillyard insists in every case on adding a Latin translation, which is perfectly unnecessary, and savours of scholastic pedantry. If we are to have translations, let them be in English if the commentary is English.

We are unable to devote more space to the discussion of the Spartan discoveries, owing to the claims to notice of much other interesting matter in this volume of the "Annual." Also, it is perhaps best to postpone further comment until next year, when the work will have been further advanced.

Of these other articles, all are of interest and many of importance, with the exception of a note on "Boats on the Euphrates and Tigris," which seems hardly appropriate to the "Annual of the British School at Athens," and contains no new information; we have known all about *keleks, shahtûrs* and *kûfas*, and have compared them with Herodotus, i., 194, since the days of Rawlinson and Layard.

Of the other articles, perhaps Mr. Droop's and Mr. Dickins's are the most "geistreich." Mr. Droop on Cretan geometric pottery is illuminating, and Mr. Dickins's article on "Damophon of Messene" is an example of good archæological criticism, on which the author may be congratulated. The travel articles by Messrs. Dawkins, Wace, Hasluck and others are interesting, as usual, and we welcome a contribution by a native Cretan archæologist, Dr. Xanthoudídes, who speaks our language, and, apparently, writes it as well. Finally, Mr. Traquair contributes to our knowledge of the deeply interesting period of the Frankish domination in the Morea, with an article on the mediæval fortresses of Laconia, which will interest heralds as well as archæologists.

H. R. HALL.

THE FUTURE WATER SUPPLY OF LONDON.

IN an interesting paper on "London's First Conduit System," just published in the Transactions of the London and Middlesex Archæological Society, Dr. A. Morley Davies gives an account of the lines of pipes which were laid in the thirteenth and succeeding centuries to carry water to London from springs in the gravel at Paddington, Marylebone, and other rural districts. At a later date, to meet the growing wants of London, the great engineering effort of the New River was undertaken, and later still deep wells were driven into the chalk, and the Thames was tapped above Teddington Weir by several private companies. The unification of the London waterworks under one comprehensive and representative Board which bought out the old companies is so recent that it is almost surprising to find how soon the organisation of the Board has been perfected and its members set free to consider the tremendous problem of the future water supply of London.

A good many years ago much was heard of the necessity for obtaining a totally new supply of water for London from a pure and distant source which should be beyond the suspicion of impurity and capable of supplying the highest parts of the metropolitan area by gravitation. The sentimental argument that the water companies pumping from the Thames and Lee had to purify a raw material which has sometimes been described as "diluted sewage" is one which cannot fail to appeal to the imagination of every water-drinker, despite the reassuring result of the supreme test—the death-rate of London. But the restrictive activity of the Thames Conservancy and the discovery of the remarkable action on raw water of storage and thorough filtration have robbed the argument of its old force, while the exhaustive bacteriological examination of the raw and filtered water by Dr. Houston and his staff in the Metropolitan Water Board's laboratory has satisfied even those who heartily dislike lowland rivers as a source of water supply that the safeguards in the case of London are adequate to ensure purity.

The sufficiency of the supply is another matter, and on this point the Water Board, after prolonged discussion at two meetings, came to a decision as to their future policy on December 6. The Works and Stores Committee prepared a careful report reviewing the situation which, after amendment, was adopted. The whole subject of London water supply had been gone into by two Royal Commissions in recent years, one under Lord Balfour of Burleigh in 1892, the other under Lord Llandaff in 1897, and the committee's report does not repeat the details elicited by those inquiries. It is noted, however, that the average daily supply to London in 1881 was 143,821,000 gallons, or 33·20 gallons per head for a population of 4,331,600, while in 1906–7 the average daily supply was 225,000,000 gallons, or 32·84 gallons per head for a population of 6,851,000. Of the present daily supply of 225,000,000 gallons, 57 per cent. comes from the Thames, and the remainder in nearly equal proportions from the Lee and from wells or springs, the actual figures being:—

	1906–7	Maximum
From the Thames	128,842,695 ...	300,000,000
,, ,, Lee	44,150,290 ...	52,500,000
,, wells in Lee Valley, Kent, &c.	51,355,797 ...	67,500,000
,, Hanworth gravel beds ...	564,008 ...	—
,, Hampstead and Highgate ponds	87,893 ...	—
Total	225,000,683	420,000,000

The maximum column gives the figures which the Balfour Commission held to be the greatest average daily yield of the whole district.

The total amount of water which the Board can abstract from the Thames in existing conditions is 228,500,000 gallons per day, and even this amount cannot be obtained until additional storage reservoirs have been constructed. The maximum supply to be relied upon from sources other than the Thames is estimated by the chief engineer to the Water Board at 120,000,000 gallons per day, the total available being thus 348,500,000 gallons per day.

It is estimated that by 1941 the population to be supplied by the Board will be 12,000,000, and in 1960 16,286,000, and, assuming a consumption of thirty-five gallons per head, this means 420,000,000 gallons in 1941, and 570,000,000 gallons in 1960. Of the various sources of supply, that from the Thames alone is capable of considerable expansion, and in 1960 it is estimated that 450,000,000 gallons per day may be taken from that river. In order to admit of this expansion, immense storage reservoirs would require to be constructed; the amount of storage necessary in 1916 would be 6,436,000,000 gallons, in 1941 as much as 27,276,000,000 gallons, and in 1960 the prodigious amount of 54,059,000,000 gallons, the necessary storage increasing at a greater rate than the supply. The chief engineer believes that 450,000,000 gallons is the limit which could be taken economically from the Thames in any conditions.

The works at present in existence or authorised will suffice for the supply of London until 1917, and to provide the additional works required at that date it will be necessary to approach Parliament for new powers in 1910. The new scheme which has been definitely adopted as the policy of the board is to develop the supply from the Thames valley, and to trust to that as sufficient for the next fifty years, but at the same time to acquire powers for securing a supplemental source of supply to be utilised when the existing sources can no longer be developed economically. In the report as issued reference is merely made to "a distant source" being necessary fifty years hence, but in the debate the source was referred to plainly as Wales. It is remembered that before the creation of the Metropolitan Water Board the London County Council as water authority developed a scheme for supplying London with water from Wales in competition with the companies, and it was proposed in the debate on the report before the Water Board to proceed forthwith with a Welsh scheme, but a very large majority agreed to endorse the recommendations of the report in this particular. The three important resolutions as amended in another particular and adopted are as follows:—

"(a) That in the opinion of the Board it is desirable to seek Parliamentary powers enabling them to provide additional supplies from the Thames for as long a period as is economically practicable.

"(b) That as the increase in population will eventually render resort to some other source than the Thames watershed imperative, the Board view with great alarm the increasing tendency of authorities throughout the kingdom to appropriate water-supplying areas for their particular use, and in these circumstances desire to urge upon Parliament the necessity for regulating the appropriation of water-supplying areas, so that the needs of the metropolis as well as of other populous places may receive due consideration.

"That a copy of the foregoing resolution be sent to the President of the Local Government Board, and that he be asked to receive a deputation from the Board on the subject; and further, that in the event of such request being granted, the Works and Stores Committee be authorised to make all necessary arrangements with regard to the deputation.

"(c) That it be an instruction to the Works and Stores Committee to prepare and submit to the Board as early as practicable a scheme to give effect to the foregoing resolutions."

The Metropolitan Water Board is the largest and most important water authority in the United Kingdom, being responsible for the supply to one-sixth of the population of the British Isles. The distribution of rainfall, on which water supply depends immediately or ultimately, is, speaking broadly, the inverse of the distribution of population. Taking the part of England and Wales south of the Trent, it may be said that most people live in the Thames valley, while most rain falls in Wales. Much rain falls also on Dartmoor, Exmoor, and in the Lake District, all of them distant and unpeopled places on which the eyes of nearer populations have been turned for some time. It is the custom of Governments to assume control of the distribution of natural treasure and to regulate the pegging-out of claims for hewing out gold or diamonds, and the Water Board now proposes to ask for the extension of this principle to the drawing of water for great communities. The suggestion is not new, but it will none the less meet with keen opposition, for the large towns with great and distant water supplies are usually permitted and sometimes compelled by Parliament to sell surplus water to the communities along the track of their aqueducts, and hence municipal foresight may involve taking thought also for possible interference with spheres of interest.

It is interesting to compare the proposed appeal to Government to keep a place in the struggle for water-yielding grounds for the supply of London half a century hence with the arguments employed by Mr. Urquhart A. Forbes in a paper on "The Water Supply of the United Kingdom" in the October number of the *Quarterly Review*. Mr. Forbes urges the appointment of a central water board for the country with subordinate watershed boards in order to check the depredations of the great towns on the upper reaches of rivers, and to ensure the maintenance of the lower streams in a condition fit for navigation and fishing. It must not be forgotten that rivers not only water the land, but drain it as well, and to the mind detached from all municipal or commercial schemes it appears self-evident that the same channel should not be required to act both as an aqueduct and as a sewer. On the other hand, it is an acknowledged fact that the insertion of a properly proportioned artificial lake in the upper waters of a river benefits that river by checking floods in wet weather and maintaining a good flow in dry weather, while it enables a permanent and pure supply to be drawn for the uses of a distant population. To the scientific mind the surprising thing is that steps have not been taken long ago to gauge the flow of all the rivers in the country and to establish rain gauges in remote and uninhabited places where the treasure of the heavens descends in fullest amount. Not until this has been done can the alliterative dictum of Mr. John Burns—"Rain to the rivers, sewage to the sea"—become an effective mandate.

NOTES.

The Nobel prizes, of the value of nearly 7700*l*. each, were presented at the Academy of Sciences at Stockholm on Tuesday. In science, the prizes were awarded as follows:—physics, Prof. Michelson, University of Chicago; chemistry, Prof. Buchner, University of Berlin; medicine, Dr. Laveran, Pasteur Institute, Paris.

The Glasgow Corporation has decided to confer the freedom of the city on Lord Lister.

A telegram from Largs states that Lord Kelvin has not been well for more than a fortnight, and has been confined to his bed. His condition on Tuesday night had improved.

Mr. J. D. Rockefeller has just given an additional sum of more than 520,000*l*. to the Rockefeller Institute for Medical Research in New York, to be held as an endowment the income of which is to be used at the discretion of the management.

The death is reported, in his seventy-ninth year, of Dr. Asaph Hall, professor of astronomy at Harvard since 1895. Prof. Hall received an elementary-school education in his boyhood, and worked for some time at farming and carpentry. In 1857 he became an assistant at Harvard Observatory, which he left in 1862 to enter the service of the Naval Observatory of the United States.

AN International Congress of Low Temperature Industries will be held at Paris for the first time in June, 1908. The general effects of low temperatures and their use in connection with food, horticulture, mines, metallurgy, commerce, and transport are to be discussed. Full particulars may be obtained from the secretary to the congress, 10 rue Poisson, Paris.

DR. J. COSSAR EWART, F.R.S., commenced a course of twelve Swiney lectures on geology in connection with the British Museum (Natural History) on Friday last, December 6. The subject of the lectures, which are being delivered on Mondays, Fridays, and Saturdays, at 5 p.m., in the lecture theatre of the Victoria and Albert Museum, South Kensington, is "Horses of the Past and Present." The lecture to-morrow (Friday) will be on the fossil horses of Central Europe compared with Prejvalsky's horse. Admission to the course is free.

THE Duke of Argyll, honorary president of the Franco-British Exhibition, the Earl of Derby, president, the vice-presidents, and the executive and finance committees are this afternoon giving a reception in the exhibition grounds, to be followed by an inspection of the progress of the works.

THE annual conversazione of the Royal College of Science and Royal School of Mines will be held in the new buildings of the college on Wednesday next, December 18. Many interesting exhibits will be shown in the various departments, and Mr. G. S. Newth will deliver a popular lecture on "Coal-mine Explosions."

THE annual meeting of the British Science Guild will be held at the Mansion House on Wednesday, January 15, at 4.15 p.m. The Lord Mayor has consented to preside and to become one of the vice-presidents of the Guild. Mr. Haldane, the president of the Guild, and other gentlemen will address the meeting. Steps are being taken by the Guild to bring the proposals for legislation for the prevention of the pollution of rivers before many societies and local bodies.

WE are requested to make it known that a meeting will be held under the auspices of the Essex Field Club on Saturday, December 14, at the Essex Museum, Stratford, for the discussion of rivers' pollution from the naturalist's point of view. The subject will be opened by Prof. Meldola, F.R.S., and spoken to by Sir William Ramsay, K.C.B., F.R.S., Mr. E. B. Barnard, M.P., Sir Alexander Pedler, F.R.S., Mr. William Whitaker, F.R.S., Dr. Thresh, and other gentlemen well acquainted with the question of water supply. All interested in the matter are invited to attend. Mr. W. Cole, Buckhurst Hill, Essex, will be glad to send cards.

A PROPOSAL made to the Public Control Committee of the London County Council by Signor D. Maggiora to apply the process of discharging cannon of special construction, known in Austria as weather shooting, "to prevent the formation of fog or to disperse it in case it is already formed, and also to disperse and destroy all clouds, and to prevent rain, hailstorms, lightning, and thunder," has been under the consideration of the Council. It was referred to the director of the Meteorological Office for report. The proposal is even more ambitious in its scope than its predecessors of more or less similar character in other countries of the old or new world. As might be expected, Dr. Shaw's report, based largely upon Prof. Pernter's article in the *Meteorologische Zeitschrift* of March last, and on official reports of the Vienna Meteorological Office, is entirely unfavourable, and the County Council has therefore not been asked to vote money for the proposed experiments.

THE Brent Valley Bird Sanctuary consists of a wood, nineteen acres in extent, which comes into the London postal district. About eighty species of birds have been seen in or near the enclosure, while nearly half that number are known to have bred within it; and for four years a number of members of the Selborne Society and other lovers of natural history have with their own hands maintained the fences and brought them into a state of greater efficiency, or have contributed towards the wages of temporary watchers. Much more should be done, and the committee has therefore made an appeal for annual subscriptions from people who are interested in birds, so that a permanent custodian may be appointed. Subscriptions should be sent to Mrs. Webb, Odstock, Hanwell, W., honorary secretary of the committee and of the Brent Valley branch of the Selborne Society.

AT a meeting of the epidemiological section of the Royal Society of Medicine on December 2, papers were contributed by Dr. Haffkine, on the present methods of combating plague, and Dr. Ashburton Thompson, of Sydney, N.S.W., on protection of India from invasion by plague. Dr. Haffkine considers that the following propositions are now more or less generally recognised, viz. that (1) plague is what has been termed, in a general sense, a disease of locality; (2) it is contracted principally at night; and (3) the part which man plays as direct agent in its propagation is a more or less subordinate one. After discussing such measures as desertion of the locality, disinfection, and rat destruction, the conclusion was arrived at that the ultimate method of combating the bubonic plague in the areas in which it becomes endemic is that of conferring on the population immunity from the disease by means of an artificial treatment. Dr. Ashburton Thompson, in his paper, said the fundamental *data* acquired in the investigations at Sydney are that (1) the epidemic spread of plague occurs independently of communication of the infection from the sick, consequently the infection of plague spreads by means which are external to man; (2) the plague-rat is harmless to man, but is, nevertheless, the essential cause of epidemics; and (3) the intermediate agent between rat and man (and between rat and rat) is the flea. The infection of man is most usually contingent on his being within buildings together with plague-rats.

WE learn from the *Lancet* that Prof. Alfonso Sella, professor of experimental physics in the Royal University of Rome, died on November 25 at forty years of age. From an interesting obituary notice by the Italian correspondent of our contemporary, we extract the following particulars of Prof. Sella's scientific career. Prof. Sella inherited from his father, Quintino Sella, one of Italy's greatest statesmen, a love of science, abstract and applied, which carried him with special distinction through the mathematical and physical curriculum of the University of Turin. Like his sire he took his annual holiday in the Alps, where, in his seventeenth year, he was the first to scale the summit of the Dent-du-Midi; and he found another pastime in aëronautic adventure, a field in which he had many followers, in conjunction with whom he founded the "Società Aeronautica Italiana." For the ten years between 1889 and 1890 he acted as assistant to the Senator Pietro Blaserna in the Roman "Istituto Fisico," after which he was made professor extraordinary of experimental physics in the University. From that post, after a year's success in the class-room and the laboratory, he was promoted ordinary professor of the same subject, giving also post-graduate instruction (the so-called "Corso di Perfezionamento") to those students who were to make pure and applied physics the business of their lives. His scientific papers, read and discussed before various scientific congresses and societies, were numerous and important, always rich in independent speculation and research. Among these may be mentioned his study on "L'Influenza dei Raggi Röntgen e della Luce Ultra-Violetta sulle Scintille" and his "Ricerche sulla Radio-attivita dell' Aria." To him, in concert with Guglielmo Romiti, professor of anatomy and embryology in the University of Pisa, Italy owes her "Association for the Advancement of Science," organised on British lines and convened for the first time in September last at Parma, where it achieved a gratifying success. A committee, composed of Profs. Blaserna, Cerruti, Reina, Volterra, and Tonelli, the Rector of the University, is taking steps to place a memorial of Prof. Sella in the Istituto Fisico in the form of a bust in marble. Subscriptions should be sent to Prof. Reina at the school of applied engineering of the University.

THE second annual general meeting of the National League for Physical Education and Improvement was held on December 6 under the presidency of the Bishop of Ripon. The report of the executive council stated, in regard to the medical inspection of school children, that it will be possible, now a medical department has been established, to advise the Board of Education that under efficient supervision and control the best uniform system may prevail and be carried out under conditions sufficiently elastic to suit the requirements of different districts. The knowledge and experience gained in other countries are sure to have important results in their bearing upon the work of the league. On the question of pure milk, a joint committee of the league and the National Health Society, on which were members of the Infants' Health Society and other similar organisations, the Royal Commission on Tuberculosis, and the Royal Veterinary College, has now been formed, and has drawn up a preliminary report, in which it is recommended that the periodical veterinary inspection of all cows, the milk of which is being offered for sale for human consumption, should be made compulsory throughout the United Kingdom. The Milk Committee is now preparing recommendations with regard to milking and handling, transport and distribution.

AN account of an expedition in the Himalayas, which included the first ascent of Trisul (23,406 feet), has been given to Reuter's representative by Dr. T. H. Longstaff. The party consisted of Major C. G. Bruce, Mr. A. L. Mumm (late hon. secretary to the Alpine Club), Dr. Longstaff, and guides. Originally the object of the journey was to attempt the ascent of Mount Everest from the Tibetan side, but for political reasons this was found to be impossible. It was decided to go to the central Himalayas, to Garhwal, and from that point attempt Trisul. After two marches along the Trisul glacier the party started up the snow slopes of the mountain on June 7, and that evening reached a height of 20,000 feet. During this period Dr. Longstaff had by far the worst experience in his foreign travels. On the third day the party descended to the foot of the mountain, and again camped at 11,000 feet. On June 11 Dr. Longstaff and his guides marched rapidly round his old track, camping the same afternoon at a height of 17,450 feet. On the following morning the party started at 5.30 a.m., and five hours later reached its highest camp of 20,000 feet. As dangerous crevasses half covered with snow and ice were ahead, the explorers roped themselves together, and at noon reached 21,000 feet. The party now followed the narrow N.N.E. ridge of Trisul, which leads straight to the summit. At 4 p.m., after ten hours' continuous climbing, the summit was reached. The cold was so bitter that it was only possible to remain for fifteen minutes. To the west the view was one of extraordinary vastness, as the horizon extended over the whole of the lower Garhwal and the snow peaks beyond. To the north lay the Tibetan frontier, obscured by rolling masses of black cloud. To the east were the frowning cliffs of Nanda Devi and its untrodden glaciers. The party now turned its attention in the direction of the Tibetan frontier, and during July explored glaciers to the east and west of Kamet (25,450 feet), reaching on one occasion an altitude of 20,000 feet on the mountain. In August and September Dr. Longstaff explored the valleys to the south and west of Trisul, while Major Bruce and Mr. Mumm made more ascents in Kashmir.

THE report of the council of the Royal Agricultural Society, presented at the annual general meeting held on Wednesday, December 11, states that the frosty weather in the spring caused injury to white clover, broad beans, and wheat, and the wet summer and autumn led to extensive injuries by parasitic fungi. Many investigations have been made into these diseases. Another unobserved enemy to the potato, *Stylanus capitatus*, has been proved by experiment to attack the living plant. A hawthorn hedge was seriously affected by *Botrytis cinerea*. Bacterial injuries to potatoes, broad beans, and oats have been investigated. Scouring in stock was found to be due to the mould developed on the feeding cake. In the zoological department nothing of special importance was reported, except the recurrence of the pygmy mangold beetle, which is probably a more frequent and serious pest to mangold than has hitherto been supposed. With the abnormally wet summer came a large number of complaints of caterpillar attack, and in many instances the caterpillars were of species not usually seriously troublesome. Later again, certain pests generally associated with particularly dry seasons began to be complained of, as the results of the continued fine weeks of the late summer and autumn. The council, at its last meeting, considered a suggestion that the Board of Agriculture should be urged to schedule tuberculosis, and, after discussion, the following recommendation of the veterinary committee was unanimously adopted:—"That in the event of the promotion of legislation dealing with the question of tuberculosis and other diseases of cattle, the council of the Royal Agricultural Society of England is of opinion that any regulations for dealing with this question should be issued by the Board of Agriculture and not to any other department." A discussion ensued as to the desirability of forming a national representative body to safeguard, so far as possible, the interests of agriculturists in connection with any measures to be adopted for dealing with the question of tuberculosis in cattle, and it was resolved:—"That a committee be formed to communicate with other societies for the purpose of watching the interests of agriculture, in view of possible legislation with regard to the tuberculosis question." The society's show will be held at Newcastle-upon-Tyne in 1908, and at Gloucester in 1909.

THE Hon. Walter Rothschild has recently received half-a-dozen specimens of the Californian elephant-seal (*Macrorhinus leoninus angustirostris*), a race which had for some time been regarded as extinct. The specimens were obtained from Guadaloupe Island, off the coast of Lower California, and before they were shot the collector was fortunate enough to obtain several photographs of them as they lay on the beach, which consists of huge boulders of volcanic rock, some black and some white, with intervening stretches of sand. Enlargements of these photographs have been presented by Mr. Rothschild to the British Museum (Natural History). The Californian elephant-seal is somewhat smaller than the typical elephant-seal of Heard Island, the Crozets, and other islands in the southern ocean, but can scarcely be regarded as more than a local race. With the exception of a specimen destroyed in the late San Francisco fire, adult male examples of this animal have hitherto been unrepresented in museums. Two of Mr. Rothschild's specimens are being mounted for the museum at Tring by Rowland Ward, Ltd.

AMONG the papers in vol. lxxxviii., part ii., of *Zeitschrift fur wissenschaftliche Zoologie* is one by Dr. M. Nowikoff, of Heidelberg, on the dorsal sense-organs of chitons, with remarks on the structure of the shell in those molluscs. Certain tropical chitons, it will be remembered, possess eyes on the dorsal surface of the shell, but all, it appears, have a canal-system within the shell itself which is likewise sensory in function. Both the eyes and the canal-system are described in detail by the author, who also directs attention to the peculiarities presented by the fibrous layer connecting the eyes with the epidermis. The dorsal eyes are of two types, one characteristic of the subfamilies Toniciinæ and Liolophurinæ, and the other restricted to certain species of chiton itself. It is remarkable that in certain species, especially *Tonicia chiloensis*, the dorsal eyes are attacked, and apparently destroyed, by an alga, which develops within the substance of the shell.

THE Health Committee of Liverpool has issued a report (published by C. Tinling and Co., Ltd.) on investigations undertaken by Mr. R. Newstead, of the School of Tropical Medicine, Liverpool University, on the habits, life-history, and breeding-places of the house-fly, as observed in the city. The chief breeding-places were found to be in pits for the store of stable manure, fermenting heaps of hop refuse, and ash-pits containing fermenting vegetable matter, the infection being equally as great in closed as in open receptacles. Although the ordinary disinfectants appear to be of no avail in checking the development, barndoor fowls are of great value in reducing the numbers of grubs and pupæ. The period of development (which in ordinary circumstances may last from three to five weeks) is reduced by the heat of fermentation to a minimum of ten days, and this accounts for the fact that in ash-pits emptied weekly in summer no flies are produced. The emptying of these and other receptacles for refuse at intervals of seven days in summer is therefore recommended; while, in connection with other remedial measures, attention is directed to the importance of early removal of fermentable matter from streets and other public places.

THE Board of Agriculture and Fisheries has issued an order, the short title of which is the "American Gooseberry Mildew (Prohibition of Importation of Bushes) Order of 1907," under which the landing in Great Britain of any gooseberry bush or currant bush brought from any place out of Great Britain is strictly prohibited. The order also provides that if, on any examination, an inspector finds any bush which is affected with American gooseberry mildew, he is forthwith to communicate the fact to the Board, and serve on the occupier of the premises on which the bush is found a notice prohibiting, until the notice is withdrawn by a like notice, the removal of any gooseberry or currant bush from those premises.

AMONG the papers in the September issue of the Proceedings of the Philadelphia Academy, reference may be made to one by Dr. H. A. Pilsbry on the barnacles of the genus Megalasma—a genus established on the evidence of a specimen dredged during the cruise of H.M.S. *Challenger* in the Philippine archipelago. In the author's opinion the genus should, however, be taken to include one sectional group of the numerous species hitherto included in the nearly allied Pœcilasma.

EXTERNAL parasites infesting domesticated animals in India form the subject of a special investigation by the entomological division of the Department of Agriculture. The first results of the investigation, dealing with ticks, are published in Bulletin No. 6 of the department in question. According to the author, Mr. C. Warburton, over the greater part of India the ticks infesting domesticated animals belong for the most part to four species only. Two other species may, however, occur sporadically in some numbers, but the occurrence of any other type is so rare as to be of no economic importance. Means of identifying the six species are given in the paper.

THE current number of the *Annals of Tropical Medicine and Parasitology* contains articles on a variety of matters bearing directly or indirectly on the subjects named in the title. An important memoir by Mr. J. E. Salvin-Moore and Dr. A. Breinl breaks new ground, and will excite much interest, perhaps also some controversy, amongst the many investigators of this important class of parasites. Valuable contributions upon African parasitic protozoa, and upon *Spirochaeta duttoni*, the parasite of African tick fever, are furnished by the late Dr. J. L. Dutton, Dr. J. L. Todd, Dr. E. N. Tobey, and by Dr. A. Breinl respectively. It looks at first curious to see included in this journal two almost purely zoological memoirs on Cyclopidæ from the Gold Coast, by Dr. W. M. Graham and Dr. G. S. Brady, but Cyclops comes into indirect relation to tropical medicine by acting as a host for the guinea-worm. Dr. C. W. Branch writes on yaws. The contents of the journal bear testimony to the broad scientific spirit in which the Liverpool School of Tropical Medicine carries on its work.

PROF. E. DE JANCZEWSKI has rendered a service to the botanical community by the publication in vol. xxxv., part iii., of the *Mémoires de la Société de Physique et d'Histoire naturelle de Génève* of a valuable monograph on the genus Ribes, embellished by some excellent illustrations. It is particularly interesting to find that the author has examined numerous living specimens, and has cultivated many of the species. Six subgenera are demarcated, of which two are characterised by the production of diœcious flowers. In the subgenus Parilla the flowers bear sterile organs, but in the species of the subgenus Berisia the staminate flowers have no distinct ovary, nor do the pistillate flowers produce pollen. The chief centres of the genus are found in North America and in China, except for the species of the subgenus Parilla, that are almost confined to South America. Eighteen hybrids are described, most of them representing crosses between species in the same subgenus.

FOUR parts, numbered 16 to 19, of the "Materials for a Flora of the Malayan Peninsula," have been published as an extra number of vol. lxxiv. of the Journal of the Asiatic Society of Bengal. Three numbers appeared in

1905; the fourth has recently been issued. Apart from the account of the genus Psychotria, that concludes the Rubiaceæ, these numbers contain the orders—following the sequence of Bentham and Hooker's system—Valerianeæ to Loganiaceæ. The authors, Sir George King and Mr. J. S. Gamble, have assumed responsibility for separate orders in addition to certain others undertaken by Colonel D. Prain. For the twenty-eight orders collated, the species amount to 686, of which 190 are new to science. The additions are numerous in the Myrsinaceæ and Sapotaceæ, notably in the genera Ardisia and Bassia, also in the genus Diospyros. A new genus, Pernettyopsis, and five species of Rhododendron, form an increment to the Ericaceæ. Many of the genera of the Apocynaceæ are very fully represented in Malaya, *e.g.* Urceola, Anodendron, and Willughbeia. The Sapotaceæ and Apocynaceæ are rich in rubber, gutta, and other economic species.

Three memoirs have recently been issued by Dr. Leather, of the Agricultural Research Institute, Pusa (India). One, on the composition of Indian oil seeds, gives the percentage of oil in eleven different varieties, including cotton-seed, linseed, and others less known here. Among other interesting points, it is stated that Indian linseed contains about 40 per cent. of oil, and is consequently richer than seed grown elsewhere. Further investigations of oil seeds are much needed on account of the commercial value of the oil and the agricultural value of the residue left after extraction. In another memoir a description is given of the pot culture house at Pusa; the only novel point is the method of watering. The soils under investigation cracked and caked if water was poured direct on to the top; it was therefore allowed to diffuse out from a porous pot placed in the soil. This method is commonly employed to irrigate trees in parts of India, a porous spherical vessel being sunk in the ground near the root of the tree and kept full of water. The last memoir deals with experiments on the availability of phosphates and potash. The general result is that Dyer's citric acid method for determining phosphates is likely to be useful in examining Indian soils. This, indeed, might reasonably have been expected.

In the Journal of the Franklin Institute (vol. clxiv., No. 3) Dr. E. Goldsmith describes a meteoric stone which was seen to fall on April 30, 1906, on the New Jersey shore. On analysis the stone yielded 44·36 per cent. of iron, 42·80 per cent. of silica, 4·18 per cent. of alumina, 2·00 per cent. of nickel oxide, 1·90 per cent. of titanic acid, and 1·84 per cent. of carbon.

We have received from the author, Mr. J. P. Johnson, a pamphlet (Johannesburg, price 1s.) containing two short papers on the auriferous conglomerate of the Witwatersrand and on the antimony deposits of the Murchison range. The former, while containing little that is new, gives a concise review of the geology of the goldfield, and the latter contains a description of some interesting antimony ore deposits which appear to be impregnations of a bed of metamorphosed limestone. The antimony occurs as sulphide, altered at the surface into a yellow oxide and the hydroxide.

In the Journal of the Franklin Institute (vol. clxiv., No. 5) Mr. L. E. Levy gives an appreciative obituary notice of Prof. Angelo Heilprin, the eminent American geographer and geologist, who died on July 17. In 1876 he studied in London at the Royal School of Mines, where he gained the Edward Forbes medal. He was the author of numerous important works, the most interesting being "The Arctic Problem" (1893), which contains the story of the Peary Relief Expedition, which he organised. He lived but fifty-four years, yet within that brief period he accomplished work that would well suffice the compass of the longest lifetime.

An important report, compiled by Miss A. M. Anderson and Dr. T. M. Legge, has been issued on dangerous and injurious processes in the coating of metal with lead, or a mixture of lead and tin. The Blue-book also contains the results of an experimental investigation into the conditions of operating tinning workshops, which has been written by Mr. G. E. Duckering, one of His Majesty's inspectors of factories, who carried out the investigation. The most important of the suggested regulations set forth in the report is that no lead shall be used in the tinning of metal hollow-ware.

The president of the International Aëronautical Committee has sent us a summary of the places that took part in the scientific balloon ascents of July 22–27, and the heights reached, so far as at present known. This series of ascents was made in compliance with a suggestion by the recent Aëronautical Conference at Milan that a special effort should be made to obtain information regarding the conditions obtaining in the upper regions of the atmosphere on consecutive days; the results will be eventually published in detail by the Aëronautical Committee. About fifty places took part in the investigation, the extra-European ascents being at or near the Azores, Spitsbergen, Iceland, China Sea, Cairo, and the United States; at Simla unfavourable weather prevented experiments from being made. Twenty-five balloons were sent up in England and Scotland alone, and (so far as yet known) some of the balloons from Manchester reached the highest altitude attained in any of the ascents, viz. 21,500 metres. From Uccle (Brussels) a height of 21,140 metres was reached, and 20,000 metres near the Azores. We learn that nearly all the English balloons drifted to the eastward, and that the temperature records proved conclusively the existence of isothermal conditions above some 12,000 metres, thus confirming the interesting theory put forward by M. Teisserenc de Bort. We understand that similar special ascents extending over a week will probably be made next year, and that, through the efforts of Prof. Schuster, arrangements have been made by the University of Manchester for the kite station on Glossop Moor to be continued.

A clear and concise statement of our present knowledge of the masses of the electrons which play so important a part in electrical phenomena was presented to the Italian Physical Society in the form of a report on the subject by Prof. Levi-Civita at the recent congress at Parma, and is published in full in the October number of *Nuovo Cimento*.

After careful consideration of the various methods of determining the ratio of the electromagnetic to the electrostatic unit of electricity, Messrs. E. B. Rosa and N. E. Dorsey came to the conclusion, several years ago, that the most accurate were Maxwell's bridge method, in which a condenser rapidly charged and discharged replaces one of the resistances of a resistance bridge, and the method in which the charges or the discharges of a condenser rapidly charged and discharged are sent through one coil of a differential galvanometer, while a steady current from the charging battery is sent through the other coil. The October number of the Bulletin of the U.S. Bureau of

Standards contains an account of a determination they have made by the latter method, according to which the ratio for vacuo is $2{\cdot}9971 \times 10^{10}$, with an uncertainty not exceeding 1 part in 10,000. It is interesting to compare this result with the most probable value of the velocity of light, which, according to M. Weinberg's recent discussion of the measurements available, appears to be *in vacuo* $2{\cdot}9986 \times 10^{10}$, with an uncertainty not exceeding 1 part in 10,000.

A METHOD of preserving eggs by dipping them in recently boiled water at a temperature of about 110° F., then into boiling water, and afterwards into cold water, was described in an article in NATURE of November 28 (p. 84). In reply to an inquiry, the writer of the article states that the time during which the eggs are immersed in the water at 110° F. in this method should be about ten seconds.

THE Silica Syndicate, Ltd., of 82 Hatton Garden, has issued a new price-list of chemical apparatus made from transparent vitreous silica by their special process. The apparatus includes evaporating basins, beakers, crucibles, flasks, retorts, and test-tubes; the prices are about 75 per cent. lower than those ruling a year ago, and it is anticipated that as the demand grows for fused silica ware further reductions will become possible. We have had an opportunity of examining the various pieces of apparatus made by the syndicate, and have been struck by their wonderfully clear and homogeneous character as compared with that of silica ware made by other processes. They are, moreover, comparatively thin and light, a fact which makes them useful for many purposes for which coarser vessels would be unsuitable; crucibles of fused silica, for instance, can often be used in place of platinum crucibles. In spite of their thinness, the quartz vessels are very strong and tough, and much less liable to break than either ordinary or Jena glass; even if broken they do not splinter, but merely crack, so that they can easily be repaired by fusing the broken parts together. Such repairs are executed by the syndicate at a trifling cost. To those unacquainted with the properties of fused silica, the following points may be of interest. It does not crack when subjected to the most violent and sudden changes of temperature. It is not attacked by acids, with the exception of hydrofluoric acid, and is harder than ordinary glass. Its melting point is approximately that of platinum, whilst it has a coefficient of expansion of 0·00000059 per degree, that is, about one-seventeenth the value for platinum. So far as is at present known, it shows no tendency to devitrification.

A NEW catalogue of lantern-slides has been received from Mr. C. Baker, 244 High Holborn, W.C. The list contains slides suitable for the illustration of lessons or lectures on natural history, and includes many from photomicrographic negatives, as well as photographs taken from nature with an ordinary camera. Sets of slides have also been arranged to illustrate some leading books on microscopic objects.

MESSRS. J. H. DALLMEYER, LTD., inform us that they have recently appointed several new wholesale agents for their lenses and apparatus abroad. They state that British lens manufacturers, like British dry-plate manufacturers, are able to hold their own in foreign markets in face of high tariffs walls and severe competition. In the United States the duty alone amounts to 45 per cent. of the value of the goods, whilst Germany is the home of the keenest competitors of manufacturing opticians.

WE have received from Messrs. Siemens Brothers and Co., Ltd., two well-produced and conveniently arranged catalogues. One deals with thermoelectric pyrometers and temperature indicators and recorders which can be used for all processes in which the accurate determination of temperature between the limits of about −190° C. and 1600° C. is a necessary factor. The other supplies a descriptive account, with abundant illustrations, of a great variety of electro-medical apparatus. Among these attention may be directed to the patent tantalum X-ray tubes, which can be worked with the anti-kathode at red heat, and the induction coils with variable primary windings. Medical men and others should find the clear diagrams of assistance in understanding the characteristics of the apparatus described.

MESSRS. NEWTON AND CO. have sent us a copy of a descriptive lecture on the moon, illustrated by sixty lantern slides, arranged and prepared by Mr. R. Kerr. The notes upon the characteristic points of the various slides, all of which are from Messrs. Newton's collection, will enable anyone to give an interesting reading on our satellite without possessing special knowledge of astronomy. Another pamphlet containing notes on lantern-slides, intended for purposes of popular lectures, deals with general astronomy. This pamphlet is now in its fifth edition, and has been revised and enlarged. It comprises much information of an old-fashioned type, and can scarcely be considered as representing the work and results of modern astronomy; nevertheless, many instructive notes may be extracted from it. A more careful revision of the pamphlet would have prevented such errors as:—"Of the nature of this ring [of Saturn] . . . we are not acquainted"; 1006 instead of 1066 as the date of an appearance of Halley's comet; "Mr." Huggins for Sir William Huggins; and HB instead of Hβ.

OUR ASTRONOMICAL COLUMN.

PHOTOGRAPHS OF JUPITER'S SATELLITES VI. AND VII.—During the opposition of 1905–6 eighty-six photographs of Jupiter's sixth satellite were secured at the Greenwich Observatory, with the 30-inch reflector, between August 23, 1905, and February 15, 1906. Nineteen photographs of the seventh satellite were taken between October 22, 1905, and January 26, 1906. The opposition of 1906–7 was somewhat marred by bad weather, but on twenty-eight nights, spread over a period of 222 days, fifty-six photographs of the sixth satellite were obtained. Only on seven nights, during a period of eighty-seven days, were photographs of the seventh satellite secured, amounting to twelve in all. From these photographs the positions of the satellites were determined, and the results are shown graphically on two diagrams published in the Monthly Notices for November (vol. lxvii., No. 9, p. 561). The orbits of the four major satellites are shown for comparison, and the difference in the size of the orbits of the four inner and two outer satellites is very striking.

TEMPERATURE CONTROL OF SILVERED MIRRORS.—No. 122 of the Lick Observatory Bulletins contains a short paper by Dr. Heber D. Curtis on the temperature control of silvered specula. The writer discusses first the previous records of changes in the focal lengths of large specula, briefly referring to the experience of Profs. Keeler, Perrine, Hale, and Wright in this matter. He then describes a method of artificial cooling which he has tried, and found to be effective, with the 37-inch Mills reflector, which is being used by the D. O. Mills expedition to the southern hemisphere, of which he now has charge.

The large mirror has a clear aperture of 36·56 inches and a focal length of 17·46 feet, and, during his work with this instrument, Prof. Wright found that a progressive lengthening of the focal length, amounting to from fifteen to twenty-five millimetres, took place during the first four or five hours of each night's work, the drop in temperature being some 5° C. or 6° C. In the first place, Dr.

Curtis increased the ventilation apertures about the mirror so that about one-sixth of the area of the back of the mirror was directly exposed. This, apparently, had little effect, so a refrigerating machine was obtained and put into operation. The machine is of the anhydrous ammonia type, and is automatic in action. To cool the mirror the telescope is placed vertical, and a movable box brought into position to enclose the cooling pipes and the mirror end; two electric fans circulate the cooled air freely around the mirror. This operation is commenced about three hours before sunset, and when the thermometer shows a fall of 5° C. or 6° C. the case is removed, about forty minutes before sunset. No moisture forms on the silvered surface, which may be 3° C. or 4° C. below the temperature of the surrounding atmosphere when observations commence. This method has proved very successful, for focal changes are, as a rule, not noticeable, and scarcely ever exceed five millimetres. Dr. Curtis's account of his experiments also appears in the current number of the *Astrophysical Journal*, and is there illustrated by two photographs, the one showing the telescope and spectrograph, the second showing the wooden cooling chamber in position.

ORBITS OF SPECTROSCOPIC BINARIES.—From plates taken with the Mills reflector, the orbits of the spectroscopic binaries α Carinæ, α Pavonis, and κ Velorum have been determined by Dr. Curtis, and their elements are published in No. 122 of the Lick Observatory Bulletins. α Carinæ is a star of magnitude 3·5, and its spectral type is given as B3A in the Harvard classification. According to the elements now published, its period is 6·744 days, the velocity of the system is +23·3 km., and the length of the semi-major axis of the orbit is 1,960,000 km. For α Pavonis (mag. 2·0) the period is 11·753 days, the velocity of the system is +2·0 km., and the length of the semi-major axis is 1,170,000 km.; the orbit is nearly circular. The period of κ Velorum (mag. 2·6) is 116·65 days, the velocity of the system = +21·9 km., and the length of the semi-major axis = 73,200,000 km. All three stars are of the same type of spectrum.

MELLISH'S COMET, 1907*e*.—A new set of elements and an ephemeris extending to December 31·5 are given in Lick Observatory Bulletin No. 124 for Mellish's comet. The position for December 11·5 is α=0h. 12m., $\delta = +27° 2'$, about $1\frac{1}{2}°$ south-east of α Andromedæ, and the brightness is about one-third that at the time of discovery. The following positions are taken from the ephemeris:—December 23·5 (G.M.T.), α=23h. 56m., $\delta = +26° 30'$; December 31·5, α=23h. 52m., $\delta = +26° 30'$ (brightness = 0·09).

SOLAR PROMINENCES IN 1906.—Prof. Riccò's annual summary (1906) of the prominence observations made at Catania appears as an abstract from vol. xxxvi. (1907) of the *Memorie della Società degli Spettroscopisti Italiani.* The following are the mean values for the year:—daily frequency = 2·7, complete extension along the limb = 7°·5, height of prominences = 44″·2. As one would expect near the epoch of maximum, these values are nearly equal to those obtained in 1905. It is interesting to note that whereas the sun-spot frequency curve showed maxima in February and November, 1905, the prominence maximum appears to have been relatively retarded, the second greatest maximum recorded at Catania having occurred in March, 1906. Considering the heliographic latitude of the prominences in 10° zones, the principal maximum took place in ±20° to ±30°, as in 1905, but the secondary maximum was elevated ten degrees from ±60° to ±70° to ±70° to ±80°; this is another characteristic of the maximum epoch. Excepting the fourth trimestre, the number of prominences observed in the northern hemisphere of the sun was greater than that observed in the southern hemisphere, the numbers for the year being 284 and 185 respectively.

SEARCH EPHEMERIS FOR COMET 1907*a* (GIACOBINI).—Believing that comet 1907*a* might still be observed in large instruments or found on long-exposure photographs, Prof. Weiss publishes a search-ephemeris for this object in No. 4218 of the *Astronomische Nachrichten* (p. 300, December 2). The comet is now some 10 m. west of α Persei, and its estimated magnitude is 13·8.

PRIZES AWARDED BY THE PARIS ACADEMY OF SCIENCES.

Geometry.—The Francœur prize is awarded to Émile Lemoine, for the whole of his work in mathematics; the Bordin prize to F. Enriques and F. Severi jointly, the Vaillant prize being divided between J. Hadamard, Arthur Korn, Giuseppe Lauricella, and Tommaso Boggio.

Mechanics.—A Montyon prize is awarded to M. Cuënot, for his experimental studies on the flexure of rails; an exceptionally honourable mention to M. Petot, for his work on the theory of automobiles; the Poncelet prize to Colonel Renard, for his mathematical and experimental researches in mechanics, and for his contributions to aëronautics.

Navigation.—The extraordinary prize of six thousand francs is divided between M. Gayde (two-thirds) and J. Estève (one-third), the Plumey prize not being awarded.

Astronomy.—The Pierre Guzman prize is not awarded. T. Lewis receives the Lalande prize, M. Giacobini the Valz prize, and M. Gaillot the G. de Pontécoulant prize.

Geography.—The Gay prize is awarded to Jean Charcot, for his Antarctic explorations, the Tchihatchef prize being divided between Jacques de Morgan and Paul Crépin Bourdier de Beauregard.

Physics.—Lucien Poincaré receives the Hébert prize, for his book on modern physics; P. Langevin the Hugues prize, for his work on the mobility of gaseous ions and the properties of electrons; M. Mathias the Gaston Planté prize, for his work on terrestrial magnetism; Paul Villard the La Caze prize, for the whole of his researches in physics; and Pierre Weiss the Kastner-Boursault prize, for his experimental and theoretical work in magnetism.

Chemistry.—The Jecker prize is divided between MM. Blaise, Marcel Delépine, and Hamonet, and the Cahours prize between MM. Gain, Mailhe, and Guillemard. A Montyon prize (unhealthy trades) is awarded to M. Bonneville, for his discovery and manufacture of a cement in which metallic zinc replaces the red lead commonly used.

Mineralogy and Geology.—M. Martel is awarded the grand prize of the physical sciences, for his studies on underground waters, and J. J. H. Teall the Delesse prize, for his researches in petrography.

Botany.—The Desmazières prize is awarded to General E. G. Paris, for his "Index Bryologicus"; the Montagne prize to F. Guéguen, for his work on the lower fungi; the De Coincy prize to F. Gagnepain, for his work on the classification of the Zingiberaceæ; the Thore prize to M. Bainier, for his work on the lower fungi; and the de la Fons-Mélicocq prize to C. Houard, for his memoir on the parasitic deformations of plants in northern France.

Anatomy and Zoology.—Charles Alluaud receives the Savigny prize, for his work on the invertebrates of Upper Egypt and the adjacent portions of Africa.

Medicine and Surgery.—Montyon prizes are awarded to J. Henniquin, for his work on the treatment of fractures; C. Levaditi, for his researches on *Treponema pallidum*; and Maurice Villaret, for his researches in connection with urinary secretion. Mentions are accorded to A. Thiroux and M. d'Anfreville, for their memoir on malaria in Senegal; MM. Nicolle and Mesnil, for their memoir on the treatment of trypanosomiasis by the benzidine colours; and René Gaultier, for his memoir on the functional exploration of the intestine by analyses of the fæces. Gustave Martin, Georges Pécaud, Pierre Breteau and Paul Woog, A. Desmoulière, and M. Guisez receive citations in connection with this prize. J. Guiart and L. Grimbert receive the Barbier prize for their book on chemical, microscopical, and pathological diagnosis. The Bréant prize (interest only) is divided between MM. Vaillard and Dopter, for their researches on bacillary dysentery, and J. Ferran, for his work on the cholera bacillus. The Godard prize is given to Victor Nicaise, for his memoir on the indications and therapeutic value of total or partial nephrectomy in the treatment of hydatoid cyst of the kidney; the Baron Larrey prize to G. H. Lemoine, for his work on military hygiene; the Bellion prize to A. Chantemesse and F. Borel, for their memoir on the protection of the country from diseases introduced from abroad; the Mège prize to J. Castaigne and F. Rathery, for their work on the lesions of the convoluted tube of the kidney; and the Chaussier prize to A. Lacassagne, for his work on forensic medicine.

Physiology.—The Montyon prize in experimental physiology is divided between Maurice Nicloux and Denis Brocq-Rousseu, the former for his work on the physiological saponification of fatty substances, and the latter for his researches on the alterations of seeds, cereals, and forage. H. Bierry receives the Philipeaux prize, for his studies in cytoxines; Gaston Seillière the Pourat prize, for his memoir on the utilisation of the pentosans by the animal organism; M. Laulanié the La Caze prize, for the whole of his work in the field of general physiology, the Lallemand prize being divided between E. Régis and Étienne Rabaud.

Statistics.—A memoir on statistical methods and their applications, by Lucien March, is accorded the Montyon prize in statistics. J. A. Fleury receives a very honourable mention for his memoir on the statistics of the city of Rouen, and Dr. Conor an honourable mention for his memoir on hysteria in the army.

History of Science.—Prizes are awarded to Gino Loria and F. Brunet, F. de Mély being accorded a very honourable mention.

General Prizes.—Adolf von Baeyer receives the Lavoisier medal; MM. Blaise, Delépine and Hamonet, Berthelot medals; Charles Frémont, the Trémont prize; J. H. Fabre, the Gegner prize; Mmes. Beclard, Cusco and Ruck, the Lannelongue prize; Charles Nordmann and Jean Brunhes, the Wilde prize; MM. Gonnessiat and de Seguier, the Saintour prize; Pierre Duhem, the Petit D'Ormoy prize (mathematical sciences), J. Künckel d'Herculais, the Petit D'Ormoy prize (natural sciences); A. Cotton, the Pierson-Perrin prize; Léon Daum, the prize founded by Mme. la Marquise de Laplace; and Léon Daum, Georges Jean Painvin, Charles Marie Joseph Cambournac, and Louis Eugène Galatoire Malégarie, the prize founded by Félix Rivot.

The Leconte prize is not awarded this year.

THE JOURNAL OF THE ROYAL ANTHROPOLOGICAL INSTITUTE.

THE new volume of the Journal of the Royal Anthropological Institute is dedicated, on the occasion of his seventy-fifth birthday, to Prof. E. B. Tylor, of whom a fine portrait forms the frontispiece. The dedication dwells on his classical contributions to the science of anthropology—his "Researches into the Early History of Mankind" and "Primitive Culture"—works which enjoy the almost unique distinction of never having been superseded by the studies of later writers; on his career as professor of anthropology at Oxford, where, as the result of his teaching and personal initiative, a diploma course in the science has been established; and on the generous encouragement bestowed by him on the students of a younger generation. This compliment to a scholar who stands in the foremost rank is graceful and well deserved.

The president, Prof. Gowland, in his annual address continues his studies of burial mounds in Japan which were begun by his well-known paper contributed to vol. lv. of "Archæologia." Here he deals with the remarkable structures which cover the remains of the early emperors. Some of these are of enormous extent; one when first erected must have been not less than 1000 feet long and 600 feet broad, while in spite of denudation its summit now rises to the height of 84 feet. It seems certain that several of these mounds are as early as the first or second century of our era, and their construction continued for some five or six centuries after that date. It ceased with the establishment of Buddhism, when the custom of inhumation was replaced by cremation. The examples of metal work found in these monuments—iron armour, swords, horse-trappings of iron covered with thin gilt copper foil—illustrate the national skill in metallurgy in those early times. Terra-cotta figurines mark the transition from the custom of burying attendants with the dead sovereign, a reform which the "Nihongi" Chronicle attributes to the Emperor Suinin, who reigned at the beginning of the Christian era. At many of these monuments the Japanese, ardent worshippers of ancestors, still perform annual rites, and the mounds are protected from desecration.

The most important contribution to physical anthropology is the account, by Prof. Cunningham, of perhaps the most remarkable head of one of the Australian aborigines which has ever reached this country. It is that of a man who died in 1905 in a lunatic asylum, and it was most skilfully prepared by Dr. Ramsay Smith by means of injections of formalin. This head is distinguished by the great prominence of the supraorbital regions of the forehead, which is receding and sloping, by the width of the zygomatic region, and by the retreating chin and almost complete absence of a mental prominence. The type does not, as might have been expected from the reported cause of death—organic disease of the brain—seem to be abnormal.

Mr. H. Balfour contributes a good museum article on what he terms the friction drum, a curious musical instrument consisting of a drum with a single membrane, to the centre of which is attached a string, horsehair, or short stick, which on being rubbed with the moistened or rosined forefinger and thumb creates rapid vibrations communicated to the membrane. The instrument appears in Europe, North and South America, Africa, Japan, and India. It seems impossible to discover the original centre of dispersion; in fact, there appears no reason why it should not have been independently discovered in Africa or India, where it appears earlier than in other regions.

Archæology is represented by an account, by Canon Greenwell, of a remarkable find by Major Sykes of bronze weapons, implements, and vessels at Khinámán, in south-east Persia. "It is impossible," he writes, "to over-estimate the interest and value of this discovery. This arises not only from the nature of the articles themselves, but from the light it throws upon the early metallic stage of cultivation in that country, about which our information is very scanty." The axes are the most important and interesting. They could never have been used in war or for any other useful purpose, but were representative weapons made to be buried with the dead man in place of those which he used in life, or more probably were employed in processional rites, to be carried as a mark of dignity before a personage of rank. In the ornamentation, as in the case of two similar weapons previously discovered within the same Asian area, the lion appears as a prominent feature of the design.

EXPERIMENTS ON WIND-PRESSURE.

FURTHER experiments on wind-pressure were described by Dr. T. E. Stanton before the Institution of Civil Engineers on December 3. The first part of this research, of which the results were communicated to the same institution in December, 1903, was the investigation of the resultant pressure and distribution of pressure on flat plates normal to and inclined to the direction of a uniform current of air. The value of the constant K in the pressure velocity relation $P = KV^2$ was found to be 0·0027, a result somewhat smaller than those found by Dines, Frowde, and Langley. On the completion of this part of the work it was decided to make observations on flat surfaces of areas ranging up to 100 square feet when exposed to the wind, since general experience tended to show that in actual winds the velocity of which was not uniform over time or space, the mean pressure per square foot on a large surface was considerably less than that on a small one. For the purpose of the work a steel windmill tower was erected in the grounds of the National Physical Laboratory at Teddington. The experimental boards and models of structures were attached to a light framework carried by the cap of the tower, the height of the centre of the boards from the ground being 50 feet.

The results of observations on three pressure-boards, one 5 feet by 5 feet, one 5 feet by 10 feet, and one 10 feet by 10 feet, gave practically identical values of the constant in the pressure-velocity relation. In units of pounds per square foot and miles per hour, the mean value of this constant for the three boards was 0·0032. Further observations on the intensity of the pressure at the front and back of the boards appeared to show that the cause of the higher value of the constant compared with that obtained in the case of the small plates of the earlier experiments was the relatively greater intensity of the negative pressure at the back of the boards compared to that at the back of the small plates. Experiments were also made on a model of a braced girder 29 feet long by 3 feet 7 inches deep, and on a roof model the sides of which were 8 feet by 7 feet. The ratio of the resistance per unit of area of the model girder to that of a square board in the wind was found to be precisely the same as the ratio of the resistance per unit of area of a small model of the girder made to a linear scale of 1 in 42 to a square plate in the experimental channel and uniform current used in the previous experiments. The resultant pressures on the roof were obtained, for both windward and leeward sides, at angles of 30, 45, and 60 degrees inclination to the horizontal, and indicated the considerable suction effects on the leeward side of a roof when the pressure inside the building is augmented from the windward side by open doors or windows. The results lead to the conclusion that the resistance of a complicated structure in the wind can be accurately predicted from a determination of the resistance of a small model of the structure in an experimental channel.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Sir James Dewar has nominated Mr. H. O. Jones, of Clare College, as deputy for the Jacksonian professor of mental philosophy during the Lent term 1908. This nomination has received the consent of the Vice-Chancellor and the Sex Viri.

The sites syndicate recommends that a site on the Downing ground 40 feet wide, situate to the south of the botanical laboratory and parallel to it, be assigned for a building in connection with the Department of Agriculture.

Mr. W. Bateson, F.R.S., has been appointed reader in zoology.

Dr. Baker has been appointed chairman of the examiners for the mathematical tripos, part ii., 1908.

Prof. Nuttall has appointed F. P. Jepson, Pembroke College, to the studentship in medical entomology in place of A. H. Lees, who has resigned the studentship.

The board of agricultural studies is of opinion that the subjects which come under its cognisance are now too wide and too complex to be entrusted to a single professor. The appointment of Mr. T. B. Wood, of Gonville and Caius College, to the Drapers' professorship of agriculture has adequately provided for the teaching of agricultural chemistry, but the board is of opinion that it is urgently necessary that a professor in agricultural botany should be appointed without delay. This proposal has been brought within the range of possibility by the munificence of the Drapers' Company, which has offered a further grant of 200*l.* a year towards the stipend of a professor of agricultural botany. The general board has now put forward a report in which it recommends the establishment of such a professorship. This report will be discussed at an early date next term. The teaching of practical agriculture is entrusted to Mr. K. J. J. Mackenzie, late of the South-Eastern Agricultural College, Wye.

LONDON.—The committee of University College will shortly proceed to appoint a Derby scholar in zoology. The value of the scholarship is 60*l.* per annum, the scholarship being tenable for two years. An examination for the award of the scholarship will be held at University College on December 18. Full particulars can be obtained on application to the secretary, University College, Gower Street, W.C.

MANCHESTER.—The University will eventually benefit under the will of the late Prof. Thomas Barker, who from 1865–1885 was professor of mathematics at Owens College. The legacy, which it is estimated will amount to about 36,000*l.*, is to found a professorship of cryptogamic botany, and to establish scholarships for the assistance of students, especially those of slender means, in the departments of botany and mathematics.

OXFORD.—A portrait of Dr. A. J. Evans, F.R.S., the keeper of the Ashmolean Museum, painted by Sir William B. Richmond, was presented to the University on Saturday, December 7, in the presence of a large and distinguished company. The presentation was made on behalf of the subscribers by the principal of Brasenose, and the Vice-Chancellor accepted the portrait for the University.

MR. HALDANE, M.P., will, on Saturday, December 14, unveil the statue of the King, to be placed over the central entrance of the new buildings of University College School, Hampstead.

THE Melbourne correspondent of the *Daily Chronicle* reports that Mr. T. W. Stanford, brother of the founder of Stanford University, San Francisco, intends to leave by his will 50,000*l.* to found eight annual scholarships at Stanford University for young Australians. All candidates must pledge themselves to return to Australia and use the knowledge gained at the University in developing their native country.

SPEAKING at the Derby Municipal Technical College on December 5, Mr. Victor Cavendish, M.P., said he wished they could send forth from that gathering a message to those engaged in educational controversies that would result in placing education out of the range of controversy. He believed that money spent in extending the operations of institutions of that character was money well spent, and money from which, at no distant date, a most adequate and healthy return would be seen. Another subject was as to what extent we could improve our industrial and commercial position in the world. Upon such a question as foreign competition he felt that, however much they might differ on certain points, at any rate on the question of education they could unite in doing something for the future of the country by seeing that the youth of the nation had the very best technical education that could be given. Any money spent on such objects ought to receive the greatest support and consideration from all parties.

DURING the course of last week the Society of Merchant Venturers concluded the final arrangements for the reconstruction of the main building of their technical college in Bristol, and the work will now proceed with all possible speed. The society has devoted a large sum for additions to and improvements in the equipment of the departments of engineering, chemistry, and applied physics. In order to benefit by the most recent experience gained elsewhere, the principal and other members of the staff have visited some of the best-equipped technical and university colleges in Germany and in the United Kingdom.

To encourage the teaching of facts regarding weather and climate in schools, the council of the Royal Meteorological Society invites elementary teachers and others to send in essays in the form of an original nature-study lesson on weather or climate (not exceeding 1500 words in length), together with a brief synopsis of five other lessons to cover the whole subject of climate and weather. If essays of sufficient merit are received, three prizes will be awarded of 5*l.*, 3*l.*, and 2*l.* respectively. The essays are to be sent in before January 31, 1908, and addressed to Mr. William Marriott, assistant secretary, Royal Meteorological Society, 70 Victoria Street, London, S.W., from whom further information can be obtained.

THE fifth annual prize distribution of the Sir John Cass Technical Institute was held on Tuesday, December 3, when the prizes were distributed and an address given by Dr. R. T. Glazebrook, F.R.S. The chair was taken by Sir Owen Roberts, chairman of Sir John Cass's foundation. Dr. Glazebrook, in reviewing the work of the institute, dwelt upon the importance of the average amount of work done by each student rather than the number of students in attendance as a criterion of the value of the instruction given, and also pointed out the desirability of encouraging students in every possible way to follow grouped courses of study of a continuous character if real advantage is to follow from their labours. Further, it is necessary always to remember that learning and the assimilation of knowledge, admirable though they are in themselves, are not all there is to strive for, but that research or discovery of new laws or of more complete order rests on a higher plane. Dr. Glazebrook then contrasted the lot of the students of the institute with that of men in similar positions a hundred years ago, pointing out in a review of the early life and struggles of Faraday how difficult it was then to obtain the least help in study compared with the accessible advantages that are so widely distributed over the country to-day. The students accordingly should fully appreciate their opportunities and use them to the best advantage, not merely as a means for the acquisition of knowledge, valuable and important as this is, and, above all, not as something which may lead to material advancement, but as a means of training the powers possessed by each so as to develop them for action beneficial both to themselves and to their fellows. A hundred years ago men like Faraday, Watt, and Arkwright worked at a time when the world was comparatively young in knowledge; they had a clean slate to write upon. But while the difficulties of their pioneer work were enormous, and they started from a position of comparative ignorance of scientific principles, and simple in character as their respective discoveries were, the applications which have followed from them have led to a high general level of scientific knowledge to-day which has become the starting point for modern conditions of study. Accordingly, if the country is to profit by the modern progress of science, the mass of the people must be educated up to this higher plane of knowledge, for it is by intelligent action and patient effort and devotion on the part of the rank and file of workers that general advances come. The work of the Sir John Cass Institute and of similar schools throughout London is exerting a most important influence in securing this higher level of knowledge for those engaged in work associated with the industries of the country.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 20.—"On the presence of Sulphur in some of the Hotter Stars." By Sir Norman **Lockyer**, K.C.B., F.R.S.

In this paper the author gives an account of the discovery of the strongest spark lines of sulphur in the spectrum of Rigel. These lines had not previously been traced in any celestial spectrum. It is also shown that two strong sulphur lines (4253·8, 4285·1), which are of abnormal behaviour in the spark and vacuum-tube spectra, are lacking in the Rigel spectrum. They have been found to occur, however, in the Crucian (Bellatrix) and Alnitamian (ϵ Orionis) types of stellar spectra, which represent higher stages of temperature than the Rigelian type. In the two types mentioned the Rigel-sulphur lines are either lacking or very weak.

Concisely, the following represents the relative and inverse behaviour of the two sets of lines in stellar spectra:—

Group	Type Star	Sharp Lines (4253·8, 4285·1)	Diffuse lines
Alnitamian	ϵ Orionis	Well shown	Absent
Crucian ...	γ Orionis	Present, but weaker than in ϵ Orionis	Strongest lines present, but weaker than in β Orionis
Rigelian ...	β Orionis	Absent	Well shown

November 7.—"Note on the Association of Helium and Thorium in Minerals." By the Hon. R. J. **Strutt**, F.R.S.

The question has been often raised of whether or not helium is a product of thorium radio-activity. The author's view throughout has been that it is (Roy. Soc. Proc., vol. lxxiii., p. 191, 1904, also March 2, 1905). Mr. Boltwood has recently argued that the helium in radio-active minerals may always be attributed to the action of the uranium-radium series of transformations (*Am. Journ. Sci.*, vol. xxiii., February, p. 77). In the present note the author directs attention to a case where that view is clearly untenable.

Prof. Julius Thomsen, of Copenhagen, described, in 1898 (*Zeit. physikalische Chemie*, vol. xxv., part iii.), a helium mineral from Ivitgut, Greenland, similar in some respects to fluor-spar, but containing rare earths. Recently he has determined the quantity of helium liberated on heating as 27 c.c. per kilogram (*Bull. de l'Acad. Royale des Sciences*, Copenhagen, 1904, 53–57).

Prof. Thomsen kindly sent a supply of this mineral to the author, who has carefully tested it for radium, and finds that it contains no more than the traces which are ubiquitous in rocks and minerals. The quantity found was, in fact, about the same as in average rocks, and is insufficient to account for one-hundredth part of the helium present.

On the other hand, a solution of the mineral gave abundant thorium emanation. The author is inclined to think that there is some unknown complication about the thorium-emanating power of solutions which makes it unsafe, in certain cases at least, to infer from it the quantity of thorium present; but enough thorium emanation was given off by the solution to show that thorium was a substantial constituent of the mineral. He regards it as entirely certain that the helium in this mineral has not been generated *in situ* by uranium or radium, and has no hesitation in connecting it with the presence of thorium.

"On the Measurement of Temperatures in the Cylinder of a Gas Engine." by Prof. **Callendar**, F.R.S., and Prof. W. E. **Dalby**.

It is important in the experimental investigation of the internal-combustion engine to be able to measure the temperature at a suitable point in the cycle.

The difficulty of making this direct measurement arises from the fact that during the cycle of operations in the working cylinder the temperature rises above the melting point of platinum or of any thermoelectric couple which can be used for the observation. Also, since the temperature is changing so rapidly, whatever apparatus is used to measure the temperature must have small mass; moreover, its insertion in the cylinder of the engine must not alter the volume or disposition of the clearance space, otherwise there will be danger of pre-ignition.

The authors use a platinum wire 0·01 inch diameter and 1 inch long in conjunction with a compensator of the same diameter and ⅜-inch long, and the temperature is measured by measuring the change of resistance corresponding to the middle ⅝-inch of the 1-inch wire. To avoid the difficulty experienced by previous experimenters in this direction, the platinum thermometer is screened from the high temperature by placing it in a valve which allows the thermometer to be exposed during any part of the cycle for a suitable interval of time, and to be perfectly protected from the high temperature when the valve is closed. This valve is contrived in the spindle of the admission valve, and the gear for operating it is clearly shown in the figures in the paper. The advantage of this position is that as the whole charge of air and gas streams into the cylinder around the spindle of the admission valve the temperature of the valve and the thermometer inserted in it are brought continually into approximation during the whole of the suction stroke, so that at the instant when the contact is made for the measurement of the temperature, namely, just after the close of the admission valve, the thermometer and the temperature it is required to measure do not differ widely in temperature; moreover, at this point in the cycle the rate of change of the temperature is nearly a minimum. In measurements of this kind it is essential that there should be no missed explosions, and the authors therefore arranged the engine so that this condition should be exactly fulfilled during the whole of the experiments.

Experiments were made to determine the lag of the platinum thermometer behind the temperature of the fluid it purported to measure, and to determine the effect of the valve carrying the thermometer on the temperature indicated by the thermometer. The conclusion arrived at by the authors is that the method may be used to give the temperature of the charge at the beginning of compression within 1° C.

A few experiments were quoted in the paper, from which it appears that at full load the temperature rises to a point between 2000° C. and 2500° C. when the mixture is rich.

Geological Society, November 6.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—A collection of fossil plants from South Africa: Prof. A. C. **Seward**. The material on which this paper is based was, for the most part, collected by members of the Geological Survey in Cape Colony from the Molteno and Burghersdorp beds. The Molteno beds are placed at the base of the Upper Karroo, or Stormberg series; the Burghersdorp beds constitute the uppermost strata of the Middle Karroo, or Beaufort series. Mr. A. L. Du Toit, who has contributed accounts of the stratigraphy of the plant-bearing and associated rocks, describes the occurrence of a transitional zone between the Molteno and the Burghersdorp beds. A description is also given of *Schizoneura africana*, Feistmantel, a species originally figured by Hooker in an appendix to Bain's paper, published in 1845. The additional plants recorded from the Molteno beds afford further evidence in favour of assigning this member of the Stormberg series to the Rhætic period. While possessing certain Rhætic species, the Burghersdorp flora as a whole indicates a somewhat lower horizon.—Permo-Carboniferous plants from Vereeniging (South Africa): Prof. A. C. **Seward** and T. N. **Leslie.** The majority of the specimens described in this paper were obtained by Mr. Leslie from a sandstone quarry 1½ miles from Vereeniging, on the banks of the Klip River; the sandstones are associated with shales, coal-seams, and glacial conglomerates. In the opinion of the authors, the plant beds should be included in the Ecca series (Lower Karroo). While recognising certain well-marked differences between the Glossopteris floras and the Upper Carboniferous and Permian floras of the northern hemisphere, they are inclined to think that there are more types common to the two botanical provinces than is generally supposed.—The structure and relations of the Laurentian system of Canada: Prof. F. D. **Adams.** This paper contains an outline of the results of the examination by Dr. Barlow and the author of an area of 4200 square miles, comprised within the Haliburton and Bancroft sheets of the Ontario and Quebec series of maps. The main conclusions reached by the author may be thus summarised:—(1) The Laurentian system of Sir William Logan consists of a very ancient series of sedimentary strata, largely limestones, invaded by great volumes of granite in the form of bathyliths. (2) This sedimentary series is one of the most important developments of the pre-Cambrian rocks in North America, it presents the greatest body of pre-Cambrian limestones on the continent, and it is best designated as the Grenville series. (3) The invading masses of granite are of enormous extent; they possess a more or less distinct gneissose structure, due to the movements of the magma, which developed a fluidal and, in the later stages of intrusion, a protoclastic structure in the rock. (4) The granite gneiss of the bathyliths not only arched up the invaded strata into a series of domes, but "stoped" out portions of the sides and lower surface of the arches, the fragments torn off from walls and roof by the invading granite being found scattered throughout the mass of the invading rock; this "stoping," however, probably developed only a small part of the space which the granite now occupies. (5) The invading granite not only exerted a mechanical action upon the invaded strata, but also gave rise to a variety of metamorphic products, among others amphibolite, produced by its action in the limestone, which accounts for the fact that while the invaded strata are chiefly limestone, the fragments of the latter, where found in the granite, consist of amphibolite. (6) The invading bathyliths and allied intrusions of granite occupy the greater part of the great northern protaxis of Canada, which has an area of approximately 2,000,000 square miles. It has, therefore, been considered advisable to restrict the name Laurentian to this great development of the "fundamental gneiss," which, although intrusive into the Grenville series, nevertheless underlies and supports it. (7) The relation of the Grenville series, which forms the base of the sedimentary portion of the geological column in eastern Canada, to the Huronian and Keewatin series, which are the oldest stratified rocks in the western part of the protaxis, has yet to be determined, the two not having so far been found in contact; nowhere, moreover, either east or west, has the original basement on which the first sediments were laid down been discovered; these are everywhere torn to pieces by the granite intrusions of the Laurentian.

Linnean Society, November 7.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The origin of the ditrimerous floral whorls of certain dicotyledons: Rev. G. **Henslow.** The object of the present paper was to show that the ternary arrangements of monocotyledons are not derived from the same source as those of certain dicotyledons, every verticil of three members in the former being a *single cycle* of the ⅓ divergence, while in the latter the usually *double* verticils are derived from the ⅖. This divergence is unknown in the foliage of monocotyledons, ½ or ⅓ being the natural sequence from a single cotyledon, whereas ⅖ necessarily follows on the two cotyledons or from opposite and decussate leaves.—Eight very remarkable new species of Acari from New Zealand, from the collection of the late E. Bostock, six Oribatidæ and two Gamasidæ: A. D. **Michael.** The species are to be called *Oribata bostocki*, distinguished by the pteromorphæ being attached to the anterior margin of the abdomen instead of its lateral margin; *Notaspis spinulosa*, carrying spinulated hairs of extraordinary size; *Notaspis caudata*, with a posterior projection not hitherto found in the genus; *Hermannia phyllophora*, with great leaf-like processes on the legs; *Nothrus cophinarius* and *N. unguifera*, extreme exaggerations of that section of the genus represented in Europe by *N. spiniger*; *Trachynotus sclerophyllus*, in which the great leaf-like transparent hairs found on many Acari have become opaque, hard, brown chitin; and *T. fimbriatus*, with singular flattened borders to the first pair of legs, much broader than the legs themselves.—*Ænigmatistes africanus*, a new genus and species of Diptera: R. **Shelford.**

November 21.—Prof. W. A. Herdman, F.R.S., president, in the chair.—*Exhibits.*—C. W. **Anderson**: A specimen of a light-giving larva brought by him from near the boundary of British Guiana with Brazil, exhibiting when living a ruby light in its head, and a double row of phosphorescent spots along the body, two on each segment. These lights were not intermittent, but glowed continuously. This presumed coleopterous larva was called "Macadoub" by the natives, and is not uncommon in the region named.—Prof. **Dendy**: Two living specimens of Peripatus from the Cape, which he had succeeded in keeping in excellent health by supplying them with woodlice as food.—*Papers.*—Abnormal structures in leaves and their value in morphology: W. C. **Worsdell.** *Dichotomy*, as in crested fern leaves, is a reversion to a primitive type of frond-branching. In cotyledons it represents a tendency, which in this case is progressive and not reversionary, to increase the number of cotyledons. *Phyllotaxis:* Dichotomy of foliage leaves is, in the author's opinion, a reversion from the opposite, or distichous, arrangement to form a greater number of leaves on the axis; it is probably a step towards the original spiral arrangement. *Spiral torsion* is due to a reversion from the opposite or whorled arrangement of leaves to the spiral arrangement. *Terminal leaves:* This is regarded as a reversion to the primeval structure in which, according to the phyton theory, each leaf terminates each segment of the stem above which it is situated, every leaf being thus essentially a terminal organ and not lateral. *Enations and ascidia:* The foliage leaves of *Saxifraga ligulata* show formation of basal pockets on upper side of leaf and transformation of entire leaf into a cup-shaped structure; also infolding of basal lobes, which infolding may extend right up midrib to apex. This infolding may also occur for a short distance from the apex downwards. A similar structure may be represented merely by slight enations on either side of the midrib. Lobing may occur at the apex; small lobes may become abstricted off as stalked structures, which may either be terminal or carried over on to the dorsal (lower surface) of the leaf in form of small, stalked ascidia. *Virescence:* The various foliar organs of the flower may revert to the condition of foliage leaves, *e.g.* phyllody of the calyx in the rose, phyllody of carpels in Trifolium. *Monocotyledonous seedlings in dicotyledons:* Normal cases of this occur, as in *Ranunculus Ficaria*, L.; here the conditions are regarded as primitive. Abnormal cases occur in which the two cotyledons arise congenitally fused into a single one, as in Umbelliferæ. This is a reversion to the primitive condition.—Two new species of

Amphipoda: Rev. T. R. R. **Stebbing**. The species were described as *Lepechinella chrysotheras*, representing a new genus in the family Paramphithoidæ, and *Rhachotropis palporum* in the family Eusiridæ.—The preservation of specimens in Australian museums: J. G. Otto **Tepper**. The author pointed out that the life-cycle of *Anthrenus musaeorum* involved visits to flowers, and that the presence of their destructive larvæ in museum collections was due to the eggs being laid in proximity to the cases, and the active and minute larvæ subsequently finding their way into the containing cases by cracks or similar apertures.

Mineralogical Society, November 12.—Prof. H. A. Miers, F.R.S., president, in the chair.—Hopeite and other zinc phosphates and associated minerals from Broken Hill mines, north-western Rhodesia: L. J. **Spencer** (see NATURE, vol. lxxvi., p. 215). Hopeite is abundant as brilliant water-clear crystals or as larger white crystals reaching 2 cm. across. The crystals are orthorhombic, with $a:b:c=0{\cdot}5786:1:0{\cdot}4758$. Cleavage flakes parallel to the brachypinacoid show a zonal intergrowth of two substances, distinguished as α-hopeite and β-hopeite; these differ considerably in their optical characters, and slightly in sp. gr. (3·0–3·1) and the temperature at which water is expelled. Associated with the hopeite crystals on the bone-breccia are brown botryoidal masses of vanadinite. The other zinc phosphates occur, not in the bone cave, but with cellular limonite and crystals of descloizite and pyromorphite in connection with the zinc-lead ores (which consist of an intimate mixture of cerussite and hemimorphite with interspersed limonite). The new species, *tarbuttite*, occurs in great abundance, and is a basic zinc phosphate, $Zn_3P_2O_8.Zn(OH)_2$, with sp. gr. 4·15; the crystals are anorthic with $ac=55° \; 50'$, $ab=84° \; 34'$, $bc=76° \; 31'$, c being a direction of perfect cleavage. Pseudomorphs of tarbuttite after calamine ($ZnCO_3$), descloizite, and hemimorphite are not uncommon. Another new species, named *parahopeite*, has the same chemical composition as hopeite, $Zn_3P_2O_8.4H_2O$, but is anorthic, with sp. gr. 3·31. The platy crystals somewhat resemble hemimorphite in appearance; they have one perfect cleavage, approximately perpendicular to the plates, through which emerges one of the optic axes.—The question of a relation between isomorphous miscibility and parallel growths: T. V. **Barker**. A study of the growths on each other of immiscible or slightly miscible pairs of substances has shown that, although miscibility and parallel growths are favoured by the same factor—similarity of molecular volume—yet the two properties do not always go hand in hand, for many immiscible or only slightly miscible substances form parallel growths quite readily. Mixed crystals, therefore, should not be regarded as built up of alternating parallel layers.—Notes on zeolites from Cornwall and Devon: A. **Russell**. The occurrence of zeolites in various localities was described, *e.g.* that of heulandite near Okehampton, stilbite at Botallack and St. Ives, chabazite at Luxullian, apophyllite and analcite at Lostwithiel.—Note on the crystallisation of potassium bichromate: Prof. H. A. **Miers**. Two stages of growth of potassium bichromate crystallising from a drop of solution were described and illustrated by lantern-slides.—Various minerals from the Lengenbach quarry and the Ofenhorn, Binnenthal: R. H. **Solly**. Crystals of binnite, one of them a unique twin, and examples of the regular intergrowth of sartorite and baumhauerite, were described, and the occurrence of brookite and molybdenite on the Ofenhorn was for the first time recorded.—Mr. L. J. Spencer exhibited on behalf of Dr. H. J. **Johnston-Lavis** some minute crystals of hæmatite found in association with chlormanganokalite in blocks ejected from Vesuvius during the eruption of 1906. The crystals have the form of acute scalenohedra $\beta\{31\bar{3}\}=\{24\bar{6}1\}$.—A fine series of zeolites from the neighbourhood of Belfast was shown by Mr. F. N. A. **Fleischmann**; a new meteoric stone from Simondium, Cape Colony, by Dr. G. T. **Prior**; specimens of reconstructed ruby and blue spinel, and of the new gem, benitoite, by Dr. G. F. Herbert **Smith**; and a specimen of artificial hæmatite by Mr. C. J. **Woodward**.

Royal Anthropological Institute, November 19.—Mr. F. W. Rudler, past-president, in the chair.—Excavation of a barrow at Chapel Carn Brea, Cornwall: H. C. **King** and B. C. **Polkinghorne**. The barrow was opened in August, and was found to contain a cist built of flat-faced irregular stones with capstone. A very fine large urn, ornamented with the characteristic pattern, was found, containing partly calcined bones. Flint flakes were found, but these were of earlier date than the urn, and were probably placed in the kist from traditional motives. The barrow may have been surrounded by standing stones, as one is still in position. Above the cist at the north end another somewhat smaller urn was discovered.—Holed stone at Kerrow, St. Just in Penwith, Cornwall: H. C. **King** and B. C. **Polkinghorne**. This consists of a circular slab of granite with a cylindrical hole in the centre, very well worked, apparently by iron tools. Wood charcoal was discovered underneath. Its purpose is unknown. Small cist and urn at Tregiffian Vean, St. Just in Penwith: H. C. **King** and B. C. **Polkinghorne**. The cist is a small one with a broken capstone. The urn, which is also small, dates about 400 B.C. No bones or ashes were found.—The wild tribes of the Ulu Plus, Malay Peninsula: F. W. **Knocker**. The tribes dealt with occupy the upper waters of the Plus River in Perak. They are apparently of mixed Semang-Sakai characteristics. The paper dealt with their habits of life, manners, and customs.

Chemical Society, November 21.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—Emulsions: S. **Pickering**. Paraffin oil, when churned with solutions of soap, glue, starch, albumen, &c., forms an emulsion, which rises, like cream, to the surface of the excess of water, and contains from 65 per cent. to 82 per cent. by volume of oil. The percentage of oil can be increased to 99 per cent., the emulsion then being practically solid. Emulsification seems to depend on the separation from the liquid of very minute solid particles, which are attracted by and surround the oil globules, thus preventing them from coalescing. Any precipitated substance which is sufficiently finely divided will act as an emulsifying agent, but, after becoming agglomerated by drying, it loses this property.—Aromatic azoimides, part iii., the naphthylazoimides and their nitro-derivatives: M. O. **Forster** and H. E. **Fierz**.—The triazo-group, part i., triazoacetic acid and triazoacetone (acetonylazoimide): M. O. **Forster** and H. E. **Fierz**. The interesting properties displayed by the triazo-group when occurring in the complex

$$\begin{array}{l}-CH.N_3\\ \;\;|\\ -CO\end{array}$$

have led the authors to prepare the simplest typical compounds of this class, triazoacetic acid and triazoacetone.—Studies of dynamic isomerism, part vii., note on the action of carbonyl chloride as an agent for arresting isomeric change: T. M. **Lowry** and E. H. **Magson**. Labile solutions of nitrocamphor, in which isomeric change has been suspended, have been prepared (1) accidentally by dissolving nitrocamphor in choloroform, and (2) deliberately by adding acid to the solvent chloroform. In the latter case the solutions acquired a powerful odour of carbonyl chloride, and there can be no doubt that this is the efficient agent in arresting isomeric change in chloroform solutions. By means of this new agent it is possible to arrest the isomeric change of nitrocamphor in other solvents.—The electrometric determination of the hydrolysis of salts: H. G. **Denham**.—The interaction of metallic sulphates and caustic alkalis: S. **Pickering**. Alkalis, added to solutions of various metallic sulphates, precipitate a definite basic sulphate, except in the case of manganese and magnesium, where the hydroxide is precipitated. The further addition of alkali converts the basic sulphate either into another, sometimes consecutively into two other, more basic products (for example, copper and nickel), or into the hydroxide.—The chemistry of Bordeaux mixture: S. **Pickering**. The substances formed on the addition of lime to copper sulphate, as in the preparation of Bordeaux mixture, are dependent on the proportions of lime used, and may be either

(1) $4CuO,SO_3,0\cdot06CaSO_4$;
(2) $5CuO,SO_3,0\cdot25CaSO_4$;
(3) $10CuO,SO_3,1\cdot3CaSO_4$;
(4) $10CuO,SO_3,4CaO,SO_3$;
(Possibly 5) $10CuO,SO_3,10CaO,SO_3$; or
(6) $CuO,3CaO$;

that present in most cases probably being (4). The fungicidal action of Bordeaux mixture seems to depend on the liberation of copper sulphate by the action of carbon dioxide on the basic sulphate. The alcohols of the hydro-aromatic and terpene series, part i., resolution of the alcohols into their optically active components and the preparation of the borneols: R. H. **Pickard** and W. O. **Littlebury.** The alcohol is combined with phthalic or succinic anhydride, and the resulting acid ester resolved by *l*-menthylamine or other strong optically active base.—The electrolytic preparation of disulphides, part i., dibenzyl-disulphide and diethyldisulphide: T. S. **Price** and D. F. **Twiss.**—The influence of solvents on the rotation of optically active compounds, part xi., ethyl tartrate in aliphatic halogen derivatives: T. S. **Patterson** and D. **Thomson.** The interaction in solution of ferrous sulphate and copper sulphate: H. R. **Ellis** and W. H. **Collier.** No action takes place between ferrous sulphate and copper sulphate solutions in the cold, but on boiling, the copper sulphate slowly oxidises the ferrous hydroxide produced by hydrolysis. An account is also given of the action of ammonia solution on mixtures of ferrous and cupric sulphates in water.—Mercurous hyponitrite: E. **Divers.**—Decomposition of mercurous and silver hyponitrites by heat: E. **Divers.**—Cupric nitrite: E. **Divers.**

MATHEMATICS IN BOTANY.

Mathematische und mikroskopisch-anatomische Studien über Blattstellungen. By Dr. G. van Iterson, Jun. Pp. xii+331+plates. (Jena: G. Fischer, 1907.) Price 20 marks.

THE subject of Phyllotaxis, which formerly involved the study of the arrangement, though now more particularly the mode of origin, of the lateral members of a plant-shoot, since it was first placed on a scientific footing by Bonnet in 1754, has afforded one of the most fascinating branches of botany, and, it must be frankly admitted, one which is very inadequately treated in text-books; this being again the expression of the fact that the more that is known with regard to it, the more complex do its problems appear, and the more hopeless of final solution. The subject, again, possesses possibly a special interest in that it is strictly non-utilitarian, and remains a field of abstract scientific work dealing with some of the most fundamental questions of protoplasmic life, which attain but little emphasis in the animal kingdom, owing to the restricted output of systems of ramification and appendage-production in the more condensed type of animal-organisation. The literature of the subject is, however, very voluminous, and slowly increases, the present volume of Iterson being the only important contribution since the loss of Schumann, and the publication of some of the work of Church (1904).

In that the arrangement of lateral members in the case of shoot-construction usually involves phenomena of periodicity or rhythm, phyllotaxis becomes capable of a certain amount of mathematical treatment; and it is to this fact, perhaps, more than to any other that the subject is often viewed with a vague distrust by the majority of botanists; mathematical results can only follow from given premises, which must first be interpolated into the question; for example, Church pointed out in 1901 that the accepted usage for seventy years of mathematical expressions based on systems of regular helices rendered all discussions of the arrangement of members on growing apices purely nonsensical, and vitiated all deductions based on the apparent imperfection of such constructions. Some working hypothesis is clearly necessary to start with, and the assumption of different data may involve a completely different mathematical presentation. Iterson's volume, including 300 pages on the botanical aspect of the question, devotes 190 to mathematical speculations, the greater part of which will therefore not appeal to the average botanist at all. The mathematician necessarily starts with a severe handicap, since the data of the actual appearances presented at the apex of a vegetative shoot are so illusive. New primordia rise up as rounded pimples, wholly independent of the segmentation of the apex into constituent cells, and often without any visible connection with each other, yet falling along the paths of what is often a very elaborate pattern, most readily defined as a meshwork of intersecting radiating curves; and it is admittedly impossible to measure any lines or angles, or even to plot the form of the actual primordium with any such degree of accuracy as a precise mathematical presentation would appear to demand; hence observers who are more familiar with the conditions obtaining at a growing-point become naturally suspicious of mathematical speculations which are incapable of verification.

In all the speculations which have been introduced into the subject, the difficulty is to find anything whatever which can be established as a reasonable proof of the working hypothesis selected; thus in Dr. Iterson's volume, models of spheres in helicoid or conical arrangements may edify the beginner, but they have no particular relation to the origin of leaf-primordia on the surface of a shoot-apex; systems of circles in tangential contact must remain unsatisfactory while there is no evidence that primordia can be treated as circles, or that the tangential contact is absolute; the mathematics of a conical surface which can be unrolled has little reference to the curved dome of a plant-shoot, the curve of which is beyond present calculation, while any unrolling of the systems destroys the only essential feature of the system of intersecting curves; again, the projection of a spherical primordium to a "folioid" curve gives suggestive imitative results, when these folioid curves are continued in a log. spiral system; but there is no evidence to connect the folioid with the shape of a leaf-primordium; and it does not, as a matter of fact, fulfil the normal demands of a phyllotaxis-system.

Writers on phyllotaxis in the past may be divided into three categories: first, those who seek merely for a method of simply enumerating and cataloguing the phenomena observed in the beautifully rhythmic patterns, usually expressed as spiral curves, in plant-shoots and buds, familiar examples of which are observed in the Pine-cone and the arrangement of the disk-florets of Composites. For these the empirical helical formulæ of Schimper and Braun (1835) still afford a sufficient basis, so long as observations are restricted to adult structures, and no very rigid accuracy is required. A second class of writers start off on the attempt to *imitate* the appearances, hoping thereby to explain them; the most unscientific line of approach conceivable, the physiological fallacy of such mimetic methods having been fully exposed by Sachs. To this line of argument botany is indebted for numerous theories of "torsion," since torsion will give a spiral effect! Such imitative conceptions culminate in the contact-pressure theory of Schwendener. Lastly, there is a more modern class of investigators who require something more fundamental, in the nature of a physical cause for the phenomena of rhythm, which clearly lies behind the first visible rise of rounded primordia, these being but the expression of more concealed growth-factors.

The treatise of Dr. Iterson, who apparently remains in the imitative line of approach, may be briefly described as an attempt to harmonise the largely accepted theories of Schwendener and older writers with a corrected mathematical presentation which in itself renders the difficulties of these writers largely illusory; as in the case of these observers, Iterson gets little further than the expression of certain facts of general observation, which in themselves constitute no proof. Schwendener's theory of the influence of mechanical contact has long held the field, in spite of the fact that no such contact can be invariably proved to exist, or even to exert any mechanical action; so much so, in fact, that it has been regarded as possible to dilute the theory to one of vague "stimulation." Dr. Iterson, by following along the well-worn paths of previous observers, has reached very similar conclusions; and it must be admitted that continual study of the best exhibitions of the uniform construction of vegetative shoot-systems naturally impels the observer to the old and familiar view of Hofmeister, that appendages cannot help themselves, but arise in the next "widest gap" between pre-existing ones, as they are seen to do; such a statement represents no solution of the problem, but is, in fact, a confession of failure.

On the other hand, by approaching the subject from the standpoint of floral ontogeny, in which the most complex phyllotaxis-systems can be observed developing before one's eyes according to a perfectly defined architectural plan, in which the relation of the individual members may, however, be practically anything whatever, wide gaps being left in some places, spirals mixed with circular construction, and members apparently "omitted," as well as appearing "out of their turn," an investigator equally inclines with Schumann to the view that contact-relations present no contributory cause whatever to the phenomena of the initial phases, which can only be referred to autonomous growth-impulses within the substance of the shoot-apex; a region which, consisting as it does of undifferentiated cell-units, is beyond further possibility of observation. Among the general conclusions for straightforward "constant-phyllotaxis," Iterson reiterates the stock considerations of "bulk-ratio," "contact-relations," and the principle of the "widest gap" (p. 291).

The fallacy of the widest gap has been exposed over and over again; it is sufficiently obvious to the unprejudiced eye in the appearances presented at the apex of the common Fern, or shoots of Water-lilies; primordia do not invariably arise in close contact with each other, but may be widely spaced out at first. The same want of contact, or any connecting sequence between one series of members and the next, is a common phenomenon in floral ontogeny which also includes cases of such absolute irregularity that the necessity for a "mechanical law" for their production becomes an absurdity; while in examples of perfect regularity of construction, the case of extreme mathematical interest centres in those few instances in which successive whorls do not fall into the gaps of their predecessors at all, but are accurately superposed; such cases occur in certain living species of Mesembryanthemum, though the significance of this formation in the case of fossil plants may still be open to question. It is thus a matter for regret that Iterson should revive the conceptions of "close-contact" and "widest-gaps," which have seen so much service in the past; while again the conception of "bulk-ratio," or the relative size of the primordium with regard to the axis on which it is "inserted," though extremely useful in dealing with the difficulty of distinguishing between systems which involve numerals of the same summation series, *e.g.* 3 : 5 : 8, &c., can yield no practical solution of the difference, for example, between a 3 : 5 construction and a 3 : 4, or, again, of the essential difference between spiral and circular arrangement. It is also sufficiently obvious that the causes which determine the relative rates of growth (which lie behind the relative size) must have existed in the actual substance of the growing-point some time before the primordia became visible to the eye as a definite outgrowth, and, admitting the absence of any necessity for close-contact, the spacing of the new centres of growth is presumably more important than their actual size; once the centres are initiated, the new growth-impulses from them are continued until they ultimately make lateral contacts as a wholly secondary phenomenon.

Dr. Iterson's volume affords an admirable introduction to the subject, and most of the branches are indicated; considerable value attaches to the *résumé* of the theories of Schwendener and Celakovsky, copiously illustrated with excellent figures (more than 100 text-illustrations, and 16 plates); these bear sufficient witness to the enthusiasm of the author in this most absorbing field of speculation, though when all is said we appear to be no nearer the solution of the problem than ever; it only gains in complexity where it seems to be most regular and simple; since an absolutely irregular construction can clearly have no explanation at all, it simply grows as one sees it grow, and can neither be accurately described nor imitated. To those who seek for the inner and ultimate cause of the phenomena, the subject still presents an indefinite field of research.

Few botanists appear to realise the extent to which a proper appreciation of the subject of phyllotaxis is involved in the morphological consideration of plant-growth, and floral construction and even phylogeny; the marvellous standpoint that a dimerous flower is simpler, and therefore more primitive, than a trimerous one, and a trimerous than a pentamerous, constitutes one of the vitiating factors of the systematic work of Eichler, and is still reflected in the modern German school of classification.

ORGANIC CHEMISTRY FOR MEDICAL STUDENTS.

Text-book of Organic Chemistry for Medical Students. By Dr. G. v. Bunge. Translated with additions by Dr. R. H. A. Plimmer. Pp. ix+260. (London: Longmans, Green and Co., 1907.) Price 6s. net.

THE rapid advance which has marked the progress of physiological chemistry in the last twenty years, owing mainly to the remarkable researches of Prof. Emil Fischer, has emphasised the necessity of a sound knowledge of organic chemistry for all students of medicine. But organic chemistry has undergone developments in many other directions, and new compounds have multiplied at a most bewildering rate. It is clearly undesirable for the student of medicine to become acquainted with any large proportion of the hundred thousand compounds which organic chemistry is said to include. He might, after a firm foundation had been laid, study with advantage only those special subjects which come within his sphere of interest. He cannot very well know how to select these for himself, and Prof. Bunge has therefore attempted to do it for him.

On the whole, Prof. Bunge has been very successful in the choice and arrangement of his materials, and has produced an eminently readable book. But the task cannot have been an easy one. In a small volume of 250 pages, which is assumed to start with the rudiments and finishes with such complex vital products as the purines, the proteins, and the alkaloids, there is a danger that the treatment may be diffuse and superficial. But though this is certainly not the case, it must be confessed that some preliminary knowledge of analysis, molecular-weight determinations, and especially about methods of studying structure, is desirable, if not indeed necessary, if the subject is to be understood. In support of this it may be pointed out that the structural formula of oxalic acid is given on p. 2, of glyceric aldehyde and dioxyacetone on p. 5, and of hippuric acid on p. 8, without any previous reference to Kekulé's structural laws. But this appears to be the only serious defect, and one which the student can easily remedy by a little preliminary study.

The chapters are written in a manner well calculated to stimulate the reader; indeed, no organic text-book within the writer's knowledge is so full of human interest. The following few errors have been noted:—Chlorine does not convert aldehyde into chloral, but mainly into butyl chloral (p. 50). It is not true that "no one has yet succeeded in obtaining directly by synthesis either a *d*- or a *l*-compound" (p. 79). On the contrary, *asymmetric synthesis* is an accomplished fact. A racemic compound and a mixture of enantiomorphs are not synonymous, and the difference is indicated by *r* and *dl* (p. 89). The author refers to the separation of synthetic tartaric acid into its *d*- and *l*-components by Jungfleisch as causing a great sensation, "for up to that time many chemists thought that optically active compounds could only be formed by the living cell" (p. 89). There must surely be some confusion here, for did not Pasteur resolve racemic acid? Pasteur, it is true, considered asymmetric synthesis, or the formation of one enantiomorph without the other, as a peculiar property of living matter, but that is another thing altogether. Finally, on p. 147 occurs the old story of Wöhler's discovery of artificial urea in 1828, a date which tradition and the text-books have fixed upon as that of a two-fold event—the first organic synthesis and the downfall of the vital-force theory. In reality it was neither the one nor the other, and perhaps the following observations may help to put the matter in a clear light.

The preparation of natural products in the laboratory began before Wöhler was born, for in 1776 Scheele obtained oxalic acid by oxidising sugar. Doebereiner's preparation of formic acid from tartaric acid in 1822, and Hennel's synthesis of alcohol from olefiant gas were both prior to Wöhler's discovery. That Doebereiner's discovery received contemporary recognition is evident from Berzelius's reference to it in the *Jahresbericht* for 1823. "Doebereiner," he says, "has made the remarkable discovery that formic acid may be produced artificially." Now Liebig, in his treatise of 1840, falls into a curious error, which may lie at the bottom of the text-book myth. In reference to formic acid he writes, "Doebereiner was the first who prepared it by chemical means," whilst in another place he says, "Woehler found a way of obtaining urea artificially, and it was the first substance formed in the animal-life process which had been successfully reproduced by chemical means." Now formic acid is as much a product of the animal-life process as urea, and no real distinction can be drawn between them.

It is clear, therefore, on Liebig's own showing, that of the two artificial products, Doebereiner's has the prior claim. How little Wöhler's discovery served to remove the belief in a vital force is very clearly indicated in Gerhardt's "Précis de Chimie Organique," published in 1844.

"A number of animal and vegetable substances have been reproduced by acting with oxygenating agents on more highly carbonised compounds . . . thus, the chemist has followed a path entirely opposed to that pursued by vegetable life . . . one need not therefore feel astonished that he has not yet produced cerebral matter, nor the constituents of the blood, nor equally complex substances."

Thus the vital-force theory did not suddenly collapse, as generally stated; on the contrary, it died a slow and lingering death. We may, indeed, ask, is it quite dead yet? For to quote the words of an authoritative contemporary writer, "the testimony of pure chemistry cannot as it at present stands be legitimately interpreted into a direct negation of vitalism in any form."

There only remains to add a reference to the work of the translator. Dr. Plimmer has not only rendered the German into excellent English, but has added very considerably to the text. J. B. C.

OUR BOOK SHELF.

(1) *Some Nature Biographies: Plant, Insect, Marine, Mineral.* By J. J. Ward. Pp. xvii+307; illustrated. (London: John Lane, 1908.) Price 5*s*. net.

(2) *The Fairyland of Living Things.* By R. Kearton. Pp. viii+182; illustrated. (London: Cassell and Co., Ltd., 1907.) Price 3*s*. 6*d*.

(1) MR. WARD'S little work, which consists of a series of articles originally published in the *Strand*, *Pall Mall*, *English Illustrated*, and other magazines and periodicals, may be regarded as a kind of kinematograph in book form, and may be unreservedly commended to all nature-lovers. One great feature of the several life-histories is that they are in the main based on actual personal observation, and that, too, of a kind which demands constant attention and the expenditure of no inconsiderable amount of time. In his preface the author very modestly suggests that he is entitled to the credit of being the pioneer in certain forms of insect photography, and to this credit, so far as our information goes, he is fully entitled. Nothing in nature-photography can, indeed, be more interesting than his pictures of the sequence of events which herald the complete liberation of the butterfly or the moth from its chrysalis,

or of the marvellous evolutions of the caterpillar of the swallow-tail when about to pupate. As the author very pertinently remarks, to obtain photographs of this description the artist has in most cases only a single brief opportunity; and if one single link in the chain be missed, the whole series of pictures is spoilt. Needless to say, the reader sees only the successes; the failures are labour lost.

Among such an excellent series, it is difficult to select particular figures for mention, but those of the white admiral butterfly are especially noteworthy. Equally instructive and interesting are the photographs of developing and retrograding vegetable-life; more especially those connected with the fall of the leaf—a progress of which comparatively few persons know the physiological history.

The senses of insects, illustrated with exquisite pictures of antennæ and the fly's "tongue," form another chapter. The book closes with 12 photographs representing the monthly changes in a landscape as seen from one particular spot—a fuller development of the idea of photographing particular trees in summer and again in winter. A better book of its class we have never seen.

(2) In the "Fairyland of Living Things" Mr. R. Kearton, aided, as usual, by his brother's camera, offers an attractive Christmas book, which should delight many households of young people. In place of confining himself to birds, the author includes in his purview quadrupeds (both hot- and cold-blooded), insects, and plants, and endeavours to interest his *clientèle* by dwelling on habits, instincts, and character rather than by describing structural details. Whether the author has touched the right note must be left for the class of readers to whom he appeals to decide; but we have never yet seen a "Kearton book" that has not proved a success. R. L.

Physiologisches Praktikum für Mediziner. By Prof. Max Verworn. Pp. xii+262; illustrated. (Jena: Gustav Fischer, 1907.) Price 6 marks.

The practical class in physiology as known in this country has never been adopted to the full in Germany. There each student works out his own salvation by independent laboratory work, and research is started at an early stage in his career, as a means to teach him methods and resource. Elaborate German handbooks have been written as guides to such workers, most of them dealing with one branch of physiology, and not with all.

The aim of Prof. Max Verworn has not been to write an ambitious work of this character, but to furnish the average medical student with a guide to certain fundamental exercises, most of which it ought to be possible for each one to perform for himself, possibly in a class, as is the English custom. The remainder are appropriate for demonstrations.

In such a book it is obvious that there should not be over-specialisation, and thus we find in the subject, say, of the blood the study of its circulation closely following on that of its chemistry. In this way the various chapters see-saw between chemical and physical matters. In a theoretical book this is an ideal plan, but for a practical guide it has its drawbacks. Prof. Verworn is so well known for his writings on cells and what he terms "general physiology" that it is not surprising to find that some of the opening pages deal with this branch of science, and simple exercises on galvanotaxis, chemotaxis, and the like are introduced.

In some cases the directions are purely practical, and the descriptions of certain simple dissections are most precise. In other cases, theoretical matter and explanations are interspersed. These necessarily deal with the subject very briefly, and the very briefness is in some cases apt to cause bewilderment. The description of the causes of blood coagulation cannot possibly be clearly given in a single short paragraph.

On the practical side we are surprised to find a study of the pancreatic juice omitted, and on the theoretical side no allusion is made to Emil Fischer's work on the ultimate cleavage products of the proteins. Some passages read as though the action of pepsin and trypsin stopped at the albumose and peptone stage. Surely every student nowadays must know something of polypeptides and amino-acids.

The illustrations, as a rule, are clear and judiciously selected, but the diagram of the absorption spectrum of hæmoglobin is very imperfect; indeed, the whole subject of blood spectroscopy is given in the merest outline.

Every teacher has, of course, his own ideas on the relative importance of the different parts of his subject; it is even possible that another reviewer might commend what the present one feels inclined to criticise. Two actual errors are, however, present; one is that fibrin is spoken of as a calcium compound of fibrinogen; the other is found in the description of the Adamkiewicz test for proteins, the colour reaction being described as due to the carbohydrate radical, whereas it has been proved to be due to tryptophan. W. D. H.

River Discharge. By J. C. Hoyt and N. C. Grover. Pp. viii+137. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1907.) Price 2 dollars.

We have from time to time directed attention to the hydrographic survey that has been in operation for several years by the Geological Department of the United States Government. This survey is for the purpose of ascertaining the water resources of the country available for domestic use, irrigation or power.

The authors of the book now under notice have both been engaged in the survey work, and give in a thoroughly practical and useful way the result of their experience, and of the methods adopted in carrying out the work.

The information both as to the methods and the instruments used should be of great value to engineers engaged in hydrographic work and to students. The text is accompanied by twenty-four illustrations showing the various forms of current meters in use, the method of rating these, the floats used, the cables and cages used for obtaining velocities across wide rivers, weir stations, &c.

The book is divided into six chapters, dealing respectively with rainfall and evaporation; instruments used for obtaining velocities and depths; cable-station equipments; wading stations; theory and practice of measuring discharges; weirs and weir formulas; discussion and use of data; together with seventeen tables for facilitating the computations in various hydraulic problems.

Constructions in Practical Geometry. By the Rev. H. F. Westlake. Pp. viii+50. (London: George Philip and Son, Ltd., 1907.) Price 1s.

A collection of simple geometrical constructions without proofs, which is said to represent the minimum knowledge of the subject required of candidates in the Oxford and Cambridge School Examinations, is here provided. All the work can be done with a ruler and pair of compasses. The diagrams are clear and the instructions simple. A boy of twelve years of age should have no difficulty in mastering the course of work.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The International Memorial Statue of Lamarck.

THE subscription list for the purpose of erecting a statue of the great French naturalist Lamarck in the Jardin des Plantes, Paris, where he did much of his work, will shortly be closed.

English men of science will, it is hoped, realise that it is now time to send subscriptions in order to show their regard for the memory of the great man whose name stands by the side of that of Darwin as a philosophical naturalist.

Subscriptions of any amount may be sent at once to me at the Natural History Museum, Cromwell Road, S.W.; their receipt will be acknowledged, and the subscriptions sent to the committee of French naturalists who are collecting funds, and will issue a list of subscribers; or subscriptions may be sent direct to Prof. Edmond Perrier, director of the museum, Jardin des Plantes, Paris.

E. RAY LANKESTER.

British Museum (Natural History), Cromwell Road, London, S.W.

Mulattos.

MAY I have a line to correct Sir William Thiselton-Dyer's impression (p. 126) that the tragic story of The Pure White Mother and the Coal-black Babe was accepted by me "as accurate and in perfect good faith"? I suppose I ought to have underlined the gentle sneer at a blackness transcending the natural blackness of a negro baby. At any rate, I told the anecdote simply to illustrate the nonsense people will talk under the influence of race mania, and I hope it will not be added too hastily to the accumulation of evidence on the Mendelian side.

H. G. WELLS.

Nest Eggs of Platypus.

MY attention has been directed to the review of Mr. le Souef's book on "Wild Life in Australia" (NATURE, October 24) and to the reviewer's subsequent note on the eggs of Platypus (NATURE, November 28). The reviewer states that there "appears to be no definite evidence that the eggs" of Platypus "are really laid entire." As I had the good fortune to find some in that condition a few years ago, I think it well to record the fact. I have already shown these eggs in Sydney and to the British Association (1890), the Royal Society of Edinburgh, and other scientific bodies, but, alas! I have not found time to write a full account of my material, and I have been putting off—perhaps too long—in the hope of getting sufficient leisure for the task.

In September, 1897, I visited Gayndah, in Queensland, in search of the eggs of Ceratodus and Platypus. I had at once abundant success as regards the Ceratodus material, and so was tempted to devote most of my time to it. I shot a few specimens of Platypus, however, and did a little digging for eggs, without finding any. I did, nevertheless, have success of a kind with Platypus. On the last day of my fortnight in the district (September 20) I managed to find a nest with an adult female Platypus and a young male $5\frac{1}{8}$ inches in extreme length. The mode of finding was both interesting and instructive. My two men and I, after trying several burrows in vain, came on the productive one. After following it for about 10 feet we reached the "breathing hole"; after another 7 feet we came to an apparent end of the burrow, and were greatly disappointed, as we had seen clearly the wet and inwardly directed footprints of a Platypus all the way from the external opening. One of the men groped about eagerly for any sign that the Platypus was working away from us, and finally we were able to track the burrow—filled though it was—through the hard surrounding soil. It soon appeared that the tube had only been blocked for a short distance by loose soil, which was doubtless of use in keeping out intruders. After a short distance we got beyond the plug, and came again to an open passage. Fully 21 feet from the bank we came upon the nest. It was just large enough to permit of the adult Platypus turning in it. The top was about 9 inches above the bottom, and was about a foot from the surface of the soil. The nest itself was made of bark, leaves, &c. The mother and her offspring were quite buried in the material of the nest.

In 1898 I was again able to spend a few days in Gayndah, and I secured several uterine eggs from Platypus and three entire nest eggs. On August 31 I got two nest eggs adhering together, each of them about 15 mm. in greatest diameter. The eggs were perfectly intact, and the shells firm. The embryos were far advanced, and measured about 1 cm. in length.

On September 1 I got another intact nest egg and a female adult at the end of a burrow. The embryo in this egg was even more advanced than in the others.

I secured about the same time several nest embryos, and I was inclined to think that my visit was rather late in the year for nest eggs.

I may add that, as a rule, in following a productive burrow I had to work through one or several "plugs." It would seem as if the mother Platypus, even when at home, adopts the same method of securing safety as rabbits make use of when leaving their young in a burrow.

Queen's College, Belfast. GREGG WILSON.

Sulphur as an Insulator.

THE gold-leaf electroscope, simple as it is, has proved itself to be an excellent instrument for showing the properties of statical electricity; but usually it has this drawback, namely, that it does not retain an electrical charge at a constant value for a conveniently long period of time. Recently an aluminium-leaf electroscope has been tested by me for insulation; the results, which speak for themselves, may be of interest to others who employ this electrical instrument. The electroscope was designed by Prof. J. S. Townsend, F.R.S. Its excellence depends on the metal leaves being supported by means of sulphur. The appended table shows how it behaved during ten days, on many of which rain fell, and from the air in the room where the experiment was made moisture was freely formed on bottles and metal instruments. Each division indicates a potential difference of 100 volts. The charge was positive; * indicates rain:—

Date	Time	Divisions	Date	Time	Divisions
*Nov. 26 ...	11 a.m. ...	8·0	Dec. 1 ...	Noon ...	4·0
* „ 27 ...	11 a.m. ...	7·0	„ 1 ...	6 p.m. ...	4·0
* „ 28 ...	Noon ...	5·0	* „ 2 ...	Noon ...	3·5
* „ 28 ...	6 p.m. ...	5·0	* „ 2 ...	6 p.m. ...	3·5
„ 29 ...	11 a.m. ...	4·75	„ 3 ...	10 a.m ...	3·0
„ 30 ...	11 a.m. ...	4·5	* „ 4 ...	11 a.m. ...	2·75
„ 30 ...	6 p.m. ...	4·25	„ 4 ...	3.30 p.m. ...	2·5
			„ 5 ...	Noon ...	1·0
			„ 6 ...	6 p.m. ...	0·0

I have also a quadrant electrometer having a long suspension of metal ribbon. All parts of this instrument are supported on pure sulphur; an experience lasting over many years has proved the excellence of sulphur as an insulator. Of course, an instrument so constructed requires careful handling, but when once erected in a suitable niche it will be found to give hardly any trouble and to keep its charge well. It seems somewhat strange that with some few and noteworthy exceptions, sulphur as an insulator should not be more frequently employed in the physical laboratory at the present day, as its excellent qualities were known and utilised in the early days of electrical science before 1797 by Wilcke, Œpinus, Henley, and others. I may add, in conclusion, that in the construction of the interesting little electrical dry pile apparatus, whereby a small bell has been constantly struck for forty-two years in the Clarendon Laboratory, Oxford, sulphur was employed as the insulator.

F. J. JERVIS-SMITH.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

III.—*Some Measurements in South Wales.*

THANKS to the kindness of the Rev. John Griffith, Col. Morgan and other friends, I was enabled last August to visit several monuments in South Wales.

I had previously inquired of persons living in North Wales about the existence of cromlechs and other memorials of the past in that region, and had been informed that they were very rare; but before my visit to Swansea the Rev. J. Griffith had told me that he personally knew of forty cromlechs in South Wales, so one would suppose that the conditions are very different in different parts of the Principality; but this does not appear to be so, for I have since found that Anglesea is richer in these monuments than Glamorgan. Perhaps the explanation is that there is little *general* interest taken in these matters.

The most important cromlech I visited under the auspices I have mentioned was that of Maen Ketti, or Arthur's Stone, in Gower, whither we motored from Swansea.

FIG. 10.—Arthur's Stone.

The antiquities in this region, which are very numerous and important, and include the remains of one or more avenues as well as the cromlech, were carefully studied by Sir Gardner Wilkinson.[2]

In his most interesting account of them he begins by pointing out the important place the cromlech itself occupies in Welsh tradition:—

"If the Greeks recorded the 'wonders of the world' in their time, under the mystical number seven, four of which might be claimed as their own, the Cymry have also recorded the wonders and mighty labours of the Britons in one of their Triads under their favourite, an equally mystical, number three: namely 1, raising the Maen Cetti; 2, erecting the work of Emrys; and 3, heaping the pile or mound, of Cyfrangon. The first of these is the stone of Cetti, or 'Arthur's Stone'; the second, Stonehenge; and the third, apparently, the mound called Silbury Hill, near Abury."

For Sir Gardner the cromlech was a great tomb, as his description will indicate:—

"The great cromlech, called Arthur's Stone, stands on that part of the hill called Cefn Bryn in Gower, which is an outlying branch projecting from the north side of the main ridge Cefn, or 'backbone'; and the great number of carns in that locality show that it was selected as the most appropriate spot for the burial of the dead in early British times. For though several carns, or tumuli, are found on other parts of the hill, they are more scattered, and evidently occupy positions not so peculiarly chosen for the purpose."

He next refers to the avenue.

"Near to the great cromlech is a line of four, or perhaps five, stones, standing at irregular distances from each other, and in a direction nearly east and west, which has every appearance of being the remains of an avenue. If so it passed a little to the north of the cromlech; and though these stones only form a portion of one side, or of one row of that avenue, some of the corresponding stones may be traced on the other side, and give the avenue a breadth of about 49 feet. The five most conspicuous stones on the north side may be the isolated remains of a great number which once stood there, the intervals between them being respectively 165 feet, 79 feet, 149 feet, and 107 feet; and the whole length of the line, from the most easterly to the westernmost stone, nearly opposite or to the north of a drive or grass road apparently made there in later times, which passes to the north of the cromlech; and as the stone opposite the cromlech (the westernmost of the five above mentioned) is distant from it about 60 feet, this alone suffices to show that the avenue did not run direct to that monument. It is difficult to determine whether a corresponding line of stones formerly stood on the opposite or south side, so as to form a real avenue; but even if this were so, the avenue would not, as we have already seen, lead to, but past, the cromlech, as the grass road does at the present day. It is also difficult to decide whether the road has taken the place of an older one, once the centre of the avenue, or is a drive of entirely recent origin made for the purpose of passing near the cromlech, and round the great carn beyond it to the west; whence it continues over the adjoining part of the hill. It certainly has the usual appearance of old paths, such as we find in the vicinity of ancient ruins, the grass being short and smooth; though this may have been caused by the removal of the fern and furze, and the constant use of the road after it was formed into a drive. It is, however, reasonable to suppose that the few stones, which stand here and there to the south of the grass road, constituted part of the corresponding side of the

[1] Continued from p. 84.
[2] "Avenues and Cairns about Arthur's Stone in Gower," by Gardner Wilkinson ("Arch. Cambrensis," fourth series, vol. i., pp. 23–45).

avenue, though the intervening distance of 49 feet (6 feet more than the width of the eastern avenue at Abury) may appear an unusual breadth for one, the stones of which do not exceed 3 feet to $3\frac{1}{2}$ feet in height. I may also state that other stones appear here and there, on both sides of the grass road, beyond the limits of the portion of the avenue marked by the five stones, which may be a continuation of the same double line to the east and west. They would not, however, be sufficiently conspicuous to suggest the existence of an avenue, if the five stones had not been present to prove it. Many also stand at the extreme end, to the south-east, where the first carns are met with on this part of the hill."

Next follows a statement which shows what a keen and practised observer Sir Gardner was. Had I known of it earlier it would have saved me much trouble.

"I need scarcely observe that it is by no means necessary that the avenue should lead direct to Arthur's Stone, and it is more usual to find a cromlech at one side of, and at a short distance from, it; that near Merivale Bridge, on Dartmoor, stands about 50 feet to the south of the avenue, and the Dolmens in Brittany are, in like manner, placed outside the avenue. A carn also stands about 80 feet south of the same avenue near Merivale Bridge; but about 560 feet west of the cromlech, in the centre of the avenue, is a concentric carn, of which the diameter is about three times the breadth of the avenue. The position of Arthur's Stone with respect to the avenue is, therefore, similar to that of some other cromlechs in this country and in Brittany, but while we see that the avenues of Merivale Bridge, and in some other places on Dartmoor, terminate in an upright stone, a carn, a concentric aisle, or some other sepulchral monument, we are unable to ascertain how the two ends of the Cefn Bryn avenue were closed or to what they led."

The avenue, which was perfectly obvious, lay on our way to the cromlech, so I measured it first. The azimuth (magnetic) to the south-east was S. 136° E., height of horizon 1° 30′. In the north-west direction the elevation of the horizon was 0°.

The cromlech from its state of wreckage was much more difficult to measure. The length of the quoit is roughly north-west and south-east, and the long faces are not parallel, and, indeed, a large mass has been detached, but the north-west side is pretty plane. I measured its direction as N. 82° E., and on examining the supporters as well as one was able, the opening of the cromlech appeared to lie in that direction. I have no note of the height of the horizon, but Mr. Griffith tells me that it is hilly, let us assume 1°.

Now what do these azimuths mean? I can answer this question best by giving the following table, which shows without any possibility of doubt that these Gower monuments, like those in Cornwall, deal with the May-year sunrises, the avenue with the rise in November, and the cromlech with the rise in May.

Gower, lat. 51° 37′ N., variation 18° W. May-year values, theoretical.

Conditions	May		November	
	True	Magnetic	True	Magnetic
Sea horizon: refraction and semi-diameter ...	N. 62° E.	80°	S. 64° 40′ E.	133° 20′
1° hill: refraction and semi-diameter	N. 63° 36′ E.	81° 36′	S. 62° 33′ E.	135° 27′
2° hill: refraction and semi-diameter	N. 65° 10′ E.	83° 10′	S. 60° 58′ E.	137° 2′

To compare theory with the actual magnetic observations we have :—

	Computed value	Measured
Avenue, November sunrise	136° 14′	136°
Cromlech, May sunrise	81° 36′	82°

Need I say that these results of the first measurements made in Wales are very encouraging, and, more than that, *helpful*, because they show that the Cornish experience can be fully utilised, as we are dealing with no new thing.

Another cromlech we visited is one of great interest. I suppose its quoit is the largest in Britain. The north side is entirely closed by a large supporter; the south entirely open along its top; in the east and west ends there are openings. This large rectangular cromlech is situated in the parish of St. Nicholas in Duffryn Golych or Goluch (The Vale of Worship), near Cardiff. It is called by the natives Castell Corrig (Dwarf's Castle), a name which suggests belief in the presence of fairies there.

It seemed at first probable that this monument might have a high south-east alignment. Mr. Griffith noted the openings in the east and west supporters, and found the eastern azimuth of the north supporting slab to be N. 76° E. (true), with a height of horizon of 2°. This particular wall need not necessarily be parallel to the outlook of the cromlech, which for the May sunrise should be, as the previous table shows, N. 65° E. It is too early, therefore, to claim it as oriented, like Arthur's Stone, to that sunrise; we may be dealing with the Pleiades, but to settle matters some excavations and further measures are required, and I am glad to learn that the Cardiff Naturalists' Society has made arrangements with Mr. Cory, on whose estate the cromlech stands, for the necessary excavations in the spring of next year.

A few yards to the west of the large cromlech there are the remains of another not nearly in such a good state of preservation, but one side support is fairly in position, and, as I shall show later on, we are justified of taking this in the absence of more precise information.

The azimuth of this stone towards the E. is S. 51° E.

Evidently, then, we are not dealing with the May-year. Is it a solstitial cromlech? I give, as before, the theoretical azimuths.

Solstice azimuths in lat. 51° 30′ for 2′ of the disc showing above a sea-horizon, refraction being taken into account.

Summer solstice	... ...	N. 48° 42′ E. or W.
Winter ,,	... ...	S. 51° 35′ E. or W.

We see that the azimuth tallies exactly, so we must accept it as a cromlech directed to the winter solstice sunrise.

With regard to another cromlech, St. Lythan's, in the same neighbourhood, known locally as Gwâl y Vilast, "the lair of the greyhound bitch," the azimuth of the north stone, S. 88° E., shows it to have been oriented to the equinoctial sunrises in March and September. The cromlech opens to the east.

On a previous visit Mr. Griffith found outside the cromlech chamber a red sandstone pebble used both as a pounder and a rubber or burnisher. It may have been taken out of the chamber when the latter was uncovered or cleared out. It was right on top of the cairn shell, in which the chamber was once embedded.

I have now referred to all the sun-temples we found in our two days' inquiries. Both Mr. Griffith and myself made measures of other monuments, but space fails me to refer to them now; still, I must make one exception.

We measured still another cromlech of very considerable interest, as in it we dealt with a presentation to the rise of a clock-star, and no longer to the sun. This is the remaining interior of a four-chambered barrow situated at Parc y Braose, or Parc Cwm, or the Green Combe. It was excavated by Sir John Lubbock, now Lord Avebury. The true azimuth is N. 8° E., the height of the horizon 6°. These data give us Arcturus 2600 B.C., a little earlier than the Cornish monuments with somewhat similar orientations.

It will be very instructive at some future day to compare the plans of the Castell Corrig cromlechs and that of Arthur's Stone with a view of determining the exact alignments of the supporters. I have already done this work on the plans of the Cornish cromlechs.

A study of Lukis's plans, especially of the stones still upright, brings out many interesting points, among them the fact that there were two general methods of building. One was to plant one or two stones in the exact direction of the alignment. The location of the other stones did not matter so long as the quoit was properly supported, but in many cases they were set up parallel to the directing stone, as we may call the first one erected. Another system was to support the quoit on a tripod. When this was done its greatest length was sometimes at right angles to the direction of orientation, this direction being indicated by the alignment of the single stone at one end.

It often struck me in Cornwall that the exact alignments, especially to the May-year sunrises, *which really required a knowledge of the number of days which had elapsed since the last solstice*, were the work, not of each local druid, but of peripatetic astronomer-priests who went from place to place establishing and orienting the circle and the priests' house (cromlech), and then leaving subordinate priest-druids —curates—in charge, who could not go far wrong when the alignment of both circle and cromlech fixed the May, August, November and February festivals; the solstices they could easily fix for themselves, because then the sun rose in the same place on three successive mornings.

The study of Lukis's plans shows that the work of the peripatetic priest might really have been limited in the first instance to the setting up of the single directing stone. Of course he would examine the finished work in his tours of inspection, probably at the critical times of the year—the quarter days.

I sent this suggestion some little time ago to the Rev. J. Griffith, who has greatly helped me by permitting me to draw upon his vast store of Welsh tradition. His reply really supplies us with a new line of evidence as to the tenancy of cromlechs by living men, in addition to those I have already put forward.

"I have spotted your travelling time-keeper, though I seem never to see anything until you point out what to look for. He is very conspicuous in Welsh cave legends. There is the lonely watchman—your 'curate'—waiting and waiting for him. All over the country a couplet is known as having been uttered by the 'curate.'

'Long the day and long the night,
And long it is to wait for Aaron.'

"Sometimes his name is Noah. It is clear why the pagan should have a Bible name; Aaron is the rationalised form of the name of a Welsh legendary hero—Arawn.

"In two cave legends the curate is heard exclaiming:—

'The hour is come, but the man is not.'

In one case it is the eve of New Year's Day.

"Who could the mysterious man be if not your peripatetic astronomer-priest? He was evidently very much wanted for the great festival. Your surmise or conclusion has lit up a round dozen tales I now remember, and doubtless I can find many more."

NORMAN LOCKYER.

THE INCREASED ENDOWMENT OF UNIVERSITIES.

WE are glad to see that the Press is again directing attention to the importance of an increased endowment of our universities, not so much, at the present moment, of the older universities as the younger ones. It is, in fact, the Government action in regard to Manchester University which has directed attention to the subject. That opinion is getting more enlightened is evidenced by the fact that it is now beginning to be recognised that the real gainer by such endowment as this is not any particular locality or university, but every student throughout the length and breadth of the land who is debarred by high fees from attending university courses, the university being compelled to charge high fees in order to go on at all in consequence of the absence of adequate income from any other source.

Here are some extracts from a recent article in the *Morning Post*, to take one instance:—

"It is necessary if the nation is to continue to be an independent Power to have a Navy able to defeat and destroy its rivals, and an Army able to do all such fighting, in case of war, as the Navy cannot do. But this necessity, of which no one is enamoured, does not absolve the Government from the duty of doing the very best it can for the training not only of the rank and file, but of the leaders of its population. Mr. Asquith will provide in his estimates some fifty million pounds for the needs of the Navy and of the Army. This of course cannot be reduced. For the modern universities and colleges that represent a great popular effort towards providing a better training for leaders than existed for the fathers of men now at work, and for many of those men themselves, Mr. Asquith cannot imagine that he ought to provide more than 100,000*l*. But this sum might be increased without reducing the other. The fifty millions are unproductive expenditure. They are mere insurance, a disagreeable necessity. But the money spent on educating young people is the most remunerative outlay possible to a nation.

"The University of Manchester is the means, in most cases the only means, open to the inhabitants of a great area in South-east Lancashire, Cheshire, and part of Yorkshire, a population numbered by millions, of obtaining an education going beyond school work. It is admittedly among the best of modern universities, with a large staff of first-rate professors, an admirable set of buildings, and an assiduous, devoted, and capable governing body. It represents the chance of South-east Lancashire providing itself with leaders in industry, commerce, the sciences, and the humanities.

"Manchester may have to compete with some place like Berlin, the centre of a comparatively small population. Berlin does not limit its Government grant to university and other forms of higher education to such a sum as ten thousand a year, therefore, and Berlin tends to eclipse Manchester in the fields of industry, trade, science, art, and the humanities.

"Mr. Asquith knows as well as anyone else how many millions such men as Sir Robert Giffen and Sir Norman Lockyer think the British Government will have to spend on universities and colleges if England is to keep her place among the nations. They may talk, but he draws the line at one hundred thousand pounds. But does he not see that the welfare of England and her people depends above all things on their personal character and qualities twenty years hence, on the kind of men and women that she is turning year by year into citizens and mothers?"

Mr. Asquith we suspect knows more of these matters than the writer in the *Morning Post* thinks. The Chancellor of the Exchequer, in speaking at the London Chamber of Commerce in November of last year [1] said:—

"The strain of foreign competition presses upon us in every walk of business and every market in the world, and, whatever are the contributory causes of the pressure which we all in a greater or less degree experience, there is not a man acquainted with the facts who will not agree that in the case, at any rate, of some of our most formidable competitors—for instance, Germany and the United States—one of the great sources from which they have derived exceptional strength in their commercial and industrial struggle with us has been the superior development of their technical and educational system."

But it may, after all, be that Mr. Asquith is unacquainted with the methods adopted by the German Government, to take one instance, to secure this superior development. German universities are considered by our statesmen as a *quantité negligeable*; all their attention is directed to the German ironclads. This is not so in Germany, as witness the increased endowment in fifteen years of some German universities taken at random:—

State Funds.

	1891–2 £	1906 £
Berlin	107,057 ...	161,539
Bonn	45,806 ...	59,192
Breslau...	44,749 ...	66,375
Göttingen	20,877 ...	35,303
Greifswald	13,974 ...	28,889
Halle	33,284 ...	59,819
Kiel	28,188 ...	53,072
Königsberg	39,930 ...	57,344

The same growth of enthusiasm for higher education which is characteristic of German statesmanship is met with throughout the more densely populated eastern United States. When a comparison is instituted between the income of universities and colleges in the States in the year 1899–1900 and the income in 1904–5 (the latest year for which detailed official statistics have been published), that is fifteen years later, an enormous increase is found to have taken place. In the earlier year the total income of these institutions of higher instruction was 2,399,000*l.*, while in 1904–5 the amount had grown to 7,110,000*l.* But large though these sums are, they take no account of the generous benefactions of American men of wealth referred to later. From this source the universities and colleges received in 1899–1900 2,399,000*l.*, while fifteen years later the amount given for the spread and development of higher learning reached the magnificent sum of 3,335,800*l.* Harvard University alone received during the later year 466,000*l.*, Yale benefited to the extent of 279,000*l.*, and Columbia was enriched by 236,000*l.* Figures such as these serve better than any words to exhibit the comparative insignificance of the 122,000*l.* which, as we shall show, represents the total State endowments of English universities.

But British statesmen cannot be held responsible for the unpopularity of universities and colleges as the object in this country of the bequests and gifts of wealthy men and women. In the following table, therefore, benefactions are excluded, and the growth in the income of the universities of five important eastern States in America is given, as typical of the advance made in the eastern half of the United States in the provision for higher instruction during the fifteen years under consideration.

Total Income, Excluding Benefactions.

	1899–1900 £	19·4–1905 £
Massachusetts ...	521,800 ...	614,000
New York	705,700 ...	981,300
Pennsylvania	390,100 ...	534,400
Ohio	266,600 ...	387,000
Illinois...	388,800 ...	585,800

The decision of Mr. Asquith to reduce the grant of Manchester University from 12,000*l.* to 10,000*l.* a year, we presume, is based on the stern argument that as little money as possible should be spent on the higher education; even although it is the true source of national development; it is a question, not of national, but of party politics.

In the case of party politics, of course, economy may be thrown to the winds. Mr. Haldane, when he opened the new college at Reading,[1] told us:—"The present Government proposes to spend an extra 1,000,000*l.* a year on elementary instruction, and the late Ministry spent more than that sum additionally for the same purpose, *but these payments arose out of controversies which had* LITTLE TO DO WITH EDUCATION."

Dealing with the modest contribution of the British Government to the universities and colleges of England, the estimates show us that in 1903 the endowment of universities amounted to 14,800*l.*, which we find increased in 1907 to 22,000*l.* In 1903 the grant to English colleges stood at 26,000*l.* This has now been increased to 100,000*l.*, we believe in consequence of the strong representation made by the British Association deputation in 1904. It is seen that at present the total State endowment of the English universities—22,000*l* + 100,000*l.* = 122,000*l.*—is some 40,000*l.* short of the German State endowment of one university alone, that of Berlin.

We are told that to provide the "superior development of our technical and educational system," which even Mr. Asquith acknowledges is necessary to meet "the commercial and industrial struggle," we must trust to private endowment. Cambridge has recently asked for a private endowment to provide funds which the university wants at once. At the rate at which this private endowment has been coming in during the last few years, ninety years will elapse before all these funds are in hand. This is a fair sample of what private endowment does for university education in England, while the competing universities and colleges of the United States last year received nearly 5,000,000*l.* from this source,[2] every penny of which tended to reduce fees and extend the benefits of university instruction to a greater number of students, the peace army of a nation.

In addition to this it is important to remember that American experience all goes to show that the best results are obtained when universities are chiefly dependent on the State and not upon private generosity. It has been pointed out recently in the United States (NATURE, vol. lxxvii., p. 93) that as a result of the gifts of millions of dollars from great American financiers, the universities are in danger of being reckoned the purchased servants of a narrow caste. It is being urged there, as we have urged here, that it is the duty of the State to provide higher education for the people; and there is every indication that American authorities may be trusted to maintain the efficiency of their universities and colleges.

The increase in the efficiency of colleges and universi-

[1] NATURE, December 6, 1906 (vol lxxv., p. 141).

[1] NATURE, November 1, 1906 (vol. lxxv., p. 22).
[2] *Ibid.*, January 3, 1907 (vol lxxv., p 137).

ties in this country is too pressing a need to be dependent upon party politics. Unless our statesmen can be made to realise the supreme importance of this matter and be persuaded to deal with it in a patriotic manner, generously and expeditiously, as if there were no votes to retain or secure, we must reconcile ourselves to the idea that as a manufacturing and distributing people we shall in due course have to occupy a third or fourth place among the nations of the world. In Germany, the United States, and now in Japan rulers have learnt the lesson that efficient education and industrial success are related to each other as cause and effect; and, moreover, they appear to be supported by an enlightened public opinion.

If our statesmen refuse to lead, we must make every effort to educate the voters of the country to realise the certain results of a policy of drift from which the most important of our national questions—so far as the future welfare of the British Empire is concerned—is suffering. If, meanwhile, our present supremacy is lost, it will not be because men of science have failed to warn their countrymen of the scientific spirit and energy which are yearly increasing the industrial efficiency of our great competitors.

NOTES.

On the day of going to press we learn of the death of Lord Kelvin, an announcement which will be received with deep sorrow throughout the civilised world. To men of science, Lord Kelvin's achievements in the realm of scientific thought and discovery have long been familiar; and thirty-one years ago, in Nature of September 7, 1876 (vol. xiv.), his remarkable contributions to natural knowledge were described in our Scientific Worthies series, of which he was then the subject. His death is a loss to science which only scientific workers can adequately realise. The world has to deplore the departure of a brilliant and inspiring figure; while science mourns that a leader whose influence has stimulated progress in many directions during a remarkable period has passed into stillness. For the body of one who has brought such honour to the British nation, the only appropriate place of burial is Westminster Abbey. We trust that steps will be taken at once to secure this mark of national recognition of the greatness of one who has long been regarded as the most distinguished man of science of modern times.

A life of Lord Kelvin has been in preparation for some months by Prof. Silvanus Thompson, who was entrusted with this work, and to whom Lord Kelvin himself furnished numerous biographical details and other matter for the purpose. It will be published in the course of next year by Messrs. Macmillan and Co., Ltd.

The Prince of Wales was elected an honorary member of the Royal Irish Academy at the last meeting of the academy. In the case of the election of a member of the Royal Family the election is by resolution, which was moved by the Earl of Aberdeen, Lord Lieutenant, who is the visitor of the academy, and seconded by Mr. D. H. Madden, Vice-Chancellor of the University of Dublin.

Sir Norman Lockyer, K.C.B., F.R.S., has been unanimously elected president and an honorary member of the Penzance Natural History and Antiquarian Society in recognition of his services to the study of the circles and other prehistoric remains in west Cornwall.

M. Edouard Cuyer has been elected president of the French Anthropological Society for 1908.

Two lectures suitable for a juvenile audience will be delivered for the Society of Arts on January 1 and 8, 1908, at 5 p.m., by Mr. F. Martin Duncan, on "The Scientific Applicatiuns of the Kinematograph."

A course of six lectures on the geographical distribution of rainfall in the British Isles will be given by Dr. H. R. Mill in the map room of the Royal Geographical Society on Thursday evenings in January and February, 1908, beginning January 23 at 5.30 p.m.

Prof. R. W. Wood, professor of experimental physics in the Johns Hopkins University, has been awarded, *Science* states, the John Scott legacy premium and medal of the Franklin Institute of Philadelphia for his discoveries in colour photography.

The Russian Physico-chemical Society has arranged to hold a conference of general and applied chemistry in honour of Mendeléeff at the beginning of January, 1908, at the University of St. Petersburg. Several discourses will be delivered on the great chemist's life and works. We learn also from the *Revue scientifique* that the journal *Russj* has inaugurated a subscription for the purchase of a Mendeléeff House, which, like the Hofmann House in Berlin, would be used for the meetings of learned societies.

The eleventh International Congress of Navigation will be held at St. Petersburg from May 31 to June 7, 1908, under the patronage of the Emperor of Russia. The previous meetings were held at Brussels, in 1885; Vienna, 1886; Frankfort-on-the-Main, 1888; Paris, 1889; Manchester, 1890; London, 1891; Paris, 1892; the Hague, 1894; Brussels, 1898; Paris, 1900; Dusseldorf, 1902; Milan, 1905. Arrangements have been made for communications and discussions on several questions relating to inland and maritime waterways, including the industrial and agricultural utilisation of rivers, and for scientific excursions and inspections of some of the rivers, canals, and sea ports in Russia. The address of the general secretary of the congress is 7 Ismailovsky Prospect, St. Petersburg.

The current number of the *Revue Scientifique* contains an account of "La Caisse des Recherches scientifiques." The fund was founded by law on July 14, 1901, on the proposition of M. Audiffred, with the double object of assisting medical science in its researches and of providing financial assistance to original workers in pure science. The fund receives from the French Government an annuity of 5000*l*., and at its inauguration M. Audiffred gave 2400*l*. The idea of the fund has not proved altogether popular, for in 1906 the Caisse des Recherches received general donations to the extent only of just under 200*l*. But there has been considerable improvement this year, and it is anticipated that the amount will be much larger; the Paris Municipal Council itself gave 200*l*., and several general councils have given small sums. Since its creation the Caisse has distributed more than 24,100*l*., of which about 1000*l*. only was available for work in other than medical and biological science. M. Rigaut may well say that these sums are wholly inadequate so far as the needs of science are concerned.

Prof. Asaph Hall, whose death we announced last week, will always be remembered as the discoverer of the satellites of Mars, since the sensational character of the discovery appealed powerfully to the public mind; but in many ways he accomplished much useful work in every department of astronomy, and exhibited an industry which placed him in the forefront of American astronomers.

Diligence and energy were his principal characteristics from the time when he entered Harvard Observatory, as a junior, fifty years ago, until he retired from the honoured position of professor of astronomy in 1901. The greater part of his work, however, was accomplished at Washington, and it is difficult to say what department of astronomy he did not enrich. He was one of the earliest to appreciate the value of the observations of Mars as a means for deriving the solar parallax, and he took part in solar eclipse expeditions for physical work on the sun. His observations of planets, whether for position or for surface detail, were frequent and accurate. He was an industrious observer of double stars, and his work on stellar parallax, as well as in the determination of the relative positions of stars in clusters, is well known. On the theoretical side of astronomy he contributed papers on the secular perturbations of the planets, the computation of orbits, and many similar problems. As a geodetist, the value of his work in the determination of longitudes and on the employment of the occultation method has long been recognised. His career was that of a typical practical astronomer, and the recognition of his work was shown by his election into many learned societies. He was both gold medallist and foreign associate of the Royal Astronomical Society.

THE subject of river pollution from the naturalists' point of view was introduced by Prof. R. Meldola, F.R.S., at a largely attended conference meeting, convened under the auspices of the Essex Field Club, and held in the Municipal Technical Institute, Stratford, on Saturday, December 14. The Mayor of West Ham was in the chair at the beginning, and subsequently the president of the Essex Field Club (Mr. Miller Christy). Among other speakers upon the subject were Mr. E. B. Barnard, M.P. (chairman, works committee, London Water Board), Mr. David Howard, J.P. (past-president Society of Chemical Industry), Dr. Parsons (Local Government Board), Sir Alexander Pedler, K.C.I.E., F.R.S. (hon. secretary, British Science Guild), Sir William Ramsay, K.C.B., F.R.S. (president Chemical Society, and chairman Royal Commission on Sewage Disposal), Dr. Sanders (medical officer of health, county borough of West Ham), Dr. Sommerville (lecturer on public health, King's College, London), and Dr. J. C. Thresh (medical officer of health, Essex County Council). At the close of the meeting the following resolution was moved by Sir Alexander Pedler, seconded by Mr. E. B. Barnard, carried unanimously, and ordered to be transmitted to the Local Government Board and the British Science Guild:—"That this meeting, having heard the expert testimony of many qualified speakers interested in the improvement of the state of our rivers, streams, and water-ways, it is of opinion that legislative action is urgently needed, and would regard with satisfaction the creation of a central authority under Government for dealing with the general question of water supply throughout the kingdom, as well as with the disposal of sewage and of effluents from factories; such central authority to be given power to apportion expenditure on sewage treatment or other necessary work of purification amongst the communities deriving benefit from such expenditure."

British Birds for November contains an excellent portrait of the late Mr. Howard Saunders to illustrate an obituary notice by Mr. Abel Chapman. The portrait is also published separately by Messrs. Witherby and Co., price 1s. 6*d*. The other contents include a paper by Dr. E. Hartert on races of birds peculiar to the British Islands, and a note by Mr. N. F. Ticehurst on the capture in Romney Marsh of a specimen of the American sandpiper, *Ereunetes pusillus*, this being apparently the first record of the species in Europe.

To the *Times* of December 14 Sir T. Digby Pigott communicates an account of a luminous bird—believed to be an owl—recently seen at night in Norfolk. The idea that the "powder-down" patches of certain birds are luminous has been held, we believe, in America, but is generally discredited by ornithologists. The circumstantial account of the Norfolk bird may, however, lead to a reconsideration of the evidence, although we cannot admit that the name *Strix flammea* has anything to do with the alleged phenomenon, as it almost certainly refers to the colour of the feathers of the back. The story that the heron emits a phosphorescent light in order to attract fish also seems "shaky," seeing that the bird is diurnal in habits.

AT the close of a paper published in the November issue of the *Quarterly Journal of Microscopical Science* on the muscles of the head in birds (as exemplified by the domesticated fowl) and reptiles, Prof. H. F. Edgeworth attempts to formulate the leading anatomical features of the common ancestor of those two groups. The list is too long and too technical to be quoted here, but it may be noticed that in certain respects the author finds that birds have more in common with chelonians than with any other group of reptiles. "These features of resemblance suggest at first sight a very distant chelonian relationship for birds, but are in reality very ancestral traits, which are also present in embryonic stages of other sauropsidan groups. The secondary fixation of the pterygo-quadrate and atrophy of the elevator of the pterygoid process, which occur in Chelonia, are strongly marked differences from birds."

IN connection with the preceding note, reference may be made to a paper by Dr. W. Sippel on the structure of the roof of the mouth in birds and mammals, published in vol. xxxvii., parts ii. and iii., of *Gegenbaur's Morphologisches Jahrbuch*. The greater portion of the paper is devoted to the soft-parts of the palate, and it is shown at the conclusion that in homologising the constituent elements of this region in birds and reptiles several misidentifications have been made by previous workers. The long, posteriorly widened median slit in the palate of the bird does not, for instance, represent the secondary choanæ, but rather the orbito-subchoanal cleft. The paper concludes with a comparison of the bones of the palate in reptiles, birds, and mammals, as illustrated by the monitor, the duck, and the dog, and here, too, some important differences distinguishing this region in the three classes are indicated.

IN the December number of the *Popular Science Monthly* Prof. Bashford Dean gives his impressions of the chief museums of Asia, as gathered during a recent eastern tour. Among the institutions referred to is the Raffles Museum and Library at Singapore, of which the author writes in terms of high commendation, the Colombo City Museum, the Madras Museum, and the Indian Museum, Calcutta. Dr. Willey's arrangement of groups of animals to give an adequate idea of the wild life of Ceylon is regarded as one of the great features of the Colombo Museum, while, under Mr. E. Thurston's administration, the institution at Madras is described as one of the most successful of its kind in India. The Calcutta establishment must, however, stand at the head of all the museums of Asia, its success, in the author's opinion, being very largely due to the policy of selecting as directors men eminent, not only in science, but in administrative ability. Reference may also be made to an interesting article in the same issue on the origin of slavery among ants, by Dr. W. M. Wheeler.

The training of foresters for India and the organisation of the scientific work of the department form the subject of a leading article in the *Indian Forester* (September), in which the writer points out the necessity for a systematised programme arranging for the compilation of forestry data and research. An article on improvement fellings is concerned with the problem of increasing the growing stock of teak. Premising that many saplings are killed by creepers and faster growing trees, the author, Mr. H. C. Walker, adduces arguments and statistics in favour of taking measures for saving young teak trees by a judicious system of thinning.

Among the experimental work referred to by Mr. W. Fawcett, director of the Public Gardens and Plantations, Jamaica, in his annual report for the year 1906–7, the raising of selected seedling sugar canes and the cultivation of Havana and Sumatra tobacco are of primary importance. It is recorded that as a result of comparative experiments a better yield of coffee has been obtained at the Hope Gardens under shade than without shade, and preference is given to the guango, *Pithecolobium saman*. The satisfactory results attending the instruction of small landholders by travelling instructors are noteworthy; by this means, as also by the establishment of agricultural banks and prize-holding schemes, the agricultural population is developing an appreciation for improved methods of cultivation.

Much valuable information on insect pests attacking crops is being disseminated by the Bureau of Entomology, forming part of the United States Department of Agriculture. In Bulletin No. 68, part iii., Mr. A. L. Quaintance deals with the trumpet leaf-miner of the apple, *Tischeria malifoliella*, a Tineid moth that is destructive to species of Cratægus and Pyrus. The mines are burrowed by the larvæ in the palisade layers of the leaf. Spraying with kerosene emulsion is recommended for destroying the larvæ and pupæ. Mr. A. A. Girault describes the life-history of the lesser peach-borer in Bulletin No. 68, part iv. The species, formerly referred to Sesia, a genus of moths of the family Sphingidæ, now receives the name of *Synanthedon pictipes*. It occurs principally on plum and peach trees, and must be distinguished from the better-known peach-borer, *Sanninoidea exitiosa*.

In his annual address to the Australasian Association for the Advancement of Science, Dr. A. W. Howitt gives an account of his reminiscences of Central Australian exploration, and in particular of the search for the ill-fated members of the Burke-Wills expedition. The causes of the failure of this enterprise lay, he shows, in the extravagant amount of supplies provided, for which carriage was inadequate, in the impetuosity of the leader, and in want of cooperation on the part of certain members of his staff.

The second number of the Journal of the revived Gypsy Lore Society, with its headquarters at 6 Hope Place, Liverpool, contains a reprint, revised by the author, Mr. C. G. Leland, of an article on the remarkable dialect known as Shelta, spoken by wandering tinkers, and apparently of Celtic origin. This a preliminary to a further study of this dialect. Mr. J. Sampson gives an interesting account of his experiences with a gang of German Gypsies at Blackpool. Mr. D. MacRitchie has collected much curious information to prove that throughout eastern Europe the Gypsies were formerly subjects of certain great noblemen, not of Gypsy race, who were appointed to that position by the rulers of those countries. Mr. W. M. Gallichan furnishes a report on the Gypsies of Andalusia, Mr. B. Gilliat-Smith on those of the Rhine Province, and Dr. T. R. Gyorjevic on those of Bosnia. A collection of interesting miscellaneous notes completes an excellent number, which has as its frontispiece a portrait of that eminent Gypsy scholar, Dr. A. G. Paspati.

The *Reliquary*, under the editorship of Dr. J. C. Cox, in succession to the late Mr. J. Romilly Allen, continues to be one of the most scholarly of our archæological publications. In the last quarterly number, issued in October, one of the most interesting articles is that by Mr. G. Le Blanc Smith on some dragonesque forms on, and beneath, fonts. Numerous examples of such a form of decoration are found in Sweden, but some in this country are equally interesting. One favourite type is that of the salamander, which is always represented as a lizard with bifurcated tail, in which there is one coil or twist. It has two legs set very far back on its body, a rather humped back covered by a pair of wings, longish ears, and a dragon-like head. In many cases the body of the animal is covered with scales, and the wings are clothed with feathers. The toes or claws are invariably three in number. Its countenance bears a look of loathing or disappointment, the symbol of its defeat as representing the powers of evil by the baptismal rite. The best examples of such figures are found on fonts at Norton and Youlgreave, both in Derbyshire. The second type represents dragons or grotesque monsters, humbled and abased, grovelling under the font itself, of which they form the base. Such are the fonts at Hereford Cathedral and at Castle Froome, in Herefordshire. A curious development is that at Ashford, where the animal is carved as though it actually protruded through the shaft of the font—the head at one side, the curly tail at the other. Mr. Le Blanc Smith asks for aid in discovering similar representations of monsters in other parts of the country.

A paper on the predetermination of train-resistance was read by Mr. C. A. Carus-Wilson before the Institution of Civil Engineers on December 10. Among the practical conclusions arrived at are that the resistance of the air with a train of bogie-coaches, running at sixty miles per hour, amounts to about one-half the total tractive effort required to haul the train. Experiments conducted by the St. Louis Electric Railway Test Commission show that a large reduction can be made in the front and rear air-resistance by shaping the ends, and that by this means a saving can be effected of 10 per cent. of the total tractive effort with a long passenger train, and 30 per cent. with a single coach.

A Colonial Office report (Cd. 3794) has been issued giving Major E. H. Hill's report on the Survey Department of British East Africa. The work at present in progress is the main triangulation of the country. Major Hill says that an additional section of two officers and six or eight surveyors is imperative to prepare topographic maps before the trigonometrical beacons are destroyed. He recommends that topographic maps should be issued on the scale of 1 to 125,000. He discusses a proposal for a school to train African natives for the survey work; but he regards the natives of British East Africa as at present quite useless for this purpose, while those trained on the west coast could not be employed in the highlands of East Africa. Indian natives are being employed, but have not proved altogether satisfactory.

REVIEWING the world's tin-mining industry, Mr. A. Selwyn-Brown, in the *Engineering Magazine* (vol. xxxiv., No. 2), shows that the world's production of tin last year was 96,196 tons. The active tin-mining fields are few in number, and, as a rule, not in a very prosperous condition, notwithstanding the high value of tin and the large existing demand for it. The alluvial deposits in the Dutch East Indies and in the Malay States are approaching exhaustion, and difficulties are being caused by the scarcity of coolie labour. Bolivia is advancing its consumption, but it is upon Australia and Tasmania that consumers will have to depend for the principal part of their tin supplies, unless Africa should develop into a tin-mining country of importance.

A STRONG gale traversed Scotland and the north-east of England during Friday night and Saturday in last week. During its progress over our island the cyclonic system increased greatly in depth, the lowest reading of the barometer reported being 28·39 inches, at Spurn Head, at 8 a.m. on Saturday. The greatest strength of the wind was from the north-west, and was due to a sharp rise of the barometer in the rear of the disturbance. The heaviest part of the storm occurred over the southern portion of the kingdom, where considerable damage was occasioned, and wrecks, accompanied with loss of life, occurred in the English Channel. Heavy rain preceded the storm, and large tracts of land were flooded in the Midlands and in the southern districts. A fall of temperature was experienced after the passage of the storm area, and frost has occurred in several places.

IN a lecture delivered before the meeting of German Naturalists and Physicians at Dresden in September last, Dr. E. Herrmann directed attention to his researches on the periodical variations of atmospheric pressure, and to the possibility of submitting the phenomena to numerical investigation. For this purpose he used the well-known daily synoptic weather charts of the North Atlantic Ocean and adjacent continents issued by the Deutsche Seewarte and the Danish Meteorological Institute. The diagrams which accompany his paper, a copy of which he has sent to us, seem to show that a succession of analogous phenomena occurs at regular intervals, and that areas of low and high barometric pressure follow each other at certain distances. He asserts that the periods exhibited are due to the moon's movements or to a combination of these with that of the sun. We remember that Sir J. Herschel stated that the moon's influence is "utterly insignificant as a meteorological cause." Nevertheless, Dr. Herrmann's paper may be considered as a painstaking endeavour to throw light upon the intricate processes involved in the general atmospheric circulation.

MR. GUSTAV FISCHER, of Jena, has just published the second edition of Prof. L. Jost's "Vorlesungen über Pflanzen-physiologie," the first edition of which was very favourably reviewed in NATURE of July 14, 1904 (vol. lxx., p. 242). The work has been translated into English, and a review of this edition appeared in NATURE of December 5 (p. 97).

A THIRD edition of "Practical Forestry and its Bearing on the Improvement of Estates," by Prof. Charles E. Curtis, has been published by Messrs. Crosby Lockwood and Son. The work has been revised and also enlarged by the addition of an appendix on the planting of waste lands, a project which the author hopes may not only add to the wealth of the nation, but give employment to the rural population, and so keep them upon the land. It is pointed out in the volume that the management of our woodlands is improving, and that what was once a source of loss is becoming a source of profit.

THE twenty-third issue of "Hazell's Annual," that for 1908, is even more complete than previous editions. It is an alphabetically arranged, cyclopædic record of men and affairs designed especially to be of use in 1908. Articles are provided, for example, on the Olympic games, the Franco-British Exhibition, and on recent work in colour photography. The most important of the Blue-books published during 1907 are summarised, and among these abridgments likely to be of special assistance to readers of NATURE may be mentioned those dealing with agriculture, education, and sea fisheries. The busy worker in many departments of knowledge will find the annual a trustworthy and useful work of reference.

THOUGH it has not increased in price, "Who's Who" continues to grow in size. Messrs. A. and C. Black, the publishers of this work of reference, which may justly be described as indispensable, have this year added eighty-three pages of biographies, and the new volume contains 2040 pages. The biographical notices vary much in length, and, unfortunately, the longest notices are not always those of the most important persons; but, despite such inequalities, the book may be unreservedly recommended to those readers whose necessity it is to know something about the men and women who, for one cause or another, have become prominent in work or play. "Who's Who Year-book, 1908," is also larger than its predecessors, and its clearly arranged and exhaustive tabular matter will continue to be consulted by everybody desiring a minimum of trouble in the task of reference.

THE Rev. Robert Harley, F.R.S., has written an interesting biographical sketch of Robert Rawson, who achieved some distinction in the scientific world by his work in mathematics and on the dynamical stability of floating bodies. Rawson was originally a Midland miner whose mathematical ability attracted the notice of Stephenson and Prof. Eaton Hodgkinson. He became a teacher of mathematics at Manchester, and contributed several papers to the Literary and Philosophical Society of that city. In 1847 he was appointed the first headmaster of H.M. Dockyard School, Portsmouth, upon the recommendation of Prof. Hodgkinson, and he occupied this post for twenty-eight years, among the men who passed through the school during this period being Sir Philip Watts, K.C.B., F.R.S., Sir John Durston, K.C.B., and Dr. Francis Elgar, F.R.S. Rawson died in March, 1906, and was buried in Havant cemetery. Mr. Harley's appreciative account of his career is published by Messrs. J. Clarke and Co., 13 and 14 Fleet Street, E.C., and Messrs. Griffin and Co., Portsea.

IN the "Day by Day" Tellurian which Messrs. G. Philip and Son have submitted to us, a simple and novel means is used to preserve the constant direction of the terrestrial axis in the course of the revolution of the earth around the sun. The tellurian is intended to be suspended on a wall or some other convenient vertical plane. The sun and earth are represented by two globes connected by a rod upon a diagram showing the months and other divisions of the year. As the terrestrial globe is moved around the globe representing the sun, a heavy bob attached by thick wire to the axis is maintained vertical by the attraction of gravity, and this constant direction enables the axis to be kept inclined at the same angle to the plane of the diagram throughout a revolution. The result is that the terrestrial globe only rotates on its axis once during a complete revolution. This is misleading, and it will be necessary for the teacher to explain that though the device illustrates the different aspects of the earth presented to the sun during the year on account of the constant inclination of the axis, it does not represent accurately the relation between the day and the year. With this reservation, the model may be found of service in teaching astronomical geography.

MESSRS. TAYLOR AND FRANCIS have now published the first part of the fourth volume on Rhynchota, by Mr. W. L. Distant, of "The Fauna of British India, including Ceylon and Burma." These volumes are published under the authority of the Secretary of State for India in Council, and edited by Lieut.-Colonel C. T. Bingham. The third volume on Rhynchota was reviewed in NATURE of July 5, 1906 (vol. lxxiv., p. 221). The present fasciculus gives an account of the homopterus families Membracidæ and Cercopidæ, and four subfamilies of the Jassidæ. The second part—in the appearance of which there is likely to be some delay owing to the necessity of examining material at present contained only in certain Continental museums—will contain the remaining subfamilies of the Jassidæ and an appendix to the whole work.

MESSRS. J. AND A. CHURCHILL have published a tenth edition of Valentin's widely known "Practical Chemistry." Prof. W. R. Hodgkinson has added to the present issue easy experimental work in the early chapters, on the composition of air and water, some carbon compounds, sulphur and sulphuric acid, exercises on quantitative analysis, volumetric analyses, and methods of ascertaining molecular weight. The microscopic structure of some common alloys has been illustrated by photographs, and the whole work revised and brought up to date. The volume now runs to 476 pages, and its price is 10s. net.

OUR ASTRONOMICAL COLUMN.

THE MAXIMUM OF MIRA, 1906.—Mr. Naozo Ichinohe, of the Yerkes Observatory, observed Mira, for magnitude, from October 10, 1906, to March 8, 1907, and publishes his results, with a curve, in No. 4219 of the *Astronomische Nachrichten* (p. 311, December 5). These show that the maximum brightness occurred on December 12, 1906, which was about seven days before the predicted date. This early date is confirmed by the results of other observers, which give December 13, 12, and 7 respectively.

A FURTHER OBSERVATION OF COMET 1907*a*.—A telegram to the Kiel Centralstelle from Prof. Wolf states that comet 1907*a* was re-observed at the Königstühl Observatory on December 4. At 11h. 3·3m. on that date its position was α=3h. 23m. 40s., $\delta=+50^\circ$ 35′, a little to the north-east of α Persei, and its magnitude was 12·5. The motion of the object was found to be in accordance with the ephemeris (*Astronomische Nachrichten*, No. 4219, p. 315, December 5).

SPECTROSCOPIC DETERMINATION OF THE ROTATION OF THE SUN.—In a paper published in No. 4, vol. xxvi., of the *Astrophysical Journal* (p. 203, November), Prof. Adams describes at some length the instruments and methods employed by him at the Solar Observatory, Mount Wilson, in a spectroscopic determination of solar rotation period, and, after discussing them, he compares his results with those obtained previously by Dunér and Halm.

In the lower latitudes of the solar disc the recent results agree very well with the values obtained by Dunér and Halm, but in higher latitudes they lie between those of the previous observers. The rate of change of the velocity with the latitude attains a maximum in latitude 30°, becoming less in higher latitudes, and almost disappearing beyond 70°. Twenty lines, lying between λ 4190 and λ 4300, and attributed to different elements, were employed in the research, and it was found that different lines gave different rotational velocities. The titanium line at λ 4290·38 gave a systematically low value, although it is an enhanced line, and might therefore be expected to have its origin in the higher levels of the solar atmosphere. Two lines of manganese, λ 4257·82 and λ 4266·08, gave a consistently high value. Two carbon lines and a line due to lanthanum give low values, thus agreeing with the conclusion that these two elements reside in the lower layers of the sun's atmosphere. There are no indications of a variable velocity for any one latitude during the fourteen months of observation (May, 1906, to June, 1907), and the results appear to show that the photographic method displays a considerable gain of accuracy over the visual method so far as accidental errors of measurement are concerned.

NEWLY DISCOVERED SPECTROSCOPIC BINARIES.—Bulletin No. 123 of the Lick Observatory announces the recent discovery of the variable radial velocities of ten stars. Two of these, x Carinæ and ι Gruis, were found to be binaries on examining plates taken at Santiago; the other eight were discovered at Mount Hamilton. They are o, f, and d Tauri, 7 Cameleopardalis, A Boötis, β Coronæ, ξ Cygni, and ζ Cephei.

In the same Bulletin Mr. A. B. Turner publishes a set of elements, and a velocity curve, for the spectroscopic binary ω Draconis, showing the period to be 5·27968 days and the length of the semi-major axis of the orbit to be 2,632,300 km. The velocity of the system is $-13·68$ km., and the orbit appears to be nearly circular, its eccentricity being only 0·0107.

THE ASTROGRAPHIC CATALOGUE.—We have received from the Catania Observatory the first part of their contribution to the International Astrographic Catalogue. Catania undertook the region dec. $+46^\circ$ to dec. $+55^\circ$, and the present volume contains the results for the region dec. $+50^\circ$ to $+52^\circ$, R.A. oh. to 3h. In an introduction Prof. Riccò, the director of the observatory, describes the instruments employed—photographs of the astrographic equatorial and the micrometer appear as a frontispiece—and discusses the methods followed in the reduction of the plates. The positions (1900) of some 7000 stars are included in the present work.

STARS HAVING PECULIAR SPECTRA.—From the examination of Henry Draper memorial photographs, Mrs. Fleming has discovered a number of variable stars and other objects having peculiar spectra, particulars of which are given in Circular No. 132 of the Harvard College Observatory. The Harvard plates show that D.M. $+66^\circ$.780, given by Dunér and by Krüger as a fourth-type star, gives a spectrum at times which contains no bright lines, whilst at other times the spectrum contains Hβ bright; the intensity of the spectrum also varies in certain regions.

WEAKENED LINES IN SUN-SPOT SPECTRA.—In No. 3, vol. xxvi., of the *Astrophysical Journal*, Mr. Nagaraja, of the Kodaikánal Observatory, gives the wave-lengths of, and discusses, 167 lines which he has found to become weakened in passing from the spectrum of the photosphere to that of sun-spots. The photographs from which Mr. Nagaraja obtained his data were taken with a Rowland grating camera fitted up by Mr. Evershed, and include the region F–D. Considering the forty or so lines due to iron, titanium, and chromium given in this region as enhanced lines by Sir Norman Lockyer, and four more recently announced by Prof. Fowler, Mr. Nagaraja finds that the majority of them are weakened in spots.

Two enhanced lines of iron at λ 5169·07 and λ 5169·22, one enhanced titanium line (λ 5188·87), and two enhanced lines of chromium ($\lambda\lambda$ 5502·9 and 5621·7) appear to be exceptions, however. With one exception (λ 5284·281, Ti), all the titanium and chromium lines weakened in spots are of the enhanced type. A comparison of the chromospheric and spot-weakened lines shows that only a fraction of the former are weakened in spots, and that a large number of the weakened lines belong to the higher levels of the chromosphere.

EXHIBITION OF PHYSICAL APPARATUS.

THE third annual exhibition of physical apparatus, held under the auspices of the Physical Society of London at the Royal College of Science on December 13, was an unqualified success. Notwithstanding the inclemency of the weather there was a good attendance, many members of the society coming up from distant towns in order to take advantage of the opportunity of inspecting the apparatus itself in lieu of looking through the catalogues of so many makers. Printed and verbal information was available in abundance, and in connection with the former it may not be out of place to offer a word of advice to makers. Any catalogue, however carefully compiled, is in the case of a progressive maker out of date a few months after publication, and is generally supplemented by separate sheets sent out to customers. Very few makers have these sheets cut the same size as their catalogues, and fewer still provide clips at the ends of their catalogues by means of which the additional sheets, sent out punched in the left-hand margin, can be permanently incorporated in the catalogue. They lie about on desks instead until they look dusty and disreputable, and are then consigned to the waste-paper basket, and the information contained in them is forgotten.

As one would naturally expect, the exhibition was strongest on the electrical side, but other branches were not neglected. In general physics, the silica ware exhibited by Messrs. J. J. Griffin and Sons attracted a considerable amount of attention. Bowls of 6 inches diameter, boiling flasks of 3 inches, and tubes of all kinds can now be made of transparent silica, while much larger objects are made of the opaque variety.

Messrs. C. F. Casella and Co. exhibited a telemeter with an 8-feet base, arranged to measure both distances and differences of level, the telescopes rotating about the base and the base about a vertical axis through its centre to eliminate errors. They showed also a direct-reading anemometer on which the revolutions are given by an ordinary engine counter. Messrs. Elliott Bros. exhibited their new "motormeter," or speed indicator, for motor-cars, which is driven from a flat rubber ring attached to the front off-side wheel of the car by means of a friction wheel and flexible shaft.

In heat, the most interesting exhibit was that of the Meteorological Office, which consisted of balloon and kite meteorographs and traces obtained by means of them. Mr. Dines's instrument for recording pressure and temperature on a square inch of thin copper weighs one ounce only, and is most ingenious. Records of ascents of 18 to 20 kilometres, made at the same time at four stations in this country, showed a fair agreement in the temperatures at the same heights over the four stations at comparatively low levels, but considerable differences at high levels.

In photometry there appeared to be a general adoption of the flicker photometer and of the inclined screen method of varying the effect of one of the sources. The movement of the screen is effected by means of a cam rotated by a milled head outside the photometer box, to which a pointer reading on a scale marked directly in candle-power is attached. The uniformity of the divisions is secured by the shape of the cam.

Messrs. A. Hilger, Ltd., exhibited a large spectroscope the telescope of which was moved by a tangent screw graduated on the head directly in wave-lengths. They also had on view a Fabry and Perot interferometer with the interference bands visible, so that the displacement produced by separating the plates could be observed.

Two new photographic lenses giving very flat fields were exhibited, the "Isostigmar" by Messrs. R. and J. Beck, and the "Homocentric" by Messrs. Ross, Ltd.

The work on radio-activity, which is being carried on so vigorously, has raised the electroscope to a position undreamed of a dozen years ago, and amongst the many new forms it now takes may be mentioned one constructed by Mr. C. W. Cook, of Manchester, for Prof. Rutherford, and exhibited by Messrs. J. J. Griffin. It contains a compartment below the leaves in which the radio-active material to be investigated can be placed.

Resistance bridges for the most accurate work appear to be tending towards the enclosed type, with oil circulation to ensure uniformity of temperature. The Cambridge Scientific Instrument Co. showed a Callendar and Griffiths bridge in which plug contacts were replaced by mercury, also enclosed, to prevent the mercury getting to the brass-work.

Several makers seem to be alive to the possibilities of the flat form of resistance coil owing to its compactness and freedom from inductance and capacity. Mr. L. Miller's machine for winding the wire of induction coils in flat vertical sections, the wire passing from outside to inside and back again without a break throughout the whole length of the coil, seems to make it possible to build larger coils without insulation troubles arising. His mica-disc valve, which interposes a disc of mica in a short air gap in the secondary circuit of the coil during the make, and so cuts down the make current that the secondary current is practically unidirectional, should prove a great aid in vacuum-tube work.

Moving magnet galvanometers show a tendency to take the Broca form, in which astaticism is secured by making the poles between the coils consequent poles at the centres of two magnets placed vertically. Instruments so constructed were shown by the Cambridge Scientific Instrument Co. and by Messrs. Clark Fisher and Wadsworth. A very useful addition to the moving coil type of galvanometer was exhibited by Messrs. Gambrell Bros. It consists of a resistance within the galvanometer case, which when placed across the terminals of the instrument renders it aperiodic. One end of it is connected to one terminal of the instrument, and the other to a third terminal, so that it may also be used to diminish the sensitiveness of the galvanometer.

Messrs. Paul exhibited a Campbell vibration galvanometer, which is a moving coil instrument of very short period, the control being of the bifilar type, and the *amplitude* of the oscillations being observed in working with the instrument. Other instruments for small alternating currents were Duddell's thermo-ammeter, on the same principle as his thermo-galvanometer, shown by the Cambridge Scientific Instrument Co., and Cohen's barretter, shown by Mr. R. W. Paul. This instrument is of the bolometer type, the filaments the resistances of which are changed by the current to be measured being those of the 24-volt lamps used on telephone switchboards.

Of instruments intended for commercial work, the iron-clad indicating wattmeter shown by Messrs. Nalder and Thompson may be mentioned, as it illustrates the present tendency to secure larger torques by placing the moving coil in the field of a laminated series or shunt electro-magnet.

Messrs. Nalder Bros. exhibited a compact testing set weighing only 14 lb., capable of measuring insulations up to 2000 megohms with 100 volts, and Messrs. Evershed and Vignoles several of their "meggers" of various ranges up to 1000 megohms.

The Physical Society is to be congratulated on the success of its exhibition, and the various exhibitors on the interest which their display evoked. C. H. L.

ON THE INCIDENCE OF DAYLIGHT AS A DETERMINING FACTOR IN BIRD-MIGRATION.[1]

THE existence of the phenomenon of bird migration is only explicable, like that of all other phenomena of life in both animal and vegetable kingdoms, by the theory of natural selection. It has proved beneficial to certain families of birds in the struggle for existence to wander at certain times of the year in particular directions, and to greater or less distances, such wanderings having led them to regions which were more suitable than others for feeding or breeding. On this general question there can be no difference of opinion at the present day.

But if we leave the general problem and come to deal with specific parts of it, such as the nature of the directing force in migration, or why for certain birds northern latitudes are more suitable as breeding quarters than southern, why for others eastern longitudes than western, we at once enter upon questions regarding which there is

[1] Address to the Scottish Natural History Society, November 7, by Prof. E. A. Schäfer, F.R.S.

great divergence of opinion, and as to which scarcely any two naturalists who have studied the subject are in complete agreement.

The part of the problem that I propose here to consider can be thus stated:—Is there any physiological reason to account for the fact that for that class of birds which we may call the north-south migrants northern latitudes have determined themselves as the most suitable for summer quarters and breeding grounds, and southern latitudes for winter quarters?[1]

The physiological reason for this choice of quarters which most naturally suggests itself concerns the presence or absence of food, or its relative abundance and the means of procuring it. From the Arctic circle, where during winter the whole of nature, sea and land alike, is in the grip of an intensity of cold of which we can form little conception, and which few animals can withstand, birds, at any rate, must move southward, or they would inevitably perish of cold and starvation. It thus appears easy to account for one aspect of the north-south migration problem by referring it to the necessity of avoiding destruction by starvation; but even for this aspect of the question the answer is not quite so simple as at first sight appears. For it fails to account for the distances which such migrations often take, since a passage into the north temperate region alone would suffice to obviate this difficulty; yet this region is, for the most part, passed in the migration of many Arctic birds, which may not stop until a tropical or even a southern hemisphere region is attained; and not only so, but the north-south migrants of the north temperate zone themselves share in the migration, passing away for the winter to a southerly clime. Many of these cannot be said to be driven south by the lack of food, for at the time the migration occurs food is usually still abundant, and there is plenty of food during the whole winter in many of the countries which are passed to support, not only the permanent avine inhabitants, but in some regions myriads of east-west migrants besides.

Moreover, there is evidence that during the Tertiary period the climate of the Arctic circle was entirely different from that which now exists—warm and mild, and abounding with vegetable and animal life—and there was then no necessity for north-south migration on the score of want of food materials. Yet it is impossible not to suppose but that migrations occurred then as now, since the habit of migration is so ineradicably engrained in the nature of the bird that it is difficult to believe that it was not evolved along with the development of the organs of flight.

If we now turn to the other aspect of the north-south migration problem and consider the causation of the movement from south to north, we see that the explanation *re* food supply, which seems easy to formulate for the north to south movement, at once breaks down, for the tropical and temperate regions are at any rate not less abundantly provided with food during summer than the regions of the far north to which the majority of these migrants wend their way. The difficulty is a serious one. The explanation which was used to account for the north to south movement is not available for the opposite movement; some other explanation must be found. Here the weakness of the original explanation manifests itself, for it would be natural to suppose that the reversal of an effect would be the result of the reversal of the cause which produced the effect, and this is not the case in the present instance.

What, then, are alleged to be the reasons for the south to north migration in the spring? One of these supposed reasons is both given and at the same time refuted by Gätke ("Birds of Heligoland," English translation, p. 144) in the following passage:—"From very old times, mainly in consequence of the phenomena which succeeded migration, it was conceived that in spring, with re-awakening life in Nature generally, the reproductive instinct of birds also was roused afresh, and that it was this which urged them to wander to their nesting places; while in autumn, dearth of food and cold admonished them to make a temporary home in warmer latitudes. This view has, in part, held its ground up to recent times, for it is not so long ago that Brehm, in one of his talented discourses on this inexhaustible theme, maintained that the two great factors in the world's action, *Hunger* and *Love*, also dominated the migratory movements of birds. . . . These explanations, however, do not suffice . . . it cannot be the reproductive instinct which prompts birds to set out on their spring migration, for many species do not breed in the first, second, or even third year of their life, and yet migrate to their homes just like those of their congeners who are endowed with the capacity of breeding; nor are they induced to travel by the example of their parents, for they start on their journey alone, and independently." Gätke concludes as follows:—"In regard to this question as to the immediate cause of the departure of birds in their migration . . . we are confronted with a riddle which has hitherto defied every attempt at a solution, and which indeed we may hardly expect will ever be likely to receive a final explanation."

We may take it, then, that the hypothesis that the commencing recrudescence of the generative functions in spring is the determining agent for the migration from south to north does not furnish an adequate explanation of the phenomenon, even if it were certain, as is by no means the case, that such recrudescence begins before the commencement of the movement. It seems obvious that there must be something in the higher latitudes which is favourable to breeding or to the rearing of offspring. Are we to suppose this favourable factor to be relative coldness? *Prima facie* this seems improbable. Other animals, including non-migrant tropical birds, breed freely in the hottest regions of the earth's surface, and warmth is favourable for incubation. Many of the east-west migrants have their breeding grounds in the interior of the great Asio-European continent, which is in the summer much warmer than its western shores. I have been unable to come across any fact which would lead one to suppose that mere diminution of temperature assists breeding. There are, it is true, some fishes and possibly a few other animals that produce their eggs and young in the winter, but in by far the majority it is the warmer season of the year which is occupied with the propagation of the race. We are therefore forced to conclude that the south to north migration is not brought about because of the necessity or advantage of a colder climate for breeding and nesting. Is there, then, any other means of explaining why it is advantageous for certain birds to pass the summer, and especially to breed, in high latitudes, which will equally account for the fact that lower latitudes present corresponding advantages during the winter season? It is an answer to this question that I will now attempt to give.

Let us begin by admitting that bird-migration must have been brought about by the necessity for procuring a sufficient supply of food. The importance of this at all periods is self-evident, but it becomes accentuated in the breeding season, when not only the needs of the parent birds, but also those of their voracious offspring, have to be met. It appears to have been assumed by most writers that for the north-south migrants the higher latitude or summer region of distribution, to which they resort for the breeding season, represents their original home or habitat, to which it is only natural they should desire to return when the desire for breeding comes upon them, and that the migration to lower latitudes is brought about by climatic conditions, such as frost and cold, which render the procuring of food a matter of difficulty or impossibility during winter. There are, however, as has already been pointed out, difficulties in accepting the climatic conditions and accompanying deprivation of food supply as affording the only or even the chief explanation of migration, and more especially of the acquisition by birds of the north-south migratory habit. Thus it fails, as we have seen, to explain the south to north migration in the spring, and would be an inadequate reason for much of the autumnal migration which occurs from the northern temperate zone, such as that of those migratory marine birds the food of which is abundant in the northern seas throughout the winter. It at first sight appears also to fail to account for the fact that with many species of birds autumnal migration occurs before the advent of severe weather, and at a time when the food supply in the higher latitude is as abundant as ever, and that their

[1] For convenience of description the migrants are here assumed to belong to the northern hemisphere.

return from lower latitudes often takes place when the food supply there is more abundant than in the higher latitude to which they are travelling, and may even remain abundant. But although a deficiency of food could not in such circumstances be the immediate determining cause of the movement, an approaching deficiency might, nevertheless, be the ultimate cause, for the most appropriate time for leaving a region which is to become uninhabitable would be determined for each species by natural selection, and might thus appear to have no immediate connection with deficiency of the food supply, although in reality dependent upon it.

It is known, however, that, as has already been stated, during the whole Tertiary period there was a mild or warm climate and abundant vegetation throughout what are now the Arctic and sub-Arctic regions, and it was under these conditions, which presuppose abundance of food supply during the whole winter, even in the highest latitudes, that many existing genera of birds were evolved. We may take it, therefore, that at that period the autumnal migration was not rendered necessary by the approaching severity of the winter months.

This being the case, the question has suggested itself whether the relation of daylight to darkness may not have furnished the factor of most importance in the determination of both the south to north and north to south movements, *in consequence of the necessity to most birds of daylight for the procuring of food.*

In no other class of vertebrate animals is the sense of sight more important than in birds, and in no other is it so highly developed. For detecting and obtaining food most birds depend entirely upon vision, with perhaps, in some, assistance from audition, and, in the case of soft-billed birds, from palpation, but with little or no aid from the olfactory sense, which is in so many animals the most important of the senses in this connection. But vision is not possible in the total absence of light, nor, without special retinal adaptation, in semi-darkness. Hence the great majority of birds—diurnal birds—are dependent upon daylight for the procuring of food; relatively few, such as most owls and nightjars (crepuscular and nocturnal birds), are able to obtain food only in semi-darkness (twilight, moonlight, or starlight); a certain number, *e.g.* many waders, appear to possess retinal adaptation both for ordinary light and for light of low intensity; but, so far as I am aware, no birds, except those which are provided with tactile bills, are able to seek food in total darkness.

From this consideration it is obvious that the proportion of the twenty-four-hour cycle which can be utilised by birds for obtaining food becomes greatly diminished during the winter months in high latitudes, and may be reduced to *nil* within the Arctic circle, while during the summer months the amount of daylight in high latitudes is proportionately increased. Many birds are voracious feeders, and during the hours of daylight are almost constantly engaged in the search for food. It is therefore a necessity that the time during which alone they can see to engage in the search shall not be unduly restricted, as would be the case in high latitudes during the winter, even in parts which are rarely or never frost-bound. This the north to south or autumnal migration provides against. During the breeding season, when the young birds also have to be fed, it is important that the time which can be occupied in the search for food should be prolonged, and this is provided by the south to north migration in the spring. Everyone who has lived in northern latitudes must have been struck with the time occupied by many birds during the long summer days in procuring food for themselves and their young; in fact, no more striking object-lesson of the utility of prolonged daylight for the rearing of their offspring can well be afforded.

The objection might be taken to the relative incidence of daylight and darkness at different seasons being regarded as a factor in causing north-south migration, that in the case of nocturnal birds the course of migration ought to be the other way, viz. from south to north in autumn and from north to south in spring (in the northern hemisphere); but, as has been already pointed out, the so-called nocturnal birds are not, as is popularly supposed, birds which can see in the dark, but birds the vision of which is adapted permanently for light of low intensity, such as twilight. Migration with such birds occurs in the same sense as with diurnal birds, *i.e.* north to south in autumn and south to north in spring (in the northern hemisphere). This is, in fact, what might have been anticipated, seeing how greatly the summer twilights are prolonged in high latitudes.

Again, it might be objected that the circumstance of many birds leaving the higher or lower latitudes before the autumnal or vernal equinox militates against the assumption that the autumnal migration is determined by a relative deficiency of light in higher latitudes during the winter months, and that the vernal migration is determined by the longer daylight which obtains in those latitudes during the summer months. This objection is, however, obviously met in the same manner as with the analogous objection raised to the "food-supply" theory pure and simple, viz. that the most appropriate time for the actual commencement of migration will have been determined for each species by the process of natural selection.

Further, the assumption that the relation of light to darkness rather than severity of climatic conditions has been the determining factor in producing the north-south migrations would better explain the singular constancy in the times of year at which these migrations occur. For not only are the times of migration in many cases independent of the actual climatic conditions which are supposed to be the determining cause of the movement, but the climatic conditions themselves vary considerably from year to year in their inception and progress. On the other hand, the incidence of the proportion of light to darkness is a constant factor, and might even be conceived to be operative in exciting the migratory instinct into activity in the same manner as it is here assumed to have been the original determining cause of north-south migration. That there are other stimuli seems probable from the circumstance that some birds have their winter quarters in the equatorial region, where the proportion of day to night does not vary throughout the year. There are, however, very regular seasonal changes in that region, which are accompanied by marked differences in amount of daylight, and for those migrants which winter there these seasonal changes may serve as the initiating stimulus to northerly migration. That it is a result of developmental changes in the sexual organs is improbable, since sexually immature individuals are also subject to the migratory tendency; nor is there any evidence that such changes begin prior to migration. In any case, the regularity with which migration occurs indicates that the exciting cause must be regular. There is no yearly change, outside the equatorial zone, that occurs so regularly in point of time as the change in the duration of daylight. On this ground this may well be considered a possible determining factor in migration, and it has the advantage over other suggested factors that it applies to the northerly as well as to the southerly movement.

Besides the north-south migrations with which we are more immediately concerned, there are also the great east-west vernal and autumnal movements which are so prominent a feature in the eastern parts of these islands, and also migrations of a more local character, both of which merit some allusion in connection with the general question of migration.

As regards the east-west movements, which are, in fact, for many species a part of the general north-south migrations,[1] it has been supposed that these divarications from the main north-south stream have become evolved either as the result of changes in the earth's surface, which have produced a modification of the general north-south trend,[2] or that they are the expression of the course of expansion of the breeding range of the species as it approaches its northern limit.[3] The physiological reason for the east-west movement must ultimately be sought, as in the north-south movement, in facility for the obtaining of food, and it may fairly be assumed that in the case

[1] For the evidence of this see Gätke, "Heligoland an Ornithological Observatory," pp. 39–43. Also the British Association reports on bird migration, especially the "Digest," by W. Eagle Clarke, in report of Liverpool meeting, 1896.
[2] Evans, Cambridge Natural History, "Birds," p. 18.
[3] Dixon, "The Migration of Birds," 1897, p. 35, also p. 40.

of species which show no north-south tendency in migration and which are confined to the temperate zones there is sufficient opportunity, even in shortened days, of obtaining such food as they require for subsistence in the region to which they have betaken themselves for winter quarters. Many of these east-west migrants are either graminivorous or live on insects and grubs which they seek in the ground or on trees. In the summer their food is most abundant in the great grain-producing or forest-clad central regions of the Asio-European continent, while in the winter they are compelled to seek their subsistence in a less severe climate.

Another kind of migration is that which may be produced by local conditions of food and pressure of bird population. If in any particular zone food of appropriate character is obtainable at all times of the year in sufficient abundance, the necessity of migration to a higher or lower latitude is no longer necessary for a specific number of individuals, and their migration, and that of their descendants, will accordingly tend to limit itself to that zone, within which such migration as does occur will be more or less local.

Newton[1] suggested that the arrival of a large batch of migrants in a particular area or zone which is already occupied by birds of the same species may compel the individuals of that species which are in possession to move on in any direction where food is readily obtainable. It is perhaps more probable that later migrants into a zone already occupied by birds of the same species or habits may, on finding others already in possession, themselves push on into other regions. In this case the *later* migrants of species which vary in the extent of their migration would tend also to become the *more extensive* migrants, and would by natural selection transmit this tendency to their descendants. This conforms to the statement that those individuals of a species which migrate to the higher latitudes in the range of distribution of the species start their spring migration later than the individuals which migrate to less high latitudes.[2]

The theory that bird migration in the Holarctic area was originally determined by the encroachment and subsequent retreat of the ice-sheet over the temperate zone during the Glacial epoch (or epochs) is one which appears impossible to accept. Such a theory in its bare form involves the assumption that the habit of migration which so extensively pervades the avine class of vertebrates has been acquired during comparatively recent geological times, for which there is neither evidence nor probability. When we consider how extensively diffused is the tendency to migration of some kind amongst birds, it appears reasonable to assume that the habit was acquired at a comparatively early period of their evolutionary history. It may even be that the advantage gained by a more and more extensive movement of the kind was the predetermining cause, in the hands of natural selection, of the complete evolution of the avine type of vertebrate.

I have been able to find in the literature only two references dealing directly with the subject of the influence of light on bird migration. Seebohm ("The Geographical Distribution of the Family Charadriidæ," London, 1888, p. 34) writes as follows:—"The first migrations of the ancestors of the Charadriidæ were probably not in search of *warmth*, for the climate of the Polar Basin was in those remote ages mild enough: nor in search of *food*, which was probably abundant all the year round; but in search of *light* during the two or three months when the sun never rose above the horizon. The habit of migration thus formed became deeply rooted in the species, in accordance with the law of heredity: and doubtless acquired additional force when the terrors of a glacial epoch exterminated the conservative party amongst the Charadriidæ (if any of them were foolish enough to neglect to adapt themselves to the changed circumstances), and compelled the survivors to extend their migrations far and wide, until the shores of nearly all the rest of the world were visited on passage, or included in the winter range of some species of the family."

Seebohm evidently realised that, however warm the circumpolar area and however well stocked with food, it would be impossible for birds to subsist there all the year round *on account of the absence of daylight during the winter months*. It is the more strange that he should have failed to perceive the obvious corollary that these birds might seek such high latitudes during the summer months in the breeding season on account of the advantage offered for the procuring of food by the prolonged daylight.

Some fourteen years prior to the publication of Seebohm's work there appeared in the *Academy* (1874, vol. vi., p. 262), under the head of "Notes and News," the following paragraph,[1] which, however, bears no indication of the source whence the information it contains was derived:—

"The aged poet Runeberg, the greatest scald that Sweden has ever had, has been in extremely weak health for many years past. It appears that as he has lain on his sick bed, at Helsingfors in Finland, he has occupied himself by close observation of the habits of birds, and specially with regard to the causes of migration, and he has at last put forward a singularly beautiful theory on the latter point. He believes, in fact, that it is the longing after light, and that alone, that draws the birds southwards. When the days shorten in the north, the birds go south, but as soon as ever the long northern nights (*sic*) set in, with all their luminous and long-drawn hours, the wanderers return to their old haunts. It is generally supposed that they move southward to get more abundant food; but why, asks Runeberg, do they leave their rich hunting-grounds to return to the north? The central regions of Europe are in every way more desirable than the wastes of Scandinavia. Only one thing is richer there, and that is light. The same instinct that makes plants firmly rooted in the ground strain towards the light, spreading upwards in search of it, works in the birds, who, on their free wings, fly after and follow it. This very suggestive and poetical notion is further carried out by reference to various analogies in natural history, and the final sentence is quite epigrammatic: 'The bird of passage is of noble birth; he bears a motto, and his motto is *Lux mea dux*.'"

The idea which is given voice to in the above paragraph bears a certain resemblance to that which I have endeavoured to set forth in this paper, but on close consideration it will be seen that the resemblance is purely superficial. What I have tried to urge is, not that these north-south migrants seek light *quâ* light, but that the sense by which alone they are for the most part able to obtain food necessitates their passage to regions where at one or another time of year there will be sufficient daylight to procure it. This is a special part of the general problem of food supply, itself an all-important agency in natural selection, which last there can be no doubt has been instrumental in determining the habit of migration. The theory attributed to Runeberg, in so far as it seeks to explain north-south migration by the endeavour of the bird to follow light alone without reference to the ultimate reason for such movement, in no way explains why birds rather than other animals should require light, and may well have merited the criticism to which it was at the time subjected by Prof. Newton (NATURE, September 24, 1874, p. 415), who pointed out that since "the southern movement not only begins but is with many species in great part accomplished long before the autumnal equinox, when consequently the birds are journeying to increasingly shorter days; and in like manner their northward movement is set on foot before the vernal equinox," the theory (that it is light alone that is the attraction) "contains its own refutation."

The object of this paper has been to endeavour to give a reasonable explanation of the north-south tendency, which is the most prominent feature of bird-migration. No attempt is made to explain all phenomena of migration. Obviously there are some migrations which cannot be explained on the assumption that the object of move-

[1] "Dictionary of Birds," art. Migration.

[2] This appears to be the case with the swallow (see W. Eagle Clarke, British Association Report, 1901, p. 10), the individuals which are to summer in Scandinavia passing through this country after our own swallows have arrived. Similarly, the return of the Scandinavian swallows also appears to be somewhat later than ours (middle of September, p. 12). (See also the same author's "Digest," British Association Report, 1896, p. 17).

[1] The paragraph was copied in the *Times* for September 18, 1874.

ment is to obtain more extended daylight. This, however, is not to be wondered at, since the quest of daylight is itself only a part of the greater problem of food supply. Any condition, local or other, which tends to restrict food supply in a particular area must produce migration from that area into more favoured areas. This is alone sufficient to account for the winter migrations which many birds exhibit, sometimes to a large extent, and for the localised migrations which some species, not usually regarded as migrants, exhibit in spring and autumn, moving from one area into another, not necessarily in a different latitude, although often of a different altitude. Further, it must be borne in mind that some birds, and those not few in number, find both sufficient food and sufficient daylight to acquire it in the same region all the year round, and exhibit no tendency to migrate. This can in no way be employed as an objection to the view that the true north-south migrants have been driven to seek more extended daylight for the purposes of obtaining a sufficiency of food; it would equally apply to any other explanation that might be given to account for the migratory tendency, and could only be used to prove that there is no necessity for any migration at all, which, as Euclid would say, is absurd. Given a food supply adequate in nature and amount to maintain the species in any region, and sufficient light all the year round to procure it, there would be no need for migration.

But these are not, and never have been, conditions which obtain in all regions and for all species. On the contrary, a very large number of species appear to require the prolonged daylight of the northern summer to procure a sufficiency of food for themselves and their offspring, while, apart from severity of climate, the shortened hours or absence of daylight which supervene there necessitate that they should pass the winter months in southern latitudes. Thus we can comprehend how the north-south migratory instinct became evolved, and we no longer wonder at the existence of this phase of the phenomenon. That the great east-west migrations are more complex and more difficult of explanation I am free to admit, but it must not be forgotten that we know, on the whole, less about these, and especially less about the climatic and other conditions which accompany them and may be supposed to produce or influence them, than we do about the influences to which the north-south migrants are exposed. The fact that we are not in a position to solve the whole of a complicated problem need not prevent our attempting to deal with any part for which our existing knowledge enables us to devise an explanation. If I have approached the question entirely from a physiological aspect, it is because it is in the main a physiological question. Nevertheless, no physiologist has hitherto attempted to deal with the subject, and it is only with diffidence that I encroach upon a domain which the morphologist has up to the present regarded as his own.

CRETAN EXPLORATION.

AN appeal is made by Dr. Arthur J. Evans, F.R.S., for funds to complete the excavation of the "Palace of Minos," which has now been carried on for seven years. At the beginning of the present year it was thought that supplementary explorations on a comparatively small scale would be sufficient, and that by the close of the season something like finality might be attained as regards at least the palace site of Knossos. This forecast, however, was by no means borne out by the result. The season's work, which was intended to be of a more or less supplementary nature, broadened out into a somewhat extensive excavation, the result of which is to show that another great campaign must be carried through before the excavation of the palace site at Knossos approaches completion. It is estimated that at least another 3000*l*. is required to complete the work, and this must be met by public subscription, for, as Dr. Evans points out, in this matter it is unfortunately impossible for an English explorer to rely, like his French, German, and Italian colleagues, on Government grants or large subventions from national academies. Writing in support of the appeal in the *Times* of November 21, Prof. C. Waldstein, referring to Cretan exploration as a scientific labour which has brought credit to the British nation all over the world, says:—"In any other European country the Government would have subsidised, if not paid, all the expenses of what can in no way be considered a private enterprise. . . . Does not a wider public take some interest in the higher research carried on by the scientific representatives of the nation, and can the wealthier classes in England not be brought to give material support to the efforts of those who thus stand for the nation's higher culture? Is it impossible to hope for a Government subsidy? If it be not the 'tradition,' good traditions can be inaugurated by those who lead the nation. No amount of immediate effort to raise our industries by direct technical education will prepare us to cope with the competition of the other leading nations of the world. We must raise the tone of intellectuality by arousing the national interest in the highest forms of intellectual life." Subscriptions for the Cretan Exploration Fund can be sent either to Mr. G. A. Macmillan, St. Martin's Street, W.C., or to Messrs. Robarts, Lubbock, and Co., Lombard Street.

A LUNAR "NEW JERUSALEM."

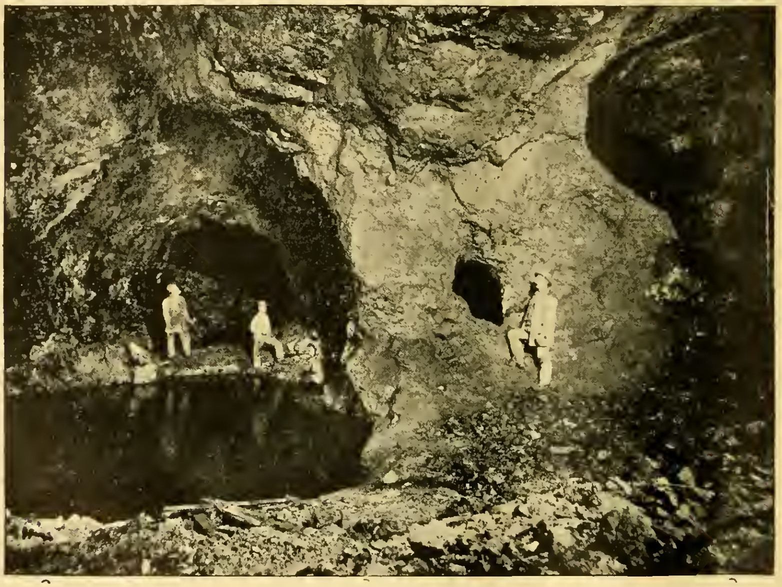
A PAMPHLET has been received containing a series of lectures by the Rev. G. B. Berry on "The New Jerusalem," with a preface by the Lord Bishop of Exeter. With the spiritual interpretation of the Apocalypse we are not concerned in these columns, but an astonishing speculation put forward in the last lecture demands a word of comment. Mr. Berry suggests that the invisible part of the moon has the same size and shape as the mighty pyramid which, according to Revelation, forms the heavenly Jerusalem. Eventually the lunar hemisphere visible to us is to bury itself in the earth, and the pyramidal portion is to project above "the rack and ruin of the elements" caused by the catastrophe, and to be the Celestial City in which the faithful will pass eternity. As a vision, this picture may appeal to imaginative minds, but from the point of view of celestial mechanics it can scarcely be taken seriously. A pyramid of the dimensions of that upon which Mr. Berry's New Jerusalem rises tier upon tier would be crushed by its own weight even if it were built of steel. As, however, the structure is visionary, we imagine that this material fact affords no valid objection to it. The changed moment of inertia of a moon with the invisible side of a pyramidal form would necessitate modification of the whole theory of the physical librations of our satellite; but perhaps Mr. Berry does not appreciate the force of this difficulty. He is certainly not familiar with the theory of tidal friction or with the fact that Laplace, who studied the physical librations, showed that one side of the moon always faces the earth because that position is one of dynamical stability. A fuller knowledge of celestial mechanics might have made Mr. Berry hesitate before erecting such a visionary structure as he describes upon so slender a foundation. His views would have pleased mediæval schoolmen, but modern science demands that even the most fascinating hypothesis should be based upon results of observation capable of being put to the test of inquiry rather than upon "revealed truth" to be accepted without criticism.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE governing body of the South-Western Polytechnic has appointed Dr. Louis Lownds head of the department of physics. Dr. Lownds is the author of papers on the thermoelectric and thermomagnetic properties of bismuth crystals and on other subjects. Dr. W. H. Eccles, formerly head of the joint mathematical and physical department, has been made head of the department of mathematics.

THE annual distribution of prizes and certificates at the Borough Polytechnic Institute was held on Thursday, December 12, when Sir Edward Carson, K.C., M.P., presented the prizes and delivered an address. Mr. Spicer, the chairman of the governing body of the institute, in the course of his remarks referred to the building extension which is now being carried out at the polytechnic, at a cost of 12,000*l.*, toward which the late chairman of the governing body, Mr. Edric Bayley, has generously contributed the sum of 5000*l.*, the remainder being made up by a grant from the London County Council. Mr. C. T. Millis, the principal, in his report, stated that there were nearly 3000 individual students in attendance during the past session, of whom 330 were day students.

WE have received the calendar of the Camborne Mining School, Camborne, for 1907–8. This school, now in the twentieth year of its existence, has rapidly expanded, and has proved very successful in giving facilities to students for acquiring a thorough knowledge of metalliferous mining. The success has been largely due to the organisation of a systematic course of practical mining, the South Condurrow, now known as the King Edward mine, having been purchased for the purpose in 1897. Students there obtain an acquaintance with practical mining, ore dressing, and engine testing, as well as practice in mine surveying under the supervision of practical men under the direct authority of the school. Moreover, in consequence of the situation of the school in the centre of the chief mining district of Cornwall, students have the privilege of visiting the mines. The calendar is illustrated by a number of admirable photographic views, many of which have been taken by Mr. J. C. Burrow, the leading exponent of underground photography. The photograph here reproduced represents the so-called "cathedral" at the 460-feet level of King Edward mine.



View underground in King Edward Mine.

MR. HALDANE, M.P., unveiled a statue of the King at University College School, Frognal, Hampstead, on Saturday, December 14. The statue has been erected in a niche above the main entrance, and is presented to the school by the architect, Mr. Arnold Mitchell, in commemoration of the opening of the school by the King on July 25. In a subsequent address Mr. Haldane said:—"There is no subject of greater general importance than education, and if Prince Albert had lived there is no doubt that education would have been ten years in advance of its present stage. The work at South Kensington, as is well known, is largely due to his instigation and interest, and the new Technological Institute which will begin in the coming year will be a natural outcome of that work. By means of it we hope to be brought more into line with other nations."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 7.—"The Diurnal Variation of Terrestrial Magnetism." By Prof. Arthur **Schuster**, F.R.S.

In a previous communication (Phil. Trans., vol. clxxx., p. 467, 1889) the author proved that the diurnal variation of terrestrial magnetism had its origin outside the earth's surface, and drew the natural conclusion that it was caused by electric currents circulating in the upper regions of the atmosphere. If we endeavour to carry the investigation a step further, and consider the probable origin of these currents, we have at present no alternative to the theory, first proposed by Balfour Stewart, that the necessary electromotive forces are supplied by the permanent forces of terrestrial magnetism acting on the bodily motion of masses of conducting air which cut through its lines of force. In the language of modern electrodynamics, the periodic magnetic disturbance is due to Foucault currents induced in an oscillating atmosphere by the vertical magnetic force. The problem to be solved in the first instance is the specification of the internal motion of a conducting shell of air, which shall, under the action of given magnetic forces, determine the electric currents producing known electromagnetic effects. Treating the diurnal and semi-diurnal variations separately, the calculation leads to the interesting results that each of them is caused by an oscillation of the atmosphere which is of the same nature as that which causes the diurnal changes of barometric pressure.

The mathematical analysis is simple so long as we take the electric conductivity of the air to be uniform and constant; but the great ionisation which the theory demands requires some explanation, and solar radiation suggests itself as a possible cause. Hence we might expect an increased conducting power in summer and in day-time as compared with that found during winter and at night. Observation shows, indeed, that the amplitude of the magnetic variation is considerably greater in summer than in winter, and we know that the needle is at comparative rest during the night. The variable conducting power depending on the position of the sun helps us also to overcome a difficulty which at first sight would appear to exclude the possibility of any close connection between the barometric and magnetic variations; the difficulty is presented by the fact that the change in atmospheric pressure is mainly semi-diurnal, while the greater portion of the magnetic change is diurnal. This may, to some extent, be explained by the mathematical calculation, which shows that the flow of air giving a twenty-four-hourly variation of barometric pressure is more effective in causing a magnetic variation than the corresponding twelve-hourly variation, but the whole difference cannot be accounted for in this manner. If, however, the conductivity of air is greater during the day than during the night, it may be proved that the twelve-hourly variation of the barometer produces an appreciable periodicity of twenty-four hours in the magnetic change, while there is no sensible increase in the twelve-hourly magnetic change due to the twenty-four-hourly period of the barometer.

A good test of the proposed theory may be found in a closer examination of the diurnal magnetic changes in the equatorial regions, because, owing to the inclination of the magnetic to the geographical axis, the magnetic changes ought to have a term which does not depend on local time, but on the time of the meridian containing the geographical and magnetic pole. This term has its greatest importance at the equator and at the time of the equinox.

The value of the conductivity necessary to explain the diurnal variation in the manner indicated depends on the thickness of the layers which carry the currents. If e be the thickness and ρ the conductivity, and the amplitude of oscillation in the upper layers is assumed to be the same as that deduced from the barometric variation, it is found that $\rho e = 3 \times 10^{-6}$. If e is equal to 300 kilometres, the conductivity would have to be as high as 10^{-13}, while the observed conductivity of air at the surface of the earth under normal conditions is of the order 10^{-21}; at a height at which the pressure is reduced to one degree per square centimetre, the conductivity would be 10^{-18}, assuming the rate of re-combination to be independent of temperature and the ionising power to be the same. The conclusion is that there must be a powerful ionising agent in the upper layer of the atmosphere.

November 21.—"The Silver Voltameter." Part I. "On a Comparison of many Forms of Silver Voltameters." By F. E. **Smith**; and "A Determination of the Electrochemical Equivalent of Silver." By F. E. **Smith** and T. **Mather**, F.R.S.

Part II. "The Chemistry of the Silver Voltameter." By F. E. **Smith** and Dr. T. M. **Lowry**. Communicated by Dr. R. T. Glazebrook, F.R.S.

Part I.—Very large voltameters were experimented with. Four of the kathode bowls had a capacity of 500 c.c. each, and in general from 300 c.c. to 400 c.c. of electrolyte were employed. The anodes were coated with electrolytic silver. With a Rayleigh form of voltameter containing an electrolyte of pure silver nitrate, the mean of fifty-two determinations of the electrochemical equivalent of silver was 1·11827 milligrams per coulomb, the current being indirectly measured by the Ayrton-Jones balance. With a Richards's form of voltameter, in which the pot had previously been baked in an electric furnace, the value 1·11828 was obtained, and with a syphon and other modified forms of voltameter the value 1·11827 resulted, pointing to little or no irregularities in the large-size Rayleigh form of voltameter. Deposits were made when the voltameter was subject to a gaseous pressure of 2·4 cm. of mercury, and were found to be identical with those made at atmospheric pressure. The temperature coefficient is probably *nil*, and is not greater than 1 part in 1,000,000 per 1° C. The range in the current intensities was from 0·5 ampere to 8 amperes.

Part II.—Before a definite value could be assigned to the electrochemical equivalent of silver it was necessary to demonstrate that silver nitrate solutions, giving constant products, could be obtained. This was done by preparing silver nitrate from electrolytic silver, from much used silver nitrate, and from commercial samples of the salt. Attempts to confirm the observations of Novak, Rodger and Watson, Kahle, van Dijk, and others, on the effect of repeated electrolysis of a solution, show that in the form of voltameters described in Part I. there is no increase in the deposit with continued use of a solution which is comparable with that obtained by the observers mentioned. High values for the electrochemical equivalent are obtained if the solution contains oxide, carbonate, chloride, nitrite, or hyponitrite; low values are caused by acid. Silver chlorate and silver perchlorate appear to give normal deposits, but are more troublesome in use, and have no advantage over the nitrate.

"On the Normal Weston Cadmium Cell." By F. E. **Smith**. Communicated by Dr. R. T. Glazebrook, F.R.S.

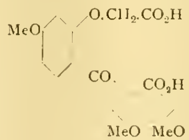
In the past many investigators have pointed out that the depolariser may produce variations in the E.M.F. so great as 0·002 volt. A mode of manufacture of mercurous sulphate was first sought which could be relied on to give a constant product. The salt was prepared in four ways:—(1) electrolytically; (2) by chemical precipitation; (3) by re-crystallisation from a solution in strong sulphuric acid; (4) by the action of fuming sulphuric acid on mercury. The mean E.M.F. of the cells set up with the electrolytic salt is 1·01828 volts; with No. 2 product, 1·01830 volts; (3) gives 1·01832 volts, and (4) 1·01831 volts. The effect of the size of the crystals of the depolariser, to the importance of which attention has been directed by H. v. Steinwehr, was investigated by using crystals varying in size from 5 to 30 microns, and it is concluded that no large crystals which are sufficiently soluble to act as an efficient depolariser can give an E.M.F. appreciably lower than that due to crystals from 5 to 30 microns long. The recuperative power of the cell was tested by short-circuiting for from one minute to five days. The temperature coefficient for the range 10° C. to 30° is given by

$$E_t = E_{17} - 3{\cdot}45 \times 10^{-5}(t-17) - 0{\cdot}066 \times 10^{-5}(t-17)^2.$$

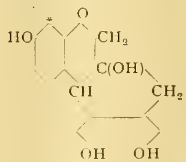
Geological Society, November 20.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—Glacial beds of Cambrian age in South Australia: Rev. Walter **Howchin**. The known extension of these beds is 460 miles from north to south. The greatest width across the strata is about 250 miles. The beds form part of a conformable series, with Cambrian fossils in the upper part. The rocks above the glacial beds are purple slates and limestones; below they are quartzites, clay-slates, and phyllites, passing into basal grits and conglomerates, resting on a pre-Cambrian complex. The beds consist of a ground mass of unstratified indurated mudstone, carrying boulders up to 11 feet in diameter. The thickness of the glacial series has been proved up to 1500 feet. The commonest rock-type among the boulders is a close-grained quartzite. The discovery of ice-scratched boulders has indicated the origin of the beds. The striæ are often as distinct as those in a Pleistocene Boulder-clay. Eighty definitely glaciated boulders have been secured, and other erratics too large for removal noted. Under pressure and movement in their bed some boulders exhibit abrasion, but this produces features not to be confounded with glaciation. In the movement due to pressure, which induced cleavage, some stones have become distorted, and many show pseudo-striation on exposed surfaces. The lines, however, are of equal size and depth, and parallel to each other over wide surfaces, while the glacial striæ are patchy in their occurrence, of varying intensity, and divergent in direction. Mr. H. P. Woodward's suggestion, that the "Boulder-clay" had its origin from "floating ice," is considered most in accordance with facts.—A formation known as "glacial beds of Cambrian age" in South Australia: H. **Basedow** and J. D. **Iliffe**. Eight miles south of Adelaide an exposure of the conglomerate is bounded to the east by alternating quartzitic and argillaceous bands of rock, comprising the central and western portions of a fan-fold, partly cut off by a fault. Further evidence of stress in this margin is given. On the west side the conglomerate is bounded by the "Tapley's Hill Clay-slates," and there is evidence that the conglomerate is isoclinally folded. In that portion of the conglomerate adjacent to its confines, "boulders" of quartzite are apparently disrupted portions of quartzite-bands, since these are in alignment with the truncated portions of bands still existing, and are of similar composition. The presence in the conglomerate of boulders of rocks foreign to the beds that border the conglomerate is not yet accounted for.

Entomological Society, November 20.—Mr. G. H. Verrall, vice-president, in the chair.—*Exhibits.*—W. **West**: Examples of *Tropideres sepicola*, F., taken in the New Forest near Matley Bog, July 7, 1904; *Oxylaemus variolosus*, Dufs., from Darenth Wood, March 2, 1903; and *Apion annulipes*, Wenck, from Darenth Wood, August 27, 1905.—H. J. **Turner**: Two cases to show the complete life-histories of *Coleophora onosmella* and *C. bicolorella*.—Dr. F. A. **Dixey**: Several species of five African genera of Pierine butterflies for the purpose of showing the strong mimetic parallelism that existed between them.—W. **Gardner**: A remarkably small specimen of *Meloë proscarabaeus*, with an example of the normal size.—W. G. **Sheldon**: A case containing many examples of *Araschnia levana*, var. *prorsa*, and intermediates, bred from larvæ found in the department of the Aisne, France, in June last.—Dr. T. A. **Chapman**: Specimens of *Araschnia levana*, type, bred 1907, to give a fuller view of this form in assistance to Mr. Sheldon's report.—Mr. **Shelden** also showed strings of the ova *in situ* on nettle, these being base to apex, and in position resembling those of *Polygonia c-album*.—G. **Arrow**: A specimen of a handsome exotic cockroach (*Dorylaea rhombifolia*) found alive in the Natural History Museum, one of an apterous species inhabiting China, India, Madagascar, South Africa, &c.—Dr. G. B. **Longstaff**: A case containing thirty-five Ithomiine butterflies of eleven species, belonging to six genera, taken at Caraccas, Venezuela, some 3600 feet above sea-level, and affording a striking exception to Darwin's principle that closely allied forms are not usually found together.—Lieut.-Colonel N. **Manders**: A collection of some 200 specimens of tropical butterflies belonging to the genera Melanitis, Mycalesis, Attella, Papilio, and Catopsilia, which had been subjected to abnormal degrees of temperature, mostly in the pupal stage. The object of the experiments was to ascertain the effect of climate on the colours of tropical butterflies.—W. J. **Kaye**: A convergent group of Heliconine butterflies, from the Potaro Road, Potaro River, British Guiana.—*Papers.*—Mimicry in North American butterflies of the genus Limenitis (Basilarchia): Prof. E. B. **Poulton.**—The life-history of *Lomecosus strumosa*, F.: H. St. J. **Denisthorpe.**

Chemical Society, December 5.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—The affinity constants of bases determined by the agency of methyl orange. Preliminary note: V. H. **Veley.** The author has applied his tintometric method to the determination of the degree of hydrolysis of hydrochlorides of a large number of organic bases ranging in type from hydroxylamine to cinchonidine. Several results are found to be in accordance with the expression of Arrhenius, $k_b/k_w = (1-x)v/x^2$, whilst in the case of bases of analogous composition the ratio of the hydrolysis values found is nearly equal to the ratio of the heats of neutralisation with hydrochloric acid.—The constituents of essential oil of nutmeg: F. B. **Power** and A. H. **Salway.** Ceylon nutmeg oil contains eugenol, *iso*eugenol, *d*-pinene, *d*-camphene, dipentene, *d*-linalool, *d*-borneol, *i*-terpineol, geraniol, a new alcohol yielding on oxidation a diketone, a citral-like aldehyde, safrole, myristicin, myristic acid (free and in the form of esters), formic, acetic, butyric, and octoic acids, and a new monocarboxylic acid, $C_{13}H_{18}O_3$, all in the form of esters.—The resolution of *sec*-octyl alcohol: R. H. **Pickard** and J. **Kenyon.** *d-sec*-Octyl hydrogen phthalate is obtained by fractional crystallisation of the brucine salt from acetone and the *l*-salt by fractional crystallisation of the cinchonidine salt from aqueous acetone.—The velocity of reduction of the oxides of lead, cadmium, and bismuth by carbon monoxide, and the existence of the suboxides of these metals: F. J. **Brislee.** The results of the experiments confirm Tanatar's statement that the suboxides are definite chemical compounds, but do not prove their stability.—The relation between unsaturation and optical activity, part i., the menthyl and bornyl esters of β-phenylpropionic, cinnamic, and phenylpropiolic acids: T. P. **Hilditch.** The boiling points and specific gravities increase with increase of unsaturation, but the refractive indices rise with the change to an ethylenic linking, but fall to an intermediate value for the further change to an acetylenic linking. Walden's view that increase of saturation is accompanied by increase of optical rotation is confirmed so far as the change to an ethylenic linking is concerned, but not with reference to the effect of a triple bond on the optical rotation.—Methyl ethers of some hydroxyanthraquinones: A. G. **Perkin.**—The colouring matters of the stilbene group, part iv., action of caustic alkalis on *p*-nitrotoluene and its derivatives: A. G. **Green,** A. H. **Davies,** and R. S. **Hersfall.**—The replacement of alkyl radicles by methyl in substituted ammonium compounds: H. O. **Jones** and J. R. **Hill.** The authors find that in amines or quaternary ammonium compounds the ethyl, propyl, *iso*propyl, butyl, *iso*butyl, and *iso*amyl groups are all replaced by methyl, sometimes in the cold, but more easily on heating with methyl iodide.—Note on the formation of abnormal platinichlorides. A correction: A. E. **Dunstan.** The three platinichlorides of the type $B_{11}H_2PtCl_6$, described previously, are now found to belong to a group of such substances already noted by Werner and others.—The nitrates of dimethyl- and methylethylthetine menthyl esters: S. **Smiles.** These were prepared by precipitating aqueous solutions of the bromides with aqueous ammonium nitrate.—Synthesis of brazilinic acid and the lactones of dihydrobrazilinic and dihydrohæmatoxylinic acids. Preliminary note: W. H. **Perkin** and R. **Robinson.** Brazilinic acid is formed when trimethylbrazilin is oxidised by permanganate, and on reduction is converted into the lactone of dihydrobrazilinic acid. Brazilinic acid is produced synthetically by condensing metamethoxyphenoxyacetic ester with *meta*hemipinic anhydride, and must be represented by the following formula (I.):—



I.



II.

From this and other syntheses it is concluded that brazilin, the colouring matter of Brazil wood, must be represented by the constitutional formula (II.) first assigned to it by Werner and Pfeiffer, and that hæmatoxylin, the colouring matter of logwood, is derived from that of brazilin by the introduction of a hydroxyl group at the point indicated by the asterisk in formula (II.).—Condensations of ketones containing the group

$$CH_2.CO.CH:$$

with esters in presence of sodium ethoxide: R. W. L. **Clarke,** A. **Lapworth,** and E. **Wechsler.**—Acylogens and thiocarbamides: A. E. **Dixon** and J. **Tayler.**—The alkyl compounds of gold: W. J. **Pope** and C. S. **Gibson.**—The refractive power of diphenylhexatriene and allied hydrocarbons: Miss I. **Smedley.** The results recorded show that in each case the refractive power of the group increases with the number of unsaturated groups present, and that the influence of the hexatriene structure is always greater than that of the benzene ring.

Royal Anthropological Institute, December 3.—Prof. W. Gowland, ex-president, in the chair.—Some Papuan children's games: Captain F. R. **Barton.** The games dealt with are those played by children in British New Guinea, and included fishing games, cat's cradle, hide and seek, and others. Whilst the games are being played the children sing, and the songs are of particular interest, as in many cases the words are quite archaic, and the meaning has been lost.

CAMBRIDGE.

Philosophical Society, October 28.—Dr. Hobson, president, in the chair.—The longitudinal impact of metal rods with rounded ends (second paper): J. E. **Sears.** In this paper the effect of the rounded ends is discussed mathematically by means of a combination of the theories of Hertz and St. Venant. Further experimental results are brought forward for purposes of comparison. In these experiments rods of unequal lengths were used, and observations made both of the durations of impact and of the velocities of rebound. The results in nearly every case agreed within 1 per cent. with those given by the theory. Interesting laws are found for the variation in the duration of the impact when the length of *one* of the rods is continuously increased, and also for the case when the velocity of impact is allowed to vary. The paper concludes with a suggestion as to the application of the theory to plane-ended rods, and a calculation of the stresses set up at the ends of the rods during impact.—The fatigue of secondary radiation due to radium rays: J. A. **Crowther.** The object of the experiments was to ascertain if the continuous impact of the radium radiations upon a metal plate over a prolonged period of time produced any alteration in the amount of secondary radiation given out by the plate. Experiments were made both with the β and γ rays, and also with the α rays. The results of the experiments showed (1) that the continuous impact of radium rays upon a metal plate does not cause any diminution in the amount of secondary radiation given out by the metal under the action of the radium rays themselves; (2) that the continuous impact of radium rays upon a metal plate does produce an alteration in the amount of secondary radiation given out by the plate under the action of Röntgen rays, in amount similar to that produced by the continuous impact of Röntgen rays; (3) that the continuous action of radium rays produces a very marked diminution in the amount of secondary radiation given out by the plate under the action of ultra-violet light.—Laws of motion: P. V. **Bevan.**—Ionisation by ultra-violet light: Prof. **Thomson.**—The asymptotic approximation to functions defined by highly convergent product forms: J. E. **Littlewood.**

PARIS.

Academy of Sciences, December 9.—M. A. Chauveau in the chair.—An apparatus designed for stars composed partly of gas and partly of solid particles, and capable of giving separately the image of each of the two elements: H. **Deslandres.** A photograph of the star spectrum is made, and from the negative a screen is made with a diaphragm cutting out any desired lines, and this screen is placed in the focal plane of the spectrum. A diagram of the complete apparatus is given, which is arranged so that the spectrum photographed may include either the lines of both gas and solid particles or those of the gas or particles separately. The apparatus is easily applicable to comets, nebulæ, the middle and upper chromosphere of the sun during eclipses, and even the corona.—The supposed poisonous nature of Hungarian beans: L. **Guignard.** Contrary to the results obtained by MM. Evesque, Verdier, and Bretin, the author has not been able to obtain the smallest trace of hydrocyanic acid from Hungarian beans (*Haricots de Hongrie*). The method of estimation of the hydrocyanic acid used by the above-mentioned chemists is subjected to a critical examination, and the author's own method described in detail.—The claims of M. Loeb in the question of experimental parthenogenesis: Yves **Delage.** A reply to some criticisms of M. Loeb on the author's work.—Some Lepidostrobus from the Pyrenees region: R. **Zeiller.** Three illustrations of the fossil are given.—The direct hydrogenation of some aromatic diones: Paul **Sabatier** and A. **Mailhe.** The direct hydrogenation by means of reduced nickel of the aromatic diones gives results corresponding to the ordinary hydrogenation of these ketones, aromatic hydrocarbons being formed. Benzil and benzoin gave symmetrical diphenylethane. Benzoylpropanone gave principally butylbenzene.—The visibility of Saturn's ring at the present time: J. **Guillaume.** An account of the appearance of the ring on the night of November 23. The results confirm the observations of W. C. Bond and of Secchi.—The Giacobini comet 1907*a*: MM. **Giacobini** and **Javelle.** Observations of the position of the comet were taken on December 4, 6, and 7. The comet had a stellar appearance of about 15″ diameter, and showed a nucleus of the fourteenth magnitude.—Observation of the transit of Mercury of November 14 made at the Fabra Observatory at Barcelona: J. Comas **Solá.** The conditions of observation were good. The times of the second, third, and fourth contacts are given. The mean of five observations of the equatorial diameter was 8″·94, the form of the planet being sensibly circular.—Certain ruled surfaces: M. **Tzitzéica.**—The permutation of the integrals of a system of differential equations: A. **Buhl.**—The function D(λ) of Fredholm: T. **Lalesco.**—The systems of partial differential equations leading to (1) the study of the finite deformations of a continuous medium in space of n dimensions; (2) the determination of the systems of orthogonal curvilinear coordinates with n variables: M. **Riquier.**—General mechanics: Eugène and François **Cosserat.**—An electromagnetic compass particularly suitable for armoured blockhouses and submarines: Louis **Dunoyer.** The transmitting compass is placed in a part of the ship where the field gives no trouble, or may be compensated, the readings being transmitted by the arrangement described to the receiver, from which the ship is steered.—The number of free electrons of metals and the electromotive series: V. **Schaffers.**—The condensation of water vapour in the presence of the radium emanation: Mme. **Curie.** Moist air containing the radium emanation always contains a fine fog more or less opaque, and formed of very fine particles. A very much smaller amount of water vapour than that required for saturation is sufficient to produce this phenomenon, but it is not produced when the air is perfectly dry. This effect is quite separate from the known phenomenon of condensation of water vapour by gaseous ions.—The lithium contained in radio-active minerals: Mlle. **Gleditsch.** In view of the observation of Sir William Ramsay that radium transforms copper into lithium, it appeared of interest to see if minerals which contain both copper and radium also contain lithium. In agreement with the result of McCoy (NATURE, November 28), Joachimsthal pitchblende has been found to contain a minute amount of lithium.—Singing flames and tubes with flames of several notes: M. **Athanasiadis.** Experiments are described showing that a manometric flame can produce a perceptible sound, the number of vibrations of which is equal to the number of vibrations of the manometric membrane. A manometric flame can also produce simultaneously two or more notes.—The use of very low temperatures for spectrum analysis and for the study of magneto-optic phenomena in solutions: Jean **Becquerel.**—The propagation of telephone currents through subterranean lines: Henri **Abraham** and M. **Devaux-Charbonnel.** Underground telephone lines are only available for very moderate distances; the pitch of the notes exercises a considerable influence on the power of transmission to large distances, low voices being better transmitted than high ones, as the line absorbs the high harmonics.—The saturation intensity of magnetisation of iron and nickel: Pierre **Weiss.**—The application of the law of Poiseuille to the measurement of high pressures: A. **Perot.** The volume of water forced through a very fine capillary tube, applying Poiseuille's law, has been used as a basis of a manometer for high pressures, 300 kg. per sq. cm. The accuracy was found to be about 0·5 per cent.—The use of heavy hydrocarbons for lighting: Louis **Denayrouze.**—The action of an incandescent electric conductor on the gases which surround it: M. **Couriot** and Jean **Meunier.** An explanation is put forward of the cause of the non-inflammation of certain explosive mixtures of oxygen and hydrocarbons by means of a wire carried to incandescence by electricity. It is assumed that the wire repels the oxygen molecules and attracts those of the hydrocarbon, so that the actual composition of the gaseous zone immediately round the wire is not in explosive proportions.—The method of limiting densities and its application to the atomic weight of nitrogen: Ph. A. **Guye.** An answer to some criticisms of M. Daniel Berthelot. The author prefers to base his calculations on the idea of corresponding states rather than on that of limiting densities, and compares the two methods in detail as applied to the experimental ratios $N_2O:O$, $N_2O:N_2$, $N_2:O$, $NO:O$, $NO:N$, and $N:O$. These lead to a mean value for the atomic weight of nitrogen of 14·010 instead of the 14·005 of M. Berthelot.—The non-existence of a common solvent for white and red phosphorus: Alb. **Colson.** The author has been unable to dissolve red phosphorus in essence of turpentine, and there seems to be no solvent known which will dissolve both varieties.—The equilibrium of the nickel-bismuth system: A. **Portevin.** The state of equilibrium is only attained for alloys of the pure metals.—An apparatus designed for the production of spark spectra of solutions: A. **de Gramont.** In the apparatus, a drawing of which is given, the spark is produced between two drops of the liquid held up in capillary tubes of fused quartz. The spectra are free from the lines of platinum and silicon.—The identity of graphite and the graphitic carbon set free from castings during tempering: Georges **Charpy.** The experiments described lead to the conclusion, contrary to the views of Forquignon and of Wust and Geiger, that these two forms of carbon are the same.—The action of phosphorus trihydride on mercuric chloride and bromide: P. **Lemoult.**—Carbon monoxide in coal gas: Léo **Vignon.** The larger the amount of oxygen in the coal the larger is the proportion of carbon monoxide and dioxide in the gas obtained from it. At a temperature of 900° C., rather less than one-third of the oxygen of the coal is found in the gas in the form of these two oxides.—The transformation of barbaloin into an isomeric aloin; β-barbaloin and the existence of the latter in several kinds of aloes: E. **Léger.**—The dissociation of combinations of colouring acids to basic colours by adsorbing substances: L. **Pelet-Jolivet.**—Sparteine. The isomerisation of α-methyl-sparteine: Charles **Moureu** and Amand **Valeur.**—The synthesis of symmetrical phenylated anilidophenosafranine: Ph. **Barbier** and P. **Sisley.**—The deposit of evergreen copper: Étienne A. **Ritter.**—The occurrence of granite in the diamond-bearing chimney of De Beers: L. **De Launay.** Some time ago the author predicted that granite would be encountered in a boring at Kimberley at a depth of about 600 metres, and his views have been confirmed by the discovery of granite in this chimney at a depth of 641 metres.—Remarks on the affinities of the Malpighiaceæ of Madagascar, concerning the new genus Tricomariopsis: Marcel **Dubard.**—The variations of dry weight in the higher plants under different luminous intensities: W. **Lubimenko.**—The influence of the hygrometric state of the air on the preservation of seeds: E. **Demoussy.** When the hygrometric state, at 25° C., is above 0·7, many seeds rapidly perish, the seeds of the Cruciferæ being the most resistant.—The inosites from Gui: Georges **Tanret.**—A colour reaction for use with fungi: L. **Arnould** and A. **Goris.**—The fatigue of earth: J. **Pouget** and D. **Chouchak.**—Two hybrids of the peacock and Cochin China fowl: G. **Pays-Mellier** and E. **Trouessart.**—Histolysis of the muscles after the nuptial flight in ants: Charles **Janet.**—The periodic variations of sign of phototropism in *Clibanarius misanthropus*: Mlle. Anna **Drzewina.**—The action of the ichthyotoxins on the nervous system of animals immunised against these substances. Contribution to the study of immunity: E. **Gley.**—The favourable influence of small doses of zinc on the vegetation of *Sterigmatocystis nigra*: Maurice **Javillier.**—The presence of phosphorus in the fatty material of micro-organisms: E. **Axilaire.**—The conditions of hydrolysis of the protoplasmids: A. **Etard** and A. **Vila.**—The effects of light on the vision: Jules **Amar.** Excluding pathological conditions, an excess of light puts the eyes into a bad condition for their normal working.—The influence of the illumination round the observer on the acuteness of vision for night signals in navigation: André **Broca** and M. **Polack.**—The presence of yeasts in the fatty bodies of several Coccideæ: A. **Conte** and L. **Gaucheron.**—The trypanolytic property of the serum in experimental nagana: A. **Ridet** and G. **Vallet.**—The pathogeny of glaucoma: A. **Terson.**—The death of infants by the thymus and in chloroform anæsthesia. Anatomical, physiological, and clinical study: R. **Robinson.**—The action of chlorine on the tubercle bacillus: MM. **Moussu** and **Goupil.**—The presence of the Trias in the mountains of Gigondas (Vaucluse), and the phenomena of *charriage* which are observed in this *massif*: L. **Joleaud.**—The Neocretacean of Argolide: Ph. **Négris** and Const. A. **Ktenas.**—The discovery of vertebrates in the Oligocene of Fronsadais, basin of the Gironde: G. **Vasseur.**—Some new fossil plants in the Sparnacean of the Paris region: P. H. **Fritel.**—Study of a specimen taken from the sea bottom of the Channel near the coast: J. **Thoulet.**

CALCUTTA.

Asiatic Society of Bengal, November 6.—Note on the common English merlin (*Æsalon regulus*) and its training: Lieut.-Colonel D. C. **Phillott.**—A case of lateral floral proliferation of the inflorescence of the pine-apple—*Ananas sativus*, Schult. f.: Captain A. T. **Gage.** Descriptions with figures of a pine-apple surrounded by many small elongated pine-apples after the manner of a hen-and-chickens daisy.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 19.

CHEMICAL SOCIETY, at 8.30.—Derivatives of Tetramethyl Glucose: J. C. Irvine and A. M. Moodie.—The Characterisation of Mercerised Cotton; Preliminary Note: J. Hübner.—Attempted Synthesis of $\begin{matrix}\beta\text{—N—}\beta\\ |\\ \beta\text{—CH—}\beta\end{matrix}$ Di-naphthacridine; Condensation of Methylene Dichloride and 1-Substituted-2-Naphthylamines: A. Senier and P. C. Austin.

LINNEAN SOCIETY, at 8.—On Mendelism and Sex: Dr. Archdall Reid.

INSTITUTION OF MINING AND METALLURGY, at 8.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electrical Power in Railway Goods Warehouses: H. Henderson.

FRIDAY, DECEMBER 20.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Mechanical and Therma Efficiency of a Petrol Engine: L. G. E. Morse.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Notes on the Manufacture and Upkeep of Milling Cutters: Dr. H. T. Ashton.

ELECTRIC TRACTION.

Electric Traction. By Prof. Ernest Wilson and Francis Lydall. Two vols. Vol. i., Direct Current, pp. vii+475; vol. ii., Alternating Current, pp. vii+328. (London: Edward Arnold, 1907.) Price 15*s*. net each.

THERE is no announcement on the title-page that this work is a second edition of a book which appeared in 1897. This omission, however, is fully justified, for although technically the present work may be considered a new edition, it is in reality a new work. Progress during the last ten years has been so great that to bring the work up to date it had practically to be re-written and very greatly enlarged. Even in its present form of two handsome volumes, comprising together some 760 pages, the authors have not treated the subject exhaustively. This statement is not meant as a reproach, but simply as an illustration of the fact that the application of electric traction to tramways and railways has become so many-sided that an exhaustive treatise of the subject can hardly be expected. All that can be expected is that the authors should make a judicious selection of types and systems, and this expectation is on the whole fulfilled in the present work.

There is, however, one rather important omission, namely, the use of the three-wire system on direct-current railways, as suggested by Krizik and carried out by his firm on the Tabor-Bechyne line in Bohemia. It is true that the authors give on p. 416 a sketch of the circuits and a short description of the system adopted on the City and South London line, which is a three-wire system in the sense that the trains in one direction are worked from a positive 500-volt trolley and the trains in the other direction from a negative 500-volt trolley, but this is a far less advantageous system than that devised by Krizik, where the positive and negative side of the three-wire system are utilised in the same train, and the earth or rail return is only called into requisition in the event of a breakdown on one side of the system.

Of the two volumes the first is devoted to direct-current and the second to alternating-current railways. The treatment is mainly descriptive, without much criticism on the authors' part, and on the whole there is a tendency to give prominence to American designs or to English designs of American origin. This favouring of American work goes so far that the authors, whilst referring to standardisation of tramway motors as determined by the American Institute of Electrical Engineers, completely ignore the standard rating adopted by the International Association at the Milan Congress last year. Possibly they may think the American standard better, but that is no reason why they should keep their English readers in ignorance of the fact that there is a standard in use on the Continent of Europe which will have to be complied with by those firms who secure contracts on the Continent.

A little more than half of the first volume is given up to tramway work, and deals in succession with the motor, the controller, resistances, trolleys and bows, rolling stock including brakes, the track, overhead equipment, slot and contact systems, feeders, generating stations, car sheds, storage-battery traction and regenerative control. Approximately the same order in the treatment of details is followed in the part devoted to railways, with the addition of a chapter on substations. Then follows a chapter on cost of tramway work, which, being taken from actual practice, should prove very useful when getting out preliminary estimates, also a chapter on working expenses, traffic receipts and tramway accounts in general, and finally there is an appendix giving all the Board of Trade regulations.

As already remarked, the treatment is mostly descriptive, but not always complete. Thus the suspension of tramway motors is dealt with in only four lines on p. 78, and in the description of magnetic brakes we miss the magnetic friction brake on the axle, although magnetic track brakes are not only well described but also critically compared. The tables relating to turn-out, cross-over and transition curves on pp. 112 to 116 are well arranged, and will be found very useful in laying out the track. Also the details of overhead equipment are well represented, but we miss the bridge wire round the ears which has of late years been introduced as a precaution to avoid the trolley wire coming down in the event of its breaking, which, as is well known, takes place generally close to the ear.

As regards buffer batteries, the authors seem to be under the impression that Mr. Highfield made their use possible by his automatic reversible booster. This is not so. Buffer batteries have first been suggested by Dr. Edward Hopkinson in 1893 in a paper read before the Institute of Civil Engineers on the City and South London Railway, and very shortly after, the first buffer battery was installed by the Tudor Accumulator Co. in the power house of the Zurich tramways, the economic success being so remarkable that buffer batteries had become a quite regular feature in tramway power houses on the Continent long before Mr. Highfield designed his very ingenious system of boosting.

On p. 197 the authors show a diagram (Fig. 144) and call it a negative booster wrongly connected. In this case the booster is supposed to be a series machine driven at a constant speed. There is nothing wrong about its connection; the only wrong thing in the diagram is the direction of the current as marked by arrows. A moment's consideration will show that if the machine is run at the critical speed in relation to the resistance of the return feeder, it is the very best possible negative booster, since it will relieve the rails from return current to even a greater extent than the booster with excitation from the positive feeder.

The authors' treatment of the complicated subject of controllers is excellent. They always give first a diagram showing the principle and then the actual arrangement of circuits and contacts, thus rendering the study of an intricate subject comparatively easy. The same praise may be given to their way of working out running diagrams and the determination of the best acceleration. They show that although high acceleration means low energy per ton-mile, it does not necessarily mean low running cost, because the cost of substations and feeders increases considerably with the acceleration provided for. All these matters are treated from a thoroughly practical point of view.

The second volume begins with a chapter on the theory and design of the polyphase railway motor, with useful examples of such motors as applied to the Valtellina and other lines; then follows control, overhead equipment, rolling stock, energy consumption, and other details. In view of the increasing importance of single-phase working, the authors have done well to restrict the three-phase part of the book and to devote the space saved to the more recent single-phase system. Here they break new ground by going at some length into the question of single-phase commutator motors, both with and without commutating poles, compensating winding, and other refinements. There is, however, a certain ambiguity about the motors described, and the reader will not find it easy to know what particular type is meant, especially as diagrams of windings and vector diagrams are too sparingly used. Neither will he find mention of the designers by the names of which particular motor types have become known; there is no mention of Lamme, Fynn, Winter-Eichberg, Richter, Latour, and so on, yet each of these men have produced distinct types. To give an instance of the ambiguity: we are told that the London Bridge to Victoria line is being equipped with "compensated repulsion motors," but nothing is said of the particular type being the Winter-Eichberg.

The chapter on overhead work is distinctly good, both as a theoretical treatise and as a collection of examples from the best modern practice, whilst the chapters on feeders, inductive drop in rails, energy consumption, and capital outlay on single-phase railways will repay careful study on the part of the engineer who has work of this kind to design.

GISBERT KAPP.

VETERINARY ANATOMY.

The Surgical Anatomy of the Horse. Part ii. By John T. Share-Jones. Pp. xii+190. (London: Williams and Norgate, 1907.)

WHY do British veterinary anatomists adhere so tenaciously to a nomenclature which is absolutely indefensible? Many of the terms at present employed in the various English text-books on the anatomy of the domestic animals are admittedly unsatisfactory; yet British veterinary writers persist in their use, with the result that a Continental reader wishing to consult an English work is put to an infinity of profitless trouble. Not only are the English names incompatible with comparative anatomy; sometimes they are strikingly absurd. No more deplorable instance of misdirected ingenuity is to be found than in the names given to the three phalanges. The first phalanx rejoices in the name of "*os suffraginis.*" Not only is this an unknown expression in scientific anatomy, it is also the outcome of error. Its inventor—possibly a French writer, be it said—completely mistook the meaning of the Latin word *suffrāgo* (*suffraginis*), which is generally defined as "the ham or hough of a quadruped's hind leg," and is used by Pliny and others as opposed to *armus*. If, then, an *os suffraginis* is to be recognised, it seems more reasonable to regard it as the femur. It certainly is not the first phalanx.

The second phalanx is known to the quasi-scientific veterinarian as the *os coronae*, a term which may be passed over by saying that the only defence for its use is the application by the stable-man of the name *coronet* to the region of the limb in which the bone is situated. To speak of the third phalanx as the *os pedis* is to subvert the meaning of the word *pes* as used in anatomy. The *pes* of the scientific anatomist includes the tarsal, metatarsal, and phalangeal regions of the posterior or pelvic limb; and has its parallel in the *manus* of the anterior or thoracic member.

In no part of the body are objectionable terms applied so frequently as in the limbs. This is doubtless due to the extreme degree of modification from the mammalian type which has been produced during the evolution of the modern horse, a modification so marked as to lead the original inventors of veterinary anatomical nomenclature to devise terms which to them seemed fitting, irrespective of their incompatibility with anatomical terminology in general. The time has come, however, when there is little excuse for aberrations. The BNA was devised with the intention that it should make the writings of an anatomist easily intelligible to his brother men of science. Works on anatomy, whether they be purely anatomical or partly surgical, should embody the universal nomenclature. If thought necessary, as is doubtless the case in books written largely for the practitioner, the customary English equivalents might be set down side by side with their Latin synonyms.

Mr. Share-Jones, in the volume before us, employs exclusively the undesirable names found in other English text-books, with the result that he cannot expect to appeal to a wider circle of readers than those who speak the English tongue. What exactly the aim of Mr. Share-Jones may be is difficult to determine. He certainly cannot claim to have produced a surgical *anatomy*, since he deals at some length with fractures and other traumatisms, diseases, symptoms, and even treatment. How far he was justified in including such subjects as "sore-shins," "breakdown," "speedy-cutting," &c., in a work entitled "The Surgical Anatomy of the Horse" is doubtful; but it is beyond question that microscopic structure is out of place in such a production.

Reputable books on anatomy—surgical or otherwise—are now produced with illustrations which may be termed artistic without doing violence to the English language. Indeed, the illustration of scientific works in general is now an art in itself. This being so, a work the value of which depends mainly upon its plates is apt to be judged by a fairly high standard. Most of Mr. Share-Jones's figures would not stand such a judgment. Apart from their execution, it is difficult to see why some of them are printed on so large a scale as to require quarto plates. It is, further, not easy to decide on the value to the surgeon of large plates showing merely the bones of the shoulder and elbow joints, or figures of the various bones of the limb, or purely diagrammatic representations of the arterial arches and veins.

As the surgeon is well aware, veins are very much larger than the arteries they accompany. Figures of sections, therefore, should show this; and, in order that they may do so in a serviceable manner, should be made from formol-hardened bodies. Again, in the limbs, not infrequently two veins accompany an artery; and this is especially common in the region illustrated in plate ix. Figures of sections, furthermore, should be accompanied by some key to the precise level at which the cut has been made. In some regions, as, for example, about the carpus, a very small deviation in the level of two sections produces an appreciable difference in their appearance. The relationship of the vessels, &c., in plate xxi. may be correct, but where is the tendon of the flexor carpi radialis? Plate xxv., though semi-schematic, should show the slip passing from the tendon of the extensor communis to that of the extensor digiti minimi.

It is evident that the writer has been too ambitious, and has endeavoured to display encyclopædic knowledge in an utterly inadequate space. Consequently some subjects have had to be treated in a manner all too brief. A description of the nerve to the latissimus dorsi in three lines and two words, or of the subscapular nerve in two and a half lines, is of little value to the surgeon and none at all to the student.

The volume before us forms the second part of the complete work, and deals with the anterior limb. The printers and publishers are to be commended for their share of the work.

THE ROMANCE OF SAVAGE LIFE.

The Romance of Savage Life, describing the Life of Primitive Man, his Customs, Occupations, Language, Beliefs, Arts, Crafts, Adventures, Games, Sports, &c. By G. F. Scott Elliot. Pp. 384. (London: Seeley and Co., Ltd., 1908.) Price 5*s*.

A POPULAR yet accurate account of savage life would supply an obvious want; and though Mr. Scott Elliot's contribution is interesting and readable, it still leaves the field open to some more competent writer. The model for a book of the kind is the "Anthropology" of Prof. Tylor, a volume popular and at the same time truly scientific, with which Mr. Elliot does not seem to be acquainted. Like this it might dispense with a bibliography and footnotes. Mr. Elliot, however, professes to give references, but these and his list of authors are inadequate. If authorities are to be quoted full references should be given, and it is worse than useless merely to name without further detail books like Gibbon's "Decline and Fall" or the "Polynesian Researches" of Ellis.

A bibliography, again, which ignores Messrs. Spencer and Gillen and Dr. Howitt's last book on Australians; Col. Dalton, Sir J. G. Scott and Mr. Thurston on Indian forest tribes; Catlin and Schoolcraft on North American Indians; Dr. Rivers on the Todas; Miss Kingsley and Col. Ellis on West Africa; Dr. Haddon's "Cambridge Expedition to Torres Straits"; the Journal of the Folk-lore Society; and last, but not least, the works of Dr. Frazer when totemism, death rites, and savage religion are discussed, is obviously of little value. The ethnographical chapters are naturally the best part of the book; but when the writer deals with the theory of the ghost as affecting methods of disposal of the corpse, with the belief in a future life, and with savage animism generally, he is evidently on unfamiliar ground.

It may seem hard to tax a popular writer with inaccuracies and omissions such as these. But if, as he might reasonably have done, he frankly declined to quote authorities, the case would have been different. When he professes to write in a scientific way he is bound by the laws which govern scientific work; and this is the more necessary in the case of anthropology, which claims to be an exact science. Finally, the time is past when a book like this can be illustrated by fancy drawings of prehistoric men attacking a bemired mammoth, or of a young lady of the Swiss Lake-dwelling period doing up her back hair. It would have been much more instructive to supply photographs of modern savages at home, of the horses of La Madelaine Cave, or the man and bison from Laugerie Basse.

Even with all these drawbacks the book is a readable contribution to the excellent series of which it forms a part. Mr. Scott Elliot, without any pretensions to style, writes pleasantly, and though his personal experience of wild men seems to be confined to a part of Africa and Madagascar, he possesses a sufficiently vivid imagination to grasp the relation of the savage to his environment. From a comparison of their mode of life with that of Fuegians and Tasmanians, he is able to give a vivid sketch of life in the Cro-Magnon and Lake-dwelling periods, and his accounts of savage war and weapons, boats and huts, cookery and dancing, are often well done. The book will supply excellent reading to an intelligent boy, and may lead him to study the scientific literature of the subject.

OUR BOOK SHELF.

Die Vegetation der Erde. VII., Die Pflanzenwelt von West Australien südlich des Wendekreises. By Dr. L. Diels. Pp. xii+413. (Leipzig: W. Engelmann, 1906.)

THE Australian flora is of extraordinary interest, not only by reason of the complex problems connected with its origin and development, but also on account of the wonderful range of adaptation to their environment displayed by so many of its constituent species. It is with special pleasure, then, that we welcome the appearance of Dr. Diels's treatise on the flora of the south-western part of the continent. The method of treatment pursued by the author is a good one. He gives a fairly full historical account of the investigations of his predecessors, and incidentally criticises the "Flora Australensis," in common with other colonial floras, on account of the frequently insufficient data as to locality of a species. It must, however, be remembered that much of the material for these floras is collected through channels which would render it impossible to furnish such data, and it is better to have the description of the plants, even if their habitats cannot be ascertained from the collectors.

The author, who spent many months going over the ground himself, gives a very good account of the physical and chief geological features of the country, and then discusses the general character of the flora, its chief geographical subdivisions, the latter of course depending on the amount and on the periodic distribution of the annual rainfall, and he then touches on the ecological side of the vegetation, and finally gives his views as to the relationship of the south-west Australian flora to that of the rest of the continent and thence to those of other lands.

He divides the flora into eastern, Eremæan (including the central regions), and western provinces. Of these, the eastern shows strongest affinities with the plants of other lands, *e.g.* with Indomalayan on the north and Antarctic in the south; whilst the Eremæan, though largely peculiar, yet betrays north-eastern relationship. The south-western region is far the smallest region, and also is the most peculiar. Dr. Diels considers, in opposition to the views advanced by some other writers, *e.g.* A. R. Wallace, that the flora of this region is a derived and specialised one rather than the starting point whence the typically Australian plants have arisen and spread over the rest of the continent.

It is impossible in a notice of reasonable length to deal at all fully with the contents of the book. It is one that should interest not only botanists, but all who can appreciate the bearing of plant distribution on geographical problems. The illustrations are good and the sketch-maps useful, though, perhaps, the inclusion of a general map in the volume might have rendered them more convenient for purposes of reference.

Das inneralpine Becken der Umgebung von Wien. By Dr. Franz X. Schaffer. Pp. viii+128. (Berlin: Gebrüder Borntraeger, 1907.) Price 2.40 marks.

THIS little work, truly a book for the pocket, is one of the latest additions to Borntraeger's "Sammlung geologischer Führer." It guides the pedestrian to the excavations in the flat land close to Vienna, and shows how the sections in sands and marls illustrate the later phases of the struggle of central Europe against the old Mediterranean Sea. The history of successive marine invasions, penetrating the hollows of the rising mountain-chains, is well and succinctly expressed in three pages (pp. 7–9) quoted from the author's "Geologie von Wien." The Vienna basin results from the falling in of the area after the Middle Miocene uplifts and foldings. The south-eastern European sea then invaded it for the last time (p. 117), depositing in a gulf the marine Leithakalk, with a fauna partly tropical, and ultimately the Sarmatian and Pontic strata, which show increasingly brackish-water conditions. The boundary of the sunken area is still marked by hot springs and outflows of mineral waters, those of Baden occurring where the western margin of the basin is crossed by dislocations that follow the strike of the limestone Alps (p. 121).

The Vienna basin has a charm of its own, and a scientific visitor may well spend a few days in it with this little volume as his companion. He should, of course, also read the story of the larger area around the city in the monumental "Bild und Bau Österreichs" (see NATURE, vol. lxx., p. 49), which is not a book that anyone could possibly carry in the field. We can soon escape from the noise of the very ill-paved suburbs, and at Schwechat are out along the quiet reaches of the Danube, making perhaps for the purple "horst" of Hainburg, where the towers still climb up the rock, as a memory of invasion from the east. Or we go south along the main "Bruchlinie," under sombre wooded hills, until we penetrate the Alpine zone at Gloggnitz; or south-east across the Goldene Lacke, where the great Hungarian cattle plough the plain, which spreads here, as the result of subsidence, close against the mountain-spurs. The Leithagebirge that rises gently in the south actually lies in Hungary; and the line of Miocene fracture may still be perceived, when we attempt to carry the German language into the Slav and Magyar villages beyond it.

The British Journal Photographic Almanac and Photographer's Daily Companion for 1908. Edited by George E. Brown. Forty-seventh year. (London: Henry Greenwood and Co., n.d.) Price 1s. net.

THIS is the forty-seventh issue of an indispensable publication. Year by year the volume makes its appearance, and on each occasion it is found to contain just that collection of photographic matter which is so useful and valuable to the everyday photographer.

The arrangement of the material is on similar lines to that of its immediate predecessors, but we are glad to see that all indices to advertisers, text, &c., are placed together at the end of the volume, undoubtedly the proper place for easy reference.

Naturally, the new Lumière colour process of photography, the chief topic of the year and a wonderful advance in colour photography, is referred to at some length, and this by the editor, who includes it under the heading "Screen-plate Processes of Colour Photography."

The section entitled "Epitome of Progress" will be found as useful as ever, summarising as it does in abstracts, papers, communications, articles, &c., which have appeared in either home or foreign journals, adding—and this is a valuable feature—the full reference.

In "Recent Novelties in Apparatus" we have a very useful section. The editor only describes those articles which have come under his own personal examination, and only those introduced since the last issue of the almanac.

The approved formulæ, tables of chemical and optical data, lists of photographic societies, &c., have all been brought carefully up to date, and the mass of advertisements is, as usual, an important feature of the publication.

In addition to numerous illustrations, the frontispiece is an example of the autotype carbon tissues, 25,000 copies of which were printed by the Autotype Co., and mounted by the Adhesive Dry Mounting Co., Ltd., on paper provided by Messrs. R. T. Tanner and Co. An excellent coloured plate is reproduced by the Sanger Shepherd Colour-printing Syndicate, while another coloured plate is shown, the three-colour blocks and printing of which are the work of Messrs. Hood and Co., Ltd.

It may be stated in conclusion that the volume is a marvellously cheap shillingsworth, and will no doubt find its usual place on the shelf of every photographer's work-room.

Science of Nature-History. By Nasarvanji Jivanji Readymoney. Pp. 103. (London: *Times of India* Office, 1907.) Price 4s.

THE author provides what he describes as "A guide showing how or where to think on events or collect facts in nature-history order so as to describe and define events from nature-history point of view." It will serve to define the author's object if some of his technicalities are explained. Nature-history is a short, less luminous name for the practical study of nature. To record an event according to nature-history is to fix its place in nature; and to assist the student in his record a series of skeleton classificatory schemes is provided. These tabular statements contain many terms new to orthodox science, and serve to illustrate the compiler's predilection for classification.

Nietzsche in Outline and Aphorism. By A. R. Orage. Pp. viii+188. (Edinburgh and London: T. N. Foulis, 1907.) Price 2s. 6d. net.

AFTER a short introduction dealing with Nietzsche's works, a few pages of "definitions" and a sketch of the philosophy formulated by the champion of nihilism, the compiler brings together a series of his author's aphorisms classified under such headings as "Philosophers and Philosophy," "Morality," and so on. As indicative of the searching character of the maxims, one may be quoted from each of the sections mentioned:—"The doer alone learneth"; "Education ruins the exception for the sake of the rule."

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Photoelectric Property of Selenium.

I HAVE lately constructed small seleno-aluminium *bridges* for the electrical measurement of starlight, and it occurred to me to put these bridges into a vacuum to see whether their sensitiveness to light is thereby increased or diminished. One of them, formed, of course, with conducting selenium, had a resistance of 61×10^6 ohms in air and great sensitiveness to light. It was placed in a glass tube connected with an air-pump. About twelve hours after the tube was exhausted to a pressure of about 0·01 mm., the resistance of the bridge had dropped to 61 ohms! From this it fell gradually, and it has now (three days after exhaustion) a resistance of 17·5 ohms.

I conclude, after repeating the result with three bridges, that conducting selenium when placed in vacuo drops in resistance about four million times, and possibly still more. Also it loses completely its sensitiveness to light.

Other things connected with this strange result are under investigation. I use the term "bridge," in preference to "cell" or "resistance," at the suggestion of Dr. A. A. Rambaut. These bridges are far more simple and easily used with a telescope than the "cells" which I used in the observatory of Dr. W. E. Wilson in Westmeath. The selenium employed was specially purified by Prof. Threlfall, who very kindly gave me a supply.

GEORGE M. MINCHIN.

The Electrical Laboratory, Oxford, December 21.

Early Chinese Description of the Leaf-Insects.

"YUEN-KIEN-LUI-HAN," a Chinese encyclopædia completed in 1703, tom. cdxlvi., fol. 9, b, has the following quotation from the "Tau-hwang-tsah-luh," written *c.* ninth century:

"In Nan-hai a peculiar manner of bees (or wasps) live on the *kan-lan* tree (*Canarium pimela* or *C. album*). They look as if this tree's leaves were grown with hands and legs, wherewith to grasp branches and so deftly adpress themselves thereto that they are quite indistinguishable from the foliage. Therefore, to collect them the southern people used to fell the tree first and await the withering and falling of its leaves; and only then they are enabled to discern and gather the insects, which they employ as philter."

Nan-hai, literally "Southern Sea," was anciently the appellation of a province, the present Kwang-tung, but sometimes it was applied to the Indian Archipelago (Bretschneider, "Botanicon Sinicum," part iii., p. 579).

But for specifying them as bees or wasps, this Chinese account of the mimetic articulate would appear fairly to tally with that of the leaf-insects (Phyllium). Probably it is a very early, if not the earliest, description of these Orthoptera.

KUMAGUSU MINAKATA.

Tanabe, Kii, Japan, November 14.

THE SALMON.[1]

WE have no hesitation whatever in advising all persons interested in the salmon, whether as fishermen, naturalists, or legislators, to add this book to their libraries. The blue and grey covers of the official reports of the Scotch Fishery Board and the Irish Department of Agriculture contain a great deal of most valuable information bearing upon the life and habits of the salmon, and, so far as Scotland is concerned, Mr. Calderwood has now collected into the book under review the information spread over a series of reports. In the case of Ireland the reports of salmon-marking experiments are now published separately in pamphlet form, and deserve a far wider circulation than they possess.

Mr. Calderwood, we think wisely, confines his book almost exclusively to the life-history of salmon in Scotch waters, but is careful to direct attention to points in which the habits of the same fish in some or all Irish rivers appear to differ in points of detail. He would have us, in the first place, regard the salmon as essentially a marine fish, and in this he may be right, though we see no real reason why an anadromous species need be definitely relegated to the category of either fresh-water or marine forms. We are, however, quite in agreement with his view that the Salmonidæ are derived from originally marine ancestors, and would even hazard the suggestion that the presumably herring-like stock from which the Salmonids and Alepocephalids are derived may have been driven in the struggle for existence either to adopt an anadromous life or fresh-water habitat (as in Osmerus, Salmo, Thymallus, and Coregonus), or to retire into the deep sea like the Alepocephalids, Argentina, Microstoma, and Bathylagus found off our own coasts.

We must, in any case, look upon the salmon as a fish growing and feeding in the sea, resorting to fresh waters when feeding ceases on the approach of the spawning season, and spending the early part of its life near the place of its birth until strong enough to venture seawards; this is the standpoint from which we must regard and seek to explain the known phenomena of its life-history.

It is now more than forty years since the discovery was made that the first two years of the salmon's life are normally spent in the parr stage, while a few parr may move seawards in the first year and a certain proportion may spend three years in fresh water. Mr. Calderwood attributes this discovery to the Stormontfield investigations, but we fancy he is so far in error here that the percentages he quotes were really derived from Dunbar's Thurso experiences, communicated by him to Archibald Young when Commissioner of Scotch Salmon Fisheries.

At a length (in the Tay) of five or six inches, the parr assumes the silvery livery of the smolt, and passes seawards, in Scotland, so far as observed, always in spring. The second late summer or early autumn migration of smolts, noted annually in some Irish rivers, and intermittently in others, has not yet been observed in Scotland, and accordingly is not here dealt with.

On reaching the sea the smolt for a time eludes the ken of man, or, at all events, all fishing gear ordinarily employed by him, until it reappears as a grilse. This, hitherto little known, period of the fish's history is admirably handled by Mr. Calderwood. The few British and Irish records of young salmon between the lengths of six inches and two feet are carefully examined, and Dahl's Norwegian researches are cited

[1] "The Life of the Salmon; with Reference more especially to the Fish in Scotland." By W. L. Calderwood. Pp. xxiv+160. (London: Edward Arnold, 1907.) Price 7s. 6d. net.

to show that this period is normally spent in offshore waters, as occasional captures in mackerel nets would suggest. The marking of Tay smolts and control observations of the rings upon the scales of grilse have now shown that the first fish re-appear in the estuaries as grilse twelve to fifteen months after leaving the river as smolts, and that some fish may spend a further summer in the sea before seeking fresh water, then to re-appear as small spring fish. It would, however, be premature to assume that no fish re-ascend in the year of their descent as smolts.

This observation leads us naturally to the second essential fact of a salmon's life-history, that of the distinction between the "short migration" and the "long migration"; that is between the fish which return to fresh water in the summer or as spawners in the autumn or winter of the year of descent as kelts, and those which spend a longer period in the sea and return as clean fish early in the following spring. The difference may be well illustrated by the cases of two Irish fish of the same sex (female), weight (5 lb.) and length (2 feet 1 inch), marked as slats on the same day, January 18, 1902, and at the same place, one of which was re-captured on July 22, 1902, weighing 11 lb. and 2 feet 5 inches long, while the other was re-captured on June 16, 1903, weighing 18 lb. and 2 feet 11 inches long. It is possible that in some cases the "long migration" period may extend over two years, and it by no means follows that any individual fish is either always a short-period fish or always a long-period fish. A remarkable fact shown by results published up to date is the preponderance of short-period fish in Ireland and of long-period fish in Scotland.

Another problem is raised by the winter and spring fish of some rivers; do such fish merely ascend a short distance and then drop back again to the tideway for further feeding before finally running to spawn, or do they ascend to the head-waters of the river they enter so soon as the physical conditions admit? The unfortunate sacrifice of the Lismore Weir marking experiments to the objections of certain anglers has undoubtedly deprived us of an opportunity of reaching some conclusion upon this most important point; so far as the experiment went it certainly pointed to such fish not remaining in the Blackwater until the following spawning season, but dropping back to the estuary before ascending to the redds. Mr. Calderwood, in former papers, has adduced evidence of what he terms a "pausing habit" of winter clean fish in the lower waters of the Spey, but he now states that "in Scotland we have not evidence that clean fish are in any sense temporary visitors to fresh water or habitually drop back into the sea" He moreover notes that the spring fish entering the Ness have already reached the Garry by early in February, while the Tay fish are not found above Loch Tay until May or later. This question is closely connected with the further one, why are some rivers early rivers and some late rivers? To the latter question Mr. Calderwood devotes considerable space, and his remarks, whether accepted as providing an answer or not, are well worthy of attention.

A male salmon in full spawning livery, fresh from the sea in November. The fish has just been marked on the dorsal fin before its return to the river Tay at Almondmouth. From "The Life of the Salmon."

We can but briefly allude to many other points of interest touched upon by this book, such as the causes prompting a salmon to seek fresh water, the effects of temperature on a run of fish, and the question of fish "changing rivers."

Of the salmon's life in the sea until it comes coastward we can but assume at present that it is spent in pursuit of the shoals of herring or mackerel, while noting that the drift-net fishery for salmon off the west and north-west coasts of Ireland is conducted in late spring and early summer, sometimes as much as ten miles from the coast.

We reproduce an illustration showing a November fresh-run male salmon in full spawning livery, photographed before its return to the Tay after marking; the silver marking plate is seen on the dorsal fin. The Irish marks are similar in form and similarly affixed, but oxidised in place of being left bright. Recently a new mark has been introduced in Ireland, consisting of a small numbered tag attached to the base of the dorsal fin by means of a ring; marks of this pattern are made of various size to suit any fish from a smolt upwards.

ENTOMOLOGY FOR THE YOUNG.

THIS book is not a scientific treatise; it is intended, as the author tells us in the preface, "to encourage the intelligent life-study of insects by our younger folk, to discourage collecting, and to stimulate the profitable employment of one's eyes and ears in town or country." This object is a very estimable one, and the author has done much to produce a book admirably adapted for this purpose.

It is divided into seven chapters, each containing many stories of insect life. The general introduction

Green-veined White Butterfly resting. From "The Story of Insect Life."

deals with all manner of subjects in a clear and very simple way, such as structure, eggs, metamorphosis, fertilisation of plants, the story of the wild arum, resemblance of plants to insects, &c. Then follows a chapter on beetles, some of our common forms being simply described. Earwigs, cockroaches, crickets, and grasshoppers form the theme of chapter iii., and dragon-flies, May-flies, &c., that of chapter iv. Now and again the author, unfortunately, pounces on scientific names. For many reasons, in a book for young people, these are best left out, particularly if wrong ones are used, as on p. 104, where the steel-blue wood wasp (*Sirex juvencus*) is called *Sirex noctilo*!

Some of the stories form delightful reading, such as the story of the hive bee, p. 207.

Seventy-six pages are devoted to butterflies and moths, and then the final chapter gives a few brief notes on bugs, frog-hoppers, gnats, and other flies that may attract the young person's attention.

The illustrations from photographs are mostly excellent, and some beautiful pictures are reproduced of localities where water insects abound. The author, unfortunately, in one has made a grievous error, for in Fig. 119 he gives the head of a male mosquito, *Theobaldia annulata*, as that of a female gnat, and refers to this in the text. For the young we should be just as careful to be accurate as for people more matured.

The eggs of the vapourer moth are not in a natural position in Fig. 17, and, again, a badly set and damaged tortoiseshell butterfly is clumsily stuck on an iris blossom (Fig. 86) in a very unnatural way. There are also many entomological errors.

The plates will be sure to attract the young mind, and they are excellently reproduced, but the artist appears to have a quaint idea of some of the insects, such as the blow-fly on plate viii., and also the water boatman. In spite of such faults, the book is one that may be recommended to all young folk, as it not only supplies a want, but fills that want in a clear and pleasant style. FRED. V. THEOBALD.

[1] "The Story of Insect Life." By W. P. Westell. Pp. 339; illustrated. (London: Robert Culley, n.d.) Price 5s. net.

LORD KELVIN.

IN NATURE for September 7, 1876, there was published, with the engraved portrait by Jeans, in the series of "Scientific Worthies," an account of Lord Kelvin, then Sir William Thomson, and of the scientific work, extending then over more than thirty years, by which he had rendered himself illustrious in physical science. Thirty-one years have elapsed since that appreciation was written, and now we have to mourn that this life of wonderful activity has come to its natural close. At the ripe age of eighty-three, as full of honours as of years, Lord Kelvin has passed away. To say that his eye was not dimmed, nor his natural force abated, would be scarcely strictly true, yet he retained to the last the exercise of his intellectual powers. The vigour and keenness with which he entered into the discussions at the British Association meeting at Leicester in August last were truly remarkable at his advanced age. It was in the course of making experiments in a corridor in his country house, Netherhall, Largs, that he contracted the chill which brought about the fatal end.

The article of 1876 gave in some detail those scientific achievements which had then made him famous; and a glance at its contents will show in brief what these were. While still an undergraduate at Cambridge, he had made valuable mathematical investigations in relation to Fourier's theorems, and in their applications to the motion of heat and to hydrodynamics. In these investigations will be discovered the foundation of the method of evaluating geological dates from underground temperatures upon which subsequently he built his famous conclusions as to the age of the earth. In the years which followed, during his early occupancy of the chair of natural philosophy at Glasgow, Lord Kelvin was largely occupied, in constant association with Joule, with the development of thermodynamics, to which not his least contribution was the theory of the dissipation of energy. This was followed by investigations into electrostatics and the theory of magnetism, contact electricity, thermo-electricity, the mechanical energies of the solar system, the calculation of the tides, the size of atoms, and vortex motion. That which, however, directed popular attention to his scientific attainments was not so much these deep investigations as his connection with the more practical problems of ocean telegraphy. The possibility of an Atlantic cable was in the early 'fifties a much-discussed question: and the mathematical investigation which Lord Kelvin made of the conditions governing the propagation of signals in long submarine cables proved to be the most important contribution to the practical solution of that problem. He showed that the retardation must be proportional to the square of the length of the cable; and, further, he applied the theorems of Fourier to predict the degree of attenuation of the impulses on their arrival at the distant end. This was followed by the invention of the mirror galvanometer, and later by the siphon recorder, with both of which instruments his name will ever be associated. The final success of the Atlantic cables of 1865 and 1866 was a triumph for his inventive ingenuity no less than for his mathematical skill and insight. He had likewise been brought intimately into nautical matters, leading him to devise the method of taking flying soundings, and to publish a set of tables for facilitating the use of Sumner's method at sea. To heighten his public fame he also re-modelled the mariner's compass by radical improvements which quickly established its superiority to all earlier forms.

All this was duly recounted in the article of 1876, and might well suffice to place him in the very first rank of physicists had he achieved nothing more. Von Helmholtz, summing up his intellectual attainments at that date, had remarked upon his method of treating the problems of mathematical physics how he had "striven with great consistency to purify mathematical theory from hypothetical assumptions which were not a pure experience of facts." He maintained that "the gift to translate real facts into mathematical equations, and *vice versâ*, is by far more rare than that to find the solution of a given mathematical problem"; adding, "And in this direction Sir William Thomson is most eminent and original." Happily for science this gift continued to be exercised for thirty years after von Helmholtz penned this appreciation of his friend. As the years went on Lord Kelvin continued with marvellous activity of mind and body to add to his long list of scientific labours.

It has been noted above at how early a date, namely, in 1842, Lord Kelvin had published the germ of his theories about the age of the earth. This was in a paper on the linear motion of heat which appeared in the *Cambridge and Dublin Mathematical Journal*. This same subject he had made the topic of his inaugural lecture in 1846 on taking up his professorship at Glasgow. He returned to it in 1876 as the theme of his address as president of the Physical and Mathematical Section of the British Association at Glasgow. To the geologists who demanded unlimited time for the operation of these formative actions, which, on the abandonment of catastrophic notions, they had assumed to proceed with constant uniformity, Lord Kelvin announced with the utmost confidence that they must hurry up their phenomena, since the age of the earth as a habitable planet, so far from being unlimited, could not possibly exceed four hundred millions of years, and was more probably within twenty millions of years. The proposition was supported by several converging lines of argument. The surface temperature could not be what it was, considering the average conductivity of rocks and the gradient of temperatures found underground, if the cooling process had proceeded from an unlimitedly long anterior date. The heat of the sun itself must be constantly dissipated, and its temperature sinks; and with the cooling of the sun the earth also cools. Its form, in relation to centrifugal forces, was incompatible with the hypothesis of an unlimited time since it was a fluid mass. The controversy which arose, as the biologists and geologists endeavoured to combat these arguments, lasted for a quarter of a century; and the end is indeed not yet.

Hydrodynamics is a branch of natural philosophy in which the Cambridge school under Stokes has always been strong; and Lord Kelvin, as a pupil and friend of Stokes, worked much at it. Hydrodynamics was indeed continually in Lord Kelvin's thoughts. His brilliant speculation of the vortex-atom remains—if we are to except recent electric theories of matter—the one and only hypothesis of the ultimate structure of matter that has yet been found to hold its own against destructive criticism. It has not yet been shown to be impossible or self-contradictory. Apart from this, his other investigations into hydrodynamics have been most fruitful. He discussed the conditions of stability of fluid motion in a large number of cases, some of them of practical importance. Within the past two years he contributed to the Royal Society of Edinburgh a series of papers on deep sea waves, papers which are full of characteristic applications of Fourier's theorems, and show unabated keenness in following out an intricate analysis. In elasticity and the kindred problems of dynamics, the influence of the master's hand is no less evident. The article which he contributed to the "Encyclopædia Britannica" on elasticity will remain a classic of science for many years. Those who are intimate with Lord Kelvin's work generally will know how much in this article there is that lies behind his other studies. His continual reference to the analogies which he found between the phenomena of magnetism and of electricity and those of elastic solids shows the working of his mind, and the fundamental views which he held on elasticity dominate alike his Baltimore lectures of 1884 and the papers on molecular physics of his latest years.

To the science of electricity, Lord Kelvin's contributions have been no less notable. Imbued with admiration for Faraday's experimental work, Lord Kelvin early set himself to ascertain whether the phenomena of electromagnetism can be explained on an elastic solid theory. Although it was left to Maxwell to carry to fruition this part of the subject, it was Kelvin's merit to have first applied mathematical analysis to the facts revealed by Faraday's researches. It was in 1847 that he first proposed a mechanical representation of magnetic force; and to this subject he returned in 1890, in an article first published in the third volume of his collected mathematical and physical papers. It was in the early days, too, that he investigated the conditions of the discharge of a Leyden jar in circuits possessing self-induction, predicting mathematically the fact that under certain conditions these discharges would be found to consist of electric oscillations. This discovery was published in 1853. Later, Fedderson and others observed these oscillations experimentally; and in the 'eighties this abstract research of Lord Kelvin's became the starting point of the investigations of Sir Oliver Lodge and of the lamented Heinrich Hertz, leading directly to wireless telegraphy.

In 1851 Lord Kelvin, impelled by the characteristic precision of his scientific character, and urged by the needs of exact measurement in telegraphy, had already adopted the absolute system of measurement initiated by Gauss, and extended by Weber. In Lord Kelvin's hands the absolute system of measurement, and with it the adoption of the metric system of standards, became almost an article of creed. In season and out of season he urged the superiority of the decimal measures over the ordinary British ones; and, consistently, he strove to bring all scientific measurements into terms of the fundamental metric units of length, mass and time. Moreover, toward the end of the 'fifties, electric measurement, in the hands of the cable engineers, had become much developed, and instruments of a precision exceeding anything known then in the physical laboratory had been devised for practical use. In 1861 Lord Kelvin secured the appointment by the British Association of a committee on electrical standards, a committee of which also Wheatstone, Matthiessen, Fleeming Jenkin, and, later, Siemens, Clerk Maxwell, Joule, and Carey Foster were members. Year after year this committee, with younger men added, has produced its reports with little intermission, and the system of units which it evolved is practically that which is internationally recognised and of legal force. Twice Lord Kelvin gave public expositions of the system in set addresses, at a South Kensington conference in 1876, and before the Civil Engineers in 1883. The latter of these discourses is in Lord Kelvin's most characteristic style, and even now, after twenty years, some of it is hard reading for any but a professed physicist. But mere hardness never daunted Lord Kelvin. In the same lecture, speaking of a particular point in the system of absolute measurement, he said:—"It may be hard to accept, but the harder it is the more it is worth thinking of." The acceptance and rapid development of the international system, based on the centimetre, the gram, and the second, is due to Lord Kelvin more than to any other man.

After the adoption of the new units by the International Congress at Paris in 1881, Lord Kelvin devoted much attention to the production of commercial instruments for the measurement of current, potential, and electric power. Relying confidently on the rightness of abstract principles, he produced a series of ampere-balances for currents of different strengths, thus putting into the hands of practical engineers a set of instruments of remarkably great accuracy and of remarkable range. When occupied with the tides, in the 'seventies, he had devised a machine for analysing the harmonic components of the periodic tidal variations, the essential part of this harmonic analyser being a mechanical integrating device of globe, disc, and cylinder, first suggested by his brother, Prof. James Thomson. It seemed a bold thing to apply such mechanism to evaluate the integrals indicated by Fourier's analysis; but Kelvin's machine justified the hardihood of the conception. When in the 'eighties he had before him the problem of constructing an electricity meter which should continuously integrate the varying product of current and voltage of an electric supply, he again had recourse to the same integrating mechanism. And, here, it may be remarked in passing that it is to Lord Kelvin's evidence before the Parliamentary Committee in 1879 that we owe the circumstance that the Board of Trade adopted as its official unit of electric energy the value of one thousand volt-ampere-hours. It was once upon a time proposed to denominate this unit—now universally employed—by the name of one "kelvin." Lord Kelvin's innate modesty caused him to reject the suggestion. Surely the time has now come for the final incorporation of his name into the international system, thus linking it with those of Volta, Ampère, Ohm, Coulomb, Watt, Faraday, Joule, Henry, and Gauss.

Lord Kelvin had a peculiar predilection for illustrating recondite notions by models. He once said that he could never understand a thing until he could make (or conceive) a model of it. His chain of gyrostats to illustrate the rigidity of the ether, his systems of crystal models made of little wooden rods and balls held in stable equilibrium by india-rubber bands, are but two examples of a mode of using the concrete to realise the abstract that he practised continually. He was fond of introducing into abstract dynamics terms derived from other sciences, geodesy, and crystallography. Amongst the bye-products of his genius may be found enshrined in the Proceedings of the Royal Society a short paper containing the essentials of the theory of the designing of wall-paper patterns; its title, however, is "The Homologous Partition of Space."

Of Lord Kelvin's later work on molecular physics, the "tactics of a crystal," the problems of æolotropic elasticity in relation to optical as well as magnetic and electric phenomena, it is less easy to speak. The lectures which he gave at Baltimore in 1884 to "his twenty-one coefficients," the members of the group of accomplished physicists who then sat at his feet day after day, while he led them through the mazes of the elastic-solid theory and the newly-invented spring-shell molecule, remain a witness to his extraordinary fertility of intellectual resource. All his life he had been endeavouring to discover a rational mechanical explanation for the most recondite phenomena—the mysteries of magnetism, the marvels of electricity, the difficulties of crystallography, the contradictory properties of ether, the anomalies of optics. And during the preceding decade he had been confronted with a great generalisation which did not fit in with this method of intellectual apprehension, which had become to him instinctive. While Kelvin had been seeking to explain electricity and magnetism and light mechanically, or as mechanical properties, if not of matter, at least of ether, Maxwell had boldly propounded the electromagnetic theory of light, and had drawn all the younger men after him in acceptance of the generalisation that the waves. Lord Kelvin had never accepted Maxwell's theory. It is true that in 1888 he gave a nominal adhesion; but later withdrew it, preferring still to think of things in his own way. Kelvin's Baltimore lectures of 1884, abounding as they do in a host of brilliant and ingenious points, and ranging from the most recondite problems of optics to speculations on crystal rigidity and molecular dynamics, leave one with a sense of being a sort of protest of a man persuaded against his own instincts, and struggling to find new expression of his thoughts so as to retain his old ways of regarding the ultimate dynamics of physical nature. During the last few years of his life Lord Kelvin himself revised these lectures, enriching them with a variety of new materials, and coordinating the old. He was intensely interested in the new problems raised by the discovery of radium; and in its astonishing property of continuously emitting heat. He combated strenuously the hypothesis of Rutherford that this was to be explained by a spontaneous decomposition of the atom; and to the very last he was seeking for other explanations.

At the present time, when so much of the new knowledge is in a state of flux, it would be entirely premature to attempt to evaluate the ultimate importance of Lord Kelvin's later writings on radium and on the "electrions." Suffice it to say that he brought to bear on these things the same illuminating genius, the same keen analytical instincts, that he had shown throughout his long career.

To two generations, if not three, of scientific men his work, his presence, his mathematical genius, his enthusiastic faith in first principles, and his unfailing gentle courtesy have been an inspiration and a perpetual stimulus. So he rests from his labours, and his works do follow him.

SILVANUS P. THOMPSON.

LORD KELVIN'S FUNERAL IN WESTMINSTER ABBEY.

The decision taken by the Dean of Westminster to accord to Lord Kelvin burial in Westminster Abbey met at once with a warm and responsive echo of satisfaction on the part of men of science and the community generally. In the Abbey he has joined a noble company of departed worthies—Newton, Herschel, Lyell, Spottiswoode, Darwin—names that perpetuate some of the most glorious and imperishable achievements in natural knowledge. Especially gratifying must it be to the Royal Society to feel that the remains of their illustrious past-president find a resting-place side by side with those of Sir Isaac Newton.

The representative gathering that filled the Abbey on Monday, December 23, afforded ample testimony to the wide and varied interests, apart from pure science, that dominated the career of Lord Kelvin. Not only a brilliant moving figure in the hierarchy of science, he was also a great citizen, ever mindful of the best traditions of English public life.

The funeral service, which commenced at noon, was of the most impressive character. The King was represented by His Grace the Duke of Argyll, K.G.; the Prince of Wales by Lt.-Col. Sir Arthur Bigge, G.C.V.O.; and the Duke of Connaught by Major L. Green-Wilkinson. The Princess Louise (Duchess of Argyll) was present, attended by a lady and gentleman in waiting. Seats in the choir stalls were occupied by:—

Lady Rayleigh, the Russian and Italian Ambassadors, Mr. J. Ridgely Carter, representing the American Ambassador; Baron von Stumm, representing the German Ambassador; and Mr. Ijiuin, representing the Japanese Ambassador; the Lord Mayor of London (who was robed), and the Master of the Clothworkers' Company. The First Lord of the Admiralty, Lord Tweedmouth, accompanied by his secretaries, attended to represent the Board of Admiralty. The Lord President of the Council was represented by Mr. Almeric FitzRoy.

At the Chapter House a procession was formed, which, headed by the choir and officiating clergy, slowly wended its way from the Chapel of St. Faith through the cloisters, and, while the hymn "Brief life is here our portion" was being sung, to the nave, and thence to the lantern, beneath which the coffin was temporarily deposited. The order was as follows:—

Clergy and choir; bier; pall bearers; chief mourners; Institute of France, M. G. Lippmann, For.Mem.R.S., M. Henri Becquerel, in addition to M. Darboux, For.Mem.R.S., perpetual secretary, who took part as a pall bearer; Lord Mayor of London; Master of Clothworkers' Company; the Royal Society; the Royal Society of Edinburgh and other British and foreign learned societies; Universities of Cambridge and Oxford; University of Glasgow and other Glasgow delegations; University of Edinburgh and Corporation of Edinburgh; other British universities.

A guard of honour of the Electrical Engineer Volunteers, of which Lord Kelvin was Colonel-in-Chief, lined the cloisters, Colonel R. E. B. Crompton, C.B., commanding. The guard fell in at the end of the procession, and took up a position in the nave.

The pall bearers and chief mourners were as subjoined:—

Pall Bearers.

Lord Rayleigh, O.M. (President of the Royal Society).	Sir Edward H. Seymour, O.M. (Admiral of the Fleet).
Mr. J. Morley, O.M. (Secretary of State for India).	M. Gaston Darboux, For.Mem.R.S. (Perpetual Secretary of the Paris Academy of Sciences).
Sir Archibald Geikie, K.C.B., Sec.R.S. (President of the Geological Society).	The Lord Strathcona and Mount Royal (High Commissioner for Canada).
Prof. A. Crum Brown, F.R.S. (Royal Society of Edinburgh).	Sir George Darwin, K.C.B., F.R.S. (University of Cambridge).
The Master of Peterhouse, Cambridge (Dr. A. W. Ward).	Dr. MacAlister (Principal of the University of Glasgow).
Sir J. Wolfe-Barry, K.C.B., F.R.S. (Institution of Civil Engineers).	Dr. R. T. Glazebrook, F.R.S. (Institution of Electrical Engineers).

Chief Mourners.

Dr. J. T. Bottomley, F.R.S.	Mr. James Thomson.
	Mr. W. Bottomley.
Mr. G. King.	Sir Alex. Brown.

Mr. W. Crum and two others, with four grandnephews, Mr. D. King, Mr. J. F., Mr. W., and Mr. G. Bottomley.

On the part of the Royal Society, in addition to pall bearers and other Fellows who also represented universities, there were present Mr. A. B. Kempe (treasurer), Prof. Larmor (secretary), Sir W. Crookes (vice-president), Sir J. Stirling, Sir John Evans, Major MacMahon, &c., and Mr. R. Harrison (assistant secretary).

It is unfortunately impossible to find space here to print the long list of representatives of British universities, scientific societies, and institutions present at the funeral, and we are only able now to state that the following foreign societies were represented in addition to the Paris Academy of Sciences already mentioned:—

Imperial Academy of Sciences of Vienna, Lord Rayleigh; Accademia dei Lincei, Rome, Sir Norman Lockyer, Prof. J. J. Thomson, Sir David Gill, and others; the Elektrotechnischer Verein of Berlin, Mr. A. Siemens; Societá Italiana di Fisica, Associazione Elettrotecnica Italiana, and Phys. Verein Frankfurt a.M., Prof. Silvanus P. Thompson, &c.

NOTES.

We announce with deep regret the death of Dr. Janssen, director of the Meudon Astro-Physics Observatory, at eighty-three years of age.

A Reuter message from Copenhagen states that experiments made by the Amalgamated Radio-Telegraph Company of London and Copenhagen, owners of the Poulsen system of wireless telegraphy and telephony, show that wireless Poulsen telegrams between Newcastle and Copenhagen and Berlin and Copenhagen can be written directly from the receiver with ink as in the case of telegraphy by wire.

The Royal Statistical Society's Guy medal in gold has been presented to Prof. F. Y. Edgeworth for his services to statistical science.

Dr. Thomas Annandale, Regius professor of clinical surgery in the University of Edinburgh, died on December 20 at sixty-nine years of age.

On Saturday next, December 28, Sir David Gill, K.C.B., F.R.S., will deliver the first of the annual course of juvenile lectures at the Royal Institution on "Astronomy, Old and New." The remaining lectures will be delivered on December 31, January 2, 4, 7, and 9.

Mr. Elihu Thomson, writing from the General Electric Company, Lynn, Mass., U.S.A., comments upon the description of the exhibition of globe lightning in West Australia described in our issue for October 31 (vol. lxxvi., p. 671), and provides particulars of another case brought before his notice by a friend. The phenomenon referred to by Mr. Thomson is said to have appeared as a ball of yellow flame continuously in motion with a central nucleus rose-red in colour, and to have exhibited many points of similarity with the globular lightning seen in Australia on the occasion mentioned in our previous note. From Mr. Thomson's letter it is not clear whether the report made to him relates to globular lightning or to a fireball.

In the report of the Bristol Museum and Art Gallery for 1907 the committee announces that the success of the combined institution during the period under review has been very pronounced, the total number of visitors considerably exceeding half a million. A new departure is the installation in the museum of a section devoted to economic biology, galls and gall-flies, together with the various animal and vegetable pests infesting orchards and forests, forming the main exhibits at present before the public.

THE luminiferous properties of the brittle-star, *Amphiura squamata*, and other echinoderms form the subject of an article by Irene Sterzinger in vol. lxxxviii., part iii., of *Zeitschrift für wissenschaftliche Zoologie*. The light is displayed at the summits, and not, as hitherto supposed, at the bases, of the "feet," where it emanates from slime secreted by the epithelium. There is, however, a luminiferous and a non-luminiferous slime. Similar slime-glands occur in certain other echinoderms. Both kinds of slime are soluble in hydrochloric acid.

WE have received a copy of Bulletin No. 72 of the U.S. Entomological Bureau, in which Messrs. W. D. Hunter and W. A. Hooker record the results of investigations into the life-history of the North American fever-tick (*Margaropus annulatus*), and the best modes of keeping the species in check. In parts of Texas and some of the other southern States cattle-breeding is almost impossible owing to this pest, which is estimated to cause an annual loss of one hundred million dollars.

AN important addition to the somewhat scanty literature of galvanising is made by Mr. Alfred Sang, who has published in the Proceedings of the Engineers' Society of Western Pennsylvania an elaborate monograph on old and new methods. The hot process of galvanising dates from Crauford's patent of 1839, and the origins of electro-galvanising, or cold galvanising, as it is often called, are also remote, but commercially it is a new process. In 1902 Mr. Sherard Cowper-Coles patented his process for galvanising metal goods by packing them in zinc dust in an air-tight retort, and heating the retort to a temperature below the melting point of zinc. This process is known as sherardising. The first attempt to coat metals by means of zinc vapour was made by Jean Pierre Chambeyron in 1864. Mr. Sang's investigations on the volatilisation of zinc from zinc dust at low temperatures have led him to important improvements in the vapour process, and there is every reason to hope that this method will soon take its place in the metal industries as a powerful antidote to corrosion. Undoubtedly the proper place to search for further improvements in protective coverings for iron and steel is in the study of the true causes of corrosion.

IN the Bulletin of the Moscow Imperial Society of Naturalists for the year 1906, Prof. E. Leyst, director of the meteorological observatory of that place, contributes an important article on the estimation of the amount of cloud. The matter at first sight would appear to be one of the simplest of meteorological observations, but very few stations are so placed as to have a clear horizon, especially when situated in towns or in valleys. Prof. Leyst has submitted the Moscow observations for several years to a careful discussion, dividing the whole sky into three zones of 30° each. Taking the zenithal zone 60°–90° as the unit of comparison, he finds that in the lower zone the yearly mean of cloudiness is twice as great as in the zenithal zone, and that for the whole of the sky the yearly amount of cloud is 43 per cent. greater than in the zenithal zone, the amounts differing according to the season and to the time of observation. All things considered, the results seem to show that observations of amount of cloud in the zenithal zone are to be preferred; the author also considers that observers should be instructed how to divide the area under observation, so as to estimate cloud in tenths.

THE physiology and habits—the "behaviour," as it is now the fashion to call these factors in the life-history—of a common American starfish, *Asterias forrieri*, are discussed at considerable length by Mr. H. S. Jennings in a paper issued as one of the zoological publications of California University. The modes by which the creature manages to hold its own in the struggle for existence, the way in which it obtains its food, and kindred subjects, are in turn discussed, and the results of the investigation of all these factors will, it is hoped, afford an insight into the complex life of the sea-shore generally, and manifold inter-relations of the numerous organisms which make this zone their home.

IN vol. xxi., art. 11, of the Journal of the College of Science of Tokyo University, Mr. S. Hatta concludes his account of the gastrulation of the ovum of the lamprey (Petromyzon). In the neighbourhood of Sapparo the species during the spring spawning season resorts in numbers to the streams, and thus affords abundant working material, which was developed by means of artificial fertilisation. The author considers that the ovum exhibits a kind of belated development, the blastulation and gastrulation stages overlapping one another, so that what should be the blastula appears to be really an old morula stage. The prime cause of this belated development is indisputably due to delay in segmentation, owing to the accumulation in the ovum of a great amount of yolk.

THE culture of marine fishes and crabs and lobsters in America, by Mr. G. M. Bowers, U.S. Commissioner of Fish and Fisheries, forms the subject of an illustrated article in the November number of the *National Geographic Magazine*. The United States, according to the author, is a long way ahead of any other nation in the matter of marine fish-culture, the only country coming anywhere near it in this respect being Norway, which was, indeed, the pioneer. This, in the author's opinion, is accounted for by the fact that in many countries it is believed to be an impossibility to make any marked increase in the numbers of sea-fishes by artificial culture, as it is seriously to diminish them by fishing. This, however, is far from being the view entertained by the Government of the United States, which carries on fish-culture, and crab and lobster propagation, to an enormous extent in species hatcheries and laboratories. The fishes regularly cultivated—by collecting and artificially fertilising the spawn—are cod, flounders, pollak, and, to a less degree, mackerel, bass, &c., while lobsters are reared at several stations, more especially the one recently established at Boothby Harbour. The general plan of operations is described very graphically by the author.

A MEMOIR by Mr. David Heron on the statistics of insanity and the inheritance of the insane diathesis has been issued by Messrs. Dulau and Co. for the Francis Galton Laboratory for National Eugenics, University of London. The material on which the memoir is based was provided by Dr. A. R. Urquhart, physician superintendent of the James Murray's Royal Asylum, Perth, and consisted of 331 family trees of asylum patients, giving very full details of the brothers and sisters, parents, and in some cases grandparents and children of the patient. The general results are very similar to those of the memoir, previously issued, by Prof. Karl Pearson on pulmonary tuberculosis. The inheritance of the insane diathesis is very marked, the correlation-coefficient between parent and offspring (as calculated by Prof. Pearson's method) lying between the values 0·52–0·62. The figures are bound to be somewhat uncertain, for they involve an estimate of the proportion of the inhabitants of Scotland who have been at any time certified as insane; the census and the Lunacy Commissioners' returns, of course, can only give the number of patients at a given time or during a given period. Taking the figures for tainted stocks only (pedigrees of asylum patients), 21 per cent. of the offspring were insane when both parents were sane, 24 per cent. when one parent was insane, and 50 per cent. when both parents were insane, the last figure being, however, somewhat doubtful, as it is based on very few cases. There does not appear to be any lack of fertility in the tainted stocks, the mean size of family in 331 families containing at least one insane member being 5·97; eighty-seven matings in which one parent was insane gave a mean of 5·18 children, matings which were not necessarily completed.

Mr. T. Sheppard, the curator of the Hull Museum, continues his useful work of issuing bulletins at the cost of one penny each, describing the collections under his charge. The most recent issues are devoted to "Notes on the more Important Discoveries in East Yorkshire," and to an account of a British chariot burial discovered during the present year at Hunmanby, in the same district. In the first pamphlet he has collected records of the most notable discoveries, adding useful references to the publications in which they are described. Many valuable relics have passed into other museums or into the hands of private collectors, while several have altogether disappeared. Now that a suitable building has been provided, the collections are rapidly increasing. The British chariot burial at Hunmanby presents many features of interest. The bottom of the grave was occupied by a great wooden shield, apparently of oak, ornamented with thin plates of bronze. The greater part of the woodwork was, unfortunately, destroyed in the landslip which directed attention to the interment. The bones were in a state of decay, but the recovery of two teeth of a horse indicates that the animal was buried with its master. Considerable portions of the chariot were recovered; and while in other Yorkshire burials of this class the bridle-bit is usually of iron coated with bronze, here it is of bronze throughout. The date of the interment is fixed in the first or second century B.C. In more than seven hundred early British burial mounds excavated by Canon Greenwell, Mr. Mortimer, and others, only about half-a-dozen chariot burials were discovered. The "find" at Hunmanby is thus of considerable archæological importance.

The first appendix to the *Kew Bulletin* for 1908, being the list of seeds of hardy herbaceous plants and of trees and shrubs available for exchange with botanic gardens and correspondents of Kew, has been received.

Prof. W. Trelease contributes to the annual report (No. 18) of the Missouri Botanical Garden a note on the genus Yucca, supplementing his monograph published in a former report (No. 13). Under the group of Sarcoyucca the author revises the species allied to *Yucca valida*, making a new species, *Yucca decipiens*, and indicates their distribution on a map. Characteristic illustrations of *Yucca periculosa*, and a new species, *Yucca Endlichiana*, are given. The latter, sent under the vernacular name of "pitilla," is said to yield good fibre; it is acaulescent, and bears very small, often dark, flowers.

An account of the chemical examination, by Mr. E. A. Mann and Dr. W. H. Ince, of certain West Australian poison plants is published in the progress reports issued as two pamphlets by the Department of Agriculture for the colony. About fifty poisonous plants are said to occur in the State, of which several belonging to the genera Gastrolobium and Oxylobium are regarded as the most general sources of stock poisoning. One species of each of these genera was examined, and from each a strongly toxic alkaloid was isolated. The authors also attempted to find an antidote; this, so far as experiments go, is furnished by a preparation of which permanganate of potash is the important constituent.

In the course of investigations into the nature of Para rubber, Dr. D. Spence was led to examine the constituent, always present, that is insoluble in choloroform or similar solvents. Proceeding from the known occurrence of protein substances in the latex, he comes to the conclusion that the insoluble portion is a protein giving a strong xanthoproteic reaction, and comments on the peculiar fibrous structure shown markedly in sections stained with silver nitrate. This conclusion raises the practical question whether the presence of this insoluble constituent in the latex does not exercise an important physical function in the raw product. The paper is published by the Liverpool Institute of Commercial Research in the Tropics as journal reprint No. 13.

The Journal of the Department of Agriculture of South Australia for October contains an account of the law relating to certain specified noxious weeds, with popular descriptions of them. Any landowner suffering these weeds to grow on his land, or on the adjoining roadsides, is liable to severe penalties. Should the District Council not enforce the law—and it appears this sometimes happens—the Commissioner of Crown Lands is authorised to have the weeds destroyed, and recover the cost from the council.

The October numbers of the *Transvaal Agricultural Journal* and of the *Cape of Good Hope Agricultural Journal* have recently come to hand. The former contains an excellent article by Mr. F. B. Smith on agricultural education and research. Mr. Smith's department has been so successful in dealing with agricultural problems, and has appealed so strongly to the Boer farmer, that his plea for a sound and comprehensive system of agricultural education in the Transvaal is not likely to pass unheeded. There are also a number of articles dealing with practical farming matters, and some analyses of Transvaal fodder crops. The Cape of Good Hope has not the advantage of a large agricultural department, and its journal is consequently smaller. Some experiments are described by Prof. Duerden in which the rate of growth of ostrich feathers was found to be $1\frac{3}{4}$ inches per week.

Worcestershire fruit growers suffer a great deal from the attacks of the apple sucker (*Psylla mali*), and arrangements were therefore made last year for Mr. Kenneth G. Furley, acting under the supervision of Mr. F. V. Theobald, to visit certain districts and carry out spraying experiments. The results are now issued as a report by the Worcestershire Education Committee. Very few eggs were found on the trees at the beginning of October, though the winged "Psylla" were flying about in great numbers; but about the middle of the month the eggs were thick on the trees, especially on the spurs. The dates of hatching varied; some came out on April 3, while others in the same orchard only appeared on April 10; the blossom and leaf buds were then attacked. Of the various washes tried, the most effective was the mixture of lime and salt recommended by Mr. Howard Chapman. The experiments were evidently well carried out, and the example of the Worcestershire Education Committee might well be followed by others. Considering the enormous losses caused to fruit and hop growers and gardeners generally by insect or fungoid pests, and the great amount of money spent on washes, it is surprising how little systematic work on the subject is done in England.

Dr. C. M. Luxmoore has sent us a copy of his final report on the analysis of one hundred soils from the county of Dorset, preliminary reports upon which, by Dr. Luxmoore himself and by Prof. Percival, have already been issued from the University College of Reading. The soils and their subsoils have been taken from typical localities situated upon all the formations, ranging from the Bagshot Sands to the Lower Lias, which are exposed in the county, and the report contains detailed analyses, both mechanical and chemical, together with certain determinations of their physical constants. In this latter connection one or two novel methods of examination have been proposed, designed to obtain some information as to the behaviour of the soils in the field. In addition to the analytical figures, the report contains a full discussion of the results, in which attempts are made to estimate the interdependence of some of the constituents and the extent to which they may be correlated with the properties of the soil. The report represents a very considerable piece of work, which has occupied Dr. Luxmoore for many years.

In Nature of December 27, 1906 (vol. lxxv., p. 197), attention was directed to the remarkable book by Dr. F. Oswald on the "Geology of Armenia." A second edition of this work is now promised; and the author has issued a large lithographed map of the country described, on which the geological features are coloured by hand. This map and an explanatory pamphlet are published by Messrs. Dulau and Co., London (25*s.* net), and should obviously be secured by those libraries that possess the original work of reference. The country dealt with includes, as a central feature, the great lacustrine and volcanic plain north of Lake Van, and its extent may be judged from the fact that the scale of the map is 1 inch to sixteen miles, and that the sheet measures 37½ inches by 21½ inches. In the pamphlet, which is in itself a guide to the geological structure of Armenia, the striking extent of the marine transgression in early Miocene times is emphasised, the present country being due to Middle Miocene folding, followed by fault-block movements during the Pliocene period.

The annual report of the State geologist of New Jersey for 1906 (Trenton, 1907) is a volume of 192 pages, containing, in addition to the administrative report for the year, valuable papers on building stones, on the glass-sand industry, on the Triassic copper ores, and on trap rocks for road construction. Mr. W. E. McCourt has made some careful tests to determine the fire-resisting qualities of New Jersey building stones. The crystalline rocks at a temperature of 550° C. were not greatly affected. The gneisses cracked parallel to the banding, and, as a rule, it is safe to assume that a gneiss will be more damaged than a crystalline rock of the same texture and composition without the banding. Clay rocks suffered badly. The sandstones resisted fairly well, while the limestones seem to have suffered the least injury of all the stones tested. The paper by Messrs. H. B. Kümmel and R. B. Gage on the glass-sands of New Jersey shows that they contain more iron, and consequently obtain lower prices at the glass factories than do the Pennsylvania sands with which they compete. If the iron-bearing minerals could be removed by improved methods of washing, by magnetic separation, or by sieving, a grade of glass-sand superior to the best Pennsylvania sand would be obtained. Mr. J. Volney Lewis gives the results of his investigations of the petrography of the trap rocks and of the origin of the copper ores commonly found in proximity to them. The view put forward that the copper ores are deposits from ascending magmatic waters expelled from the great intrusive mass in the vicinity appears to be well supported by facts. Lastly, a record is given of tests of the resisting qualities of the trap as determined by a series of experiments carried out in cooperation with the Department of Agriculture. As the trap rocks are extensively used for road metal, these tests of their wearing qualities should prove of value when considered with regard to the results already shown by actual use.

A coloured supplement to the December number of the *Quarry* conveys an admirable impression of the appearance of the green marble now being quarried on the island of Iona. The marble occurs in gneiss of pre-Cambrian age as a well-defined vein, and its beautiful green colour is due to the presence of serpentine derived from forsterite by hydration.

An important contribution to the study of weathering phenomena in building stones is afforded by a paper by Mr. E. Kaiser on the Stuben sandstone of Wurttemberg in the *Neues Jahrbuch für Mineralogie* (1907, ii., pp. 42–64). This stone was largely used in 1842 to 1868 on Cologne Cathedral, and now exhibits marked disintegration, the weathered material showing an external layer of scale, and below it a layer of soluble calcium and magnesium sulphates. In the quarry, on the other hand, the weathering consists in solution of the calcium and magnesium constituents of the brown spar in the rock with deposition of the iron as hydrated ferric oxide. It is evident that the disintegration in Cologne is caused by sulphur derived from smoke gases.

A detailed account has been published by Mr. N. W. Lord (United States Geological Survey, Bulletin No. 323) of the experimental work conducted in the chemical laboratory of the United States fuel-testing plant, St. Louis, between January 1, 1905, and July 31, 1906. Interesting results have been obtained in the determinations of specific gravities of coal, in laboratory methods of determining the adaptability of coals to improvement by washing, and in the estimation of volatile matter in coals and lignites. It is shown that the value obtained for volatile matter in coal is affected by the method of heating the sample, by the fineness of pulverisation, and by the amount of loosely held moisture present.

The question of the concentration of ores is one to which much attention has recently been devoted, and inventors have been busy in the new field of flotation processes in which the concentrate is removed from the top and the tailings from the bottom, apparently in contravention of the law of gravity. A new process invented by Mr. A. P. Macquisten, and successfully applied in the United States, is described in the *Engineer* of December 13. It is based on the utilisation of the surface tension of liquids, it having been found that sulphide ores possess some property that prevents them from becoming wetted, whilst gangue minerals do not possess this property, and readily sink. At the Adelaide mine, Nevada, the process has been applied to copper pyrites, iron pyrites, blende, and galena with heavy gangue minerals, the presence of which rendered ordinary methods of concentration ineffective.

We have received from Dr. Van Rijckevorsel parts iii. and iv. of his laborious investigation entitled "Constantly Recurring Secondary Maxima and Minima in the Yearly Range of Meteorological Phenomena." For details as to the methods employed we would refer our readers to the notice of part ii., relating to temperature (Nature, vol. lxxiii., p. 504), where it is explained that the author claims that the observations over the whole earth, collectively, and in the northern and southern hemispheres, separately, show half-yearly and other periods the epochs of which are identical. Part iii. deals with barometric pressure, for which 2755 years of observations are used, but are necessarily very unevenly distributed, 2255 years being to the north of the tropics, and only 381 years to the south. The similarity between the curves for the north and south hemispheres is not so pronounced as in the case of the temperature curves, as the years available for the south are altogether insufficient for the purpose, but the author thinks that with sufficient materials the results would probably be nearly identical. The results with regard to rainfall are much less satisfactory; the elimination of disturbances caused by heavy downpours in thunderstorms requires a much longer period of observation than is at present available. The paper is accompanied by tables and curves showing the variations exhibited by both elements.

The foundations of geometry form the subject of the presidential address to section iii. of the Royal Society of Canada, by Prof. Alfred Baker, published in the Transactions of the society, 1906–7. The author traces the history of the axiom of parallels from an anecdote about Lagrange, and from the early writings on the subject of Gauss, Bolyai, and Lobachevski, and he gives a detailed abstract of Hilbert's assumptions. Referring to an attempt made in 1570 by Sir Henry Savile, of Oxford, to stimulate interest in Greek geometry by explaining the first eight propositions of Euclid to a class of university students, and comparing this result with the performance of modern schoolboys, Prof. Baker thinks that a time may come when schoolboys will find no difficulty with the abstractions of Hilbert's geometry, and the truth of Prof. Halsted's claim may be felt that "geometry at last made rigorous is also thereby made more simple."

The August Bulletin of the Bureau of Standards of Washington contains a detailed comparison of the four most accurate methods of comparing the capacities of condensers, from the pen of Mr. F. W. Grover. He finds that the four are about equal in accuracy when the various sources of error inherent in each method are eliminated. He advocates the use of an auxiliary adjustable air condenser to enable comparisons to be made by the method of substitution, and shows that the power factor can readily be determined at the same time. This quantity gives valuable information as to the quality of the condenser, the absorption, and the change of capacity of the condenser with frequency.

M. Charles Féry has constructed a very simple calorimeter for determining the calorific power of gases and liquids, and gives a description of it in the November number of the *Journal de Physique*. The combustion is effected at the base of a glass chimney, the top of which supports a nickel plate pierced with a number of holes. The air necessary for combustion passes down a similar chimney, which is connected at its base with the former. The two junctions of a constantan-copper thermo-circuit are placed at the tops of the chimneys, and M. Féry finds that the electromotive force in the circuit is strictly proportional to the calorific power of the combustible and to the volume of it consumed in unit time.

Messrs. Bemrose and Sons, Ltd., have published the twelfth volume of the new series of the *Reliquary and Illustrated Archaeologist*, which contains the quarterly numbers of the review published during 1907. The separate issues have been referred to from time to time in these columns. It will suffice to state here that the review is now edited by the Rev. Dr. J. Charles Cox, and is devoted to the study of the early Pagan and Christian antiquities of Great Britain, the development of the arts and industries of man in past ages, to the survival of ancient usages, and kindred subjects. The price of the volume is 12*s*. net.

OUR ASTRONOMICAL COLUMN.

Nova Persei, 1901.—To test the question of possible proper motion in Nova Persei (No. 2), Prof. Barnard has recently repeated his measures of the Nova's position in regard to other stars in the neighbourhood, using the 40-inch refractor of the Yerkes Observatory. Comparing the results with those obtained in 1901–2, he finds no evidence of measurable motion. The present magnitude of the Nova is about 11·6, the star having apparently increased somewhat in brightness of late (*Astronomische Nachrichten*, No. 4220, p. 323, December 12).

Provisional Elements for the Spectroscopic Binary α Andromedæ.—In No. 4220 of the *Astronomische Nachrichten* (p. 327, December 12), Dr. H. Ludendorff publishes a provisional set of elements for the orbit of α Andromedæ, which star has been announced, by several observers, as a spectroscopic binary. This following set of elements has been calculated from the measurements of thirty-eight plates:—

$U = 97{\cdot}0$ d.	$\infty = -70^\circ$
$V = -14$ km.	$e = 0{\cdot}4$
$A = 34$ km. $B = 26$ km.	$T = 1904$ Dec. 2
$u_1 = 98^\circ$	$a \sin i = 36{,}000{,}000$ km.

Photographs of Mars.—The second of Prof. Lowell's series of articles on Mars, which is appearing in the *Century Magazine*, is published in the December number (vol. lxxv., No. 2, p. 303). In it the author gives an account of the inauguration and the work of, and of the results obtained by, the Lowell-Todd expedition to the Andes for the observation of Mars under conditions which could not be obtained in higher latitudes and less favourable climates. One of the reproductions illustrating the article shows the Amherst telescope in position at Alianza, Chile, surrounded by the members of the expedition; five other reproductions show prints from some of the plates obtained, each plate containing from sixty to ninety images of the planets, and, alongside, drawings made at the same time by Prof. Lowell, located some 6000 miles away, show how faithfully the photographs confirm the visual observations made at the Lowell Observatory. On the best series of photographs, obtained on July 25, are to be seen delicate canaliform markings which entirely refute the suggestions that such markings, previously recorded visually, are merely subjective phenomena.

Prof. Lowell states that the results greatly exceed his most sanguine expectations, and concludes his article with the following paragraph:—"That life is there is founded on no assumption, but on massed evidence that is conclusive, and the reader should realise that opposition to the idea that we now have proof of life on Mars is not based on reason, but on emotion, however speciously cloaked. All scientific objections have been met and shown untenable as to temperature, snow, &c., but human prejudice, as with the Copernican system or the origin of species, time alone can dispel."

Saturn apparently without Rings.—In the December *Bulletin de la Société astronomique de France* (p. 513) M. Flammarion discusses the recent observations of Saturn, paying particular attention to the phenomenon of bright knots, observed by Prof. Campbell, and confirmed by Prof. Lowell and others. In this connection he reproduces two drawings made by Bond showing "breaks and prominences" on October 28 and November 3, 1848. These interruptions in the light of the ring were then so easily seen that the observer did not hesitate to explain the phenomenon by the light reflected from the interior edges of the rings.

PRIZES PROPOSED BY THE PARIS ACADEMY OF SCIENCES FOR 1909.

GEOMETRY.—The Francœur prize, 1000 francs, is awarded annually for discoveries or work useful to the progress of pure and applied mathematics. For the Bordin prize, 3000 francs, the question proposed is as follows:—The absolute invariant which represents the number of distinct double integrals of the second species of an algebraic surface depends on a relative invariant ρ, which plays an important part in the theory of the integrals of total differentials of the third species and in that of algebraic curves traced on the surface. It is proposed to make a profound study of this invariant, and especially to find out how to determine its exact value, at least, for numerous kinds of surfaces.

Mechanics.—A Montyon prize, 700 francs, for inventing or improving instruments useful to the progress of agriculture, the mechanical arts, or sciences. The Poncelet prize will be awarded for a work on applied mathematics. The question for the Vaillant prize, 4000 francs, is to improve in an important point the application of the principles of the dynamics of fluids to the theory of the screw. The Boileau prize, 1300 francs, is for researches on the motion of fluids, sufficient to contribute to the progress of hydraulics.

Navigation.—The Plumey prize is for improvement of steam engines or any other invention which has most contributed to the progress of steam navigation.

Astronomy.—The Lalande prize, 540 francs, is for the most interesting observation, memoir, or work useful to the progress of astronomy, and the Valz prize, 460 francs, is awarded on similar terms. The G. de Pontécoulant prize, 700 francs, is for the encouragement of researches in celestial mechanics.

Geography.—The Tchihatchef prize, 3000 francs, for the recompense or encouragement of young naturalists distinguished in the exploration of the lesser known parts of Asia.

The Gay prize, 1500 francs, for the study of the geographical distribution of one class of cryptogams.

Physics.—The Hébert prize for the author of a treatise or discovery for the application or practical employment of electricity; the Hughes prize, 2500 francs, for a discovery or work contributing to the progress of physics; the Gaston Planté prize, 3000 francs, for the discovery of an invention or important work in the field of electricity; the L. La Caze prize, 10,000 francs, which cannot be divided, for works or memoirs contributing to the progress of physics.

Chemistry.—The Jecker prize, 10,000 francs, for works contributing to the progress of organic chemistry; the Cahours prize, 3000 francs, for the encouragement of young chemists; the Montyon prize (unhealthy trades), a prize of 2500 francs and a mention of 1500 francs, for the discovery of a means of rendering an art or trade less unhealthy; the L. La Caze prize, 10,000 francs, which may not be divided, for the best work in chemistry.

Mineralogy and Geology.—The grand prize of the physical sciences, 3000 francs. The question proposed for 1909 is the stages of evolution of the most ancient quadrupeds found in France. The Delesse prize, 1400 francs, for a work concerning geology, or, in default, mineralogy.

Botany.—The Desmazières prize, 1600 francs, for a work on cryptogams; the Montagne prize, 1500 francs, for important work bearing on the anatomy, physiology, development, or description of the lower cryptogams; the de Coincy prize, 900 francs, for a work on phanerogams; the Thore prize, 200 francs, for a memoir on the cellular cryptogams of Europe.

Anatomy and Zoology.—The Savigny prize, 1500 francs, for the assistance of young travelling zoologists, not receiving Government assistance, who occupy themselves more especially with the invertebrates of Egypt and Syria; the Da Gama Machado prize, for the best memoir on the coloured parts of the tegumentary system of animals.

Medicine and Surgery.—The Montyon prize, a prize of 2500 francs, and mentions of 1500 francs, for works or discoveries useful in the art of healing; the Barbier prize, 2000 francs, for a discovery in surgical, medical, or pharmaceutical science or in botany with relation to medicine; the Bréant prize, 100,000 francs. The capital sum will be awarded under the terms of the legacy to anyone discovering a radical cure for Asiatic cholera, either by a specific medicine or by discovering the causes and indicating an undoubted method of destroying these causes. In default of this, the annual interest will be awarded for a memoir demonstrating in a rigorous manner the presence of materials in the atmosphere playing a part in the production or propagation of epidemic diseases. The Godard prize, 1000 francs, for the best memoir on the anatomy, physiology, or pathology of the genito-urinary organs; the Baron Larrey prize, 750 francs, for an army or navy doctor or surgeon for a work treating of military medicine, surgery, or hygiene; the Bellion prize, 1400 francs, for work forwarding the progress of medicine; the Mege prize, interest on 10,000 francs.

Physiology.—The Montyon prize, 750 francs, for work in experimental physiology; the Philipeaux prize, 900 francs, for similar work; the Lallemand prize, 1800 francs, for researches on the nervous system. The question proposed for the Pourat prize, 1000 francs, for 1909, is the origin of the anti-ferments.

Statistics.—A Montyon prize, prize 1000 francs and a mention of 500 francs, for work having a bearing on French statistics.

History of Science.—The Binoux prize, 2000 francs, for works on the history of science.

General Prizes.—The Arago, Lavoisier, and Berthelot medals. The Gegner prize, 3800 francs, for researches in the positive sciences; the Lannelongue prize, 2000 francs, for the assistance of the relatives of scientific men; the Trémont prize, 1100 francs. The Wilde prize, one of 4000 francs and two of 2000 francs, for work in astronomy, physics, chemistry, mineralogy, or experimental mechanics; the Longchamp prize, 4000 francs, for a work on the diseases of man, animals, and plants, from the special point of view of the introduction of excess of mineral substances as the cause of disease; the Saintour prize, 3000 francs; the Victor Raulin prize, 1500 francs, to facilitate the publication of works relating to geology and palæontology, mineralogy and petrography, meteorology and physics of the globe, the prize for 1909 being limited to mineralogy and petrography; the prize founded by Mme. la Marquise de Laplace; the Félix Rivot prize, 2500 francs; the Jean Jacques Berger prize, 15,000 francs, for work concerning the City of Paris; the Petit d'Ormoy prize, two prizes of 10,000 francs, one for pure and applied mathematics, and the other for natural science; the Pierson-Perrin prize, 5000 francs, for a physical discovery; the Parkin prize, 3400 francs, for researches on the curative effects of carbon in cholera, different forms of fever, and other diseases, or on the effects of volcanic action on the production of epidemic diseases; the Cuvier prize, 1500 francs, for a work on zoological palæontology, comparative anatomy, or zoology.

Of the above, the Lalande, Tchihatchef, La Caze, Delesse, Desmazières, and Wilde prizes, and the Lavoisier medal, are expressly offered without distinction of nationality; the Gaston-Planté, Montagne, and Pierson-Perrin prizes are limited to persons of French nationality.

RECENT WORK OF GEOLOGICAL SURVEYS.

THE Geological Survey of Great Britain has issued its "Summary of Progress for 1906" (1907, price 1s.), from which it is clear that a large part of the work of the staff must always be devoted to the revision of geological details in areas already mapped. This is not work that can be carried out hurriedly, or in response to every change in popular geological opinion; but the real need for re-consideration in accordance with modern discovery is at once apparent from the results recorded on pp. 2 to 5 of the present summary. Geological surveys have an important educational duty in addition to their economic functions, and one can never predict where an accurate knowledge of the earth may not lead to the foundation of an industry, or where an industrial inquiry may not suddenly illumine our relation to this globe on which we have to spend our lives.

It is pleasant to observe (p. 6) that the Geological Survey of Great Britain has been in conference with the Agricultural Education Association "for the purpose of testing the relationship of the geological boundaries and the soils." On p. 110 the palæontologists report in favour of the view that the rugose corals were primarily hexamerous, a question still under discussion, as may be seen from a note in NATURE, vol. lxxvi., p. 117. The original papers in the appendix, corresponding to the well-known Bulletins of the Geological Survey of the United States, include one by Dr. Flett on the scapolite-bearing rocks of Scotland, and a valuable summary by Mr. D. A. Macalister of the quantity of tin, copper, and other minerals produced in Cornwall.

The "solid" and "drift" maps, Nos. 230 and 247, are issued simultaneously with the memoirs describing them, under the care of Dr. Aubrey Strahan, and cover parts of the great South Wales coalfield (1907, memoirs, price 2*s.* 6*d.* each; maps, 1*s.* 6*d.* each). The former memoir deals with the country round Ammanford, north of Swansea, where the Silurian strata, through the Ludlow Tilestones, pass up into the Red Marls that form the base of the Old Red Sandstone. The usual unconformity of the latter on a Caledonian land-surface is revealed, however, by the fact that it oversteps every member of the Silurian system (p. 53), until it rests directly on the Arenig rocks in the extreme north-west of the map. The details shown on these modern maps necessitate a good deal of freedom in the use of colours, and blues and greens and yellows are used for lithological divisions (which are, of course, supported by palæontology) in a way that would hardly commend itself to the soul of William Smith. Would not a variety of linings and stipplings in the same colour, which produce all the effect of separate tints, serve on such colour-printed maps for minor subdivisions of our British systems? The American and New Zealand surveys often provide us with examples.

We note (p. 37 of Memoir No. 230) that "Ordovician" now officially replaces the "Lower Silurian" of the older survey; but is it wise to restrict "Silurian," in the face of almost all the geological world, to the former "Upper Silurian" alone? Prof. De Lapparent in 1893 at any rate showed us a clear way out of the difficulty.

Memoir No. 247 includes the busy town of Swansea, and the map brings us to the southern edge of the great coalfield. Mr. E. E. L. Dixon (pp. 11–20) furnishes an interesting account of the dolomitisation of the limestone soon after its deposition in the Carboniferous sea, and the plates and descriptions ought to be useful to workers in many other districts. The growing difficulty in drawing a line between the Lower and Upper Carboniferous series in Britain is well seen by the remarks on pp. 28–29. Mr. Tiddeman (p. 121) has traced a pre-Glacial raised beach from Mumbles Head westward, the fauna of which shows that the whole Cainozoic Glacial epoch was an episode of our own times, if we take the mollusca as our guide. It is now urged (p. 127) that Rhinoceros, Elephas, Bos, and Cervus, found in the Gower Caves, lived here before the arrival of the ice, since raised beach deposits admittedly appear in the cavern-floors. The subsidence that was shown at the Barry Docks in Cardiff to be later than Neolithic times has carried peat in the Swansea area (p. 145) to a level of 44 feet below high water.

The memoir on the geology of Islay has also appeared (1907, price 2*s.* 6*d.*). The author, Mr. S. B. Wilkinson, is referred to in other memoirs as Mr. B. S. N. Wilkinson, a point of which bibliographers should take notice. The maps here described were issued some years ago, and cover a little visited and very attractive district. The ordinary pedestrian in Jura and Islay will find much romantic ground, and may still travel by introduction from one farm to another, in the good old highland style. The present writer well remembers how he was waylaid by an old peasant woman early one morning on the Jura pathway, and forced to accept a parcel of oatcake, lest he should weary before reaching the ferry at the north end of the island.

Mr. Wilkinson enables us, in his first chapter, to realise the main features of Islay, and he rightly directs attention to the extreme brilliance of the colouring on sunlit days along the coast. The rocks include much crushed and mylonitic Lewisian gneiss; sediments regarded as Torridonian; phyllites, limestones, and quartzites, correlated with the Central Highland series; and, resting on these with a slight unconformity (p. 44), a series in which dolomite is prevalent. A considerable thrust-plane separates the quartzite and conglomerate of this series in the north of the island from the rocks referred to the Torridonian. Drs. Teall and B. N. Peach have made important contributions to this memoir. It is illustrated by photographic plates of exceptional beauty. It was unnecessary, however, to supply Plate ii. in our copy in the condition of a "proof before letters."

In the *Verhandlungen der k.k. geologischen Reichsanstalt* for 1907, Herr Vacek (p. 159) continues the controversy with Herr Heritsch on the basin of Graz, and we are led to understand that the junior author, whose youth is greatly insisted on, may now be carried off the field. He is sagely advised not to quote authorities, but to become one himself. Surely we have heard something of this kind in geological exhortations nearer home.

Herr Ampferer (p. 192), in his usual systematic style, gives a reading of the structure of the Rhätikon range on the Swiss and Austrian frontier, in which he shows that he is not fascinated by what Schardt has called "Ultranappismus." Ampferer goes so far as to suggest that certain foreign blocks amid Tithonian limestone, regarded by von Seidlitz as evidence of a "Fenster," and thus connected with overfolding, have been brought into their present position by ice which overrode the chain.

The *Jahrbuch* of the same institute for 1907 contains many descriptive papers, from von Troll's study of the Pontic fauna in the basin of Vienna (p. 33) to Schubert's work on the north Dalmatian coast (p. 1). Dr. Schubert incidentally opposes the suggestion, made from a study of old maps, that extensive geographical changes have occurred in the Adriatic isles within historic times.

Dr. Hinterlechner (pp. 115–374) contributes an important memoir on the sheet of the map round Deutschbrod (Německý Brod, the German ford), in eastern Bohemia. A broad plateau of gneiss and granite here unites Bohemia and Moravia; the traveller may find it monotonous, but for the fantastic architecture of its towns. Dr. Hinterlechner shows what problems of metamorphism lie beneath its undulating fields and little woods. He urges (p. 332) that the great mass of the cordierite and biotite gneisses result from the contact-alteration of a sedimentary series, which has been left intact in one particular zone. Rocks once regarded as Archæan are shown to be intrusive in this sedimentary envelope (p. 351), the age of which remains uncertain. Here again we note the striking change of opinion forced on observers in many lands when careful field-investigation comes to be carried on. Almost all our recent researches lead us farther away from the supposed Archæan crust of purely igneous origin.

Walery Ritter von Loziński describes in the same journal (p. 375) the glacial deposits and löss of northern Galicia, and traces the ice-tongues of the epoch of maximum glaciation into the northern valleys of the central Carpathian range. He finds (p. 395) that the thin marginal ice of the great continental sheet moved to a considerable height up gentle slopes, but was unable to climb steeper hillsides. Unglaciated areas therefore appear, say 250 metres above the sea, side by side with others invaded by ice to a height of 300 metres.

Among palæontological papers may be cited a long memoir by Dr. A. Till on the jaws of fossil cephalopods (*ibid.*, pp. 535–682), an outcome of his previous studies on the examples found in the Neocomian (*ibid.*, 1906, p. 89). Four new genera are proposed, and the jaws belonging to Nautilus are marked off clearly from all others (p. 658). The latter types diminish rapidly at the close of Lower Cretaceous time, and the author (p. 680), in consequence, suggests that they were connected with the Belemnoidea. Throughout both the memoirs referred to, Dr. Till writes "Rhynchotheutis" and "Palæotheutis" consistently; but surely this is a curious error in one who is so much a specialist.

The *Bulletins de la Commission géologique de Finlande* are always of interest. In No. 23 (June, 1907) Mr. Sederholm writes, with an English summary, on "granite and gneiss, their origin, relations, and occurrence in the pre-Cambrian complex of Fenno-Scandia." The subject is one in which the author has already made a reputation. Like Hinterlechner, quoted above, and many others, he has been forced here to oppose the notion of a primitive crystalline crust, revealed to us in a region of Archæan rocks, and urges that the oldest rocks in this district are of sedimentary origin, penetrated by younger granites. "The strongly contorted structure" (p. 99) "characteristic of most Finnish gneisses . . . is not a secondary phenomenon in truest sense, but originated when the rock was in a melting condition." This is supported by a series of photographs of rocks intimately penetrated by granite veinlets. The author "regards the foliation of the granites, where it is not of dynamo-metamorphic origin, as formed by the incomplete melting and re-crystallisation of schistose rocks. Also the spotting of granites, he ascribes, in most cases, to the existence of incompletely resorbed fragments of older rocks." At the same time, he believes that the foliation of many Finnish granites was due to pressure after they had become solid (p. 100), and that in Finland "the basement complexes of the typical Archæan sedimentary formations are often preserved." But the base of the whole series in Fenno-Scandia has been melted up; mixed rocks, therefore, play a very important part in this area. Hutton's conception of the circulation of types of rock through denudation of the crystalline masses and their gradual renewal, appears to Sederholm to be fully justified (p. 102). The word "migmatite" is proposed for the rocks that have been called by others "composite gneiss."

FIG. 1.—Miocene strata, near Rockville, west of Golden Bay, Nelson, New Zealand.

In Bulletin No. 21 Mr. Tanner continues his studies on the glacial phenomena of Finmark, and urges that, allowing for temporary advances of the ice during a general epoch of recession, the glaciation may here be regarded as continuous, without an interglacial break.

Turning eastward, we find Dr. W. F. Hume reporting on the geology of the eastern desert of Egypt (Ministry of Finance, Survey Department, Cairo, 1907). Gold-mining was carried on here in ancient days, and has recently been revived; the gold occurs in quartz-veins. The present account of the geology is merely preliminary, but includes the record (p. 29) of a new marine fauna in the Cretaceous sandstone.

In the "Administration Reports of Ceylon for 1906 (Mineralogical Survey)," Dr. Coomaraswámy records the discovery of thorianite *in situ* by Mr. Parsons in a vein of pegmatite, to which the mineral was traced by following up the alluvial deposits in the bed of a seasonal stream. About 6 lb. of thorianite occur in a ton of the wet decomposed pegmatite. A geological map of part of the Kandy district is added to the report.

Vol. vi. of the "Records of the Mysore Geological Department" contains several coloured maps. It is suggested that the manganiferous laterite in the Shimoga district, now being mined, may represent an old lake-deposit. The work done by the survey is of a wide character; but may we suggest that such terms as "geology student" and "topo sheets" do not fairly represent the English language?

The "Geologists' Report of Progress for September, 1903, to January, 1907, for the Federated Malay States," by Mr. J. B. Scrivenor (Kuala Lumpur, 1907, price 1 dollar), is another interesting piece of evidence as to present geological activity. A distinct foundation is laid in this pamphlet for a conception of the structure of the south end of the Malay peninsula, but the dense vegetation is here, as in Borneo, a serious obstacle to the explorer. On p. 18 there is a remarkable reference to Mr. H. N. Ridley's discovery of an alga instrumental in producing laterite. Of this we shall hope to hear much more; possibly Mr. T. H. Holland, the originator of the organic view of laterisation, has already looked into the matter.

Bulletin No. 3 of the New Zealand Geological Survey contains Mr. J. M. Bell's report on the Parapara subdivision, Karamea, at the north-west corner of the South Island. It is well furnished with landscape illustrations, as is usual with these publications, and a series of beautifully executed maps is inserted in a pocket at the end. The geological history of the district in Cainozoic times emphasises our growing convictions as to the almost world-wide occurrence of the same physical phenomena in certain geological epochs. In this corner of New Zealand, as in central Europe and Armenia, for example, we have a Miocene depression, with a marine invasion (see Fig. 1), occupying the valleys of the previous land, and then "a

FIG 2.—Bued River Valley, northern Luzon, Philippine Islands.

period of secular elevation, accompanied by faulting on an extensive scale. Gradual uprise of the land was continued practically into modern times." An epoch of extensive glaciation, with the formation of an ice-sheet in the basin of Boulder Lake, then opened in Pliocene or post-Pliocene times (p. 22). Especial attention is directed in this bulletin to the immense deposits of limonite iron-ore associated in the district with an ancient series of carbonate rocks. The ore is ascribed to the decay of iron pyrites, and to the reaction of the resulting ferrous sulphate on the carbonates. The ferrous carbonate has finally been altered to limonite, probably as a surface-phenomenon; but the resulting ores occur on a vast scale, highly encouraging for their future prospects (pp. 75–88).

The Bureau of Science of the Government of the Philippine Islands is responsible for the admirably produced *Philippine Journal of Science*, an example to our Government printers in India, or perhaps an example of the disparity of the funds officially devoted in the two countries to scientific publications. In vol. ii., No. 4 (Manila, August, 1907), Mr. A. J. Eveland describes the geology and geography of the Baguio mineral district. Here again, in the island of Luzon, we find an old crystalline basis, marine Eocene (?) and Miocene beds laid down upon it, and then an epoch of elevation and denudation. The Miocene limestone is cut through by the present Bued River valley, which reaches down to the basal diorite (Fig. 2).

G. A. J. C.

ARCHÆOLOGY IN AMERICA.[1]

THE first part of the second volume of the Transactions of the University of Pennsylvania's Department of Archæology, Free Museum of Science and Art (it is a pity that this cumbrous title cannot be simplified), contains the usual instalment of articles on Cretan and Mexican archæology, with interesting contributions by Mr. G. B. Gordon on the western Eskimo of Alaska and on an engraved bone from Ohio, the decoration of which is very Mexican in character. The author of the article on Mexican archæology, Miss Adela Breton, draws interesting analogies between the Mexican conventional representations of serpents and the dragons of Chino-Japanese art. There certainly seems to be some connection, however it may be explained. The explanation, when it arrives, will, however, be a genuine one, and not on the lines of the late Mr. Donnelly's "Atlantis," with its curious comparisons of Maya signs with "Egyptian hieroglyphics," most of which had no real existence. It is a pity that the investigation of possible connections between Mexican culture and those of the rest of the world has been so seriously discredited by the "Atlantis" idea. Miss Breton's description of the Xochicalco temple is interesting reading.

Mr. Gordon describes, among other "ploys" of the Eskimo, their elaborate cat's-cradle games. From a personal trial we cannot say that his recipes for their production are as clearly put as they might be. The photographs of these Eskimo which Mr. Gordon publishes show a Mongol rather than American type; plate v., 2, might, but for the eyes being rather too deeply set, be a Japanese.

The Cretan contribution is a good article on "The Decorative Art of Crete in the Bronze Age," by Miss Edith H. Hall, who worked at Gourniá with Miss Boyd (Mrs. Hawes). As a succinct description of the most striking characteristics of the succeeding "Minoan" periods of Cretan artistic development it is very useful, and supplements Dr. Evans's "Essai de Classification" and Dr. Mackenzie's articles on pottery in the "Journal of Hellenic Studies" and the "Annals of the British School at Athens." In tone Miss Hall is perhaps just a trifle too dogmatic, and dismisses the opinions of others (*e.g.* Messrs. Hogarth and Welch once or twice) too summarily. On Egyptian matters, too, she is inclined to regard as certain what those who deal with Egyptian things at first-hand know to be thoroughly uncertain. The later system of Egyptian dates is adopted (p. 12) from Prof. Breasted's history with hardly a qualm, in spite of the fact that it is not yet accepted by Petrie, Maspero, von Bissing, or Budge (to give only the most prominent names). There are growing reasons in favour of it, true; but equally there are most serious considerations to be urged against it. To talk dogmatically of the VIth Dynasty as ending "*in* 2475 B.C." (the italics are mine), or the XIIth as dating "from 2000 to 1788 B.C.," is absurd, though Miss Hall is not responsible for the absurdity.

Also, Miss Hall makes the usual mistake of the Greek archæologist, a mistake which we had occasion to correct in the case of her colleague Mr. Seager last year, in persistently regarding all Egyptian representations of plants, flowers, and so forth, as stiff and conventional. They are not invariably so, as a study of plant designs on XVIIIth Dynasty pottery from Deir el-Bahari and elsewhere shows; it is these, and not the formal dadoes of papyrus plants in wall paintings, that we must compare with the plant designs of the Cretan artists. Miss Hall's Fig. 29 is quoted as a Cretan "adaptation of the lotus clumps of Egyptian art. Here the method of arranging the flowers," she says, "is the same as in Egyptian art, yet every trace of Egyptian stiffness is gone." I could quote several examples of Egyptian representations of flowers that are far less stiff and formal than this Cretan one. The designs of Figs. 35, 48, and 49 could all be paralleled on Egyptian pottery.

Miss Hall's classificatory table of "Cretan Bronze Age Design" is very useful as a conspectus of the chief examples of the designs of the "Minoan" periods.

H. R. HALL.

[1] University of Pennsylvania: Transactions of the Department of Archæology, Free Museum of Science and Art, vol. ii., part i. Pp. 105; 29 plates. (Philadelphia: Published by the Department of Archæology, 1906.) Price 1 dollar.

THE PELYCOSAURIAN REPTILES.[1]

ALMOST exactly thirty years ago the late Prof. Cope brought to the notice of the scientific world remains of certain remarkable carnivorous reptiles from the Permian strata of Texas, for which he proposed the group-name Pelycosauria. The group was regarded as a suborder of the Rhynchocephalia, and was provisionally taken to include the theriodont reptiles of South Africa. Among the more typical representatives of the pelycosaurs are Dimetrodon and Naosaurus, extraordinary reptiles in which the dorsal spines of the trunk vertebræ are so enormously elongated (sometimes with the addition of transverse projections) that they exceed in height the depth of the body below them. Restorations of both the skeleton and the external form have now rendered these creatures familiar even to the man in the street.

As to the systematic position of these reptiles and their kindred, considerable diversity of view has obtained. By many writers they are classed with the theriodont anomodonts, but this, according to modern ideas, is altogether unjustifiable, the structure of the temporal arches in the two groups being different. Dr. Case therefore reverts to the original view that pelycosaurs form a primitive section of the rhynchocephalians.

The group is of special interest as illustrating, perhaps better than any other, the rapid evolution from a generalised type to a complex organisation that may have been the potential cause of early extinction, the life of these reptiles being coterminous with the duration of the Permian epoch. Why these specialised structures were evolved within such a comparatively short time is a subject upon which we can only conjecture. Carnivorous in habit, and easily masters of their contemporaries, these reptiles, Mr. Case suggests, may have developed their spines from mere exuberance of growth from a utilitarian beginning, but that these structures eventually became useless cannot be doubted.

That pelycosaurs existed outside of North America is proved by the occurrence of Naosaurus in the Permian of Bohemia and of Stereorhachis in that of France, while certain reptiles from central Germany may also belong to the group. On the other hand, they are unknown in South

[1] "Revision of the Pelycosauria of North America." By E. C. Case Publication No. 55. Pp. 176+35 plates. (Carnegie Institution, Washington, D.C., 1907.)

Africa or India, and it is improbable that they are represented in the Russian Permian. If this be so, pelycosaurs are unknown in any country where anomodonts (in the wider sense of that term) occur, so that the two groups may apparently be regarded as belonging to totally distinct faunas.

Dr. Case appears to have done his work very thoroughly, and the memoir is profusely illustrated. Before, however, expressing an opinion as to whether his restorations of cranial, and especially palatal, osteology are trustworthy, it would be essential to compare the original specimens with the figures. R. L.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

By the will of Sir William G. Pearce, Bart., chairman of the Fairfield Shipbuilding and Engineering Co., Ltd., who died on November 2, Trinity College, Cambridge, will benefit to the extent of more than 400,000*l.* upon the death of Lady Pearce, should he have left no child.

The joint matriculation board which directs and controls the matriculation examination of the universities of Leeds, Liverpool, Manchester, and Sheffield has issued its report for the year 1907. The number of candidates in July was 1,294, of whom 705 passed; and in September was 438, of whom 179 passed. The board has appointed a committee to draft a scheme for the inspection and examination of schools, and it has been assured by the universities of their general approval of the objects of the proposal.

A conference of teachers, arranged by the London County Council, will be held at the Medical Examination Hall, Victoria Embankment, London, on January 2, 3, and 4. Two meetings will be held each day, and begin at 11 a.m. and 2 p.m. The subject for the first meeting will be nature-study, and addresses will be delivered by Dr. T. P. Nunn and Messrs. H. E. Turner and J. T. Winkworth. At the second meeting the teaching of botany will be discussed, and the speakers will include Miss Lulham, Miss Lilian Clarke, and Miss von Wyss. At the fifth meeting, manual work in the lower standards of elementary schools will be considered, and Dr. Slaughter and Messrs. J. C. Hudson and P. B. Ballard will speak. At the last meeting Mr. W. J. Hazlitt will read a paper on open-air geography. Applications for tickets of admission should be made to Dr. Kimmins, Education Department of the London County Council, Victoria Embankment, W.C.

The annual meeting of public school science masters will be held at Westminster School on January 14, 1908. The meeting will commence at 10 a.m., when an exhibition of scientific apparatus will be opened. During the morning the president, Prof. H. A. Miers, F.R.S., will deliver an address upon the order in which science subjects should be taught (*a*) in public schools, (*b*) at the universities. In the morning also a discussion on teaching mechanics will be opened by papers on the educational value of mechanics by Mr. C. F. Mott, of Giggleswick School, and on the teaching of practical mathematics by Mr. H. Wilkinson, of Durham School. In the afternoon a discussion on teaching physics will take place, when papers will be read by Mr. C. Cumming, of Rugby School, on a scheme of laboratory work in physics; Mr. W. E. Cross, of Whitgift Grammar School, on a suitable curriculum for the first and second years; and Mr. J. M. Wadmore, of Oldenham School, on the compulsory teaching of elementary physics to junior forms.

SOCIETIES AND ACADEMIES.

London.

Royal Society, December 5.—"On the Distribution of the Different Arteries supplying the Human Brain." By Dr. C. E. **Beevor.** Communicated by Prof. David Ferrier, F.R.S.

The area of distribution of the different arteries of the brain was ascertained, when they were injected simultaneously under the same pressure with gelatin containing soluble colours, a method not used before.

The number of brains injected was eighty-seven. The arteries injected were the posterior communicating, the anterior choroid, the anterior cerebral, the middle cerebral, and the posterior cerebral.

The *method of investigation* consisted in injecting simultaneously by means of pressure bottles, three, four, or five of these arteries with different soluble colours. The injection mass used was gelatin, coloured with soluble carmine, Nicholson's blue, naphthol green, acridine yellow, and Bismarck brown. Twelve different classes of experiments were described. The brains were hardened in formalin, and subsequently cut and examined in the sagittal, horizontal, or coronal planes.

The parts of the brain, the arterial supply of which hitherto has not been described, or which was found to be different from that described by other observers, are:—

The regio subthalamica, with the corpus subthalamicum and Forel's field; the pes pedunculi; the corpus mammillare; the anterior limb of the internal capsule; the caudate and lenticular nuclei; the different nuclei of the optic thalamus (the thalamus is not supplied by the lenticulo-optic arteries of Duret); the anterior part of the choroid membrane, which is supplied by the anterior choroid artery; the fornix and the anterior commissure. The absence of anastomoses of the three arteries supplying the posterior limb of the internal capsule and of the two arteries to the head of the caudate nucleus was also noted.

In the cortex, the anterior cerebral area extends on the outer surface along the median line posteriorly, most frequently to mid-way between the Rolandic fissure and the external parieto-occipital fissure, and inferiorly to the sulcus frontalis superior. The middle cerebral area on the outer surface reaches the middle line for the posterior half of the parietal lobe, and posteriorly the posterior pole, or half an inch in front of it, and inferiorly the middle of the third temporal gyrus. The occipital fibres of the optic radiations in the superior lip of the calcarine fissure are usually supplied by the middle cerebral artery, and in the inferior lip by the posterior cerebral, except for about the posterior inch, which is supplied entirely by the posterior cerebral.

The knowledge of the exact part of the brain which is supplied by an artery is of great importance in the diagnosis of the parts of the brain which undergo softening when this particular artery is blocked by a blood clot.

"The Influence of Increased Barometric Pressure on Man. No. 4. The Relation of Age and Body Weight to Decompression Effects." By Leonard **Hill**, F.R.S., and M. **Greenwood**, jun.

Conclusions.—(1) Small mammals are relatively immune from decompression effects.

(2) This immunity depends on rapidity of circulation, and may be destroyed by damaging the latter with chloroform.

(3) Age is probably important *per se*, but of far less importance than body weight. We have no convincing proof that two animals of the same weight but different ages would exhibit unequal resisting powers.

(4) There is no evidence that small animals are more quickly poisoned by high pressures of oxygen than large ones.

The practical outcome of this research is that young men of small body weight and possessing a vigorous circulation should be selected for compressed air works.

Royal Meteorological Society, November 20.—Dr. H. R. Mill, president, in the chair.—Reports on the results obtained by the balloon observations made in the British Isles, July 22–27. The International Aëronautical Commission has for some years set apart the first Thursday in each month for the ascent of kites and balloons, but at last year's conference it was decided to make a special effort to obtain information on a series of consecutive days, and the last week in July was finally decided upon for the purpose. Twenty-five balloons with registering instruments were sent up in England and Scotland during the week, under the direction of Mr. W. H. Dines, at Pyrton

Hill, Oxon, and at Crinan, on the west coast of Scotland; Mr. J. E. Petavel, at Manchester University; Captain C. H. Ley, R.E., at Sellack, Herefordshire; and Mr. C. J. P. Cave, at Ditcham Park, Petersfield. Fourteen of the registering instruments have been found. Prof. W. E. Thrift also sent up a number of pilot balloons from Dublin. Nearly all the balloons drifted to the eastward, but several which reached a fair height fell within twenty miles of their starting point. The heights ranged up to more than $12\frac{1}{2}$ miles, the average being about $7\frac{1}{2}$ miles. The records showed that above $7\frac{1}{2}$ miles the temperature remained almost unaltered with change of height.—Discussion of the meteorological observations at the British kite stations, session 1906–7: Miss M. **White**, T. V. **Pring**, and J. E. **Petavel**. The authors found that the temperature gradient varies with the direction and the velocity of the wind, and also with the amount of clouds, being greatest for a north-west wind, and on clear and fine days. It appears that the direction of the wind alters at high levels, rotating in a clockwise direction; thus a south wind tends to become more westerly.

December 18.—Dr. H. R. Mill, president, in the chair.—The possibility of a topography of the air, based on balloon observations with special theodolites: Capt. C. H. **Ley**. The author gave the results of his own observations in Herefordshire in connection with the international balloon ascents which were carried out during the past summer. His method of observing is based on the direct estimation of the range of the balloon from its apparent diameter as measured by cross threads in a telescope; the range being thus determined, an altitude and azimuth are read, and the position if the balloon fixed and plotted on a map. The author, in conclusion, states that the varying topography of the earth's surface produces disturbances in the atmosphere with effects which are transmitted throughout the lower and middle strata; and that the general effect on a current is to increase its velocity over a hill and decrease it over a valley, and this is especially the case with the vertical velocity. The origin of the phenomena is to be sought in the mechanical effect of obstruction of the lowest stratum, but there are probably various ensuing complications which may accentuate the result. The measurement of these effects can be carried out by a topography of the air made in any locality.—Indications of approaching frost: R. **Strachan**. For the purpose of making forecasts, the dry and wet bulb thermometers should be noted at or after sunset, or at 9 p.m., and the amount of cloud at the time, and during the forepart of the night if convenient. The dew point can be found by reference to hygrometrical tables. When the dew point is at or below 32° frost is in evidence, but may be evanescent, due to a rise of temperature, with change of wind, rain, or overcast sky. Even when it is above 32°, if the sky is clear it is possible that the temperature on the ground will become low enough for frost to form. Thus the evening observations should lead to a good idea of what may happen during the night.

Royal Microscopical Society, November 20.—Lord Avebury, president, in the chair.—*Exhibits*.—Conrad **Beck**: Two specimens under microscopes of photographic plates prepared by the Lumière starch-grain process for colour photography. One specimen had been exposed and the other had not. The starch grains, which were about 1/2000-inch in diameter, were stained red, violet, and green. If the object-glass of the microscope showing the unexposed plate be racked out of focus, so that the colours be blended, a very close approximation to white light is obtained. If the objective be only partially out of focus, patches and channels of colour are visible, due to the fact that the coloured grains are not sufficiently intermingled. These patches are what were seen under the microscope exhibited; to see the individual grains a much higher power than the $\frac{1}{4}$-inch used would be required.—C. L. **Curties**: Two inexpensive microscopes. The first, termed the "nature-study" microscope, was mounted on a heavy square foot. It was non-inclinable, and for observing large objects the stage and mirror could be removed and the specimen placed on the flat base. The other instrument, named the "meat examiner's" microscope, is of similar design, but the stage has grooves on its upper surface, from front to back, of a pitch equal to the field of view of a 1-inch objective; a compressor having points projecting from its under side to fit into the grooves is supplied; by sliding the compressor in one groove and then in the next, until the whole length has been traversed, the entire specimen can be examined without going over the ground two or three times.—J. T. **Pigg**: Photomicrographic lantern-slides from nature, showing the various stages in the development of the fern spore from its germination to the mature frond with its fructification.—E. **Moffat**: A new form of filter for agar and other media.—*Papers*.—The François Watkins microscope: E. M. **Nelson**.—Mercury globules as test objects for the microscope: J. W. **Gordon**.—Light filters for photomicrography: E. **Moffat**.—Demonstration of the use of colour photography in metallurgy: E. F. **Law**. A number of photomicrographic lantern-slides were exhibited showing the brilliant colours produced on the polished surfaces of alloys by the varying degrees of oxidation caused by the heat-tinting process.

Physical Society, November 22.—Prof. J. Perry, F.R.S., president, in the chair.—Specimens of singing sand from New England: S. **Skinner**. The specimens shown were from two sea-beaches in New England, one at Manchester, Mass., and the other near Small Point, Maine. The beaches are alike in character in being surrounded by hard rock walls and in not having streams which might bring silt flowing through them. The sands are consequently very clean and free from small particles, and this especially so after each tidal washing. The sand consists chiefly of angular clear quartz fragments. Mr. Skinner has been able to verify most of the facts observed by Mr. Carus Wilson (NATURE, 1891), viz.:—(1) the sounds are best obtained by plunging a hard plunger into a glazed cup containing the sand; (2) after a time the production of the sounds becomes difficult; (3) the sounding may be restored by washing, which presumably removes fine powder formed by attrition between the particles; (4) it is necessary that the displacement of the sand by the plunger should occur easily. If there is resistance due to the shape of the vessel, or due to clogging by dust, the sounding is stopped. The theory put forward in "Sound" by Profs. Poynting and Thomson seems a reasonable explanation.—A micromanometer: L. **Bairstow**. The instrument exhibited was one of two which are in regular use at the National Physical Laboratory for measurements of pressures due to air currents. When the pressures on the two sides of the gauge are balanced, the whole of the liquids employed are in their zero positions, and errors due to capillarity and viscosity are avoided. The gauge exhibited has a sensitiveness of 1/10,000th of an inch of water and a range of three-fourths of an inch of water. The gauge is slightly sensitive to temperature due to the expansion of the castor-oil used, but the changes are small and easily allowed for by taking time readings of the zero. The gauge is not suitable for rapidly varying pressures, as considerable distortion of the oil surface leads to an irregularly displaced zero.—A diabolo experiment: C. V. **Boys**. The diabolo spool exhibited has the peculiar merit that no one can spin it. It is based upon the following principle. Either the ordinary spool of commerce, which has its moment of inertia about its axis of rotational symmetry a minimum, or a spool not generally made which has the corresponding moment of inertia a maximum, has stable rotation about this axis or about a transverse axis, *i.e.* if it is temporarily rotating about an axis inclined to one or other, it will tend to shift its momentary axis of rotation and gradually settle down so as to spin about one or other. If, however, the spool is so proportioned that the moment of inertia is identical about any axis, it has no tendency to spin stably about any particular axis, and the axis of rotation wanders about so rapidly that it cannot be spun. A heavy conical sheet projecting equally on either side of the vertex, the semi-vertical angle of which is equal to $\tan^{-1}\sqrt{2}$, has this property, but such an ideal construction is impracticable. All added matter beyond the sheet in the direction of the axis makes the momental ellipsoid more prolate, while any outside the sheet makes it more oblate. Treating, then, the ideal cone as a skeleton, and clothing it with matter within and without, a material double hollow cone may be made of the form of a diabolo spool, but with the dynamical properties of a sphere. It is preferable, however, to make the spool with an axial hole and with a slight preponderance of moment of inertia about its rotational axis. It will then spin perfectly. It may, however, be easily adjusted by the insertion of a stick, which is cut off of such a length as to make the moments of inertia equal, as tested by suspension from a torsion wire.—A gyroscope illustrating Brennan's mono-railway: Prof. H. A. **Wilson.** A gyroscope is mounted in bearings so that it can spin about a horizontal axis and precess freely. The gyroscope is further mounted at the top of a rectangular framework. The axis of spin of the wheel is first placed at right angles to the plane of the framework. Attached to the vertical axis about which the precessional motion occurs is a short crank with a spiral spring attached, so that when precession occurs in any direction the precessional couple is increased and the top returns towards its initial position. The oscillations of the gyroscope about its mean position become continually larger until the stability of the arrangement disappears.

Zoological Society, November 26.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—Some new and little-known Araneidea: Rev. O. **Pickard-Cambridge.** Eleven species were noted or described and figured:—one from Lagos, Portugal; three from Cape Colony, South Africa; one from Mashonaland; five from the Canaries; and one from Old Calabar. Seven species were described as new to science. Five of the spiders had been accidentally imported to England in packages of bananas.—New species of beetles of the cryptocephaline division of the family Chrysomelidæ from tropical South America: M. **Jacoby.**—The correlation of certain modifications of the limpet-shell (*Patella vulgata*) with definite environmental conditions: E. S. **Russell.** The method adopted by the author had been to measure the dimensions of a large number of shells from one environment and to compare them with similar measurements of shells from a second environment. The author had found the limpet a suitable animal for such investigations, as all limpets above 15 mm. "home" accurately. Limpets from high-water localities were found to be larger, broader, and higher, but narrower in proportion than those from low-water localities. Limpets from exposed localities were lower, narrower, thicker, and more irregular in outline than those from sheltered spots. On the area from which the shells were collected two types occurred, a "rough" type with strong coarse ribs and irregular margin, associated with rough stones, and a "smooth" type on polished stones.—Anatomy of the batrachian family Pelobatidæ: F. E. **Beddard.**—The Microlepidoptera of Tenerife: Lord **Walsingham.**—Dates of publication of the separate parts of Gmelin's edition (thirteenth) of the "Systema Naturæ" of Linnæus: J. **Hopkinson.** The paper stated that the first volume of this edition, containing the animal kingdom, was in seven parts, with a date, 1788, in the first part only, but that there was internal evidence of a later date of issue of subsequent parts. Investigations in the library of the British Museum had revealed the years of publication with some indication also of the period of the year in which each part appeared. The dates were:—part i., 1788; parts ii. and iii., 1789; parts iv. and v., 1790; part vi., 1791; part vii., 1792. The second volume, containing the vegetable kingdom, was in two parts, and the date of issue of part ii. had been found to be 1792. Contemporary authorities were given for the dates.—A small collection of Mammalia brought from Liberia by Mr. Leonard Leighton: R. I. **Pocock.** The paper recorded the presence in Liberia of two mammals hitherto unknown from that locality, and contained descriptions of one species of Genet and one Linsang new to science.

December 10.—Sir Edmund G. Loder, Bt., vice-president, in the chair.—The origin of the mammal-like reptiles: Dr. R. **Broom.**—A revision of the African silurid fishes of the subfamily *Clariinae*: G. A. **Boulenger.**—A new species of hæmogregarine from the blood of a Himalayan lizard, *Agama tuberculata*, from Kasauli, India: Prof. E. A. **Minchin.**

Society of Chemical Industry, December 2.—Mr. R. J. Friswell in the chair.—The estimation of naphthalene in coal gas and spent oxide of iron: C. J. **Dickenson-Gair.** The methods of estimation described are (1) the acetic acid method; (2) the re-precipitation method.—Note on the influence of formal on the properties of *Funtumia elastica*: Dr. P. **Schidrowitz** and F. **Kaye.** The authors find that the rubber obtained from the latex, treated by formal, although less elastic and resilient than that obtained by other means, was extraordinarily tough. They suggest that a rubber of this character might be particularly suitable for some purposes—*e.g.* for the covers of motor tyres—where toughness is of relatively greater importance than resiliency, and that it may in the future be found desirable to use different methods of coagulation for the same latex according to the purpose for which the rubber is intended.—Polarimetric determination of sucrose: F. **Watts** and H. A. **Tempany.** The authors have investigated (1) the effect of basic lead acetate on the optical activity of sugar solutions; (2) the effect of clarification with basic lead acetate on cane juice.—Niam fat: Dr. J. **Lewkowitsch.** Niam fat was obtained from the seeds of *Lophira alata*, Banks, a tree indigenous to Senegambia, Sierra Leone, and the Egyptian Soudan. The fat, freed from extraneous matter, forms 41 per cent. of the kernels. It is a soft, buttery mass melting at 24° C., and is used by the natives for culinary purposes and as a hair oil.

Entomological Society, December 4.—Mr. C. O. Waterhouse, president, in the chair.—*Exhibits.*—Dr. G. C. **Hodgson**: A number of examples of *Anthrocera trifolii*, collected on the same ground in Sussex, and showing a wide range of variation, including three fine melanic forms, and several showing six spots on the upper-wings.—W. J. **Kaye**: A specimen of *Papilio thoas thoas*, with the central portions of both tails removed, apparently by a narrow-billed bird. The injury appeared so symmetrical that it was thought likely that the specimen was an abnormality, but microscopical examination showed that this was not so.—The **President**: Two photographs of an African locust, which had apparently caught a mouse and was preying upon it. The specimen was found in the Congo State.—R. S. **Bagnall**: Notes on many species of Coleoptera, Thysanoptera, and Aptera from Northumberland, Durham, and Scotland, of which ten were new to Britain.—L. W. **Newman**: A long and varied series of *Ennomos autumnaria* (*alniaria*); a series of *Polia xanthomista* (*nigrocincta*), bred from ova and fed on carrot, the specimens unusually large (N. Cornwall); three pairs of hybrid *Notodonta ziczac* ♂ × *N. dromedarius* ♀, = *N. newmani*, Tutt; three very fine *Xylina conformis* bred by Evan John, S. Wales; three cocoons (*in situ*) of *Dicranura bicuspis*, collected wild in Tilgate Forest; and a fine melanic ♂ *Oporabia dilutata*, taken wild in Bexley Woods, 1907, this being the first melanic specimen of the species reported from Kent.—Dr. F. A. **Dixey**: Male and female specimens of a new Belenois allied to *B. zochalia*, Boisd., but quite distinct from the *zochalia* group. These were captured by Mr. Wiggins in the Tiriki Hills, north-east of the Victoria Nyanza.—*Papers.*—(1) The natural enemies of *Bombyx rubi* in Scotland; (2) note in further illustration of the convergence of Limenitis (Basilarchia) in America: Prof. E. B. **Poulton.**—The rest attitude of *Hyria auroraria*: J. C. **Moulton.**—The family tree of moths and butterflies, traced in their organs of sense: A. H. **Swinton.**—Notes and descriptions of Pterophoridæ and Orneodidæ: E. **Meyrick.**—Studies on the Blattidæ: R. **Shelford.**—Notes on the bionomics of British East African butterflies: Rev. K. St. A. **Rogers.**

Geological Society, December 4.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—The faunal succession in the Carboniferous Limestone (Upper Avonian) of the Midland area (north Derbyshire and north Staffordshire): T. F. **Sibly.** The area is the periclinal mass at the south end of the Pennine anticline. The series exposed constitutes an expanded development of the Dibunophyllum zone. The most extensive section shows a thickness of 1500 feet. Three subzonal divisions are distinguished:—D_3, subzone of *Cyathaxonia rushiana*; D_2, subzone of *Lonsdalia floriformis*; D_1, subzone of Dibunophyllum θ. An abnormal development of the Lonsdalia subzone forms a conspicuous local feature in parts of the western area. A local unconformity occurs in the eastern part of the area. A close similarity exists between the Dibunophyllum zone of the Midland area and that of North Wales. A comparison of the Dibunophyllum zone of the Midland with that of the S.W. province brings out important differences:—(*a*) the brachiopod fauna of the Lonsdalia subzone of the Midland province is richer than that of the equivalent part of the S.W. sequence; (*b*) the Cyathaxonia subzone of the Midland province is practically undeveloped in the S.W. province.—Brachiopod homœomorphy: *Spirifer glaber*: S. S. **Buckman.** The smooth, catagenetic stage of shells may have been attained by the loss of distinctive features, pointing to polygenetic origins. The series of shells figured by Davidson as *Spirifera glabra* do not all agree in being smooth. There is evidence that some forms ranged under this species are Reticulariæ (M'Coy). The use of the generic name Martinia for various smooth Spiriferids becomes unjustifiable. The author restricts the genus Spirifer, and allocates several British and foreign species among the genera Fusella, Choristites, Trigonotreta, Brachythyris, Martinia, and Reticularia.

Linnean Society, December 5.—Prof. W. A. Herdman, F.R.S., president, in the chair.—A series of specimens of *Spartina townsendi*, representing different stages of development and tall and dwarf forms, and for comparison also typical specimens of *S. alterniflora* and *S. stricta*: Dr. O. **Stapf.** The specimens of *S. townsendi* and *S. stricta* were collected by the exhibitor in the Isle of Wight; those of *S. alterniflora* near Millbrook Station in Southampton Water.—A collection of plants from Gunong Tahan, Pahang: H. N. **Ridley.**—Report on the Alcyonaria of the Sudanese Red Sea: Prof. J. A. **Thomson** and J. M. **McQueen.** The collection was made in 1906 by Mr. Cyril Crossland, from Suakim, Khor Dongola, and nine other localities, and includes three species of Stolonifera, eighteen of Alcyonacea, one being new, and four of Pseudaxonia.—Report on the Crinoidea of the Sudanese Red Sea: H. C. **Chadwick.** The collection consisted of six species, only two of which had been previously recorded from the Red Sea.—Notes on some marine algæ from the Red Sea: Prof. R. J. **Harvey-Gibson.** From material collected by Mr. Cyril Crossland in 1904 and 1905, under the direction of Prof. Herdman, F.R.S. The total number is thirty-five species; twelve belong to the Chlorophyceæ and as many to the Phæophyceæ, with eleven Rhodophyceæ. In an appendix the following phanerogams were mentioned as having been collected at the same time:—*Cymodocea nodosa*, Aschers., *Halophila stipulacea*, Aschers., *Najas major*, All., and fragments of *Salicornia fruticosa*, Linn.—Report on the Hydroida of the Sudanese Red Sea: Miss L. R. **Thornely.**

Mathematical Society, December 12.—Prof. W. Burnside, president, in the chair.—A formula in finite differences and its application to mechanical quadrature: S. T. **Shovelton.**—Weierstrass's E-function in the calculus of variations: A. E. H. **Love.**

Institution of Mining and Metallurgy, December 19.—Prof. William Gowland, president, in the chair.—The assay of telluride ores: G. T. **Holloway** and L. E. B. **Pearse.** The authors have, in view of the difficulty experienced by assayers in the determination of the precious metals in ores containing tellurium and selenium and the discrepancies observable between duplicate assays by different assayers, endeavoured to ascertain how and why, and in which portion of the assay work, the losses occur, and what means should be adopted to prevent them. The possible sources of loss appear to be as follows:—volatilisation during roasting; volatilisation and slag loss in the scorification assay; volatilisation and slag loss in the crucible assay; loss by volatilisation or in the slag in scorifying the lead button obtained in the scorification or crucible assay; or loss by volatilisation and absorption during cupellation. The paper contains details of a number of actual assays, and gives much valuable information in regard to the methods adopted and the results obtained.—A cheap form of cyanide plant: C. **Hunter.** A description of some cyanide plants of a light and portable nature actually supplied to small mining propositions in Rhodesia, with copies of the contracts and detailed specification. The cost of running such a plant is also stated.—The deep leads of Victoria, or the Cainozoic buried auriferous river deposits: H. L. **Wilkinson.** A review of the buried auriferous gravel deposits occupying the beds of ancient rivers once forming the drainage channels of Victoria at the period when large areas were covered by Pliocene seas. These include the Loddon, Avoca, Campaspe, Smythesdale-Pitfield, Stawell, and Ararat leads and their tributaries, and cover the districts of Ballarat and Bendigo. The author points out the effects of enriching belts in aggregating the rich portions of a lead and other factors determining the quantity of alluvial gold in the wash. At the end of the paper are several pages of tabular matter relating to the working costs of alluvial mines.

CAMBRIDGE.

Philosophical Society, November 11.—Dr. Hobson, president, in the chair.—A critical description of three cases of single hypogastric artery in the human fœtus: Dr. **Duckworth.**—The inheritance of white in poultry: R. C. **Punnett.**—Sexual phenomena in the free-living nematodes (preliminary note): F. A. **Potts.** The paper commenced by summarising the work of Maupas, and emphasised the interest and importance of the supplemental males found in the hermaphrodite species. These are chiefly remarkable for their withdrawal from the economy of the species, though in no sense degenerate, or unfitted for reproduction. Confirmation of Maupas's results was drawn from the study of a species of Diplogaster; some details of the culture methods used were given, and it was pointed out that this species shows that a race propagating exclusively by self-fertilisation does not of necessity show signs of degeneracy.

November 25.—Dr. Hobson, president, in the chair.—The orientation of 3:5-dichloropyridine: Dr. **Sell.**—The action of metallic magnesium on certain aliphatic acids, and the detection of formic acid: Dr. **Fenton** and H. A. **Sisson.** In a previous communication (Trans. Chem. Soc., 1907, 687) it was shown that both carbonic and formic acids may be reduced by means of metallic magnesium to formaldehyde. Experiments have now been undertaken with the object of ascertaining whether an analogous reduction can be effected in other acids, and the results so far obtained appear to indicate that this is only possible in the lower members of a series. Further, it is shown that this reduction by means of magnesium affords a characteristic and fairly delicate test for formic acid, the special reactions for formaldehyde being of a far more positive character than those for formic acid.—Some colour-reactions of organic acids with phenols: Dr. **Fenton** and G. **Barr.** Remarkably brilliant colour-reactions are often obtained when certain organic acids are treated with phenolic compounds in presence of strong sulphuric acid, and it appeared desirable to tabulate the results obtained with some of the less common acids in order to ascertain whether the reactions might be employed for the purpose of preliminary identification. By comparing the colours obtained in this way with two or more phenols, information of a positive character may often be obtained. The method has the advantage of being applicable, not only to the acids themselves, but also to their salts or esters, and is useful for provisional identification when only minute quantities of the substance are available.—Contributions to the knowledge of the oxaloimidochlorides: S. **Ruhemann.**—The absorption spectra of collidine and 9-chlorcollidine: J. E. **Purvis** and W. H. **Foster.** The curve obtained from a study of collidine showed that it was very similar to that of pyridine and lutidine previously studied by Hartley and by Baker and Baly. The differences were that there was a slight shift of the band towards the red end of the spectrum, and also that the persistence of the band was decreased a little less than that of lutidine and pyridine.—The decomposition and nitrification of sewage (1) in alkaline solution, (2) in distilled water: J. E. **Purvis** and R. M. **Courtauld.** The results showed that after incubations extending over eight weeks there were only small quantities of nitrates produced; also that (1) there were smaller quantities of nitrates produced in the alkaline solution than in the non-alkaline; (2) a larger comparative increase of the free ammonia in the alkaline than in the non-alkaline solution; and (3) a progressive diminution in the total ammonias.—The influence of light and of copper on fermentation: J. E. **Purvis** and W. A. R. **Wilks.** The results showed that fermentation under sterilised and non-sterilised conditions in glass vessels under the influence of various spectral colours, as well as of white light, was not very seriously influenced. The most marked effects were in differences in the acidities of the fermented wort; the fermentations under the influence of red rays were more acid than those in the white light, but the differences in the numbers obtained from the optical activities were not sufficiently marked to draw definite conclusions. The influence of copper on the fermentation was very marked. Very small quantities were sufficient to cause great differences in the numbers obtained from the optical activity, the copper oxide reducing power, the attenuation, and the acidity.—Resolution of optically active ammonium salts by means of tartaric acid: H. O. **Jones.**—Studies on platinocyanides: L. A. **Levy.** The crystals of barium platinocyanide may be obtained in two forms, which exhibit a great difference in physical properties—notably in their fluorescence and colour. The present communication contains an account of the author's experiments on the nature of the two varieties and the fluorescence exhibited by them.—Orientation of substituted bromanilines: J. R. **Hill.**—The solutions of ordinary linear differential equations having doubly periodic coefficients: J. **Mercer.**

DUBLIN.

Royal Dublin Society, November 19.—Prof. Sydney Young, F.R.S., in the chair.—The synthesis of glycosides: some derivatives of xylose: H. **Ryan** and G. **Ebrill.** By the action of acetyl chloride on xylose in a sealed tube acetyl-chloroxylose was obtained. The substance, which crystallised well, melted at 101° C. From it the xylosides of α-naphthol and carvacrol, and the tetracetyl derivative of xylose were prepared. βα-Naphthyl-xyloside was formed by addition of acetyl-chloro-xylose to a solution of potash and α-naphthol in absolute alcohol. It crystallises in long needles, which melt at 192° C. to 193° C. The substance is soluble in alcohol, acetone, and acetic ester, and almost insoluble in ether, carbon bisulphide, chloroform, and petroleum ether. It does not reduce Fehling's solution. Emulsin has no action on it. In a similar manner acetyl-chloro-xylose was converted into carvacryl-xyloside. The latter substance crystallises in needles, which are soluble in alcohol, ether, chloroform, acetic ester, and acetone, but are insoluble in carbon bisulphide. Its melting point is 105° C. Like the corresponding α-naphthyl compound, it reduces Fehling's solution only after inversion by hot dilute acids. Tetracetyl-xylose, which was obtained by the action of silver acetate on acetyl-chloro-xylose, is a crystalline solid which melts at 119° C. (uncorr.).—The radio-activity of sea-water: J. **Joly.** Examination of five samples of sea-water from various points round the Irish coast seems to show that when care is taken not to precipitate the radium in a non-emanating form when concentrating by evaporation (and for this purpose it is necessary to add a few c.c. of pure HCl when evaporating), the quantity of radium found is much greater than has been ascribed to sea-water hitherto. The larger values found may be in part due to suspended coastal materials. Experiments on mid-ocean waters are in progress.

MANCHESTER.

Literary and Philosophical Society, October 29.—Prof. H. B. Dixon, F.R.S., president, in the chair.—The atomic weight of radium: Dr. H. **Wilde.**—The production and origin of radium: Prof. E. **Rutherford.** An account was given of the historical development of our ideas in regard to radium. On the disintegration theory, radium is regarded as a substance undergoing slow spontaneous transformation with a period of about 2000 years. In order to account for the existence of radium in minerals of great age, it is necessary to suppose that radium is produced from another substance of long period of transformation. There is a genetic connection between uranium and radium, for investigation has shown that the amount of radium in minerals is in all cases proportional to their content of uranium. If this be the case, radium should gradually appear in a preparation of uranium, initially freed from radium. No such growth of radium has been observed over a period of several years, although a very minute growth of radium can be easily detected. This is not necessarily inconsistent with the disintegration theory, for if one or more products of slow transformation exist between uranium and radium, no appreciable growth of the latter is to be expected in a short interval. A search for this intermediate product has recently proved successful. Boltwood found that a preparation of actinium, initially freed from radium, grew radium at a constant and rapid rate. Boltwood at first considered that actinium was this intermediate product, and that actinium changed directly into radium. The growth of radium in actinium solutions was confirmed by the author, who had commenced experiments in that direction three years before. The experiments showed, however, that actinium did not, as Boltwood supposed, change directly into radium. By a special method, a preparation of actinium was obtained by the author which showed no appreciable growth of radium over a period of 240 days. The growth of radium, if it occurred at all, was certainly less than 1/500th of that ordinarily observed. In another case, a solution of actinium was obtained which produced radium faster than the normal. These results are completely explained by supposing that a new substance of slow transformation is present with actinium, and this substance is transformed directly into radium. This parent of radium has distinct chemical properties, which allow it to be separated from both actinium and radium. The absence of growth of radium observed in the actinium solution mentioned above is due to the fact that, by the special method, the parent of radium had been completely separated from the actinium. In recent letters to NATURE, Boltwood confirmed the results of the author, and described a satisfactory method of separating the radium parent from actinium. He has shown that this new body, which he proposes to call "ionium," gives out α and β rays, and has the chemical properties of thorium. The Royal Society recently loaned the author the actinium residues from about a ton of pitchblende. These residues contain the parent of radium, and experiments are in progress to isolate and concentrate both the actinium and ionium in these residues.

November 12.—Prof. H. B. Dixon, F.R.S., president, in the chair.—(1) The cone of *Bothrodendron mundum* (Will.); (2) on the ulodendroid scar: D. M. S. **Watson.** In the former it was pointed out that the small hermaphrodite lycopodiaceous cone described by Williamson in part x. of his series of monographs on the organisation of the fossil plants of the Coal-measures had an axis which agreed very closely with the wood of a small stem of *Bothrodendron mundum.* On the evidence of the characters of the axis and of the sporophylls, supported by constant association of the cone or its characteristic megaspores with stems of *Bothrodendron mundum*, it was concluded that the cone in question was really that of *Bothrodendron mundum.* In the paper on the ulodendroid scar, the theory that ulodendroid scars were produced by the pressure of the bases of sessile cones was shown to present difficulties, *e.g.* cones large enough to have produced scars 6 inches in diameter were unknown, and it was difficult to see how the scars would have grown appreciably without becoming wider laterally than vertically, which was never the case. It was shown that all the ordinary features of a ulodendroid scar could be explained on the theory that it represented the base of a branch attached to the whole area of the scar.

NEW SOUTH WALES.

Linnean Society, September 25.—Mr. J. H. Maiden, vice-president, in the chair.—The genus Petalura, with description of a new species (Neuroptera: Odonata): R. J. **Tillyard.** This remarkable isolated genus is probably a relic of an ancient Australian odonate fauna, which is now being steadily displaced by an Asiatic invasion. *P. gigantea*, Leach, occurs round Sydney and on the Blue Mountains, and was described nearly a hundred years ago. It is about $4\frac{1}{2}$ inches across the wings. The new species, *P. ingentissima*, is found in northern Queensland. It is the largest dragon-fly known to exist at present (about 6 inches across the wings), and seems to show connection with the huge Tertiary Gomphinæ which have been found in a fossil state. It is exceedingly rare, and becoming obsolete; the only two specimens known are the types.—The dragon-flies of south-western Australia: R. J. **Tillyard.** The district worked was that lying between Perth on the north and Cape Leeuwin on the south, which has a regular and abundant rainfall. It may be divided into two portions, the Darling Ranges with their running streams, and the low coastal strip with lagoons and marshes. The Odonata of the two portions were found to be very distinct. Twenty-six species were noted, of which six are new and very interesting forms (referable to the genera Synthemis [2], Austrogomphus, Austroæschna, Argiolestes, and Pseudagrion); four or five others are very rare, and the rest are common eastern species. Many of the species are black or nearly so, and seek protection on the burnt stumps or in the foliage of the "black-boys" (Xanthorrhœa), which are abundant everywhere.—Note on a glaucophane schist from the Conandale Range, Queensland: H. I. **Jensen.**—Chemical note on recent lava from Savaii: H. I. **Jensen.**—Revision of Australian Lepidoptera, part iv.: Dr. A. J. **Turner.** This paper continues the revision of the family Geometridæ, and is mainly concerned with the subfamily Sterrhinæ. When Mr. Meyrick revised this group in 1887, he recognised thirty-two species, referred to five genera; the present revision treats of one hundred and two species, ascribed to twenty genera. Five species, referable to the subfamily Hydriomeninæ (dealt with in the preceding paper), are also described as new.

October 30.—Mr. A. H. Lucas, president, in the chair.—The Tertiary limestones and foraminiferal tuffs of Malekula, New Hebrides: F. **Chapman.** These rocks form part of the collection made by Mr. D. Mawson in 1903. The paper deals with the Miocene and the post-Miocene rocks of Malekula, south of Santo. Trillina has been found to occur in the New Hebrides; this genus has already been proved to exist in South Australia and the Philippines, which thereby connects the south coast of Australia with the islands of east Australasia and portions of the East Indian Archipelago, along which line in Oligocene times there probably existed a shallow-water area where such forms could flourish. A new species of Alveolina found in the Malekula limestone had already been figured from Javan Miocene limestones. *Lepidocyclina angularis*, found at Malekula, and already known from Miocene limestone in the Loo-Choo Islands, off Japan, shows a further extension of the Miocene shore-line as far north as Japan.—A collection of dragon-flies from Central Australia, with descriptions of new species: R. J. **Tillyard.** The collection was made by Mr. J. F. Field, and is probably typical of the odonate fauna of Central Australia. Though well within the tropics, yet the locality exhibits no definite tropical forms. The 320 specimens examined comprise ten species; eight are common over Australia, two are new. One, *Lestes aridus*, is allied to *L. leda* and *L. analis*; the other, *Austrosticta Fieldi*, is the type of a new genus.—Memoir on a few heteropterous Hemiptera from eastern Australia: G. W. **Kirkaldy.** This memoir records the Heteroptera collected by Mr. A. Koebele and Dr. R. C. L. Perkins in Queensland, and by Mr. Koebele in New South Wales. Seven genera and twenty-five species are proposed as new.—The geographical significance of floods, with especial reference to glacial action: E. C. **Andrews.** The forms of roadside gutters and of miniature cañons admit of explanation, since the time occupied in their formation falls within decades. Storm-formed cañons show, in the initial stages, spurless trenches **U**-shaped in cross-section, the trench bases possessing deep basins. At a later stage these cañons show double slopes, the upper **V**-shaped, the base **U**-shaped, in cross-section. This lower contour represents the *flood* contour. In river valleys, along shore-lines, and in glacial cañons, forms similar to these occur. Along miniature cañons generally the flood alone does the corrosive work. The application of such truths to glacial cañons explains drumlin forms and other apparent anomalies.—Solandrine, a new midriatic alkaloid: Dr. J. M. **Petrie.** The alkaloid belongs to the atropine group, and resembles hyoscine. It differs from hyoscine in its aurochloride in not reddening phenolphthalein, and it yields atropic instead of tropic acid when hydrolysed. Though the exact constitution of the alkaloid has not been worked out, the results afford evidence of the existence of a tropeine alkaloid in *Solandra laevis*, for which the name solandrine is proposed.—Description d'une nouvelle Espèce d'Oxylæmus (Coleoptera: Colydiidæ): A. **Grouvelle.**

THE INHERITANCE OF "ACQUIRED" CHARACTERS.

Sur la Transmissibilité de Charactères acquis. By Eugenio Rignano. Pp. 320. (Paris: F. Alcan, 1906.) Price 5 francs.

A MAN of science to command general attention and interest must do two things; first, he must make interesting discoveries or profound generalisations; and, secondly, he must do these things at the right time. Darwin made his name because he fulfilled both these conditions. Mendel died an unknown man because he did not fulfil the second. He was forty years too soon. Supposing that Mendel's paper *had* been completely lost sight of, as it actually was for thirty-five years, and very nearly was altogether, his results must, sooner or later, have been obtained by somebody else, who would then have won the laurels which now belong to Mendel, not because he made a greater discovery than Mendel, but because he made it at a time when the state of biological thought was such that it could appreciate the significance of the discovery.

If it is possibly fatal to make discoveries too soon, it is certainly fatal to make them too late. It is therefore with a certain sense of weariness, mingled with surprise, that we note the appearance of a work on the transmission of acquired characters. Lamarck's theory of evolution involved a belief in the thesis that acquired characters are transmitted. Darwin believed that evolution was due to the natural selection of both innate and acquired characters, and his theory of pangenesis was more than anything else an attempt (shirked by Lamarck) to provide a hypothesis to account for the transmission of acquirements. Darwin's suggestion that innate characters played a part in evolution as well as acquired ones paved the way for the great step taken by Weismann, who in his theory of the continuity of the germ-plasm laid the foundation of the modern, and still infant, science of heredity by doing away with the transmission of acquirements once and for all.

The step taken by Weismann is far and away the most important in the history of evolution, or at any rate of genetics, because it divides that history into two periods, in the first of which the problem to be solved was: "How do the characters of an organism get into the germ-cell which it produces?" whilst in the second the problem has become: "How are the characters of an organism represented in the germ-cell which produces it?"

Weismann showed that the problem of the first period was as unreal as the question about the apple dumpling which puzzled one of the Georges, by opening our eyes to the fact that the characters of an organism do not get into its germ-cells any more than the apple gets into its crust, but that both the germ-cells and the apple were there all the time.

Darwin, although he made a great step in advance of Lamarck by elaborating a theory of evolution which did not rest solely or even largely on the transmission of acquirements, did not go to the length of throwing that theory overboard altogether. It was left for Weismann to do this and thereby rid biology of a belief which has been the occasion of more futile discussion than any other that can be named. The full significance of Weismann's action is seldom appreciated, and cannot be done justice to here, but it is not too much to say that without it the problem of heredity would have been doomed to insolubility, and, to take a concrete example, that the Mendelian work of the last seven years would have been impossible.

Whether it is due to the general truth that a view once widely held is difficult to stamp out, or whether it is that there is something peculiarly fascinating in the belief that acquired characters are transmitted, the fact remains that there are still to be found isolated biologists and whole hosts of medical men who still hold it. However, as a belief in telegony, though rare, still exists, we perhaps ought not to be surprised at anything.

The author of the book before us, who is an engineer interested in sociology, believes in the transmission of acquirements, and has invented a theory of centro-epigenesis to account for the phenomenon. If the book is read it must be read in conjunction with the appendix dealing with this topic in Mr. Archdall Reid's "Principles of Heredity," and with Weismann's "Deszendenztheorie," which has been translated into English by Prof. J. Arthur Thomson.

A. D. D.

PROBLEMS OF VISION.

Zur vergleichenden Physiologie des Gesichtssinnes. By Prof. E. Raehlmann. Pp. iv+58. (Jena: G. Fischer.) Price 1.50 marks.

THIS short pamphlet contains a discussion of three interesting problems in vision. It has long been known that the arrangement of the retinal elements in regard to the light falling upon the eye is reversed in the vertebrata and some invertebrates as compared with the majority of the latter. The author wishes to direct attention to the problem of explaining how in these "inverted eyes" the stimulus of light affects the retina. He puts forward the view that the morphologically outer end of the rods and cones acts in these cases as a reflector, and causes the light to re-enter the inner limb where the visual stimulus commences. In that sense, therefore, the vertebrate retina is no exception to the general statement that the rods always face the effective light rays. The isolation of the rods by pigment leads the author to an interesting account of the various forms of iris and of retinal pigments.

The second problem is the function of the tapetum. The significance of this brilliant structure has received little attention. Hatschek has attempted to show that it reinforces the incident light. The author, however, proceeds to show that the incident light is not effective even partially, but that it is the rays reflected from the concave and asymmetrical tapetal mirror which illuminate the inner portion of the peripheral retina. This area, weak in perception of detail, but strong in detection of movement, catches the images of objects moving laterally. The tapetum would thus be put out of action by "blinkers," and, on the other hand, would aid carnivores both by detecting movements of their prey and by bringing these movements to the analysis of the central vision.

The third problem discussed in this pamphlet is that of colour-vision amongst insects. Insects are chosen because there seem good *a priori* grounds for believing that they possess colour-perception. The problem is raised in this form: Is any morphological peculiarity in the structure of these presumably colour-perceptive animals associated with this faculty, and can we picture their colour-field? The author points out the well-known composite nature of the rhabdoms or rods in the higher crustacea and insects, how they are composed of denser and more refractive plates alternating with feebly refracting layers, and how white light becomes broken up, partially absorbed and partially resolved into interference colours. He concludes that diurnal insects must view objects as we should see them through a tinted glass. Those coloured with the like tint would stand out from the rest, the majority would be blurred, and the whole field would be dim in any but a strong light. Hence, the author infers, the activity of diurnal lepidoptera only in very bright weather. Some of the suggestions made in this speculative essay are of great interest. Allied species often exhibit very different choice of stations, and comparison of their eyes may throw some light on why they do so. Again, the form of the rods of diurnal insects is certainly broadly different from that of nocturnal insects; the former are clear, the latter suffused with red pigment. But, on the other hand, both kinds of insect-eye show a similar lamellar structure, and it would require a far more rigid demonstration than is given by the author of this work before we could accept the view he takes, fascinating and suggestive as it is.

A LANCASHIRE FLORA.

The Flora of West Lancashire. By J. A. Wheldon and A. A. Wilson. Pp. iii+511. (Liverpool: J. A. Wheldon, 60 Hornby Road, Walton; Ilkley: A. Wilson, 4 Eaton Road, 1907.) Price 12*s.* 6*d.*

WHEN the ravages of the jerry-builder are fast obliterating the comparative solitudes on the outskirts of our great cities, and the equally destructive, though more localised, irruptions caused by dock and railway extensions and industrial enterprises are slowly exterminating the flora of our country-sides, it is a matter for congratulation that there are to be found men like the authors of this flora, prepared to sacrifice hours of leisure and recreation in the task of cataloguing for future reference the plant inhabitants of such botanically doomed districts. As the authors point out, Lancashire is sadly deficient in such records, and the present result of their painstaking efforts is to be welcomed for that reason, if for no other.

The volume is, in the main, a catalogue of the plants of the district known in Watson's "Topographical Botany" as "Vice-County No. 60," embracing the West Lancashire spurs of the Pennines, the coast district between Carnforth, Morecambe and Lancaster, and the extensive flat lands reaching from the estuary of the Lune to that of the Ribble. The catalogue is prefaced by a summary of the general topographical and botanical features of the district, by a chapter on meteorology and climate, and a brief synopsis of the relation of plant distribution to latitude and to edaphic factors. The flora follows, as the authors say in their preface, "the conventional models," yet one could have wished that they had departed from these models—at least in a few fundamental particulars.

One of the most remarkable features of recent British floras is the inclusion of gymnosperms under the head of dicotyledons. It is incomprehensible to the general botanist that a taxonomy so archaic should be repeated so persistently in successive editions of the London catalogue, in local floras like the present, and even in the latest list of British plants compiled by Britten and Rendle.

Again, the value of this flora would have been greatly enhanced had the authors deemed it advisable to add some critical notes on local forms and varieties special to the district, on the model of Townsend's excellent flora of Hampshire.

Although they do not profess to give "a botanical survey" of the West Lancashire area, the authors have devoted nearly a quarter of the volume to what is to all intents and purposes a digest of that aspect of their subject—to the general reader by far the most interesting part of the book. Moreover, this section is illustrated by fifteen most excellent photographs, of characteristic ecological features. One does not wish to depreciate the value of records of "first finds," nor the claim to recognition of the "first finders," but there remains a lingering desire for a more succinct treatment of such records—which, after all, can be only of local interest—and a fuller statement of the main general topographical features, a statement which the authors are, apparently, so well qualified to give.

It has been customary, for some unexplained reason, to include in local (and even general British) floras only dicotyledons (including—saving the mark! Coniferæ), monocotyledons, Pteridophyta and Characeæ. Messrs. Wheldon and Wilson have had the courage to include mosses, Hepaticæ and lichens, on which groups, if we mistake not, one at least of the writers is an acknowledged authority. It is unfortunate that they have not been able to enlist the aid of a fungologist and algologist, and so present us with a *complete* flora of the area.

It seems almost ungracious to direct attention to the many typographical errors, especially in the first quarter of the volume (over and above the few errata mentioned), and, too, the haphazard distribution of commas and full stops, authorities for species, and so on, but these criticisms are made with no intention of depreciating the merits of the work under review, but rather of indicating what we think are deficiencies and blemishes on what is otherwise a valuable contribution to the field botany of a hitherto neglected district.

SELENOLOGY AND GENERAL ASTRONOMY.

(1) *The Moon in Modern Astronomy.* By Ph. Fauth, translated by Joseph McCabe, with an introduction by J. E. Gore. Pp. 160; illustrated. (London: A. Owen and Co., n.d.) Price 10*s.* net.

(2) *Astronomical Essays, Historical and Descriptive.* By J. Ellard Gore. Pp. viii+342; illustrated. (London: Chatto and Windus, 1907.) Price 6*s.*

(3) *Evolution of Planets.* By Edwin G. Camp. Pp. 166. (Bristol: T. Thatcher, College Green, 1907.) Price 1*s.* net.

(1) THIS volume contains Mr. Fauth's summary of his twenty years' selenographic work, together with a discussion of the many problems which face the selenographer of to-day. Mr. Gore's introduction is purely descriptive of the general classification of lunar features, of which he defines the general terms, thus enabling the non-astronomical reader to study Mr. Fauth's work with some measure of understanding.

The theme of the work is the substantiation of the author's conclusion that our satellite is covered with a thick layer of ice. Both the "meteoritic-bombardment" and the "plutonic" theories of selenological evolution are critically examined, and their fallacies exposed. In the first chapter the author gives an interesting historical survey of selenology from early Grecian times to the present, paying special attention to the various maps which have from time to time been published. In this connection he rather deprecates the possibility of photographs, even of the excellence now attained, being as efficient as the eye in delineating the fainter shades of difference to be found in the lunar landscape.

The second chapter discusses appearance and reality, going into details as to what can really be seen with certainty, and as to the best means to employ for selenographical work. The essential differences between terrestrial volcanic craters and the so-called "craters" of the moon are emphasised strongly, and this leads to the discussion of the terminology generally adopted by selenologists.

Under the headings "Light and Colour," "The Ring Mountains," and "The Remaining Elevations and the Rills" respectively, the next three chapters are devoted to a critical examination of the various lunar features, showing how the results obtained by an experienced observer are incompatible with the older theories of lunar evolution. In the next, and concluding, chapter (vi) we are introduced to the theory which, in Herr Fauth's opinion, best explains the multitudinous appearances seen on the moon, viz., "*the moon is covered with a thick layer of ice.*" This conclusion is not a novel one, but it probably has never been so ardently advocated as in the present volume. Probably our satellite obtained the thick coating of solid H_2O, around its globular nucleus, by accretion from the intensely cold depths of outer space; possibly minor meteoric bombardments occasioned the breaches through which the sub-glacial, warmer water was expressed and formed the "seas," the "walled plains," &c., which now make up the lunar surface. On this theory the author is able to explain the large number of lunar objects which twenty years of devoted study have revealed to him, and he promises in a future work to establish it further. In conclusion, he subjects to severe criticism the records of recent changes in certain lunar formations, and expresses his conviction "that no eye has ever seen a physical change in the plastic features of the moon's surface.

(2) Nine of the twenty-four essays in this volume have previously appeared in various astronomical journals; the others are now published for the first time. The range of subjects is extensive, including such items as "Primitive Astronomy" and "Modern Theories," "The Ringed Planet," and "The Stellar Universe," "The Names of the Stars," and "The Size of Stellar Systems," &c.

As all those who are acquainted with Mr. Gore's writings would expect, all the essays are very interesting and instructive, but some will probably attract more general attention than others. For example, Mr. Gore gives a most interesting account of Michell, a divine of the eighteenth century, who, amongst other matters, discussed the probable parallax and magnitude of the fixed stars in an original and suggestive manner, extensively justified by more recent researches, and who seems to have been lost sight of in the blaze of glory which attended his immediate successor, Sir William Herschel. The theories and observations of the latter are also discussed in the light of recent knowledge, in a style that cannot fail to interest even the general reader.

The essays on the light, the secular variation, the number, and the brightness and density of the stars are more of the general style, but, as treated by Mr. Gore, are certain to attract and maintain the reader's attention.

"A Possible Celestial Catastrophe," involving an illuminating discussion of the subject of dark bodies in space, and "The New Cosmogony," in which the "planetesimal hypothesis" is expounded, are typical of the more speculative essays, and here again the problems are clearly stated and judicially examined.

Generally speaking, Mr. Gore employs data which have accrued from the most recent investigations, and the value of the volume is enhanced by six reproductions from actual photographs taken by Profs. Barnard and Wolf, and the late Dr. Roberts.

(3) It is difficult to see what useful purpose this posthumous publication of Mr. Camp's notes will serve. The author, in respect to accepted scientific theories, was a confirmed iconoclast, and treated dogma with scant ceremony. Yet we find the following on p. 35:—

> "That the earth is a cool, hollow sphere may have been inferred by many minds, but it has not yet been taught as a matter of fact. Such, however, it is, and such it can be proved to be."

Similarly, all the planets, and the sun, are hollow spheres, coal is not compressed vegetable matter, the interior heat of the earth's crust is caused by the friction between magnetic currents as they come in contact with each other and with non-conducting material; and so the book proceeds throughout its four hundred and sixty-seven disjointed articles, which were originally written as "Ideas from Port Shepstone" for the *Natal Mercury*.

W. E. ROLSTON.

OUR BOOK SHELF.

The Climber's Pocket Book. Rock-Climbing Accidents, with Hints on First Aid to the Injured, some Uses of the Rope, Methods of Rescue and Transport. By Lionel F. West. Pp. 79; illustrated. (Manchester: The Scientific Publishing Co., n.d.) Price 2*s*. 6*d*. net.

ACCIDENTS are possible even to the most careful climbers, and they may happen in places from which a disabled man cannot readily be extricated. In such a case Mr. West's handy little book will be of the highest value, for his directions are terse, clear, and adapted to the various circumstances in which a mishap may be critical—on the face of a cliff, in a narrow gully or "chimney," when crags have to be climbed, or narrow ledges traversed before reaching a position which is easy of access. He explains and illustrates by photographs the different modes of using the rope, and how, by means of it, the disabled man may be lowered down precipitous rocks, transported across snow slopes, and carried on a stretcher, readily improvised, when the going becomes easy.

We are also told the symptoms indicating the nature of an injury, what to do and what to avoid, the articles of general equipment, and the few simple medicines and appliances which a climbing party should carry with them. That party, Mr. West rightly declares, should not number less than three; four is better, but more than that on a rope much retards progress, and the climbers in front, especially if the party be divided, may dislodge stones which imperil those in the rear.

If a man chooses to climb alone he must take the risks, for a simple fracture may then mean a lingering death; and two are not enough, for if assistance be needed the injured man must be left to pass hours, perhaps a night, in solitude. Frostbite, snow-blindness, and mountain sickness are described, with instructions for treating them, and Mr. West gives some valuable hints on the best way of avoiding mountain dangers, with a chapter of "don'ts," of which we must be content to say that, were it more generally followed, accidents would be far less frequent.

What Rome was Built With. A Description of the Stones employed in Ancient Times for its Building and Decoration. By Mary Winearls Porter. Pp. viii+108. (London and Oxford: Henry Frowde.) Price 3*s*. 6*d*. net.

EVERY intelligent visitor to Rome feels more or less curiosity about the varied stones that were used in such profusion for purposes of construction and decoration. Ordinary guides and guide-books are prone to err in the identification of the stones, and still more in any attempt to trace their origin or explain their formation. To deal adequately with the subject needs, in truth, the knowledge of both antiquary and geologist. The writer of this work, without professing any originality, has carefully collected from both sources a great deal of interesting information, and has examined critically several collections of typical specimens, with the result that she has produced a little volume that ought to be decidedly helpful to the inquirer.

The nomenclature of the ornamental stones employed by the ancients is often perplexing, leading occasionally to downright error. Even so common a term as "alabaster" is apt to be a source of some confusion, inasmuch as it is applied to both the carbonate and the sulphate of lime. Still more confusing is the use of the word "serpentine," for the antiquary often applies it to the green porphyry of Greece, a material very similar to the well-known rock of Lambay Island, near Dublin. On such points of terminology, as on other matters, the writer may be safely trusted, for her quotations show that she has not failed to consult the highest authorities.

A list of works of reference is appended, but its usefulness would have been increased if the dates of publication had been generally given. In the few cases where dates are quoted, accuracy is not always conspicuous. Thus a paper by R. Swan on Paros is here cited as having been read at the British Association in 1877, whereas on p. 83 the date is given as 1887; but, as a matter of fact, neither is correct, for the paper was read in 1889, and in Section C, not G, as here stated. A little more care might also have been well spent in the arrangement of the matter. What can be the use of explaining the meaning of the word "breccia" in a note on p. 50 when it has already been explained in words almost identical on p. 37? But these are only trifling blemishes, which detract but little from the value of an interesting compilation. It is difficult to point to any other work on the subject equally convenient and trustworthy.

Nature's Hygiene and Sanitary Chemistry. By C. T. Kingzett. Fifth edition. Pp. xvi+527. (London: Baillière, Tyndall and Cox, 1907.) Price 7*s*. 6*d*. net.

THIS is a book written with a purpose, and the purpose is to proclaim the virtues of a certain disinfectant in which the author is interested. There is no secret about the matter; he shows us the axe he is grinding, and every now and then holds it up, as it were, that we may admire the nice sharp edge he is putting on the implement.

By "Nature's Hygiene" the author means the process of oxidation, as shown more especially in the absorption of moist atmospheric oxygen by certain terpenes, with the concurrent production of hydrogen peroxide and oxidised terpenes. Enormous quantities of these substances arise in forests; the peroxide destroys decaying vegetable matter, and the terpene-products act, in the author's view, as antiseptics.

The early chapters of the book deal with elementary chemistry, and lead up to the consideration of ventilation, fermentation, putrefaction, water supply, and the treatment of sewage. Thence we pass to theories of disease, and so on to the question of disinfection. Remembering that the author is writing for people who are presumed to be ignorant even of very elementary science, we may say, without endorsing all his opinions, that he gives an interesting and readable sketch of the various matters dealt with. It is marred, however, by vain repetitions; thus the author's views upon the question of whether microorganisms or their toxins are the *causa causans* of disease crop up about as often as King Charles's head did in the writings of Mr. Dick. Moreover, much of the book is ancient history; the footnotes teem with references to obsolescent matters dating back to the '70's and '80's of last century, whereas modern results are sometimes overlooked. Thus, although there are some notes upon argon and electrons, radium and radiobes, yet when we turn to the chapter on malarial fever to learn what our author has to say about the work of Ross, Grassi, and others during the last few years, we find him talking of *Eucalyptus globulus*, and telling us that "Laveran and others claim that the disease is produced by certain microorganisms allied to the Flagellata, but this is contested by Tommasi-Crudeli." Certainly this is a book that requires to be read with discrimination. C. S.

Étude sur les Foudroiements d'arbres constatés en Belgique pendant les Années 1884–1906. By E. Vanderlinden. Pp. 79. (Bruxelles: L'Observatoire Royal de Belgique, 1907.)

A PHENOMENON of very frequent occurrence, and one that has been much studied, is the injury occasioned to trees by lightning, and yet we have no satisfactory explanation of the many difficulties that the problem presents. It must be admitted that these inquiries have not always been pursued on scientific lines, and the facts that have been collected and the theories that have been suggested need a thorough sifting and examination. This is the task to which M. Vanderlinden has applied himself with very considerable success. If he has not satisfied curiosity in all directions, he has at least overthrown some popular errors, limiting and indicating the field of strictly useful inquiry.

It has long been held that some trees are not liable to be struck by lightning. M. Vanderlinden examines this assertion, and finds that in Europe no kind of tree is free from this damage. Some kinds, such as the oak, the poplar, and some species of fir, are more frequently injured than others, but there are not sufficient data to show how far this result is effected by situation, by size, by exposure, or by the greater number cultivated. The causes which may be expected to influence the selective power of lightning are also investigated, but with only negative results. Among these we find the character of the soil, the chemical constitution of the timber, the proximity of water surface, the formation of the leaf, the shape of the tree, and particularly the character of the bark. In this last, the author thinks that possibly we have a source of explanation that has not been sufficiently examined. Trees possessing a smooth bark, such as beeches, are less liable to be struck than those having irregular, rugged, roughened surfaces, the external portions of which, becoming dry and dead, are bad conductors of electricity.

Other questions discussed are the manner in which lightning affects the tree, the character of the so-called spiral injuries, the actual combustion of the tree material, and the manner in which men and animals suffer injury when in the neighbourhood of trees that have been struck. The whole forms an admirable examination of a very scattered literature, and accurately exhibits the present position of an unexhausted inquiry. Detailed tables accompany the paper giving information concerning the locality, the number, and variety of trees, reported as being struck by lightning in the years under review.

The Laws of Health. A Handbook on School Hygiene. By Dr. Carstairs G. Douglas. Pp. vii+240. (London: Blackie and Son, Ltd., 1907.) Price 3s. net.

THIS should prove a useful book for school teachers and others interested in the important subject of school hygiene. Anatomical and physiological details are briefly dealt with, as the author justly remarks that there are several excellent manuals dealing with these subjects. On the other hand, the really important and fundamental portions of hygiene as applied to school life, such as ventilation, warming and lighting, and the fittings of the school buildings, the nutrition, ailments and deformities of the pupils, are discussed with sufficient fulness, and these sections are copiously illustrated with diagrams and drawings. In dealing with fatigue, we are glad to see the stress the author lays on a proper amount of sleep, and that he ascribes a good deal of the listlessness and inattention, &c., met with in public elementary schools to deficient sleep. We have nothing but praise for the chapters on the slight ailments of children, the eye and ear, and infectious diseases; even the "fourth disease" is referred to. The only omission we have noted is a reference to the cleansing and periodical disinfection of school premises. R. T. H.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Wehnelt Kathode in a High Vacuum.

THE interesting experiments on the Wehnelt kathode in a high vacuum described by Mr. Soddy in NATURE for November 21, 1907 (p. 53), do not, I think, necessarily conflict with the experiments of either Dr. Wehnelt or myself, nor do they appear to vitiate the conclusions we drew from them.

The experiments by which Dr. Wehnelt showed that the negative leak from a lime-covered kathode was independent of the gas pressure were made with currents much smaller than those used by Mr. Soddy. When currents of the order of an ampere per square centimetre of kathode surface are obtained, the phenomenon appears to be accompanied by a glow round the kathode implying that ionisation in the gas itself is playing a part. Prof. J. J. Thomson ("Conduction of Electricity through Gases," second edition, p. 477) has shown that the potential fall required to produce ionisation by collisions with these large currents decreases rapidly as the current increases, so that even the comparatively small fall of 30 volts quoted from Wehnelt's paper would be sufficient to produce a considerable effect of this kind.

When the pressure of the gas falls below the value required to maintain this glow under the assigned conditions as to difference of potential, pressure, &c., there will be a sudden drop in the value of the discharge current. This appears to be what Mr. Soddy has observed.

I do not wish to imply that the negative emission is in all circumstances independent of the presence of gas in the tube. It is well known that the negative discharge from hot metals is particularly sensitive to hydrogen. In a recent paper (Phil. Trans., A, vol. ccvii., pp. 53 *et seq.*) I have described experiments which seem to prove conclusively that the leak from hot platinum is not due to traces of absorbed hydrogen. As the experiments in gases other than hydrogen show that the negative leak from hot platinum is independent of the pressure at low pressures, it is very unlikely that it is caused primarily by traces of any other of the common gases. These gases only appear to increase the fundamental electronic discharge from the hot kathode by a process involving the occurrence of ionisation by collisions.

The foregoing explanation of Mr. Soddy's result is only offered as a suggestion, for two reasons. In the first place, Mr. Soddy's letter is not sufficiently definite as to some of the salient facts, as, for example, the magnitude of the pressure before the current dropped. In the second place, there is a good deal about the behaviour of these Wehnelt kathodes which is imperfectly understood, and which merits further investigation.

O. W. RICHARDSON.

Princeton, N.J., December 7, 1907.

I AM glad to learn Prof. Richardson's view is much the same as that expressed in my letter to NATURE of November 21, 1907, that the currents in question are carried mainly by the residual gas, not by the electrons expelled from the kathode. Into the views that have been expressed in earlier communications it is therefore unnecessary to enter; but certainly Prof. J. J. Thomson has recognised the important part played by the residual gas, for example, in his lecture reported in NATURE of March 22, 1906. So far as I have yet been able to see, the action of the residual gas in the passage of large currents is much the same whether a Wehnelt kathode or an ordinary electrode is used. There appears to be a definite pressure at which the conductivity is a maximum, and a steady diminution of conductivity when this pressure is either increased or diminished. I do not think, with large currents at least, there is a sudden drop in the discharge current when the pressure is gradually reduced. Of course in the experiment I quoted there was a sudden cessation of the current, but then there is a sudden absorption of the residual gas when the calcium volatilises. The practical difficulties in the way of maintaining a high vacuum in an apparatus containing incandescent bodies by ordinary methods probably led to the earlier view that it was possible to make a vacuum a good conductor by use of an incandescent kathode.

F. SODDY.

British Association Seismology.

AN ancient Bogie has again appeared upon the scene. The object it has in view is to show that the seismological work done by the British Association is practically useless. It owes its existence to Prof. Bruno Weigand, of the Strassburg Kais. Hauptstation für Erdbebenforschung, and it was introduced to the notice of seismologists as a "Begrüssung" at the second International Seismological Conference. On this occasion, as a welcome to the British and other delegates, Dr. Weigand dilated at considerable length upon the defects of the instruments used by those who had kindly cooperated with the British Association. At Strassburg a Milne pendulum did not record so many earthquakes as a pendulum of the Reubeur-Ehlert type, and the records from the first of these instruments indicated very late commencements.

This statement, which month after month and year after year Strassburg has published in the form of registers, has just been emphasised in two new works on seismology, "La Science séismologique," by Comte de Montessus de Ballore, and "Earthquakes," by Prof. W. H. Hobbs. These gentlemen, who I do not think claim to have any practical acquaintance with seismology, candidly tell us that their information came from others. What Dr. Weigand has said about his experiences at Strassburg is no doubt absolutely correct. It is not, however, sufficiently complete; he ought to have added that, although records were not being obtained at Strassburg, they were being obtained from similar instruments in Britain and at stations in other parts of the world. As to whether a seismograph gives satisfactory results or not depends upon its foundation, its adjustment, and, amongst other things, upon the light which is used for photographic purposes. If the light is too high, halation steps in, and all small vibrations are eclipsed in a broadened line.

As Dr. Weigand correctly points out, a factor of great importance connected with the working of a seismograph is the speed with which record-receiving surfaces move. In the early form of the Milne instrument, unless great care was exercised with regard to the light and adjustment of the boom, in consequence of the slowness with which the paper moved, very small earthquakes or preliminary tremors might be lost by the thickening of the line. In the modern form of record-receiving surface, now in use for some years, where the paper moves at 24 cm. per hour, nothing of this sort takes place. The seismograph remains exactly as it was first designed, and with its new recording surface yields results as useful and accurate as those obtained from any other type of instrument, and this it does at a cost of less than 3*l*. per annum. An instrument of higher sensibility than the Milne pendulum cannot be used on soft ground, whilst one which uses a very large quantity of photographic paper per year is beyond the means of small observatories. I am quite content to continue with the instrument I now possess, and, in spite of all criticism, I have no desire to change the same.

JOHN MILNE.

Shide, December 30, 1907.

The Photoelectric Property of Selenium.

IN the letter which appeared in NATURE of December 26, Prof. Minchin does not state what kind of air-pump he used to exhaust the tube containing the light-sensitive selenium "bridge." If he used a mercurial pump, the presence of mercury vapour would explain the great fall in resistance observed.

In a paper published many years ago (Proceedings of the Royal Society, 1876–7, vol xxv., p. 22), I showed that mercury combines at ordinary temperatures with selenium, producing a superficial film of comparatively low resistance. This effect is produced with vitreous selenium as well as with the granular or metallic form.

Selenium converted from the vitreous to the metallic form, in a vacuum free from the vapour of mercury, behaves like selenium rendered light-sensitive in the air in the ordinary way (Draper and Moss, Transactions of the Royal Irish Academy, 1876, vol. xxvi., p. 231). A specimen prepared *in vacuo* was found to have a high resistance, attributable, no doubt, to its spongy form; it was, however, highly sensitive to light.

RICHARD J. MOSS.

The Laboratory, Royal Dublin Society, December 27, 1907.

PROF. MINCHIN's observation (p. 173) that the resistance of his selenium cells, or "bridges," when placed *in vacuo*, becomes enormously diminished is strongly suggestive of internal contact or short circuit, possibly brought about mechanically by the expansion of a small body of confined air in some part of the arrangement. Such short circuits occur not infrequently under ordinary conditions, and may generally be burnt out, and the cell restored to its original state, by the application for a moment of an E.M.F. of 50 volts or 100 volts.

Selenium cells have often been tested in a vacuum. They are supplied commercially, enclosed in highly exhausted glass tubes, by Dr. Ruhmer, of Berlin.

SHELFORD BIDWELL.

Beechmead, Oatlands Chase, Weybridge, December 30, 1907.

Echelon Spectroscope.

WHILST employing a thirty-three plate echelon spectroscope, constructed by Messrs. Adam Hilger for Prof. Schuster, my attention has been directed to a feature of the instrument which needs to be considered in drawing conclusions as to the nature of the light. Using an Arons mercury lamp as the source of light, the bright green line, for example, is resolved by the echelon into a bright and broad principal line with narrower companion lines on either side, and the principal line sometimes shows a narrow dark line not far from its centre.

Like others who seem to have observed the same effect, I supposed that the principal line showed reversal until I found that, on rotating the echelon slowly about a vertical axis, the dark line moves across the broad bright line, and disappears at the side; then another dark line appears at the opposite side, moves across, and disappears like the first; and so on.

These effects are probably produced by interference bands that have not been considered in the theory of the echelon, but have been described by Gehrcke ("Über eine Interferenzerscheinung am Stufengitter," *Annalen der Physik*, xviii., p. 1074, 1905).

If the echelon is tilted about a horizontal axis, parallel to the plates, these secondary bands become more inclined to the vertical, that is, to the direction of the slit, than the ordinary spectrum lines, and their mutual intersection gives to the spectrum lines a screw-like appearance.

A further investigation of these bands is being made, and it is hoped shortly to publish additional details of their behaviour that may help to explain their origin.

H. STANSFIELD.

The University, Manchester, December 26, 1907.

A Point in the Mathematical Theory of Elasticity.

PROF. PEARSON has recently made a statement which if correct is of very great importance to engineers. He declares that the distribution of the stresses due to the water pressure on, and the weight of, a dam is entirely different in the case of a thin slab cut from the dam than it is in the complete structure, because in the former case the slab can expand freely, whereas in the other case this lateral expansion is prevented.

If some portion of the total load was taken by the dam acting as a horizontal beam, this claim would not be challenged by me, but Prof. Pearson states that his proposition is true independent of any action of this character. On a question of pure mathematics it is no doubt very rash for a mere engineer to differ from Prof. Pearson, but as the point is of great practical importance I make the venture, since the statement appears to me to be opposed to the mathematical theory of elasticity as usually taught. The sole difference between the two cases lies in the fact that when the slab constitutes a portion of a complete dam it is subject to a certain normal stress which Prof. Pearson calls $\widehat{yy}$.

Now the characteristic of this stress is that it produces no appreciable shear in planes parallel to itself or in planes at right angles to itself. In fact, Prof. Pearson states that in both cases we may put $\widehat{yx}=\widehat{yz}=0$, and that $\widehat{xz}$ is identically the same in both cases.

Consider, then, the slab, taking first the case in which the sides are left free to expand, but in which stresses are produced in it due to the water pressure and its own weight. Taking $\widehat{xx}$ as the stress parallel to the horizon and $\widehat{zz}$ as that parallel to the weight, we have, Prof. Pearson says, the following equations which these must satisfy:—

$$\frac{\partial}{\partial x}\cdot\widehat{xx}+\frac{\partial}{\partial z}\widehat{xz}=0$$

$$\frac{\partial}{\partial x}\cdot\widehat{xz}+\frac{\partial}{\partial z}\cdot\widehat{zz}+\rho g=0.$$

Under these internal stresses the sides of the slab undergo a displacement $v=f(xz)$, say. This displacement, it should be noted, is everywhere finite and continuous.

Now apply, to the slab, forces $\widehat{yy}=\mathrm{F}(xz)$, so distributed as to cancel the above displacement, and we get the conditions of the equilibrium when the slab forms part of a complete dam.

Next consider these forces $\widehat{yy}=\mathrm{F}(xz)$ to act alone. The characteristic of the internal stress then produced is, as already pointed out, that $\widehat{yx}=\widehat{yz}=\widehat{zx}=0$, so that the conditions of internal equilibrium reduce to

$$\frac{\partial}{\partial x}\cdot\widehat{xx}=0$$

$$\frac{\partial}{\partial y}\cdot\widehat{yy}=0$$

$$\frac{\partial}{\partial z}\widehat{zz}=0.$$

These and the boundary conditions are obviously satisfied by putting $\widehat{xx}=\widehat{zz}=0$ and $\widehat{yy}=\mathrm{F}(xz)$ throughout. If, at the same time, the conditions of continuity are satisfied, this should be the solution. It would seem that the continuity of the material is necessarily satisfied by the fact that v, the displacement of the surface under the forces, is everywhere finite and continuous. If I am right in this, the stresses $\widehat{xx}$ and $\widehat{zz}$ should be the same in the complete dam as they are in the slab, but Prof. Pearson says this is not the case.

H. M. MARTIN.

Croydon, December 22, 1907.

LORD KELVIN: AN APPRECIATION.

LORD KELVIN occupied for a long time a unique and cosmopolitan position as the universally venerated head of the physical science of the age. Where he did not himself create new knowledge, he constantly inspired discovery. Always accessible, always keenly attracted by the work of others and ready to learn, with universal interests, and mental activities untiring even to the end, he for more than half a century was the main practical scientific influence in this country; while for the latter portion of this period his point of view, through the generous advocacy of Helmholtz and other fellow-workers, became naturalised throughout the world. He was representative, more than any other person, of the combination of abstract scientific advance and mechanical invention which led to the still recent electrical transformation of modern engineering; he sustained and elevated industrial progress by the fire of intellectual genius.

In his earliest scientific work he was the interpreter of Faraday, at a time when support and mathematical elucidation of the intuitions of his genius were much required. In addition to special advances of his own into new domains, such as the theoretical prediction of electric vibrators and their laws forty years before they were utilised by Hertz, and the assertion of the thermochemical principles controlling voltaic batteries, he early became the founder, or rather restorer, of a school—the modern British school of physical science—which aims at moulding the course of general physical theories, even of abstract mathematics itself, by aid of intuitions drawn from exact formulation of the observed course of nature, assisted by illustrations such as may be gleaned even from the study of artificial practical mechanisms. A typical example of this kind of activity was the vortex theory of the molecular structure of matter, which he built on Helmholtz's fundamental discovery of the absolute permanence of vortical motions in a frictionless fluid medium; to a superficial view this is now in the main only an abandoned theory; but those most conversant with the history of the coordination of physical activities, which is the ultimate aim of the science, will allow that the vortex-atom theory was the first illustration that included any adequate idea of the type of interaction of the material atoms and the universal æther in which they subsist, and as such has been the direct ancestor of all subsequent advances towards the mental representation of ultimate physical reality.

In particular Lord Kelvin was the inspirer of Clerk Maxwell, his avowed pupil in all important respects, and was thereby an essential factor in that consolidation and reconstruction of physical science, on a refined electric, or subelectric, basis, which is still in progress, and has been a main glory of recent years.

In another region of his activity he combined delicate mathematical methods of investigation with broad industrial application of the results. It was largely the determined and prolonged struggle to carry through to success the enterprise of Atlantic submarine telegraphy that led to the invention of those appliances for exact measurement which afterwards made general electrical engineering feasible. In this new branch of applied science, his active perception of the essentials for progress assumed the form of generalship; most of the details of development naturally came from others, but he was always ready to emphasise the salient problems, and to acclaim, early and enthusiastically, such nascent inventions as would be pertinent to their mastery.

An example of his firm grasp of the connection of theory and practice is afforded by his work on the prediction of the tides. The recognition that the tidal oscillation is compounded of a limited number of simple harmonic constituents, of known periods, was an outgrowth of physical astronomy, and is mainly due to Laplace; the principle that any oscillatory movement arising from permanent causes is resolvable into simple harmonic constituents, and is to be treated on that basis in all exact science, was the fundamental contribution of Fourier. It remained largely for Lord Kelvin to combine these two principles, supplying the mechanical contrivances necessary for rapid computation, and thereby to control all that is requisite to be known about the tides, while avoiding the complexities, arising from the irregular forms of the oceans, that would choke any attempt at direct dynamical calculation in detail. Other examples of the same faculty are afforded by his fundamental improvements in ships' compasses and in deep-sea sounding; while his life-long work on problems relating to the speed of ships, the waves they produce and the energy lost in their formation, has been a chief influence in the rational study of the conditions and limitations of marine propulsion.

He will be known to future ages, possibly even more widely, as a main pioneer and creator in the all-embracing science of energy, the greatest physical generalisation of the last century. He was the first to grasp and insist on the universal dynamical, even cosmical, importance of the principle of reversible cyclic processes, which sprang almost in advance of its time from the genius of Carnot. Concurrently with Clausius he soon supplied the necessary logical adjustment of its thermal application; and by his own work, and his collaboration with Joule, he largely constructed the practical essentials of the fundamental, because unifying, modern science of thermodynamics. The depth and generality of the conceptions, which pervade his fragmentary and often hurried writings on this subject, have been recognised sometimes only after the same ideas have been slowly evolved afresh, and acclaimed in their varied applications as advances of the first rank, on the part of other investigators.

In Lord Kelvin there has passed away one of the last commanding figures, perhaps in genius and the variety of his activities as great and memorable as any, in the scientific and intellectual development of the nineteenth century. J. L.

LORD KELVIN AND THE UNIVERSITY OF GLASGOW.

AT a college meeting in 1891, Sir William Thomson said :—" I have been a student of the University of Glasgow fifty-five years to-day, and I hope to continue a student of the University as long as I live." In 1899, when he retired from the professorship which he had held for fifty-three years, Lord Kelvin (as he had then become) applied to the Senatus Academicus to be appointed a research student. His name thus remained to the last upon the College roll, and in the list of those who have a right to pursue investigations in the laboratories of natural philosophy.

An academic connection so long, so intimate, and so fruitful is not severed without a deep sense of personal bereavement on the part of the survivors. The university, of which, since 1904, Lord Kelvin was the venerated head, was plunged into deep mourning by the news of his death. Special meetings of the court and senate, and of the executive of the general council, were held, and passed minutes of regret and sympathy. The regular classes were suspended; the courts were silent; the flag that usually waves high over the Kelvin drooped at half-mast. The new institute of natural philosophy which the Chancellor, at its opening in April last, took such pride in displaying to the Prince and Princess of Wales, was closed; and throughout the city, which regards the university's glories as its own, the signs of mourning were everywhere visible. Telegrams and messages from local public bodies, learned societies, and representative men, arrived hourly at Gilmorehill. The note of admiring affection for a great fellow-citizen was prominent in these, for Lord Kelvin was a freeman of the city, and a leader in its technical enterprises, no less than a teacher and investigator in the university. Hence came about a certain wistful acquiescence, on the part of Glasgow men, in the arrangement whereby he was to be laid to rest beside his intellectual peers in Westminster Abbey. The national tribute was felt to be right and fitting; though not a few were hoping that his burying-place would be in the City Necropolis, where his father and others of his kindred are laid.

In order that expression might be given to the *genius loci,* a memorial service was held by the university in the Bute Hall on Sunday afternoon, December 22, simultaneously with that held at Largs before the funeral company started on their journey southward with Lord Kelvin's body. The hall, which serves as the university chapel, was draped with black, and filled with a congregation of nearly two thousand mourners. All stood, as to the strains of the Dead March the long academic procession, representing the court, senate and other teachers, general council, and students, preceded by the ancient mace swathed in crape, filed in and occupied the stalls and platform. Many of the congregation wore the graduate's robe, and students, men and women alike, wore their undergraduate gowns of scarlet. The Vice-Chancellor, Principal MacAlister, presided, and read the lessons (Job 28, and 1 Corinthians 15) from his stall. The simple service of prayer and praise was conducted by two professors of the faculty of divinity (Drs. Reid and Cooper), and was marked by devout resignation, and by thanksgiving for a great example, rather than by the gloom of unrelieved mourning. The anthem Nunc Dimittis, sung by the university voluntary choir, and a special prayer for the university, that in it all science and scholarship might be consecrated to the honour of God and the promotion of human welfare, gave the characteristic notes. There was no sermon or funeral discourse; this will more fittingly be given hereafter. The venerable Lord Blythswood, the Lord Provost, Sir William Bilsland, the president of the faculty of physicians and surgeons, Admiral Bearcroft, Dr. William Wallace, Dr. George Neilson, and many other men of note in the west of Scotland were present. Relatives and others connected with the Chancellor's family, and the officials of the electrical manufacturing firm of Kelvin and White, which he founded, occupied seats near the daïs. The funeral march of Chopin closed the ceremony, as the university procession passed out of the hall into the darkness of the winter afternoon, and the silence of the courts that the Chancellor had loved so well.

Telegrams of condolence with the university were received during the week from Mr. Marconi, Glacé Bay; the University of London; University College, Nottingham; the Duke of Argyll, representing His Majesty the King; the Faculty of Science of the University of Rome; Prof. Egoroff, director of the Central Chamber of Weights and Measures, St. Petersburg; Principal Voinarowsky, of the St. Petersburg Electrotechnical Institute; the Chancellor of the Exchequer, Lord Rector of the University; Sir James King, Bt., Dean of Faculties; Rector Borgman, of the Imperial University of St. Petersburg; the Russian Physico-chemical Society; Rector Syniewski and professors of the Polish Technical College, Lvov; Rector Bagatey and professors of the University of Charkow; Rector de Mbinski and Senate of the University of Lemberg; the Royal College of Surgeons of Edinburgh; the Senatus of the U.F. Theological College, Aberdeen; the students of physics of the University of St. Petersburg; President Dini, and the Faculty of Science of the University of Pisa; the University of Liverpool; the Ambassador of France; the Senatus of the University of Aberdeen; the St. Petersburg Society of Electrical Engineers; the pro-rector and professors of the University of Jurjew (Dorpat); &c.

FLUCTUATIONS IN HIMALAYAN GLACIERS.[1]

NEARLY half a century ago the glaciers of the Alps began to shrink. Their retreat was most rapid in the decade following 1860; since then it has been generally slow, and of late years the ends have been mostly stationary or oscillating. Traditional and other evidence exists of earlier fluctuations, and it suggests that the cycle of change is completed in about half a century. For some time past these fluctuations have been watched in various places, and an International Commission of Glaciers is now occupied in collecting and systematising evidence bearing on the secular and annual oscillations of the ice.

The glaciers in other parts of the world—the Caucasus, parts at least of the Himalayas, and of North America, even of the southern hemisphere—show signs of a recent retreat. As this is indicative of more than local causes, extended and accurate observations have become more than ever desirable. In 1905, Mr. Douglas Freshfield, so well known as a scientific geographer and explorer, urged the authorities in India to record the secular movements of the principal Himalayan glaciers. They undertook the task, and charged the Geological Survey with the collection and distribution of the observations. Last year twelve glaciers were examined, six in the Kashmir region, surveyed by Mr. H. H. Hayden; two in the Lahaul, and four in the Kumaon.

The report before us gives a general account of each glacier and its past history, so far as this can be ascertained, and describes the marks placed to measure its future movements, with sketch-maps and reproduced photographs. In the Hunza region, the glaciers reach lower levels—from seven to eight thousand feet—than in the Lahaul and the Kumaon, where they do not descend below about eleven thousand feet. They may, as usual, be divided into two classes—those flowing in valleys transverse to the trend of the range, and those the course of which is approximately parallel to it; the former, which have the more rapid slope, being the shorter, but descending lower; the latter, such as the Hispar and the Biafo, which attain lengths of twenty-four and thirty-nine miles respectively, being arrested at about ten thousand feet.

Of the six observed, no certain evidence of gain or loss could be obtained about the Barche and Minapin. The great Hispar glacier, traversed by Sir Martin Conway in 1892, has since then slightly retreated. The Hinarche glacier, the lower part of which was explored by the same traveller, has evidently advanced. This, however, may not mean much, for the people of the country assert that it fluctuates in a cycle of six years, advancing and retreating over a distance of some three hundred yards, and was at its maximum when Mr. Hayden saw it. The Yengutsa glacier, however, has gained about two miles in length since Conway's visit, and this, according to native testimony, by a sudden advance about two years before Mr. Hayden's visit, since when it has been stationary. The Hassanabad glacier, a year earlier, made a yet more rapid and extensive progress, for in the course of two and a half months its length was increased, on the lowest estimate, by six miles, but it is now stationary. The chief official in Hunza also stated that many years ago it had reached, and then retreated from, its present position. The accompanying illustration, from one of the sixteen excellent reproduced photographs in the first part, shows the end of the glacier at the time of the surveyors' visit.

The two glaciers in Lahaul, surveyed by Messrs. Walker and Pascoe, are both in the Chandra valley—one of them, the Sonapani, ending at about 13,000 feet above sea level, has in advance of it a desiccated lake-bed dammed by an old terminal moraine, below which are three similar moraines. The other glacier, the Bari Shigri—the boulder covered—has been already noticed more than once by travellers, and their accounts show it to have retreated considerably during the last seventy years. Of the four glaciers in Kumaon, examined by Messrs. Cotter and Brown, the Pindari is already well known to tourists. It descends from lofty peaks, but the ice appears to move rather slowly, and is not much crevassed. It is said to be retreating, but the surveyors could not succeed in obtaining any exact details. The Milam glacier was described early in the last century as the source of the Ganges. It is now about twelve miles long, but, as old moraines show, was once larger. The terminal ice-cave, about fifty years ago, was some 800 yards in advance of its present position. The Shankalpa glacier is much crevassed, and is probably retreating, though no old moraines are found much in advance of its present snout. Of the fourth, the Poting glacier, old terminal moraines exist lower down the valley, but no evidence was found of a recent retreat. Here also the excellent photographs and sketch-maps will make future movements of the ice easily detected.

Hassanabad Glacier.

These fluctuations, whenever they may occur, must be due either to an increased supply on the upper snow-fields, or to a diminished waste of the ice on the lower parts, or to a combination of both; though sometimes, as in the case of the Glacier Blanc and Glacier Noir in the Pelvoux district of Dauphiné,[1] one ice stream may be advancing while another is in retreat. That,

[1] Records of the Geological Survey of India, vol. xxxv., parts iii. and iv. 1907. Containing a Preliminary Survey of Certain Glaciers in the North-west Himalaya, by Officers of the Geological Survey of India. Part iii., Notes on Certain Glaciers in North-west Kashmir, by H. H. Hayden. Pp. 15; 23 plates. Part iv., Glaciers in Lahaul, by H. Walker and E. H. Pascoe; Glaciers in Kumaon, by G. de P. Cotter and J. Caggin Brown. Pp. ix+18; 26 plates. however, may be a consequence either of a difference of alimentation or of the rate at which the ice is moving. Thus long and careful observations are necessary of the latter, of the nature of the advance or retreat, and of other matters, before sufficient data can be obtained to allow of the results obtained in different regions being compared, and their bearing on questions of general meteorology ascertained, but the investigation now begun in the vast northern mountain barrier of Hindustan must ultimately prove to be highly valuable.

T. G. BONNEY.

TIDAL INVESTIGATIONS IN CANADA.

THERE are few countries which possess so large an extent of navigable land-locked waters as does Canada. In such situations the tidal currents are apt to assume great importance, and the prediction of the tides is a task of great difficulty. The Canadian Government has naturally paid much attention to this complex subject, and they are fortunate in having so able an officer as Mr. W. Bell Dawson to place in charge of the operations.

In a paper on "The Currents of the Belle Isle Strait" (Government Printing Office, Ottawa, 1907), Mr. Dawson gives an account of the investigations carried out in the seasons of 1894 and of 1906. The run of the tide in the strait in places is sometimes apparently capricious, but Mr. Dawson shows that in many cases the abnormalities become explicable when properly examined. The results should prove of much value to mariners.

Mr. Dawson has also contributed a paper on "Variations in the Leading Features of the Tide in Different Regions" to the Royal Astronomical Society of Canada (July–August).

It is obvious that in the vast tract of navigable Canadian waters, the cost would be prohibitive of erecting tide-gauges at all the places at which tide-tables are wanted. Hence the calculation of the tides by reference to neighbouring harbours becomes a matter of necessity. It is a subject to which Mr. Dawson has already paid much attention. The ordinary rough rule is to multiply the range of tide at the port of reference by a constant factor, and to apply a constant correction to the times of high and low water. But such a simple rule often leads to enormous errors of prediction. Now Mr. Dawson shows that this factor and correction of time should not be regarded as constant, but should be taken as variable with the position of the moon.

The three points in which the position of the moon is influential are phase, declination, and parallax. These undergo variations in months of slightly different lengths, called the synodic, the tropical, and the anomalistic months. The corrections should be dependent on all these three periods, and thus they acquire a considerable amount of complexity. The most interesting point in Mr. Dawson's investigation is that he finds that, in some cases, it is one of the three factors which is dominant, and elsewhere it is another. So much is this the case that it is often possible to omit all corrections except those which are periodic in one of the three months. The determination of the dominant factor appears to be empirical, and no physical explanation is assigned for this curious conclusion. May we not suspect that when one or two of the monthly variabilities in the corrections are evanescent as regards time and height of high and low water, they are really affecting the tidal currents?

In any case these partially empirical corrections are found to be satisfactory in providing fairly trustworthy tide-tables, by reference to ports where there are tide-gauges and directly computed tide-tables.

G. H. D.

EDUCATION AND RESEARCH IN INDIA.

THE battle between those who believe the sole duty of our professors in universities, colleges and other high educational institutions is to teach, and the best professor one who devotes the whole of his time to teaching, and those who believe that the highest and most fertile kind of teaching is that carried on by a professor who is an investigator as well as a teacher, has been fought out on many occasions and in many places.

Fortunately the latter view in late years has largely prevailed over the former, though the battle has still to be actively carried on in many places. The universities of Europe, at all events those which are the most progressive and of greatest importance, have accepted the fact that in the selection of their professors they must now take only such men as have given distinct proof of capacity for original work in one or other of the great departments of knowledge, and who may be expected to continue their original researches at every possible opportunity.

Unfortunately, in England this spirit has not always been acted on, and the condition of a good many of the institutions devoted to the highest culture is in the matter of research most unsatisfactory, and compares most unfavourably with institutions of similar grade on the Continent.

Nor, indeed, is this lack of original work in England confined to what may be called centres of the highest intellectual activity, but it largely pervades educational and technical institutions of all grades, and it is stated that in many cases where the management of such institutions is in the hands of committees, whose members are distinguished mainly by their success in trade, original research on the part of the staff is practically barred, and, if a professor or teacher is known to be an enthusiastic investigator, he is at once considered to be one who is not doing full justice to the students entrusted to his charge.

It is to be hoped that such instances will become more and more rare as the proper functions of a teacher are better understood, and it is for our universities, and for all educational institutions more or less controlled or influenced by Government, to take the lead in this matter and to insist on the inseparability of research from the highest branches of teaching.

An opportunity of taking such a stand and of doing an almost incalculable amount of good to the higher teaching of a country now appears to lie in the hands of the Indian Government. For a good many years India may be said to have been suffering from an educational unrest, for it was understood by all those who had studied the subject that Indian education had been working on unfortunate lines. Lord Curzon, during the time he was Viceroy, was the first who boldly faced a very difficult problem, and under his direction Indian education was placed upon a much more satisfactory basis. The changes brought about by Lord Curzon's action were very numerous; primary education was largely extended and made more practical, female education was fostered in every possible way, secondary education was also improved, and, lastly, university education was dealt with. Under a new Indian University Act a complete set of new regulations has been prepared, and speaking generally of these regulations it may be said that they have aimed at, first, the influencing of the characters of the students in the colleges and high schools, and, secondly, at securing a practical rather than a book knowledge of the subjects dealt with.

It may also be mentioned that, in cases where a science is being studied, the regulations require each student to have had personal practical instruction and so far as possible to be practically examined. In the case of the higher degrees, such as D.Lit. and D.Sc., original work on the part of the student is an essential preliminary to his getting the degree, and even with lower degrees provision is made for anyone showing any practical originality to be excused a certain part of the usual theoretical book work.

It is, of course, understood that these regulations will require a stronger professorial staff to man the colleges of the universities than if merely theoretical instruction had to be given. A good many of the colleges attached to the Indian universities, indeed all the largest and most important, are directly managed by the Indian Government, and it is on the action of this body that to a large extent the effective working of the new Indian University Act will depend. The colleges must be dealt with liberally in the matter of staff, or the Act will be inoperative, for if Government colleges, with the resources of Government behind them, do not take the lead, it is useless to expect any others to work up to the desired standard.

An important article in the influential Indian newspaper, *The Pioneer*, of October 31, describes the condition of things in the Indian colleges as being rather critical at the present time. The following is an extract from the article:—

"The first commotion created by Lord Curzon's measures of University Reform has died away long ago; but it must not be overlooked that the work merely initiated by new Acts and sets of Regulations has yet to be actually done, and that rather momentous issues depend on the spirit in which it is done. We are reminded of this by certain papers of a controversial nature, written by members of the Bengal Educational Service, into which we have been allowed an insight. The controversy on the face of it would appear to be one of purely local interest, turning on the question whether the present professorial staff of the Presidency College, Calcutta, is adequate to the demands made on College teaching by the new Regulations of the University. But a perusal of the papers shows that matters of deep importance—the future of all teaching, learning and research in this country are involved in the discussion. An educational officer specially deputed by Government to report on the state and requirements of the Presidency College maintains that if the College is to satisfy the new demands on teaching the Science Professors must at once largely curtail the research work in which they have been indulging in the past, and another officer, closely connected with the College, in endorsing these remarks, tells us that research in the Presidency College has of late become 'something of a bogey,' even demonstrators and assistants being 'involved in researches.' This, he assures us, has led to neglect of pure teaching, and the first measure demanded by the new era of higher education is that the entire staff, from the senior professors downwards, should put aside their researches which, as far as the interests of the College are concerned, are not only useless but positively injurious. Against these views the Science Professors maintain that they and their subordinates have not neglected, and do not mean to neglect, 'teaching,' but that research and training in the methods of research constitutes an important, in fact essential, element in all higher stages of instruction. It is evident that what is being discussed here is no less than the entire future character of the upper sections of our large Colleges and the standing of their Professors. Is it to be a principle recognised, and eventually to be enforced, that Professors lecturing to B.A., B.Sc., M.A., and M.Sc. classes must limit themselves to *mere* teaching, whereby the antagonists of research evidently understand the assiduous inculcation into the minds of students of established facts and theories with the special aim of training the recipients of knowledge rapidly to reproduce in writing at examination time as much of the matter committed to memory as they can possibly manage; or should higher teachers in our Colleges be encouraged, possibly definitely expected, to combine with such teaching efforts to rouse in their students the appetite and capacity for original work and research? The latter alternative, of course, would imply that the men to whom higher teaching is entrusted should not be mere schoolmasters, but should themselves take some active part in the advancement of knowledge and learning."

It is greatly to be hoped that the Indian Government will seize the opportunity and properly strengthen all its colleges with professors who are investigators as well as teachers, and thus at once set a proper standard for the highest education in India. On the action taken now the future of Indian education largely depends, and on the giving of a proper education to the future leaders of the Indian community will depend the peace, progress and prosperity of our Indian Empire.

NOTES.

WE understand that Sir Norman Lockyer has been in communication with the French Minister of Public Instruction with the view of securing active support for the science section of the Franco-British Exhibition to be held in London this year. The Minister has referred the matter to the Paris Academy of Sciences, and it is hoped that the result will be a satisfactory and substantial representation of scientific work in France at the forthcoming exhibition. The various divisions of the British section of the exhibition were described in NATURE of November 21, 1907 (p. 67). This section was instituted with the assistance of the British Science Guild, and is in the course of organisation by a committee including leading representatives of all branches of pure science. The British committee has been given an area of eleven thousand square feet, gratis, for the purpose of exhibiting apparatus, appliances, and results of scientific research. This free grant of space is equivalent to a gift of about 3000*l*., and in addition the committee has been granted a sum of money in aid of the science section. The executive committee of the British side of the exhibition has thus provided a very favourable opportunity of exhibiting some of the achievements of scientific research and enlightening the general public as to the instruments or methods employed. It is the duty of the men of science of Great Britain to show appreciation of this generous treatment by assisting the committee in every way within their power to make the science section of the exhibition instructive, illuminating, and inspiring to the many thousands who will visit it.

SIR GEORGE DARWIN, K.C.B., F.R.S., has been elected a foreign correspondant of the Paris Academy of Sciences in the section of geography and navigation. Lord Brassey has also been elected a correspondant of the academy.

PROF. RAPHAEL MELDOLA, F.R.S., past-president of the Chemical Society, has been elected president of the Society of Dyers and Colourists in succession to the late Sir W. H. Perkin.

IT is announced in *Science* that Mr. Andrew Carnegie has added 400,000*l*. to the endowment of the Carnegie Institution of Washington.

SIR OTTO JAFFE, president of the Belfast Natural History and Philosophical Society, has taken preliminary steps to form a committee to honour the memory of Lord Kelvin by erecting a statue or other suitable memorial in his native city of Belfast.

WE regret to see the announcement of the death of Sir Alfred B. Garrod, F.R.S., in his eighty-ninth year. Dr. Garrod graduated as M.D. of the London University in 1843, and became a Fellow of the Royal College of Physicians in 1856. He was elected a Fellow of the Royal Society in 1858, and received the honour of knighthood in 1887.

THE Belgian Government is organising an Arctic meteorological expedition which will start next summer. The *Revue scientifique* announces that the expedition will be under the command of M. Georges Lecointe, director of the Royal Observatory at Uccle.

REUTER'S representative has received details regarding the Antarctic expedition which is being organised by Dr. Jean Charcot, who hopes to start in July, and expects to be absent for two years. Sufficient provisions to last three years will, however, be taken. The expedition is bent on scientific work. The best route to the Pole is, Dr. Charcot thinks, by way of the Ross Barrier, but this he regards as belonging to English explorers. and does not propose to travel that way. On reaching the Antarctic it is proposed to return to Graham Land, and endeavour to reach Alexander Land, where it is hoped a barrier similar to that of Ross's will be found. The expedition will then endeavour to go as far south as possible. An important part of the equipment will be motor-sledges, which are being built by the Marquis de Dion. With these sledges experiments will be made in the Alps during this winter. The ship for the expedition will be specially strong in view of the ice pressure, and will be of barquentine rig, with compound engines of 550 horse-power. She is to be 135 feet in length, with a beam of 30 feet, and will carry 230 tons of coal and 100 tons of provisions. The crew will consist of twenty-two men, ten of whom were members of Dr. Charcot's last expedition. The scientific staff, in addition to the leader, will number three naval officers, two zoologists, one geologist, and one physicist for magnetic and photographic work. The French Chambers have voted 12,000*l.*, while another sum of equal amount will also be voted by Parliament. Private subscriptions have yielded 2600*l.*, and Dr. Charcot is endeavouring to get a further 3400*l.* The Academy of Sciences has prepared the scientific programme, and the Committee of Missions of the Ministry of Public Instruction has drawn up a favourable report on the subject of the proposed journey. The Marine Department is giving the necessary coal and a valuable collection of scientific instruments, while the Oceanographical Institute of Paris, founded by the Prince of Monaco, is also helping.

IN his presidential address to the Royal Society on November 30, 1907, Lord Rayleigh referred to a movement to promote the publication of standard scientific works in embossed type suitable for the use of the blind. Mr. H. M. Taylor, F.R.S., has written out the whole of Mr. C. Smith's "Elementary Algebra" in Braille type; and the embossed edition of this work, consisting of five large royal quarto volumes, containing in the whole eight hundred pages, has been published by the British and Foreign Blind Association at the price of 16*s.* 6*d.* The blind who are interested in subjects of a scientific character are heavily handicapped, because an embossed copy of any book occupies a much larger space than a printed copy of the same book, and is therefore expensive to produce. The result is that though books in embossed type are needed on such subjects as mechanics, physics, astronomy, chemistry, and geology, very few blind persons could afford to purchase these books if their prices were comparable with that at which the embossed edition of the algebra has been published. Accordingly, a fund has been formed to assist the publication, for the use of the blind, of embossed books on scientific subjects at prices which would not be so high as to be almost prohibitive. This object would be attained by making grants from the fund to Braille printers towards the cost of embossing the plates from which the books are printed. It is thought that 600*l.* or 800*l.* would form a fund large enough to test the usefulness of the scheme, and would be ample for an experiment to last three or four years. The sum of about 300*l.* has already been subscribed or promised in support of the scheme. Donations may be paid to the secretary, Mr. H. M. Taylor, F.R.S., Trinity College, Cambridge, or direct to the "Embossed Scientific Books Fund" at the Cambridge branch of Messrs. Barclay and Co.'s Bank.

THE weather for 1907 affords several features of interest, and the results obtained for London from the observations of the Meteorological Office probably differ somewhat from the common expectation. The aggregate rainfall for the year is 19·5 inches, which is 4·9 inches less than the average for the past thirty-five years. The only months with an excess of rain were April and December. Rain fell on 162 days, and one of the special features of the year was the great frequency with which rain occurred. In October rain fell on twenty-two days, although the aggregate rainfall for the month showed a deficiency of 0·47 inch on the average. The mean temperature for the year was 50°·2, which is 0°·1 above the average. The highest mean in any month was 60°·8, in August, and the mean for each of the three summer months was considerably below the normal. The lowest monthly mean was 38°·5, in February, and with this exception all the six winter months had a temperature in excess of the average. The total range during the year was 57°, the highest temperature being 80°, in September, and the lowest 23°, in January. There were during the year only thirty-four frosty nights, and of these thirty-three occurred in January to March. The sun shone for 1234 hours, which is ninety hours in excess of the average. The Registrar General's returns show that the death-rate for the year was 15·2 per 1000 persons living; this is probably the lowest on record, so that however unpleasant the weather for the year may have proved, there has been a decided gain on the score of mortality.

THE contents of the first three numbers of the Records of the Indian Museum include a large number of papers, chiefly devoted to invertebrates, among which attention may be directed to a series, by Dr. Annandale and others, on the fauna of brackish-water pools at Port Canning.

IN the course of a paper on a collection of fishes from Victoria (Australia), published in the October (1907) issue of the Proceedings of the Philadelphia Academy, Mr. H. W. Fowler describes two new species of sea-horse, which, together apparently with the New Zealand *Hippocampus abdominalis*, are referred to the new subgenus Macleayina, on account of the greater number of long dorsal fin-rays in comparison with the more typical representatives of the group.

THE barnacles in the collection of the U.S. National Museum form the subject of a long paper by Dr. H. A. Pilsbry constituting Bulletin No. 60 of the museum. Only the pedunculate group and the members of the sessile family Verrucidæ are, however, dealt with in this communication. Hitherto the pedunculate species recorded from American waters number about a dozen, while the Verrucidæ have been unknown; the author is now enabled to raise the numbers of the former group to fifty-six, and to add five species of the latter.

It has long been a matter of common knowledge that squirrels aid the forester by burying nuts, of which some sprout and ultimately develop into trees, but that he is also indebted to earthworms for aid of a similar nature is claimed by Mr. E. A. Andrews in the November (1907) number of the *American Naturalist* to be a new discovery. In America it appears that the dry, flat fruits of the silver-maple are frequently employed by worms to plug the apertures of their burrows, in the fashion long since described by Darwin. In districts too dry for them to germinate under ordinary conditions, a certain proportion of maple-seeds thus drawn into their holes by the worms were found to sprout and grow into seedlings, and although these ultimately perished under the influence of the late summer drought, the author is of opinion that under less unfavourable conditions a certain number would survive. Worms, he concludes, "probably more than amend, by planting trees, the damage with which they are credited through destroying seedlings in gardens."

Early in 1906 Prof. W. B. Benham communicated to Nature (vol. lxxiii., p. 559) a note to the effect that the doubts expressed a short time previously with regard to the alleged carnivorous habits of the kea were not justified by the facts. Since that date he has been endeavouring to obtain more definite information on the subject, and the results of his investigation are published in the Transactions of the New Zealand Institute. A second investigator, Mr. G. R. Marriner, of Canterbury College, has likewise been pursuing inquiries, apparently independently, on the same subject, a summary of which is also published in the same volume. Both writers are in accord in regarding the accusation against the kea of worrying sheep for the sake of feeding on their flesh as now fully proved, and both likewise agree that the prime object of attack is not the kidneys and kidney-fat. Mr. Marriner, in addition, records some very interesting facts concerning the breeding-habits of this bird, notably that the eggs are laid and the young reared in mid-winter at an elevation of between three and four thousand feet above sea-level, where the winter cold is intense.

Rats, in connection with plague, form the subject of a pamphlet and two articles recently published in India. In the first number of Memoirs of the Indian Museum, Dr. W. C. Hossack gives an account of the species of rats found in Calcutta, illustrated with several coloured and other plates, and a key to their identification. The so-called Indian mole-rat (*Nesocia bengalensis*) appears to be the species most abundant in the Indian metropolis, where it is probably the one most concerned in the dissemination of plague, as it is extremely common in grain-stores, which are notorious as being centres whence the disease has spread. Originally a field-hunting, grain-storing species, it has in Calcutta become a parasitic inhabitant of stables, grain-stores, &c. "Aids to the Identification of Rats connected with Plague" forms the subject of a pamphlet, by the same author, published by the trustees of the Indian Museums, and printed at the Pioneer Press, Allahabad. Finally, to the third part of another new zoological journal—Records of the Indian Museum—Captain C. A. Gourlay contributes a note on the rats of Dacca, eastern Bengal, where the black rat (*Mus rattus*) is the most abundant species.

No. 18 of the *Bulletin biologique* (Dorpat) contains an editorial article on the need for exhibitions devoted to modern biological technique. It is pointed out that the progress of biological science is now so dependent upon improvements in technique, while the methods in use are so varied and elaborate, and demand an acquaintance with so many branches of science, that without exhibitions of this nature it is almost impossible for workers to keep thoroughly abreast of the times, or to find out in what direction improvements are required. Histology, for example, cannot advance without the aid of chemistry, while the physiologist is largely dependent upon the aid of the mechanician. Similarly, there is a close connection between the study of the tissues and minute structure of animals and optics. It is recommended that an exhibition of this nature should be divided into the following main sections:—(1) methods of collection; (2) the care of living animals and plants; (3) preservation of specimens; (4) transport of living organisms; (5) anatomical methods; (6) methods of microscopic work; (7) methods of studying development; (8) methods of chemical investigation of animal structures; (9) physiological research; (10) the methods of bacteriological investigation; (11) methods of illustration; (12) modelling; (13) museum installation and arrangement.

To the *Times* of December 26, 1907, Sir T. Digby Pigott contributes further information concerning the luminous owl recently seen in Norfolk, from which it appears that the phenomenon was observed by several independent witnesses. A letter from a Welsh fisherman is quoted to the effect that on the night of December 12, 1907, the woollen garments of the writer and his companions were observed to be luminous, and that such phenomena have long been known is demonstrated by an extract from a work published in London in 1704. A very important piece of evidence appeared in the issue of the *Times* of the same date, with the signature of "A Country Teacher." In this the writer states that in February, 1890, he first noticed a luminous appearance in a pair of barn-owls, which then inhabited a farm-building near his school, in Somersetshire. "I saw the luminosity several times," he writes, "but it was not so bright as Sir Digby Pigott's correspondent observed, and usually lasted only for a short time, though I could see the birds flying about after the luminous gleam had ceased. I never saw both birds luminous at the same time, and I am unable to say whether the male or female, or both, possessed this power. . . . I thought the luminosity might be connected with the electrical condition of the atmosphere, but though it was usually brightest and lasted longest when the electrical potentiality of the atmosphere was highest, it was not always so. . . . I could observe nothing to indicate that the luminosity was under the control of the owl." The writer also mentions that the phenomenon was perfectly familiar to the children in his school, who spoke of the bird as a "glim ullert."

The importance of cacao cultivation in Grenada is evident from the report for 1906–7 of Mr. R. D. Anstead, superintendent of the botanic station. Plots have been established in five districts with the view of instructing peasant proprietors, and some of the planters have laid out large experimental areas on their estates for carrying out manurial tests. Seedling sugar-canes, of which the variety D. 95 was distributed, cacao, coffee, and bananas were the economic plants chiefly in demand, also seeds of Castilloa and Hevea. A feature of the report is the inclusion of several photographs. The collection of palms, amounting to eighty named species, contains many valuable kinds for the seeds of which there is a brisk demand.

PROF. A. C. SEWARD contributes to the Transactions of the Geological Society of South Africa, vol. x., a description of a collection of Permo-Carboniferous plants from Zululand and Natal. The material contained a large number of specimens referable to Glossopteris, but few of the forms were distinct. Sporangia were discovered on some of the leaves of *Glossopteris indica*, but this does not preclude the possibility of the genus being a pteridosperm; in this respect the association of small winged seeds with the leaves was noted. Other specimens referred to are the genera Phyllotheca, Bothrodendron, Vertebraria, and Cordaites. The specimens do not furnish sufficient evidence for determining the precise horizon in the Permo-Carboniferous system of the coal-bearing strata of Zululand and Natal.

THE Memoirs of the College of Science and Engineering, Kyoto Imperial University, Japan, of which the current issue (vol. i., No. 3) has been received, contains original memoirs by members of the University. Of the thirteen papers, eleven are written in English and two in German. The subjects dealt with comprise the equilibrium between reciprocal salt pairs, reaction between carbonic acid and lead acetate in an aqueous solution, experiments on the utilisation of scrap metal, formation of amines from the halogen imido esters, the refining of copper, electrolytic dissociation of partially neutralised weak acids, short-period magnetographs, the theory of the rotary converter, Beckmann's rearrangement, determination of the solubility of a given substance by means of Pulfrich's refractometer, and dynamometer car experiments. The varied nature of this list affords an indication of the large amount of attention that is now being devoted to research work in pure science in Japan. Of the papers dealing with applied science, that by Mr. D. Saito on the refining of copper should be carefully studied by metallurgists. The author has made a systematic study of the process of dry refining, his investigations having been made upon the blister copper from the Beshi mine in Japan. The blister copper, which is comparatively pure, is refined in a reverberatory furnace using coal as fuel, and the author finds that the greater part of the impurities is oxidised in the earlier stages of refining. Thus, after the end of the first rabbling, the copper contains only 0·03 per cent. of iron and 0·003 per cent. of sulphur, whilst after the second rabbling the iron contents remain almost unchanged, and the copper is practically free from sulphur. If the copper could be re-melted more quickly and the third rabbling period dispensed with, there would be a great economy in fuel and labour. The effect of the first poling is so great that the second poling seems unnecessary, or at least could be shortened.

MR. J. W. PATTERSON, of the Technical College, West Hartlepool, has sent us two very successful colour photographs of rock sections taken between crossed Nicols. They were taken by the Lumière autochrome process, the illuminant being an electric arc light, and reproduce very satisfactorily the interference colours given by plagioclase felspar, augite, and olivine. It is obvious that this places in the hands of teachers of petrology and geology a very useful aid for illustrating lectures. Autochrome photographs are most successful with slides which are fairly transparent, and should be inspected in a strong light. Mr. Patterson has also obtained photographs of the interference figures yielded by uniaxial and biaxial crystals in convergent polarised light. Some weeks ago we saw a series of colour photographs of this kind exhibited in Kelvingrove Museum, Glasgow. Three-colour photographic plates appeared two years ago as illustrations of an annual report of the Geological Survey of the Transvaal, and about the same time Prof. E. J. Garwood showed some colour lantern slides of rock sections at the Geological Society, which were the finest of their kind we have seen. They were taken by the Sanger Shephard process, we believe. Undoubtedly methods of colour photography will prove to be of great use in reproducing microscopic slides, not only of rocks, but also of other subjects.

IN *Symons's Meteorological Magazine* for December, 1907, Mr. W. Ellis, F.R.S., formerly superintendent of the magnetical and meteorological department of Greenwich Observatory, gives a useful summary of Greenwich air-temperature observations published for the sixty-five years 1841–1905. The lowest mean daily temperature, 37°·47, is reached on January 12; after February 12 the rise towards spring begins, receiving, however, a slight check in the last week of April. The highest mean daily temperature, 64°·01, is reached on July 15; after August 13 there is a continuous fall to the minimum of winter. The mean annual temperature is 49°·56; the warmest year is 52°, in 1868, and the coldest 46°·28, in 1879. The mean monthly temperature is 38°·6, in January, and 62°·7, in July. The absolute highest reading was 97°·1, on July 15, 1881, and the absolute lowest 4°, on January 9, 1841. The observations give no information on secular change, for which purpose a much longer period than sixty-five years is necessary; there are several interesting differences shown by dividing the series into groups, but Mr. Ellis states that these are clearly due to accidental causes. Nor is any influence traceable to sun-spot variation, which the author considers is practically insignificant in all questions of weather change.

AT the meeting of the Royal Academy of Sciences of Amsterdam of October 26, 1907, an interesting paper by Dr. E. Van Everdingen was read on the relations between mortality of infants and high temperatures. It had been previously pointed out in a paper published by the Statistical Bureau of Amsterdam that a distinct maximum in the mortality of children under one year of age existed in the summer months, but an endeavour to find any connection between this maximum in various places and the monthly means of temperature only led to a negative result, although it was still thought probable that the mortality was due to fluctuations of temperature. Following up this idea, Dr. Van Everdingen tabulated the meteorological data for various places in several different ways, one of which was to extract the days on which the temperature exceeded 25° C. between the middle of one month and that of another. In this case the agreement between the deviations of mortality and the number of hot days was so satisfactory that little doubt remains that the high temperatures must be considered as the cause of the increased mortality. The author expresses the hope that, with the aid of other temperature limits and possibly with other methods of grouping the observations, those competent in medical matters will feel inclined to trace the more direct relations of the phenomenon.

IN the *Physical Review* for November, 1907, Mr. W. P. White, of the geophysics laboratory of the Carnegie Institution at Washington, makes a thorough examination of the potentiometer methods of measuring temperature by means of the resistance thermometer or the thermoelectric junction, in order to determine the best arrangement to use in melting-point measurements. He comes to the conclusion that the thermoelectric method is the better, that the best time of swing of the galvanometer is five seconds, and that greater use should be made of galvanometer deflections than is done at present, so as to reduce as far as possible potentiometer manipulations. Slide wire potentiometers should be avoided, switch instruments being much more satisfactory, and leakage disturbances should be prevented by surrounding the circuit with a continuous or nearly continuous metallic shield.

The September (1907) number of *Terrestrial Magnetism and Atmospheric Electricity* contains an abstract, by Mr. J. A. Fleming, of the results obtained by the Ziegler Polar Expedition of 1903–5. Astronomical, survey, tidal, meteorological, and magnetic observations were made during one year at several stations in the Franz Josef Archipelago. Two new maps embody the results of the survey, and indicate the two channels by which the tidal wave from the Atlantic reaches the archipelago. The mean barometric pressure was 29·6 inches, and the mean temperature 8° F.; the mean declination 22° east, the dip 83° north, and the total intensity 0·57 C.G.S. unit. The morning maximum of easterly diurnal declination occurred between five and six o'clock, and the afternoon minimum between eight and nine o'clock.

The employment of the conversion temperatures of crystallised salts as fixed points in thermometry has been shown recently to possess a real practical value, sodium sulphate having been shown to give the point 32°·383, and sodium bromide 50°·674, both on the international hydrogen scale. In a recent number of the *Zeitschrift für physikalische Chemie* (December 3, 1907) Messrs. T. W. Richards and Franz Wrede put forward manganese chloride, $MnCl_2+4H_2O$, as a suitable substance for another fixed point. One re-crystallisation of the commercially pure salt is sufficient to give a point within 0°·06 of its final value, and after six re-crystallisations the point is fixed to within 0°·001 C. A simple and effective form of thermostat is described and figured, by means of which the correction for the emergent column is reduced to one or two thousandths of a degree. The transition temperature of the tetrahydrate into the dihydrate of manganese chloride is finally given as 58°·089, with a limit of error of ±0°·005.

The number of the *Zeitschrift* referred to above contains a paper by Mr. A. Hantsch giving the result of experiments on the cryoscopic behaviour of sulphuric acid. It is shown that, as a criterion of purity, the cryoscopic method far surpasses the ordinary analytical method. The pure monohydrate H_2SO_4 melts at 10°·46, and the addition of either water or sulphur trioxide causes a lowering of the melting point. This result is confirmed by conductivity measurements, the maximum melting point corresponding with the minimum electrical conductivity. It was found possible to determine the molecular weight of various organic substances, methyl sulphate, trinitrobenzene, phthalic anhydride, &c., in pure sulphuric acid, and from the mean results of nine substances by the application of van 't Hoff's formula a latent heat of fusion of 22·94 calories was deduced. The latent heat of fusion, directly determined, was found to be 22·82.

We have received from Messrs. Philip Harris and Co., Ltd., Birmingham, a copy of their latest price list of chemical apparatus and chemicals. A special feature of this list is the arrangement into sections, which is likely greatly to facilitate its use. The earlier sections deal with general apparatus, such as instruments for weighing and measuring, apparatus of glass, porcelain, and metal; thermometers, microscopes, spectroscopes, &c.; each of the later sections deals with apparatus used in a special branch of chemistry, for example, brewing, iron and steel analysis, mining, cements, oils, fats and waxes, water and agricultural analysis. Sections are also devoted to physicochemical work, and to driving, stirring, and shaking apparatus. The list is admirably printed and illustrated, and is furnished with a very complete index.

A series of striking addresses delivered on the occasion of the inauguration of Dr. W. A. Noyes as professor of chemistry at the University of Illinois has been printed in *Science* (vol. xxvi., No. 673, pp. 689–714). Prof. H. A. Webber, in discussing the relation of chemistry to agriculture, emphasised in particular the great improvement both in quantity and quality of agricultural crops owing to the utilisation of the results of modern science. Dr. McMurtrie, speaking on the relation of chemistry to the industries, dealt with the need of developing the power and judgment of the industrial chemist by research work carried out in university laboratories; the fact that scientific research is a nation's "greatest financial asset" was especially emphasised. Prof. J. Stieglitz, while deploring the lack of active investigators in the past among teachers in American universities, pointed out that recently there has been a great development in all branches of research, especially since Clark University and the University of Chicago were founded mainly with this object in view. The American teacher is, however, still as a rule overburdened with an excessive amount of routine work, consisting of lecturing, laboratory instruction, and administrative duties, and is seldom afforded aid by the provision of suitable research assistants; funds also are too often lacking. Prof. G. B. Frankforter, in discussing the teaching of chemistry in State universities, pointed to the wonderful growth of German chemical industry as a specimen of what can be done by hearty cooperation between the universities and the leaders of industry of a nation. Chemistry has too often been taught in such a way as to convey the idea that it "serves no other purpose than to be simply dabbled with in college laboratories"; it is not therefore to be wondered at that few realise that its "laws and principles are the foundation stones of our great industrial structures." In his speech on the contribution of chemistry to modern life, Prof. Noyes took as his keynote the supreme importance of purely scientific work undertaken without reference to its technical application; he illustrated his subject by referring to the history of the coal-tar colours and the development of several industries from a purely scientific nucleus. The speeches, taken collectively, constitute a powerful plea for greater support and sympathy being accorded to purely scientific work.

The second edition, revised and enlarged, of "A Bibliography of the Works of Sir Isaac Newton, together with a List of Books illustrating his Works, and Notes," by Mr. G. J. Gray, will be published this month by Messrs. Bowes and Bowes, Cambridge.

Messrs. George Philip and Son, Ltd., have sent us two specimen sheets of their "Imperial" series of maps. The price of each sheet is 2*s*. 6*d*., but the maps can also be obtained on cloth, with rollers and varnished, at 3*s*. 6*d*. each. Each sheet is about 28 inches by 19 inches, and contains several physical maps. One sheet provides a map of the world in hemispheres, showing physical features in the familiar shades of green, brown, and blue, together with three maps of the world indicating isobars, rainfall, and regional vegetation respectively. The other sheet includes maps of the polar regions on a scale of 1 : 35,000,000, and three isothermal maps of the world.

WE have received two volumes of the "Agricultural Statistics of India" for the years 1901–2 to 1905–6. The statistics have been compiled in the office of the Director-General of Commercial Intelligence for the Department of Revenue and Agriculture of the Government of India. The first volume deals with British India, and the second with native States. The total area of India is given as 1,133,977,169 acres (1,771,839 square miles), and the total area of the British provinces is 744,907,040 acres (1,163,605 square miles). From a prefatory note to vol. i. the actual area of British India for which statistics are prepared appears to be 557,236,906 acres (870,683 square miles). Less than two-thirds of this area is available for cultivation; 67,976,325 acres are under forests, and land absolutely barren or unculturable, or covered by buildings, water, and roads, and so on, amounts to 135,329,173 acres. The balance represents the area available for cultivation, of which 207,683,741 acres were actually cropped during the year. Detailed information is supplied in the volumes as to the kind of crops and extent of each, the live-stock, revenue, and transfers of land. Full particulars as to the production of tea and coffee are also supplied. The table dealing with the estimated number of acres on which indigo is cultivated, and the yield in hundredweights, reveals the interesting fact that there was a revival in the indigo industry during 1906–7. The number of acres under cultivation and the yield both show a decided increase over 1905–6, and the yield an increase over that of 1904–5, but both sets of numbers still show a great falling off when compared with 1903–4.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JANUARY:—

Jan. 2–3. Epoch of January meteors (Radiant 230° + 53°).
3. 1h. 51m. to 6h. 42m. Transit of Jupiter's Satellite IV. (Callisto).
,, Total eclipse of the Sun, invisible in England.
4. 17h. Neptune in opposition to the Sun.
5. 8h. 20m. Venus in conjunction with Moon. Venus 0° 45′ N.
15. 3h. 32m. to 7h. 14m. Transit of Jupiter's Satellite III. (Ganymede).
17. 4h. 19m. to 4h. 34m. Moon occults δ Geminorum.
19. 2h. 57m. Jupiter in conjunction with Moon. Jupiter 1° 33′ S.
,, 11h. 56m. Minimum of Algol (β Persei).
22. 6h. 48m. to 10h. 31m. Transit of Jupiter's Satellite III. (Ganymede).
,, 8h. 45m. Minimum of Algol (β Persei).
25. 5h. 34m. Minimum of Algol (β Persei).
29. 9h. Opposition of Jupiter to the Sun.
,, 10h. 4m. to 13h. 46m. Transit of Jupiter's Satellite III. (Ganymede).

DANIEL'S COMET, 1907*d*.—In No. 4223 of the *Astronomische Nachrichten* (p. 375, December 20, 1907) Herr Kritzinger publishes a continuation of his ephemeris for comet 1907*d*, extending from January 1 to March 5. From this we see that the comet is now apparently travelling, very slowly and in a direction nearly due east, through the constellation Libra. On January 1 its position was α = 14h. 47m., $\delta = -9° 14'$, and its computed magnitude was 9·9. On February 1 the position will be α = 15h. 8m., $\delta = -9° 0'$, and its magnitude 10·2. Thus, on the latter date, the comet will be very near to the star β Libræ, and during the present month it will rise some five hours before sunrise.

EPHEMERIS FOR ENCKE'S COMET.—According to elements published in No. 4222 of the *Astronomische Nachrichten*, as an abstract from the *Bulletin de l'Académie des Sciences de St. Petersbourg*, 1907, Encke's comet should arrive at perihelion on February 22. An ephemeris, calculated by M. Kamensky and Frl. Korolikov, is given for the period January 3 to April 30. On the former date the comet's position will be α (app.) = 23h. 1m. 30s., δ (app.) 1° 45′·7; after that it will apparently move in a north-easterly direction through the constellation Pisces in a line nearly parallel to the stars γ, ι, and ω Piscium, being very near to ι on February 4.

ABSOLUTE SCALE OF PHOTOGRAPHIC MAGNITUDES.—The November (1907) number of the *Astrophysical Journal* (No. 4, vol. xxvi., p. 244) contains a description of a method devised by Messrs. J. A. Parkhurst and F. C. Jordan for the absolute photographic magnitudes of stars. An ingeniously constructed sensitometer box is employed for illuminating certain areas of a photographic plate simultaneously by lights differing in intensity by a known ratio. Plates thus prepared were measured for the opacity of the different areas by means of a Hartmann "mikrophotometer," which was also used to measure the opacity of the extra-focal star images. A comparison of the results obtained for the Pleiades stars with those published by Schwarzschild proved satisfactory, and indicated that within narrow limits the scale obtained was correct. It also showed that the method is capable of yielding results of extreme accuracy over a range of about two magnitudes on a single plate; that it should prove useful for determining the light curves of Algol-type and short-period variables is shown by some results given in the paper.

ANNUAL ASTRONOMICAL PUBLICATIONS.—The *Annuaire* for the year 1908, published by the Bureau des Longitudes, is of the usual form, and, in addition to its numerous invaluable astronomical tables, occupying 400 pages, it contains some 360 pages of chemical and physical data. Of the six appendices, dealing with astronomical subjects, we would direct our readers' particular attention to two, the first by M. Bigourdan on "Les Distances des Astres," the second by M. E. Guyou describing "L'École d'Astronomie pratique de l'Observatoire de Montsouris."

The *Companion to the Observatory* is practically of the same form as in previous years. The increase in the number of known variable stars renders it impossible to add all the new ones to the list, year by year, so it has been decided to reduce the number of ephemerides given, subsequently adding to them if it proves desirable. Complete lists of the Algol variables are given, but only a selected few of the ephemerides. The "inferred" magnetic elements for 1908 (Greenwich) are:—dec., 15° 55′ W.; horizontal force, 0·1854 (C.G.S.); dip, 66° 55′.

Mr. Arthur Mee's card calendar, "The Heavens at a Glance, 1908," is of the usual form, and is an extremely useful publication for astronomical observers. It may be obtained from Mr. Mee, Llanishen, Cardiff, price 7*d*. post free.

THE CANYON DIABLO METEORITES.—Part ii., vol. iv., of the Smithsonian Miscellaneous Collections (p. 203, No. 1725) contains an interesting illustrated discussion of the Canyon Diablo meteorites, by Messrs. G. P. Merrill and Wirt Tassin. The former discusses the distribution and physical characters of the "shale balls" found in such large quantities in the vicinity of the canyon in Coconino County, Arizona. These balls are roughly globular in outline, of all weights up to 50 lb., and consist of an exterior coating of hydrated oxide of iron frequently enclosing unoxidised iron centres, or nuclei, the intermediate shell showing a green hydroxide of nickel mingled with oxides of iron. The inspection of a number of these balls and of the ground in which they are found apparently strengthens the theory of the meteoric origin of the crater.

Mr. Tassin deals with the chemical analysis of the "finds," and shows that these "shale balls" differ to some extent in their chemical composition from the ordinary Canyon Diablo iron. They contain appreciable quantities of chlorine, whereas none has been found in the ordinary "iron," and also contain more phosphorus; to the presence of these two elements the increased oxidation of the "shale balls" may be ascribed.

THE STRESSES IN MASONRY DAMS.

THE memoir[1] referred to at the foot of this column embodies the results of further work, mainly experimental, on the design of masonry dams, and is a continuation of the work of Atcherley and Pearson described in an earlier memoir of the same series.[2] In the latter paper the authors discussed the imperfections of the present theory of masonry dams, in which the normal stress on horizontal sections is assumed to be linear, and nowhere tensile. This leads to the well-known condition of stability, that the centre of pressure on horizontal sections must fall within the middle-third, and the linearity of normal stress involves a parabolic distribution of shearing stress. Atcherley and Pearson criticised the action of engineers in ignoring the shear stress distribution, and in merely considering frictional stability as the criterion of safety as regards horizontal sliding. They demonstrated the existence of tension on some vertical sections of existing dams using the common theory, and showed that the mid-third rule was not followed consistently throughout the design.

In the memoir now under review, the authors point out the conditions for a true beam problem, viz. :—(1) the dimensions of cross-section are small compared with the length and with the radius of curvature; (2) true cross-sections, *i.e.* sections perpendicular to the line of centroids, exist. As these conditions are not rigidly fulfilled in a masonry dam, the authors refuse to accept any results based on a simple beam analysis, and proceed to an endeavour to throw experimental light on the current mid-third theory, which they summarise as follows :—

(1) The dam shall not be subjected to tensile stresses.

(2) This involves the line of resistance lying in the middle-third of horizontal sections.

(3) Condition (2) has meaning solely on the assumption that the normal stresses are linear.

(4) Linearity of normal stress involves the distribution of shearing stress being parabolic.

The case of an infinitely long dam, or a dam of finite length abutting against rigid supports, is considered mathematically. It is assumed to be straight, to have a plane face at any batter, and a flank curved in any manner. Regarding it as a homogeneous isotropic material, the laws of elasticity lead to a differential expression of a stress function V, which function has to fit the boundary conditions of the dam, viz. :—(*a*) on face where shear = o; normal stress = water pressure; (*b*) on top and flank, where shear = o; normal stress = o; (*c*) on base, where the shear and normal stresses have their actual values. It is stated that (*c*) is generally ignored, and its existence prevents a mathematical solution being obtained.

The memoir proceeds :—" The engineer using the middle-third rule, and thus assuming the hypothesis of linear normal stress, has *actually* (the italics are ours) assumed the stresses over the base. Consciously or unconsciously he has asserted that the pressure is linear and the shear parabolic." The engineer has perhaps some excuse for his assumption, as a mathematical difficulty cannot stand in the way of building a dam. In many other cases, say that of a large masonry arch, in the light of purely theoretical considerations, the action of the engineer, usually ***conscious*** we imagine, may savour a little of fools stepping in where angels fear to tread. In saying this, we would in no sense wish to convey the impression that the authors hold engineers responsible for what they regard as the uncertainty in the design of dams. Indeed, they expressly disclaim any such intention, frankly recognising the difficulties of the problem. Their results are put forward as preliminary only to further investigation, which they suggest might possibly be undertaken by some such body as the Institution of Civil Engineers. Their investigation shows that the boundary conditions are best fitted by a triangular dam, but that the conditions cannot hold for rectangular or trapezoidal sections. To quote from the memoir :—" *Purely* mathematical researches suggest no great hope of real advance in what is notwithstanding an urgent practical problem. It does not seem probable that they would provide any but the roughest approximations to the actual conditions." The method by which engineers escape from the horns of the mathematical dilemma is viewed with some misgivings, and the authors seek, in experimental work, a fold in which both engineers and mathematicians may dwell together in harmony.

Experimental Work.

The object of the work was to determine the actual straining actions in model dams by direct measurement, and, at the suggestion of the late Sir Benjamin Baker, jelly was adopted as the material of the dams. After much experiment suitable cream-white material made of gelatin, glycerin, and colouring matter was obtained. The size of models was as follows :—base, 45 cm.; height, 35 cm.; breadth, 9 cm. to 10 cm.; substratum, 45 cm.; by 9 cm. or 10 cm. deep. Fig. 1 shows a typical model with lines ruled on the face for the distortion measurements. After much trouble in satisfactorily fixing the models to a rigid wooden base, copper gauze was nailed to the wood and heated. The model was then placed on it, and on cooling was bonded securely to the gauze.

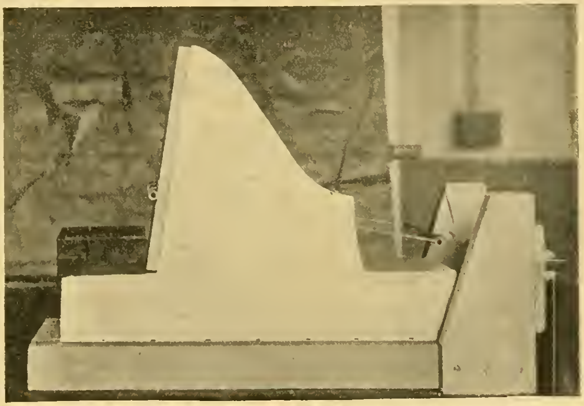

FIG. 1.—Vyrnwy-type dam, moderate water pressure.

Noting the experimental difficulty of attempting to use a dam with rigid, parallel ends, the authors proceed to a mathematical investigation of the stresses in a sheet of elastic material with free sides, *i.e.* a vertical plate with fixed base, no stress on sides, and subjected to a normal stress on part of its edge only. They conclude that with certain limitations there is an identity of stress equations, and that an experimental plate dam without side supports can be used to test the distribution of horizontal shear, by measurement of the distortion of lines ruled on its sides. If the distribution is not parabolic the normal stresses are not linear. The difficulty of measuring the local values of the stretch and squeeze of the jelly prevented any direct estimate of normal stress being obtained, and only the

[2] "On Some Disregarded Points in the Stability of Masonry Dams." By L. W. Atcherley and Karl Pearson, F.R.S. Pp. 44+plates. (London: Dulau and Co., 1907.) Price 3s. 6d.

existence of tension in the substratum and the manner of final rupture were noted.

Experiments were made on five models:—

(*a*) Water gelatin model, Vyrnwy type, tested to rupture, and illustrating preliminary difficulties.

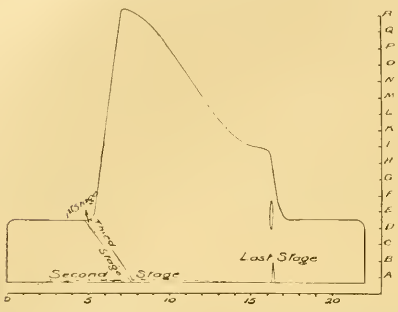

FIG. 2.—Rupture history of a large jelly-dam of the Vyrnwy type.

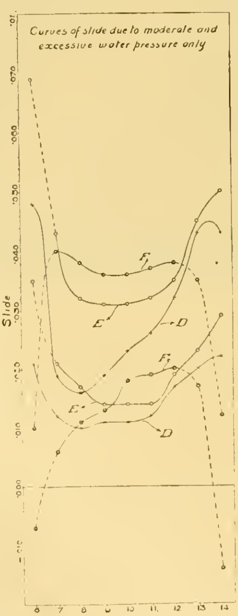
(*b*) Control dam, Vyrnwy type, very stiff jelly.

(*c*) Dam of Vyrnwy type, moderately stiff jelly.

(*d*) Dam of Assuan type, moderately stiff jelly.

(*e*) Dam of Assuan type, moderately stiff jelly, tested by optical methods.

The pressure was applied to the face of the models in three ways:—(1) By a board pressing against the face and loaded normally at the centre of pressure by means of a stirrup and shot bucket. A rubber tube was placed between the board and model to distribute the load so as to imitate water pressure (2) By a board as in (1) without tubing, the jelly itself distributing the load. (3) By an elastic water bag resting on the front of substratum and against the face of the dam, the sides of the bag being rigid and independently supported. The last method gives a true distribution on the face and substratum, and obviates the necessity of piling weights on the latter to maintain equilibrium; but the pressure cannot be varied relatively to the density of the dam as in methods (1) and (2), nor can the dam be tested to rupture. The strains were, in fact, only measurable by delicate optical means.



Curves of slide on the horizontal sections D, E, F.

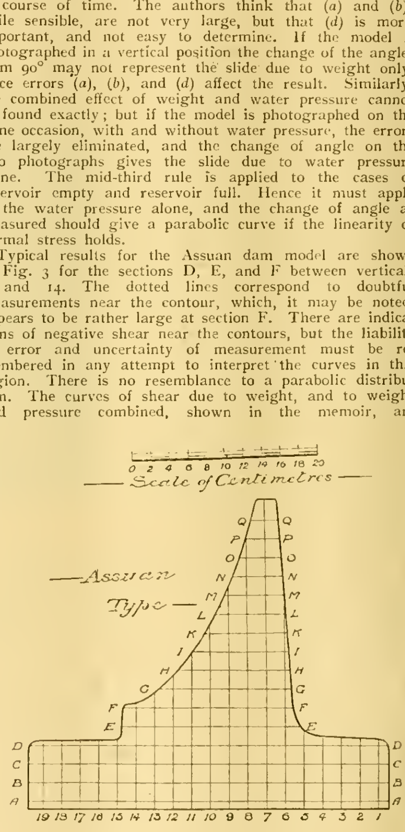
The Vyrnwy model, tested to rupture, behaved as shown in Fig. 2. The initial cracking gradually extended across the entire front, being followed by the tearing of the jelly from the cement or of the cement itself at the base connection. Then followed the third and last stages, the dam finally toppling over the tail, which separated at the vertical cracks. This experiment indicates weakness in the substratum, and tension across vertical sections at the tail. It may be remarked that the failure occurred at the section of discontinuity of contour, where the stresses in any actual dam become distributed through the surrounding earth in an indeterminate manner, and further that the extent to which the connection of such a model to a rigid base (though good experimentally) imitates the bedding of the substratum of an actual dam is also unknown. The existence of tension on vertical sections is emphasised by the authors.

Distribution of Shear.

This was determined by measuring the angular displacement of lines ruled on the ends of the models. It is admitted that no great exactitude is possible, and the following sources of possible error are indicated:—

(*a*) Inaccuracy of ruling on a jelly face; (*b*) ruling model while resting on its side, giving error especially near the contour; (*c*) distortion due to elastic effect of weight of vertical jelly; (*d*) set due to weight of jelly, or to shrinkage in course of time. The authors think that (*a*) and (*b*), while sensible, are not very large, but that (*d*) is more important, and not easy to determine. If the model is photographed in a vertical position the change of the angles from 90° may not represent the slide due to weight only, since errors (*a*), (*b*), and (*d*) affect the result. Similarly, the combined effect of weight and water pressure cannot be found exactly; but if the model is photographed on the same occasion, with and without water pressure, the errors are largely eliminated, and the change of angle on the two photographs gives the slide due to water pressure alone. The mid-third rule is applied to the cases of reservoir empty and reservoir full. Hence it must apply to the water pressure alone, and the change of angle as measured should give a parabolic curve if the linearity of normal stress holds.

Typical results for the Assuan dam model are shown in Fig. 3 for the sections D, E, and F between verticals 6 and 14. The dotted lines correspond to doubtful measurements near the contour, which, it may be noted, appears to be rather large at section F. There are indications of negative shear near the contours, but the liability to error and uncertainty of measurement must be remembered in any attempt to interpret the curves in this region. There is no resemblance to a parabolic distribution. The curves of shear due to weight, and to weight and pressure combined, shown in the memoir, are



Key figure to the network on the Assuan model.

FIG. 3.

extremely wavy in outline, and nothing short of a quartic would in any way represent them between verticals 6 and 14; but bearing in mind the special liability to error in these cases, the curves are not of the same interest as those shown in Fig. 3. Similar results are shown for the Vyrnwy type dam.

As a result of the first set of tests, the authors maintain that, allowing for all irregularity in measurement and material, there is no approach to linearity of normal stress up at least two-thirds, and probably up the whole height of dams of current form. The mid-third rule is, therefore, considered valueless as a stability test, and the success of engineers in building stable dams is attributed more to experience in choice of contours, and in the use of a large factor of safety than to any validity in the method of design. The complexity of the problem and the variations of shear distribution led the authors to make a second series of experiments, using many experimental refinements. The general results were of the same character, and an interesting set of curves is presented showing the actual stresses in the Assuan dam as calculated from the more refined measurements on the model. These curves, like the preceding set, are rather irregular, and it is difficult to believe that they can represent the variations of stress in a body having any approach to homogeneity.

Before concluding the memoir with some attempts at semi-empirical determination of stresses, the following processes are suggested for dealing practically with any proposed design :—

"(1) Form a glycerin-gelatin white pigmented jelly dam of the given contour. Determine the form and fixing of the substratum to represent as closely as may be feasible the local conditions. Rule the surface.

"(2) Apply water pressure and determine by the methods indicated above, using either a direct or optical micro-goniometer, the shear distributions. Ascertain the forms of the horizontal and vertical section shear curves.

"(3) Thence by integration—of course mechanical—find the distribution of normal stress along one or two base sections. From these deduce the stretches and squeezes, and take as definite conditions of stability that the maximum stretch and squeeze shall be less than certain values which may be effectively fixed by experiment."

The authors then say that, with such a test, dams like the Vyrnwy and Assuan are found to be theoretically stable, whereas the mid-third rule gives only an apparent theoretical stability.

We are grateful to the authors for their presentation of the interesting results of such difficult experiments, and hope that their work may bear fruit. Their results must stimulate discussion of a highly important subject; but we imagine that the day is not yet when the civil engineer will proceed to the design of a masonry dam, as the authors suggest, by "forming a glycerin-gelatin white pigmented jelly of the given contour, and determining the form and fixing of the substratum so as to represent as closely as may be feasible the local conditions." Here, it seems to us, there are added to the uncertainties of actual conditions, a set of experimental processes liable to error at many points. He will probably prefer to base a new project on the designs of existing dams, modified as these may be from time to time in the light of new ideas, and perhaps by suggestions coming from work of the character of that under review.

E. BROWN.

THE ETHNOLOGY OF AFRICA.

THE communication by Dr. F. C. Shrubsall—"Notes on some Bushman Crania and Bones from the South African Museum, Cape Town"—issued as part v., vol. v., of "Annals of the South African Museum," in continuation of a paper by the same author in the Journal of the Royal Anthropological Institute for 1897, is an important contribution to the ethnology of that region. Incidentally, it marks a reaction against established methods in anthropometry, which, particularly in the case of mixed races, are now treated with well-merited suspicion. In place of an induction founded upon a single "index" derived from the study of the relative magnitude of one skull dimension in terms per cent. of some other dimension, the present paper is based on no less than eighteen factors, and the figures have been subjected to statistical investigation on the most modern lines.

The inquiry starts from a series, unfortunately limited in numbers, of skulls of the race known as the Strandloopers found in caves along the south-eastern seaboard. These constitute a group more pure than that of the Bushmen, and apparently quite distinct from that of the Hottentots. The up-country Bushmen are intermediate between the Strandloopers and the Hottentots. The latter, again, present dimensions between the up-country Bushmen and the Bantu, and in many characters they approach the Negroes of British Central Africa more closely than the Kafir tribes of the east coast. The Central African Pigmies are by their prognathism clearly removed from the Bushmen, and those of the forest zone seem to be largely mixed with the Negro strain. Thus the purest dwarf race is, or was recently, located on the coast at the extreme south of the continent, the furthest point to which, under pressure, they could retreat.

Eastern and part of south-western Africa are occupied by distinct races of Bantu speech, between whom, in character as well as in position, the Hottentots seem to be intermediate. Quite distinct from these races already mentioned are the Somalis and Gallas, of whose physical character little is known. The Masai further south may be allied to these, but they are quite distinct from the Bantu-speaking Negroes. The West African Bantus, between the Rio del Rey and the Congo, in some respects resemble the eastern tribes of the same stock, in others approximate to the Pigmies.

The race history of South Africa may thus be reconstructed—the first inhabitants were of the Bushman type. Round the great lakes and in the Upper Nile valley the tall Negro tribes were developed, or at least are found in occupation of this region. Pressure from the east drove a large section of these southwards, and these in their turn pressed the Bushmen partly to the extreme southern coast, partly into the forest zone, where they intermingled with their neighbours. Some of the Negroes, again, passed north of the forest tract towards the Atlantic shores, and under pressure of tribes from across the Sahara were in part driven back to the forest, and in part down to the western sea, where in an unsuitable environment their physique deteriorated. Some of these Negroes may have been forced down the Nile valley, taking with them or driving before them any survivors of the northern Bush races, who thus came into contact with Egypt; or, as an alternative, it is not impossible that the range of the Bush peoples may have previously extended much further to the north than is usually supposed.

These conclusions rest, as we have said, on a comparatively small number of skulls. It is to be hoped that a fuller supply of African crania may soon be available by which these interesting speculations may be more adequately tested.

THE PLACE OF THE LABORATORY IN THE TRAINING OF ENGINEERS.[1]

IT is now generally conceded that the advancement and prosperity of an engineering establishment depend upon the number of well-trained employees it possesses, but much difference of opinion exists as to whether the education given in our engineering colleges is of the kind best fitted to produce the type of man who will be of real value to his firm.

As a rule, at the present day, a boy who intends to become an engineer, on leaving school takes up a three or four years' course at an engineering college. On leaving college he will be found to have a fair theoretical knowledge of engineering, to be capable of making a drawing, of testing specimens of materials, of taking indicator cards, and, generally, of carrying on an ordinary engine or boiler trial. As a rule, however, he is incapable of making much practical use of his scientific knowledge, and if compelled to act on his own responsibility in the case of some mechanical problem often fails badly. Many employers thus look coldly on a system of education which produces such poor results, and we have here an explan-

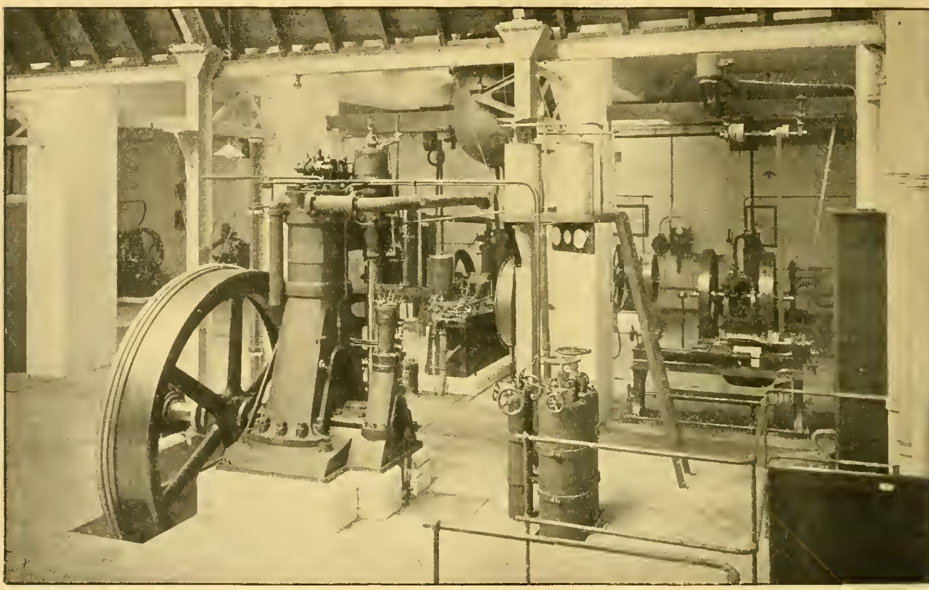
[1] Based upon a paper read before the Institution of Engineers and Shipbuilders in Scotland, by Prof. A. L. Mellanby.

ation why the chief draughtsman and foreman so often state that they would rather have a boy straight from school than one who has undergone a college training.

To one experienced in both the practical and academic departments of engineering, it is evident that the average college training is unsatisfactory. It has grown up because it created least disturbance to the existing state of things, and the development of this system is chiefly the fault of the employers themselves. Anyone who has read the literature dealing with technical instruction must come to the conclusion that the advance in education has been almost entirely due to the students alone. They have seen the necessity for information concerning the principles of engineering, and have in the past attended college courses with no encouragement from outside sources. At the present day this is fortunately changed, and employers are, on the whole, not unwilling to support a system of education which they see is advantageous to themselves.

The author is of the opinion that our college engineering courses would be vastly improved if it were made three years he would keep up his studies, especially devoting himself to mathematics and physics. At the end of this time he ought to return to college, and take during the winter the second year's course. The following summer would be again spent in the workshops, and the next winter would be devoted to the third course of college work. Before allowing an apprentice to take up his second year's course at college, it must be seen that he can give evidence of having made material progress in his theoretical knowledge during his three years at the works. The method by which the student would continue his scientific education in this period must of necessity depend upon the employer. Attendance at evening classes would produce least disturbance in the works, and there is no doubt that a hard-working student could get a fair amount of knowledge in this manner. The other alternative is that the apprentices be allowed to attend day classes for, say, two afternoons per week—a system already being tried by several firms.

The advantages of such a system are obvious. The



Gas and oil engines. Glasgow and West of Scotland Technical College.

the rule that a considerable amount of workshop practice should precede the final attendance at college. In support of this proposal it may be pointed out that if college training is to produce men who are capable of inventing new processes and improving existing methods of manufacture, then the training must not confine itself altogether to principles, but must direct attention to current engineering work. It therefore follows that the student who wishes to take up his technical studies with profit should not only be prepared with a sufficient knowledge of mathematics and physics, but must also have a working acquaintance with engineering practice. The following plan is suggested as one likely to be the most fruitful.

The student after leaving school should immediately proceed to college, and there take up the first-year general course, whereby he will gain a preliminary grounding in mathematics and science. At the close of the college session he ought to enter an engineering works, where he should remain for at least three years. During these

student would take up his second and third years' college work with such a preliminary practical and theoretical training that the whole character of present-day college classes could be changed. The elementary descriptive lectures, so necessary to schoolboys, could be omitted, and in their place lectures of vital importance to every-day engineering practice could be given, and the most recent developments could be described and discussed. The laboratories, instead of being places for elementary testing, might develop into schools for real research. Practical problems that had arisen during workshop experience might be settled by direct experiment, and an amount of information gathered that would in a short time lead to an immense improvement in our national engineering. It appears to be almost universally believed that inventions are the outcome of sudden inspiration to men of genius, and, like poetic effusions, are independent of environment and experience. Such an idea is far from the truth, for most great discoveries have only been evolved after the closest research, and then by men who have had a training of such a kind that their critical faculties are strongly developed. It cannot be too strongly impressed upon employers how much more valuable an apprentice would be were he to have an opportunity of continuing his mental training in the laboratories of our well-equipped colleges after having first been impressed with the real problems of his calling by some years in engineering works.

The plan suggested above can only be carried out with the help of the employer. His works may at first suffer some disorganisation, but he must see that this is a national problem, and that plan of training can only be the best which results from cooperation with the engineering colleges, even although such a system involves some personal sacrifice.

There must be something radically wrong with a system of apprentice education which appears to be quickly bringing British engineers to the position of manufacturers, under license, of foreign inventions. It is quite evident that by allowing a student to undergo considerable workshop experience before attending his final college course the trained engineer of moderate ability would be a sounder man, while the clever man would have an opportunity of exploiting his capacity for research work. It must, however, be insisted upon that the proper education of our young engineers depends altogether upon the attitude of the employers towards it. If they do not realise the national significance of such higher scientific training as is here contemplated, it is useless for the heads of our colleges to devote attention to schemes of study capable of promoting it.

In designing the laboratories of the Glasgow and West of Scotland Technical College, provision has been made for the comparatively large number of older students attending the final courses in engineering by putting in a number of machines adapted for research work. The illustration shows one corner of the laboratory devoted to motive-power engineering.

AMERICAN INVESTIGATIONS ON ELECTROLYTIC CONDUCTIVITY.[1]

THE two monographs here noticed owe their existence principally to the means placed at the disposal of American workers by the Carnegie Institution of Washington. Without such aid these extensive systematic researches could scarcely have been undertaken, and their publication, unless in abbreviated form, would have presented considerable difficulties.

The report by Prof. Noyes on the work of himself and his collaborators is of the utmost value to all those who are interested in problems connected with the conductivity of aqueous solutions, salt-hydrolysis, and the like. The main object of the research was to obtain accurate values for the electrical conductivity of solutions in a range of temperature from 0° to 300°, and the chief difficulty experienced was in the construction of a conductivity vessel which should be at once capable of resisting the high vapour pressure of solutions up to the critical point of water, and of yielding only traces of conducting impurity to the aqueous solutions it contained. By three years of patient labour Prof. Noyes and Dr. Coolidge succeeded in constructing a platinum-lined bomb with insulated electrodes, which even at high temperatures and with salt-solutions as dilute as 0·0005 normal gives conductivity measurements accurate within 0·2 per cent. With this apparatus the conductivities of typical substances were measured, the results obtained being given and discussed in detail in the report. The substances embraced in the investigation are the chlorides of sodium, potassium, and ammonium, the nitrates of silver and barium, the sulphates of potassium and magnesium, the acetates of sodium and ammonium, the hydroxides of barium, sodium, and ammonium, and, finally, hydrochloric, sulphuric, nitric, phosphoric, and acetic acids. In order to obtain data for calculating the ionisation constant of water, the conductivities of diketotetrahydrothiazole and its ammonium salt were also measured. The value of this constant as so determined agrees well with that obtained by Kohlrausch from the conductivity of pure water. Two special sections deal with the solubility of silver chloride, bromide, and thiocyanate at 100°, and with the transport numbers of nitric acid. From the last section it appears that the ratio of the velocity of the anions to that of the hydrogen ion is several per cent. larger at very small concentrations than at moderate concentrations, and not constant for all solutions more dilute than 0·05 normal, as is usually assumed.

Prof. Jones, of the Johns Hopkins University, has for a considerable number of years busied himself with the study of solutions, especially from the standpoint of the so-called hydrate theory, which in its present aspect differs greatly from the theory which went under that name some fifteen or twenty years ago. In this communication Prof. Jones and his co-workers give the results of their investigation of the conductivity and viscosity of certain electrolytes in water, methyl alcohol, ethyl alcohol, acetone, and in binary mixtures of these solvents. The connection between the fluidity of a conducting solution and the value of its electric conductivity has long been recognised, but comparatively little detailed experimental work has been done on the subject, so that the present research, which shows the close parallelism between the two properties, not only for aqueous, but for other solutions, is of much interest and value. The problem of the variation of conductivity with change of composition of the solvent is extremely complex, but the authors may be said to have laid a safe foundation for the theoretical treatment of the subject.

"Conductivity and Viscosity in Mixed Solvents." By Harry C. Jones. Pp. v+235. (Washington: Carnegie Institution, 1907.)

THE TUBERCULIN TEST FOR CATTLE.

THE unsatisfactory nature of the tuberculin test for cattle is emphasised in two articles published in the "Live Stock Journal Almanac" for 1908. Mr. Bruce remarks that when an animal reacts there is no indication whether the case is serious or not; that an animal which reacts freely may, when tested a month or two later, fail to do so; that change of place, of companionship, and of diet, the advent of œstrus, or, in fact, anything calculated to excite the animal or upset its digestive system, may render the test abortive.

Mr. Thornton records that testing cows in calf is apt to bring on abortion, and adds that in Germany the test is considered untrustworthy, because of the number of slaughtered animals proved to be tuberculous which have passed the test, and the number in which no tubercle could be found which have been condemned by the test. He concludes, however, with the resignation common among breeders when dealing with such matters:—"The test is naturally upheld by many veterinary surgeons, and there is not much probability of it being discontinued, as members of the profession are generally selected as advisers to the Boards of Agriculture in the colonies and foreign countries," and he might have added in this country also.

With such facts before them, with the knowledge that the disease is not necessarily hereditary, that it is by no means so infectious as has been supposed, and that it is not so largely responsible for the spread of tuberculosis among human beings as we were at one time led to believe, one can hardly blame breeders if they show unwillingness to accept the doubtful blessing of the tuberculin test.

In an article on hybrids, Mr. C. T. Davies complains that the term hybrid is often loosely applied by Mendelians and other experimentalists who have little knowledge of practical breeding, to the offspring of two varieties sprung from the same stock. He points out that "cross-breds" is the term practical breeders use for such produce, while "hybrid" is used to designate the progeny of two distinct species. He expresses the hope that biologists will adopt the ancient form of nomenclature, and so avoid confusion in the minds of those of their readers who are practical men.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LONDON.—In consequence of the incorporation of University College in the University, certain professors of the college will in future be entitled professors in the University of London, and will enjoy the status of appointed teachers. These include Profs. Trouton (physics), Oliver (botany), Hill (zoology), Starling (physiology), Thane (anatomy), Cushny (pharmacology), and Cormack (mechanical engineering). Sir William Ramsay, K.C.B. (general chemistry), and Prof. Norman Collie (organic chemistry) have been appointed teachers of the University for some years.

The announcement that the governing body of the Imperial College of Science and Technology at South Kensington has decided in principle on the appointment of a principal officer of the college has been received with much interest. The post will be an important one, as the resources of the college are considerable, and great developments are expected during the next few years. It is a curious coincidence that two principal officers should be required at the same time at South Kensington, the one at the University and the other at the Imperial College.

Among the advanced lectures in science to be delivered, in connection with the University, during the first term of this year are the following:—A course of eight lectures on "Grasses: their Structure, Biology, Distribution, and Classification," by Dr. Otto Stapf, at University College, on Mondays, beginning on January 27. Eight lectures on "Intracellular Enzymes," by Dr. H. M. Vernon, at the University Physiological Laboratory, on Tuesdays, beginning on January 14. Eight lectures on "The Chemical Constitution of the Proteins," by Dr. R. H. Aders Plimmer, at University College, on Wednesdays, beginning on January 22. Eight lectures on "The Chemistry of the Fats and Carbohydrates and some other Constituents of the Animal Body," by Dr. S. B. Schryver, at University College, on Fridays, beginning on January 24. Four lectures on "Tissue Respiration," by Dr. T. G. Brodie, F.R.S., at King's College, on Mondays, beginning on January 20. Two lectures on "The Physiology of the Emotions," by Dr. F. W. Mott, F.R.S., at King's College, on Mondays, beginning on February 17. Two lectures on "Degeneration and Regeneration of Nerves," by Prof. W. D. Halliburton, F.R.S., at King's College, on Mondays, beginning on March 2. Eight lectures on "The Physiology of Muscular Work," by Dr. M. S. Pembrey, at Guy's Hospital Medical School, on Thursdays, beginning on January 16. Eight lectures on "Inheritance in its Physiological and Pathological Aspects," by Dr. W. Bulloch, and Messrs. G. P. Mudge, M. Greenwood, and A. Bacot, at the London Hospital Medical College, on Wednesdays, beginning on January 15. Four lectures on "The Circulatory System of Reptiles," by Mr. F. E. Beddard, F.R.S., at University College, on Mondays, beginning on January 20. The reader in meteorology, Dr. W. N. Shaw, F.R.S., will resume his lectures on "Meteorological Organisation and Methods of dealing with Meteorological Observations," at the Royal College of Science, on Monday, January 13.

BY the death, on December 24, of Lady Pearce, widow of Sir William G. Pearce, Trinity College, Cambridge, becomes entitled to a sum of more than 400,000*l.*

WE learn from *Science* that the National Educational Association of the United States has appointed a representative committee to investigate the entrance requirements to the technical schools of the country, and to consider the question of establishing uniform entrance requirements.

THE annual meeting of the Geographical Association will be held at 3 p.m. on Wednesday, January 8, at University College, Gower Street, W.C. The president, Mr. Douglas W. Freshfield, will give an address, Major C. F. Close will deliver a lecture on map projections, and there will be a lantern exhibition of views of the Rhine Gorge by Mr. B. B. Dickinson.

THE Incorporated Association of Headmasters will hold its annual general meeting on January 9 and 10 at the Guildhall, E.C. The agenda paper is mainly occupied with administrative questions, and we observe that a committee is suggested for considering the medical inspection of pupils attending secondary schools. The University of London and the northern universities are urged to come to terms for the mutual recognition of their matriculation certificates. Mr. E. J. Simpson will move a resolution in favour of the inclusion of a paper on elementary physics amongst the optional papers of the northern matriculation.

AT the winter meeting of the College of Preceptors, lectures will be given on a rational comparative method of teaching geography, by Dr. Herbertson, on January 7 and 8, and the subject of geometry will be dealt with by Mr. J. Harrison, of the Royal College of Science, on January 15. During the course of the meeting there will be several lectures on psychology, personal hygiene, and the use of the voice.

SOCIETIES AND ACADEMIES.

LONDON.

Faraday Society, December 17, 1907.—Dr. F. Mollwo Perkin, treasurer, in the chair.—A physico-chemical study of the complex copper glycocoll sulphates: J. T. **Barker.** The paper deals with the constitution of the blue solution formed when glycocoll is added to copper sulphate solution. It is probable that the concentration of the cupri-ions has been lowered by the formation of complex cupri-glycocoll kations, and experiments are described to investigate this question.—The discovery of the alkali metals by Davy: the bearing of the discovery upon industry: Dr. F. Mollwo **Perkin.** After a short biographical sketch, the author refers to Davy's early experiments on galvanism, which began in 1800 and culminated in 1807 in the electrolytic decomposition of the fused alkalies, caustic soda, and caustic potash. Davy's experiments are described in detail, and it is shown that the E.M.F. of his battery must have been about 220 volts, and the current he used something under 1 ampere. The subsequent experiments on the decomposition of the alkaline earths, by which calcium, strontium, barium, and magnesium in the form of amalgams were obtained, are then described. The second part of the paper deals, among other matters, with the industrial manufacture by Wöhler in 1827 of potassium, by Ste. Claire Deville in 1854 of sodium, with Watt's suggestions (1851) for electrolysing fused sodium chloride, with Castner's chemical sodium process (1886) and his electrolytic process (1890), Rathenau and Suter's sodium process, Becker's process, and the process of Darling, who electrolysed fused sodium nitrate, using porous partitions.

Geological Society, December 18, 1907.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—Some recent discoveries of Palæolithic implements; Sir John **Evans.**—The author refers to some recent discoveries of Palæolithic implements on the southern borders of Bedfordshire and in the north-western part of Hertfordshire. In addition to the discovery of a Palæolithic floor at Caddington brickfield, at between 550 and 590 feet above sea-level, implements have since been found on the surface of the ground at 600 and 760 feet respectively; while a good ovate implement was found in thin, water-laid material, at 651 feet O.D. In Hertfordshire, Palæolithic implements have been found at Great Gaddesdon, at a brickfield about $1\frac{1}{2}$ miles north-east of Hemel Hempstead, and at Bedmond, 2 to $2\frac{1}{4}$ miles south-east of the last locality. The drifts which cap the hills in north-west Hertfordshire seem to be of very variable origin; and a great part of the material is derived from clay-deposits of Eocene age, but little *remaniés.* It seems to the author that it is safest not to invoke river-action for the formation of the high-level deposits, which extend over a wide area and are in the main argillaceous and not gravelly or sandy in character, but to adopt Mr. Worthington Smith's view that in early times lakes or marshes existed in these implementiferous spots, the borders of which were inhabited by Palæolithic man. The evidence that he has brought forward as to the implements having, in some of the Caddington pits, been manufactured on the spot, most fully corroborates this view.—A deep channel of Drift at Hitchin (Hertfordshire): W. **Hill.** Evidence is given, from nine borings running along a line slightly west of north from Langley through Hitchin, of the existence of a channel of considerable depth, now filled with Drift, occupying the centre of an old valley in the Chalk-escarpment, which may be called the Hitchin Valley.

PARIS.

Academy of Sciences, December 16, 1907.—M. A. Chauveau in the chair.—The action of nitrous acid upon allylamine: Louis **Henry.** The interaction of allylamine hydrochloride and sodium nitrite gives allyl alcohol only. Acetone was looked for, but no trace of any isomer appears to be formed in this reaction.—Report by M. **Bertin** upon a memoir entitled "The Study of the Movements of Water which can be produced in Contact and in the Neighbourhood of a Plane Vertical Wall," by MM. Fortant and Le Besnerais.—Observations of the phenomena of Saturn's ring made with the bent equatorial of 32 cm. aperture at the Observatory of Lyons: J. **Guillaume.**—Laplace's transformation and persistent conjugate systems: D. Th. **Egoroff.**—The theory of matrices: M. **de Séguier.**—Infinitesimal transformations and adjoint functions: N. **Saltykow.** Differential equations of the third order with fixed critical points: J. **Chazy.**—Flame spectra obtained by the electrical method: G. A. **Hemsalech** and C. de **Watteville.** The present paper deals with an application of a process previously described, and is especially adapted for the examination of salts of the rare earths. The salt is incorporated with either boric acid or a mixture of asbestos and sodium silicate, and the whole placed in the hollow of a carbon rod forming the positive pole of an electric arc, the arc being enclosed in a glass globe. A current of air is led into this vessel, and is then allowed to flow to the burner. Finely divided particles of the salt are thus introduced into the flame of a Bunsen burner, and 1 gram of the salt is sufficient to show the flame spectrum for five hours continuously.—The Audiffren refrigerator: MM. **Audiffren** and **Singrun.** A suitable gas is liquefied in the compressor, and the liquid allowed to evaporate in the refrigerator, the special advantage of the arrangement (a diagram of which is given) being that both the compressor and refrigerator are enclosed in an air-tight vessel, only a single stuffing box carrying the pulley through which the whole is driven communicating with the outside air. The pump is driven by the action of gravity on a heavy piston, and it is impossible for the pressure to rise above a figure fixed by the weight of the piston.—Phosphorescence at low temperatures: Joseph de **Kowalski.** Solutions of nitrates of the rare earths in alcohol become strongly fluorescent at the temperature of liquid air. For the erbium solution the tint is green, greenish-yellow for the samarium solution, and violet for the solution of nitrate of neodymium. Alcoholic solutions of phenanthrene, anthracene, and anthraquinone behave similarly. In all cases the substance was previously exposed to a strong ultra-violet light from a quartz mercury arc lamp.—The formation of ozone by the action of the silent discharge at low temperatures: E. **Briner** and E. **Durand.** At the temperature of liquid air the vapour pressure of liquid ozone is practically zero, and it has been found possible integrally to transform oxygen into ozone. For a given expenditure of electrical energy the maximum yield of ozone was obtained with a pressure of oxygen of 100 mm. of mercury. The authors point out that the dangers of explosion of the liquid ozone are much reduced if care is taken to remove all traces of grease from the ozoniser by washing with chromic acid mixture before use.—The hydrolysis of iron perchloride. The function of hydrochloric acid: G. **Malfitano** and L. **Michel.** The experiments described by the authors appear to be best explained by the hypothesis that the constitution of the colloid is formed at the expense of the products of hydrolysis or of complex ions.—The solubility of graphite in iron: Georges **Charpy.** The results given in this paper form an additional argument for considering that the solubility of graphite in iron decreases regularly with the temperature, and give a value of 1 per cent. as the most probable value for the solubility in pure iron at 1000° C.—An attempt at proving certain relations between the atomic weights of the elements: M. **Delauney.** The values of the atomic weights may be represented in the form A^2/n, where A and n are two whole numbers.—The gases occluded in steels: G. **Belloc.** The amounts of gas given off are in close relation with the critical points of iron. The gases consist of carbon dioxide, carbon monoxide, hydrogen and nitrogen, and each gas is characterised by a particular temperature of evolution. The distribution of the gases is very irregular in the different layers of the metal.—The extraction of the gases contained in metals: O. **Boudouard.** It is an extremely difficult matter to extract the whole of the gases contained in iron and steel, a third heating to 1100° C. in a vacuum still yielding some gas. The accidental breakage of a porcelain tube in these experiments showed that iron clearly commences to volatilise in a vacuum at 900° C., this effect being quite marked at 1100° C.—The qualitative examination of ciders for tartaric acid: G. A. **Le Roy.** The method is based on a colour reaction with a solution of resorcinol and sulphuric acid.—Syntheses by means of the mixed organometallic derivatives of zinc. The constitution of the β-acetoxyl-ketones: E. E. **Blaise.**—The preparation of the cyanides of methyl and ethyl: M. **Auger.** An aqueous solution of potassium cyanide can be employed with advantage as regards yield in the preparation of the nitriles.—Aromatic alcohols. Some new reactions: R. **Fosse.**—Some new Euphorbiaceæ from central and western Africa collected by M. Auguste Chevalier: M. **Beille.**—Variations in *Papaver Rhoeas*: L. **Blaringhem.**—The existence of a peroxydiastase in dried seeds: **Brocq-Rousseu** and Edmond **Gain.** One or more peroxydiastases have been found to be generally present in a large number of dried seeds examined by the authors. This peroxydiastase does not exist in the seed indefinitely, but depends on the age of the seed.—The action of a magnetic field of high frequency on Penicillium: Pierre **Lesage.** In magnetic fields of high frequency the growth of the mould is accelerated, but this effect is indirect, since it is due, at any rate to a large extent, to the heating of the wires of the solenoid.—The origin of anthocyanine deduced from the observation of some parasitic insects of leaves: Marcel **Mirande.**—The marine migrations of the common trout: A. **Cligny.**—The parasitic castration of male star-fish by a new infusoria, *Orchitophrya stellarum*: Casimir **Cépède.**—The variations of the length of the intestine in the frog: Emile **Yung.**—The action on the heart of certain metallic ions introduced into the organism by electrolysis: Jean **Gautrelet.**—The presence of Schaudinn's treponemes in the appendix of a hereditary syphilitic fœtus: Ch. **Fouquet.**—The possibility of establishing a true diagnosis of death by radiography: Ch. **Vaillant.**—A case of modification of a *thalweg* by the intervention of a volcanic intrusion (Sardinia): M. **Deprat.**

December 23, 1907.—M. A. Chauveau in the chair.—The president announced the deaths of M. Janssen and Lord Kelvin.—Observation of the transit of Mercury across the sun, November 13–14, 1907, at the Observatory of Aosta, Italy: M. **Amann.** Times of the four contacts are given, with remarks on the formation of the black ligament, luminous point, and rings.—The compensation of an electromagnetic compass for armoured blockhouses and for submarines: Louis **Dunoyer.**—Liquid dielectrics: Louis **Malclès.**—The conditions of maximum yield for telephonic apparatus: Henri **Abraham** and M. **Devaux-Charbonnel.** The problem attacked in the present paper is as follows. Accepting the telephonic apparatus at present in use, are the various elements, the transformer, the resistance of the bobbin of the receiver, &c., chosen so as to furnish the maximum effect in the transmission of speech? The theoretical investigation leads to the conclusion that the receiving instruments should have a resistance of 100 to 200 ohms, and the transformation ratio should be near 6 or 7. An examination of the transformers in actual use in telephone work showed an efficiency of only 60 per cent., and with this efficiency the transformers are too small for the work.—The application of the method of limiting densities to organic vapours:

Ph. A. **Guye.** From an examination of the experimental work of Ramsay and Steele on the densities and compressibilities of organic vapours, the author concludes that neither the parabolic extrapolations of Daniel Berthelot nor the graphical extrapolation of measurements of compressibility allows of the rigorous verification of the principle of limited densities.—The influence of temperature on the optical properties of dissolved bodies: C. **Chéneveau.** The index of refraction of a dissolved body varies only slightly with the temperature; the variation of the optical constant or the molecular refractive power of a dissolved substance under the influence of temperature appears to arise more especially from the change of volume of the solution, and appears to be produced in the same sense as the change of temperature.—The detection and estimation of nickel in the presence of any quantities whatever of cobalt, iron, and manganese: Emm. **Pozzi-Escot.** The nickel is precipitated as a double molybdate of nickel and ammonium. No test analyses are given.—The nature of some phosphorescent elements and meta-elements of Sir W. Crookes: G. **Urbain.** Starting with definite mixtures in varying proportions of pure terbium and gadolinium, the author has been able to reproduce many of the phosphorescent spectra attributed by Sir W. Crookes to separate elements.—A new chromium sulphate: Paul **Nicolardot.**—The influence of acids and bases on the fixation of acid and basic colouring matters on wool: L. **Pelet-Jolivet** and N. **Anderson.** Details of the amounts of an acid and a basic dye taken up by wool in presence of varying amounts of hydrochloric, sulphuric, and phosphoric acids are given, and it is claimed that the results are in accord with the hypothesis of contact electrification, and agree with the colloidal theory of dyeing.—Glycidic ethers and aldehydes in the naphthalene series: Georges **Darzens.** An isomer of sparteine, isosparteine: Charles **Moureu** and Amand **Valeur.** A description of the preparation of the base, its dichlorohydrate, chloroplatinate, hydriodide, and picrate. It forms a bi-tertiary saturated base, and the methyl group is not attached to the nitrogen.—Observations on the formation of the aleurone grains during the ripening of the seed: J. **Beauverie.**—Observations on the production of chlorophyll in the higher plants at different luminous intensities: W. **Lubimenko.** An important fact which appears from this work is that the best illumination for the production of chlorophyll is lower than the maximum luminous intensity of daylight. A green plant can adapt itself to a feeble light by increasing its production of chlorophyll.—The constancy of composition of plant juices obtained by successive extractions: G. **André.**—The action of tyrosinase on some substances resembling tyrosine: Gabriel **Bertrand.** Only those substances examined which contain a phenolic hydroxyl group proved to be oxidisable by a solution of tyrosinase. The length and nature of the lateral chain appeared to have only a secondary influence, provided that the chain was not too strongly acid or basic.—The excito-secretory action of the internal branch of the spinal nerve on the stomach and pancreas: F. X. **Lesbre** and F. **Maignon.** The internal branch of the spinal nerve of the pig contains, not only motive fibres, but also secretory fibres, the centrifugal fibres of the vagus.—Does the radiography of the abdominal organs permit of the diagnosis of true death? M. **Béclère.** Although the radiography of the abdomen is capable of giving assistance in the differential diagnosis of apparent and true death, the results cannot be absolutely relied upon.—The physiological properties of tubercle bacilli which have been submitted to the action of chlorine: MM. **Moussu** and **Goupil.** These chlorinated bacillary products have distinctive toxic properties, easily appreciable in healthy subjects. The thermal reaction provoked differs from that of tuberculin.—Contribution to the study of the influence of traumatisms on the localisation of tuberculosis. Results of articular traumatisms in rabbits tuberculised by the digestive canal: S. **Rodet** and M. **Jeanbrau.**—The Allier in Miocene times. A deposit of Miocene vertebrates near Moulins: Ph. **Glangeaud.**—The fossils near the tile works of Soumailles, in the commune of Pardailhan: G. **Vasseur.**—The Agout, a tributary of the Aude, and the valley of the Lhers mort: J. **Blayac.**—Researches on the variations of the terrestrial potential: Albert **Nodon.**

DIARY OF SOCIETIES.

FRIDAY, JANUARY 3.

GEOLOGISTS' ASSOCIATION, at 8.—On the Zones of the Chalk in the Thames Valley between Goring and Shiplake: C. P. Chatwin and T. H. Withers.

MONDAY, JANUARY 6.

ARISTOTELIAN SOCIETY, at 8.—Prof. James's "Pragmatism": G. E Moore.

VICTORIA INSTITUTE, at 4.30.—The Influence of the Glacial Period upon the Early History of Man: Rev. G. F. Wright.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Preparation of Paratoluidine from mixed Toluidines by means of Paratoluidine Hydrate: R. J. Friswell.—The Determination of Small Quantities of Bismuth: H. W. Rowell.

WEDNESDAY, JANUARY 8.

JUNIOR INSTITUTION OF ENGINEERS, at 8.—Recent Improvements in Electric Conduit Traction Construction: Fitz Roy Roose.

GEOLOGICAL SOCIETY, at 8.—On the Application of Quantitative Methods to the Study of the Structure and History of Rocks: Dr. H. C. Sorby, F.R.S.—Chronology of the Glacial Period in North America: Prof. G. F. Wright.

THURSDAY, JANUARY 9.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Cost of Electrical Power for Industrial Purposes: J. F. C. Snell.

FRIDAY, JANUARY 10.

ROYAL ASTRONOMICAL SOCIETY, at 5.

CONTENTS.

THURSDAY, JANUARY 9, 1908.

THE HISTORY OF AERONAUTICS.

Histoire de la Navigation aérienne. By W. de Fonvielle. Pp. 271. (Paris: Libraire Hachette et Cie., 1907.)

THE subject of aërial navigation is steadily developing into one of importance. Invention in this line is progressing so rapidly that the expert who wishes to be up to date must perforce be busy with much new literature. The work before us, by so well-known an aëronaut as M. de Fonvielle, will, then, be eagerly sought for. The student who expects to receive full information on all the recent developments may, however, feel some disappointment when he has looked through the book, since, out of its 270 pages, only some forty are devoted to the very important work which has been accomplished during the last ten years. The rest of the book is historical, throwing, no doubt, much new light on certain points, but, as a whole, containing nothing of importance that is not to be found in older works.

The first chapter deals with the soap bubbles of Tiberius Cavallo, a story well known to Englishmen who have read that savant's most interesting book, "The History and Practice of Aërostation," which was published in London so long ago as 1785. In June, 1782, Mr. Cavallo read a paper before the Royal Society in which he described how he had attempted to fill a light paper bag with hydrogen, in order to make it float in the air, but found it impossible to retain the "inflammable air," and how he then managed to blow out soap bubbles with hydrogen which rose in the air. In the following year both hot-air balloons and gas balloons were invented in France, and the accounts of them are described by M. de Fonvielle in following chapters. Elongated "dirigible" balloons, worked by hand, were designed very soon after the first ascents, but, of course, proved of little practical use.

The chapters on the first scientific ascents refer to those of Robertson, Gay-Lussac, Barral, and Green, but the better-known and more complete work of Glaisher and Coxwell is not more than touched upon in a following chapter.

The chapter on "Les Ballons-sondes" contains much that may be of interest to modern meteorologists, since this means of studying the atmosphere is now so much employed.

Three chapters are devoted to ascents during the siege of Paris, and one to aëronautical photography, but perhaps the most complete and interesting accounts in the book are those of the *Lebaudy* and other dirigible airships. It was in November, 1902, that the first free ascent was made with that vessel, which has now proved itself to be the first really practical aërial machine. Many more trials are described, including one on July 24, when 98 kilometres were covered; on November 12, when the airship travelled 60 kilometres to Paris; and on July 3, 1905, when a journey of 96 kilometres was performed in 3 hours 21 minutes.

The last chapter, on the development of aërial navigation, is somewhat disappointing, for after referring to the *Patrie* and the *Ville de Paris*, the two most recent practical airships in France, it recounts shortly what has been attempted in this line in other countries, but makes no reference to the important experiments recently made with the "heavier-than-air" type of machine.

As a history the work is not very satisfactory, since it jumps to and fro from period to period, and anecdotes are frequently narrated without specifying the dates.

The book is fully illustrated, but though they include some reproductions of photographs of recent events, by far the greater number of the illustrations are from woodcuts which have already done service in "Travels in the Air" (published in 1871) and other older works. We must take strong objection to some of these old blocks being reproduced with new titles, such, for instance, as that on p. 185, entitled "Les Concours de Vincennes en 1900," and that on p. 201, "Ballon couvert de neige . . . . ascension de l'Aéro Club," both of which appeared in the above-named book; and especially that on p. 139, "Descente de Lhoste en Angleterre," which appears in "Travels in the Air," p. 307, as "Descent of the *Neptune* at Cape Griznez." As this picture is a landscape with cliffs and a lighthouse, it cannot faithfully represent a scene on the English coast as well as one on the other side of the Channel!

TREATMENT OF HOME-WOODS.

The Garden Beautiful: Home-woods and Home Landscape. By William Robinson. Pp. xii + 170. (London: John Murray, 1907.) Price 7*s.* 6*d.* net.

THE author's expressed object in writing this book was to induce people fortunate enough to possess woodlands to make them attractive and accessible. Having already written the "English Flower Garden" and the "Wild Garden," he is careful in this case to point out that just as in the latter book his purpose was not to destroy the flower garden, so in the present instance the arguments in favour of beautifying the home-woods are intended to persuade proprietors "after thought of the needs of a true garden, to think more of their woods from æsthetic and other points of view."

We are quite in sympathy with Mr. Robinson when he states that there are hundreds of acres of beautiful woods in his district never seen by anyone but the gamekeeper. Yet how delightful the effects that may be obtained by opening up such woods, in a manner that paths are made available for foot visitors at all seasons of the year! On most estates no such thing is done, but we have in our mind several instances that afford striking testimony to the deprivations voluntarily or ignorantly suffered by those who maintain the woodlands as a closed book, so to speak, to all but sportsmen. One of these is at Keele Hall, in Staffordshire, the present residence of the Grand Duke Michael of Russia, where the woods, extending for a mile or more beyond the pleasure grounds, were laid out with suitable paths about forty years ago by the late Ralph Sneyd, uncle to the present owner of the estate.

The idea in carrying out such work should be that of bringing the most picturesque portions of the wood into view, and the paths should be arranged accordingly. It would be contrary to the spirit of the thing to try and make the woodlands a kind of pleasure-ground, for the woods are capable of yielding effects perfectly distinct from those which may be obtained from a pleasure-ground. No great amount of planting need be done, but by this statement we do not mean that regard for a supposed principle need prevent one from planting decorative shrubs, trees, or bulbs in positions where suitable sites are available for them, and the effect can thereby be greatly improved. In many situations where close planting has caused trees to develop fine, straight stems or trunks, there is no need for any under-shrub to complete the scene, for the lover of trees will have his delight in viewing the magnificent stems, often devoid of branches for twenty, or even thirty, feet from the ground.

But it is necessary, for change of scene, that in some places there should be a dense undergrowth of an evergreen shrub, such as the rhododendron, which is capable of thriving and even flowering well in comparative shade. The author of the present work rightly insists on the necessity of obtaining rhododendrons on their own roots for woodland planting, as they are usually capable of succeeding better than grafted plants, especially if the grafts have been worked on stocks of *R. ponticum*. Many gardeners have the idea that the old and somewhat unattractive *R. ponticum* is the hardiest of all rhododendrons, but this is erroneous. Some of the North American kinds are much hardier, and their effect when in flower is brilliant. Mr. Robinson specially recommends a variety known as "Cunningham's White," a most hardy plant of vigorous constitution, and bearing flowers of a rosy-lilac colour in bud, gradually becoming paler as the flowers expand. Other suitable species for forming undergrowth of a similar nature would include *Berberis aquifolium* (the evergreen barberry), *Ligustrum ovalifolium* (common privet), *Laurus nobilis*, *Gaultheria Shallon*, species of Hedera (ivy), Bambusa species, also common briars, bracken and furze, &c.

When once the owner of a wood, however, determines to make it accessible and attractive, he will soon discover various ways in which the views from the paths may be improved without interfering with the character of the wood itself. The sides of the paths can easily be planted with attractive, low-growing shrubs, and the scope for securing spring effects from flowering bulbs will be almost infinite. The bulbs from the forcing houses need never be thrown away, for suitable situations for them will present themselves in numerous instances, and snowdrops, crocuses, bluebells, and even the cheery little cyclamens may be planted in thousands.

The author reproduces two chapters from "The English Flower Garden," and then in subsequent chapters goes on to deal with the evergreen and deciduous trees of the northern forest, the best of native and European trees for the British Isles, how to produce wood and covert from seeds, and many other details connected with the subject, there being in all thirty-three chapters. We cannot agree with the suggestion on p. 76 that trees growing in isolated positions on lawns have their roots robbed by the grasses! in anything like the measure that obtains when the trees are growing together in a plantation. Mr Robinson's plea for the use of English names in garden literature we regard as unfortunate, unless the botanical names are employed also, as the use of popular names alone usually leads to the greatest confusion.

WATER SUPPLY.

Clean Water and How to Get It. By Allen Hagen. Pp. x+178; illustrated. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1907.) Price 6*s.* 6*d.* net.

THERE is probably no engineering topic at the present day of more striking importance to the public welfare than that relating to the supply of pure water for domestic purposes to large centres of population. Health, physical fitness, comfort and general well-being are all bound up in the solution of a problem which becomes daily increasingly difficult, and, at the same time, increasingly urgent, with the rapid growth and development of manufacturing towns, quite apart from the consideration of its equally essential application to the smallest hamlet and to the individual. An age which no longer recognises disease and degeneration as the unalterable and inscrutable decrees of a mysterious Providence, but as evils to be resolutely combated, with every hope of a successful issue, cannot for one moment tolerate the idea of polluted sources and germ-ridden channels for its supplies of water—that element so indispensable to existence and so inseparable a constituent of nature itself.

Any publication, therefore, which tends to throw additional light on the subject, or which collates and classifies data and information already acquired for the use of those engaged in the prosecution of waterworks, must be readily welcome. Mr. Hagen's book belongs to the latter class, and his object has been to set down some useful facts and principles for the guidance of those who have had no previous experience in the matter, and yet who are called upon, in connection with civic and urban duties, to participate in the control and distribution of water for their respective districts. The book is avowedly not intended for the expert, though even he may find some serviceable data among its pages. It is for the beginner and the "man in the street," in order that they may thereby be led to understand and appreciate something of the rudiments of a science of such vital concern to themselves and their fellow citizens.

Written exclusively from an American standpoint and based entirely on American practice, it is difficult on this side of the Atlantic to offer very effective criticism of its contents. Conditions here differ in so many respects as to afford little scope for useful comparison. Thus in this country we have no cases of towns corresponding to the Great Lake cities—Chicago, Cleveland, Buffalo, Detroit, Milwaukee and Duluth—drawing their water supplies from the same limited area into which their sewage is discharged. The risk of pollution is so abundantly evident that it is not surprising that Chicago has attempted to minimise the evil by diverting her sewage outfall, at considerable cost, into the Mississippi River. The wonder is that the example has not been copied in other cases.

Another strikingly distinctive feature is the enormous excess of supply *per caput* over that generally provided in this country. London and Liverpool are each content with less than forty gallons per head daily, whereas ten large American cities severally and individually exceed a demand of 100 gallons per head. New York takes 129 gallons; Boston, 151 gallons; Chicago, 190 gallons; and Pittsburg, 250 gallons. The discrepancy is tremendous. One feels that Mr. Hagen has hardly put it sufficiently strongly when he remarks that, "taking it right through, probably one-half the water supplied to American cities is wasted."

Mr. Hagen, in his book, first describes the various available sources of supply, viz. artificial reservoirs, small and large lakes, rivers, wells, and springs. He then discusses the chemical action of water on iron pipes and the means of effecting and maintaining the purification of stored water. There are chapters on pressure and on metering; the financial side of the subject is also considered. Altogether, the book is a most useful compendium of information relating to American methods of water supply.

VETERINARY PHYSIOLOGY.

A Manual of Veterinary Physiology. By Colonel F. Smith, C.B., C.M.G. Third edition, completely revised and in parts re-written. Pp. xvi+715. (London: Baillière, Tindall and Cox, 1907.) Price 15*s.* net.

An interval of twelve years has passed between the issue of the last edition of this text-book and the present, third, edition. So many and notable have been the advances in physiology during that time that the book has had to be practically re-written; only the chapters on the senses, locomotion, and the foot stand nearly as they were. The chapter on the nervous system has been read, and some new matter added to it, by Prof. Sherrington, F.R.S., and other sections have been amplified by the cooperation of men who have special knowledge of the particular subject dealt with.

The book is not a text-book of human physiology with a little veterinary material added, but is a treatise which takes the horse as the type, and preserves that type throughout. Other animals of interest to the veterinary surgeon are not thereby excluded; the ox, sheep and pig, where differing essentially in their physiology from the horse, are fully considered. A special feature of the work is the interest it arouses in the reader; the physiology is applied to the practical requirements of the student and practitioner, and the book is, in its way, partly a clinical manual. An appendix to many of the chapters takes up shortly the more common features of pathological interest liable to occur in the organ or organs the physiology of which has just been considered. The addition of a little pathology is, in the words of the author, meant to enforce the lesson that pathology is only physiology out of health. It certainly adds greatly to the interest of the book, and serves to emphasise the importance of a thorough understanding of the normal.

For many of the discoveries in the physiology of the horse we are indebted to the researches of Colonel Smith himself, and no one is in a better position to unfold them. This he does in the simplest and clearest language; many of his statements, indeed, throw light on processes which go on in the human body, or are at least extremely suggestive. The observations, founded on universal experience, that, in order to get a horse fit for hard work, or cattle and sheep ready for the butcher, the diets given must be strongly nitrogenous and limited only by the appetite, are quite opposed to the recent theories so strongly advocated by Chittenden. This is not the only instance where theory and practice come into opposition; the custom of watering a horse before feeding it is physiologically correct, but, according to Ellenberger, a horse, in order to derive the fullest possible nutriment from its oats, should be given hay first, then water, and finally oats. This does not accord with the English views of watering and feeding horses, which, however, as Colonel Smith says, have stood the test of prolonged practical experience.

The chapter on digestion is particularly good; the horse, ox, pig, and dog are separately considered. Occasionally one meets with statements that require further amplification; that pilocarpine is antagonistic to atropin and produces a profuse flow of saliva reads as though pilocarpine overcomes the effects of atropin, and that nicotine paralyses ganglion cells is not quite exact. The text, however, bears evidence of careful revision, and the book will prove a most valuable one to veterinary students and practitioners. Recent discoveries have been generally incorporated. Special mention may be made of the chapter on generation and development, which are particularly well treated. The work is one that can be read with interest from beginning to end, and claims the attention of all interested in veterinary work.

Percy T. Herring.

OUR BOOK SHELF.

The Polarity of Matter. By Alex. Clark. Pp. vii+134; illustrated. (London and Edinburgh: Gall and Inglis, n.d.) Price 3*s.* 6*d.* net.

This book claims to be a trustworthy text-book for the student of physics, but we cannot recommend it in this respect. Very few of the statements of fact which it contains are correctly made; and the deductions from them are supported by little consistent proof. At least, these are the conclusions to which we have come after a genuine endeavour to understand the meaning of the book. At the present time, when there has been such a rush of new facts, there is abundance of room for a book of a speculative character. The author must not think, therefore, that we speak unfavourably of his work because of its novelty. The true explanation of physical phenomena will sound exceedingly novel, we have no doubt, when it is first put forward. It may be that in the author's mind there is a germ of an idea which deserves developing. But if he wishes this to be recognised it would be well if he were to get some friend to assist him in the process.

The main aim of the book is to reduce all "forces" to one origin; and the secret by which it is done is the recognition of the "polarity of matter." Considering the thoroughgoing attempts of Sutherland and others to explain gravitation by means of polar systems of electrons, he would be a rash man who should say that the author's idea is absolutely chimerical. Whether or not he is qualified to develop it may perhaps be learned from the following extracts:—

"When the magnet is a straight bar . . . the distance between its pole being $2a$ . . . the magnetic force is 3·14 times the gravitational force. If the magnet be bent into the form of a horse-shoe so that the distance between its poles is a, the magnetic force is 12·5 times the gravitational force. . . When the poles of the magnet come together the force is unity. . . ."

"The position of a fragment of iron in a magnetic field may therefore be defined as tangential to an ellipse of which the magnetic poles are the foci."

"The force of attractive interest in each of two bodies forming the poles of an electric force is a constant quantity, and when the force radiates equally in all directions its magnitude is gravity."

"In all cases of magnetisation by means of an electric current, certain waves proceed from the current by which the effect is produced. These waves are commonly called Hertzian waves."

If the seeker after novelty finds in the above extracts the particular kind of novelty for which he seeks, we cordially commend the book to him; and we wish him greater success in unravelling its meaning than we have attained.

Wild Bees, Wasps and Ants, and other Stinging Insects. By Edward Saunders, F.R.S. With numerous illustrations in the text and four coloured plates by Constance A. Saunders. Pp. xiii + 144. (London: Routledge and Sons, Ltd., n.d.) Price 3*s*. 6*d*.

SINCE the death of Frederick Smith, probably no man has given more attention to the study of our British Hymenoptera Aculeata (the section of the order which contains stinging insects, such as bees, wasps, and ants, &c.) than Mr. E. Saunders. This order of insects is much less hackneyed than the Lepidoptera or Coleoptera, and Mr. Saunders's work will be very useful to beginners commencing the study of perhaps the largest order of insects of all, and also of the most interesting section, for there are only four groups of insects known which include species living in organised communities, three in Hymenoptera—bees, wasps, and ants—and only one in Neuroptera—the termites, improperly called white ants. The non-aculeate Hymenoptera, not here dealt with, are far more numerous, and are very imperfectly known or studied at present; they comprise the sawflies and gall flies, and also the ichneumons, and other parasitic insects, hundreds of which are of very small size, including among them the smallest known insects.

But it will be sufficient for most entomologists who are inclined to study Hymenoptera to follow the lines laid down by Mr. Saunders for the examination of the structure and habits of the more familiar and less difficult group of Hymenoptera Aculeata. The information given, though, of course, much condensed, is well arranged and thoroughly trustworthy, besides being expressed in an attractive manner. The last chapter, "On Structure," with a good diagram and clear descriptions, will be particularly useful, for nothing is more troublesome to an entomologist taking up the study of an order or group of insects unfamiliar to him than the absence of a clear explanation of the terms applied to the various details of insect structure.

Das Problem der Schwingungserzeugung. By Dr. H. Barkhausen. Pp. iv + 113. (Leipzig: S. Hirzel, 1907.) Price 4 marks.

THE author of this book discusses the conditions under which an instrument or piece of apparatus can produce undamped vibrations when the source of energy does not vary periodically.

The organ pipe and violin string illustrate the phenomenon in the case of vibrations produced by mechanical means. For the mathematical theory, however, electrical vibrations are the most convenient, and as the problem of creating undamped electrical vibrations is of present-day importance in wireless telegraphy, the greater part of the book is devoted to its consideration.

The first result obtained is that a necessary condition for the production of permanent vibrations is the presence of a variable alternating resistance, self-induction or capacity in the current system. The variation of the resistance may be due to external action, as in the microphone and in a new arrangement called the resonance interruptor, which is capable of giving high frequencies, or it may arise from the current flowing through the apparatus as in the electric arc.

The author makes frequent use of graphical methods, especially in the discussion of three different types of vibration which can be produced with the arc. These are investigated separately, and compared with regard to their capacities for resonance, high frequency, and performance of work. The questions of stability show that permanent vibrations can be obtained only when the interval for re-kindling after extinction increases more rapidly at first than it does afterwards. Various methods are given by which this can be ensured.

The book concludes with a chapter on mechanical vibrations, particular attention being paid to those produced by friction. On the whole, the exposition is good, and we can confidently recommend the book to those who wish to obtain a grasp of the principles of the subject.

H. B.

Album de Aves Amazonicas. By Dr. E. A. Goeldi. (Para: Museu Goeldi, 1907.)

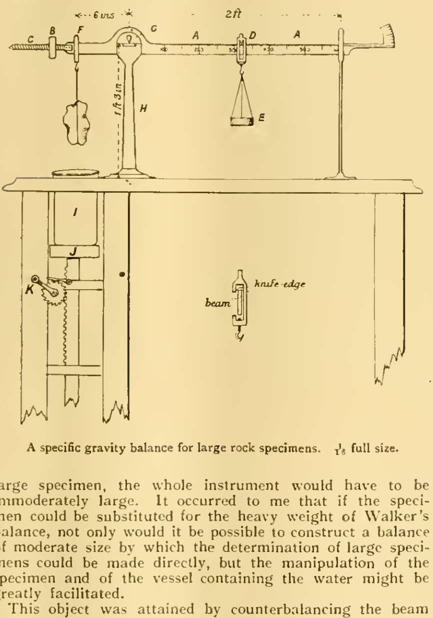
WE have been favoured with a copy of the third and final fasciculus of this superbly illustrated work, of which the first part was noticed in our issue of August 22, 1901. The present fasciculus includes plates 25–48, which are executed in the same first-class style as their predecessors, and a re-issue of the descriptions of the entire series, together with several well-arranged indices. We can add little in the way of commendation to what has been already written in our notices of the two earlier issues. Throughout the work the figures are for the most part well drawn, and coloured with such a near approximation to nature as to render the various species easily recognisable. That the work will tend to promote the study of Brazilian ornithology cannot be doubted, and the author is to be heartily congratulated on having given to the world such a splendid series of portraits of the most striking representatives of a tropical bird-fauna.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

A Specific Gravity Balance for Large Rock Specimens.

The specific gravity balance represented in the accompanying illustration was devised by me some ten years ago for the determination of the specific gravity of hand specimens of rocks in the laboratory of the Geological Survey of India, Calcutta. In the ordinary form of Walker's balance the weight used on the short arm must be considerable in order to balance even a very small fragment of rock on the longer arm, and in consequence the specific gravity of an ordinary hand specimen has to be inferred from that of a small chip, which, unless the rock is of very homogeneous composition and texture, may give a very misleading result; and it is evident that if this form of balance were capable of accommodating a fairly



A specific gravity balance for large rock specimens. $\frac{1}{8}$ full size.

large specimen, the whole instrument would have to be immoderately large. It occurred to me that if the specimen could be substituted for the heavy weight of Walker's balance, not only would it be possible to construct a balance of moderate size by which the determination of large specimens could be made directly, but the manipulation of the specimen and of the vessel containing the water might be greatly facilitated.

This object was attained by counterbalancing the beam A (see diagram) by means of a weight B, which is made so that it runs fairly easily on the screwed rod C, attached to the shorter arm of the beam. The adjustment is made before commencing a series of determinations, after removing the sliding piece D from which the scale pan E depends (the back of this sliding piece being cut away for this purpose, as shown in the separate figure), but with the hook F for the suspension of the specimen in place. Both the frames to which the hooks are attached are supported on knife-edges, that at F being fixed to the beam, while that at D is attached to the sliding-piece, so that it can be placed at any point on the longer arm of the beam. The beam itself is balanced on a knife-edge at G, supported on grooved agate bearings let into the top of the pillar H. The beam is divided along its upper edge into millimetres, measured from the point of support at G. The dimensions of the instrument are indicated in the diagram; it was constructed by the Mathematical Instrument Department of the Survey of India in Calcutta.

On the left-hand side of the table supporting the balance is shown an arrangement for raising and lowering the jar I, containing water. The jar is supported by a block of wood J, to which is attached a rack and pinion actuated by the handle K, a ratchet wheel and pawl enabling the jar to be fixed at any convenient height. This apparatus has been found very convenient in manipulating large specimens, and it enables one to get rid of the air-bubbles which attach themselves to the specimen when first immersed, by raising and lowering the jar two or three times before moving the scale pan.

In making a determination the knife-edge carrying the scale pan is placed at the 500 mm. division on the beam, and small shot are poured into the pan until the specimen in air is exactly balanced. The water-jar is then raised until the specimen is entirely immersed, and then the scale pan is moved to the left along the beam until equilibrium is again established, the weight in the pan remaining the same. The number of millimetres at which this occurs is noted, and the specific gravity corresponding is found at once from a table suspended near the instrument. A portion of this table is given here:—

mm.	sp. gr.	mm	sp. gr.
300	2·500	—	—
301	2·512	—	—
302	2·525	348	3·289
303	2·538	349	3·311
304	2·551	350	3·333
—	—	351	3·355

The specific gravities corresponding to each division might, of course, be engraved on the beam, but with millimetre divisions the figures would have to be inconveniently minute. In practice the balance has been found to be very accurate, on comparison with a large balance of the ordinary description, the error only affecting the third place of decimals; and where a large number of hand specimens has to be determined, the saving in time made possible by its use is very great.

Broken specimens and small fragments of rock may be enclosed in a cage of fine copper wire, the error introduced by which can be easily calculated. In Calcutta, when the cage is in use, the error is corrected by adding 1 to the number of millimetres read when the specimen is immersed in water.

There is, of course, nothing new in the principle of this balance, but the general arrangement, especially the water-lift, is, I think, novel, and it has been found so convenient where large numbers of hand specimens have to be dealt with that I trust it may be introduced into other geological laboratories; I shall be happy to furnish more precise details of the dimensions of the instrument to anyone desirous of having a similar one constructed if he will kindly communicate with me.

T. H. D. La Touche.

Kingstown, Ireland, December 7.

A Point in the Mathematical Theory of Elasticity.

I do not recollect that in Prof. Karl Pearson's recent memoirs embodying the results of tests on jelly models of dams he asserted that the distribution of stresses due to the water pressure on and the weight of a dam is *entirely* different in a thin slab cut from the dam from the distribution in the actual dam. In fact, Prof. Pearson used many such model slabs in an endeavour to ascertain experimentally certain stress distributions in actual dams. Prof. Pearson will doubtless be able to reply to criticisms from engineers or others regarding any statements he has made in this connection, either in his published memoirs or elsewhere; it is difficult to follow Mr. Martin's arguments (p. 198) at all points, more particularly with respect to the effects of the cancellation forces $\widehat{yy} = F(xz)$.

It seems to me, however, that the stresses in a thin slab, due to its weight and water pressure, *must* be different from those in an actual dam. A dam is fixed as rigidly as possible along its base and at its ends, and if the plan of the upper edge is originally straight there must be some horizontal displacement at the centre of the length from the line joining the abutments, quite apart from such displacement as may be due to the overturning effect of the pressure on a vertical slab. The dam resembles *in some measure* a built-in beam, and, recognising this fact, some large dams have been built slightly convex on the water face.

If a balcony consisting of a plate of variable depth is rigidly supported at its ends and along one side, I imagine that the vertical displacement caused by a load at the centre and front of the free edge of the balcony could not be estimated without some regard for its end and side supports, nor could the stresses due to it be easily determined. There *would* be *some* stress along the horizontal fibres joining its ends, and the elevation of the front edge of the balcony must show contraflexure, since its ends are horizontal and the centre portion is concave upwards.

Can we deny the existence of such effects, whatever their magnitude may be, if a masonry dam is regarded as an elastic body? An engineer should be conscious of all the forces at work on a structure which he is designing, and if these forces and their effects can be correctly estimated, a design may be prepared having due regard to the physical properties of the materials employed and their liability to variation, owing to natural causes and errors of workmanship.

When the forces and their effects are in any measure uncertain, the exercise of due caution, accompanied by mature judgment based on experience, will usually lead to a successful design. It does not seem probable that a mathematical solution can be obtained for the stresses in a homogeneous isotropic dam, rigidly fixed at its ends and base, which can take account of the conditions existing in practice. The solution of the theoretical case would be of interest, but it is questionable to what extent it would be applicable to practical conditions, in which dams are not homogeneous and isotropic, and foundations and abutments are not absolutely rigid.

Engineers recognising these facts have used a simple but approximate method of estimating the stresses in a dam, based on the flexure of beams. The solution based on the theory of elasticity, as presented by Prof. Pearson, may be nearer the truth, but it may be questioned whether this can be known to be the case in an actual dam.

E. BROWN.

Echelon Spectroscope.

FURTHER observations on the secondary bands referred to in my letter in NATURE of January 2 (p. 198) seem to indicate that they are faint spectra of a much higher order than the primary spectra.

Faint spectra of a very high order must be formed by a series of beams that have suffered two reflections at the external surfaces of the echelon. Each of these secondary beams has traversed the echelon three times, and the retardations of the beams form a series the common difference of which is seven times that for the series of beams giving the primary spectra, taking the index of refraction to be 1·5. These secondary beams would only have about one six-hundredth of the intensity of the primary beams, and I thought that the resulting spectra would be too faint to be observed until I found that the reflections that take place at the interfaces of the echelon assist in forming the same secondary spectra.

Assume that each interface reflects the same very small proportion of the light incident upon it, and neglect beams that have been reflected more than twice. Imagine the echelon being built up one plate at a time, commencing with the largest. Each plate that is put on starts a series of secondary beams and adds another term to each of the series started by the earlier plates. The retardations in each of these series have the same seven-fold common difference as the first series, and so they all help in forming the secondary spectra.

Each member of the series started by the nth plate has n times the intensity of the unit secondary beam produced from the primary beam by two interface reflections, consequently the last few steps of the echelon are much more effective in producing the secondary spectra than the steps formed by the first few plates, and the clearness of the secondary spectra given by the echelon may be much improved by covering over, say, the first half of the whole number of steps built up.

In this way better photographs of the secondary bands have been obtained, and I hope to be able to test this explanation of their formation quantitatively.

H. STANSFIELD.

The University, Manchester, January 6.

The Photoelectric Property of Selenium.

I HAVE to thank Mr. R. J. Moss (January 2, p. 198) for the true explanation of the extraordinary increase of conductivity of a selenium bridge enclosed in an exhausted tube. The air pump employed, in the first instance, to produce the exhaustions was the mercury pump of Töpler, and it occurred to me that the mercury vapour might be objectionable. The enormous magnitude of the effect, however, induced me to ignore this vapour. The drop in resistance was finally from 61 megohms to 9·7 ohms. After seeing Mr. Moss's letter I made another bridge, enclosed it in a glass tube, and exhausted this tube with a Fleuss. The result was now an *increase* of resistance in the bridge from 57 megohms to 110 megohms—an increase which can be easily explained. Whether or not the exhaustion produces increased sensitiveness to light and other benefits I cannot yet say. Dr. Shelford Bidwell's conjecture that there was a short circuit in the bridge is the first explanation that naturally occurs, but from the nature of the bridge no short circuit is possible. The metallic parts are absolutely fixed, and separated by thicknesses of glass or mica sometimes amounting to 1 mm.

The result proves the undesirability of exhausting by mercury pumps in certain cases.

Oxford, January 5. GEORGE M. MINCHIN.

Musical Sands.

IN NATURE of December 26, 1907 (p. 188), Mr. S. Skinner's recent exhibition of "singing" sand at the Physical Society is referred to. These particular sands were said to consist chiefly of angular grains. In all my investigations, which have extended over a period of many years, I have never been able to produce musical notes from any sands composed of purely angular grains; indeed, as I have frequently stated, a certain proportion of angular grains mixed with a musical sand will effectually silence it! I dealt fully with this point in my paper on musical sand published in 1888. Again, I have never yet met with purely angular grains possessing smooth and rounded surfaces—conditions which, with others, are essential in the production of music from sands. Perhaps Mr. Skinner meant subangular grains?

I do not think the explanation of the cause of the phenomenon suggested by Profs. Poynting and Thomson in "Sound" ("Text-book of Physics") meets the case. It is based on the erroneous assumption that the sand-grains are arranged as a number of equal spheres in contact. If this supposition were correct, and the condition an essential one in the production of notes, then my experiments with many sands composed of highly spherical grains (like the "millet seed," for instance) should have yielded notes of the highest quality, instead of being, as they all were, mute under the most favourable conditions.

The late Prof. Tyndall, who took a great interest in my work, and personally confirmed the results of my experiments, agreed with my conclusions, and thought *hardness* of grain an important consideration, believing that the loudest notes might be emitted from ruby and diamond sands—if I could get them! I am under the impression that if the theory proposed by Profs. Poynting and Thomson is tenable, it should be possible to obtain notes from comparatively soft spherical seeds (like fig, &c.), but though I have experimented with many kinds, I have not been successful in this direction. I still think my friction theory the simplest, and as many leading men of science have supported it, and no one has as yet disproved it, why may it not be retained?

CECIL CARUS-WILSON.

SPORT AND NATURAL HISTORY.[1]

(1) IN works of the present nature, Mr. Millais is at his best; and his best, alike with pen and with pencil, is, it is almost unnecessary to say, very good indeed. Caribou-hunting was the main object of his expedition, and in this work the author has given us an account of the local race of the reindeer which has never before been equalled, a feature of special value being a coloured plate of the animal from a sketch by himself. Some magnificent and perhaps unrivalled photographs of heads of this handsome animal are also reproduced.

Mr. Millais is never content with following in the beaten track; and during his expedition he succeeded in making his way into previously unknown tracts in the interior, where he succeeded, from a clue given by Mr. F. C. Selous, in locating a large non-migratory southern herd. It will probably come as a surprise to many of his readers that a large area of the interior of the country is still unknown, even to the Government surveyors. Here reindeer abound, these swampy tracts of the interior being, in fact, fit for nothing else than reindeer. A most satisfactory feature is that, despite an organised annual slaughter during migration, the caribou continue to increase in the island, and, in the author's opinion, are likely to do so for centuries.

Mr. Millais estimates the number of caribou in the island at 200,000. The rate of destruction is estimated as follows:—"Putting the death-rate at the highest estimate of three animals each to 4000 shooters, 12,000 would be killed out of 200,000, that is, a depreciation of 6 per cent. Now this is a much smaller rate of killing than takes place among the stags of Scotland, and they are undoubtedly on the increase."

The book is, however, by no means restricted to Newfoundland and caribou, for we have, near the middle, an interesting chapter on the author's experiences in whaling, in which the game were the blue finner and the humpback. In the course of this chapter we notice (pp. 162, 178) two different dates assigned to Svend Foyn's invention of the bomb-harpoon, the one last mentioned being correct; and at least one slip in proof-reading is observable.

The coloured plates of scenery and animals are exquisite, and ought by themselves to ensure a large sale for this charming volume; while the reproductions from photographs and pen sketches are no less admirable and interesting. As an example, we reproduce the illustration of a party of caribou swimming a lake, with Mount Cormack in the distance.

(2) In place of stirring jungle adventures and hair-breadth escapes from tigers and wild boars, we have in this attractive and beautifully illustrated volume a series of chapters on the insect and other invertebrate (we really want a word equivalent to the Spanish *becho*, which will serve for all these creatures) life of the plains of India, followed by others on Indian trees, plants, and gardening. From preface to index the work is written in a style and with a charm which cannot fail to interest a large circle of readers; while the numerous references to details connected with the habits and environment of the various species cited serve to proclaim the author (already well known to the reading public by an earlier work on the same lines) as an accurate and painstaking observer. So graphic, indeed, are his descriptions that we can almost imagine ourselves in the veranda of a bungalow on a hot night at the beginning of the rains, surrounded by pests of many sizes and sorts, or wandering in spring through the incomparably beautiful glades of the Botanical Gardens at Calcutta.

Among the larger pests to which the author pays much attention are centipedes and scorpions; and in connection with the latter he relates how a *yogi*

from Mirzapur, who had the reputation of being immune to the scorpion's sting, submitted himself to a trial in Calcutta. To make sure that there should be no "bogus" in the matter, a good supply of freshly-caught scorpions of the most venomous type was provided. After some hesitation, he allowed several of the creatures to affix themselves to his fingers, when he appeared to suffer no special inconvenience or pain, and thus demonstrated the truth of his assertions. The immunity was, in Col. Cunningham's opinion, probably due to frequent inoculation with the venom, aided possibly by an innate tendency in that direction, and the consequent development of an antitoxin, the case being, in fact, analogous to that comparative immunity to mosquito-poison which results in most persons after lengthened preliminary suffering.

Among other trials to which the resident in India is subjected, the author waxes eloquent on the difficulty of preserving books from the ravages of "silver-fish" and white ants; while he also refers to the voracity of the huge land-snails (achatinas) introduced into Cal-

cutta gardens from Mauritius, and the unpleasant results which ensue if their destruction is not conducted on special lines.

Let no one, however, imagine that an Indian life has not its lighter side. What, for instance, can equal the glory of its sunsets, so graphically described by the author, or the luxuriance and beauty of its gardens, which he brings to our notice with the aid of both camera and pen? As an example of what can be done in the way of effect with foliage alone, we reproduce

the accompanying illustration, with which we must, reluctantly, take leave of a charming, thoughtful, and instructive work.

R. L.

"KIMBERLITE" AND THE SOURCE OF THE DIAMOND IN SOUTH AFRICA.

THE origin of the volcanic pipes of South Africa and the genesis of the diamonds contained in their "blue-ground" filling are as productive of controversy as that other geological puzzle—the source of the gold in the Witwatersrand conglomerates—the discussion of which was revived by Prof. J. W. Gregory at a recent meeting of the Institute of Mining and Metallurgy; and agreement among the disputants is as little likely to be arrived at in the one case as in the other. Quite a crop of papers on the diamond-pipes has recently appeared,[1] and a perusal of these reveals so remarkable a variation of opinion that it may perhaps serve a useful purpose to give in these columns a brief summary of the different views as to the nature of the original matrix of the diamond and the place in which it was produced, that have been put forward from time to time since the discovery of the "dry diggings" at Kimberley in 1870.

Prof. E. Cohen, who visited the diamond field in 1872, gave the first scientific explanation of the origin of the volcanic pipes in a letter addressed to Prof. Leonhard, and published in the "Neues Jahrbuch für Mineralogie" (1872, p. 859). According to Cohen the diamond occurrences represent the centres of tuff-eruptions, whereby the greater part of the erupted material was provided by older crystalline rocks underlying the present known formations. These furnished not only the diamonds, but probably most of the accompanying minerals. Forced violently upward by volcanic explosions, the shattered rocks became pulverised, and the diamonds either survived as complete crystals or were broken into fragments (the "splints" of the dealers). This view explains the fragmentary character of the minerals that accompany the diamond; it also accounts for the presence of so many fragments of crystalline rocks in the pipe-material ("blue-ground"), and for the strongly brecciated character of the latter. Cohen's view was subsequently somewhat modified by Chaper (Bull. Soc. Minér. de France, ii., 1879, p. 195), who found it necessary to assume a repetition of explosive eruptions in order to account for the variation in one and the same pipe of large masses of the blue ground in colour, mineral composition, richness in diamonds, &c.

On the other hand, Dunn, who wrote in 1874 (Quart. Journ. Geol. Soc., xxx., p. 54), described the blue ground as a "decomposed gabbro or euphotide"; while Maskelyne and Flight, who gave the first description of the microscopic character of the diamantiferous rock (Quart. Journ. Geol. Soc., xxx., 1874, p. 406), considered that it "was probably the original home of the diamond, possibly at the places of its contact with carbonaceous shales." These ideas were further developed by Carvill Lewis in papers read before the British Association in 1886 and 1887, and subsequently published by Prof. T. G. Bonney under the title "Papers and Notes on the Genesis and Matrix of the Diamond." After an elaborate microscopic investigation made in Prof. Rosenbusch's laboratory in Heidelberg, Lewis pronounced the rock to be a true eruptive lava—"a porphyritic

volcanic peridotite of basaltic structure, or, according to Rosenbusch's nomenclature, the palæo-volcanic representative of a biotite-bronzite-dunite, being an olivine-bronzite-picrite rich in biotite." To this rock he gave the name of kimberlite, distinguishing between *kimberlite proper*, a typical porphyritic lava; *kimberlite breccia*, the same lava broken and crushed by volcanic movements within the pipe, and crowded with included fragments of foreign rock; and *kimberlite tuff*, the fragmental and tufaceous portion of the same volcanic rock, all these varieties passing into one another and occurring together in the same neck or crater. The kimberlite breccia constitutes, according to Carvill Lewis, the greater portion of the pipe material, but it is traversed by dykes of kimberlite proper, and contains streaks and patches of a soft, "soapy" material which appears to be kimberlite tuff. As to the diamond, it is as much a constituent of kimberlite as the more commonly occurring biotite, garnet, titanic and chromic iron and perovskite, and consequently must have been produced *in situ*.

From this view Bonney was led to dissent by a microscopic examination, made in 1899, of specimens from the Newlands mines in West Griqualand ("The Parent Rock of the Diamond in South Africa," Proc. Roy. Soc., vol. lxv., 1899, p 620). Among these specimens was a rounded boulder of a rock which was described by him as a "holocrystalline mixture of chrome-diopside and garnet, with a few small enclosures of olivine, in other words, a variety of ecklogite and of igneous origin." The interest of the specimen lay in the fact that it contained diamonds, and from this Bonney drew the momentous conclusion that the birth-place of the diamond and of the garnet, pyroxenes, olivine, &c., was not the "blue ground" itself, but the ecklogite which occurred in the latter as foreign boulders. He further concluded, from the smooth exterior of the specimen examined, that the boulders were water-worn, and were derived from a conglomerate bed "at the base of the sedimentary series in proximity to a crystalline floor." The blue ground then, according to Bonney, is a true breccia produced by the destruction of both crystalline and sedimentary rocks, the "result of shattering explosions followed by solfataric action."

R. Beck (*Zeits. für prakt. Geol.*, 1879, p. 417), to whom similar specimens from the Newlands mines had been sent, differed from Bonney as to the origin of the so-called boulders of ecklogite, which he considered to be concretions formed at great depth in the kimberlite magma—like the well-known olivine nodules in the basalt of Finkenberg, near Bonn, described by Rosenbusch and others as early segregations from the basalt magma. The serpentine breccia which represents the present condition of the kimberlite magma contains all the constituents of the nodules. The rounding of the boulders is to be ascribed to attrition during the upward course of the pyroclastic material in the pipe. Beck agreed with Bonney that the diamonds were formed at great depth, but for a different reason, namely, that only at great depths could such coarse-grained granular segregations from the magma have been produced. In a more recent paper (*Zeits. der deutsch. geol. Gesellsch.*, 1907, p. 226), Beck gives results of a further examination of the Newlands ecklogite, which, by the way, he proposes to call "Griquaïte." In addition to the constituents already named, he finds biotite, perovskite, zircon, rutile, and graphite. He repeats his conclusion that the "boulders" are deep-seated (intra-telluric) segregations from the same magma from which the pipe material is derived, and ascribes the genesis of the diamond to the presence in the original magma of metallic carbides, it being his opinion that not only the diamonds contained in the ecklogite, but also the isolated individuals in the blue ground, must have been formed at great depth.

The views of the earlier writers can be grouped into two distinct theories:—(1) The pipe material is a breccia or tuff produced with its contained diamonds, by violent volcanic agencies, from pre-existing rocks (Cohen, Chaper, Bonney, Beck). (2) It is a true eruptive lava which has solidified *in situ*, the diamonds having been separated out during this consolidation (Dunn, Maskelyne, Flight, Carvill Lewis).

Among the recent writers on the subject, H. S. Harger and G. S. Corstorphine support the view that the diamonds have been derived from a deep-seated source, the former mentioning that out of a parcel of 372 stones examined by him, 119 were found to be broken fragments of original crystals. F. W. Voit, on the other hand, regards the "splints" as either imperfectly formed crystals or as having been broken during the processes of mining and washing. (He would find it difficult, however, to explain the fractured character of the Cullinan diamond[1] by either of these hypotheses.) Voit regards the pipes as embryonic volcanoes. According to him, the igneous magma which rose in the pipes, being unable to reach the surface, was forced to solidify under the pressure of the superincumbent strata in circular or elongated moulds, thus giving rise to what he terms "conical batholites." While the extruding magma was still in the semi-plastic state, it was agitated by further gaseous eruptions, to the action of which the brecciated character of the blue ground is largely to be ascribed. He regards the ecklogite "boulders" as concretions of the kimberlite magma, formed *in situ*. He admits, however, the presence in the blue ground of boulders of granite, gneiss and crystalline schists of exotic origin.

A. L. du Toit, of the Cape Geological Commission, who during 1906 was working in the Kimberley district, has formulated a theory which combines parts of both the earlier views, and is more in accord with modern ideas of petrogenesis. According to him, kimberlite is a hybrid rock derived from a deep-seated magma (having the composition of a limburgite) which incorporated the shattered fragments of the various holocrystalline basic and ultra-basic components of the floor through which it broke. During its further ascent the eruptive mass caught up and included in its body fragments of the sedimentary beds through which it passed. A portion of its brecciated character, however, is to be attributed to movements during consolidation. Of the minerals found in the blue ground, du Toit considers the tremolite, smaragdite, epidote, orthite, tourmaline, muscovite, biotite, apatite and zircon to be xenocrysts derived from deep-seated rocks of acid composition (granite, gneiss, pegmatite, &c.); while he regards the olivine, pyroxenes, garnet, ilmenite, magnetite, chromite, spinel, sphene, kyanite, and the diamond as xenocrysts derived from basic and ultra-basic holocrystalline rocks. In addition, the original eruptive magma gave rise on consolidation to authigenic crystals of olivine, diopside, brown mica, magnetite, ilmenite, chromite, apatite, perovskite, nepheline and melilite.

In support of his view, du Toit gives instances of strong contact metamorphism effected by the pipe material during its intrusion. Few cases of contact-metamorphism, however, have hitherto been observed. Corstorphine (*loc. cit.*, p. 65), for instance,

[1] *Vide* F. H. Hatch and G. S. Corstorphine, "A Description of the Big Diamond recently found in the Premier Mine, Transvaal (*Geol. Mag.*, p. 170, 1905).

states that the fragments of sandstone, shale, &c., that he has found enclosed in the blue ground are conspicuously unaltered.

Much of the recent controversy has centred round the relation of the kimberlite dykes to the pipes. The fact that material of practically identical character to the pipe rock, and similarly brecciated, occurs in the form of dykes has long been known; but the latter have hitherto attracted but little attention, owing to the fact that the dyke material either carries no diamonds or so few as to be unworkable at a profit.

There can be no doubt that the dykes are genetically connected with the pipes, but were they formed contemporaneously, or did the dykes precede the pipes or *vice versâ?* Dr. Voit states that the pipes are younger than the dykes, which in all cases terminate, according to him, at the pipe-walls. Besides, fragments of dyke rock occur in the pipes, but pipe rock is never found in the dykes. Although chemically identical magmas, there are slight mineralogical distinctions, due, probably, to the different rate of cooling, which enable the rocks to be easily identified. Du Toit advocates the contrary view, namely, that the pipes and fissures have been formed contemporaneously. Between the extremes of occurrence in pipes or dykes he traces every gradation, and mentions "fissure-swellings," which, though dyke-like, expand at one or more points. Almost every pipe will be found to have one or more dyke-like offshoots, if not at the surface, at some greater depth. In the Newlands group, the pipes are connected below ground by a narrow dyke of kimberlite; on Secretaris, west of Kimberley, there are fissures with one or more little swellings on them, and there are numerous dykes and veins varying in width from mere stringers to belts of many feet. The strike of the fissures corresponds in some instances to that of the enclosing rocks (Newlands, Smith, and Peiser mines), indicating that the intrusion followed planes of physical weakness.

Instances might be multiplied to show the differences of opinion that obtain among South African geologists with regard to these interesting occurrences. They only emphasise the difficulties of the problems awaiting solution.

One word as to the date of intrusion. The pipes and fissures are later than the Karroo dolerites, which, in their turn, cut the Stormberg lavas. They are therefore at least of post-Rhætic age. If the melilite-basalt pipes of Sutherland are connected in origin with an intrusion of melilite-basalt in the Uitenhage beds at Spiegel River (Heidelberg, Cape Colony), then the occurrences of kimberlite are of post-Neocomian age (*vide* Rogers and du Toit, *loc. cit.*).

F. H. HATCH.

THE INDUCTION OF ANÆSTHESIA BY CHLOROFORM.

THE inquiry which was initiated seven years ago by the Council of the British Medical Association into the many-sided problem of chloroform-anæsthesia has added greatly to our knowledge, and directed particular attention to the fact that the administration of an amount of chloroform vapour above 2 per cent. in the inspired air is fraught with danger to the patient. The scope of this inquiry has been further supplemented and extended by independent researches carried out in this country and in France.

The view has been held, and to some extent verified by experiments, that during the progress of anæsthesia the drug was absorbed by the corpuscles rather than by the plasma of blood. The experiments of Benjamin Moore and H. E. Roaf first definitely proved that *in vitro*, with an adequate concentration or solution tension of chloroform in the blood, easily dissociable compounds or aggregations were formed between the drug and the proteins, including hæmoglobin, of the blood. It was a natural inference from these experiments that the production of anæsthesia, either in isolated cells or in unicellular or multicellular organisms, was due to the formation of such compounds between cell-protoplasm and chloroform. With a very small constant quantity of chloroform, 1 per 100,000, in blood it has been found that the anæsthetic effect is in no sense a cumulative one; the degree to which a living tissue is affected depends entirely upon the concentration of the chloroform in the blood, and therefore in the living cell, for the degree of anæsthesia remains constant, and persists for only so long as a definite solution pressure is maintained. Any given grade of anæsthesia is therefore entirely independent of the total amount of chloroform which is supplied at an adequate concentration. In the induction of anæsthesia in man the various stages from slight to profound must therefore essentially depend upon the gradually rising pressure of chloroform in the blood. When the amount of chloroform in inspired air is very low, the induction of anæsthesia is impossible; while that too high a percentage is lethal, the unfortunate accidents which occur from time to time bear abundant witness.

The rate of absorption of chloroform during the induction of anæsthesia has been studied by many observers, most of whom have attempted a solution of this problem by ascertaining the degree to which the lungs are ventilated during narcosis, and the extent to which chloroform is apparently retained by the body. This is determined by estimating the difference between the chloroform-content of inspired and expired air. In the case of inspired air this can easily be done with accuracy, but, especially with a low percentage of chloroform, the corrections which are necessary for temperature, amount of carbon-dioxide and aqueous vapour are so great as to render an accurate determination of the amount of chloroform in expired air a matter of much difficulty.

The rate at which chloroform is taken up by the blood can, however, be directly measured. In three papers just published in the Proceedings of the Royal Society, Dr. G. A. Buckmaster and Mr. J. A. Gardner have described the exact procedure of their experiments, which were undertaken with the view of ascertaining the function of the red corpuscles in anæsthesia produced by chloroform. Two of the papers fully describe experimental studies on "The rate of the assumption of chloroform by the blood during anæsthesia," and "The rate of elimination of chloroform from the blood after anæsthesia."

Hitherto an exact determination of chloroform in blood has been found to be difficult. It is not possible to use Neumann's method for chlorides. French observers, Tissot, Mansion, and Nicloux, have employed a method which is based on Dumas's reaction, which, as carried out by Nicloux, is rapid, convenient, and capable of giving satisfactory results, though it does not possess such a high degree of precision as an exact chemical method as does the one which was introduced by Carius for the determination of chlorine in organic compounds. This method was first used by Buckmaster and Gardner in their experiments on the anæsthetic and lethal quantity of chloroform in blood. The maximum error of this method never exceeds five per cent., and is generally much less. The amount of chloroform in the blood at any stage of anæsthesia is calculated from the difference between the chlorine-content of the blood of each individual animal before and after the induction of anæsthesia.

Buckmaster and Gardner had shown that when a mixture of chloroform and air is inhaled, almost all the drug is held by the red corpuscles; in one case no less than 98·5 per cent. of the total chlorine in the blood was found associated with the red corpuscles after 2 per cent. of chloroform vapour had been inhaled for three-quarters of an hour. It would appear, therefore, highly probable that in chloroform narcosis the transport of chloroform from and to the lungs is a function of the red corpuscles, which are the chief vehicle for the drug. If this is the case, it is obvious that although the absolute quantity of chloroform in the blood of any individual would vary with the mass of blood, the percentage amount in a sample of blood would not vary, other conditions being constant, whether the total amount of blood in the body was augmented or diminished. A large number of experiments were therefore performed, in order to elucidate this point. The general aim of these was to vary the mass of blood either by bleeding or by introducing the greater part of the blood of one animal into another of the same species. The blood was directly transfused. In experiments where the asphyxial state was reached rapidly, the average percentage of chloroform in the blood was found to be practically identical before (0·043 gram) and after bleeding (0·045 gram). In cases where the asphyxial state occurred half an hour to an hour and a half after the commencement of chloroform-inhalation, the figures were 0·048 before and 0·051 after bleeding. The paper gives full details of fourteen experiments which have been made as to the percentage amounts of chloroform in blood before and after hæmorrhage, and these, together with other experiments in which comparisons were made with a normal, with an augmented, and with a diminished mass of blood in the same animal, show conclusively that the percentage of chloroform in the blood does not vary with differences in the mass of the circulating blood. The results of the experiments are therefore in complete accord with what would be the case if, as Buckmaster and Gardner suspected, the red corpuscles were the essential agents for the transport of chloroform.

The curves which illustrate the chloroform-content of the blood during the induction of anæsthesia with 2 per cent. or 3 per cent. of inhaled chloroform vapour are of much interest. At the present time these curves, constructed from data fully given in tabular form, possess great interest. Not only are they the only curves which exist that show clearly the rate at which the percentage of chloroform rises in the blood from the commencement of the administration of the anæsthetic, but the fact which is so well known, that deaths during anæsthesia not infrequently occur within two or three minutes after the patient commences to inhale, is easily understood, for the chloroform-content of the blood mounts up so rapidly at first as to constitute a veritable danger-point. The amount or tension of the drug in the blood rises in the initial stage of anæsthesia with great rapidity to a value which approaches a maximum. If the individual passes this stage naturally, then after a distinct fall in the chloroform-content of the blood, the amount of the drug quickly rises again towards a maximum value, and an equilibrium between the factors which determine the amount of chloroform in the blood is subsequently obtained, the processes of intake and output at the surface of the lung going on side by side. This period corresponds to the second stage of anæsthesia. It may last for one or more hours, and represents the state of surgical anæsthesia. But the condition of the individual is far from one of safety, for although this stage can be maintained with an amount of chloroform in the inspired air which could not have induced anæsthesia, throughout the whole of this time the difference between the amount of chloroform which is present in the blood and what is found at the lethal point is very minute. The authors have laid special stress on this point, and from a careful examination of their curves it would appear that their contention is a sound one.

In their third paper Buckmaster and Gardner have studied the rate of elimination of chloroform after anæsthesia. Five typical experiments, accompanied with full data and curves, are given. During recovery from chloroform small quantities of blood were in some cases taken at intervals from an artery; in other cases the blood was taken by a long canula from the venous system close to the right auricle of the heart, and one curve is constructed from data obtained by analysis of samples, taken simultaneously, of arterial and venous blood from the carotid artery and the neighbourhood of the right auricle. The authors find that the rate at which chloroform is eliminated at the surface of the lungs is at first comparatively rapid, though subsequently this becomes much slower. But the initial rates of elimination are much less rapid than the initial rates for absorption, and therefore, on the whole, elimination of the drug is a much slower process than the assumption. From Tissot's observations it would appear that during recovery from chloroform anæsthesia the amount of the drug in venous blood constantly exceeds the amount in arterial, and he suggests that a study of the chloroform-content of arterial blood should be made during the induction of anæsthesia, and of venous blood during the disappearance of this state. Buckmaster and Gardner do not confirm all the results obtained by Tissot, though they are in entire agreement with him on the important fact that at the moment when the inhalation of chloroform is stopped, arterial blood always contains an excess of the drug when compared with the amount in venous blood.

The salient points of these researches have now been indicated. The application of an exact method, and the performance of a large number of experiments which were carried out under precisely similar conditions in the physiological laboratory of the University of London, have enabled Dr. Buckmaster and Mr. J. A. Gardner to complete this portion of their work, and their results will probably afford a sure basis on which a full knowledge of the physiology of the anæsthetic process during the inhalation of chloroform may in the future be built up.

ARCHÆOLOGICAL REMAINS IN WALES AND THE MARCHES.

IN the sphere of archæology the University of Liverpool bids fair to surpass all other British homes of learning, ancient or modern. Backed by a number of wealthy citizens, more cultivated than the corresponding class in any other town of the Empire, it has lent generous aid to the excavator, and is able to boast, at the present time, of a vigorous archæological school directed by men whose names are pledges of efficiency in their several departments. So far, however, it has interested itself mainly in the elucidation of classical history, in the study of Greek art, and in exploration in Asia Minor and Egypt. Now for the first time its attention is being directed to regions nearer home; at the instance of many Celtic scholars, and numbers of influential Welshmen both in the city and the Principality, it is undertaking the supervision of no less a work than the survey and systematic excavation of historic remains in Wales and the Marches. As a result of the meeting convened by the Lord Mayor of Liverpool (Dr. R. Caton)—an event already chronicled in these columns—a fund has been started and committees appointed—general, advisory, and financial—for the furthering of the scheme. The actual operations, needless to say, will be watched by the heads of the archæological school, Profs. Bosanquet, Garstang, Myres, and Newberry. Assistance has also been promised by Prof. Haverfield, of Oxford. The work will be carried out in cooperation with the University of Wales, with the Cambrian Archæological Association, with the district or county societies, and with such local committees as it may be found advisable to form from time to time. All these bodies are to be represented on the general committee, which is to include the names, not only of well-known scholars, such as Prof. Haverfield, Sir John Rhys, and Dr. Arthur J. Evans, but of patriotic Welshmen representing every interest and every shade of opinion.

The magnitude of the undertaking and its importance for the study of Welsh ethnology and history can hardly be exaggerated. Owing, it is suggested, to the absence of a capital where their records could be brought together and examined, the Welsh have unduly neglected the investigation of their past, so that the questions which beset the historian are unusually numerous and difficult. It has been the fashion hitherto to search for their solution in the national literature, the memoirs, so to speak, of the people themselves, taking them, in fact, at their own valuation. It cannot be denied that this method has its advantages, the facts which it supplies, when they can be shown to be facts indeed, stamping themselves on the mind with peculiar vividness. In this case, however, they have only too often ended as they began, mere autobiography, with little or no objective value, good material for history, it may be, but still not history. It can no longer be doubted that the study of the Welsh texts, if it is not to end in mere guess-work, must be supplemented for the early period, at any rate, by the study of evidence of another kind, the evidence, that is to say, of historic sites and monuments. That such is to be obtained has been shown by the sporadic excavations of recent years, but until last November it seemed useless to hope for a systematic archæological inquiry; now at last, under the direction of men who will not suffer a penny or the stroke of a pick to be spent in vain, the secrets of cromlech, camp and battlefield will be brought to light, and the story of the past reconstructed step by step.

There are several directions in which research seems particularly needed. It is important in the first place, through the exploring of Roman sites, to determine the relation of the mountaineers to the Roman army in possession, a subject which so far has remained shrouded in mystery. How excavation can help to increase our knowledge of the later Roman Empire may be seen from the work carried out in Germany and Austria, in North Africa and Asia Minor, where the Roman frontier defences have in each case been marked out and made available for comparison, or, looking nearer home, from the operations of the Society of Scottish Antiquaries and other learned bodies, during the past ten years, in Scotland. Though only nine or ten of the Scottish forts have been investigated, definite conclusions have already been formed. The scanty statements of civilians writing at a distance, which used to be our sole authorities for Roman Scotland, it has now been found possible to verify and amplify by means of the handiwork and personal belongings of the frontier guards themselves. At the present time there are ten Roman sites, most of them military posts, awaiting excavation in Wales and the Marches, and there is no reason to doubt that it will be as fruitful in their case as in any of those we have mentioned. We shall be disappointed indeed if it does not enable us to judge of the length of the Roman occupation of Wales, of their frontier policy, and the character and methods of their government. We need hardly point out that light shed on these subjects will be light, not only on the Silures, but on Roman Britain as a whole.

From the Roman remains the committee may proceed with advantage to the examination of the sites and monuments of early Christianity in Wales. Here also valuable data may be had for comparison from other countries, much having been done, both in Ireland and France, to preserve and record the memorials of the primitive church. Among Welsh ecclesiastical sites Bangor is y Coed in Flintshire, and Whitland (Ty Gwyn Ar Dav) in Carmarthenshire seem to promise the richest results. Again, the monasteries of Norman times might be explored with a view to the production of a Welsh Monasticon, the place and personal names in the charters to be corrected with such accuracy as to make these a help, not, as now, a stumbling-block to the student.

Other subjects for investigation will suggest themselves without doubt to all those interested in the early history of this island. The reader will have noticed that the researches specified above are mainly in the nature of digging out or clearing of the ground. We need scarcely remind him that valuable evidence may also be obtained through the observation of things on its surface. The materials for the early history of Wales, like that of other countries, must be sought with the theodolite no less than with the pick or shovel. That it will help us to fuller knowledge of the pre-Celtic inhabitants of the country has been made clear by Sir Norman Lockyer during his expeditions to South Wales. He has indicated the lines to be followed in this kind of inquiry, and the committee cannot do better than follow in his steps. It is occupied as yet with preliminary arrangements. Among the subjects which may be expected to engage its attention in the first instance are the following:—

(*a*) The preparation of an archæological map of Wales and the Marches, on which all known sites and individual finds shall be marked, together with a bibliography and index of all known information regarding them.

(*b*) The execution of an archæological survey of the whole area, to supplement the recorded material, and complete the archæological map, so far as surface evidence is required.

(*c*) The consideration of a scheme of successive excavations for the sites, which may be selected as of most crucial importance, for the solution of the questions of distribution and historical sequence, certain to be raised by the preliminary survey and mapping.

We will only remark, in conclusion, that great schemes cost money, and that those which we have been discussing are not likely to disprove the rule. The expense of surveying a county has been estimated at 150*l.*, that of excavating each of the Roman forts, together with the exploration of the adjacent roads and the subsequent publication of results, at not less than 1000*l.* Liverpool is proverbially generous, but even so there will be ample room for the liberality of sympathisers outside, both Welshmen and others. We sincerely hope that the appeal of the committee will not be made in vain; it would be regrettable indeed if its work were retarded or hampered through lack of the necessary funds.

We are given to understand that an illustrated report of the work will be presented every year to subscribers of 2*l.* 2*s.* and upwards, and for five years to all donors of 10*l.* 10*s.* Cheques should be sent to the treasurer, Mr. T. Rowland Hughes (North and South Wales Bank, Liverpool), and requests for information addressed to the organising secretary, Captain A. O. Vaughan (38 Bedford Street, North Liverpool).

DR. P. J. C. JANSSEN.

FRANCE is again called upon to mourn the loss of a veteran astronomer whose services have rendered him conspicuous among the many eminent men of science his country has given to the world. Jules Janssen, born in 1824, was first a painter, but for more than fifty years contributed to the scientific literature of his country and enriched many departments of physics by his untiring energy, his accurate observations, and his fertility of resource. He was a great traveller; his first scientific expedition was in 1857 to Peru, to study the magnetic equator. Ten years after he was studying the eruption of Santorin with Fouqué. It is not possible to do justice to his work within a small compass, but fortunately its salient features will long remain fresh in our memories.

Janssen's reputation will rest mainly upon his numerous and important researches on light spectra, and the methods he employed for pursuing his investigations. He early recognised the power of the spectroscope as an engine for research, and in its application to many problems connected with solar activity he was without rival among his own countrymen. In 1862, he published the first results of his celebrated researches on the origin of the telluric lines in the solar spectrum, and it is only necessary to recall the history of spectroscopy in the last half-century to make us appreciate the value of his pioneering services in this direction. The perseverance and ardour with which he pursued this subject was shown, first at La Villette, where he so arranged his experiments that the light the spectrum of which was to be examined passed through a tube, 37 metres long, containing steam under a pressure of seven atmospheres, and later, at Geneva, where in another series of experiments the light traversed several miles of atmosphere immediately overlying the lake. For many years the same problem in different aspects occupied his attention.

Long after the part played by water vapour in modifying the spectrum had been settled, Dr. Janssen had recourse to experiments of the same nature in order to decide the precise character of the spectrum effects due to oxygen. The pursuit of this question and his anxiety to vary as much as possible the conditions under which his observations were made, carried him to the top of Mont Blanc, where his experiments warranted him in asserting that there was no evidence of the presence of oxygen in the exterior and cooler parts of the solar atmosphere. To speak with equal confidence of the lower, and, consequently, hotter layers, it was necessary to examine the spectrum of oxygen when submitted to high temperatures and great pressure. By ingenious devices, Dr. Janssen succeeded in raising oxygen to a temperature of 800° or 900°, and in placing the gas under a pressure of 1000 atmospheres. As before, his observations pointed to the absence of oxygen in the sun's atmosphere. His researches on the effect of planetary atmospheres in modifying the spectrum of solar light were equally thorough and satisfactory.

The observations made on Mont Blanc firmly convinced Dr. Janssen of the advantages offered by high mountains for the conduct of certain inquiries, in which it was of importance to reduce as far as possible the thickness of the atmosphere, through which observations had to be made. In spite of increasing age and the inconvenience of lameness, he interested himself energetically in the construction of the Mont Blanc Observatory, and on more than one occasion personally made the ascent of the mountain to assure himself of the success of the enterprise. Under his auspices various physical inquiries have been successfully pursued in this elevated observatory.

As an observer of the sun at the time of total solar eclipse, Dr. Janssen was indefatigable. In 1868, he began that long series of observations which have so much enriched our knowledge of the sun's surroundings. For it was while observing this eclipse at Guntoor that he was impressed with the possibility of observing the prominence lines on the limb of an uneclipsed sun. How, without delay, he put his plan into operation and enjoyed the advantage of a prolonged eclipse is well known, as also the fact that the announcement of his discovery reached the Paris Academy of Sciences at the same time as a similar contribution from Mr. (afterwards Sir Norman) Lockyer informed that body of the successful results of his more prolonged researches. The claims of each have been fully admitted, and just as the names of Adams and Le Verrier are connected with a famous problem in gravitational astronomy, so those of Lockyer and Janssen are joined in the solution of a fundamental problem of physical astronomy. A medal containing effigies of the heads of the two astronomers side by side was struck by the French Government to commemorate this "Janssen-Lockyer Discovery." This is an oft-tale tale, and it would not be necessary to repeat it here but for one circumstance which is not so well known, and which it is desirable to emphasise. This is the generous recognition which Dr. Janssen ever expressed towards his English *confrère*, and his ready acknowledgment of the value of English work. Fortunately, the days of international jealousy in science have passed, but the loyal and hearty appreciation which Dr. Janssen exhibited stands out as a conspicuous example of unselfish and kindly interest, in which no unworthy considerations found a place. Needless to say that his warm-hearted sympathy and encouragement was highly valued and cordially reciprocated.

At Sir Norman Lockyer's suggestion, Janssen was invited to join the English Eclipse Expedition of 1870, and as he was then in besieged Paris, thanks to the exertions of the English Foreign Office the invitation reached him there by the hands of Bismarck, who accompanied it with a safe conduct. This he declined, and left the beleaguered city in a balloon. On that occasion he carried with him the essential parts of a reflector especially constructed to collect evidence about the solar corona. He repaired to Oran, and deserved better fortune than to find the sky completely obscured by clouds at the time of the eclipse. In 1871 and 1875 he was again in Asia, taking part in the observation of solar eclipses, while in 1883 he was one of that remarkable party of enthusiasts who repaired to the lonely coral reef in the Pacific known as Caroline Island. For this eclipse Dr. Janssen used telescopes of six and eight inches aperture, and on his photographs obtained an extension of the corona further than it could be traced in the field of the telescope, revealing a remarkable complexity of structure. Here, too, he confirmed his previous suspicions of the presence of reflected Fraunhofer lines in the spectrum of the corona. His passionate interest in solar phenomena never deserted him, and on the occasion of the eclipse in 1905, notwithstanding his advanced age, he was found among the observers stationed on the line of totality as it crossed the Spanish peninsula. At a still later period, when the International Union for Cooperation in Solar Research met at Meudon, last May, Dr. Janssen, as president of the congress, exhibited an unflagging interest in all that could promote the object of the meeting.

On the occasion of the transit of Venus in 1874, Janssen not only took part in the observations—going for this purpose to Japan—but devised an apparatus to take a number of pictures of the sun in a short space of time. In many ways the late astronomer distinguished himself by his photographic researches. Not only was he one of the first to direct his attention to the possibility of photographing comets and nebulæ, securing satisfactory pictures of Tebbutt's comet of 1881 and of the Orion Nebula, but his photographs of the solar surface, taken at the Meudon Observatory, have acquired a world-wide renown, both for the beauty of the results obtained, and the ingenuity of the devices employed to secure short and uniform exposures. These photographs were not left as mere pictures to please the eye by the infinite variety they revealed. They were studied and compared until the photospheric network of varied granulation was made to disclose its tale, and put us in possession of the beginning of a solar meteorology. In the course of his photographic experiments he was led to suggest the use of a camera with double slits, so as to allow only a narrow portion of the spectrum to reach the photographic plate, a method of observation which in the hands of Prof. Hale and Deslandres has proved so effective.

He served his country in many capacities, but perhaps rendered no service greater than that of establishing and organising the observatory at Meudon. By this act a permanent home for the furtherance of physical astronomy and solar research has been ensured, and here the work which he began and pursued with such eagerness will be carried on with more powerful instruments than were at his command; but however successful its future career may prove, it will owe its origin in no small measure to the insistence, perseverance, and reputation of Dr. Janssen.

In many ways his colleagues acknowledged the value and extent of his services. He was Commander of the Legion of Honour, Membre de l'Institut; he was the oldest member of the Academy of Sciences, having succeeded Langier in 1873. He was also a member of the Bureau des Longitudes, and had been decorated with the Lalande medal. The learned societies of many countries enrolled his name on their list of fellows. In this country he was a foreign member of the Royal Society, from which he received the Rumford medal for his researches; Edinburgh made him an LL.D. of that university, and in 1872 he was elected an Associate of the Royal Astronomical Society.

NOTES.

THE annual meeting of the British Science Guild will be held at the Mansion House at 4.15 p.m. on Wednesday next, January 15, by invitation of the Lord Mayor. Mr. Haldane, president of the Guild, will address the meeting; and among other speakers will be Dr. T. H. Warren (Vice-Chancellor of the University of Oxford), Sir Archibald Geikie, K.C.B. (secretary of the Royal Society), Sir John Rhys, Sir Wm. Bousfield, Sir John Wolfe-Barry, K.C.B., F.R.S., and Mr. A. Siemens.

THE death is announced of Prof. Albert Lévy, professor of mathematics at the Paris Municipal School of Industrial Physics and Chemistry, and director of the chemical department of the Municipal Observatory of Montsouris. Prof. Lévy was well known for his analyses of the air and water supply of Paris.

A TELEGRAM from Brownstown, Jamaica, announces that a severe earthquake occurred at 8.5 a.m. on January 3. Considerable damage is reported from Kingston and other places on the south shore.—Reuter reports on January 4 that Vesuvius is again active. The volcano is emitting clouds of vapour from large fissures near the summit of the crater, and also towards Atrio Cavallo.

A REUTER message from Rome states that Signor Rava, Minister of Public Instruction, has appointed a special commission to direct and supervise the excavations at Herculaneum, composed of Commendatore Gattini, administrative director of the Museum of Naples; Signor De Petra, professor of archæology of the University of Naples; Prof. Gabrici and Prof. Dall'Osso, both of the Naples Museum; Prof. Sogliano, director of the excavations at Pompeii; Commendatore Avena, director of the technical office of the monuments of Naples; and two civil engineers of the province of Naples.

ON Tuesday next, January 14, Dr. A. A. Gray will deliver the first of two lectures at the Royal Institution on the internal ear of different animals, and on Thursday, January 16, Prof. W. W. Watts will deliver the first of two lectures on (1) the building of Britain. On Saturday, January 18, Prof. Gisbert Kapp will commence a course of two lectures on the electrification of railways. The Friday evening discourse on January 17 will be delivered by Prof. T. E. Thorpe, on the centenary of Davy's discovery of the metals of the alkalis, and on January 24 by Colonel David Bruce, on the extinction of Malta fever.

THE discovery of a large group of dene-holes in the woods between Woolwich and Erith, close to the ruins of Lessness Abbey, was announced in the *Times* of January 3. Two of these holes have already been explored, the position having been marked in each case by a shallow cup-like depression on the surface overgrown with verdure. Excavation in the centre of the hollow exposed the shaft, which is rather more than 3 feet in diameter, and circular in transverse section. After descending for about 50 feet through loam, the shaft enters chalk, and having penetrated this for 4 feet or 5 feet expands into chambers about 18 feet in height. In the sides of the shafts are holes, evidently for supporting a rude kind of ladder for descent. A conical mound of earth, about 10 feet high, occupies the floor at the bottom of the shaft. Each cave has six chambers grouped radially around the central shaft, so as to form in plan a rough double trefoil, recalling the pattern familiar to explorers of dene-holes elsewhere.

ACCORDING to a paper by Mr. H. Beeston published in the December (1907) number of the *Zoologist*, the breeding-range of the marsh-warbler in the south of England is gradually spreading east, a nest having been observed during the past summer in Hampshire. The nest was attached to four or five reeds at an elevation of about 4 feet, like that of a reed-warbler.

To *Naturen* for November and December, 1907, Prof. A. W. Brögger contributes an illustrated article on "eoliths," in which a number of types from various parts of Europe are described and figured. The author appears to be convinced that these stones were shaped by human agency for special purposes, describing some as knives, others as scrapers, &c.

AMONG the articles in *Schriften naturfor. Ges.*, Danzig, vol. xii., part i., attention may be directed to one by Dr. A. Wallenberg on the anatomy and physiology of the central nervous system of man. The paper, of which only the first portion is now published, is based on an address delivered before the society so long ago as 1888, and has been presented to the public by request. It deals specially with modern methods of brain-research and their result, and is illustrated by several diagrams, coloured or otherwise, displaying in a remarkably clear manner the complicated system of "telegraphy" by which coordinated movements of the body are brought about.

IN his presidential address to the Indiana Academy of Science, as reported in the Proceedings of that body for 1906, Dr. Robert Hessler states that both malaria and tuberculosis seem to have made their appearance in the country since its colonisation by the white man. The advent of malaria is attributed to the felling of the forests, and the consequent periodical drying-up of the smaller rivers, and the destruction of fish, accompanied by an enormous increase in the numbers of mosquitoes. This disease rapidly attained its maximum, but, under preventive measures, as speedily declined, and has now been eliminated from large cities, and to a great extent from their suburbs. Tuberculosis, on the other hand, which is essentially a disease of civilisation, has been steadily on the increase ever since its introduction, and shows no signs of having yet attained its maximum.

THE report on agriculture in the Virgin Islands for 1906–7 refers mainly to the work done at the experiment station at Tortola under Mr. C. W. Fishlock. Although formerly cotton provided a valuable crop, the cultivation had to be re-introduced by the Imperial Department of Agriculture in 1903; since that time the industry has advanced, and is now remunerative; about one-third of the quantity grown is Sea Island cotton. It has also been demonstrated that many parts of the island are suitable for cacao cultivation. A series of illustrations of the experiment station add to the interest of the report.

IN the *Geological Magazine* (June and November, 1907) Prof. A. C. Seward publishes descriptions of fossil plants from Egypt and South Africa. Of three Egyptian specimens, only one, a new species of Clathropteris, is sufficiently well preserved to be named; it furnishes some evidence that the beds from which it was collected were of Rhætic or Lower Jurassic age. The material from South Africa yielded a Phyllotheca and an Osmundites, both made types of new species, a Lepidodendron impression, and a Bucklandia stem. The Osmundites stem and the Lepidodendron both show interesting morphological features, while the Bucklandia is the first record of a Cycadean stem from plant beds of the Uitenhage series.

OWING to the character of the leaves and the intervals that elapse between the flowering periods, the classification of the genus Agave is a difficult matter; also the existing nomenclature is so uncertain that it becomes necessary to study the species in their native habitats. Two papers on Agave and the allied genus Furcræa are published in the eighteenth annual report of the Missouri Botanical Garden. In the former, Prof. W. Trelease discusses the three species *macroacantha*, *pugioniformis*, and *Karwinskii*, belonging to the group of Euagaves. The second species is merged in *macroacantha*, for which the author gives a diagnosis and illustrations showing the plant in its natural environment. Similarly the species *Karwinskii*, that produces a trunk about 10 feet high closely set with leaves, is described. The article on Furcræa, contributed by Mr. J. R. Drummond, furnishes an epitome of the literature of the genus, with a synopsis of known species.

IN connection with the bicentenary of the birth of Euler, the great Swiss mathematician, *Engineering* of December 27, 1907, gives an account of his life, work, and character.

WITH the object of helping prospectors, the Geological Survey of Western Australia has compiled a Bulletin (No. 30) giving particulars of the distribution and occurrence of the ores of metals other than gold. The Bulletin, which covers 129 pages, has been written by Mr. E. S. Simpson and Mr. C. G. Gibson, and contains details of the occurrence in Western Australia of ores of copper, tin, lead, zinc, antimony, bismuth, iron, nickel, cobalt, manganese, aluminium, tantalum, tungsten, and molybdenum.

IN the *Engineering Magazine* (vol. xxxiv., No. 3) Dr. A. Gradenwitz gives an illustrated description of the Royal Bavarian Workmen's Museum at Munich. It is one of the most important museums devoted to industrial hygiene in Germany, where the cause of industrial betterment has been largely furthered by such institutions. The museum is intended to further any efforts made in the field of workmen's protection, while affording a comprehensive view of present achievements in the prevention of accidents, in industrial hygiene, sanitary habitation, and alimentation.

AT a meeting of the Association of Water Engineers on December 14, 1907, an interesting paper was presented by Mr. W. R. Baldwin-Wiseman on the influence of the thickness of the pipe wall on the rate of discharge of water from minute orifices piercing the pipe. The results of the experiments described show that, although the diameters of the orifice may vary considerably, yet for a similar ratio of the thickness of the wall to the diameter of the orifice, the coefficients of discharge are approximately the same at the pressures recorded of 60 lb., 40 lb., and 20 lb. per square inch, and that the coefficients of discharge are in general higher for large values of the ratio of thickness to diameter than for small values of that ratio.

AN elaborate memoir of considerable economic interest, by Mr. Mauric Alfassa, is published in the *Bulletin de la Société d'Encouragement* (vol. cix., No. 9). It deals with the reduction of the working day to eight hours, and records the experience of the French Government establishments and of works in other countries. The author considers that the eight hours' day is practically realisable in all cases. In the cases where the reduction has not been made, it is possible, as is shown by English experience, particularly at the works of Messrs. Mather and Platt, sensibly to abridge the working hours, maintaining at the same time the production and the cost of production, the increase in certain departments being compensated by savings effected in others.

To the worker in pure science who finds difficulty in following the progress of applied science, the annual retrospects published in the technical journals are of special value. The most complete record of engineering progress is contained in the *Engineer* of January 3. The achievements in 1907 in the various branches of engineering practice are ably summarised, and illustrations are given of the most noteworthy works. A report on shipbuilding in

1907, published in *Engineering* of January 3, shows that in the United Kingdom 1499 ships, aggregating 1,795,400 tons (excluding three dockyard-built warships), and propelling machinery totalling 1,712,000 indicated horse-power, were turned out in 1907. A very complete record of progress in mining and metallurgy in 1907 is contained in the *Mining Journal* of December 28.

BULLETIN No. 14, on "Tests of Reinforced Concrete Beams," by Mr. A. N. Talbot, has just been issued by the University of Illinois Engineering Experiment Station. The tests described are a continuation of the tests discussed in Bulletin No. 4. The topics investigated include the effect of quality of concrete upon the strength of beams, the effect of repetitive loading upon the action of beams, and the resistance of beams to diagonal tension failures. The results of the investigation of diagonal tension failures throw light upon the amount of the vertical shearing stress which may be allowed in reinforced concrete beams not having metallic web reinforcement. The resistance of beams to diagonal tension may be the controlling feature of relatively short beams, and as such failures occur suddenly and without much warning, a knowledge of the resistance of the concrete is essential. Some beams gave surprisingly low values, and it seems evident that the values allowed by many city building ordinances are higher than should be recommended. The tests of concrete columns and reinforced concrete columns and of reinforced concrete T-beams for 1906 have already been published.

THE spell of frost which set in immediately after Christmas over the entire country was for the time severe, and the thermometer touched a lower reading than for several years past. The region of cold spread westwards from the continent of Europe. The Weather Report issued by the Meteorological Office for the week ending Saturday, January 4, covers nearly the whole period of the frost. It shows that the deficiency of temperature for the week amounted to more than 7° in the south and north-west of England, to nearly 8° in the south of Ireland, and to nearly 10° in the south-west of England. In many places the maximum temperature did not once reach 40°. The sheltered thermometer fell below 20° in all districts except the south of England, and in many parts of Scotland, Wales, and the north-west of England it fell below 15°, the lowest temperature reported being 10°, at Balmoral and West Linton. On the grass, the exposed thermometer fell to 2° at Balmoral. In the south-east of England, as well as at some places in the Midlands, the weather was still colder on Sunday, January 5, and the succeeding night. At Greenwich, the minimum shade temperature was 18°, and on the grass 10°. At Birr Castle, in central Ireland, the shade temperature was 12°, and at both Nottingham and Liverpool 16°. An exceptional rise of temperature occurred over the whole country on Monday, January 6, when the thermometer touched 50° in many places. There was a sharp fall of snow in London and the suburbs on the morning of yesterday.

IN the *Annuaire Météorologique* for 1907, published by the Royal Observatory of Belgium, there is an interesting article by M. J. Vincent describing the upper-air investigations carried out by the Belgian observers by means of *ballons-sondes*. The instruments and methods employed are described in detail and illustrated, and the article will be found full of interest by all workers in this important branch of meteorology. Another article in the same publication deals with the humidity of the air in Belgium, the subject being dealt with exhaustively and in a lucid manner. These special articles, and the large number of tables, &c., which the *Annuaire* contains, make the publication a very valuable reference work for meteorologists in general.

A SUMMARY of the results obtained from the meteorological observations made at the Catania Observatory during 1906 is given by Profs. Riccò and Cavasino in an extract from the *Atti dell' Accademia Gioenia di scienze naturali in Catania* (series 4*a*, vol. xx.). The actual readings and reduced values are given for each element, and in a series of notes they are compared with the analogous values for 1905.

PROF. RICCO has completed his gravitational survey of Sicily and Calabria, and published the results in the *Annale* of the Central Meteorological and Geodynamical Office of Italy (vol. xix., part i.). The distribution of gravitational anomalies in Sicily is somewhat peculiar; in the centre there is a defect which reaches the greatest observed value of −67 at Caltanisetta, the unit being 0·001 mm. in the length of the seconds pendulum. Over the greater part of Sicily, however, the anomaly is positive, the lines of equal anomaly forming elongated ellipses with the longer axis running about N.E. and S.W., and cut off by the sea coast on the south. The anomaly reaches a positive value of 160 at Stromboli, and on the east coast off Syracuse, but there are some interruptions of the regularity of increase, the most important of which is on Mt. Etna. Round the foot of the mountain the anomaly has a positive value of about 70, which decreases on its slopes and sinks to −11 at the observatory near its summit. The magnetic survey of Sicily shows anomalies in the distribution of terrestrial magnetism, but as it is impossible to eliminate the magnetic effect of the superficial volcanic rocks, they cannot be correlated with those of gravitational attraction.

THE first part, just received, of the annual report for 1905 of the director of the Weather Bureau of the Philippines gives the results of hourly meteorological observations at the Manila Central Observatory during 1905. The hours of observations are given in insular standard time, that is, in the time of 120° E. longitude, adopted by order of the U.S. Government in 1899. The observations of atmospheric pressure, temperature, relative humidity, vapour tension, and the direction and force of the wind are hourly, read directly between 6 a.m. and 7 p.m., and from self-registering apparatus from 8 p.m. to 5 a.m. Each of the tables of hourly observations shows also the respective hourly, daily, and monthly means. The extreme daily values of the various elements, together with the times of their occurrence, are united in a separate table.

THOSE who in making measurements in which a spark gap has formed part of the apparatus have been troubled by the inconstancy of the results obtained, will welcome a simple device described by Dr. W. Eickhoff in the *Physikalische Zeitschrift* for December 15, 1907, which appears to increase the regularity of action of the gap to a very marked degree. It consists of a short piece of pointed wire, attached to the conductor carrying the negative sphere of the gap at a point close to the sphere, and bent over towards the positive sphere so that its pointed end is a little further away from the surface of that sphere than the two spheres are apart.

COMMUNICATION No. 99 from the physical laboratory of the University of Leyden contains two papers on the variation of the electrical resistance of pure metals down to very low temperatures, by Prof. H. Kamerlingh Onnes and Mr. J. Clay. They find that the influence of very small amounts of impurities, although insignificant down to a temperature of $-200°$ C., at lower temperatures becomes very marked. They express the effect by writing the resistance found equal to that of the pure metal *plus* a constant, depending on the amount and nature of the impurity. Platinum, gold, silver, lead, bismuth, and mercury have been tested between 16° C. and $-260°$ C. and the results agree fairly well with those obtained fourteen years ago by Sir James Dewar and Prof. Fleming down to the temperature of liquid air. They differ considerably at low temperatures from the results recently published by Mr. G. Niccolai, of Pisa, and it seems probable that the differences are due to the latter not having expressed his temperatures in terms of the international constant-volume hydrogen scale.

Messrs. N. Zanichelli, of Bologna, have published as No. 10 of their series of "Attualità Scientifiche" a recent address delivered by Prof. A. Righi before the Italian Society for the Advancement of Science; the lecture is entitled "New Views on the Ultimate Nature of Matter," and covers a wide field, dealing with the nature of atoms and electrons, and embracing the question of ordinary and colloidal solution.

The Iron and Steel Institute has published in No. 3 of its journal a detailed account of the visits and excursions during the meeting of the institute held at Vienna in September last. The report contains a large number of interesting particulars of works and mines visited by the members, together with a great deal of information regarding the development of the iron and steel industry within the Austrian Empire; the account is illustrated by several photographs.

From Mr. A. B. Porter ("The Scientific Shop"), 324 Dearborn Street, Chicago, U.S.A., we have received a number of circulars containing descriptions and prices of a large number of pieces of physical apparatus, many of which are novel in character and for use in special experiments. The different sets cannot be mentioned here, but the catalogue is an interesting item for anyone engaged in science teaching or research; many of the sets of apparatus are well illustrated and described. Mr. Porter has also favoured us with his "Catalogue D," giving descriptions, illustrations, and prices of numerous optical parts. Telescope objectives and mirrors, prisms, echelon and diffraction gratings, photographic lenses, &c., are included in this list. As showing the enterprise of this firm, we would note that Mr. Porter quotes a price of 38,000 dollars for a paraboidal mirror, grade A, of 84 inches diameter and 40 feet focal length; "prices of other sizes up to 10 feet in diameter will be quoted on request."

The virtues of celluloid as a material suitable for the sharp and clean divisions of scales or slide rules, or in its transparent form as an edge for T-squares or for set-squares, are well known. Messrs. Casella and Co. have availed themselves of these properties, and of another, viz. that fine sharp lines may be ruled upon it with some opaque black dye, in the convenient area scale, White and Bean's patent, which they have put upon the market. This is nothing more than a group of parallel lines alternately full and dotted one-quarter of an inch apart. The set of parallel lines is laid over the figure the area of which is required, *e.g.* a steam-engine diagram, taking care that it is so placed that the extremities of the area lie half-way between a pair of lines on each side. Then the sum of the included lengths of all the parallel lines is found by marking them off on the edge of a strip of paper. The total length in inches divided by four gives the area in square inches. In order to avoid the necessity of dividing by four, a scale is attached in which the unit distance is 4 inches, and this is divided into one hundred parts, and so by direct application of the strip of paper to this scale the area may be read directly. Alongside of the inch scale is another scale of equal parts such that the length of 4 inches read on this scale appears as 6·45. From this, therefore, square centimetres may be read. When less accuracy is required, alternate lines only need be used, and the result multiplied by two. In the example submitted the linear dimensions are all short by 1 in 150, which would make the areas come out too much by 1 in 75.

The current issue of Mr. Charles Baker's quarterly catalogue of second-hand optical and other instruments is now available. The list contains particulars of about 1250 pieces of apparatus on sale in this particular department of Mr. Baker's establishment.

The list of electrical novelties just published by Messrs. F. Darton and Co., of St. John Street, London, E.C., contains numerous illustrated descriptions of pieces of electrical apparatus likely to prove acceptable presents to boys with interest in science. The catalogue also includes various applications of electricity to domestic purposes, in addition to many different patterns of widely used electrical instruments.

Messrs. James Woolley, Sons and Co., Ltd., publish a compact and useful "Reference Book and Diary for 1908," intended for science teachers and students. The pocket-book contains many convenient tables of constants, brief hints as to the use of instruments, "first-aid" notes, and some advertisements, in addition to the usual form of diary. The price of the book is one shilling bound in cloth and two shillings in leather covers.

The "Science Year-book and Diary for 1908," edited by Major B. F. S. Baden-Powell, and published by Messrs. King, Sell and Olding, Ltd., contains 152 pages of useful scientific information, a full-page diary for the year—each page being provided with useful astronomical and meteorological data for the day—and numerous blank pages for notes, cash accounts, and other memoranda. The frontispiece is a portrait of Sir Norman Lockyer, K.C.B., F.R.S. New names have been added to the biographical section, but it is difficult to understand what plan has been adopted in selecting names for inclusion in this list. The price of the volume is 5*s*. net.

Messrs. Newton and Co., 3 Fleet Street, E.C., have submitted to us a specimen of an instrument termed the "Vitascope," devised for the examination of small living creatures under natural conditions. The instrument is in the form of a telescope, about $1\frac{1}{2}$ inches in diameter and a foot in length when closed, and by a novel combination of lenses it enables a magnification of about twelve diameters to be obtained at a distance of 20 inches from the object under observation, and sixty diameters at a distance of about 5 inches. With these magnifications, the observation of insects in flowers or of other small living objects, at a suitable distance from them, becomes a pleasurable and instructive pastime. The instrument has a pillar, which can be screwed upon the top of an ordinary camera stand for use in the garden to observe the structure or movements of living creatures conveniently. It should be of real assistance in the study of numerous small forms of animal life under natural conditions.

MESSRS. CHARLES GRIFFIN AND CO., LTD., have published the twenty-fourth annual issue of the "Year-book of the Scientific and Learned Societies of Great Britain and Ireland." The work is, as usual, compiled from official sources, and according to the title-page provides a record of the work done in science, literature, and art during the session 1906–7 by numerous societies and Government institutions. It is surprising to find, however, that in connection with the British Association, the only information in the book is confined to the proceedings of the York meeting in 1906, and no mention is made of the Leicester meeting in August last. Under societies concerned with geography, the Geographical Association is not included, though its membership is now nearly 650, and it has branches in various parts of this country and in South Africa. But notwithstanding such defects, which can be remedied easily in the next issue, the compilation should continue to be of real assistance as an index to British scientific associations and their work.

A LIST of publications of the Carnegie Institution of Washington, already issued or in the press, has just been received; and it reminds us of the very useful work the institution is doing by the publication of monographs on many scientific subjects of wide and deep interest. About ninety of these memoirs have been published, and most of those containing contributions to natural knowledge have been described in the columns of NATURE. Among the works now in the press, we notice an atlas of the Milky Way, E. E. Barnard; dynamic meteorology and hydrography, V. Bjerknes and J. W. Sandström; the rotation period of the sun, as determined by the motion of the calcium flocculi, G. E. Hale; inheritance in canaries, C. B. Davenport; supplementary investigations of infrared spectra, W. W. Coblentz; and botanical features of North American deserts, D. T. MacDougall. The publications are sold at a nominal price, and a list can be obtained upon application to the Carnegie Institution of Washington, Washington, D.C., U.S.A.

OUR ASTRONOMICAL COLUMN.

RETURN OF ENCKE'S COMET (1908*a*).—A telegram from the Kiel Centralstelle announces that Encke's comet was found by Prof. Wolf on January 2.

Its position at 6h. 14·5m. on that date (Königstuhl M.T.) was R.A.=23h. 3m. 16s., dec.=1° 19′ N., and its magnitude was 13·0.

The following is an abstract from the ephemeris given in No. 4222 of the *Astronomische Nachrichten*:—

Ephemeris 0*h*. (*M.T. Berlin.*)

1908	α (app.) h. m.	δ (app.) ° ′	log *r*	log. Δ
Jan. 11	23 8·8	+2 21·9	0·2829	0·3461
„ 19	23 17·4	+3 7·8	0·2617	0·3477
„ 27	23 27·1	+4 3·1	0·2385	0·3469
Feb. 4	23 38·1	+5 7·5	0·2130	0·3435

At present the comet is apparently passing through the constellation Pisces towards Aries, and sets nearly due west at about 10 p.m. The calculated time of perihelion passage is April 30, not February 22, as stated in our last issue.

SATURN'S RINGS.—No. 4222 of the *Astronomische Nachrichten* (p. 361, December 18, 1907) contains further notes on the recent appearance of Saturn's rings.

The Rev. T. E. R. Phillips states that on many occasions since the middle of October he has seen the ring clearly, as an extremely fine line of light on each side of the planet, with his 12¼-inch Calver equatorial. This line was not always uniformly luminous, but appeared continuous except on November 8, when an interruption on the following side was suspected. He believes the present visibility of the ring to be due to the sunlight passing through the Cassini division and illuminating the edge of the second ring, which is the brightest part of the system.

Dr. Lau gives the results of a number of micrometer observations of the minor axis of the rings, for position-angle, from September 3 to 28, 1907, and shows the differences between the observed and the Nautical Almanac values. The rings were seen on October 2 at 0·2h., but were invisible on October 3 at 23·1h.

THE SPECTRA OF TWO METEORS.—Using a prismatic camera made up of a Voigtländer euryscope, of 50 mm. aperture and 300 mm. focal length, with a 45° crown-glass prism placed before it, M. Blakjo, of the Moscow Observatory, obtained the spectrum of a meteor on May 11, 1904; with another camera an ordinary trail photograph was obtained at the same time. Encouraged by this chance fortune, M. Blakjo directed his cameras towards the Perseid radiant on August 12 of the same year, and was fortunate enough to secure a second meteor spectrum.

In the first case the meteor was of about the first magnitude, and of a yellow colour, and the spectrum consists of fine lines, of which, by an ingenious method of comparison with the hydrogen lines shown in the adjacent stellar spectra, M. Blakjo determined the approximate wave-lengths to the number of thirteen.

The second meteor was equally bright and of a pure green colour; during the second half of its flight it was considerably brighter than at first, and this increase of brightness increased the number of lines shown in the spectrum; the wave-lengths of ten certain and three doubtful lines were determined, and on comparison it was found that the emission spectra of the two meteors are entirely different from each other.

In the spectrum of the first meteor, the calcium lines H and K are the brightest, and are accompanied by the line at λ 4227; magnesium and potassium are also apparently represented. Helium is apparently the outstanding feature of the spectrum of the second meteor, the lines at λλ 3819·8, 3888·8, 3964·9, 4026·3, and 4121·0 being represented. M. Blakjo accounts for the pure green colour of this object by the presence of the thallium line at λ 3775·9 in its spectrum (*Astrophysical Journal*, vol. xxvi., No. 5, p. 341, December, 1907).

THE CONSTANCY OF WAVE-LENGTHS OF SPECTRAL LINES.—The importance of the constancy of wave-length of spectral lines in astronomical, as in terrestrial, spectroscopy leads Prof. Kayser to discuss the question in No. 3, vol. xxvi., of the *Astrophysical Journal*. He points out that Exner and Haschek based some of their recent evidence for variation on differences obtained by students in his laboratory, and states that, in his opinion, these differences were probably due to errors of the standards employed rather than to any real variability of wave-length. Prof. Kayser also adduces evidence, based on the recent work of Dr. Pfund and of Prof. Fabry, in support of his view that "the question of the constancy of the wave-lengths is finally settled."

NEW CHEMICAL LABORATORIES AT ABERYSTWYTH.

THE Edward Davies chemical laboratories at the University College of Wales, Aberystwyth, which were formally opened on November 1 by Mr. Asquith (see this vol., p. 22), have been erected at a cost of 23,000*l*. by Mr. David Davies, M.P., his mother and sisters, to the memory of the late Mr. Edward Davies, J.P., and have been handed over to the governing body of the University College of Wales. The laboratories are under the direction of Prof. J. J. Sudborough, and have been in use since the opening of the present session on October 2.

The laboratories form a separate block of buildings about half a mile distant from the college, and are erected in local stone with Grinshill dressings. On the first floor are two large laboratories (50 feet by 40 feet), each containing eight double benches (11 feet by 5 feet), so that sixty-four students can work simultaneously; adjoining are balance rooms and a combustion room. The laboratories are well provided with fume cupboards, placed in the window recesses, and ventilated by two main electric "blowers" placed in dormers at the ends of the building. On the same floor is the departmental library (26 feet by 15 feet), which contains complete sets of all the more important English and foreign chemical periodicals, in addition to important general works of reference. The main lecture theatre is situated at the back of the building on the first floor; it is provided with lift-up seats for 130 students, and adjoining it are the preparation room and museum.

On the ground floor are the following rooms:—the physical chemical laboratory, the director's private room and private laboratory, distillation room, two dark rooms, general stores, special stores, porter's room, demonstrator's private laboratory, lecture room with accommodation for fifty students, and two small research rooms. In the basement are a small metallurgical laboratory, extra stores, a fire-proof room, a small dynamo room, and a mechanic's room.

The physical chemical laboratory has a central table 12 feet by 5 feet, with no reagent shelves. Around the walls are slate slabs and wooden tables. The slate tables are provided with several thermostats regulated for different temperatures. The room also contains a fume cupboard for electrolytic work, and a main accumulator board. This board carries the terminals of twenty Tudor cells placed in the adjacent room. The cells are charged from a small motor generator in the basement, and are in groups of one, two, and four. The accumulator board also carries the terminals of eight working positions, four in the physical chemical laboratory and four in one of the large laboratories, and, in addition, three main terminals for the lecture theatre and the motor generator terminals. The terminals are so arranged that any position in the theatre, large laboratory, or physical chemical laboratory can be connected to any group or combination of groups of cells, and also, if necessary, to the motor generator terminals.

The "Edward Davies" Chemical Laboratories, University College of Wales, Aberystwyth.

The distillation room has no gas connections, but has a long slate slab provided with water, steam, current (220 volts), and waste. It is used for the distillation of large quantities of inflammable liquids, and the source of heat is either steam or electric current. The fire-proof room is furnished with slate slabs and an iron fume cupboard. Experiments necessitating the use of gas during the night are conducted in this room. The gas connections for this room and for the chemical physical laboratory are so arranged that flames may be left burning in these rooms when the main gas supply is shut off for the night. The general heating is by means of hot-water pipes, and the lighting by means of tantalum lamps.

The laboratories are especially arranged to give students a sound training in the various branches of chemical study, and are also admirably suited for the carrying out of original investigations. At present about eighty students are working in the laboratories, and of these five are engaged in research work, mainly on the relationship between constitution and the velocity of reaction of carboxylic acids.

SCIENTIFIC WORK OF THE LOCAL GOVERNMENT BOARD.

THE supplement to the thirty-fifth annual report of the Local Government Board, 1905–6, contains the report of the medical officer for 1905–6. The contents of this valuable volume are briefly summarised in the excellent introduction contributed by the principal medical officer, Mr. Power.

An account of the general administrative business of the medical department is given in Appendix A, which includes reports on the outbreaks of enteric fever at Basingstoke and at Lincoln.

Appendix B contains an account of the auxiliary scientific investigations carried out for the Board, of which three are contributed by Dr. Klein, and deal with plague. The first and second of these form a further contribution on the value of a new plague prophylactic prepared from the dried organs of plague-infected animals, as previously detailed by the author, who concludes that it would appear that the injection of rats with efficient material—the raw or the heated filtrate of emulsions of dried plague organs—in appropriate doses has proved protective in as short a period as seven days against subsequent cutaneous inoculation of virulent *B. pestis*, that is, against plague infection administered in the most effective manner. Further, it appears that the protection thus afforded, though inducible so speedily, may be trusted to persist many days, and even weeks. The prophylactic having been proved to protect rats was also tested on monkeys in order to ascertain whether or not there was promise of its application to the human subject proving salutary and justifiable, and 25 milligrams of dry material sufficed to protect against a supra-lethal dose of virulent plague bacilli. As regards the rat, Dr. Klein finds that various species of rat are differently susceptible to the *B. pestis*, the Norway rat apparently being less susceptible than certain other races.

Dr. Gordon reports on the micrococcus of epidemic cerebro-spinal meningitis ("spotted fever"), with special reference to its identification in the upper respiratory passages. The morphological and other characters of the meningococcus are fully described, and its differentiation from other somewhat similar cocci by means of fermentation reactions on various sugars is detailed.

Dr. Sidney Martin has continued his studies on the chemical products of micro-organisms, and reports on the products of the *Bacillus enteritidis sporogenes*. The experiments show that the poisonous products of this organism do not consist of an endo-toxin, but of a soluble chemical and non-protein substance which is formed by the bacillus by its action on proteins. Dr. Wade contributes an exhaustive experimental inquiry on sulphur dioxide as applied in the destruction of rats and in disinfection on shipboard. The conclusion is formulated that a modification of the Clayton apparatus (described in the report) to supply dilute sulphur dioxide will prove the best adapted to practical requirements.

The last paper, by Drs. Andrewes and Gordon, discusses the biological characters of the staphylococci pathogenic for man, and tests that will be useful for their differentiation are described.

It will thus be seen that the report contains matter of considerable scientific and practical interest, and it would be a great pity if this work were to be discontinued in the future, as has been rumoured it may be.

R. T. HEWLETT.

MENDELISM AND SEX.[1]

ALL science is founded on observed facts. All authenticated facts, no matter how observed, are valuable to science. Many invaluable facts cannot be observed without the aid of some special method, for example, experiment; but, of the total mass of facts garnered by science, data furnished by experiment form a very small part. Therefore to rely solely on experiment is to put on blinkers.

Since species are able to exist in their environments, they are adaptational forms. The more minute our knowledge of a species, the more certainly are we able to assign past or present utility to nearly all its structures and faculties. Adaptation extends deeper than structures and functions. Variability itself is adaptive. A greater or lesser degree of variability is a variation and material for natural selection. There is satisfactory evidence that the average degree of variability displayed by every species and structure is controlled by selection. The mass of variations are "spontaneous." Thus there are hundreds of human races and diseases, and every race is resistant to every lethal disease in proportion to its past experience of it. Therefore in this case there is adaptation. Therefore it is clear that the poisons of disease, no matter how virulent or universally experienced by the race, do not cause alteration in the germ-plasm, and consequent racial degeneration. On the contrary, since adaptation has occurred, it is plain that variations are spontaneous, and, since diseases are so many, that they occur all round the specific mean. But some races (*e.g.* European dogs in India) have been known to degenerate when removed to new environments, where the native races flourish. Therefore the insusceptibility of the germ-plasm to the direct action of the environment has been established by natural selection, and this, combined with the facts that (1) species tend to become more variable a few generations after removal from ancestral environments to which they have become closely adapted, and where, therefore, nature limits variability; (2) the degree of variability in functionally correlated structures (*e.g.* pairs of limbs) tends to be correlated; and (3) the greater the need for adaptation the less is the degree of variability when once adaptation has been attained (*e.g.* head and fore-foot of squirrels as compared to tail), affords plain evidence that variability is under the control of natural selection.

When cessation of selection as regards any character occurs, that character tends to retrogress. Therefore retrogressive variations tend to predominate over progressive variations, whereby, without an increase of mortality, species are rid of redundancies, both useless variations and old-established parts which have become useless. Since this tendency to retrogression is highly adaptive, the presumption is that it is an adaptation. That the retrogression which follows panmixia is not due to reversed selection is shown by the fact that, though variations favourable against all diseases occur in every human race, yet they retrogress unless preserved by selection, for races become resistant only to those diseases to which they are exposed.

The two central doctrines of Mendelism are :—(1) segregation of units, and (2) independent inheritance of characters. Taken by itself, the doctrine of segregation assigns no function to conjugation. It merely controverts the doctrine of blending. Taken with the doctrine of independent inheritance, it assigns to conjugation the function of effecting an exchange of germinal units between the two sets of parental units. That much Mendelism implies—that much and no more. Mendelians believe, apparently, that they have found the key to all the problems of heredity; but obviously Mendelism is concerned with nothing more than the function of conjugation. No other problem of biology with which it is concerned can be thought of. However grandiose the language used by its adherents, they are quite unable, when challenged, to indicate any other.

Mendelian inheritance is common when varieties which have arisen under artificial selection are crossed. It is comparatively rare when natural varieties (*e.g.* human) are crossed. Blending is then the rule. Latent traits, also, are commonly revealed by the crossing of artificial varieties. In the whole range of biological literature, no instance is recorded of a latent trait being revealed by the crossing of natural varieties. Even when artificial varieties are crossed, they never revert beyond the wild variety; that is, they never reveal traits that were latent in the wild variety. Presumably, therefore, characters become latent only under artificial selection, and consequently Mendelism is concerned, not with the main problem of conjugation, but only with certain anomalies which occur under conditions of artificial selection.

It is admitted on all hands that artificial selection is founded mainly on mutations, and that the inheritance of mutations tends to be alternative. It is admitted that the inheritance of fluctuations tends to be blended, and the evidence is conclusive that natural selection builds on fluctuations. Thus varieties are most numerous when mating individuals (*e.g.* birds) are enabled by good powers of locomotion to interbreed over a wide area. No interpretation of these facts save that of blending can be thought of. Human varieties, for example, arise only under conditions of geographical isolation. It has been said, on the evidence of half-a-dozen generations, that mutations are stable, and having arisen can be eliminated only by selection. This implies that only progressive variations occur in nature, and therefore that no structures ever disappear or retrogress except through reversed selection; but though variations favourable against all diseases occur in all human races, only those which are selected are preserved and contribute to evolution. Therefore it is clear that the rest retrogress, though there can be no reversed selection in this case.

When species are sexually dimorphic, mating individuals differ, as a rule, little in non-sexual characters, but much in sexual characters. Offspring reproduce *either* the paternal *or* the maternal sexual characters. That is, the *reproduction* of sexual characters is alternative, the male and female characters being "allelomorphic" to one another. But the *inheritance* of them is not alternative, for each sex inherits the characters of the other in a latent state, as is proved by a mass of evidence. Therefore, though in bi-parental reproduction there is apparently no blending as regards the sexual traits, yet the fact is that the patent characters of the one sex blend with the latent characters of the other. Sometimes the male characters are latent for a long series of generations, as in aphides, or apparently permanently, as in *Cypris reptans*. A mutation, like a sexual difference, is a large difference, and when an individual mutates and mates with the parent type, the *reproduction* of the mutation tends to be alternative. But the evidence is massive that the *inheritance* is not alternative, but, on the contrary, that the mutation is latent in those lines of descent which follow the parent type, whereas the ancestral trait is latent in those lines which follow the type of the mutant. Like the sexual traits in bi-parental reproduction, the recessive is temporarily latent in the impure dominant. Like the male characters in aphides and *Cypris reptans*, it is more or less permanently latent in "pure" dominants, as is the dominant character in the recessive. This is proved by the occasional occurrence of recessives in lines of "pure" dominants, and *vice versa*. It is even more decisively proved by the reproduction of latent ancestral characters, especially when (artificial) varieties are crossed. Cuénot's theory of colour factors attempts to interpret in Mendelian terms this fact of the reproduction of latent ancestral traits, but his hypothesis totally fails to account for the reappearance of latent ancestral traits in pure lines of descent, as, for example, when an aged female bantam reproduces, not the secondary male characters of her own variety, but those of an ancestral type. Here there can

[1] Abstract of a paper read before the Linnean Society on December 19, 1907, by G. Archdall Reid.

have been no antecedent separation of factors. Therefore the evidence is that mutations tend to be inherited in the mode of sexual characters. There are, however, differences. Sexual characters tend to alternate more perfectly, to cohere together in their respective sets more closely, and to have a lesser tendency to blend with their opposite numbers than Mendelian characters; but this is only what might be expected, for the mode of inheritance for sexual characters has been established by stringent selection. Some sexual characters, however, sometimes blend or change places with their opposite numbers, as in so-called human hermaphrodites; the dominance of some Mendelian characters is very imperfect; reciprocal Mendelian crosses sometimes produce unlike results; and the inheritance of some Mendelian characters (*e.g.* colour-blindness) is sexual. Were their occurrence the rule, not the exception, we would speak of them as sexual characters. Properly speaking, Mendelian characters are non-sexual traits which are reproduced in the sexual mode. If, however, we examine any list of so-called Mendelian characters, we find that the majority may fairly be described as secondary sexual characters, though not necessarily as sexual differences, for example, colour and form of plumage. It seems clear, then, that there is no real segregation, no real alternative *inheritance*, but only alternative *reproduction*, alternative patency and latency. Therefore blending is universal. Unless the reappearance of ancestral traits can be explained, the bottom falls out of the Mendelian hypothesis. Nevertheless, Mendelian facts are very valuable, inasmuch as they indicate the difference between natural and artificial selection. The experimental observer is able to note only large differences between mating individuals. In practice, he has almost limited his materials for study to domesticated varieties. He has altogether ignored fluctuations. Hence the mutation and Mendelian theories.

It is possible that mutations are more common amongst artificial than amongst natural varieties, in which the range of variability is more stringently limited. But amongst the entirely natural varieties of the species we know most intimately (man) mutations are common enough, and their reproduction tends to be Mendelian. But all are so injurious in the struggle for existence or for mates that when possible they are treated surgically. Never yet has a useful human mutation been recorded. Man has a written history of thousands of years, and human varieties differentiate whenever geographical isolation is sufficiently complete and prolonged. Men are fond of noting wonders. But, notwithstanding the immense range of material, never yet has the origin of a human variety by mutation been recorded. It is easy to conceive of evolution as resulting from mutations when we limit our materials of thought to the colours and shapes of flowers and leaves of plants which are preserved under human care. It is not so easy to think of it as founded on mutations when we take into account the exquisitely co-adapted internal parts of a complex animal, amongst which a mutation would have the same effect as one occurring in one of the parts of a watch.

The extreme instability of fluctuations has been noted and has furnished a main argument to the supporters of the mutation theory. There is abundant reason for believing that in a blend the retrogressive character tends to predominate. Thus racehorses degenerate unless carefully selected. Suppose a country in which malaria is prevalent and another from which it is absent. In the former, variations favourable against malaria are selected; like mates with like; therefore blending causes little or no retrogression, and the mean of the race is raised in each generation. In the latter, though favourable variations occur, unlike individuals mate; therefore blending causes retrogression, and the race is rid of a useless redundancy. Apply this reasoning to all variations and all characters, and the function of conjugation becomes apparent. It is, in effect, a selective agent of retrogression. Selection rough-hews the type; retrogression chisels out the finer lines. Reproduction is bi-parental in all the higher and more complex forms in which nature's task of closely adjusting the numerous co-adapted parts is most difficult.

If we accept the theory of blended inheritance, we are able to assign a useful function to conjugation. But to both the Mendelian and the mutationist, sex is a phenomenon to be explained away. According to the former, conjugation merely jumbles together elements which may be incongruous. According to the latter, conjugation is nothing other than an obstacle to the survival of mutations, which have the best chance of surviving when reproduction is parthenogenetic. It has been said by some Mendelians and mutationists that fluctuations are due merely to temporary effects of nutriment, temperature, and the like; mutations alone are permanent. How, then, is it possible to explain the fact that when reproduction is parthenogenetic "thousands of forms may be cultivated side by side in the Botanical Gardens, and exhibit slight but undoubted differentiating features, and reproduce themselves truly by seed" (de Vries)? This does not happen when reproduction is bi-parental. It can hardly be contended that mutations are a thousand-fold more numerous when reproduction is parthenogenetic than when it is bi-parental. We are driven to the conclusion that the fluctuating nature of fluctuations when reproduction is bi-parental is due to the retrogression caused by blending. The seeming permanency of mutations is due to their mode of reproduction. They take longer to retrogress than fluctuations only because they are bigger. All latent characters, since they are not selected, tend to retrogress.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

PROF. ADOLPHE CARNOT, latterly director, and for many years professor, of chemistry at the Paris School of Mines, has retired with the title of honorary director of the school.

IT is announced, says *Science*, that Mr. Emile Berliner, of Washington, the inventor of the gramophone, has given 2500*l*. as endowment of a research fellowship for women who have demonstrated their ability to carry on research work in physics, chemistry, or biology.

A RESEARCH scholarship or scholarships, founded by Mr. Andrew Carnegie, will be awarded shortly, irrespective of sex or nationality, on the recommendation of the council of the Iron and Steel Institute. Candidates, who must be under thirty-five years of age, must apply on a special form before the end of February to the secretary of the institute, 28 Victoria Street, London, S.W. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students, who have passed through a college curriculum or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry.

THE sixth annual meeting of the North of England Education Conference was opened at the University of Sheffield on January 3, under the presidency of Prof. M. E. Sadler. After the presidential address, Prof. Hicks read a paper on the function of a modern university, and Dr. R. H. Crowley (Bradford) and Dr. Clement Dukes (Rugby) dealt with medical inspection of school children. Other subjects discussed were holiday and open-air schools, compulsory attendance at evening schools, and the teaching of history. On the following day Sir William Clegg presided, and the morning sitting was devoted to consideration of the work of training colleges. The afternoon topics were:—(1) the treatment of defective children; (2) house-craft in girls' schools; (3) artistic perception in children.

THE London County Council Conference of Teachers was held on January 2, 3, and 4, when more than 1200 visitors signed the attendance book, and as this was the tenth of these annual meetings, it is clear that their utility is appreciated. With a wise liberality, the County Council promises to send a verbatim report of the proceedings to those who attended the conference, of which a noteworthy feature was the frank cordiality with which the Council inspectors and teachers interchanged views. The principal topics discussed were the place of nature-study in the curriculum, the study of botany by girls, the commercial education of boys, manual instruction for young children, practical suggestions for school library management, and recent pedagogic experiments in the study of literature and of open-air geography.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 7, 1907.—"Further Results of the Experimental Treatment of Trypanosomiasis in Rats: being a Progress Report of a Committee of the Royal Society." By H. G. **Plimmer** and J. D. **Thomson.** Communicated by Sir Ray Lankester, K.C.B., F.R.S.

The following results carry the work, part of which has been already described, on to October 24, 1907.

Rats treated with atoxyl and mercury are still living and well at 229, 222, 208, 178, 164, and 63 days after inoculation; and a rat treated with atoxyl and iodipin is alive at 218 days.

The principal pathological lesion in rats which have been treated with atoxyl and some compound of mercury and have lived for a very long time after inoculation, apparently cured of the disease, is a degeneration of the kidneys; and in most of these rats this was the only lesion found *post mortem.*

Considering both the experiments already recorded which have since ended fatally, and the more recent and —as regards dosage—bolder experiments, the authors are bound to conclude that, in small animals at any rate, mercury has not given altogether satisfactory results. Perhaps it may be a question of dosage; they have, however, tried to enlarge the range of dosage as far as possible, from homœopathic to large ones, without attaining a large percentage of cures. If the dose of mercury be sufficient to aid the atoxyl, they have found, in those cases which have died, chronic kidney, and in a less degree liver, lesions, which seem to be the late result of those more acute changes which have been found in those animals that have died earlier, either from disproportionate dosage, or from some want of resistance to the drug.

Potassium antimonyl tartrate has been tried, and this was found to be fatal to rats in doses of 1 centigram. The trypanosomes were observed to be greatly diminished in numbers, but it was also noticed that soon after the injection the rats appeared to be very ill. This was attributed at the time to the potassium in the compound; probably erroneously, as a similar effect has been noticed in rats treated with the compound described below, when the number of trypanosomes in the blood was very great. The symptoms may have been due to the dissolution of so large a mass of trypanosomes. But they suggested the use of the sodium compound—sodium antimonyl tartrate—with which many experiments have been made.

This substance in 1 per cent. solution is that which, of all the various bodies tried, including atoxyl, has the most marked influence upon trypanosomes in the living body. Although the experiments with it are not many, or of long duration, the results so far seemed sufficient to induce the authors to direct the attention of other workers in this field to it.

The question of dosage is still under observation. The authors have tried many ways, and at present are inclined to think that a full dose (*e.g.* 0·5 c.c. of a 1 per cent. solution for a rat of 200 grams or over) should be given when the trypanosomes are fairly plentiful in the blood, and then repeated at intervals of one, two, and three days, up to about four doses, and thereafter in weekly doses for a month. But they have good results in cases in which a dose has been given on four successive days, also when given every other day, and so on up to once every five days, without any recurrence up to as many as 52 days; but of two cases dosed at five-day intervals, one has recurred and one has not.

The quickness of the action of sodium antimonyl tartrate is remarkable. In one rat, the blood of which was swarming with trypanosomes, a dose of 0·35 c.c. of a 1 per cent. solution caused their entire disappearance from the blood within half an hour; and in two other cases, in which the blood contained very large numbers of trypanosomes, after injection of 0·33 c.c., only a few could be found at the end of half an hour, and in one after an hour none could be found, and in the other only one in an ordinary blood preparation. A few trypanosomes can sometimes be found in the liver, and these are extremely active, and in no way inconvenienced by the drug; whether these are the forms which can persist, and need to be tired out by successive doses, cannot be said at present, but their extreme activity, when all the others have disappeared, is suggestive. The authors have not detected any morphological differences in them.

A guinea-pig, moribund with sleeping-sickness, with œdema of eyelids and genitals, entirely unable to stand, and with a large number of trypanosomes in the blood, was given, on September 16, 0·5 c.c. of a 1 per cent. solution; on September 17 the trypanosomes had entirely disappeared, and 0·75 c.c. was given; on September 19 the animal to all appearances was quite well, and on this day and on September 21 and 26, 1 c.c. was given. The œdema disappeared and it continued to look well, and showed no more trypanosomes. It lived until October 14, when it died; *post mortem* the organs were congested and the kidneys were inflamed, and the urine in the bladder contained albumen. The fact that the guinea-pig was moribund when the treatment was commenced may reasonably account for the pathological conditions.

Of 36 rats treated with sodium antimonyl tartrate, 11 have died, 6 not of the disease, and there remain alive and well: 3 of 52 days, 1 of 49, 7 of 44, 8 of 43, 4 of 31, and 2 of 21; and of these 25, 23 have had no recurrence.

With the view of ascertaining what amount of immunity, if any, had been conferred on an animal which was considered to be cured, a nagana rat was taken which was inoculated on May 13, and had been afterwards successfully treated with atoxyl and succinimide of mercury, and in which no trypanosomes had been found since it had its first dose on May 16, when the trypanosomes were very plentiful in the blood. On October 7, the 147th day, the rat was re-inoculated from another nagana rat, and on October 11 trypanosomes were present in numbers in the blood; a dose of sodium antimonyl tartrate was given, and no trypanosomes have been seen since October 12. This seems to point to the fact that no immunity is conferred.

December 12, 1907.—"Magnetic Declination at Kew Observatory, 1890–1900." By Dr. C. **Chree,** F.R.S.

The paper deals with the phenomena exhibited by the magnetic declination at Kew from 1890–1900. The magnetograph curves have been measured on every day of this period, whether disturbed or undisturbed, and the data from days of the different species are contrasted. Diurnal inequalities are got out for ordinary days, excluding those of large disturbance, and separately for the highly disturbed days, and the differences between these, and the points wherein they differ from the corresponding inequalities from *quiet* days, are investigated.

The disturbed days show a well-marked regular diurnal variation, which differs in many notable respects from that observed on ordinary days.

When the inequalities are analysed in Fourier series, it is found that the difference mainly centres in the twenty-four-hour term, the amplitude and phase of which seem both largely influenced by disturbance. The variations in the phenomena presented by disturbances throughout the year are investigated from several points of view.

The *absolute range* of the declination (absolute maximum less absolute minimum) was determined for every day of the eleven years, and special attention is given to the variation of this quantity throughout the year, and from year to year. With the view of throwing light on the theories of Arrhenius, Maunder and others, on the origin of magnetic storms, a minute comparison is made of the relationship between the absolute ranges and (Greenwich) sun-spot areas throughout the eleven years. Whilst the results do not preclude the possibility that Arrhenius's theory may be true of a certain number of magnetic storms, they seem to indicate that it cannot be a complete explanation of the facts.

Chemical Society, December 19, 1907.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—Attempted synthesis of $\begin{array}{c}\beta\text{—N—}\beta\\ |\\ \beta\text{—CH—}\beta\end{array}$-dinaphthacridine; condensation of methylene dichloride and 1-substituted-2-naphthylamines: A. **Senier** and P. C. **Austin.** By condensing methylene dichloride with derivatives of β-naphthyl-amine in which the hydrogen of the α-position adjacent to the amino-group had been substituted by a halogen, either Reed's dinaphthacridine or a meso-derivative thereof was formed, thus completing the proof that this base has the constitution assigned to it.—Cobaltamine compounds (preliminary note): C. E. **Groves.** Carycino-cobaltamine carbonate is produced when freshly precipitated cobalt carbonate suspended in dilute ammonia is agitated with air and then exposed to the air for three or four days, in the form of bright crimson crystals. When the crimson carbonate is treated with excess of nitro-hydrochloric acid it is ultimately converted into "bluish-black" crystals. A bronze-green nitrate is prepared by gradually adding a solution of cobalt nitrate in dilute nitric acid to a mixture of dilute ammonia with a solution of ammonium persulphate, and, after it is thoroughly oxidised by shaking it with air, acidifying the mixture with dilute nitric acid. The bronze-green hydrochloride is easily obtained from the nitrate by heating the latter with dilute hydrochloric acid. A grass-green compound obtained from purpureo-cobaltic chloride is also described.—The direct interaction of aryl halides and magnesium: J. F. **Spencer** and Miss E. M. **Stokes.** The authors find that the Grignard reaction between cyclic halogen compounds and magnesium powder takes place without the use of ether when the two substances are heated together. In the case of aliphatic compounds, methyl iodide, methylene iodide, and *iso*-propyl iodide were indifferent, but bromosuccinic acid gave succinic acid.—Derivatives of tetramethyl glucose: J. C. **Irvine** and Miss A. M. **Moodie.** The constitution of tetramethyl glucoseoxime, deduced from its behaviour on alkylation and the hydrolysis of the product, shows that it is produced by the reaction of the sugar in its γ-oxidic forms, and this also seems to be the case with tetramethyl glucoseanilide. It was found that the silver oxide method of alkylation can be applied to the methylation of oximes, thus furnishing a convenient method of determining the hydroxyl content of such compounds.—The characterisation of mercerised cotton. Preliminary note: J. **Hubner.** After treatment with iodine in potassium iodide, mercerised cotton becomes brownish-black, whilst cotton remains white. Similarly, non-mercerised cotton remains practically white, whilst the mercerised material becomes dark navy-blue on treatment with iodine in zinc chloride solution.—Note on the action of metallic calcium on alcohols: F. M. **Perkin** and L. **Pratt.** The statement that metallic calcium has no action on alcohol is inaccurate. With ethyl or methyl alcohol, after from thirty to sixty minutes, reaction ensues, and may become very vigorous, a calcium alkyloxide being formed.—Note on the iodates and periodates of the alkalis and the ammonium radicle: T. V. **Barker.** Specific gravity and solubility determinations of the iodates of rubidium and cæsium, and the periodates of sodium, potassium, rubidium, cæsium, and ammonium, are given.—The colour of cupric salts in aqueous solution: N. V. **Sidgwick** and H. T. **Tizard.** From the results obtained, it seems probable that ionisation affects the intensity of the colour but not the tint.—Derivatives of S-phenylphenazothionium, part i.: S. **Smiles** and T. P. **Hilditch.**—A colorimetric method for the determination of small percentages of iron in copper alloys: A. W. **Gregory.** The method is based upon the colour reaction given by salicylic acid and ferric chloride. The interfering action of the blue copper salts is overcome by the addition of a weak solution of potassium cyanide. Zinc and antimony do not interfere with the reaction, but lead must be removed as sulphate.—The effect of heat on the alkyl iodides: Z. **Kahan.**—The influence of acids and alkalis on the velocity of formation of acetoxime: E. **Barrett** and A. **Lapworth.**—Action of metallic calcium on ketones: H. D. **Law** and F. M. **Perkin.**—The so-called "tetrabromodiphenoquinone" and the constitution of cœrulignone: J. **Moir.**—A note on certain pyrogenic reactions: N. T. M. **Wilsmore** and A. W. **Stewart.**

DUBLIN.

Royal Dublin Society, December 17, 1907.—Prof. G. H. Carpenter in the chair.—The separation and quantitative spectra of cerium, lanthanum, and yttrium: Dr. J. H. **Pollok** and A. G. G. **Leonard.**—The quantitative spectra of molybdenum, tungsten, thorium, and zirconium: A. G. G. **Leonard.** These two papers are in continuation of the authors' joint work on the quantitative spectra of the elements, undertaken to facilitate the use of the spectroscope in its application to ordinary chemical analysis. A reproduction of the spectrum of each element was given, together with a table of the wave-lengths of the most persistent lines, Greek letters being added to indicate the order of disappearance of the lines as the quantity of the element present diminished. In the first paper an account was given of the method of separating the rare metals of the cerite group.

Royal Irish Academy, November 30, 1907.—Dr. F. A. Tarleton, president, in the chair.—The dynamics of a rigid electron: Prof. A. W. **Conway.** A rigid electrified system of any shape is in general motion. A direct calculation is made in a series of approximations of the resultant force and couple due to the internal electric forces. To the first approximation the motion is formally the same as that of a general body moving in a liquid, to the second the motion is found to be aided by a force proportional to the rate of change of the acceleration and independent of the shape. This leads to the ordinary expression for the radiated energy. The third approximation introduces the "transverse" masses. It is shown that the usual expressions for electromagnetic mass become correct if we neglect powers and differential coefficients of the acceleration beyond the first.

December 9, 1907.—Dr. F. A. Tarleton, president, in the chair.—Presidential address on the relation of mathematics to physical science: Dr. **Tarleton.**

PARIS.

Academy of Sciences, December 30, 1907.—M. H. Becquerel in the chair.—Grafting in plants containing hydrocyanic acid: L. **Guignard.** The question as to whether chemical substances secreted by the plant can pass into the graft, or *vice versa*, has been much contested. The author has grafted a plant producing a hydrocyanic glucoside on to another plant totally free from this compound, and inversely; in neither case was there any transport of the glucoside from the graft or the plant. In the artificial symbiosis produced by grafting, each species preserves its chemical characteristics and its autonomy.—Some examples of a collective reasoning in bees: Gaston **Bonnier.** A description of some interesting experiments proving the discipline and division of labour among bees.—The recent determinations of the volume of the kilogram of water: René **Benoit.** A *résumé* of the work done at the Bureau international des Poids et Mesures by the method of contact, and methods based on the phenomena of interference. The mean of the whole of the experiments is that a kilogram of pure water, at its maximum density and under a pressure of 760 mm., measures 1·000028 cubic decimetres, with an uncertainty of about two units in the last figure.—Tables of Uranus and Neptune by Le Verrier. Rectification of the analytical theory: some new tables: A. **Gaillot.** The method followed in this re-calculation was that of Le Verrier, making use of the rectified values for the masses and elements of the orbits. A comparison of the calculated and observed positions furnishes no indication of the influence of any possible planet beyond the orbit of Neptune.—The theory of the moon: H. **Andoyer.**—Vectorial differential invariants and the theory of binary forms: E. **Waelsch.**—The decomposition of a number into a sum of eighth powers of integers: Edmond **Maillet.**—The equation $\frac{\partial^2 z}{\partial x^2} = \frac{\partial z}{\partial y}$: E. **Holmgren.**—The definition of the area of a portion of a curved surface: E. **Cartan.**—Inverse functions of integral functions: Pierre **Boutroux.**—The statics of the deformable line: Eugène and François **Cosserat.**—The variations of the absorption bands of didymium and erbium salts in a magnetic field: Jean **Becquerel.**—The spectrophotometry, viscosimetry, and electric signs of solutions: Charles **Henry.**—The specific heat and molecular field of ferromagnetic substances: Pierre **Weiss.** The hypothesis of the molecular field gives a quantitative explanation of the anomalies of the specific heats of ferromagnetic substances.—The electrolytic reduction of indigo: Henri **Chaumat.** The negative electrode of an electrolytic cell divided by a diaphragm and containing sodium carbonate solution is formed of a mixture of indigo and graphite. The reduced indigo is dissolved by the caustic soda formed in the electrolysis, and 30 per cent. to 40 per cent. of the current is utilised.—Some thermochemical data relating to the chlorine compounds derived from Millon's base: H. **Gaudechon.**—A new method for the hydration of pinene: Ph. **Barbier** and V. **Grignard.** Pinene dissolved in acetic acid is treated with a 50 per cent. aqueous solution of benzenesulphonic acid at the ordinary temperature. Terpinol can be isolated from the products of the reaction with a yield of about one-third of the weight of the pinene taken.—The ketone derived from β-hexahydrocarvacrol: Léon **Brunel.**—Two modes of individualisation of albite in the microgranitic *massif* of Genis: Jacques **de Lapparent.**—A general method of microchemical research and its application to the study of the distribution of the saponines in plants: R. **Combes.** The method is based on the formation of an insoluble compound of the saponine with baryta, followed by treatment with potassium bichromate. Each cell in which saponine has been present is stained with barium chromate.—Tea from French colonies: J. **Dybowski.** Teas from Indo-China, compared with Ceylon teas, have a slightly higher proportion of caffeine, and about half the quantity of tannin.—The adaptation of *Orchitophrya stellarum*, a parasite of the testicles of the star-fish, to a marine medium: Casimir **Cépède.**—Ethyl chloride in the blood during anæsthesia: Lucien **Camus** and Maurice **Nicloux.** Ethyl chloride penetrates into the blood with great rapidity, and its proportion may, under certain conditions, be raised considerably without danger to the organism.—Discontinuous tetanisation: N. **Wedensky.**—Maps showing the distribution of oysters on the coasts of Vendée: M. **Guerin.**

THE COTTON PLANT.

The Wild and Cultivated Cotton Plants of the World. A Revision of the Genus Gossypium. By Sir G. Watt. Pp. xiv+406. (London: Longmans, Green and Co., 1907.) Price 30s. net.

SINCE the appearance, in 1877–8, of Todaro's classic monograph on the genus Gossypium, no serious attempt has been made to deal systematically with the botany of the plants that provide the world's supply of cotton. Todaro's work—at once the first and last of any practical utility—owes its value to the fact that he worked for the most part with living plants grown by him from seed received from many parts of the world; the success this method met with justifies the dictum of De Candolle in his "Prodromus" when, speaking of this genus, he says, "Hic species a Botanicis admissas recenseam, monens tamen hoc genus monographiae accuratae et *ex vivo* elaboratae maxime egere." (The italics are not in the original.) Todaro's work requires only to be continued and extended, not to be corrected.

Any attempt at a classification of cotton plants that is based on herbarium specimens is doomed to failure owing to the impossibility of eliminating the effects that differences of soil and rainfall have in inducing differences of appearance in the leaves and other parts of specimens of the same variety that are *not grown under identical conditions*. Many varieties of the genus, even under the most uniform conditions of growth, show a sufficiently wide range of fluctuations to necessitate great care in their determination even when living plants are being examined; when we work on dried specimens, often very fragmentary, grown in widely distant parts of the world under conditions of rainfall that are not recorded, imaginary differentiations occur to such an extent as to make it impossible to deduce a classification of the varieties that more than indicates broadly the groups into which they fall; to attempt anything more than this with herbarium material is to court failure.

The latest attempt at a monograph of the genus Gossypium is the volume now under review. This, unfortunately, belongs to the category for which success is an impossibility, being based entirely—except possibly in the case of a few Indian forms—on herbarium specimens.

The volume contains some most interesting photographic reproductions of a few type-specimens in the Kew, British Museum and Linnean herbaria, and also (often in colours) of early drawings of plants. These reproductions form by far the most valuable portion of the work.

It is impossible in the space at our disposal to give even a general impression of the contents of the volume, much less to point out in detail the very numerous errors into which the herbarium method has led its author. No new information is given us, though several new species and more varieties are created on imaginary differentiations, while nearly every variety that has hitherto been described and named receives a new name.

Thus, of the forty-two varieties mentioned in the volume, Nos. 10 to 25 are cultivated Asiatic or African forms, and out of these sixteen varieties, classified as belonging to four species, all except the species themselves receive new names unnecessarily. When we state that many of the synonyms given fail under investigation, and that the descriptions of plants stated to belong to particular species often differ radically from the descriptions given by the authors of the species, it can well be imagined that the volume is rather a retrogression than an advance on the work of Todaro.

Throughout the book the reader is allowed no opportunity of judging of the correctness of the identification given, since the original definition of the variety is practically never quoted, and must be looked for in the very scattered literature on the genus. It would also have been fairer if, in the case of species here created, a photographic reproduction of the type had been given, and not merely outline drawings, which, throughout the volume, are not good and would not assist in the identification of the plants in the field.

As an example of erroneous synonymy we may take the following case:—

G. obtusifolium, Roxb., var. *Wightiana*, Watt, is stated to be synonymous with *G. Wightianum*, Tod., and to be the plant constituting the Surtee-Broach growth of India. Now, all botanical considerations apart, Todaro states that the seed that gave rise to his *G. Wightianum* was as follows:—"Cotone Hingunghatt di Bombay," "Oomrawatt di Bombay," "Howers Barree (*sic*) di Bombay," "Khandeisk (*sic*) from American seed di Bombay," "Cotone Hinghunghatt Barree (*sic*)," and "Old Dhollera, provenienza di Bombay." Now, in none of the places mentioned—Hinghunghat, Oomrawati, Barsee, Khandeish, Dhollera—will the Surtee-Broach plant grow except in Dhollera; and, curiously enough, Todaro mentions that another sample of Dhollera seed received *directly* from Bombay gave rise to plants belonging not to the species *Wightianum*, but to the species *herbaceum*, and giving "un prodotto di bellisima qualità."

Todaro having already placed the Surtee-Broach plant in the species *herbaceum*, it would appear unnecessary that, as in the volume before us, it should be removed into the species *obtusifolium*, to which it is certainly, to say the least, not more closely related. This removal is further objectionable owing to the great uncertainty as to what plant Roxburgh intended to indicate by the latter name. On this point, again, our author is at once confused and confusing; he states (p. 140) that *G. obtusifolium*, Roxb., is "fairly common in the hedges of Gujarat," while (p. 135) *G. nanking*, var. *roji*, is also said to become sub-scandent in hedgerows in the same district. The present writer has collected and sown in Gujarat many samples of seed from these hedgerow cottons, and the resulting plants have invariably been identical with one another, and also with the crop known as "roji," which our author classifies as *G. nanking*, Meyen,

 M

var. *roji*, Watt. It can safely be said that the last varietal name is superfluous, being synonymous with *G. obtusifolium*, Roxb., as interpreted in this book.

As examples of cases in which a plant is wrongly assigned to an old-established species, the following cases may be cited:—

(1) *G. peruvianum*, Cav., is stated (p. 217) to have fuzz-coated seeds, though Cavanilles states that the seeds are black, *i.e.* devoid of fuzz, and figures them so. This discrepancy would have been immaterial had not the presence or absence of fuzz on the seed been made the basis of classification (see later). This plant is stated to produce the Imbabura cotton of Peru, while the Piura cotton is stated to be produced by a somewhat similar but hairy plant, which is identified as *G. vitifolium*, Lamk. It suffices to say first that Piura cotton is produced by the plant Cavanilles called *peruvianum*, which has, as that author states, naked seeds; and secondly, that Lamarck states that his species *vitifolium* has the under sides of its leaves glabrous.

(2) Of *G. microcarpum*, Tod., its author mentions specially that the two lobes on either side of the central one were unequal, and gives a good figure of this. Our present author not only gives (plate 36) a plant with much broader lobes, but one which does not display the peculiarity of lobes mentioned, is called "red Peruvian cotton," and differs from ordinary Peruvian only in bearing brown cotton instead of white. The reviewer has grown the real *G. microcarpum*, which is an exceedingly characteristic variety, and can be distinguished with certainty at a glance. It is, indeed, the plant for which our author has created a new species, viz., *G. Schottii*, two specimens cited as types in the British Museum being exactly the plant as figured and described by Todaro, and as grown by the present writer. Examples of this kind might be multiplied almost indefinitely.

Turning to the system on which the varieties are classified in the volume under review, we find it is as follows:—

Section i., Species with fuzz but no floss.

Section ii., Fuzzy seeded cottons with united bracteoles.

Section iii., Fuzzy seeded cottons with free bracteoles.

Section iv., Naked seeded cottons with bracteoles free, or nearly so, and glands conspicuous.

Section v., Naked seeded cottons with bracteoles quite free and floral glands absent.

It will be noted that the presence or otherwise of a fuzzy covering to the seed below the cotton is made the primary basis of classification. Now it is hardly too much to say that every cultivated species of cotton comprises varieties some of which bear a fuzzy and others do not. The present writer has found among others completely naked seeded varieties in the species (to adopt the nomenclature of our author) *G. nanking* (Chinese and Japanese cottons), *G. nanking*, var. *roji*., *G. obtusifolium*, var. *Wightiana*, *G. herbaceum*, *G. punctatum*, *G. hirsutum*. The naked-seeded varieties show not the slightest trace of hybridisation with a member of sections iv. or v., and, indeed, a hybrid between any of the first four varieties named and a member of sections iv. and v. is by no means readily produced even by artificial means. Yet our author seeks to explain the occurrence of naked seeds in the "*jowari hathi*" (=country cotton) of Madras by the supposition of a naturally produced cross between *G. obtusifolium*. var. *Wightiana* (section ii.), and Bourbon cotton (*G. purpurascens*, section iv.). Similarly, those of American upland varieties that have naked seeds are said to be crosses with a naked-seeded variety for this reason alone.

If any further proof of the fallacy of this method is required, it is found in the fact that fuzzy-seeded American has in India been converted into a naked-seeded variety in a few generations by the present writer through the simple process of growing it under irrigation in well-manured soil. That such a change occurs is well known to cultivators in the West Indies and other parts of the world.

If we take the second point on which the classification is based, viz. whether the bracteoles are free or united, we find the same impossibility of applying the characteristic in the field, in some varieties there being found, *on the same plant*, flowers with the bracteoles all free, others with them all united, and still others with two united and one free.

The last chapter (thirty-one pages) is devoted to a discussion of "The Improvement of the Cotton Plant." This consists merely of a general description of the process of selection equally applicable to all crops, an attempt to trace the history of some varieties now grown, and a description of the pollen grains of some species of cotton.

Throughout the book no attempt is made to give the character of the cotton produced under given conditions of soil and climate by the several varieties described, though the author hopes in his preface that the book will be useful to "planters and seed producers throughout the world."

F. FLETCHER.

A CONCISE WORK ON EVOLUTION.

Evolution and Animal Life. An Elementary Discussion of Facts, Processes, Laws and Theories relating to the Life and Evolution of Animals. By David Starr Jordan and Vernon Lyman Kellogg. Pp. xi+489; illustrated. (New York: D. Appleton and Company, 1907.) Price 2.50 dollars net.

THERE is growing up a generation of biological students that does not read its Darwin, its Weismann, or Galton; instead, it cons manuals and text-books on the works of these masters. It is so very much less trouble, if the student's object is to satisfy an examiner, to "get up" a text-book on evolutionary problems than to extract from original sources a clear conception of the authors' theories; and yet what a world of difference is there between the *ipsissima verba* of a master and the cut-and-dried phrases of the manual-maker! The one is the advocate pleading his cause with all the eloquence in his power, the other the reporter compressing the living words and phrases into the limits of a column. The one is inspiring, stimulating, the other can scarcely avoid exceeding dulness, and certainly no one ever yet was roused to enthusiasm by a text-book.

The book before us is no worse than most of its kind; indeed, it is a great deal better than many. It is compiled from lectures delivered at the Leland Stanford Junior University, and traces of the originality which must have characterised the lectures of two zoologists of the standing of our authors may be found in the book. Refreshing oases of excerpts from original sources frequently add variety to arid plains of didactic statement, and occasionally one may stumble on a good story; such as that of the frozen fish which, bolted whole by a ravenous dog, later emerged alive and flapping from its prison; or the comment of Yves Delage on Schaffhausen's statement that life must have originated from simple inorganic substances, and taken the form of an uncoloured protococcus which later became *Protococcus viridis*. "If the thing is so simple, why does not the author produce one of these protococci in his laboratory? *On lui ferait grace de la chlorophylle.*"

There is a wealth of process-block illustrations of varying degrees of excellence; some are new, some emerge from the obscurity of scientific journals, and some old friends do duty once again. Frequently there is no reference in the text to the figures, and the intelligent student will ask himself for what purpose they are there. As an example may be taken a very poor figure on p. 306, in the chapter on palæontology; it is entitled "Flying Dragon (Draco)." What is this meant to teach our intelligent student? For all that he may find out from the text it may be a mythical monster, the restoration of some giant fossil form, or the little flying lizard of the Oriental tropics.

The ground covered in this work is immense, as the titles of some of the chapters indicate:—Variation and Mutation, Generation, Sex and Ontogeny, Geographical Distribution, Parasitism and Degeneration, Reflexes, Instinct and Reason. The bearing of palæontology on problems of evolution is discussed in eighteen pages; man's place in nature in seventeen. It is impossible to criticise such pemmican at any length; if it is inaccurate it is worthless; if accurate it is of some value. With few exceptions the accuracy of the authors cannot be called in question; we would, however, protest against the view advanced that, whilst variations in the external organs of ametabolic insects may be due to the influence of environment, the variations of corresponding structures in holometabolic insects are congenital. To use the post-embryonic development of a structure as a criterion whereby to judge the nature of its variation is most unsound, for it is not justified by the results of experiments. So that to state (p. 145), "The variations in the colour pattern of Diabrotica, Hippodamia and Vespa are congenital variations" is, to put it mildly, misleading.

The authors, it is evident, are not supporters of the theory of sexual selection, and all the familiar objections to it are paraded. In this connection it is interesting to read the recently published papers by Mr. Edmund Selous on the courtship of birds; the papers are so admirable that they should be consulted by everyone interested in the subject, but it is difficult to refrain from quoting the concluding words of the gifted author.

"I would urge that the facts here brought forward by me, in regard to four different species of birds, are, both singly and cumulatively, strongly in support of Darwin's second great hypothesis of sexual selection, and I believe that, as denial from the chair is replaced or supplemented by evidence from the field, the views of that great naturalist and reasoner will be triumphantly and often most strikingly vindicated."

The insects shown in Fig. 251 are not Membracidæ or leaf-hoppers of the order Hemiptera, but Acridiidæ or grasshoppers of the order Orthoptera. Schaudinn is misspelt Schaudin, and Chillingham Chellenham; there are also one or two obvious misprints. The names of some of the animals quoted are strangely unfamiliar. One might ask the nature of a piddock, a cusk, a silverside, a killifish if the Latin equivalents were not also given, and once again we have occasion to bless the name of Linnæus. R. S.

STUDIES IN EDUCATION.

The Practice of Instruction. Edited by Prof. J. W. Adamson. Pp. xxi+512. (London: The National Society's Depository, n.d.) Price 4*s.* 6*d.* net.

It has been a favourite plan with English publishers to issue a text-book on teaching made up of separate essays on the teaching of various subjects, with an introduction on general principles of education written by the editor. Mr. P. A. Barnett's "Teaching and Organisation" was the first in the field, and now Prof. Adamson has prepared a similar volume for the National Society.

We confess that we somewhat distrust this method of putting a book together. It is difficult to secure cohesion; some of the essays are pretty certain to disappoint the editor, and such a book can very seldom be adopted for regular use by a body of students. In the volume before us one-third is contributed by the editor, and he provides a really able introduction to the psychology of the schoolroom; there are omissions which betray the author's lack of sympathy with the more practical needs of the young, but within the prescribed limits Prof. Adamson is helpful and clear, and a section devoted to experiments in curriculum and method shows that he is both alive to what is being done at home and abroad, and that he is in sympathy with cautious educational reform.

The rest, two-thirds of the volume, is distributed among ten writers, and some of the essays are of most excellent quality; but Principal Headlam on religious instruction, and Miss Howard on history, are weak performances. Dr. Herbertson's essay on geography contains the views with which the Geographical Association has made us familiar, but it is very evident that much of the work which he prescribes for children has never been taught by himself, and an air of unreality pervades his proposals. In these three sections we feel sure that the editor would have done better to have worked up the exposition himself, for his introduction shows that he has a good acquaintance both with the capacities of children and with the way in which these studies may be utilised to serve the ends of mental development. Neither Miss Howard nor Dr. Herbertson seem to have got much beyond the primitive idea that children possess empty knowledge boxes into which geographical and historical information can be shot at will.

The other sections are on a higher level. Mr. Baker's account of mathematics is quite good, and will be helpful to teachers in any type of school; but his treatment suffers from compression, for it is impossible to cover in the space allotted the whole field of study from the infant stage to the commencement of trigonometry. Natural science fares well in the hands of Dr. Percy Nunn and Miss von Wyss, and any teacher of science, especially in secondary schools or technical institutions, will profit from studying with care their exposition of method. In their selection of sciences for the "intermediate" and "final" stages we are inclined to think the writers take too narrow a view; botany, chemistry, and physics have their place, but many would prefer, especially in view of the increasing claims of hygiene, to see more recognition given to physiology in the year or two preceding the scholar's departure from school. Languages have been placed in the hands of Dr. Rouse (aided by his colleague, Mr. W. H. S. Jones) for Latin and Greek, and Mr. Mansfield Poole for French and German. Both belong to the ranks of avowed "reformers." Many schoolmasters will rub their eyes with blank amazement on reading the specimen lessons in Greek dialogue as conducted in the Perse Grammar School, but Dr. Rouse's system is merely the application of the same general principles which Mr. Poole expounds for a modern language.

On closing the book one is encouraged to recognise the progress that English teachers are making in the serious study of professional work. Ten years have elapsed since Mr. Barnett edited the pioneer volume of this description, and the comparison is favourable to the craftsman schoolmaster of the present day.

MAINTENANCE OF ROADS.

Road-making and Maintenance. A Practical Treatise for Engineers, Surveyors, and Others. By Thomas Aitken. Second edition. Pp. xviii + 527; illustrated. (London: Charles Griffin and Co., Ltd.) Price 21*s.* net.

THE first edition of this book was published in 1901, and the fact that a second edition of a technical book of this character should be called for within so short a period testifies to its value, and also to the greater attention that has been given to the maintenance of roads within the last few years.

After the advent of railways, and the abolition of turnpikes, road-making became a very neglected science; the advent of bicycles and the inconvenience felt by a very large section of the public caused pressure to be brought on highway authorities, and a gradual improvement set in. The subsequent introduction of motor-cars brought road maintenance very much to the front, and, taken generally, the main roads of this country are now kept in very fair condition. This, however, has involved a very large expenditure. It was stated at a recent discussion on motor vehicles at the Institution of Civil Engineers by the surveyor of the county of Middlesex that the cost of main roads in his county had increased from 49,000*l.* in 1889 to 90,391*l.* in 1905. In the two years 1904–6 improvements on the roads had amounted to 86,536*l.* The cost of the main roads of England and Wales has increased from 2,120,332*l.* in 1901 to 2,478,481*l.* in 1905.

The book now under notice has been revised and brought up to date, and much new matter has been added. The question of damage done to the roads by motor-cars, and the nuisance arising from dust caused by the speed at which these vehicles are driven, has been fully treated in a new chapter. A description of the various remedies that have been tried for dealing with the dust problem is given. The conclusion at which the author has arrived is that no real solution for dealing with this nuisance has yet been found, but he has no doubt that the system of "tar macadam" or "building up the road stone coating with a matrix of tar, chips and dust as a binding medium is the best possible method of solving the dust problem in a satisfactory and permanent manner."

The advantages of tar macadam are increased durability over ordinary macadam, imperviousness to moisture, capability of being kept clean, and the surface is not liable to be disintegrated by frost. Owing to its greater durability and to the fact that the surface of the road can be renewed by a thin coating of fine tar macadam, from time to time, without disturbing the subsurface or foundations, the cost over a series of years, when everything is taken into consideration, is not more than that of a steam-rolled ordinary macadam road. The author of this book, however, expresses the opinion that its first cost prohibits its adoption on an extensive scale on rural main roads.

The book is divided into eighteen chapters, dealing in an exhaustive and practical manner with the following subjects:—Historical sketch of road-making; resistance to traction on roads; laying out new roads and the improvement of those already made; retaining walls, culverts, bridges, &c.; materials used for repairs; quarrying road stone; breaking and haulage; rolling and scarifying; prevention of dust; footways; wood pavement; asphalt; brick pavement; tar macadam; testing the surface of roads and use of the viagraph; subways.

OUR BOOK SHELF.

A History of Chemistry. By Hugo Bauer. Translated by R. V. Stanford. Pp. vii + 232. (London: Edward Arnold, 1907.) Price 3*s.* 6*d.* net.

THE philosophy of chemistry can only be properly studied by the historical method. Present-day chemical philosophy, like present-day religion, is a product of evolution, and to understand it thoroughly it is necessary to be able to trace the successive stages by which past beliefs have become merged into present doctrine. Hence the increased attention which is now paid to the history of chemistry, and especially to the history of the development of chemical theory; and hence, too, the large increase in the number of works dealing with the historical aspects of chemistry which have appeared within recent years.

Dr. Bauer's little book cannot be considered as an important addition to the list. To tell the story adequately of the origin and growth of chemistry from the earliest times down to this age of ions and electrons is hardly possible within the limits of 220 small octavo pages. The book, however, may serve to whet the student's appetite for a fuller acquaintance with the subject, although in reading it he will have something to unlearn. To accuse Priestley of "personal intolerance" (p. 69) is wholly to misjudge his character, and the translator—a Priestley research scholar in the University of Birmingham—should have been more careful of what was due to his memory. To say, too, that Cavendish "contended against Lavoisier's theory of combustion until his death" is hardly consistent with accuracy. Cavendish never "contended" against anything; "contention" was absolutely foreign to his disposition, and, as a matter of fact, he ceased to take interest in chemical subjects long before his death. Nizza, as the place of his birth, may stand in the original German, but the English reader is more familiar with it as "Nice." John Dalton is said to have led (probably from his hard up-bringing) "a very modest life," and to have "died at Geneva in 1829." If this is a faithful rendering we must suppose that Dr. Bauer got his notes into confusion, since Dalton died at Manchester in 1844. The date and place evidently refer to Humphry Davy, of whom, however, no biographical account is given. To come down to later times, Kekulé is said to have become professor of chemistry at Geneva in 1858; for Geneva read Ghent. Ultramarine is not usually classed as a dyestuff. Thallium was not discovered by Mosander in the earth from Ytterby, as stated on p. 189; nor was fluorine isolated by Moissan by the aid of the electric furnace (p. 216). The name of Lord Rayleigh is not usually associated with the discovery of helium, xenon, krypton, and neon (p. 217), nor did M. and Mme. Curie isolate radium from "natural pitchblende" as the bromide.

Boyle, we are told, "left many writings, which give us pleasure by their simple style and clearness of expression." Whatever may be the merit of Boyle's writings, their style is hardly that of Addison, and probably no man living has had the courage and tenacity to work through them. Dr. Bauer is evidently not familiar with Swift's "Pious Meditation on a Broomstick in the Style of the Honourable Mr. Boyle."

In spite of minor blemishes the book is not without merit; indeed, it is eminently readable, and interesting. But it needs careful revision, since in its present form a judicious teacher could hardly commend it to his pupils.

Neolithic Dew-ponds and Cattle-ways. By Dr. Arthur John Hubbard and George Hubbard. Second edition. Pp. xxiv+116; illustrated. (London: Longmans, Green and Co., 1907.) Price 4s. 6d. net.

This interesting work has been considerably enlarged since the appearance of the first edition (1905), which was reviewed in Nature for April 27, 1905 (p. 611, No. 1852). The older work, with its convincing argument of Neolithic man fortifying the heights in order to escape the ravages made by the wolves of the plains on his flocks, has been retained and added to, and we also find the astronomical significance of some ancient works discussed.

In chapter ii. the authors state that they have found the orientation of Maumbury Rings, near Dorchester, to coincide accurately with that of Stonehenge; it would be of great interest to have the exact azimuth of the axis, and also the angular height of the horizon over which the sun is supposed to have risen, in order that the solstitial evidence could be more rigorously tested. Should this prove a true case, the discussion of the data would probably give us an earlier date than the 1680 B.C. ± 200 years (*not* 1800 B.C. ± 200 years, as stated by Messrs. Hubbard) found by Sir Norman Lockyer and Mr. Penrose for the more imposing structure on Salisbury Plain. One of the added chapters (vii.) discusses the possible astronomical origin of some earthworks on the top of Firle Down, in Sussex, and the authors tentatively suggest that they were probably constructed about 1900 B.C. for the purpose of observing the critical seasons of the May and solstitial years. But the evidence needs very careful sifting before one may fix a solstitial date, as was shown in the above-mentioned investigation of the much more permanent stone structure at Stonehenge. Denudation, subaërial, human and animal, will probably have played havoc with earthwork alignments, and the fixing of the original lines, it seems to us, must be more or less an arbitrary proceeding. We would point out that the straight line G.O.B. on the plan given on p. 99 could not possibly indicate the rising and the setting points of the May sun, as stated in the notes; probably the authors mean the *rising* of the *November* sun of the May year, for which the azimuth S. 62° E. would be approximately correct.

The book is beautifully printed and illustrated with reproductions from photographs, and should do a great deal to increase the general interest now being taken in the ancient monuments of these islands.

W. E. Rolston.

Übungsbeispiele aus der anorganischen Experimentalchemie. By Heinrich Biltz und Wilhelm Biltz. Pp. xi+232. (Leipzig: Wilhelm Engelmann, 1907.) Price 7 marks.

There are many books devoted to the preparation of organic compounds, but one rarely comes across one written especially for the study of inorganic preparatory work. It seems to be imagined that great skill is required to prepare organic compounds, but that anyone can prepare inorganic compounds in a state of purity and with good yields without any previous study. As a matter of fact, the preparation of pure inorganic compounds is by no means simple, and it is a great pity that this branch of chemistry is very rarely taught in a systematic manner. Consequently almost all the research carried out in this country is along organic lines, because owing to the interest aroused by the preparation of organic compounds, the student naturally turns to organic chemistry.

The book before us deals in the main with inorganic preparations, and is arranged, so far as possible, upon systematic lines. Thus chapter i. deals with reductions of oxides, by means of carbon, aluminium, potassium cyanide, and other reducing agents. The sequence mercury from cinnabar and then sodium and ammonium amalgam is rather strange, as some would expect the amalgams to be treated of in connection with alloys. Chapter ii. treats of polymerisation and dissociation, for example, the allotropy of silver sulphide, the modifications of sulphur, the passive state of iron, colloidal solutions, and so on. Then follows the preparation of various oxides and hydrides, acids, bases and salts, halogen compounds and sulphides.

The preparation of the nitrides of calcium and boron strikes us as strange. The calcium or boron are heated in the air, and so one obtains a mixture of oxide and nitride. As, however, the oxide and nitride cannot be separated, there seems very little point in the experiment, except that the student's attention is directed to ammonia from the air. Certainly, but if the air is first passed over red-hot copper, thus freed from oxygen, and subsequently passed over the heated calcium or boron, surely the experiment is much more striking, and, further, the pure nitride is prepared. This method of preparation would also lead up to a discussion of argon and similar gases.

The book will undoubtedly be of great use to teachers of inorganic chemistry and others who wish to study the subject from a preparatory point of view, but it is rather too full for the average student, who would certainly require very careful direction, or he would be inclined to wander along in a rather aimless fashion. F. M. P.

The Bacteriological Examination of Disinfectants. By William Partridge. With a preface by Major C. E. P. Fowler. Pp. 66. (London: The Sanitary Publishing Co., Ltd., 1907.) Price 2*s*. 6*d*. net.

THE subject of disinfectants has lately attracted considerable attention, and Mr. Partridge's little book forms a very useful summary of the methods employed for testing bacteriologically the germicidal value of disinfectants. The Rideal-Walker or "drop" method is rightly that most favoured, and the major part of the book is devoted to it. We doubt if the explanation given on p. 17, that a forty-eight hours' culture of *B. typhosus* is less readily killed by a disinfectant than a twenty-four hours' one, because it is more vigorous, is correct; we should ascribe the fact rather to the greater number of bacilli and to clumping in the older culture. On p. 18 it is said that while a broth having a reaction of $+1·5$ is suitable for the culture of the typhoid bacillus, for the diphtheria and cholera organisms a "neutral or alkaline broth must be substituted." The broth named is quite suitable for these organisms, for it is alkaline in the ordinary acceptation of the term; though acid to phenolphthalein, it is still alkaline to litmus. On p. 34 an experiment is quoted to show that an organism from different sources may have a different resisting power from a disinfectant. Doubtless this is so, but the experiment does not prove it. The experiment shows that two strains of the typhoid bacillus, with strengths of carbolic of 1 in 70 and 1 in 100 respectively, are killed in between 5 and $7\frac{1}{2}$ minutes; obviously the one might have been killed in $5\frac{1}{4}$ minutes, the other in $7\frac{1}{4}$ minutes, and actually there might have been little difference between them. Everyone has his own method of manipulating tubes for inoculation, but we do not like either method depicted in Figs. 3 and 4. Major Fowler, R.A.M.C., contributes a useful introduction.

R. T. HEWLETT.

Ergebnisse und Fortschritte der Zoologie. Edited by Dr. J. W. Spengel. Vol. i., part i. (Jena: Gustav Fischer.)

UNDER the above title Mr. Gustav Fischer is issuing a new zoological journal, of which a variable number of parts are to appear each year, the whole to form an annual volume at the price of sixty marks. As no prospectus is issued with the part now before us, we are unable to indicate the ground which the publication is specially intended to cover. The present part contains 238 somewhat closely printed 8vo pages, illustrated by fifty text-figures; and from this we presume that plates do not enter into the scheme of the new venture. The name of the editor is a sufficient guarantee that only papers of a high order will be accepted for publication, this being fully borne out by the contents of the initial number. These comprise a discussion on chromosomes by Mr. Valentin Häcker, of Stuttgart; an article by Dr. Richard Heymons on the various types of insect metamorphosis, and their relation to the metamorphoses of other arthropods; and another, by Mr. O. Maas, of Munich, on the scyphomedusæ. The new enterprise has our best wishes for success. R. L.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Seismographs and Seismograms.

As I have had occasion to study and compare the records of nearly all the types of seismographs for recording distant earthquakes which are now in use, I may perhaps be permitted to add something to Prof. Milne's letter in NATURE of January 2. The nature of the records, and the relative merits of different types, of seismographs, are not generally apprehended in England, and appear to be misunderstood in Strassburg, from whence much of the recent seismological literature has been inspired.

The two leading problems of seismology, as it stands at present, are the determination, *firstly*, of the exact nature and amount of the movement which takes place, and, *secondly*, of the time requisite for the transmission of the different types of disturbance from the origin, to various distances, and in various directions, through the earth, or along its surface. The first of these is naturally the special object of purely seismological stations and observatories, and for it no single instrument or type of instrument will be sufficient. From the mathematical and experimental investigations of the mechanics of seismographs by Prince Galitzin, Prof. Rudzki and others, it has been conclusively established that no form of instrument, having a pendular period of vibration of its own, however perfectly the oscillations may be damped, can possibly record with exactitude an undulatory movement of the soil such as is caused by earthquakes. As every instrument giving a continuous record must necessarily be of the nature of a pendulum of some sort or other, owing to the necessity for bringing the recording point back to the zero line of the record, it is obvious that no single instrument can suffice for this purpose, and that the only way, by which an understanding of the nature of the movement of the soil can be arrived at, is by installing a number of instruments, of different types and varying response to movements in diverse directions and of unlike period.

For the second purpose a totally different set of conditions comes in. It is no longer necessary to attempt an exact, or even an approximate, representation of the actual movement of the ground, so long as the instruments give records in which the different phases of wave motion can be recognised with reasonable certainty; but, since the solution of this problem involves the collection of numerous records from many stations, it is necessary to obtain the cooperation of astronomical, physical, meteorological, and other observatories, and, consequently, certain conditions, which may be ignored in a specially seismological station, have to be taken into consideration. These are:—

(1) The instrument must not be unduly cumbrous or bulky; it must be easy of transport, occupy only a moderate floor space, and not require special and expensive foundations.

(2) It must run without much attention, and at as moderate a cost as possible.

(3) It must be sufficiently sensitive and consistent in its action to give records capable of interpretation as a general

rule—no instrument has yet been devised which will invariably do this—but should not be too sensitive, or the record of important disturbances may be lost.

(4) The records should be capable of easy and rapid reproduction.

Of the instruments which have been designed or suggested for this purpose, four types are in use to a greater or less extent.

The Wiechert so-called astatic pendulum is an inverted pendulum with a bob weighing more than a ton, kept in position by two springs, and provided with an ingenious system of air-damping of its vibrations. This instrument has been recommended for general use, because its supposed astatic nature is believed to make it record the movement of the soil in an accurate manner; as already pointed out, this condition is immaterial, and, moreover, cannot be completely fulfilled. The instrument is undoubtedly a fine one, and gives valuable records, but its proper place is in an observatory specially devoted to seismology; for general use it is too heavy, requires too much attention, and gives records which are not adapted for ready and rapid reproduction.

The Rebeur-Ehlert instrument is a horizontal pendulum, of the form devised by v. Rebeur-Paschwitz, combined with a recording arrangement devised by Prof. Ehlert. This instrument is an extremely sensitive one, and there seems to be none better for recording small disturbances; in the case of large earthquakes the record is apt to be lost. The record is photographic, and the seismograms are readily reproduced by photography. Its cost of maintenance and too great sensitiveness are the points in which it fails to meet the requirements of an instrument for general adoption.

The so-called Omori pendulum is a horizontal pendulum presenting no special peculiarities, and is a modification, in details only, of a type of instrument in very general use. It fulfils all the first three requirements, being moderate in size, needing little attention, and gives good records, easy of interpretation and measurement. It fails in the fourth requirement only; the record, being taken on smoked paper, is not readily reproduced by photography, and is on too small a scale to obviate the risk of introducing error when copied by tracing.

The fourth type of instrument is the Milne pendulum, a horizontal pendulum with photographic record on a principle quite different from that adopted in any other instrument. This fulfils all the first three requirements, and the fourth too; the seismograms are easily reproduced by contact printing on to the same photographic paper that is used for recording, and the copies are practically as serviceable as the originals. This alone, if the instrument had few other merits, would mean much; but in addition to this I have found its seismograms the most convenient of any for determining the exact time of any point on the record, and had it not been for the general adoption of this type of instrument, and the ease with which its records can be reproduced, a considerable part of what seismological work I have been able to do could not have been attempted. The only improvement I have ever desired to see is an increase in the rate of movement of the recording surface, and this has now been introduced. I have examined and studied hundreds of records of this instrument from different stations; from Victoria, Toronto, Cape Town, Bidston, Paisley, and many other places, its records are consistently good; at a few stations, whether from a defect in the particular instrument, a want of proper adjustment, or, more probably, something in the foundations or the subsoil, its records are less satisfactory, but from none do they seem to be so bad as at Strassburg; having never seen a seismogram of that instrument—it is not easy to get copies from Strassburg—it is impossible to hazard a suggestion of the reason for the failure of the instrument at this station.

No one would wish to see one pattern of instrument adopted to the exclusion of all others, nor has it ever been pretended that the pattern adopted by the organisation which has grown up under the auspices of the British Association is faultless; but for the purpose of securing a large number of records for comparison with each other, and thereby determining the rate of transmission of earthquakes across, through, and around the earth, it is no more faulty than any other pattern, and has one crowning merit which they do not possess. Can it be to this, to the ease of reproduction of its records, which renders unnecessary the centralisation of seismological research, that we must attribute the continuous vilification of a valuable type of instrument? R. D. OLDHAM.

An Early Acoustical Analogue of Michelson's Echelon Grating.

IN the "Œuvres complètes" of Christiaan Huygens (tome x., p. 571) occurs the note given below. It was destined for Ph. de la Hire, and of date November, 1693. Huygens's remarkable observation and his ingenious explanation of the musical note produced by reflection from a large flight of steps of the noise of a fountain in the park of Chantilly will be read with interest also by those who, though having no ready access to the "Œuvres complètes," are still concerned with the (reflecting) echelon grating:—

"Je veux adjouter icy au sujet de la réflexion du son une observation assez singulière, que j'ay fait autrefois estant à la belle maison de Chantilly de la Cour où est la statue Equestre on descend avec un degré large de . . . marches dans le parterre ou il y a une fontaine de celles qu'on appelle gerbe d'eau, qui fait un bruit continuel. Quand on est descendu en bas et qu'on se tient entre le degré et la fontaine on entend du costé du degré une résonance qui a un certain ton de musique qui dure continuellement, tant que la gerbe jette de l'eau. On ne sçavoit pas d'où venoit ce son ou en disoit des causes peu vraisemblables ce qui me donna envie d'en chercher une meilleure. Je trouvay bientost qu'il procédoit de la réflexion du bruit de la fontaine contre les pierres du degré. Car comme tout son, ou plustost bruit, réitéré par des intervalles égaux et très petits fait un son de musique, et que la longueur d'un tuyau d'orgue détermine le ton qu'il a par sa longueur par ce que les battements de l'air arrivent également dans les petits intervalles de temps que ses ondoiements emploient à faire deux fois la longueur du tuyau sçavoir quand il est fermé par le bout, ainsi je concevois que chaque bruit tant soit peu distingué qui venoit de la fontaine, estant réflechi contre les marches du degré, devoit arriver à l'oreille de chacune d'autant plus tard qu'elle estoit plus éloignée, et cela par des différences de temps justement égales à celuy que les ondoiements de l'air employent à aller et venir autant qu'estoit la largeur d'une marche. Ayant mesuré cette largeur qui estoit de 17 pouces, je fis un rouleau de papier qui avoit cette longueur, et je trouvai qu'il avoit le mesme ton qu'on entendoit au bas du degré.

"Je trouvay comme j'ay dit que la gerbe n'allant point l'on cessoit d'entendre ce ton. Et aiant eu occasion d'aller à Chantilly pendant l'hyver, qu'il estoit tombé beaucoup de niège qui ostoit la forme aux marches, je remarquay que on n'entendoit rien quoyque la gerbe allast et fit du bruit à l'ordinaire."

A slight confusion is caused by Huygens's first referring in his note (apparently only drafted) to a closed organ-pipe and later to an open one. Taking a pouce $=2{\cdot}7$ cm., the depth of the steps becomes $17\times2{\cdot}7=45{\cdot}9$ cm. At 10° C., the corresponding sound of about 368 vibrations per second would be given by an open pipe of 46 cm.

The effect of gratings on impulsive motion of light is now well understood, thanks to the labours of Lord Rayleigh, Gouy, Schuster, and others. It remains interesting, however, to contrast the opinion concerning the supposed regularity of white light, held by some high authorities before these discussions, with Huygens's statement that the regularity in the nature of the sound which he observed has been impressed upon it by outside influence. P. ZEEMAN.

Amsterdam, January 6.

The Inheritance of "Acquired" Characters.

MAY I ask for information upon the interpretation of two sets of facts?

(1) Prof. Henslow states that the garden parsnip "known in the trade as 'The Student' was raised from seed of the wild plant by Prof. J. Buckman in 1847 at the Agricultural College, Cirencester," and also that M.

Carrière "raised several garden forms" of radish "of various colours from the seed of the wild species (*R. raphanistrum*), and found that they produced the long form in a light soil, and the turnip-rooted form in a stiff soil. A similar result has occurred with carrots. By selecting seed from plants having the best formed roots, these" (characters) "have become fixed and hereditary" ("How to Study Wild Flowers," 1902).

(2) I was delighted in the early summer by the marvellous skill and intelligence exhibited by some collies in the annual sheep-dog trials, which reveal apparently much more than the results of individual training. I have lately seen a pack of hounds streaming over the same country after a fox. The hound (*triste lupus in stabulis*) would make an indifferent sheep-dog, and the master who brought a pack of collies to a meet would provide some novel sport for the field. The collie is trained individually, but he has an inherent, if not inherited, aptitude, just as the foolishly good-natured hound puppy who is "put out to nurse" in his earlier days readily learns his work when he joins the pack. Further than this, an ordinary dog-show displays group peculiarities in different types of dog. The fox-terriers snarl savagely at each other, the greyhounds and their allies bark and yelp continuously, and appear as though on the verge of neurotic insanity, while the foxhounds lie and appear to drowse silently with a well-bred air of tolerant boredom that forms a curious contrast to the howling multitudes around them. Yet they are all dogs, and have reached their typical specialisation by characters acquired in some way.

If we are forbidden to believe that acquired characters are hereditary, what is the explanation of the seed of the "student" parsnip and the "turnip" radish coming true to type, and why does a collie drive sheep and a hound give tongue at the scent of a fox? Is it suggested that in the "germ plasm" of the wild dog all these special qualities are already involved, just as the digestive peptones gathered functionally and localised in the leaves of Dionæa and Drosera are found wandering aimlessly and to no purpose in some fruit trees? If so, what is the nature of the directive impulse that localises these characteristics in hound, collie, Drosera, and radish immediately fertilisation takes place? And again, how does the "peppered moth" contrive to appear in the black country hatched with sooty wings that harmonise with the now smoke-stained bark whereon he must rest? The whole subject of mimicry seems to be involved, and if your reviewer is right (NATURE, January 2, p. 193) in noting with "a sense of weariness mingled with surprise the appearance of a book on the transmission of acquired characters," it is quite certain that the "isolated biologists, and whole hosts of medical men who still hold the belief that acquired characters are transmitted" would regard it as a great boon if he would tell those who "make him tired" what are the conclusions apparently already established by "the modern, and still infant, science of heredity" that will satisfactorily account for such facts as I have ventured to state.

It will hardly do to say that in one sense the problem is "as unreal as the question of the apple dumpling which puzzled one of the Georges, because the characters of an organism do not get into its germ-cells any more than the apple gets into its crust, for both the germ-cells and the apple were there all the time." "One of the Georges" would doubtless have been grateful for a little culinary instruction, just as "whole hosts" of somewhat puzzled people with open minds would be honestly sincerely grateful for a definite explanation from "the infant science of heredity" as to how the sheep-driving impulse really got into the sheep-dog. For "nature" is more luminous than a text-book.

E. C. SPICER.

Waterstock, Oxford, January 3.

The Diamantiferous Rock of Kimberley.

MY friend, Dr. Hatch, is not quite correct in stating (January 9, p. 225) that I was led to dissent from the late Prof. Carvill Lewis's view that the diamantiferous rock of Kimberley was a volcanic peridotite "by a microscopic examination made in 1899 of specimens from the Newlands Mines" (Proc. Roy. Soc., lxv., 1899, p. 223). Four years earlier I expressed the opinion that this rock was a breccia, and that the diamonds, with other conspicuous minerals, were not formed *in situ* (*Geol. Mag.*, 1895, p. 500). This belief was strengthened rather than shaken by editing Prof. Carvill Lewis's notes and examining his specimens ("The Genesis of the Diamond"), and was expressed yet more decidedly later in 1897 after examining another series of specimens from Kimberley (see *Geol. Mag.*, 1897, p. 501). To discuss the "magma" and "concretion" hypothesis would be out of place here, but elsewhere I may have something to say on those subjects.

T. G. BONNEY.

Musical Sands.

MR. CARUS-WILSON'S failure (January 9, p. 222) to obtain sounds from "millet seed" sand of highly spherical grains puts a difficulty in the way of the suggestion made in "Sound" by Poynting and Thomson, though I do not think that it finally disposes of it.

I have not been able to follow the friction explanation as given by Mr. Carus-Wilson (NATURE, August 6, 1891), and I write in the hope that he may give more detail as to the moving system which produces the musical note. It appears probable that the musical sounds excited in a body by friction are due to the natural vibrations of that body. Obviously the grains of sand are far too small to give the notes heard. I suppose that the fundamental period is of the order of the time taken by an elastic wave to travel half round the grain. With elastic moduli of the order 10^{11} and density $2\frac{1}{2}$, the fundamental frequency would be not less than 10^6. What system does the friction set in vibration?

J. H. POYNTING.

The University, Birmingham, January 11.

IN NATURE of January 9 (p. 222) Mr. Carus-Wilson's letter asks for further details of the "singing sands" that I exhibited to the Physical Society. I am able to give the mineralogical description, by Mr. A. J. Maslen, of the Maine sand from Mareen's beach, near Small Point, at the entrance of the Kennebec River.

A subangular sand very free from *very* small grains. Clean.

Quartz. Principal constituent. As perfectly colourless grains showing conchoidal fracture (rock-crystal) and as more or less coloured grains of quartzite.

Muscovite Mica. Small quantity. Flakes.

Glauconite. Dark green grains, many of fairly large size. Almost black.

Topaz (?) Square pieces due to cleavage. Yellow.

Opaque white substance. (Felspar?)

Magnetite. Small grains. Rare.

The other specimens of sands were very similar to that from Maine.

SIDNEY SKINNER.

South-Western Polytechnic, Chelsea, S.W., January 13.

Intensity of Spectrum Lines.

VERY little attention has been paid in the past to the accurate measurement of the optical intensity of spectral lines in vacuum tubes under different conditions, probably on account of the considerable experimental difficulties. Hence I may, perhaps, be allowed to indicate a relation I have obtained between the optical intensity, current strength, and pressure of the glowing gas. Throughout the whole experimental range, using the so-called "electrodeless" tube—with wholly external mercury electrodes, when the current is of a slowly oscillating character—the optical intensity, with an end-on tube, is accurately proportional to the readings of a thermo-galvanometer in series, and over a more limited range of measurement, at constant current, is inversely proportional to the pressure of the gas.

In other words, the intensity is proportional to $\lambda \int c^2 \delta t$, where λ is the *mean free path*.

Measurements on the monatomic gases are now in progress, and it is intended later to investigate the influence of temperature.

University College, London, W.C.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

IV.—*Avenues.*

I HAVE measured several avenues since "Stonehenge" was published, and I have studied others of which the orientation could be determined by the Ordnance maps. Many of them have been found to have had the same astronomical use which had been suggested in those measured on Dartmoor. The longest avenue I have seen is at Avebury—the Kennet Avenue—which, in Stukeley's time, was more than a mile long. Associated with it is the Beckhampton Avenue. These avenues must have been very imposing parts of the complete temple when it was in full use. Avebury is such a mass of ruins that it is difficult to reconstruct it in the mind's eye in its entirety, but some parts of it, considered by themselves, present no difficulty. Mr. R. H. Caird, of Devizes, has twice enabled my wife and myself to visit the region by driving us from Devizes in his motor-car, and these visits gave us time enough to see that the Beckhampton Avenue and the remains of the Cove were both oriented to the May sunrise, were, in fact, probably closely associated in the May ceremonials, the avenue abutting on the north circle, in the centre of which the remaining gigantic stones of the cove still stand.

The theoretical conditions for the azimuth of the May sunrise at Avebury (lat. 51° 30′, variation 16° 48′ W. in 1906), are, with 2′ of limb showing:

N. 62° E. with sea horizon
63° 40′ ,, hills 1° high
65° 12′ ,, ,, 2° ,,

A rough measurement on the spot gave me N. 65° E. for the outlook of the cove, the horizon being about 2° high, and on the 1-inch Ordnance the line joining the two large monoliths at the west end of the Beckhampton Avenue and the cove gives N. 64° E. Further, this line studied on the 25-inch map passes close to the stones indicated by Stukeley, who expressly says that he saw the remains of the avenue. I give his description.[2]

"The Beckhampton Avenue goes out of Abury town at the west point, and proceeds by the south side of the churchyard. Two stones lie by the parsonage gate on the right hand. Those opposite to them, on the left hand, in a pasture, were taken away in 1702, as marked in the ground-plan of Abury. Reuben Horsal remembers three standing in the pasture. One now lies in the floor of the house in the churchyard. A little farther one lies at the corner of the next house on the right hand, by the lane turning off to the right to the bridge. Another was broke in pieces, to build that house with in 1714. Two more lie on the left hand opposite. It (*i.e.* the Avenue) then passes the beck south of the bridge. Most of the stones hereabouts have been made use of about the bridge, and the causeway leading to it."

Smith's account goes on:—

"Moreover, we have some evidence of the existence of the avenue in this direction, in the fragments of sarsen stones which may still be seen there, as the Rev. Bryan King has pointed out in his note on this subject, to which I have already called attention;[1] therein he says: 'Beginning with the walls of the churchyard and of the church, and of the manor-house, with its enclosures, in an entire length of full half-a-mile from the earthwork on the west side of Avebury to the corner of the large field in which the two large stones near Beckhampton now stand, there are very few lineal yards which are not occupied by causeway, walls or cottages, all formed of sarsen stone, sufficient and more than sufficient, to absorb all the stones of the Beckhampton Avenue': and then he goes on to enumerate the several stones, or portions of stones, which still exist, and which are apparently the remnants of those described by Stukeley."

On the accompanying plan of Avebury, photographed from the 25-inch Ordnance map, I have indicated the two circles as roughly determined from the

FIG. 11.—Avebury, showing the circles and avenues.

remaining stones. It will be seen that the May-year avenue line is directed nearly, but not quite, to the centre of the northern circle, the cove occupying the centre itself, and so blocking the view from the avenue or processional road to the S.W.

I next come to the south-eastern or 'Kennet Avenue.' Stukeley[2] says of it: "The Kennet Avenue consisted originally of one hundred stones on each side, reaching from the vallum of Abury town to the circular work on Overton Hill. Mr. Smith, living here, informed me that when he was a schoolboy the Kennet Avenue was entire from end to end. The stones composing it were of all shapes, sizes, and heights that happened, altogether rude. Some we measured six feet thick, sixteen in circumference. If the stones were of a flattish make, the broadest dimension was set in the line of the avenue, and the most sightly side of the stone inward. The founders were

[1] Continued from p. 152.
[2] Avebury described, p. 34, quoted in Smith's "British and Roman Antiquities of North Wiltshire," p. 146.

[1] *Wiltshire Magazine*, vol. xviii., pp. 377–383.
[2] Avebury described by Stukeley, quoted in "British and Roman Antiquities of North Wiltshire," p. 145.

sensible that all the effect desired in the case was their bulk and regular station. When I abode here for some time on purpose, for several summers together,

Photo. by Lady Lockyer.
FIG. 12.—One of the Monoliths at Borobridge.

I was very careful in tracing it out, knew the distinct number of each stone remaining, and where every one stood that was wanting; which often surprised the country people, who remembered them left on the ground or standing, and told me who carried them away. Many of the farmers made deep holes and buried them in the ground; they knew where they lay. Lord Winchelsea with me counted the number of the stones left, 72, anno 1722. I laid it all down in the nature of a survey, on large imperial sheets of paper, and wrote a detail of every stone present or absent; but it would be very irksome to load the press with it." Mr. Long, after describing the war of extermination which had been waged against them, and how such stubborn blocks as refused to succumb to fire and hammer were buried in the pits dug for them, continues: "Two of them lie six feet underground in the premises of Mr. Butler of Kennet, and over another the Bath road passes. The work of destruction has been so successfully carried out that only nineteen stones or their stumps are now visible between West Kennet and Abury; four in the bank on the left-hand side of the road from Marlborough as it enters Kennet, and which can only be seen by going into the adjoining field: these stones lie about thirty paces apart, and that these were the original, or nearly the original, distances, seems confirmed by Stukeley's twentieth plate."[1]

As will be seen from the map, this avenue apparently was connected with the southern circle as the Beckhampton one was with the northern one. If this were so, certainly the enormous bank, erected apparently for spectacular purposes, which is such a striking feature of Avebury, was not made until after the Kennet Avenue had fallen out of any astronomical use.

The alignment of this avenue, as measured on the 25-inch map, is S. 32° E., the elevation of the horizon from the 1-inch map being 49′. This gives a declination of 31° 34′ S. I shall return to this point later on.

This avenue seems to have struck another aligned from the circle on Overton Hill, which formerly was oriented to the May sunset or the November sunrise, to judge from the positions of the stones given in Smith's map.

At Borobridge, near Harrogate, is another avenue I have visited; only three stones remain, two have disappeared in recent times, the extreme stones being separated by about 700 feet. They are not in a line. Lukis was the first to suggest that they were the remains of an avenue, and I agree with him. According to my measurements the breadth of the avenue was about 25 feet. With a clino-compass the mean of three readings gave N. 355° E. as the magnetic azimuth; taking the variation as 17° (October 4, 1907), this gives us S. 22° E. or N. 22° W.; the true northern horizon is $1\frac{1}{2}°$ high, the southern one 1°.

I give a copy of a photograph of the central stone; this seems to have been squared, and the east and west sides are slightly slewed from the general line of direction.

Mr. Lewis,[2] in an interesting account of these stones, tells us that the most northerly stone is 18 feet high by $7\frac{1}{2}$ by $3\frac{1}{2}$ feet, the second (the one illustrated), $197\frac{1}{2}$ feet away, 22 feet high by $4\frac{1}{2}$ by $4\frac{1}{2}$ feet; and the southerly one, 362 feet away, 23 feet high by $4\frac{1}{2}$ by 4 feet. They are called locally the Devil's Arrows.

Of another Dartmoor avenue, that at Assacombe, in the Chagford district, I am enabled, by the kindness of Mr. Falcon, the author of "Dartmoor Illustrated"

FIG. 13.—Assacombe Avenue looking west.

[1] *Wiltshire Magazine*, vols. iv., pp. 327-9; xvii., pp. 329-31.
[2] *Journal Anthropological Institute*, November, 1878.

(a book which everybody interested in the monuments should possess), to give two photographic views from the east and west ends. It is a May-year avenue (Az. N. 63° 30′ E., from 25-inch Ordnance map) like the Beckhampton Avenue at Avebury.

FIG. 14.—Assacombe Avenue looking east.

It will be noticed that, like the avenues at Merrivale, the row of stones is furnished at the west end with monoliths larger than ordinary, and that the other end has a well-marked blocking or sighting stone ending the avenue.

I may here refer to yet another May-year avenue which I measured in South Wales. It is near "Arthur's Stone," a famous cromlech in Gower to which I refer elsewhere. The true azimuth is S. 61° E., height of horizon 1° 30′.

There is no doubt, I think, that the "Nine Maidens" near St. Colomb, Cornwall, of which a plan is given by Lukis (plate xxxii.), is the remains of a double or multiple avenue. With Lukis's value of the magnetic variation, I found from his plan an azimuth of N. 28° E. I visited them in April, 1907, and assuming a variation of 18° W. (with hill 2°), I got the same value, giving Dec. N. 33° 47′: that of Capella in 1480 B.C.

This is a locality worthy of minute study, especially with reference to the actual commencement of the avenue, for the true azimuths of the many stones on the E. side of course depend upon this.

This avenue and the fine one at Callernish can be treated together. For the latter the conditions are as follows:—

Azimuth of Avenue.—N. 9° E.; hill, 1° 26′; dec. 32° 26′ N.; Capella, 1720 B.C.

This avenue is associated with a circle 42 feet in diameter, within which is a remarkable chambered cairn referred to elsewhere. The avenue consists of two parallel lines going off to the northward 270 feet in length, and about 27 feet in width. The total number of stones is forty-eight, and the total length of the monument, from the extremity of the double line, through the centre of the circle to the extremity of the single line beyond, is 408 feet.

It will be seen, then, that the more recent measurements give us avenues directed, on the orientation theory, both to sun and stars. The sun is the May sun, and the solar avenues are at Avebury, Assacombe, and Gower.

Of new stellar avenues parallel to others previously shown by the investigations to be aligned on northern clock-stars, we have those at Callernish and St. Colomb.

But these are not all.

NORMAN LOCKYER.

THE CALIFORNIAN EARTHQUAKE OF 1906.

ALTHOUGH only twenty months have passed since Central California was devastated and San Francisco destroyed, partly by earthquake but largely by fire, some fifty papers have appeared from technical and other journals describing this great catastrophe. The last appears as a Bulletin (No. 324, Series R, Structural Materials, 1) of the U.S. Geological Survey. It is a volume of 158 pp., illustrated by fifty-seven excellent process plates, in addition to which there are two maps. The introduction is by Dr. G. K. Gilbert, and it treats of the earthquake as a natural phenomenon.

Photo. by Lady Lockyer.

FIG. 15.—The Nine Maidens.

The earthquake, Dr. Gilbert tells us, had its origin chiefly along the line of an old fault. This can be traced from San Juan, about ninety miles south-east of San Francisco, to Point Arena, about 120 miles north-west of that city, the total length being approximately 200 miles. There are, however, good reasons for believing that the fracture extends very much farther to the north. The total length of the line of yielding would therefore have been 300 or even 400 miles. Its general appearance is that of a huge furrow, the displacement of one side of which relatively to that of the other side has varied from 2 to 20 feet. In Fig. 1 the furrow-like appearance is not visible, but the fence, which is broken across and shifted $8\frac{1}{2}$ feet, indicates the existence of a sheer, the trace of which is hidden.

FIG. 1.—Fence parted by Earthquake Fault. The fault trace or fracture accompanying the earthquake is inconspicuous although the horizontal displacement is considerable. (Photograph by G. K. Gilbert.)

The vertical displacements were comparatively small. Passing out from the main fault are branching cracks. These are particularly noticeable in soft ground. The depth to which this shattering has extended cannot be directly measured, but that it has descended to a considerable depth is indicated by alteration in the general circulation of underground waters. New springs have been created, whilst old springs have been closed or altered in their flow. The great length of the main fault suggests that it had a great depth. Further, as the initial impulse was sufficient to send earth waves round the world it is reasonable to suppose that this was occasioned by the sudden displacement of a very large earth block. We know something about its length. Its breadth may be estimated from its distance from more or less parallel faults which yielded or from the width of the area of the molar displacement. Its thickness may be that of the earth's crust. A suboceanic mass movement of this size might disturb the Pacific Ocean for twenty-four hours, or shake the world from pole to pole. Were it very much less it is difficult to imagine that such far-reaching commotions could be originated. This may be mere speculation, but to shake the world a heavy blow needs to be applied over a considerable area. A curious observation relating to the length of earthquake waves was made in Tomales Bay, where, before the earthquake, there was the usual smooth mud plain commonly seen on tidal flats. After the earthquake this plain was ridged, the crests of the ridges being ten to twenty metres apart. Whether these represent the solidification of gravity waves we are told is not quite clear, but whatever their history may have been, they illustrate the response of a mud flat to earthquake motion.

The major and most important part of the publication is written by three engineers, Messrs. R. L. Humphrey, J. S. Sewell, and Prof. Soule. All have had experience of fires, whilst Prof. Soule has for many years watched the growth of San Francisco and was present at its fall. We are told that the whole secret of earthquake-resisting power depends upon "proper design, first-class materials, and honest workmanship." The first condition, inasmuch as it involves radical changes in methods of ordinary construction, might have been underlined. The greatest destruction came from fire, and the modern structures which best resisted both fire and earthquake seem to have been those made of reinforced concrete. Tunnels, flumes, wrought and cast-iron pipes, particularly where

FIG. 2.—Memorial Arch, Leland Stanford Junior University. Earthquake Effect:—The beams designed to stiffen the walls were not tied to them, and helped to batter them down when the shock came. (Photograph by Richard L. Humphrey.)

they crossed the fault line, were interrupted, but the chief reason that fire gained the upper hand was the failure of the water systems in the city. Steel skeleton buildings withstood the earthquake, but although these and their supporting columns had been encased in fire-resisting material, under the effects of heat the protecting surfaces flaked off. Internal metal-work expanded, buckled, and then collapsed. Fire-proofing had been inefficient. Although there is much of scientific interest in the bulletin, its chief value will be to the practical engineer, who has to contend against, not simply the effects of earthquakes, but chiefly against the effects of fire.

PUBLIC CLOCKS AND TIME DISTRIBUTION.

The interesting correspondence on "Lying Clocks" inaugurated by Sir John Cockburn in the *Times* has tended to degenerate into a display of advertisements by different firms interested in various systems of clock synchronisation. But in its original form, the point raised is one of great importance, and if it is not appreciated by the public as fully as it should be, the explanation is probably to be found in the general contempt for accuracy exhibited in this country, and the non-scientific habits which have been so long cultivated or permitted. It seems impossible to get the man in the street to understand the significance of seconds. He is ready with his old adage, *De minimis non curat lex,* and thinks he has settled the question. But this is not so, and the interest taken in the *Times* discussion indicates the possible introduction of a healthier state of things. We may look forward to a time when every progressive town or city will be provided with clocks, publicly exhibited, which will declare the correct time. If such mechanism were provided, it would not only tend to economy in various directions, owing to the more complete appreciation of small intervals of time, but such clocks would furnish a wholesome lesson in accuracy, and by the introduction of scientific processes into everyday life inculcate the importance of paying greater attention to scientific methods.

The term synchronisation seems to be used very vaguely. For its successful operation, two distinct processes have to be considered—the distribution of correct time signals and the control of local clock dials. Some seem to think that the problem would be sufficiently solved if clocks were all made to show the same time. This result could be ensured by simple methods of control, and it is true that so long as we remained in one town the annoyance of a "lying timekeeper" would not have to be tolerated, but the uncertainty would reappear as soon as we entered another town, and the only way to secure uniformity is to arrange for the exhibition of correct standard time. This essential preliminary of the distribution of correct time signals is provided for by the Post Office authorities, working in cooperation with the Royal Observatory, Greenwich. The telegraphic service throughout the country is suspended for a few seconds, while the signal is sent through the trunk lines at 10 a.m. But, unfortunately, it is to be feared that the duty of forwarding this signal to the smaller towns is very carelessly and inefficiently performed, simply because the officials who are responsible for its wider distribution have not sufficiently apprehended the necessity for accuracy. From personal experience we are afraid that this signal is not sent on automatically. Here is the first necessity for reform. If it were thoroughly well known that there did exist in every town and village an office where correct time could be had, even at some personal inconvenience careful people would take the trouble to keep their clocks fairly accurate, and by so doing gradually educate the more indifferent to a higher standard.

The control of the clock dial is a much simpler matter, and has passed into the commercial stage. The convenience of having a number of clocks in one establishment indicating the same minute is so evident that a variety of patents has been secured with the view of effecting this purpose. But most of the patentees do not concern themselves with extreme accuracy, and are content if no greater difference than half a minute can be perceived between any dial and the master clock, from which the signal is sent generally at intervals of half a minute. There are several processes which can be easily utilised, some of which are admirably adapted for outside dials, and could be supplied at small cost. Probably it would not be wise to insist on extreme accuracy, but to endeavour to establish a system that could be improved. The trouble is that London, and other large towns generally, have no system of clocks under municipal control which could be synchronised. It is necessary to make a new departure, and the discussion in the *Times* is so far valuable that it tends to create a public opinion, which may induce the authorities to take the initiative.

LORD KELVIN AND THE ROYAL SOCIETY OF EDINBURGH.

On January 6, at the first meeting of the Royal Society of Edinburgh since the death of the president, Lord Kelvin, Prof. Crum Brown, F.R.S., vice-president, read the following appreciation, a copy of which has been communicated to us by the society:—

We meet here to-night for the first time since the death of Lord Kelvin.

This is not the time to enter into an enumeration or a criticism of what he did. Our thoughts now are of the loss which we have sustained. But it is impossible in our mind to separate the man from his work. For the transparent truthfulness, the simplicity and straightforwardness, the absence of the least trace of affectation or trick, which contributed so much to the charm of his manner, felt by everyone who came, even in the slightest and most transient way, into relation with him, are to be seen in all that he did. It was his love of truth and his sympathy with nature that led him in all his investigations directly to the root of the matter, and made him so zealous and successful in his searches for the essential principles underlying the phenomena of nature. And when a truly essential new view was obtained, by himself or by another, of the way in which nature works, he rejoiced greatly, and called on his friends to rejoice with him. Nature was to him very real, and no demonstration seemed to him quite satisfactory until it had been "realised." This and his sympathy with men and with their work gave everything to him a practical aspect. And so in almost every direction in which he worked he devised working models and instruments of precision. Some of these are known only to specialists, and by them used and valued, but everybody has heard of his compass and of his sounding apparatus, and knows something of the enormous benefits he has conferred on navigation.

It was not only in pure and applied science that he was interested; everything that affects the life of the people, education, politics, religion, occupied his thoughts, and on all subjects which he had seriously considered he had definite opinions. While he would, on occasion, defend with zeal and energy what he believed to be the truth, he was always perfectly fair to his opponents, as he was always courteous to everybody.

We have already had emphatic evidence that the world knows that a great and good man has left us; we who knew him more intimately also mourn a dear, trustworthy, and trusted friend.

NOTES.

M. BAILLAUD, director of the Toulouse Observatory, has been appointed director of the Paris Observatory.

SIR GEORGE DARWIN, K.C.B., F.R.S., has been elected a corresponding member of the Imperial Academy of Sciences of St. Petersburg.

LIEUT.-COLONEL R. E. CROMPTON, C.B., has been elected to the presidency of the Institution of Electrical Engineers vacant by the death of Lord Kelvin.

PROF. BOUCHARD has been elected a vice-president of the Paris Academy in succession to M. Henri Becquerel, who has passed to the presidential chair.

THE Hayden memorial geological medal of the Academy of Natural Sciences of Philadelphia has been awarded to Mr. C. D. Walcott, secretary of the Smithsonian Institution.

WE regret to see the announcement of the death of Lieut.-Colonel R. L. J. Ellery, C.M.G., F.R.S., late Government astronomer and director of the Melbourne Observatory, at eighty years of age.

WE learn from the Paris correspondent of the *Chemist and Druggist* that the appointment of Prof. E. Jungfleisch, of the Paris Superior School of Pharmacy, as successor to Berthelot's chair of organic chemistry at the Collège de France was formally signed by M. Briand on January 6.

THE Geological Society of London will this year award its medals and funds as follows:—Wollaston medal to Prof. Paul Groth, of Munich; Murchison medal to Prof. A. C. Seward, F.R.S.; Lyell medal to Mr. R. D. Oldham; Wollaston fund to Mr. H. H. Thomas; Murchison fund to Miss Ethel G. Skeat; and Lyell fund to Mr. H. J. Osborne White and Mr. T. F. Sibly.

REPORTS have appeared in the daily Press of a new treatment for consumption in which the diseased portion of the lung is removed by operation. The only novelty seems to be the use of hot water or steam to control the hæmorrhage, for excision of a portion of the lung has occasionally been performed during the last seventy years. Such a procedure could only be of service in a very few selected cases.

WE deeply regret to announce the death of Prof. C. D. West on January 10 in Tokyo. He had then been twenty-five years in the service of the Japanese Government, and was one of those men the Japanese did not wish to lose. He never cared to write scientific papers, but his thought can be traced in those written by others. "West's formula" relating to the destructive power of earthquakes is certainly the basis of all other formulæ on this subject, and these have had a wide application. He was a pioneer in the education of engineers in Japan, and is looked up to as the father of engineering in that country. A modest man has been called across the bar.

As the result of a vigorous sanitary campaign, involving an expenditure of more than 40,000*l*., bubonic plague has now been almost eradicated from San Francisco. One of the most notable features has been the destruction of 130,000 rats during the last four months. Of this number, 11,391 were examined by bacteriologists in the laboratory of the Health Department, and 108 were found to be infected. Up to the end of December, 1907, the total number of persons reported as plague-stricken was 136, of whom seventy-three died. The sanitary measures adopted have been under the control of an officer of the U.S. Marine Hospital Service, with the cooperation of the local health authorities.

NEW awards will shortly be made from the "Elizabeth Thompson Science Fund," which was established "for the advancement and prosecution of scientific research in its broadest sense," and now amounts to 5200*l*. Applications for assistance from this fund should be sent promptly, with full information, to the secretary of the board of trustees, Dr. C. S. Minot, Harvard Medical School, Boston, Mass., U.S.A. The trustees are disinclined, for the present, to make any grant to meet ordinary expenses of living or to purchase instruments, such as are found commonly in laboratories. Decided preference will be given to applications for small amounts, and grants exceeding 60*l*. will be made only in very exceptional circumstances.

IN honour of the memory of the great Russian chemist Mendeléeff, a Congress of Chemistry and Physics was held at the University of St. Petersburg on January 2–12. The congress was organised by the Russian Physico-Chemical Society, and the following telegram, signed by Prof. Borgmann, Rector of the Imperial University, who presided, was sent to Sir James Dewar:—"The Russian Physico-Chemical Society, with members of the first Mendeléeff Congress, express to you—a friend of the late Prof. Mendeléeff—great esteem for your scientific labours opening new ways for investigations of Nature." Many British men of science will be glad that their Russian colleagues have thus shown their appreciation of the greatness of Mendeléeff's work and of the high regard in which his memory is held in this country. This sympathetic feeling and unanimity of aim among scientific men is of international importance, and makes the congress at St. Petersburg an event in which the whole scientific world is interested.

MR. HENRY FARMAN on Monday won the Deutsch-Archdeacon prize by flying toward a goal previously fixed and returning to the starting point, the total distance being more than one kilometre, with a machine heavier than air. The course was marked out by delegates of the Aëro Club of France upon the military ground of Issy. Five hundred metres from the starting point, two posts were placed fifty metres apart, and the conditions of the contest were such that the aëroplane had to pass between these posts in the journeys both out and back. At the starting signal the machine ran along the ground for a few yards and then rose easily in the air and headed toward the turning post. This point was reached by a steady flight, and after sweeping round it, Mr. Farman returned to the starting point with perfect ease. The entire flight occupied 1m. 28s. A description, with an illustration, of Mr. Farman's aëroplane was given in NATURE of December 5, 1907 (p. 106).

AN electrical engineer, M. Lemoine, is under arrest in Paris charged with having obtained more than 60,000*l*. from Sir Julius Wernher in connection with an alleged invention for the manufacture of diamonds. The "secret" of the process was deposited in a London bank at the time the negotiations were entered upon, and the magistrate appears to be in a legal difficulty, since the defendant refuses to allow the document to be examined. The defendant has, it is reported, given several demonstrations of his process, and some of these were in the presence of witnesses. During the progress of the case, a *Times* correspondent states:—"An Englishman, Mr. Jackson, said that he had been present at two experiments in M.

Lemoine's laboratory. Mr. Jackson himself compounded the substances, put them into a crucible, and sealed it up. M. Lemoine then ran the crucible into an electric furnace, and after about twenty-five minutes he drew the crucible out. Mr. Jackson opened it, and found in it twenty-five little diamonds. At another time they obtained thirty. He offered the diamonds to a London jeweller, who found them very fine, and an expert to whom he showed them thought they came from Jagersfontein." A representative of the *Daily Chronicle* has had an interview with Lord Armstrong, who was present at one of the demonstrations, and affirms that diamonds were really produced. Lord Armstrong is reported to have said:—"M. Lemoine handed me a powder, which, in order to convince myself, I worked up with my fingers. It was nothing but a powder. I myself put this powder into an empty crucible, which I closed again, and I personally put the crucible into the furnace. When, under the instruction of M. Lemoine, who stood some distance from me, and could in no way interfere in the operation, I withdrew the crucible I found in it an agglomerated mass, which I allowed to cool before my eyes. I myself broke this shapeless mass, which presented the appearance of carbonised matter, and there I found these pure diamonds and these other diamonds less perfect." As the case has not yet been decided, it is undesirable to comment upon it at this stage. So far as we have seen the evidence, nothing is added to what has been known by chemists since Prof. Moissan found that diamonds could be produced by allowing carbon to crystallise from solution in molten iron or silver. Prof. Moissan used pure sugar charcoal to obtain his artificial diamonds. This carbon was compressed in a plugged cylinder of soft iron which was placed in a crucible containing iron rendered molten by an electric furnace. The best crystals were obtained when the crucible was afterwards cooled rapidly by immersion in molten lead. As these particulars have been matters of scientific knowledge for the past fourteen years, the Reuter telegram from Paris that the substance of the formula contained in the sealed envelope is as follows, is amusing reading:—"Take carbon of sugar, place it in a crucible, and heat to the requisite temperature. The result will be diamonds."

WE have to acknowledge the receipt of a copy of No. 18 of the Bulletin of the Imperial Academy of Sciences of St. Petersburg for 1907, which contains, among other articles, an account by Dr. W. Salensky of the interesting accelous turbellarian worm *Haplodiscus ussowii*, a species named in 1896.

THE fifth number of vol. ii. of the *Philippine Journal of Science* is almost exclusively devoted to ornithology, no fewer than fourteen out of fifteen articles dealing with this subject. A number of new species (one referable to a new genus) are described, but perhaps the most generally interesting article is one on the rare monkey-eating eagle (*Pithecophaga jefferyi*) from Mindanao and Luzon. None of the specimens was perfect, and no additional information appears to have been ascertained with regard to the habits of this remarkable species.

IN *British Birds* for January, Messrs. Bentham and Mouritz record the breeding of the hen-harrier and the hobby in Surrey in 1907. A nest of the former was discovered in May, originally containing four eggs, out of which two were hatched, and in due course the young took wing. Sad to relate, both parents were shot by a gamekeeper, and there is some doubt whether the young birds survived. In the same issue Mr. J. B. Nichols records a specimen of the grey-backed warbler (*Aëdon familiaris*) shot at Hythe, Kent, in July, 1907, this being the first occurrence of the species in Britain. It breeds in Asia Minor, Turkey, Greece, and further eastwards. The allied rufous warbler (*A. galactodes*) has occurred thrice in England and once in Ireland.

WHETHER or no they agree with all the opinions expressed, readers of the January number of the *Fortnightly Review* will unite in welcoming an article on "Evolution and Character" by the veteran evolutionist Dr. Alfred Russel Wallace. Despite the absence of any advance in human character during the whole period of which we have any definite ken, such an advance will, in the author's opinion, make itself apparent in the not distant future. It is added, however, that "our imperfect human nature . . . can only make a systematic advance through the thoroughly sympathetic and ethical training of every child from infancy upwards, combined with that perfect freedom of choice in marriage which will only be possible when all are economically equal, and no question of social rank or material advantage can have the slightest influence in determining that choice."

ACCORDING to the latest report of the Liverpool Marine Biology Committee, the Marine Biological Station at Port Erin, Isle of Man, has had a most successful year's work, this being especially the case at sea, where greater activity in submarine exploration than in any previous season was rendered possible by means of a steam-yacht. This yacht, although small, has been fitted with apparatus for dredging, tow-netting, and various other purposes in the comparatively deep water outside the bay, and it is hoped that she may be available for much further exploration in the Irish Sea. The aquarium, to which nearly sixteen thousand visitors were admitted during the summer, continues to be a great success. As regards the economic side of the work, the number of plaice larvæ hatched was considerably below the average, a large percentage of the eggs being infertile. Lobster-culture, on the other hand, made steady progress, although it was found that the experiment of placing the "berried" lobsters in one of the ponds did not prove a success.

A FEW weeks ago we referred to a paper by Mr. Graham Renshaw on the Californian condor (*Gymnogyps californianus*). In the *Century Illustrated Magazine* for January appears an article by Mr. W. L. Finley based on several visits to the actual haunts of the bird, and illustrated with photographs of the egg, young, and adults taken at close quarters. The interviews took place high up in the San Bernadino Range of southern California, and one of the most remarkable events was the near approach the writer and his companion were able to make to the old birds without any manifestations of alarm or fierceness on the part of the latter. These birds, it appears, lay only a single egg in a season, and the young is of remarkably slow development, the black quill-feathers not showing until the nestling is more than two months old. It has been ascertained that there are only forty-one eggs of the species in collections (against about seventy of the great auk), and the number of adult birds in captivity is half a dozen. The photographs obtained during these trips—which include several of the young at different stages of development—are claimed to be absolutely unique.

AN example of a plant which sheds its leaves in summer is afforded by *Euphorbia dendroides*. The large yellow bushes which in winter time adorn the Jurassic limestone rocks on the northern shores of the Mediterranean are represented in August by a network of bare brown ramifying stems. In September the new leaves begin to sprout for the winter growth.

PROF. M. C. POTTER records in a leaflet his observations on a barley disease prevalent in the north-eastern counties last year, producing undeveloped grains known locally as "deaf ears." Examination of diseased flowers showed that development had followed a normal course until pollination had taken place, but at this stage arrest of development in the ovary was caused by the attack of the fungus *Helminthosporium gramineum*.

IN the *Verhandlungen des Vereins zur Beförderung des Gewerbfleisses*, Berlin, is published the substance of a lecture delivered by Dr. F. Frank before the society on caoutchouc, dealing mainly with its exploitation from natural sources and on plantations, also with the methods of its preparation and the regeneration of old rubber. Reference is made to the development in Mexico of a trade in *guayule*, the substance obtained from the shrub *Parthenium argentatum*, that is worked up in local factories. Special information is furnished with regard to plantations and methods of treating the crude latex of different rubber trees in German colonies in Africa and New Guinea.

IN connection with the problem of natural regeneration of forests in tropical and subtropical climates, an article contributed by Mr. A. W. Lushington to the *Indian Forester* (October, 1907) on sucker reproduction in certain forest reserves and jungle scrub in the Kistna district of Madras points to the importance of this mode of regeneration. The grouping of shrubs of *Bauhinia tomentosa* and Ormocarpum suggested that they were not produced from seedlings, and subsequent examination showed that sucker reproduction was the potent factor, not only in the spread of the shrubs, but also of the trees. A note by Mr. Daya Ram in the same number refers to the sporadic flowering of *Strobilanthus Wallichii* and *Strobilanthus alatus* in 1906 in the United Provinces. Previous flowerings were recorded in 1894 and 1882, giving twelve years as the normal life-cycle of these species.

FROM the Royal Botanic Gardens, Kew, we have received the final part (No. 10) of the *Kew Bulletin* for 1907, and appendix v. to the same volume, containing a list of literary contributions by members of the staff during the years 1896 to 1906. In the case of systematic papers, it has been thought useful to add to the title the names of new species. In the Bulletin, Dr. O. Stapf furnishes an account of the gums ammoniac of Morocco and the Cyrenaica. The latter, which is the gum ammoniac described by Dioscorides, is referred to *Ferula marmarica*. The Morocco product has been identified as a variety of *Ferula communis*. The gum ammoniacum of European markets to-day is yielded by the Persian plant *Dorema ammoniacum*, which has ousted the African drug. Mr. W. Dallimore contributes an article on gardens of interest near Newport, Mon., making special reference to tree cultivation. In another article attention is directed to Zapupe fibre, the product of an undetermined species of Agave that is proposed as an alternative to the sisal Agave in tropical countries such as the West Indies.

THE report of the early proceedings at the West Indian Agricultural Congress, held in Jamaica in January, 1907, together with the papers that would have been read but for the earthquake, has been published in the *West Indian Bulletin* (vol. viii., parts i. and ii.). A review of the year's work in connection with the more important agricultural industries was presented by Sir Daniel Morris in his presidential address. On the subject of sugar canes, Mr. J. R. Bovell and Mr. F. A. Stockdale discuss new seedling varieties and the methods of obtaining hybrids. Artificial cross-fertilisation offers so many difficulties that other methods, such as planting alternate rows of two selected varieties throughout a plot, have been adopted. Cacao, pine-apples, limes, and cotton provided the subjects for several papers. With regard to varieties of rubber, it is noticeable that Castilloa has received more attention than Hevea. Mr. B. H. Jones, writing about the collection of rubber in the forests of British Guiana, makes special reference to three indigenous species of Sapium.

A RETURN of the frost occurred during the past week over the whole of England, and in many places the thermometer fell as low as in the severe frost in the early part of the month. At Greenwich the thermometer in the screen registered 19°·1 on the morning of Saturday, January 11, while on the grass the temperature was 11°·1, and on Sunday the shade reading was 17°·9, which is in agreement with the lowest temperature in the earlier frost, whilst the exposed thermometer fell to 8°·8, which is more than a degree lower than during the previous frost. Among the lowest temperatures reported to the Meteorological Office on Sunday, January 12, were:—18° in the screen at Bath and Oxford, 19° at Nottingham, 20° at Dover, and 22° at Dungeness.

IN the Bulletin of the Italian Geographical Society (1907, pp. 738–745) Prof. L. Palazzo, director of the Italian Meteorological Service, under the title "I brontidi del Bacino Bolsenese," gives an interesting account of the mysterious phenomenon generally known as "*mistpoeffers*," or in English as barisal guns, from its occurrence in the delta of the Brahmaputra. The paper is compiled from reports supplied by persons living on the shores of the lake of Bolsena (Latium) and adjacent parts, and deals with the sonorous character of the phenomenon, its frequency, and the accompanying meteorological conditions. The sounds generally appear to come from the shores of the Tyrrhenian Sea, about twenty-four miles distant from the lake; the description of them agrees entirely with reports from other parts, and with the accounts published by Van den Broeck, Günther, and others. The paper contributes much information on the subject, but throws no additional light upon the physical cause of the phenomenon, whether the origin be aërial or subterranean (see NATURE, vol. lii., p. 650, and vol. liii., p. 4).

IN the Proceedings of the American Antiquarian Society, vol. xviii., Prof. A. L. Rotch makes a timely publication of Franklin's descriptions of the first balloon ascents. These interesting documents consist of five copy-press letters written to Sir J. Banks, P.R.S., in 1783, when Franklin was Minister to the French Court. One of them probably has never before been published; the others are little known, although printed, with some alterations, in the editions of Franklin's works by Bigelow in 1888 and Smyth in 1906. The first ascent was made from the Champ de Mars on August 27, 1783; the balloon was filled with hydrogen, and was capable of lifting a weight of 30 lb.; about 50,000 people assembled to see the experiment. The second ascent was a hot-air balloon from Versailles, apparently in September; it carried a sheep and some poultry. The first and second manned balloons ascended on November 20 and December 1, 1783, filled with hot air kept up by burning straw and by "inflammable air" respectively; both experiments were successful. Referring to the first manned ascent, Franklin wrote:—"I am sorry this Experiment is totally neglected in England where mechanic Genius is so strong. . . . Your Philosophy seems to be too bashful. . . . This Experience is by no means a trifling one. It may be attended with important Consequences that no one can foresee."

THE most noteworthy article in the Journal of the Franklin Institute for December, 1907, is that by Prof. J. W. Richards reviewing the progress made in the electrothermic production of iron and steel. There is also a paper by Mr. E. S. Cole describing the pitometer, an ingenious instrument for measuring the leakage of water in mains.

THE current issue of the *Central*, the organ of the Central Technical College Old Students' Association, contains as a frontispiece an excellent portrait of Prof. W. E. Dalby. There is also an article by Prof. H. E. Armstrong on the nature of chemical change, in which he reviews the excellent research work accomplished by the chemical department of the college since 1885.

AT a meeting of the Association of Engineers in Charge held in London on December 11, 1907, Mr. L. Gaster read a paper on the province of the illuminating engineer, in which he directed attention to the waste which is going on in the conversion of energy into light, and to the utilisation of the illuminants so as to produce the best illumination. He suggested a method for reducing the existing waste, and indicated some of the important problems with which the illuminating engineer has to deal.

A BATCH of publications received from the Department of Mines of Queensland affords striking evidence of the excellent work that is being done by the Geological Survey in investigating the mineral resources of the colony. Mr. B. Dunstan (Publication No. 207) describes some copper, gold, and bismuth mines in the Burnett district, west of Maryborough. Mr. L. C. Ball (No. 208) gives a careful report on the Norton goldfield, where gold was discovered in 1871, the total yield since then having amounted to 10,030 ounces. The reefs have hitherto been worked for their gold and silver contents, and the returns would, but for the complex sulphides in the ore, have given a profit. If a suitable method of treating these sulphides were adopted, many reefs hitherto neglected would probably be opened up. Mr. W. E. Cameron (No. 209) describes some goldfields of the Cape York Peninsula. The same author (No. 210) gives an exhaustive account, illustrated by a map and fourteen admirable plates, of the Annan River tinfield, Cooktown district. He shows that rich alluvial tin occurs at numerous points over an area twelve miles long by eight miles broad. Recently, hydraulicing the face with water under pressure has been adopted, and an attempt has been made to deal with the deposits by machinery by dredging the alluvial flats. Mr. B. Dunstan (No. 211) describes the Stanhills tinfields near Croydon, where recent operations have revealed ore of exceptionally rich quality, and the field has become very active. The tin is found in lodes and in alluvial deposits, and the area of the field amounts to about 100 square miles. Mr. B. Dunstan also publishes a further report (No. 212) on some Croydon goldmines, with special reference to Bennion's reef and to the Highland Mary reef. Publication No. 213 is a map, on a scale of six miles to the inch, of the copper-mining district of Cloncurry, compiled by Mr. L. C. Ball.

To the Bulletin of the American Mathematical Society, xiii., 10, Prof. Cleveland Abbe contributes a short note on the possibility of studying the movements of the atmosphere by laboratory experiments with projections of a globe. It being necessary to use flat models, the conditions are necessarily different from those on our earth, and the author discusses the projections of the sphere best suited for taking account of different effects.

THE Transactions of the American Mathematical Society (viii., 4) contain a paper by Prof. A. G. Greenhill, F.R.S., on the elliptic integral in electromagnetic theory. The investigation was undertaken during the lifetime of the late Principal Viriamu Jones, F.R.S., in connection with the calculation of the mutual attraction of two coaxal helices employed in the ampere balance designed by Principal Viriamu Jones and Prof. Ayrton. The object is to exhibit the third complete elliptic integral in the form most suitable for computation.

IN the *Revue générale des Sciences* (November 30, 1907) M. Th. Reinach publishes, with an introduction by Prof. Painlevé, a translation of the manuscript of Archimedes discovered in 1899 by Papadopoulos Kerameus on a palimpsest parchment. This manuscript soon attracted the attention of Profs. H. Schoene and Heiberg, and the latter visited Constantinople in 1906 to study the precious document. It consists of four parts, some containing works already known, and the present article deals with the fourth, namely, the treatise on method (Ėphodos), which is dedicated to Eratosthenes. It deals with the quadrature of a parabola, and with the volumes and centres of gravity of spheres, ellipsoids, paraboloids and hyperboloids of revolution, and the "method of exhaustion" adopted by Archimedes distinctly anticipates its modern equivalent of integration. A further interesting feature of the problem is Archimedes' use of the principle of the lever in comparing different solids of revolution by a kind of method of balancing the elements of one against the corresponding elements of the other.

IN the *Verhandlungen der deutschen physikalischen Gesellschaft* for November 30, 1907, Drs. U. Behn and H. Geiger give 1·63 as the result of their determination of the ratio of the specific heats of helium at constant pressure and at constant volume respectively. Their method is a modification of Kundt's. The tube containing the gas is sealed at both ends, and is clamped in the middle. Its frequency for longitudinal oscillations is adjusted by attaching metal discs to the ends with sealing wax, until the lycopodium within is set in motion by the resonance of the gas. One end of the helium tube projects in the usual way into a second tube containing air, and produces dust figures in the air from which the frequency of the oscillation is calculated.

PART vii. of vol. xxi. of the Journal of the College of Science of the University of Tokyo consists of an account of the work done by Messrs. K. Honda and T. Terada on the reciprocal relations of stress and magnetisation in a number of irons and steels. The specimens, in the form of wires, were magnetised under tension in a vertical magnetising coil, and the induction was measured ballistically both with change of stress at constant field and with change of field at constant stress. The result is a verification of the theories of Prof. J. J. Thomson and others so far as the principal effects are concerned, but hysteresis effects appear to make it impossible to test experimentally the correctness of the terms of the second order, in which the theories differ from each other.

A MEMOIR by Miss E. M. Elderton, Galton research scholar in national eugenics of the University of London, assisted by Prof. Karl Pearson, on the resemblance between first cousins, has been issued by Messrs. Dulau and Co. The memoir gives the results of two series of investiga tions, the first dealing mainly with qualitative characters—such as health, ability, temper, temperament, and success in life—the second, not yet completed, with certain measurements on the hand, eye-colour and hair-colour, as well as health.

In the current number of *Science Progress*, published by Mr. John Murray at five shillings net, there are several articles of interest on applied science. In the first place we notice a paper by Dr. J. S. Haldane, F.R.S., on work under pressure and in great heat, giving a very good *précis* of the author's researches in this department, which have altered the Admiralty practice as regards diving, and should alter the factory-mining regulations, when these well-meant rules are inspired by knowledge as well as good intention. The article by Dr. F. H. A. Marshall, on nutrition and fertility, touches on matters of great importance to breeders of stock, and furnishes a curious (and unintentional) commentary on the work of Prof. Chittenden on the minimum of food-stuffs. Articles that also call for mention are those of Prof. Halliburton on the repair of a nerve, and Mr. A. D. Darbishire on Mendelism. A fine portrait of the late Lord Kelvin appears as frontispiece.

Among the subjects of lantern-slides from photographic negatives, in the supplementary list just issued by Messrs. Newton and Co., are:—steel-making, showing operations at a great steel-works; coal-mining; wild life; pathological tissues; animal life in earlier times; eruption of Vesuvius in 1906; bacteriology of tropical diseases; and colour photography. The slides should be of real service in illustrating popular lectures upon scientific subjects.

The old students of the Finsbury Technical College are to be congratulated on the first number of the magazine produced and published by their association. The cover of the magazine carries a medallion portrait of the principal of the college, Prof. Silvanus P. Thompson, F.R.S., and a portrait of the first president, Dr. M. O. Forster, F.R.S., forms a supplement. The reading matter includes a greeting from Prof. J. Perry, F.R.S., in which he refers to reformed methods of teaching mathematics and physical science.

The tenth issue, that for 1908, of "Wellcome's Photographic Exposure Record and Diary," will prove of assistance to photographers. Much useful guidance is provided, and the mechanical calculator attached to the cover will be found serviceable. In addition to a complete diary for 1908, the book also contains tables for interior work, telephotography, copying, enlarging and reducing, moving objects, night photography, and for printing by artificial light. Three editions, adapted respectively to the conditions of various latitudes, are published, and the price of the volume is one shilling.

We have received a copy of the first number of a new monthly technical magazine entitled the *Illuminating Engineer*, which is to be devoted to the subject of scientific illumination. The periodical is edited by Mr. Leon Gaster, and the price of each issue will be 1s. The first number, which runs to eighty-eight pages, contains a variety of articles and notes, some of which are well illustrated. Prof. J. A. Fleming, F.R.S., describes vacuum tube electric lighting; Dr. C. V. Drysdale deals with the production and utilisation of light; Mr. A. P. Trotter discusses the distribution and measurement of illumination; and Dr. Hugo Krüss gives an account of some researches on reflected transmitted light. The new periodical should appeal to all engineers concerned with illumination.

OUR ASTRONOMICAL COLUMN.

Comets due to Return this Year.—In No. 392 of the *Observatory* (January), Mr. W. T. Lynn publishes a number of particulars concerning the periodical comets due to return during the present year. The first named is that discovered by M. Giacobini in December, 1900, and found to have a seven-year period.

The comet discovered by Mr. Denning on October 4, 1881, has, according to the calculated elements, a period of 8·8 years. In 1890 and in 1898–9 its position was not favourable for observation, so there is a likelihood of its being re-discovered in the early part of this year.

Encke's comet has been observed at every return since it was recognised as a periodic comet in 1819, and has already been found by Prof. Max Wolf. The comet discovered by Tempel in 1869 November 27, and recognised as periodical by Swift in 1880, should reappear during the coming summer; its period was found to be a little greater than $5\frac{1}{2}$ years. It was not seen in 1903, when it was last due, or in the preceding return of 1897, but was well observed in 1891.

Determination of the Moon's Light with a Selenium Photometer.—Some interesting results, accruing from preliminary experiments on the determination of the amount of light received from the moon at different phases, by means of selenium cells, are published in the December (1907) number of the *Astrophysical Journal* (vol. xxvi., No. 5, p. 326) by Messrs. J. Stebbins and F. C. Brown.

The moonlight was compared with the light of a standard candle burning under known conditions, the values obtained being subsequently reduced by correcting for atmospheric absorption, &c. For the light given out by the full moon the observers derived a value of 0·209 candle-power, but other cells employed gave different values, the mean value being very near to the 0·23 candle-power adopted by Müller as the mean obtained from visual observations.

The results show that at full moon we receive about nine times as much light as at half moon, and they also indicate that the moon is brighter between first quarter and full than in the corresponding phase after full moon. Observations made during the partial lunar eclipse of July 24, 1907, gave the instant of least light as 16h. 23m., whilst according to the *American Ephemeris* it was 16h. 24m.

The differences obtained by using different cells are probably due to the fact that the cells are not equally colour-sensitive, and to this point the authors propose to pay considerable attention; presumably the question of colour would not enter into the determination of the values at various phases when the same cell was employed throughout.

The Appearance of Neptune in Small Telescopes.—A paper recently communicated by Mr. Holmes to the British Astronomical Association gave rise to an interesting discussion at the November (1907) meeting. The question discussed was the planetary appearance of Neptune in small telescopes, and whilst some of the members averred that it was difficult to recognise the disc with a 6-inch telescope, others, including Mr. Maw, stated that they had found such an instrument sufficiently large for this observation. The general result of the discussion appears to have been the conclusion that some of the earlier descriptions of the size and brightness of the disc of Neptune are misleading, although the form should be clearly recognised with an instrument of equivalent power to a 6-inch achromatic telescope (the *Observatory*, No. 392, p. 47).

The "Annuaire Astronomique" for 1908.—The excellent year-book of astronomy and meteorology issued by M. Flammarion is one of the most useful of its type and price to the amateur astronomer who reads French. It contains practically all the data he is likely to require in his work, besides a valuable annual review of the progress of astronomy. Many of the notes and directions are illustrated, and, in addition to the diary giving the astronomical phenomena for each day of the current year, there is a map of the sky for different times and dates in each month. The price of the volume is 1.50 francs.

SIMULTANEOUS OBSERVATIONS OF JUPITER.[1]

IN the December *Bulletin de la Société astronomique de France* for 1905 (p. 556), readers who possessed telescopes were invited to collaborate in a scheme for the simultaneous observation of Jupiter on prearranged dates, and to make drawings and notes of what they saw, which were to be forwarded to a central authority for correlation and discussion.

The valuable results likely to accrue from such a combined attack are too obvious to need recapitulation, and when M. Nicolas Poutiata suggested the idea to M. Camille Flammarion, that indefatigable organiser transmitted it immediately to the French Astronomical Society, and asked for its cooperation. A scheme was drawn up, thirty-six observers in various parts of Europe responded to the invitation in the December Bulletin, and Dr. Jean Mascart undertook to discuss all the drawings and notes sent in. The present brochure collects his discussions, which have been appearing month by month in the Bulletin, and gives some valuable hints for any similar undertaking in the future.

Briefly, the programme arranged was as follows:—(1) Observers were to draw on prepared discs all the markings they were able to see on the planet's surface, at 20h. 0m. (8 p.m.) *precisely* (G.M.T. Paris), on every clear night from January 2–20, inclusive, 1906. (2) Arrangements were made so that observers residing in other longitudes than Paris should know the exact *local time* at which the observations were to be made, thus preventing any ambiguity as to the precise hour of observation. (3) Drawings were to be made on previously prepared white discs identical in size and shape, the scale being such that 1 mm. on the disc corresponds to about 2000 km. on the planet. (4) Detailed instructions were also given as to the preparation of fair copies of the drawings, their orientation, &c., and also as to the noting of any written details which would assist the general discussion.

The instruments employed varied in aperture from 75 mm. to 380 mm., and eye-pieces of various powers were used. The number of observations varied from five, on January 15, to seventeen, on January 14, and, altogether, 172 individual observations were made.

To illustrate the general character and variety of the drawings, we reproduce the set made on January 2, 1906. It is interesting to note that the personality of many of the individual observers appears throughout the entire series. Thus, for example, No. 4 here reproduced was made by Herr Phil. Fauth, who for twenty years has been training his eye to see finer and finer details on the moon's surface, and it is decidedly characteristic of all the drawings made by him in this series. The similarity of the drawings of this observer and those of Dom Amann, of Aosta, Italy, is a feature of each of the series where both occur, and the apertures and powers employed were practically the same in each case. No. 5 was drawn by the latter observer.

Dr. Mascart gives the notes made each day by each observer, and reproduces the drawings with numbers so that each may be identified, the latter being arranged, so far as possible, in the order of the instrumental aperture employed. Thus No. 1 in the above series was made by an observer using a telescope of 75 mm. aperture, No. 5 with a refractor of 170 mm., and No. 7 with a reflector of 105 mm. aperture made by the observer himself, M. Paul Vincart, of Antwerp, who thus demonstrates to his co-workers that, lacking the necessary wherewithal to purchase an instrument of serious size, a very good substitute may be made "*par un peu de volonté et beaucoup d'huile de . . . biceps.*" Following the *seriatim* display of each day's notes, the author points out briefly the similarities and differences of the various drawings, directing particular attention to any striking peculiarity of any one of them.

These notes are too numerous to give in detail here, but it is safe to predict that they will amply repay the close study of every Jovian observer. The various undulations of the great southern equatorial band, the various tints of the polar regions, the fine rifts in the several bands, and many other features of interest, and of possible variation, are all recorded and commented upon. One item of more practical interest perhaps, illustrated, for example, in the drawings of January 5, is that the smaller apertures appear to give a greater relative intensity to the tints of the polar regions. Several curious globular structures, attached to the northern edge of the south equatorial band, and some *striae* in the north polar regions were recorded by Senor J. Comas Sola, using the 380 mm. Mailhat equatorial, on January 12. The seventeen drawings of January 14 form the most extensive and most valuable series, of which the various features provide plenty of material for a detailed study; one unique feature is the delineation of the south tropical band by M. Crouzel, who used the 380 mm. equatorial of the Toulouse Observatory, and shows this band as a chain-like series of loops.

The Planet Jupiter: simultaneous drawing made by different observers, January 2, 1906.

When the January campaign was ended, several observers expressed the desire to continue, but it was found that the notice was too brief to organise the matter effectively. Nevertheless, some of the observers did continue, and valuable results, which Dr. Mascart discusses, were obtained.

An attempt was made by M. Blum, at Dr. Mascart's request, to obtain photographs showing the combined results of each day's work. The methods employed are fully described in the paper, and some reproductions of the combined photograph for January 8, obtained by different methods of exposure, &c., are shown, and seem to give excellent promise.

[1] "Observations simultanées de la Surface de Jupiter réunies." By M. Jean Mascart. Extrait du Bulletin de la Société astronomique de France (1907.)

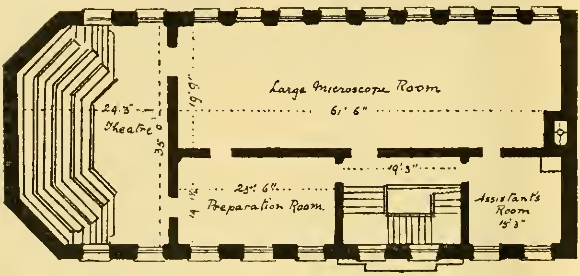
In conclusion, Dr. Mascart points out that perhaps the most valuable result of the recent attack is the experience gained, and he emphasises the details in the programme which need greater attention, such as the closer observance of the precise prearranged hour, the correct orientation of the final drawing, the care which should be exercised in confirming the presence of a faint marking before showing it on the drawing, and so on. Finally, he gives, with full detail, descriptions of various objectives and eye-pieces, showing in each case, by means of diagrams, their action on rays of light.

Taken as a whole, this preliminary campaign appears to have provided very valuable results, and it is to be hoped that future similar organisations will be guided by the experience now gained.

W. E. R.

THE NEW SCHOOL OF BOTANY, TRINITY COLLEGE, DUBLIN.

THE science schools committee of Trinity College, Dublin, is to be congratulated on the completion of the second item in its scheme for the scientific development of Trinity College. This project, which was in the first instance originated by Prof. John Joly, F.R.S., and has since owed much to his activity and devotion, was inaugurated in 1901 by a handsome subscription from the chancellor, the Earl of Rosse. At an early stage in the movement success was assured by a munificent gift from



First Floor Plan.

Viscount Iveagh. According to the terms of this gift, Lord Iveagh undertook to build those departments for which the friends of Trinity College subscribed a capital sum requisite to yield the annual upkeep. Last year the School of Physics was completed, and at the beginning of the present session the School of Botany, the second department which has been benefited by this movement, was opened for work.

The School of Botany is a two-storied building of cut granite, situated in the east end of the college park, and lies east and west. This orientation gives a large number of windows facing north, with the best light for microscopic work. The western end, being octagonal, is occupied by a lecture theatre in the upper storey, on the ground floor by a very fine laboratory for general physiology. The northern side of the upper storey is occupied by a large microscope room, which can accommodate about sixty students working simultaneously. Through a large double door in the west end of this room access is obtained to the theatre. The auditorium in the latter is octagonal, so that every seat is close to the lecture table.

On the ground floor on the north side is a room for microscopic research, a library, professor's laboratory, and the laboratory for general physiology, which also forms the west end of the building. A solidly built greenhouse running out on the north side of the building is immediately connected with the physiological laboratory; on the south side of the latter opens a chemical laboratory. In addition to the usual fittings in the physiological laboratory, there is a large dark chamber, constructed like a fume cupboard, in which plants may be grown in complete darkness, or illuminated by light transmitted through special filters. The greenhouse has a separate heating system from the rest of the building, and a centrally placed case in it may be heated by a special radiator to a higher temperature than the rest of the greenhouse. Much thought has been given to the working out of the plan and fittings of this new school, and as it stands the School of Botany in Trinity College must rank with the best in the British Isles. The architect was Mr. Wm. C. Marshall, of London, who also designed the Botanical Laboratory in Cambridge.

ON THE COLOURING MATTERS OF FLOWERS.

THIRTY or forty years ago I devoted much attention to the colouring matters in plants, studying them with my newly invented spectrum microscope. I published a few papers on particular branches of the subject, but there are other very wide questions the importance of which I did not perceive until altered circumstances led me to devote my attention to work out at sea. Amongst other things studied was the variation in the colour of flowers, which is manifestly a very extensive subject, and for which I had only limited opportunity to obtain the requisite material, having to rely to a great extent on wild plants and flowers in my garden. Though the results are incomplete, they are probably characteristic; and it may be well to publish them, since it is now impossible for me to complete them, and what I did will at all events serve to show what might be done. The whole subject is very complex in more ways than one.

The colouring matters of plants may be divided into two divisions, viz. those soluble in water but insoluble in carbon bisulphide or benzol, and those soluble in the latter reagents but not in water. Both are soluble in hydrous alcohol of the usual strength. Nearly all the blues and purples belong to the former, and most of the yellow and orange to the latter.

I found the best way of dealing with the flowers was to boil the petals or other portions in the usual hydrous alcohol, which dissolves both groups of pigments, and, after evaporating to dryness, to re-dissolve the constituents soluble in water, filter, and finally evaporate to dryness in a small saucer, in which, if kept fairly dry, the pigment will remain unchanged for a considerable time. Some pigments may be kept unchanged for a long time in a concentrated solution of lump sugar.

When re-dissolved in water many of the colouring matters soon become pale or nearly colourless, but recover their colour when evaporated to dryness. I never saw proof of this in living flowers, but it may occur when they die and fade. If there be any colour insoluble in water, it may be dissolved in carbon bisulphide, but this is seldom the case in blue, red, or purple flowers.

In those cases where the predominant colour is insoluble in water, it may be separated by agitating the alcoholic solution with carbon bisulphide, adding a little water. The bisulphide carries down the pigment in solution, which may then be evaporated to dryness in a small saucer and kept. When dissolved in alcohol or carbon bisulphide the colour fades more or less quickly, especially in the light, but if sealed up almost absolutely free from air, it will remain unchanged for many years, at all events in the dark.

Having, then, obtained the pigment in a fit state, the next thing is to examine it when in appropriate solution, either in its natural state or after the addition of a suitable reagent. To enter into full detail would make this paper far too long, but it seems desirable to give some particulars in order to show how the various pigments can be distinguished. Speaking generally, this is by their optical properties, occasionally by the fluorescence, but usually by the absorption, as studied by a spectrum microscope, and whenever possible by the position of absorption bands under identical known conditions. This latter is very important, since their position may vary considerably with the character of the solution. I never attempted to obtain the pigments pure, in a state fit for chemical analysis, so as to determine their chemical composition.

The number of distinctly different colouring matters in flowers must be very great, and to study them completely would occupy a long time. The distribution of the different kinds is sometimes very definite, but often the reverse. In the genus Hypericum are sometimes small dark spots in the petals, and sometimes small dark rounded bodies are attached to the sepals. These are coloured by a pigment which gives a spectrum with narrow, well-marked absorption bands, which could not be mistaken for any other. This occurs in all the species I examined, but in no other flowers. On the contrary, there is a blue pigment, giving a sufficiently well-marked spectrum with several absorption bands, met with in many flowers separated about as much as possible botanically.

Much may be learned by the use of reagents. Vegetable pigments may be divided into three groups by the action of sodium sulphide, which I called Groops A, B, and C. Group A is at once made nearly or quite colourless by the addition of a small quantity of this salt. Group B is not at all altered when alkaline or neutral, but is at once made nearly colourless when acid. Group C is not changed even when acid. When made colourless the pigments are not permanently decomposed, but recover their colour when evaporated to dryness. I do not fully understand the cause of these effects.

Then, again, much may be learned from the action of citric acid and a weak alkali. The colour and spectra of many reds, purples, and blues are very different in acid, neutral, or alkaline solution. Some yellow pigments are made thirty times more intense by an alkali, whilst others are unchanged. As a rule, none of the above changes is due to a permanent alteration, but in some cases it is useful to employ stronger reagents, which decompose the natural pigments, such as nitrite of soda with the addition of a little citric acid. As an example I may cite the pigment of the common yellow garden crocus. This gives a strongly fluorescent yellow substance, unlike that produced in the case of any other flower I have examined. The only objection to such powerful reagents is that they may produce highly coloured substances from colourless bodies in the plant, and not merely alter the coloured constituent. As an interesting example I may name a deep red substance produced in the case of the different species of geranium examined, but not in the case of any other plant.

My remarks so far apply only to colouring matters soluble in water. Orange, orange-yellow, and lemon-yellow flowers are in most cases coloured by one or other of the four yellow pigments met with in green leaves, or by various mixtures of them, which are distinguished by the absence or presence of two absorption bands. These vary considerably in position according to the nature of the solvent, lying much nearer the red end of the spectrum when the pigment is dissolved in carbon bisulphide than when in benzol or alcohol. These absorption bands can also be seen in the spectra of the flowers themselves, and for some time I was unable to understand why in the case of *Chelidonium majus* they lay materially nearer the red end than in nearly all other yellow flowers which gave the same spectrum when the pigment was in solution, until I came to the conclusion that in Chelidonium it occurs in a free state, and not dissolved in oil or wax. There are other cases in plants where the spectra show that the pigments exist in a solid state, which would explain slight differences in tint.

We may now consider facts very common in cultivated plants, viz. a great variety of colours. In many cases this is easily explained, because we can see that two pigments exist, either alone or mixed in various proportions, one frequently being a yellow insoluble in water, and the other a blue or red soluble in it. As an example, I refer to the common wallflower of our gardens (*Calendula vulgaris*), which is sometimes a clear yellow, sometimes a sort of crimson, but more commonly a crimson brown. The yellow is a xanthophyl soluble in carbon bisulphide; the crimson is a pigment soluble in water; the common colour is a mixture of these two, and gives the same spectrum as a yellow and a purple petal combined. We have a similar case in chrysanthemums and various other flowers. The common garden marigold is sometimes a pure yellow and sometimes a true orange or an intermediate tint, which is due to two different pigments alone or variously mixed. One or other of these may occur separate in different parts of the same flower in some plants.

In some flowers we find a considerable variety of tints, probably due to another cause. The common bedding geraniums of our gardens are a good example of this. At one time I thought that such varying tints might be due to varying acidity, but did not obtain satisfactory proofs, though it may be true in some cases. I, however, studied several closely allied pigments from other plants, and found that they seemed to agree in nearly every particular, except that the absorption bands in the spectra were not exactly in the same place. An excellent example of this kind is the red pigment of blood, giving two very well-defined absorption bands, which differ in position if the oxygen is replaced by carbonic oxide or nitrous oxide. Also the red pigment found in many birds' eggs, which I named oorhodeine, gives precisely the same remarkable and well-marked spectrum as the product of the action of strong sulphuric acid on the red pigment of blood, except that the position of the absorption bands differs distinctly. My suggested explanation of the difference in the colour and spectra of a number of the pigments in flowers is that some fundamental constituent is the same, but modified by some varying substance in combination.

A few flowers contain pigments which give spectra with unusually well-marked absorption bands. As remarkable examples I may mention the crimson Cineraria and the deep blue Lobelia of our gardens. The spectra are of almost exactly the same character, having two dark absorption bands, only they occur at a different part of the spectrum. I am unable to say whether this shows any relationship between the pigments, but the difference in the position of the bands is perhaps too great.

It will thus be seen that a very great number of distinct pigments are found in flowers, sometimes having a very restricted distribution, and sometimes the reverse. Then, again, the plant may be able to form two or more quite distinct colouring matters, either alone or mixed in varying proportions. In some cases the pigments seem to be easily subject to change, as though some constituent could be substituted for another. In one way or another there is thus great scope for variation, perhaps not brought into play, or only to a limited extent, in wild plants, but sometimes to a remarkable extent by cultivation.

H. C. SORBY.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Vice-Chancellor has received a letter from Baron von Hugel, curator of the Museum of General and Local Archæology and of Ethnology, recording a gift from the Rev. John Roscoe, of the Church Missionary Society, of exceptional value and interest. It consists of a second instalment of selected native manufactures from Uganda. The chief value of the gift lies in a unique set of relics of deceased Baganda kings, which, enclosed in ornate cases, were preserved by the people under the name of Lubare (*i.e.* the Deity) in special shrines placed under the guardianship of hereditary custodians. Of these king-gods, the most sacred objects of Baganda cult, three generations are represented in the present collection.

With the first Roscoe collection, which was supplemented by a valuable gift of objects from the Katikiro of Uganda, the University acquired Kibuka, the war god of the Baganda, who with all his appurtenances was safely unearthed from his ruined shrine in the Mawokota district. In this deity, as in the Lubare, personal relics form the essentials, and in Kibuka are enshrined the jaw-bone, &c.,

of the deified chief of that name, a renowned fighter who lived in the reign of Nakibinge, the eleventh king of the Baganda.

Objects such as these are not readily to be obtained; indeed, it required years of careful investigation and all the knowledge and experience gained in the field by this veteran missionary to negotiate their safe removal from the ancient shrines of Uganda to the show-cases of the University museum.

MANCHESTER.—Daily observations at the meteorological Observatory of the University at Glossop Moor are now being taken with kites or captive balloons, and preliminary records of the results are being published every day in the *Daily Telegraph* and other papers. The work, which has been instituted by Prof. A. Schuster, F.R.S., is under the immediate direction of Mr. J. E. Petavel, F.R.S., assisted by the following staff:—Mr. Travis Rimmer, resident observer at Glossop Moor; Messrs. T. V. Pring and W. A. Harwood, and Miss Margaret White, voluntary assistants. The generous cooperation of the meteorological observatories at Buxton, Huddersfield, Stonyhurst, Sheffield, and Manchester will facilitate the working out of comparative results, in the subsequent utilisation of the observations, and should add greatly to the value of this investigation of the meteorology of the upper atmosphere.

AT a dinner of the Bristol University College Colston Society on Tuesday, the president, Mr. G. A. Wills, stated that contributions towards a university for Bristol have in the past two years amounted to 40,000*l*. He also announced that his father, Mr. H. O. Wills, has promised 100,000*l*. towards the endowment of the university for Bristol and the west of England provided a charter be granted within two years.

THE national importance of brain-power produced by universities, as well as sea-power obtained by a strong navy, was insisted upon by Sir Norman Lockyer in his presidential address to the British Association in 1903; and a comparison was made of the expenditure on higher education with that on battleships. Prof. Turner, of the University of Birmingham, speaking at Stourbridge on January 6 in connection with the Stourbridge and District Higher Education Committee, used similar illustrations in referring to the cost of technical education. He pointed out that the Birmingham University and other local colleges and universities obtain a total grant per annum of about 100,000*l*. Let this be compared with our naval expenditure, and it is found that to build one battleship of the *Dreadnought* type absorbs the whole of the funds allocated to the local universities for seventeen years. Battleships are a necessity, but the Army and Navy cannot exist apart from the nation's third line of defence—its internal manufactures—and these depend largely upon the rearing of an educated and skilled people.

THE annual meeting of the Geographical Association was held on January 8. Mr. Douglas Freshfield, who presided, said that last year he had found it necessary to comment on the extraordinary decision of the Civil Service Commissioners to exclude geography from the examinations for the higher branches of the Civil Service, including the Foreign Office, but now he was able to congratulate the association upon a reversal of that decision. The report read supplied evidence that the association continues energetically its work of improving geographical instruction. Major Close delivered a lecture on map projection. It may be noticed that various lectures on the teaching of geography have been arranged by the association. The first will be delivered by Mr. G. G. Chisholm on January 24, at 8 p.m., at University College, and the second, on scientific method in the teaching of geography, by Prof. R. A. Gregory, on February 14 at the same place and time. The remaining lectures will be delivered on alternate Fridays upon the following subjects:—Physical geography as an essential part of school geography, Mr. T. Alford Smith; how to teach the geography of a country, Prof. L. W. Lyde; orographical maps as the basis of the geography lesson, Dr. A. J. Herbertson; and geographical laboratories, Mr. A. T. Simmons. Particulars may be obtained from Mr. J. F. Unstead, 5 Wiverton Road, Sydenham.

THE issue of *Science* for December 20, 1907, contains the annual opening address delivered last October by Prof. F. F. Wesbrook, of the University of Minnesota, before the faculty of science of the University of Manitoba at Winnipeg. Discussing the needs of the Canadian university, Prof. Wesbrook instituted an interesting comparison between what is required in the direction of higher education in Manitoba and the similar needs of the University of Minnesota, which was founded nine years earlier than the Canadian institution. Although Manitoba has had a university since 1877, it cannot be said as yet to have made provision for it which is at all adequate. Manitoba has now a population of about 380,000, and with all the demand on her for increased university facilities has only been able to expend approximately 16,000*l*. for building and permanent improvement, and for maintenance 3000*l*. per annum (which until last year was only 1200*l*.), with an addition of 5000*l*. from land grant and other sources, making a total current expenditure of 8000*l*. per annum. In the case of Minnesota University, there were in 1887 only 412 students registered out of a State population of 1,180,000, and there was available 7000*l*. from State funds and a total of practically 14,000*l*. from all sources, with a total student attendance per ten thousand population of 3·49. In 1906 the population of the State had nearly doubled, the University attendance had increased to 3956, the total funds derived from the State to 50,300*l*. per annum, the total annual current expense of the University, exclusive of buildings and permanent improvements, was 108,400*l*. per annum, and the attendance at the University for each ten thousand of State population was twenty students. The total expenditure for maintenance, exclusive of State grants for hospital maintenance, special investigations, library expenses, repairs, and so on, will this year be above 132,600*l*. Well may Prof. Wesbrook urge the people of Manitoba to emulate the American example he cites. It is to be hoped that the approaching visit of the British Association to Winnipeg will assist the Canadian authorities in developing the University.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 14, 1907.—"On the Cranial and Facial Characters of the Neandertal Race." By Prof. W. J. **Sollas.**

As a result of a comparison of the calvarium of the Neandertal race with that of the aborigines of South Australia, it is shown that a much closer resemblance exists than some authorities have supposed, especially as regards the calottal height, Schwalbe's ("bregma") angle, and the bregma index. The chief differences are to be found in the cephalic index, the continuity of the frontal torus, and the deeply impressed character of the frontal fossa.

Comparisons based on the glabella-inion line are misleading, owing to the inconstancy in position of the inion.

The exterior foramino-basal angle owes its perplexing anomalies to the fact that its magnitude is determined by five variables, one of which is connected with the cranial height, so that in depressed forms of skull it acquires a higher value than might otherwise be expected.

The Gibraltar skull is the only example of the Neandertal race which presents the bones of the face and the basi-cranial axis in undisturbed connection with the calvarium. Its characters, apart from the cranial vault, are unique; no other known skull possesses so long a face or such a large and broad nasal aperture. In profile, the nasal curve flows into that of the glabella, without any sudden change of flexure, that is, there is no nasal notch, such as occurs in the Australians.

The orbit, as in all skulls of the Neandertal race, is distinguished by its excessive height above a line drawn from the nasion to the middle of the fronto-zygomatic suture.

The sphenethmoidal angle has been measured from the limbus sphenoidalis by a line drawn to the crista galli on the one hand and the basion on the other; it exceeds the corresponding angle of the lowest known South Australian skull, similarly measured, by 16° 30′.

The palate is very dolicho-uranic. The thickness of the frontal bone, measured on one side of the crista galli, is 24 mm. The prognathism of the upper jaw, in whatever way measured, is extremely small, so that the skull must be classed as orthognathous.

The cranial capacity is estimated at 1250 c.c., a close approach to that of the Neandertal calotte. The average capacity of South Australian skulls is very similar, but ranges from 1460 c.c. to 1100 c.c. If the calotte of Pithecanthropus represents the mean of a similarly variable race, then the extreme forms of such a race would almost completely bridge over the hiatus between man and the higher apes.

Society of Chemical Industry, January 6.—Dr. J. Lewkowitsch in the chair.—Some observations on the keeping power of Fehling's solution, together with notes on the volumetric process of determining reducing sugars with it: Dr. Francis **Watts** and H. A. **Tempany**. The authors point out that, contrary to the commonly expressed idea, Fehling's solution, or at least Violette's modification of it, is not liable to deteriorate rapidly if kept in the dark, and if access of air is prevented. The solution can thus be kept mixed ready for use for many months, and it is not necessary to keep the stock in the form of two solutions to be mixed as required.—The determinations of small quantities of bismuth: H. W. **Rowell**. Methods of separation suitable for ores, copper, and base bullion are given which eventually precipitate the bismuth, together with various impurities which do not affect the subsequent colorimetric estimation, but aid in the collection of the bismuth. The colour test depends upon the solubility of bismuth iodide in excess of potassium iodide producing a yellow colour. The test is very delicate, and the amount of bismuth in copper or base bullion may be determined within five hours.

Mathematical Society, January 9.—Prof. W. Burnside, president, in the chair. The distinctive character of Lord Kelvin's mathematical investigations: Prof. A. E. H. **Love**.—A formula of interpolation: C. S. **Jackson**.—Hilbert's invariant integral in the calculus of variations: T. J. I'A. **Bromwich**. An operator related to q-series: Rev. F. H. **Jackson**.

PARIS.

Academy of Sciences, January 6.—M. Henri Becquerel in the chair.—Report presented in the name of the section of geography and navigation concerning a subject put forward by the Geographical Society of Paris relating to meteorological telegrams from Iceland: Bouquet **de la Grye**.—The transformations of the comet 1907*d*: Ernest **Esclangon**. The variations in the form of the comet on approaching perihelion were studied under very favourable conditions of weather and atmosphere, and are illustrated by six diagrams.—The use of flames as valves for alternating high-tension currents: André **Cathiard**. When two electrodes, one of which has a very small section compared to the other, are placed in a flame and in a high-tension (2000 volts to 10,000 volts) circuit, a small continuous current passes, a sort of faintly luminous arc being produced in the flame. In the experiments described, the frequency was forty per second, and a current was obtained, not exceeding 0·03 ampere, capable of producing galvanic deposits. The nature of the current has not yet been studied with the oscillograph.—Contribution to the study of the formation of certain precious stones of crystallised alumina: F. **Bordas**. Exposure to a temperature of 300° C. for a long time causes the yellow colour of both natural (Oriental topaz) and artificial yellow corundums to disappear. The Oriental emerald, a very rare stone, can be produced by starting with a sapphire-blue stone and subjecting it to the above temperature for a certain time. Further experiments with the kathode rays, analogous to the β-radium rays, do not cause colourless corundums to pass to yellow, and the yellow stones are not affected.—The harmonics of a vibrating body: G. **Sizes** and G. **Massol**.—Some new homologues of diglycollic acid: E. **Jungfleisch** and M. **Godchot**.—The mechanism of the transpositions of the phenyl group in the iodohydrins and aromatic glycols: Marc **Tiffeneau**. Although the mechanism of the transpositions of iodohydrins of the type Ar(R)C(OH).CHI.R is definitely established, the interpretation of the mechanism of the transpositions of the aromatic glycols by the formation of diethylene oxides can only be considered as provisional.—The structure of the fundamental substance of hyaline cartilage: Ed. **Retterer**. From the morphological and structural point of view, the fundamental substance of hyaline cartilage is identical with bone substance. It represents, in fact, only the second stage of evolution of the cytoplasma of the cartilaginous cell.—The development and structure of the spores of *Thelohania Giardi*: L. **Mercier**.—The existence of six branchial arches and six aortic arches in the embryo of the mole: A. **Soulié** and C. **Bonne**.—The fertilisation and development of the eggs in *Rhopalura ophiocomae*: Maurice **Caullery** and Alphonse **Lavallée**. The egg evolves into an embryo with perfectly individualised cells, and having none of the plasmodial structure of the ulterior parasitic stages. Ten figures of the egg in different stages of development accompany the paper.—Prolonged anæsthesia by mixtures of oxygen and ethyl chloride: Pierre **Rosenthal** and Albert **Berthelot**. The authors have been able to prolong the anæthesia due to ethyl chloride by administering it mixed with oxygen. In experiments with animals, a true anæsthesia lasting an hour was obtained, the subject going under very rapidly, the narcosis quiet, and recovery prompt. They hope to be able to apply the method to human subjects, more especially as this anæsthetic has the great advantage of not causing the after effects of ether and chloroform.—The slow action of chlorinated products derived from bacilli: MM. **Moussu** and **Goupil**.—The value of the magnetic elements at the Observatory of Val-Joyeux on January 1, 1908: Th. **Moureaux**.—The study of a series of specimens of sea-water collected in the English Channel: A. **Chevallier**. Determinations were made of the density, temperature at the time of collection, chlorine, and sulphuric acid. A curve is given showing the difference of density as ordinates, and the distance from Dieppe as abscissæ.

NEW SOUTH WALES.

Royal Society, October 2, 1907.—Mr. H. Deane, president, in the chair.—Law of meteorological phenomena: A. G. **Williams**.—A simple form of Sprengel vacuum pump: Prof. J. A. **Pollock**. A modified short-fall Sprengel vacuum pump of moderate dimensions is described, in which the raising of the mercury, necessary for continuous working, is effected by evaporating the mercury at a lower and condensing it at a higher level.—Note on the internal structure of some gold crystals: Prof. A. **Liversidge**. The author exhibited sections of isolated crystals and groups of gold crystals, mainly octahedra and rhombic dodecahedra, and photographs of the same before and after cutting. The simple faces on polishing and etching showed that the internal structure did not correspond with the external; *e.g.* in one case the rhombic planes of an externally simple dodecahedron were found to be made up of two triangular faces; on these triangles there were also faces of smaller crystals. Some showed a still more complex structure.

November 6, 1907.—Mr. H. A. Lenehan, vice-president, in the chair.—Notes on the Arranda tribe: R. H. **Mathews**.—A short, accurate method for the estimation of iron, alumina, and phosphoric acid when occurring together: Dr. T. **Cooksey**. When iron, alumina, and phosphoric acid occur together the iron is estimated by a volumetric process (as, for instance, by means of potassic iodide and thiosulphate of soda); the phosphates of the two metals are weighed, and the phosphoric acid in filtrate estimated, as previously described. These data are sufficient for the determination of all three quantities. The method is short and very accurate.—Note on the formation of formaldehyde in solutions of cane sugar, and its bearing on Hehner's test for formaldehyde in saccharine mixtures: A. A. **Ramsay**. The author directs attention to the production of formaldehyde when cane sugar and water are heated at a temperature below that at which caramelisation might take place. This fact explains how a reaction for formaldehyde by the Hehner test (which is one generally used, and particularly delicate) may be obtained from manufactured products such as jams, sweetened condensed milk, or saccharine liquids, &c., and to which the manufacturer has added no formaldehyde, by the usual analytical operations of distilling a slightly acidified aqueous solution of the substance and testing the distillate, since the act of distilling a saccharine liquid results in the formation of formaldehyde.

Linnean Society, November 27, 1907.—Mr. J. H. Maiden, vice-president, in the chair.—The geology of the Nandewar Mountains, New South Wales: H. I. **Jensen.** The physiography and geology of the Nandewars offer points of similarity to those of the Warrumbungle Mountains. For example, the Nandewars present the features of arid erosion, and the level country to the west of them forms an arid-erosion peneplain. In late Palæozoic times the present line of trachyte necks was practically a shore-line, with land to the west and sea to the east. By the end of the permo-Carboniferous period, the sea had given place to a fresh-water lake. In Triassic and Cretaceous times sedimentation took place west of this line, and erosion east of it. During late Mesozoic times the area of the Nandewar Mountains was reduced to a peneplain; basic laccolites were injected, and basic lavas flowed over parts. During early Tertiary times much faulting took place. Lavas escaped from the main fissure and from numerous cross-fractures. Tuffs, ashes, and breccias were ejected, and alkaline lavas solidified in their vents. Gradually more basic types of lava were emitted. In one respect the Nandewar Mountains differ from the Warrumbungles in that, in the Nandewars, sill-structure is represented on a grand scale.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 16.

ROYAL SOCIETY, at 4.30.—Alternate Current Measurement: Dr. W. E. Sumpner.—Prominence and Coronal Structure: Dr. W. J. S. Lockyer.—The Conversion of Diamond into Coke in High Vacuum by Kathode Rays: Hon. C. A. Parsons, C.B., F.R.S., and A. A. Campbell Swinton. On the Perception of the Direction of Sound: Prof. C. S. Myers and Prof. H. A. Wilson, F.R.S.—Preliminary Note on Certain Phenomena of the Electric Discharge through Rarefied Nitrogen: Dr. G. J. Burch, F.R.S., J. E. Marsh, F.R.S., and R. de J. F. Struthers.

MANX ARCHÆOLOGY.

Manx Crosses; or the Inscribed and Sculptured Monuments of the Isle of Man from about the end of the Fifth to the beginning of the Thirteenth Century. By P. M. C. Kermode. Pp. xxii+221. (London: Bemrose and Sons, Ltd., 1907.) Price 63*s.* net.

THIS handsome volume contains notes and illustrations of the inscribed and sculptured stones of the Isle of Man from the time of its conversion to the end of the Scandinavian rule, that is to say, from the close of the fifth (?) to the beginning of the thirteenth century A.D. The individual descriptions are preceded by some ninety pages on the early history of the island and the leading features of the monuments as a whole. These are of great value for the study of Celtic art in general, and many readers—all, indeed, who are unable to study the crosses on the spot—will give them more attention than the remainder of the book. In view of this fact and the somewhat recondite nature of the subject, it may not be out of place if we touch on the more important of their contents before proceeding to speak of particular instances.

The earliest monuments in the island are, without question, the rude boulders inscribed with Oghams. In language, formula, and characters these do not differ from those of the fifth century in Pagan Munster, but if we are to judge from the frequency with which the names of Irish ecclesiastics occur in the appellations of the Manx keeils or chapels, and the dedications of the parish-churches, it seems reasonable to suppose that the Irish came to Man to christianise it, and that the Ogham writing was introduced by, and the stones erected to the memory of, Christians. The date of the conversion of the Celtic Manx is uncertain, but we know that it was in the sixth century that the Irish missionaries began to wander over Europe, and it would have been strange indeed if they had neglected a people so near at hand. The advance among them of the new creed, though never actually checked, was fated to be disturbed some three centuries later by the raids of the Vikings. They appeared in the Irish Sea in 798, and harried the island at intervals during a considerable period. At the end of the ninth or the beginning of the tenth century, it began to be definitely occupied by the Scandinavian invaders, and for the next hundred years it was ruled by the successors of Olaf the White, King of Dublin.

The Northmen, as we have said, did not attempt to stamp out Christianity among their Manx subjects; on the contrary, our author thinks it not unlikely that the Celtic church revived, and that the later Celtic pieces carved in relief and highly decorated were erected during this period. The conversion of the settlers themselves he shows ground for assigning to the first quarter of the eleventh century, and it is significant that after 1050 we hear of a Norwegian bishop, "Hroolwer or Hrolfr," who, according to the chronicle, was succeeded by another, William, before Godred Crovan began to reign in 1075. The year of Hroolwer's coming or death is unknown, but this mention of him enables us to fix approximately the date of our first Scandinavian monuments, which cannot be earlier than 1025 or 1030, and as in one of his inscriptions (Kirk Michael 74) Gaut claims to have made all the crosses in Man, we must suppose enough time to have elapsed for the late Celtic pieces to have been overlooked. Yet neither from this nor from the appearance of the Norwegian ecclesiastics should we be justified in assuming a break in the continuity of the Celtic Church; that there was no such thing is shown by the fact that the later Scandinavian pieces preserve the Celtic type, and are found on ancient sites dedicated to Celtic saints. But if its ascendency was undisputed by the Northmen it was fated to pass away before another power; the year 1170 saw the foundation of the Abbey of Rushen, and this resulted in the virtual subjection of the Manx hierarchy to the great English house of Furness. Under these new conditions the native school of art ceased to develop, the foreigners being opposed to anything savouring of paganism, such as the Runic inscriptions, or likely to interfere with the spread of Catholicism. The Gothic coffin-lid at Rushen may well have belonged to one of the last of the Scandinavian rulers. In any case it is unlikely that the specimens of Celtic art in the island are, any of them, later than the beginning of the thirteenth century.

From the circumstances of their production our author passes on to speak of their distribution and artistic features. As most of us are aware, they form part of the monumental system of the early British Church, which was an extension westward of that of Christian Rome in the period succeeding the death of Constantine. They will be found, however, to show distinct local peculiarities. Of the 116 pieces discussed in the book forty-five are classed as Scandinavian, seventy-one as of earlier date. Maughold has by far the greater number, thirty-seven; Michael comes next with ten, Braddan with nine. Both groups alike are of local rock, usually clay-slate, derived from the immediate neighbourhood. Almost all are sepulchral, and though described as crosses, they are, strictly speaking, cross-slabs, upright, rectangular blocks, varying from 2 feet 6 inches to 6 feet in height, by about fifteen to twenty-four inches wide, and from two to four inches thick. A few are wheel-headed or rounded; only in two late instances is the stone itself cruciform.

We are not surprised to find that the pre-Scandinavian monuments are more numerous in the old parishes Maughold, Braddan, Conchan, Rushen, Lonan and German. After the Ogham-stones already mentioned come a certain number with crosses incised, linear or in outline, all of them plain except for three with hexafoil and one with triquetra. A further stage is reached by those with the figure sculptured in relief. Of the stones of this group, seven show practically no decorative treatment, thirteen are plain or have decorations only of the simplest, crosslets, pellets, bosses, &c., while the remaining eighteen have geometrical designs, zoomorphic interlacings, and figure subjects. These latter are hard to date exactly, but they clearly reached down to the period of the Scandinavian occupation if they did not overlap

N

it. We must not forget to mention, midway between the incised and decorated pieces, six monuments with sunk background or design.

These pre-Scandinavian crosses vary greatly in shape, particularly those of the earlier groups. Among those incised in outline we find some pure Latin, some equal-limbed, some with expanded arms, one crux ansata, &c. At first, at any rate, we are not confined to the type with recessed limbs and joined ends, which it is customary to associate with Celtic art, and which came to predominate here as in other Celtic countries. The art motives remind us, if anything, of those of the Irish school, but it would be a mistake to suppose that the Manx artists were slavish imitators of foreign models, Irish or otherwise. Some well-known designs, viz. the step, the key-fret, and the spiral, are feebly represented or altogether missing. Nor do we meet with the lacertine and bird-like figures with interlaced top-knots, tongues, tails and legs, which are regarded as Irish *par excellence,* the nearest approach being the dragon-plait on the fragment from Cardle (Maughold 60). On the other hand, these monuments boast a certain number of patterns, *e.g.* the double twist with diamond ring and the various developments of loop-plait, which cannot be matched elsewhere, and show originality of conception as well as technical skill.

Except at Maughold and Braddan, the Scandinavian monuments are most numerous where there are few or no Celtic, as at Andreas, Michael, and Jurby. A few pieces are unadorned—these are late, strange to say—the remainder are handsomely decorated on both fronts, sometimes even on the edges. As we have pointed out, this series is to all intents and purposes a continuation of the earlier one. The crosses are Celtic in form; the decorative treatment and the designs are of Celtic origin. For one feature, indeed, it is not indebted to any Celtic, or indeed any Christian, model; we allude, needless to say, to its inscriptions in Runes. These occur on twenty-six out of the total of forty-five stones, eighteen in the northern and eight in the southern district. All are Scandinavian, in the Norwegian tongue excepting, perhaps, that on Maughold 104, which Prof. Bugge believes to be in Swedish. The one Anglo-Saxon example occurs on a stone of the Celtic group.

A good deal of space is devoted to this subject, not only to the Runes of Man, but to runes in general, and we do not doubt that this section will prove of great value to the student. Though the designs on these monuments are based on Celtic types, it would be a mistake to imagine that the men who made them drew their inspiration from pieces already in the island. On the contrary, several of their patterns, the step, the divergent spiral, and the chevron, are entirely absent from the Celtic pieces. The tendril and the forms of link-twist introduced by Gaut, Mr. Kermode believes to have been suggested by the carved stones of Scotland and the north of England; the other designs on these later pieces he derives from the Celtic MSS., basing his view on the frequent use of the triquetra and other local peculiarities. The origin of the figure-drawing is harder to determine. It is true that some of the stones have zoomorphic patterns of Norse type, and scenes from Norse mythology. Yet for all that, these latter have no more in common with the drawings of Scandinavia proper, which are inferior and rare, or the Viking-pieces of the lake-district, than with the rude efforts of the Welsh or the later Irish work. They have some affinities with the drawings on the stones of East Scotland, but what we find on them for the most part are original representations taken direct from nature. Generally speaking, these Scandinavian monuments show less regard for accuracy, a bolder treatment, and greater freedom than the earlier pieces.

It remains to say something as to individual crosses, no easy task when the space is so limited, and there is so much to detain the artist and antiquarian. We must be content to touch very briefly on a few of those most worthy of attention. Of the stones of the Celtic group a great number are interesting mainly for the light they shed on the development of the figure or the design; the most striking in itself, far more striking than the more highly decorated pieces, is the stone found in the Calf of Man (50) with a unique example of the Byzantine treatment of the Crucifixion. We have alluded more than once to the Ogham stones of the fifth century Irish type. To these must be added two monuments, not Celtic, by the way, but Scandinavian, inscribed with scholastic or Pictish Oghams. On one of these, the beautiful Mal Lumkun Cross (Michael 104), along with Runic legends we find one of the earliest instances of the Ogham alphabet. Of the Latin inscriptions, that on Maughold 48 is perhaps the most interesting, the Guriat to whom it refers being connected in all probability with Cynan, King of Gwynedd, whose daughter Etthil he may be supposed to have married. The Anglian Runes on Braddan 25 form the word "Blagkimon," a known Anglo-Saxon personal name.

Among the Scandinavian monuments the most remarkable beyond a doubt, though not always the best preserved, are those with Norse mythological scenes (Jurby 93, Malew 94, Andreas 95, Bride 97, &c.). The representations of Sigurd slaying the dragon Fafni, or Heimdal blowing his horn, of Vidar spearing the Wolf, show great vigour and originality.

We have endeavoured to give an idea, however imperfect, of the contents of this long and interesting volume. We have but little to offer by way of criticism. One thing strikes us, and that is that the author is not of those antiquarians who are for ever wresting facts to support a theory. If anything, he is afraid of being thought dogmatic. In expressing his own opinions he is careful not to shut out possible alternatives. He agrees, for instance, with Mr. Romilly Allen in deriving the Celtic cross from the monogram of Constantine's dream; he points out, none the less, that it might well have been developed from a form similar to that of the lost cross at Braddan, with equal limbs and circles between them. So, too, in the chapter on runes already mentioned, he places at the disposal of the reader a complete *résumé* of all the views on the subject. Except for many repetitions the arrangement of the work is admirable, and the style, all things considered, unusually lucid. The erudition displayed in it is considerable, and the standard of accuracy a high one. Mr. Kermode may fairly claim to have bestowed on the student a lasting possession, and to have done for the Isle of Man what Dr. Anderson and the late Mr. Romilly Allen did for Scotland.

A word must be said in conclusion as to the plates, which greatly enhance the value of the work. They are taken, not from photographs, but from reduced copies, made with the greatest care, of full-sized drawings, founded on rubbings of the stones.

CHEMICAL AND PHYSICAL TABLES.

Van Nostrand's Chemical Annual, 1907. Edited by Dr. J. C. Olsen. Pp. x+496. (London: A. Constable and Co., Ltd., 1907.) Price 12*s*. 6*d*. net.

CHEMICAL and physical tables required by various kinds of chemists have been collected in this annual. Among the ninety-three tables it contains are five-figure logarithms, constants of the elements, some very complete tables of factors and their logarithms for the calculation of gas, volumetric and gravimetric analyses, constants of fats, oils and waxes, the more important constants (molecular weight, specific gravity, melting point, boiling point, solubility, crystalline form and colour) of some 4000 inorganic and 5000 organic compounds, specific gravities of solutions, vapour pressure, conversion, and heat of combustion tables. The remainder of the book is taken up with classified lists of the chemical papers and books published since the beginning of 1905, and an index.

This matter forms a volume which has been much needed, and will be most useful to all chemists. No pains have been spared to make many of the tables accurate and comprehensive, as, for example, the above-mentioned data for some 9000 compounds. The classified list of chemical papers, on account of its conciseness, should, if kept complete, be quite useful even to those who have the fuller abstracts of the Chemical and American Chemical Societies; the list of books will be even more valuable.

Unfortunately, references have been given only in a few cases to the original observers of the data used in the annual. In future editions such references should be made more complete. The following quantities are not defined:—electrical conductivities, specific heat of gases (whether C_p or C_v), and the various "constants" and "values" for oils, fats and waxes. To give Reichert-Meissl values without definition when two sets of values are current is confusing. The table of gas densities is quoted, unfortunately, from Landolt-Börnstein-Meyerhoffer Tabellen, where the densities are calculated on certain assumptions (clearly wrong in the light of the work of D. Berthelot, P. Guye, Lord Rayleigh and others) instead of being the observed densities; further, the values found by E. Morley for hydrogen and oxygen in his classic work are not given.

While laborious determinations are being made to improve the second decimal place of atomic weights, there are scarcely any other physico-chemical constants known to anything like the accuracy which atomic weights now have. The energies of many of the workers on atomic weights might now with great advantage be turned to improving the accuracy of many other constants. Boiling points are an example of this; scarcely any are known to $0^{\circ}\cdot1$, and many current values for the same substance differ by whole degrees. The boiling points of organic substances in this book are from Beilstein, yet for five out of the six esters we have tried, the very careful determinations of Young and Thomas are not given.

We have detected few misprints; the logarithm of 2011 is incorrect. The value of the inch in millimetres is given to eight places, or to 10^{-9} cm.; this is less than the accepted value for the diameter of an atom, and the minimum length visible. The boiling point of helium is given as -267°; we were not aware that it had been liquefied; Olszewski failed to do so by cooling it to a calculated temperature of -270°.

We know of no other tables of this kind in English which are so complete and so up to date as this annual. It is convenient in size, and clearly printed on good paper. The five-figure logarithms are the best arranged we have seen. T. H. L.

A NEW TEXT-BOOK OF PSYCHOLOGY.

Elements of Psychology. By Dr. S. H. Mellone and Margaret Drummond. Pp. xvi+483. (Edinburgh and London: W. Blackwood and Sons, 1907.) Price 5*s*. net.

THIS book is the joint work of two authors who are evidently well acquainted with the needs of the examinee, as well as those of the more genuine student of the science of psychology. It is therefore not surprising to find in the preface the statement that the book is intended as "a contribution to the *teaching* of psychology." Every stone of offence is carefully removed from the learner's path. Even the usual order of treatment is altered for his benefit. After a few introductory chapters on the method and subject-matter of the science, the student is brought face to face with the most essential characteristic of consciousness, viz. mental activity, and in its most pronounced form—volition. Not until the emotions and pleasure-pain have been treated with like fulness and concreteness do the authors descend to the conventional sequence of sensation, perception, &c. This order is determined by relative difficulty of introspection, the prominent complexes of mental life being taken before their more abstract elements.

It will thus be seen that the introspection standpoint is avowedly adopted as the fundamental one. Although the objective conditions of consciousness are by no means neglected, no attempt is made to develop that objective and functional view of mental life which is so popular in certain quarters at the present day, and, to the present writer's mind at least, seems so full of promise. The standard authorities—Ward, James, Stout, &c.—are closely followed, and to such good purpose that the book forms an excellent introduction to the study of these authorities themselves. A notable feature is the list of detailed references inserted at the end of each section.

Altogether, the book will be found admirably suited for its purpose, viz. to serve as a general text-book for pass examinations in the subject at a university, and will probably earn a well-deserved popularity. One is tempted, however, to look for something more in a text-book on such a science as psychology. The science is a comparatively new one, with an ever-broadening outlook, and a text-book such as we have before us might well be expected to extend or at least define this outlook by discussion of the most recent experimental results attained by psychologists, where they appear to involve important modification of theory. Yet we look in vain for any reference to the important experiments of Drs. Head and Rivers on cutaneous sensibility, or, again, to those of Prof. Sherrington on the relation between the two eyes in their response to intermittent light stimulations. A treatment of the latter would probably have reminded the authors likewise to discuss the general problem of psychical fusion, over which they preserve a disappointing silence. These are two instances out of several that might be quoted.

Objection might also be made to the method of treatment of the general psychophysical relation in the chapter headed "Mind and Brain." A more concrete and detailed discussion would have given greater relevance to the suspense of judgment therein advocated, or might even have opened up the prospect of a reconciliation of interactionism and parallelism on metaphysical lines. Not even a beginner is likely to be satisfied with a crude "either—or" in this case.

The book should be valuable alike to teachers and students, as being a compact, sound, and thorough statement of current views in psychology. W. B.

OUR BOOK SHELF.

Die Physik Roger Bacos. By Sebastian Vogl. Pp. 106. (Erlangen: Junge und Sohn, 1906.)

In this dissertation, Dr. Vogl has collected a large number of interesting facts relating (i) to Roger Baco's, or, as we commonly say, Bacon's, biography, his education and his friends and colleagues; (ii) the literature of the Greeks, Romans, and Arabs, from which he derived his physical ideas; and (iii) his physical works. As the result of this study, Dr. Vogl has given us a typical insight into the state of science in the thirteenth century. Baco was born about the time that the Dominican and Franciscan orders were founded, and in these circumstances the position of a man who was far in advance of his times is not difficult to understand, especially in such an atmosphere as that of Oxford, where he remained until 1240.

As usually happens, Baco's claims to fame can hardly be said to be well understood even at the present time. Dr. Vogl considers that no great importance can be attached to his predictions of steam engines, flying machines, and other modern inventions, all of which only reproduce ideas current in Arabic and other writings. On the other hand, Dr. Vogl considers Baco has claims to be regarded as the founder of mathematical physics, and the large portion of the *opus majus* devoted to the uses of mathematics in science doubtless constitutes one of the most important advances with which Baco was associated. His physical writings dealt mainly with optical problems, and this is scarcely to be wondered at, for geometrical optics is the simplest and at the same time the most perfect branch of applied mathematics. When we remember the great hostility and apathy which exist at the present time against mathematicians in England (as exemplified by a remark on p. 49 of NATURE, November 21, 1907, if this is to be taken seriously), we cannot wonder that in an age of religious superstition and ignorance Baco fared badly. Although seven hundred years have elapsed, the world has not yet realised the great extent to which ignorance of mathematics is responsible for human crime, poverty, and misery.

The Preservation of Infant Life. A Guide for Health Visitors. By Emilia Kanthack. Pp. iv+92. (London: H. K. Lewis, 136 Gower Street, W.C.) Price 1s. net.

This small book consists of six lectures which were delivered by Miss Kanthack to voluntary health visitors in St. Pancras. In the words of Dr. J. F. J. Sykes, the medical officer of health of that borough, who has written a short preface, it "may be strongly recommended to those who intend to undertake health visiting amongst the poor."

It would be difficult to conceive of the subject of the preservation of infant life being better presented to the class of audience to which Miss Kanthack had to address herself, and the lectures furnish evidence of a considerable study of her subject, together with a sound practical acquaintance with it. They will well serve as models for those who may have to address similarly constituted audiences, and they may be read with pleasure and profit alike, not only by every woman health visitor, but by every educated woman. The information is so happily expressed and tellingly presented that one lays down the book with the sincere wish that Miss Kanthack may give us more.

In her opinion, personal influence is the keynote of success in dealing with infantile mortality. She emphasises the fact that the baby is an entity long before it is born; therefore, to give it a good start the mother must be looked after during pregnancy. Speaking of the dangers of the artificial feeding of infants, she makes the following stricture:—"If one of the brute creation refused to suckle its young it would be thought a monstrous violation of nature, and yet a woman may evade this natural function and it arouses no comments."

Sanitation in Daily Life. By Ellen H. Richards. Pp. ix+82. (Boston: Whitcomb and Barrows, 1907.) Price 60 cents net.

It is now generally agreed that in every efficient school the pupils should receive instruction in the simple laws of personal hygiene and of public health. The short, bright chapters which this book contains on subjects like "the clean city," "the clean house," and "habits of cleanliness" should be of value to teachers, especially those in elementary schools, as indicating the possibility of explaining vitally important truths in a manner which can be understood by children. The illustrative experiments at the end of each section should be studied by teachers who give lessons on health.

Der neue Leitfaden. By L. M. de la Motte Tischbrock. Pp. x+126. (London: John Murray, 1907.) Price 2*s.* 6*d.*

A SATISFACTORY course for students—juvenile or adult—commencing the study of the German language is provided in this book. In addition to being grammatically and educationally sound, and of good literary quality, the volume contains many extracts on scientific subjects as exercises for reading and translation.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Stresses in Masonry Dams.

IF Prof. E. Brown will refer again to my letter published in NATURE of January 2, he will see that I specifically stated that I did not question that in so far as the dam acted as a horizontal beam, the stresses $\widehat{xx}$ and $\widehat{zz}$ will be different in an actual dam and a slab dam. The real point is that Prof. Karl Pearson has said that, apart from any action of this kind, the stresses $\widehat{xx}$ and $\widehat{zz}$ in a slab dam and in an actual dam are widely different. Thus, on p. 11 of Pearson and Pollard's paper, he says Messrs. Wilson and Gore put the stress $\widehat{yy}$ zero, and "hence the vertical and horizontal pressures they calculated have no direct application to real dams." He has since explained in *Engineering*, September 20, 1907, that he did not here refer to any action of the kind mentioned by Prof. Brown and by myself in my original letter to you, but that, apart from any action of this kind, the stresses $\widehat{xx}$ and $\widehat{zz}$ are entirely different in a slab dam and a long dam. Messrs. Wilson and Gore deduced the stresses for their slab by the equations

$$\widehat{xx} = \frac{E}{\left(1 - \frac{1}{m^2}\right)}\left(e_1 + \frac{e_2}{m}\right)$$

$$\widehat{zz} = \frac{E}{\left(1 - \frac{1}{m^2}\right)}\left(e_2 + \frac{e_1}{m}\right),$$

where E is Young's modulus, e_1 and e_2 the measured strains, and m Poisson's ratio. So far as I can see, these equations give correctly the stresses $\widehat{xx}$ and $\widehat{zz}$ for the slab, and if my reasoning in my previous letter to you is correct, these stresses will be unaltered when the slab forms part of a complete dam and is then exposed to stresses $\widehat{yy}$ at right angles to the plane of the other two.

H. M. MARTIN.

83 St. James's Road, Croydon, January 10.

MAY I ask whether the interesting experiments on gelatin models of masonry dams, recorded in your issue for January 2, p. 209, do not ignore one factor on which the stability of actual dams is calculated largely to depend, namely, the weight of its materials?

This factor does not seem to be reproduced in the model, and I conceive that it may account for the rupture depicted on p. 210, which is hardly of a kind that one would expect to have to guard against in a real dam.

OLIVER LODGE.

MR. MARTIN in his letter to NATURE of January 2 cites the body stress-equations of elasticity

$$\left.\begin{aligned} \frac{d\widehat{xx}}{dx} + \frac{d\widehat{xz}}{dz} &= 0 \\ \frac{d\widehat{xz}}{dx} + \frac{d\widehat{zz}}{dz} + \rho g &= 0 \end{aligned}\right\} \quad \ldots \quad (i)$$

and appears entirely to overlook the fact that two equations will not suffice to determine the *three* stresses $\widehat{xx}$, $\widehat{zz}$, and $\widehat{xz}$. There is another relation between the stresses, and this relation depends on the relation between the strains, which is purely geometrical, namely,

$$\frac{d^2\sigma_{xz}}{dxdz} = \frac{d^2 s_x}{dz^2} + \frac{d^2 s_z}{dx^2} \quad \ldots \quad (ii)$$

In substituting for these strains in terms of the stresses the resulting third equation differs for the cases of the dam and of the slab.

For the case of the dam abutting at its terminals against rigid supports:—

$$4\frac{d^2\widehat{xz}}{dxdz} = 2\eta\left(\frac{d^2}{dx^2} + \frac{d^2}{dz^2}\right)\left(\widehat{xx} + \widehat{zz}\right) + \left(\frac{d^2}{dz^2} - \frac{d^2}{dx^2}\right)\left(\widehat{xx} - \widehat{zz}\right) \text{ (iii)}$$

For the slab with free faces:—

$$4\frac{d^2\widehat{xz}}{dxdz} = \frac{1 + 2\eta}{3 - 2\eta}\left(\frac{d^2}{dx^2} + \frac{d^2}{dz^2}\right)\left(\widehat{xx} + \widehat{zz}\right) + \left(\frac{d^2}{dz^2} - \frac{d^2}{dx^2}\right)\left(\widehat{xx} - \widehat{zz}\right) \quad \ldots \quad \text{(iv)}$$

where η is Poisson's ratio.

Messrs. Wilson and Gore have determined their $\widehat{xx}$, $\widehat{zz}$, and $\widehat{xz}$ from measuring σ_{xz}, s_x, and s_z on an india-rubber slab with, I presume, $\eta = \frac{1}{2}$. Their values for these stresses therefore ought to satisfy (i) and (iv); it is difficult to understand how Mr. Martin can believe them to satisfy (i) and (iii) with $\eta = \frac{1}{4}$, which is needful in the case of the masonry dam.

To Sir Oliver Lodge I can only reply:—"Read our memoir and you will find that the influence of the weight of the dam is fully discussed, and experimentally determined. You will also find that the actual *tearing* was only reached by 'excessive water pressure.'"

With regard to Prof. Brown's views on the effect of the terminals, the following words are used to limit the actual theory applied:—"Let us suppose an indefinitely long dam, or if it be of finite length that its terminals abut against rigid supports." The words *abut against* were purposely used instead of *are built-in* to mark what conditions were being assumed. It is quite another point how far my theoretical dam may be considered an approximation to a real dam. Prof. Brown, emphasising the variability of conditions in any practical case, says that engineers "have used a simple but approximate method of estimating stresses in a dam, based on the flexure of beams." My criticism is that this is not an approximation at all, and that if it were they have neglected to apply their own conditions to the vertical sections, in which case they would have found any existing dam so lacking in stability that they would have promptly dropped a theory which, if carried to its logical conclusion, condemns all existing dams! Now, when an engineer treats a dam as a beam, he forgets two points:—(1) That the length of a beam must be large compared to the linear dimensions of the cross-section. In the case of the dam, its base, the built-in cross-section, is of the same dimension as to depth as the length of the beam, *i.e.* the height of the dam. The ordinary formulæ of flexure are thus absolutely inapplicable, as anyone who knows de Saint-Venant's classical memoir on flexure will at once realise. (2) That the faces of the beam must be free to expand in order that the theory may apply. In applying his theory of flexure, therefore, the engineer, so far from building-in his terminals, does not even suppose them to abut! I contend that if Prof. Brown's balcony were 100 feet broad, but *half a mile or a mile long*, he would find little difference in the stresses except relatively close to the abutments, whether he supposed the terminals abutted or were built-in. In any case, I am convinced on both theoretical and experimental grounds that for the bulk of the dam far better results will be obtained by applying the uniplanar equations of stress than by any attempt to deal with a solid practically as broad as it is long by a theory of flexure.

That the terminal conditions produce effects goes without saying; I agree with Prof. Brown that we should, if possible, consider them, but their order of importance is that of two terminal supports to a balcony, say 1 foot broad, 1 foot deep at the built-in edge, uniformly loaded, and perhaps 50 feet long. Such effects are purely secondary, and it will be time enough to consider them when we have reached some agreement as to the main stresses; these stresses can be fairly reached by taking, as I have done, an indefinitely long straight dam *abutting* against rigid terminals.

With most of Prof. Brown's statements in his appreciative criticism I am in complete harmony. No theory will replace local knowledge—that of the geologist as well as that of the engineer—no theory will perhaps be of equal value with past experience, but it can be helpful and even suggestive. Mr. Pollard and I did not smooth our observations, as has been done in some other cases, because it was desirable to show how much variability is due to local conditions, how much to observational error. Much of what Prof. Brown would attribute to want of homogeneity in our material I know to be due to the changes in external contour, and this is one of the urgent problems of dam construction. Our experimental work shows that very large changes are made by modification of the contour. Is it not possible to reach experimentally better forms for the flank of a dam than are at present in use?

The cost of experimental work on a suitable scale is prohibitive to the individual experimenter, but it appears to me that something on a really big scale ought to be done by the Institution of Civil Engineers. The problem is a very important one, and I do not believe, notwithstanding what I have read to the contrary, that the keen mathematician feels anything but intense awe in the presence of the creative engineer, who has succeeded, notwithstanding the weak-kneed theory provided by men of science, in producing such monumental works as the Assuan and Vyrnwy dams by the force of mechanical appreciation alone.

KARL PEARSON.

The Nature of γ and X-Rays.

IN a letter to NATURE of October 31, 1907 (vol. lxxvi., p. 661), a copy of which arrived here recently, Mr. Barkla criticises a paper of mine which was published in the *Philosophical Magazine* for October. In that paper I tried to show how closely the properties of γ and X-rays were in agreement with the hypothesis that they consisted mainly at least of neutral pairs, and I pointed out that even the peculiar polarisation effects which Mr. Barkla had shown to exist might be explained, not unreasonably, as a consequence of the rotatory motion which such pairs would probably possess. I suggested that a pair might be more likely to become entangled with and deflected by an atom revolving in the same plane as itself.

Mr. Barkla describes an experiment in which he has measured the amount of scattering of X-rays in different directions, and compares his results with those which he expects to obtain as the result of calculations based on each of the two hypotheses in turn, that of the neutral pair and that of the ether pulse. He states the results to be against the former theory.

But for the result from his calculations in the case of the neutral pair, he makes the assumption that the probable direction of motion of a neutral pair on emergence from an atom with which it has been entangled is independent of its original direction of motion.

There is no justification for this assumption. It does not even appear to be probable. Consequently, the experiment has no value as a critical test. Yet I fully agree with Mr. Barkla that the dependence of the amount of secondary radiation upon the angle which its line of motion makes with that of the primary ray is a very proper subject of study; it might be expected to furnish much-wanted information.

For this reason I also have been investigating one aspect of this question. With the assistance of Mr. J. P. V. Madsen, of this University, I have been comparing the secondary radiations issuing from the two sides of a plate through which γ rays are passing. On the ether pulse theory there should be complete symmetry, provided that the rays have not been appreciably absorbed on their way through. Secondary radiation, whether material or not, originated in an atom by a passing pulse, is just as likely to go forwards as backwards. This is, indeed, always assumed by writers on the ether pulse theory, *e.g.* by Mr. Barkla himself in the letter already referred to.

On the other hand, if the γ rays are material, it is quite possible, though not necessary, that the secondary radiations on the two sides of the plate should be different.

As a matter of fact, there is the most remarkable want of symmetry, and this is fatal to the ether pulse theory of the γ rays. Moreover, all our experiments so far show that, on the whole, the kathode radiations from a given stratum of matter traversed by γ rays possess momentum in the original direction of motion of the rays, and this shows that the rays are material.

The experiments are very simple, and are not wholly new. The secondary kathode radiations due to a stream of rays impinging on a plate have been studied by many observers, who all concur in the statement that they increase with the atomic weight of the material of the radiating plate. For example, the figures for Pb, Al, and C are about as 100 to 30 to 15. In fact, they follow almost the same law as in the case of β particles. The reason for this will appear presently. The secondary kathode radiations that appear where γ rays *emerge* from a plate have been less studied, but Eve has shown that they consist largely of kathode particles, and Dawes (*Phys. Rev.*, xx., p. 182) that they do not appear to follow the same law as what may be called the "incidence" radiations. Further, Wigger has made the very important observation ("Jahrbuch der Radioaktivität," Bd. ii., pp. 428–430) that in certain circumstances the γ rays issuing from a plate of Al which they have traversed make *more* secondary rays than when they issue from Pb.

All these facts may be conveniently studied together. Let an ionisation chamber be made of cylindrical form with plane ends, and let a pencil of γ rays be directed along the axis. Let the rays first pass through a cm. or so of lead. Let them then pass through a pair of plates which can be inverted; a convenient pair may be made of a lead plate 1 mm. and a carbon plate 1 cm. thick; these are to form one end of the chamber. It will then be found that there is more current through the chamber when the C plate is next to it, and the "emergence" secondary rays are produced in the carbon, than when the Pb plate is next the chamber. But if the plate closing the other end of the chamber be at one time Pb, at another time C, the reverse effect occurs. At this plate "incidence" secondary rays are produced by the same pencil of γ rays, and these are greater when the plate which is struck is Pb than when it is C. The differences are of the order of 10 per cent., 20 per cent., up to 60 per cent., depending on the circumstances of the experiment. The materials and the form of chamber may be largely varied, but the same want of symmetry is always there.

It appears that the "emergence" radiations from the plate through which the γ rays have entered are more important than the "incidence" radiations from the other plate. The latter serves mainly as a reflector or scatterer of the rays from the former, and this is the reason why there is less current when it is formed of a material of smaller atomic weight, following the usual rule for β rays. This effect is a general one, and it serves to explain why all observers have found less kathode radiation due to γ rays from Al or C than from Pb, when actually the rays produce more from the former than the latter when they have been first sifted by a cm. or so of lead. A stream of γ rays contains β particles derived from the γ rays by the influence of the last substance traversed. It is the scattered portion of these which constitutes the main portion of the secondary radiations due to γ rays, and the reason why the incidence radiations run parallel to those of β rays is obvious. Nevertheless, there are small variations due to secondary rays formed in the material of the plate itself, the quantity of which is influenced by the nature, not only of this material, but of the screens through which the rays have previously passed. This is because the γ rays are heterogeneous, as first shown by Kleeman. It is when the rays have passed through some thickness of lead that they are acted on with greater effect by Al or C than by lead. The quantity of kathode radiation set free in the radiator itself depends on the quality of the rays as well as on the radiating material. The particles at first move mainly, perhaps entirely, in the original direction of motion of the γ rays, but are subsequently scattered, and contribute to some extent to the "incidence" secondary radiation. But the principal portion of the incidence radiation is due to β particles which were in the stream of γ rays before it struck the plate.

It would make this letter too long if I were to discuss these results with any fulness, or to show their relations to results already obtained. I hope to publish a fuller account in a short time. Meanwhile, I will point out that the experimental proof of the material nature of the γ rays carries with it, almost surely, a corresponding proof as regards the X-rays. The points of similarity are too numerous for it to be otherwise. Only, as I have said in the paper already quoted, there should, of course, be ether pulses in the X-ray stream, and the γ stream also for that matter, and it may possibly be these which have been the subject of experiment by Marx, and which show Mr. Barkla's polarisation effects. But I think it is certain that at least the γ rays are material, and those X-rays which give rise to a secondary kathode radiation of a speed due to a few thousand volts. W. H. BRAGG.

The University of Adelaide, South Australia, December 12, 1907.

Drifted Ice-crystals.

THE accompanying photographs, showing the incipient freezing of the sea during severe frost on January 4 at

FIG. 1 – Bank of drifted Ice-crystals.

Littlehampton, may be of interest to readers of NATURE. They were taken about high water, at 11 a.m. A high

FIG. 2.—Layer of drifted Ice-crystals.

N.E. wind and the flowing tide had drifted ice-crystals formed on the surface of the sea into the slack water in the angle between the east side of the small pier and the shore, until they were collected in a viscous layer covering the whole angle. The layer seemed to be more than an inch thick.

The photographs show the border of ice-crystals thrown up on the beach, with a vertical front towards the sea about 18 inches high.

The effect disappeared rapidly when the tide began to fall. The timbers of the pier were thickly coated with ice at high-water mark, and as far above as the splashing reached, but remained perfectly clear below this line.

WALTER LEAF.

The Interpretation of Mendelian Phenomena.

DR. G. ARCHDALL REID has recently suggested (1) that Mendelian phenomena occur only under artificial conditions, and (2) that they are to be explained in terms, not of segregation, but of "latency" and "patency." As regards the latter contention, it appears to me that it would be justified if, in the case of experiments conducted under stringent conditions, dominant characteristics were, even occasionally, to appear in recessive generations or *vice versâ*; but if this is not the case it seems an abuse of language to describe a thing as "latent" which never gives any manifestation of its existence. Further, Dr. Reid's theory does not explain—as the Mendelian theory does—why these characteristics not only appear and disappear, but play this game of hide-and-seek in accordance with strict numerical rules.

As to the other point, that Mendelian phenomena are confined to cultivated varieties, it is extremely difficult to prove or disprove, because to ascertain the phenomena you must experiment, and to experiment is to place under artificial conditions. But the well-ascertained facts of conjugation and cell-mitosis, which Mr. R. H. Lock regards as affording considerable support to the doctrine of gametic purity, are certainly not confined to cultivated varieties. That all inheritance may be particulate was long ago suspected by Galton, who speaks of skin colour as possibly "a fine mosaic too minute for its elements to be distinguished in a general view" ("Natural Inheritance," p. 12).

May I suggest one line of inquiry that may possibly prove fruitful in competent hands? Is there any connection between the variability of a plant or animal and the number or size of its chromosomes? Man, for example, has a large number of chromosomes, and is extremely variable. The correspondence would no doubt be far from exact if we suppose with Mr. Lock that the biological units are not the chromosomes themselves, but the chromomeres or some even minuter subdivisions. But it might be assumed, at any rate as a first approximation, that the ultimate units were roughly proportional to the number and size of the chromosomes, and in that case species possessing many and large chromosomes would be likely to have a larger stock of the raw material of variation than their fellows. H. H. O'FARRELL.

East India United Service Club, St. James's Square, S.W., December 30, 1907.

Musical Sands.

IN reply to Prof. Poynting's letter (NATURE, January 16), may I say that the article which appeared in NATURE (August 6, 1901) was only intended to supplement my paper of 1888, by recording the results of further investigations up to date, and to show that I claimed, both by analytical and synthetical methods, to have proved the theory previously dealt with in detail?

In that paper (1888) I rejected the conception that the notes emitted from musical sands were due to the vibration of the individual grains as separate particles, because the contact of one grain with another would prevent such vibrations, and suggested that the only other explanation possible was that certain grains, in *rubbing* one against another, might produce the required vibrations through surface friction.

The music from sands is a cumulative effect, and only possible under the prevalence of numerous favourable conditions, and I found that if I eliminated one apparently insignificant factor from the conditions upon which my theory was based, the production of musical sands artificially became impossible.

Until an artificial musical sand can be produced exclusively under the conditions suggested by Profs. Poynting and Thomson in "Sound," I submit that my explanation may be retained. CECIL CARUS-WILSON.

Filtration of Rain Water.

I WISH to ask the opinion of someone in regard to the filtration of rain water, and the removal of any sediment, before it finds its way into large underground cisterns holding fully 15,000 gallons.

It will not be difficult or costly to collect the water and pump it up for use in a large laundry. A pump can be worked by the engine close by.

The point is how to prevent a lot of smuts, &c., finding their way into the cisterns, which would necessitate the frequent removal of this stuff, an operation that would be both difficult and expensive.

Is there any way by which filtration can be carried out above ground?

I shall be glad to know of any way to meet the difficulty.

January 13. ENQUIRER.

THE HIGHLAND OVERTHRUSTS.[1]

THE controversy regarding the structure of the north-western Highlands was a disturbing factor in the progress of geology from 1819, when the problem was first raised by Macculloch, until it was closed in 1884 by Sir Archibald Geikie's announcement in NATURE (vol. xxxi., p. 29) that the generally accepted view could no longer be maintained. The NATURE article—perhaps the most sensational announcement in geological literature—was followed in 1888 by a report from six members of the Scottish Geological Survey (Messrs. Peach, Horne, Gunn, Clough, Hinxman, and Cadell), giving a summary of the evidence which they had collected as to the structure of the north-western Highlands; and it has taken another twenty years to complete the survey of the whole overthrust region and prepare the detailed observations for publication. The full results are now issued in an elaborate monograph, the most important and the cheapest publication ever issued by the British Geological Survey. It includes 700 crowded pages, 52 artistic and instructive plates, and a beautiful colour-printed geological map of the whole area on the scale of four miles to the inch. The price of the book is 10*s*. 6*d*. The Survey is to be congratulated on having secured for this memoir a style of production far superior to the usual standard, and on its issue at a price which should ensure for it a wide circulation.

The book no doubt suffers from the inevitable compromise between conflicting requirements. Many readers will never have the opportunity of visiting north-western Scotland, and they will seek in this volume for a clear statement of the general results; their needs are satisfied by the fine photographic plates of the scenery, which show the overthrust structures more clearly than they are often visible through the persistent mists of the west Highland hills, and by the masterly introductory statements by Dr. Horne in chapters i., iii., xxxii., and xl. (of the last of which Dr. Teall is joint author), and the corresponding chapters by Hinxman on the Torridonian, and by Horne and Peach on the Cambrian. The memoir has also to serve as a field handbook to those who can visit the district. Accordingly it has to give precise information, which cannot be too detailed, as to localities and sections. The bulk of the book consists of detailed local descriptions, written by Messrs. Peach, Horne, Clough, Hinxman, and the late W. Gunn, with notes by Cadell, Greenly, and Harker. A third group of geologists will turn to the volume for help in the investigation of other regions of crystalline schists, for nowhere has so large and comprehensive an area of these rocks been subjected to such a searching investigation. The conclusions of this work and the most important evidence are given in a detailed account by Dr. Teall of the gneisses, and altered sedimentary rocks associated with them. The appendix includes a list of fossils and fossiliferous localities, a chemical study of the Durness Dolomites by Dr. Pollard, and a full bibliography by Mr. D. Tait.

The book therefore combines chapters which can be read with advantage by any geological student and others which have to be judged as a collection of materials for reference by specialists. The memoir is appropriately edited by Sir Archibald Geikie, who started the work in 1883, and carefully supervised its progress for eighteen years, until his retirement from the Survey in 1901. It is doubtless due to his literary skill and sense of proportion that the book enjoys a greater uniformity in style and treatment than would be expected in a work extending over so many years, and written by so many men.

The history of the north-west Highlands controversy is summarised in a chapter by Dr. Horne, who lucidly states the results of all previously published geological work on the district. The geological interest of the area dates from the announcement by Macculloch, in 1819, of his discovery of fossiliferous rocks lying above gneisses, and covered by the gneisses and schists that form the great bulk of the Scottish Highlands. Murchison, with his keen scent for a good clue, visited the area, and he re-examined it after the discovery by C. Peach, in 1854, of the better fossils (now known to be Cambrian) in the Durness limestones. Murchison was convinced that the fossiliferous rocks were covered by the eastern gneisses, and, in accordance with the law of superposition, accepted the eastern gneisses as younger than the rocks beneath them. He regarded the fossils as Lower Silurian, and therefore did not shrink from the apparently inevitable corollary that most of the crystalline rocks of the Scottish Highlands are post-Lower Silurian in age. This conclusion had a world-wide influence. Similar crystalline schists form vast regions in all the continents, and they were at first regarded as all pre-Palæozoic; but if the Scottish schists are altered Palæozoic sediments, then the similar rocks elsewhere may include rocks of any geological age. To this day vast regions of schists and gneisses are mapped as altered Silurian, in consequence of Murchison's work on the north-west Highlands.

Murchison's views were at once opposed. The common-sense judgment of James Nicol showed him the improbability of Murchison's conclusions, and his keen and careful field-work revealed that the superimposing of schists over sediments was not an original arrangement, but was due to subsequent earth movements. The first controversy was short. Nicol's inter-

[1] Memoirs of the Geological Survey of Great Britain. The Geological Structure of the North-west Highlands of Scotland. By B. N. Peach, John Horne, the late W. Gunn, C. T. Clough and L. Hinxman, with Petrological Chapters and Notes by J. J. H. Teall. Edited by Sir A. Geikie. Pp. xviii+668: plates lii., map. (Glasgow: H.M. Stationery Office, 1907.) Price 10*s*. 6*d*.

pretation of the evidence had not the fascinating simplicity of the other theory, and it was not wholly right. The eastern and western gneisses are not simply repetitions of the same series, and Murchison was apparently right in his view that the upper gneisses and schists are an independent and younger series than the Lewisian gneisses, which underlie the Cambrian band to the west. Moreover, Nicol failed to realise that the apparent bedding planes in the eastern gneisses were not original, but secondary structures due to earth movements.

Murchison, with a theory attractive by its charming simplicity and far-reaching results, and right in his recognition of the essential differences between the eastern and western gneisses, swept his critic from the field. Nicol, disheartened by the fate of views Nicol's researches" (p. 23), was not enough, although it was supported by the work of Callaway and Hudleston. In 1882–3 Prof. Lapworth mapped in detail the classic sections on the shores of Loch Eriboll; he proved that the apparent sequence was deceptive, and that the eastern gneisses were older than the fossiliferous rocks, and had been placed above them by earth movements; and it was his crowning glory to recognise that many of the fine-grained, shale-like rocks, which look like comparatively unaltered sediments, are the most intensely altered rocks of the area; they consist, like ordinary shales, of fragments of primary rocks, but instead of having been formed by the usual agents of denudation and deposition, they are due to crushing along planes of earth movement.

Unconformability of Cambrian quartzites on Torridon sandstone. Loch Coire Mhic Fhearchair, Beinn Eighe, Ross-shire. Reproduced with the authority of the Controller of H.M. Stationery Office.

which he knew to be essentially correct, practically gave up geological research, and went to his grave, his geology despised and his conclusions rejected—by all except his wife. In 1878, the year before Nicol's death, the controversy was re-opened by that geological knight-errant, Dr. Hicks, who ran a tilt against the Murchisonian theory. It survived his onslaught, but two years later it received an almost fatal blow from Prof. Bonney, who, by work near Loch Maree, demonstrated that some of the rocks of the eastern series were the old Lewisian gneiss brought up by faults. The establishment of this fact, which is described in the memoir as "the first important advance towards the solution of the problem of the succession in the north-west Highlands since the publication of

The close of the controversy was now near at hand. In 1883 Sir Archibald Geikie arranged for the detailed mapping of the Loch Eriboll district by the Geological Survey. The work was soon found to be far more complex than had been expected; it was attacked with invincible patience and thoroughness by the surveyors under Peach and Horne; the essential conclusions of Nicol and Lapworth were confirmed, and it was promptly announced in NATURE that the Murchisonian theory must be abandoned. In 1888 a preliminary report on the Survey's investigations was published by the Geological Society, but it has taken another nineteen years to extend the survey along the whole of the overthrust line, and to prepare the materials for publication.

The work is of the highest geological importance, and in spite of its necessary descriptive details, every page contains observations of interest. The account of the Torridonian series, for example, describes the oldest considerable land surface known, and some traces of fossils in these pre-Cambrian rocks. The part of most interest is the account of the movements by which the eastern gneisses have been overthrust on to the younger rocks. The movements have taken place along a line more than 100 miles in length, and have carried the rocks in places for ten miles westward. The thrusting forward of these hard rock slices has produced a most intricate system of faults, and extreme changes in the rocks, some of the fresh structures, as in the pseudo-rhyolites, simulating those of igneous rocks. The extent of the metamorphism is one of the secondary questions of most interest. Its range appears to be very variable; in places the alteration is confined within very narrow limits; elsewhere it may extend to a mile from the plane of movement; but it never appears to be regional, and evidence is given that some of the schists had their present structures before the great disturbances. The problems connected with the eastern schists are handled with reserve, as there seem to be marked differences of opinion as to their age and origin; but on the main question, the relation of the schists to the fossiliferous rocks, the memoir, with its convincing combination of fulness of detail and clearness of exposition, leaves no room for doubt.

J. W. GREGORY.

THE TOTAL SOLAR ECLIPSE OF JANUARY 3, 1908.

THE first cablegram, containing news relating to the eclipse of January 3, observed by the parties stationed on Flint Island in the South Pacific, reached this country on Saturday last. The cable was from Mr. F. K. McClean, and was dispatched immediately on his arrival at Auckland, New Zealand. It read as follows:—"Partial success, fine morning, heavy rain several minutes until totality; first minute cloudy, remainder clear. Four corona results; none spectrum; bad plates; other observers not developed. Campbell reports success."

The above news is really very satisfactory, because it was anticipated by those at home that the weather conditions which generally prevailed at that time of the year would most probably prevent any observations at all being made. There is, however, no doubt that the parties were very fortunate, since, according to the above account, the clouds only just cleared from the neighbourhood of the sun in time.

Those who have been on like expeditions will be able to picture to themselves the anxiety which must have prevailed among the observers as totality was approaching. The heavy rain must have necessitated the covering up of all the instruments, more especially the silvered mirrors and object glasses. The clearing up, after totality had begun, must have created a condition of affairs which was probably not legislated for in the "rehearsals" which had no doubt been daily gone through.

The fact that the length of totality was of four minutes' duration gave probably sufficient time for all the instruments to be brought into use. It is hoped, therefore, that a very complete record has been obtained of the latter portion of totality, and, if this be so, then the term "partial success" may be changed to complete success.

With regard to actual results obtained little is known at present. The reason of this is that the development of the negatives secured was not completed on the island. Mr. McClean provided himself with a dark room on board the steamer he had chartered, so he may have developed his corona negatives on his way back to Auckland. According to his cable four of the plates he exposed were successful, but the words "bad plates" seem to suggest that the results he obtained were not so good as they might have been.

Reuter reports that the observations of the different parties at Flint Island and Samoa were, generally speaking, fairly successful, and mentions specially that the bolometric measurements of the heat of the corona made at Samoa were successfully made.

WILLIAM J. S. LOCKYER.

THE BRITISH SCIENCE GUILD.

THE second annual meeting of the British Science Guild was held on January 15 at the Mansion House, the Lord Mayor being in the chair. The large assembly of fellows and members, and the presence of distinguished representatives of many departments of intellectual activity and national interest, show that the Guild is strengthening and extending its influence over a wide field.

The report, which was adopted, referred to the missionary work of the Guild in educating the public in the following terms:—

The executive committee believes that in this direction the labours of the Guild are becoming more effective each year, and there is a gradually increasing volume of opinion chronicled or expressed in the daily and weekly Press in harmony with the main objects of the Guild.

For this result a large debt of gratitude is due to the president, Mr. Haldane, who has taken many opportunities of expressing and emphasising the views of the Guild before large audiences in connection with various educational institutions.

It is in the direction of primary education that the most rapid advance in public opinion has taken place, and on this the nation is to be congratulated, for it is on the proper education of the children that all future progress must ultimately depend. At the inaugural meeting of the Guild in 1905, the chairman of committees, in referring to the subject of education, pointed out that a complete education must be based upon things and thinking as well as words and memory, and that we want "one kind of education for everybody—the Best." Further, that no one should be stopped on his upward course save by his own incapacity; and that all impediments should be removed. These views are now being acted on in many places.

The Guild is not alone in pointing out that our great commercial competitors are those lands where there is the greatest number of complete and State-aided universities, and in which as a consequence "all the national activities are carried on in the full light of modern science by men who have received a complete training both in science and the humanities, in close touch with the Governments."

Some of the City livery companies have shown great interest in the work of the Guild. The Clothworkers' Company has made a donation of 100*l.* to the funds, and the Drapers' Company one of 105*l.* This evidence of the interest taken in the movement is very gratifying, and it is hoped that other City companies will similarly assist in furthering the objects of the Guild.

Numerous subjects have occupied the attention of the executive committee during the year, and several deputations to various Ministers of State have been arranged. Among questions thus dealt with may be mentioned the amendment of patent laws, the anthropometric survey of school children and adults, and the prevention of pollution of rivers. Deputations had also been planned to the Colonial Premiers and in connection with vivisection licences, but subsequent circumstances made these unnecessary.

In addition to this work of the executive committee, committees have been appointed by the Guild to deal with education, inexpensive apparatus in science teaching, agriculture, chemical industries, the Franco-British Exhibition, postal reform, and biological subjects.

The question of university endowments has received the earnest attention of the Guild; and the following considerations relating to it are stated in the report:—

The necessity for increased endowment has been, to a large extent, conceded, especially by the last Chancellor of the Exchequer, Mr. Austen Chamberlain. In 1904 the then endowment was increased, and a still greater increase was promised. But it was pointed out that, until the universities themselves had considered to what extent they were willing to come under inspection, it was difficult to deal with the question of still higher endowments.

The existence of large college endowments at Oxford and Cambridge places these universities in a different position from the rest, although the small endowments of the universities themselves are felt as strongly as in the other universities.

The Scotch universities, like Oxford and Cambridge, receive no Government assistance. The University Act of 1889 gave to the Scotch universities, not as a boon or gratuity, but as an absolute right, 42,000*l.* a year. This represented obligations which the Government had taken upon itself when it assumed possession of property which belonged to the universities, and which, had it remained to them, would have brought in a larger revenue. In 1892, 30,000*l.* a year was added; it was not a special grant from Government, but came entirely from the Scottish Local Taxation Fund, in which no other part of the kingdom had any concern. England might, had it pleased, have assigned a share of the English Local Taxation Fund to the universities, but she did not do so.

Whether or no it is desirable that a large proportion of the college funds at Oxford and Cambridge be applied to various branches of real university teaching and of post-graduate research is a matter on which members of the Guild might have much to say.

It is also hoped that in time the new universities will be provided with funds for the establishment of hostels, such as the Oxford and Cambridge colleges are to a large extent. This provision, however, may fairly be made in the case of the newer, as of the older foundations, by private munificence, and not by Government aid.

The ultimate aim should be State, municipal, and private endowment for all universities.

Universities supported entirely by municipalities are impracticable, as the influence of a university must extend over a large area, which will increase as its specialisation is proceeded with; this renders the application of local rates, and therefore local control alone, unfair and undesirable.

It is possible that the old English universities themselves would be among the first to welcome an inquiry which might consider the best way of placing matters on a more satisfactory footing.

In July the question of a Royal Commission on the older universities was brought forward in the House of Lords by the Bishop of Birmingham. Lord Crewe, in communicating to the House the decision of the Government, stated, "it is important for us, before arriving at a final conclusion, to know what the most thoughtful and the most competent opinion at both universities really demands, and we also must either inform ourselves or be informed exactly what the universities cannot do of their own motion, and for what purposes legislation would be required."

In consequence of this decision no further action has so far been taken by the executive committee.

After the meeting had been opened, Mr. Haldane, Secretary of State for War, and president of the Guild, gave an address to the members. For the subjoined report of his remarks, and of those made by Dr. T. H. Warren, vice-chancellor of the University of Oxford, we are indebted to the *Times* of January 16:—

Mr. Haldane said that the Guild was a body of people who had come together for the purpose of organising interest in science, an interest which had not been, as they thought, sufficiently great. It also aimed at assisting those who had scientific objects to accomplish to find the means of accomplishing them. They endeavoured to stimulate successive Governments. Governments were very apt not to be quite as scientific as everybody might desire, and the most perfect embodiment of the work of the Guild was when they got the two functions combined. For instance, the War Minister in this country was apt to take an easy-going view of organisation, but if the president of the Guild was always at his elbow to remind him that what he was doing was unworthy of one who was acquainted with the principles of the Guild, then something was gained, and if the two happened to be rolled up into one person physically who could divide himself spiritually into two, then they had an ideal combination. It was encouraging to see signs of progress everywhere in this country. Only that morning he had seen the announcement that Mr. Wills had offered the University College of Bristol 100,000*l.* if it was incorporated into a University of Bristol. This enterprise would come within the range of the criticisms of those who complained of small universities, but the matter had been threshed out before the Privy Council when the question of the granting of a charter to the University of Liverpool came before it. The special committee of the Privy Council selected to give a judicial opinion on that question pronounced in favour of an increase in the number of universities in England. That policy had been carried out with the utmost success. An extraordinary development was going on just now in the direction of the application of science to industry. At Armstrong College, Newcastle, which was a part of the University of Durham, he found the other day a change which he could hardly have credited had he not witnessed it. In certain buildings there were organised the scientific foundations of the shipbuilding industry in a fashion which was beyond praise. The professors of mathematics, of engineering, of physics, of applied mechanics, of designing were all working with one purpose, which was to provide a school of the university type, for, among other people, those who were to be engaged in the practical business of shipbuilding. On the other hand, the shipbuilders on the Tyneside were sending up their young men in order that they might acquire knowledge of the principles of the construction of compound engines, and how to solve the thousand and one problems constantly coming up in the construction of a great liner. The effect of that was immense, not only in stimulating the interest in university work, but upon the great industries in the neighbourhood. He saw the same thing at Sheffield. Part of the university looked very much like a steelworks. There were places with great crucibles and all the apparatus for the purpose of casting steel. There were brawny workmen there, obviously come from the works, and students of the university were working with them and mastering that most important work of metallurgy. He did not suggest that they should bring down the university to the simple function of applying science to industry—far from it—but they would gladly see in our provincial centres, which the Universities of Oxford and Cambridge could not reach, facilities given which existed in other countries, but did not exist in our own country. He wished God-speed to the new enterprise, and he knew that his colleague in the Government, Mr. Birrell, who sat for the city of Bristol, was deeply interested, like himself, in the success of the movement. This year, moreover, the Government had in its programme the giving of teaching of a university type in an enlarged and extended degree to Ireland. Ireland had one great university, the University of Dublin, consisting of Trinity College, but they felt that, valuable as was the work and greatly to be reverenced which the University of Dublin had done, it could not provide for the needs of the Irish people, who suffered much from there being no outlook, no career for the talent of their young men, and particularly of the Catholic and middle classes. The Government had to provide education, not of a sectarian kind, but in an atmosphere which would not offend sectarian prejudices. The negative was a very different thing from the affirmative in that matter, and if that was attained he did not see why education could not be given to Belfast and Dublin, to the Presbyterians and Catholics of Ireland alike, an education of a university type which would not run athwart those feelings and considerations which obtained to so high a degree among the Irish people. That was a step in the direction of solving a very difficult problem which had embarrassed Governments before now and which might embarrass this one, but they hoped to try, and it was a sign of the times that they should try. In Scotland a step forward in the spirit of that guild had been taken very recently. They had brought the teachers into close relation with the Scottish universities. The training of those teachers used to be undertaken by the churches. It was no want of reverence or respect for the churches which led him, speaking from that platform, to say that in Scotland they preferred that the universities should train their teachers rather than that they should be trained in any denominational atmosphere, however excellent. He was not touching in the least on the question of denominational colleges. The university, after all, ought to be at the head of education, and to permeate downwards, and could not do that unless it trained the teachers for the work. It was not only in the direction of university teaching that the signs of the permeation of the new spirit were to be seen, and in the departments of the Government numerous little things had happened lately to show how progress was being made. In these days science was becoming more and more of moment in the race between nations. No industrial community could retain its place unless it had got the highest science at its disposal. If he were to adopt a motto for that guild, it would be the motto of a German trade association, which ran :—" Science is the golden guiding star of practice ; without science there can be only a blind groping about in the region of undefined possibilities." The change that had come over things in the last fifty or sixty years was immense. Without science no one could organise his business ; without science no nation could keep its place in the van. Therefore he said that one of the great responsibilities of a nation was not only to keep her knowledge in the minds of a few individuals abreast of the age, not only to produce her Kelvins and her Darwins, but to see that her science was disseminated, and that it had entered the minds and actuated the endeavours of her captains of industry generally. That was the creed of that guild, and that was the lesson which they had come together to endeavour to teach.

In moving the adoption of the report, the Vice-Chancellor of Oxford said that in the report they would find some remarks and some criticism, implied rather than developed, upon the older universities. Speaking for Oxford, he did not deprecate that criticism. He desired measures and large measures of reform in Oxford and her colleges. He did not agree with his friend the Bishop of Birmingham in invoking as a first step the interference of the State. He would like to see Oxford reform herself. But he fully recognised that when the Government had given her, as it had, this opportunity of doing so, if she failed to use that opportunity this Government, or any other Government, would have strong justification for stepping in and reforming her from outside. He wished to see reform both in her constitution and her curriculum, both in the colleges and the university. On what lines should that reform proceed? He would say on the lines indicated by the British Science Guild. They would find in the report a suggestion that college funds might be more largely used to aid the university. He believed they might, and he believed they ought to be more largely used in this way. But they would find also a recommendation that the new universities should be provided with funds to establish hostels such as the colleges at Oxford and Cambridge very largely were. He took it that the British Science Guild did not want to abolish the colleges. He certainly thought that would be a pity. Hostels they were, but they were something more than hostels. Some would say they were only glorified hostels. He would say they were glorious hostels. Trinity College and King's College at Cambridge and Christ Church and New College and Magdalen at Oxford—he thought all who knew them would agree that they merited that description, and that their glory was part of the educating influence and the attracting spell of the older universities, that they were an academic, aye ! and a national asset which it would be folly to throw away or destroy. In the appendix to the report there were some remarks about the tardy and sluggish response on behalf of the private benefactor to the appeal of the University of Cambridge, to the unattractiveness of the universities generally to the benefactor. To bring that appendix up to date mention should be made of a new fact. The president had brought the report up to date by referring to the splendid gift that was announced in the *Times* of that morning, the gift that one of the heads of a great and generous family in the ancient city of Bristol had made to its college. Might he, as an old Bristolian, ask them to send their thanks to that generous family which had already done so much for that city, and had now come forward with this benefaction? He remembered the famous motto in which Bob Lowe suggested that money might be made out of matches—*ex luce lucellum*. He thought the Wills family had taken a better motto. Theirs seemed to be *ex fumo dare lucem*. They had all read, a few weeks ago, of the magnificent bequest left by Sir W. Pearce to the Royal and religious foundation of Trinity College, Cambridge—money made, by the way, in applied science ; it was enough to make, and he believed made, mouths water, not only in the University of Cambridge, but in the other colleges of Cambridge, and in some colleges in Oxford too. For his part he welcomed that bequest. He congratulated his old friends of Trinity College. It was a great example. If Trinity used it well, and he believed the college of Newton and Clerk Maxwell, and Macaulay and Tennyson, would use it well for the public benefit of the university, not for any self-aggrandisement, it would be a greater example still, and might well prove contagious. He thought that college funds should be used much more largely for the university, and that the college should be brought into closer and more responsible relation with the university. He thought, too, that the university needed reform in its curriculum. If there was anything about which he had been persistently keen all through his academic course it had been the desire to introduce science into the regular and compulsory curriculum of Oxford, to ensure that everyone who took the ordinary degree should at least know what science and the scientific attitude of mind were like. But he did not want literature excluded. The ideal was, he thought, that all literary men should be scientific and scientific men literary. The highest ideal, to his mind, would be that Oxford scientific men should know Greek, for Greek literature was the most educating literature, and the Greek language the finest language that an Englishman could study. But he was afraid that was not practicable, and if they were not to know Greek, they should know our own splendid literature, the next in fertility and force to that of Greece. They should know, too, the lucidity of French and the philosophy of German. If they could not study Sophocles and Plato, let them at least study Bacon and Pascal, Goethe and Tennyson.

Sir A. Geikie, K.C.B., Sec.R.S., in seconding the motion, remarked that one great function of the Guild is to lose no opportunity of saying a word in season and out of season to educate the Government and the people to realise that, unless we have a scientific spirit and method, we cannot compete with nations which are working in that spirit and by that method.

After the adoption of the report, the following vice-presidents were appointed upon the proposal of Sir William Bousfield, seconded by Sir John Rhys :—Lord Curzon, the Rev. the Hon. E. Lyttelton, Lord Iveagh, and the Prime Ministers of Australia, Cape Colony, New Zealand, and Natal.

Sir E. Busk moved, and Mr. F. Verney, M.P., seconded, a resolution, which was carried, approving of the members of the executive committee. Prof. R. Meldola, F.R.S., then moved a vote of thanks to the

Lord Mayor, and in the course of his remarks referred to the attitude of science toward the public and of the public toward science; he pointed out that although there are branches of science which cannot be popularised, the practical results can be described.

The vote of thanks was heartily accorded, and the Lord Mayor having briefly acknowledged it, the meeting dispersed. The following telegram was dispatched to the Lord Mayor of Bristol:—

"Lord Mayor of London, on behalf of British Science Guild at annual meeting, sends warm congratulations to Lord Mayor and city of Bristol on generous munificence of Mr. Wills to Bristol University College, and hopes soon to welcome University of Bristol."

The following reply was subsequently received from the Lord Mayor of Bristol:—

"On behalf of my fellow-citizens and myself I beg to thank your lordship and the British Science Guild for your warm congratulations on the munificent promise towards the endowment of a Bristol University by our fellow-citizen, Mr. Harry Overton Wills."

J. MACFARLANE GRAY.

We regret to announce the death of Mr. John Macfarlane Gray on January 14, at his residence in Edinburgh, in his seventy-sixth year. Mr. Gray had a varied experience as an engineer, and was for many years chief examiner for marine engineers at the Board of Trade. The work which first brought him into prominence was his invention in 1866 of the steam steering gear which was first applied to the *Great Eastern*. The results led eventually to the general adoption of the system. Mr. Gray contributed numerous important papers to the various institutions to which he belonged, and frequently took part in discussions at the meetings, his contributions being characterised by pawky humour and sound knowledge of the subject. His contributions to scientific knowledge were for a time curtailed by the action of the Board of Trade, who, on the ground that the individual opinion of any of their engineering officers must not be made public, refused him permission to discuss the report of a research committee of the Institution of Mechanical Engineers. Fortunately he had previously been able to publish the results of his important investigation of the Theta-Phi diagram.

The most valuable of Mr. Gray's papers were probably those on the theoretical duty of heat in the steam engine (Institution of Naval Architects, 1885); the ether pressure theory of thermodynamics applied to steam (*ibid.*, 1889); the rationalisation of Regnault's experiments on steam (Institution of Mechanical Engineers, 1889, and Royal Society, 1900); and the variable and absolute specific heats of water (Institution of Civil Engineers, 1901).

Mr. Gray was a member of the Institution of Mechanical Engineers. He was a vice-president of the Institution of Naval Architects, and vice-president of the Institution of Marine Engineers from its inception. Of humble origin, he was essentially a self-trained engineer, and his early training undoubtedly influenced his attitude towards scientific research, his independence of judgment being specially noticeable. His seventy-six years show a record of useful activity, and he may be said to have created a field of investigation for younger engineers, who have fully recognised the influence of his guidance. An excellent portrait of Mr. Gray accompanies the lengthy biography published in *Engineering* of January 17, from which source these brief particulars have been drawn.

NOTES.

We regret to see the announcement of the death, on January 4, of Prof. C. A. Young, for many years professor of astronomy at Princeton University, at the age of seventy-three.

Dr. Feodor Černyshev, St. Petersburg, has been elected a foreign correspondent of the Geological Society of London.

Prof. Reginald W. Brock, professor of geology in the Queen's University, Kingston, has been appointed director of the Geological Survey of Canada.

At the annual meeting of the Royal Meteorological Society on January 15, the Symons memorial gold medal was presented to M. Leon Teisserenc de Bort, of Paris, "in consideration of the distinguished work which he has done in connection with meteorological science, especially the study of the upper air."

The freedom of the city of Glasgow was conferred upon Lord Lister on Tuesday at a large and representative meeting of citizens, over which the Lord Provost, Sir William Bilsland, presided. In making the presentation, the Lord Provost recalled Lord Lister's connection with the city while professor of surgery at the University and visiting surgeon at the Royal Infirmary, where he achieved world-wide distinction as an investigator and a surgeon by discovering and perfecting the antiseptic system of treating wounds, which marked a new epoch in modern surgery. Lord Lister was unable to be present at the meeting owing to his condition of health, but a letter was read from him in which he said:—"Having in due time been elected by the managers of the Royal Infirmary as surgeon to that institution, I experienced uniform consideration at their hands when applying to the treatment of wounds the great truth which had been recently revealed by the illustrious Pasteur regarding the nature of fermentative changes in organic substance. That truth, though it seemed to me to shine clear as daylight from Pasteur's writings, was for many years not generally recognised, and thus it was my privilege to witness in my own practice, as the application of the principle became greatly improved, the revelation of pathological truths of fundamental importance and a revolution in practical surgery, and I looked upon the years spent in your city as the happiest period in my life."

On Tuesday next, January 28, Prof. F. J. Haverfield will deliver the first of two lectures at the Royal Institution on Roman Britain. The Friday evening discourse on January 31 will be delivered by Prof. Rutherford, on recent researches on radio-activity, and on February 14 by Dr. C. W. Saleeby, on biology and history. The discourse on March 13 will be delivered by Signor G. Marconi, his subject being Transatlantic wireless telegraphy.

At the annual meeting of the Entomological Society on January 15, the following fellows were elected as officers and to serve on the council for the session 1908–9:—*President*, Mr. C. O. Waterhouse; *treasurer*, Mr. A. H. Jones; *secretaries*, Mr. H. Rowland-Brown and Commander J. J. Walker; *librarian*, Mr. G. C. Champion; *other members of the council*, Dr. T. A. Chapman, Mr. A. J. Chitty, Mr. A. Harrison, Mr. W. J. Kaye, Dr. G. B. Longstaff, Mr. H. Main, Mr. G. A. K. Marshall, Prof. R. Meldola, F.R.S., Prof. L. C. Miall, F.R.S., Prof. E. B. Poulton, F.R.S., Mr. R. Shelford, and Mr. G. H. Verrall. The president read his address, which dealt chiefly with the present unsatisfactory state of nomenclature in entomological science. He also advocated the establishment of a central "type" museum, on the lines of an experimental collection now formed at South Kensington, for the purpose of loaning specimens to institutions, whereby it was suggested that the existing confusion might be avoided, and the general work of identification made easier.

AT a meeting of friends of the late John Samuel Budgett held in Cambridge on February 8, 1904, it was decided to perpetuate his memory by the publication of a memorial volume which should contain reprints of his various zoological papers, together with descriptions of the more important material brought back by him on his various expeditions. The syndics of the Cambridge University Press undertook the responsibilities of publication, the necessary expenses of illustration being met by a fund subscribed by Budgett's friends. The volume has been edited by Prof. Graham Kerr, and Mr. A. E. Shipley, honorary treasurer of the fund, has contributed a biographical sketch. The preparation of the volume has taken a considerable time, particularly the working through of the extensive embryological material of Gymnarchus and Polypterus so as to make it possible to give a fairly complete sketch of the development of these forms.

WE regret to announce the death of Dr. H. G. Knaggs in his seventy-sixth year. Though little known to the present generation of entomologists, his name deserves to be honoured as that of one of the founders of the *Entomologists' Monthly Magazine* in 1864. At that time he possessed one of the finest collections of British Lepidoptera in existence, but ten years later he found that his professional engagements required all his attention, so he sold his collection and withdrew from the staff of the magazine, to which, however, he continued to contribute occasionally up to July, 1906. He also published one or two small books and pamphlets, especially "The Lepidopterist's Guide," one of the most useful publications on the collection and preservation of these insects which we possess. It originally appeared in separate papers in the early volumes of the *Entomalogists' Monthly Magazine*, and was afterwards enlarged and published in book form, and has gone through several editions. Dr. Knaggs was born on March 21, 1832, in High Street, Camden Town, and was educated at University College School, and trained for the medical profession at University College Hospital. He practised as a medical man in Kentish Town and Camden Town until about ten years ago, when he retired in consequence of ill-health, and settled at Folkestone, where he died after a long and painful illness on January 16. His remains were interred in Highgate Cemetery on January 20, in the presence of a small company of relatives and friends.

Nos. 5 and 7 of vol. li. of the Bulletin of the Museum of Comparative Zoology at Harvard College are devoted to echinoderms. In the former, Messrs. A. Alexander and H. L. Clark describe the echinuses collected during the cruise of the *Albatross* in the North Pacific. In the latter, Mr. Clark publishes a revision of the Cydaris group, with a full account of the intricate questions connected with nomenclature.

THE "waltzing instinct" in ostriches forms the subject of an article by Dr. J. E. Duerden in the Journal of the South African Ornithologists' Union for December, 1907. Ostriches, it appears, are in the habit of running off suddenly with a peculiar whirling movement, sometimes one way, sometimes another, simultaneously spreading their wings, which are alternately raised and depressed. These movements, the author suggests, may be connected with escape from the clutches of the large Carnivora. "Indulged in instinctively as play while young, and even when adult, the performance gives the bird expertness in the rapid jerking movements which are those first followed on alarm."

THE use of chrysanthemum powder as a means of destroying mosquitoes in houses is strongly recommended by Dr. A. L. Herrera, of Mexico City, in a paper published in the Proceedings of the nineteenth annual meeting of the Association of American Economic Entomologists (U.S. Department of Agriculture, Entomological Bulletin No. 67). Care has to be exercised in order to avoid the production of throat-inflammation in the operator, and also against ignition, but if proper precautions are taken in these respects, the powder seems to produce most satisfactory results. The consumption of the powder has largely increased during the last year, while the sale of tablets, which only paralyse the insects, and at the same time give off noxious fumes, has shown a corresponding decrease.

AN interesting addition to the exhibition galleries of the British Museum (Natural History) has been made in the shape of a copy of a water-colour drawing made about 1585 by John White, containing the earliest known representation of the American king-crab, *Limulus polyphemus.* John White, who was one of the first settlers in Virginia, of which he was for some time Governor, served as lieutenant to Sir Walter Raleigh. In three volumes of drawings by him preserved in the department of prints and drawings in the British Museum, many of the delineations of natural objects are of great beauty, and show a fidelity to nature rare at the period. The drawing in which the king-crab is depicted was engraved, with some modifications, for de Bry's "America" ("Grands Voyages," part i., pl. 13) in 1590. In the engraving the king-crab is, however, shown in somewhat greater detail, thus suggesting that the engraver had an actual specimen or another drawing from which to copy.

IT is encouraging to find Dr. Whitehead, Bishop of Madras, giving an example to other missionaries of the true method of dealing with the beliefs of those non-Aryan tribes which offer the most promising field for Christian work in India. He is, we believe, a comparative stranger to the people of the south, and hence his essay lacks that intimate familiarity with these strange cults which is essential to one whose mission is to comprehend and refute them. But in his pamphlet on "The Village Deities of Southern India," recently published in Mr. Thurston's valuable series of Bulletins of the Madras Museum, he has collected much curious information hitherto inaccessible to English students. Although most of his facts appear to have been derived from Christian converts, his account of these strange beliefs seems as complete as is possible in the present state of our knowledge. He points out that these deities are usually female, are almost universally worshipped by animal sacrifice, and that their priests are not Brahmans, but drawn from the lower castes. He describes in detail the grosser modes of sacrifice, which he regards as not in the nature of gift or propitiation, but as methods of gaining communion with the deity. This study of the seamy side of Hinduism shows that this comprehensive faith is not, as is too commonly believed, a purely philosophical creed. His essay will be useful to ethnologists as a study of the lower beliefs of a pagan polytheism, which, crude and monstrous as some of its practices are, is still on a higher level than the foul Sákta worship current in Bengal, to which it presents many obvious analogies.

In the *Times* of January 17, Dr. H. R. Mill gives an interesting statement of the rainfall of the British Isles during the past year, compiled from a preliminary examination of the large mass of material so far received from the observers of the British Rainfall Organisation. It shows that, for the United Kingdom generally, the year 1907 was not a wet one, despite the popular belief, but that, in fact, the rainfall was very close to the average of thirty years (1870–1899). Expressing the amounts in percentages, the following provisional values are obtained:—

General Rainfall in 1907. *Average* = 100.

England (South)	Wales	England (North)	Scotland	Ireland	British Isles
99	101	97	106	102	101

The most prominent features were the very wet three months of spring and early summer, and the extremely dry September; this month scarcely yielded a quarter of its average rainfall in England and Wales, and less than a third fur the British Isles as a whole. In London (Camden Square) the annual fall was 23·01 inches, 8 per cent. below, and the number of rain-days 9 per cent. above, the average of fifty years (1858–1907). Dr. Mill states that the large number of rain-days, combined with the unusually low temperature of the summer, quite account for the general impression that last year was very wet in London.

In *Mitteilungen aus den deutschen Schutzgebieten* (vol. xx., part iii.) there is an important discussion of the climate of Swakopmund by A. Gülland, based on observations for the years 1899–1905. Swakopmund lies in 22° 42′ S. lat., on the west coast of the German South-West African Protectorate.

A paper on the fruits and seedlings of *Rhus succedanea*, contributed by Mr. S. Tabata to the Journal of the College of Science, Tokio (vol. xxiii., article 1), furnishes a brief account of a microchemical examination of the substances found in the fruits. The fruits are the source of the fat or tallow that enters into commerce as Japan wax. The fat is present in all parts, but only assumes a waxy consistence in the mesocarp. Before germination of the seeds, the cotyledons contain fat, magnesia, and proteins in considerable quantity, but no starch. Starch is formed during germination at the expense of these substances.

An article on the absorption spectrum of protochlorophyll is communicated to the *Bulletin du Jardin impérial botanique*, St. Petersburg (vol. vii., part ii.), by Mr. N. A. Monteverde. An alcoholic solution of the colouring matters prepared from the leaves of etiolated oats and wheat plants provided the protochlorophyll and accessory yellow pigments. Five bands were observed in the absorption spectrum, of which one in the blue is attributed to the yellow pigments, and the other four, in the orange, yellow, green, and blue, are referred to the protochlorophyll.

The first of a series of papers by Dr. L. Cockayne dealing with the coastal vegetation of the South Island of New Zealand is published in the Transactions of the New Zealand Institute, vol. xxxix. In this part the author presents a general sketch of the coastal plant covering. Although the saline nature of the soil and the strong winds are recognised as potent factors influencing distribution, the opinion is expressed that the coastal plants as a whole occupy their peculiar station, not from choice, but from necessity, having been driven out of more favourable situations by better equipped competitors. The vegetation of the South Island below the parallel of 42° S. bears the impress of a subantarctic origin in some of the coastal formations, whereas in the North Island a subtropical element is more characteristic. Of ninety-four species enumerated, more than half are endemic and thirteen are subantarctic.

Under the title of "Heredity and Forestry," Prof. W. Somerville discusses in the Transactions of the Royal Scottish Arboricultural Society (vol. xxi., part i.) an interesting matter with regard to the results obtained by sowing seed of forest trees from different localities. Comparative experiments in Switzerland have shown that plants raised from the seed of the common spruce grown at a high elevation, *e.g.* 6000 feet, make much slower growth than plants raised from seed grown at a lower elevation, *e.g.* 2000 feet. Similar results have been recorded for spruce in Austria. Other characters, such as the weight of the seed, length of growing period, and possibly tendency to disease, appear to vary with the situation of the trees from which seed is taken. It becomes, therefore, important to obtain seeds for afforestation purposes from a locality similar to that in which the plantation will be made. The conclusions appertaining to the spruce do not necessarily apply to other trees, such as the Scots pine, for which data are not available.

Mr. Drysdale Turner contributes to the December (1907) number of the *Agricultural Students' Gazette*—the organ of the Royal Agricultural College, Cirencester—an interesting summary of the life-history of the warble-flies *Hypoderma lineata* and *H. bovis*. Considerable losses are caused by the ravages of this insect in Great Britain, and farmers and stock-keepers are fully alive to the necessity of keeping it in check. *H. lineata* resembles a bee in appearance, and can be seen from the middle of May to the beginning of September. It attaches its eggs to the hair on the various parts of the bodies of cattle, particularly the legs, just above the hoofs. The animal licks the place where the eggs are deposited, and the larvæ are carried by the tongue into the mouth and to the gullet, through the walls of which they pass, and eventually lie just under the skin on the animal's back; the developed maggots finally work their way out of the skin about June, and fall to the ground, where they pupate. *H. bovis* probably has a similar history. Various remedial measures are quoted, and in particular it is stated that the parish of Bunbury, in Cheshire, has been freed from the pest by systematically destroying the maggots. The same journal also contains a *résumé*, by Prof. Duncan, of the regulations that have been made from time to time concerning contagious diseases in animals.

The Journal of the Department of Agriculture of South Australia for November, 1907, contains an account of the wheat yield during the last decade, and the estimated yield for the present season. The figures are very striking; they are as follows:—1897–8, 2·64 bushels per acre; 1898–9, 4·91 bushels; 1899–1900, 4·64 bushels; 1900–1, 5·88 bushels; 1901–2, 4·60 bushels; 1902–3, 3·64 bushels; 1903–4, 7·72 bushels; 1904–5, 6·53 bushels; 1905–6, 11·46 bushels; 1906–7, 10·19 bushels. The fact that the last two seasons gave much higher yields than usual is attributed to the use of artificial manures and to timely rains. As the rainfall during the past twelve months is below the average, a yield of only 8·75 bushels is predicted for the present season. When we remember that the average wheat yield in Great Britain is 30·9 bushels, and the average of the yields of all other countries is 17·5 bushels, it would appear that there is considerable scope in South Australia for agricultural investigation, and that a strong scientific staff would prove a really sound investment.

In a paper on "ghost images" published in the Journal of the Royal Microscopical Society, clxxxi. (December, 1907), Mr. A. A. C. E. Merlin discusses the resolution of the images of a substage stop formed by the secondary markings of the diatom *Coscinodiscus asteromphalus*. The diameter of the secondaries was 1/83300th of an inch, and the images appeared well defined under a magnifying power of about 3200. In connection with this effect, the author discusses the advantage of high magnification, independently of the question of resolving power, and especially advocates the use of powerful eye-pieces in studying minute structures. While a structure may be equally well defined under a lower magnification, and may be visible when it is known to exist, the author considers that for the recognition and detection of unknown detail a powerful eye-piece is a necessary adjunct to a picked objective.

The Transactions of the Theosophical Congress for 1907 contain much matter that falls outside the range of "science" as included in the columns of Nature. There are two papers on the dimensions of space which form in some ways an exception to the above statement, and the writer of one of these, who does not publish his full name, gives some diagrams by which it is possible to construct models of projections of the simpler four-dimensional solids. The author, however, considers that the sections of the 600-cell and the 120-cell "become so complicated as not at present to be worth calculating," and on p. 258 he shows by his own statements that he is unaware of the work that has been done in "exhausting" the regular figures in space of higher dimensions than four. Indeed, he says:—"It seems to me quite possible that we might find that in a five- or six-dimensional world *no regular hypersolids at all were possible*." But a little thought can be made to show anyone with a small mathematical knowledge that the triangle-tetrahedron series, the square-cube series, and the octahedron series are capable of extension to space of any dimensions whatever.

The December (1907) number of the periodical of popular science, *Himmel und Erde*, published by the scientific society "Urania," of Berlin, contains an article on the microscopic structure of photographic films by Dr. W. Scheffer. It is illustrated by twenty-two reproductions of photomicrographs, which show how the nuclei of silver salt are affected by various modifications of the times of exposure, the method of development, and the use of intensifiers and of restrainers.

The December (1907) Bulletin of the Bureau of Standards contains the results of a long investigation on the Clark and Weston standard cells, by Messrs. F. A. Wolff and C. E. Waters. They conclude that the agreement between cells set up with different samples of mercurous sulphate prepared by any of the recognised methods, or by treatment of commercial sulphate with sulphuric acid, is highly satisfactory, and suggest that the standard cell should serve as one of the two fundamental electrical standards. It has been shown that the cells now constructed can be carried long distances without changes of electromotive force of more than a few parts in 100,000 being produced. It will be seen from this statement that the results obtained in America are in agreement with those found at the National Physical Laboratory and communicated to the Royal Society a few weeks ago.

An article on some of the present problems of radio-activity, by Dr. G. A. Blanc, appears in the December (1907) number of *Le Radium*. The author considers that Rutherford's disintegration theory is the explanation of radio-activity, and asks whether disintegration is not taking place in all forms of matter? After reviewing the evidence for the α particle being either half an atom of helium with a unit charge or an atom with a double charge, he comes to the conclusion that neither is satisfactorily established. Nor is the genealogical tree of the radio-active elements yet made out. Is it possible, he asks, that lead and silver, which are so intimately associated in nature, belong to this tree, and that one is the parent of the other? The amount of radium in the earth's crust is more than sufficient to maintain the temperature constant, and now he finds there is more thorium present than is necessary to supply the heat required. He is sanguine that some means will eventually be found which will allow us to stimulate radio-active disintegration, and thus obtain a source of energy the utility of which we can scarcely at present conceive.

The product of the world's gold mines for the year 1906 could be all packed in a room 10 feet square and 9 feet high, says Mr. T. F. Van Wagenen in an article on gold in the current number of the *Popular Science Monthly*. The value of this 90 cubic feet of gold was nearly eighty-one and a half millions sterling, and its weight nearly 674 tons. Very nearly one-third of this amount was obtained in South Africa, about one-fifth from Australasia, and nearly a quarter from the United States and Alaska. Eighty-three per cent. of the total output was secured by the Anglo-Saxon world. According to calculations and estimates made in 1900 by the director of the United States mint, the gold taken from the mines of the world since the discovery of America has amounted in quantity to about 21,424 tons, and in value to more than 2,520,000,000*l*. Nineteen per cent., or nearly one-fifth of the whole, has been mined in the last ten years, and 30 per cent. in the last twenty years.

Messrs. Samuel Bagster and Sons, Ltd., have published a fifth edition of Mr. W. T. Lynn's "Astronomy for the Young."

A second edition of Mr. George J. Gray's "A Bibliography of the Works of Sir Isaac Newton, together with a List of Books illustrating his Works," has been published by Messrs. Bowes and Bowes, of Cambridge. The work has been revised and enlarged, and many important additions have been made.

The first volume of the sixth edition of A. Wüllner's "Lehrbuch der Experimentalphysik," dealing with general physics and sound, has just been received from Mr. B. G. Teubner, Leipzig. The volume contains more than a thousand pages, about seven hundred of which are concerned with the general properties of matter, while the remainder deal with wave motion and sound. The price of this elaborate treatise on the fundamentals of physics is sixteen marks.

The "International Geography," edited by Dr. H. R. Mill, and written by seventy authors, with special knowledge of the subjects on which they contribute articles, has been re-published by Messrs. Macmillan and Co., Ltd. The work is now issued, not only in one complete volume, but also in parts. The sections dealing respectively with the British Isles, Europe, Asia, Australasia, North America, South America, and Africa can be obtained separately. The parts each contain a selection of original questions and exercises, and a miscellany of questions set in various public examinations, and they should prove of great service in the higher classes of schools.

OUR ASTRONOMICAL COLUMN.

OBSERVATION OF ENCKE'S COMET ON DECEMBER 25, 1907.—From No. 4226 of the *Astronomische Nachrichten* (p. 31, January 7) we learn that, having found Encke's comet on January 2, Prof. Wolf examined some earlier plates, and found an image of the comet on one taken at 7h. 20m. December 25, 1907 (Königstuhl M.T.). Its position at that time was R.A. = 22h. 57·4m., $\delta = +0^\circ\ 54'$, and its magnitude 13·0. Owing to its being near the edge of the plate, this image was overlooked at first. From this observation it appears that the recently published ephemeris (*Astronomische Nachrichten*, No. 4222) requires corrections of +2·4m. and $-24'$.

A NEWLY DISCOVERED BRIGHT MINOR PLANET (1908 B.M.).—A comparatively bright planet was discovered by Dr. Kopff at Heidelberg on January 4. Its position at 12h. 27·6m. (Königstuhl M.T.) was α = 7h. 33m. 48s., $\delta = +14^\circ\ 57'$, and its daily motion −1·4m. and $-20'$. The magnitude of this object was recorded as 9·2. Dr. Przybyllok observed the planet with the 12-inch refractor of the Astronomischen Institut on January 5, and found it to be equal in magnitude to B.D. + 14°.1717 (magnitude, 9·4) (*Astronomische Nachrichten*, No. 4226, p. 31, January 7).

MEASURES OF DOUBLE STARS.—In No. 4227 of the *Astronomische Nachrichten* (p. 33, January 8), Messrs. C. P. Olivier and R. E. Wilson publish the results of 420 observations of 116 double stars made at the Leander McCormick Observatory, University of Virginia, during the years 1904–7. Seven of the doubles in this list were discovered by Mr. Olivier, and are now published for the first time. Notes as to the probable motions of some of these doubles are appended to the paper.

EPHEMERIS FOR COMET 1907*e*.—A bi-daily ephemeris for comet 1907*e*, covering the period January 13 to February 22, is published in No. 4226 of the *Astronomische Nachrichten* by Herr M. Ebell. An observation by Dr. Wirtz, made at Strassburg on December 4, gave the magnitude as 12·7.

THE ABSORPTION OF D_3 (HELIUM) IN THE NEIGHBOURHOOD OF SUN-SPOTS.—In an article appearing in the *Observatory* (p. 51, No. 392, January), Father Cortie discusses some photographs of sun-spot spectra obtained by Mr. Nagaraja at the Kodaikánal Observatory last year. The special point of these photographs was that, with a spot near the limb of the sun, they are supposed to show the bright line at the limb and the dark absorption line in the region of the spot at the same time. Father Cortie's discussion tends to show that the dark line in question is, possibly, not coincident with D_3, and is perhaps the water-vapour absorption line at λ 5875·963. He has many times recorded lines attributed to water-vapour in the spectra of sun-spots, and suggests the possibility of the presence of superheated steam in sun-spots.

In regard to the recent suggestions that a permanent dark D_3 line occurs in the solar spectrum, Father Cortie points out that Mr. Higgs and he thoroughly investigated the question seventeen years ago, and concluded that there was no permanent dark line coincident with the bright D_3; since then no conclusive evidence has been adduced to lead him to alter that conclusion.

THE ORBIT OF THE SPECTROSCOPIC BINARY θ AQUILÆ.—No. 6, vol. i., of the Journal of the Royal Astronomical Society of Canada (p. 357, November–December, 1907) contains a preliminary set of elements for the orbit of the spectroscopic binary θ Aquilæ. This star has a photographic magnitude of 3·6, and its spectrum is of the type VII*a*. Mr. W. E. Harper, of the Dominion Observatory, Ottawa, who publishes the elements, finds that Deslandres's conjecture of a 16·8-day period and a high eccentricity is confirmed. The present elements give 17·17 days as the period, −26·7 km. per sec. as the velocity, 0·725 as the eccentricity, and 8,455,500 km. as the length of the semi-major axis of the orbit.

ECLIPSE OBSERVATIONS, AUGUST, 1905.—No. 15 of the *Bulletin de l'Académie Impériale des Sciences de St. Pétersbourg* contains M. Donitch's report of the results obtained by the expeditions dispatched by the academy to observe the eclipse of 1905. Two expeditions were organised, one going to Alcala de Chisvert (Spain), the other to Assouan. The object of the former was to study the chromosphere and corona, whilst the attention of the latter was chiefly devoted to observations of terrestrial magnetism. In the present paper M. Donitch, who directed the expedition to Spain, discusses the purely astronomical results. Photographs of the chromospheric spectrum were obtained, and the wave-lengths and origins of some 110 lines are given in tabular form. In addition to those of H, He, Ca, Sc, Ti, Cr, Fe, Sr, Yt, and Ba, there are indications of the presence of lines of Co, Zr, Eu, and, possibly, Ge in the spectrum. The depths of the layers of these various elements in the chromosphere were measured, those of hydrogen and calcium giving the highest numbers, 49,300 kilometres and 44,000 kilometres respectively. The dimensions of five prominences as shown in radiations of various wave-lengths are also given.

The photographs of the corona show it to have been of the "maximum" type, as one would expect in 1905. Reproductions from several of the photographs obtained accompany the paper.

We have also received a finely illustrated volume containing a full discussion of the results obtained by the astronomical section of the Observatory of Cartuja, Granada, Spain. In this work, published under the direction of P. José Mier y Terán, S.J., most of the questions and theories arising from eclipse observations are discussed at length, so that the volume, which is printed in Spanish, forms a useful reference work for future observers.

SCIENCE AT RECENT EDUCATIONAL CONFERENCES.

THERE is no ebb in the tide of educational congresses. On the contrary, the number of teachers' organisations increases year by year, the number holding annual meetings during the last month in London alone running well into double figures. Nor is there any falling off in the vigour of the individual associations; indeed, in the case of the London County Council Conference, large numbers were unable to gain admission owing to the crowded state of the hall. This particular conference brought together more than twelve hundred workers in education, the majority of whom were teachers in L.C.C. elementary and secondary schools and technical institutes. We propose to review this meeting and that of the Public Schools Science Masters' Association, but desire to preface a few remarks on the effect of the multiplication of societies for the furtherance of various branches of education.

The time has gone by when a schoolmaster was expected to be able to teach all the subjects of the curriculum. Improved methods of teaching have in every subject called for a greater mastery on the part of the teacher, so that just at present we appear to be saved from having a specialist for every subject in the curriculum solely by considerations of financial economy. The science master teaches nothing but science, and is apt to lose interest in, and to be out of touch with, other subjects, and, *mutatis mutandis*, this is true of the modern language master and of the others. Hence we find segregation of teachers into their respective associations, each dealing with its particular branch of study. The advantages of these independent meetings are not far to seek. If the discussion refers to the teaching of physics, for example, the whole audience may be assumed to have some expert knowledge and to be intimately concerned in arriving at a right judgment. The informal and social side of the meetings, not their least valuable function, may be easier to promote, because each feels that he can exchange views with his neighbour to their mutual profit. But there are drawbacks to this segregation. Nothing was more frequently insisted on during the debates of the Public Schools' Science Masters than the need for cooperation between the teachers of mathematics and physics. One speaker urged that nominees of the Public Schools' Science Masters' Association should confer with nominees of the Mathematical Association to promote this end. In our opinion, this proposal falls very short of what is required. It would be better to hold a joint general meeting of the two associations, which would be better calculated to lead to an appreciation on the part of individual members in each body of the aims and difficulties of their colleagues in the allied camp. It would be easy to suggest other joint meetings of associations which would be helpful just now. Sections of the British Association unite to discuss problems on their boundaries, and this with better effect than by joint committees. Moreover, the various sections of the British Association belong to one body, and the general public recognises the importance of conclusions carrying its imprimatur. Would not teachers have more public influence if the existing associations were federated? The specialising influence to which we have referred should not be allowed to become a narrowing influence, and to that end teachers should from time to time hear addresses from first-rate men on subjects outside their own branch. The influence of science is probably weakened at the present time by the confinement of all scientific subjects to a technical society or body of experts. Science was practically omitted from the agenda of all the educational conferences this winter, except of the two which we will now describe.

London County Council Conference.

The subjects dealt with fall under the four heads nature-study, commercial education, manual work, and pædogogic experiments, and we will omit all further reference to the second of these.

"The Place of Nature-study in the School Curriculum" was the title of the opening paper by Dr. Percy T. Nunn, and it would be difficult to imagine a better introduction than the philosophical exposition given by the vice-principal of the London Day Training College. The basis of Dr. Nunn's arguments was the principle that it is the business of the educator to cultivate groups of interests rather than to teach useful subjects. While recognising that nature-study could well contribute to the æsthetic side of the curriculum, it had clearly to be recognised on the whole as an integral part of the instruction in science. The science curriculum should be so thought out as to secure continuity of development in conformity with the characters which distinguished the successive levels of the scientific process. Of these levels or stages, the highest and latest was the stage of system pursued for its own sake, a stage scarcely reached at school by ordinary pupils. Before this was the utilitarian stage, in which the greater part of elementary science teaching should fall. The foundation should be the nature-study stage, in which "science is born of wonder." These stages were not separable by clear lines of demarcation, and it was a mistake to allow their continuity to be interrupted, as when topics introduced in the nature-study lessons were afterwards allowed to drop. In the case of rainfall, for instance, the first simple studies should lead through the investigation of dew-point to hygrometry, the measurement of vapour-pressure, and thence to the doctrine of the continuity between liquids and gases. Dr. Nunn stated, in conclusion, that science of the higher type could not be a completely healthy growth unless it sprang out of the foundation of nature-study. The papers which followed, on school excursions, and the use of the school museum, dealt with practical points in the management of these aids to teaching. Both authors and subsequent speakers emphasised the importance of observations being made under conditions as little artificial as possible. The superiority of open-air work was generally admitted, but, in addition to difficulties with regard to time and place, some speakers found obstacles in the regulations under which they worked.

The afternoon discussion was practically confined to the subject of botany teaching in girls' schools, Miss Lulham discussing the approach to the subject through nature-study, Miss Lilian Clarke describing the botanical laboratory and school gardens at Dulwich, and Miss von Wyss tackling the difficult problem of teaching large classes in elementary schools. Space does not permit us to enter into detail, so we must content ourselves with stating that each of these papers bristled with practical suggestions based on actual experience, and suited to ordinary conditions of work, where the pupils are many and the time circumscribed. We may remind our readers that a verbatim report of the conference will be issued by the County Council, and advise teachers working with strictly limited funds and a lack of cupboards and other fittings to study the very helpful recommendations made by Miss von Wyss. It is not surprising that, stimulated by her teaching, a natural history club could be started and be continued as an evening class after leaving school in a district which at first sight appeared unpromising. In passing, we may note that Miss Lulham pointed out the virtues of colt's-foot as a plant for all-the-year-round study by beginners, so we may bless as teachers the persistent weed which as gardeners we are disposed to ban. In the discussion the papers met with hearty approval, an inspector of secondary schools pointing out that many important girls' schools had given up botany after trying to teach the subject on wrong lines. There was general agreement that the study of botany became highly interesting and educative if the following conditions were fulfilled:—(1) the living plant must be studied; (2) the pupils must keep plants under observation for lengthened periods, making notes and diaries illustrated by their own sketches direct from nature; (3) the pupils must experiment; (4) the teacher must prepare the lessons very carefully, and then leave as much as possible to be done by the pupils themselves. The moral and æsthetic influences of the study of nature were not forgotten, and it was rightly pointed out that the teacher must not forget that plants are living and beautiful. Is it too much to hope that a love of nature may attract youngsters to healthier interests than those stimulated by the poor silly trash which is so much read?

Sir John Cockburn presided at the discussion on manual training, and pointed out its importance from the physiological standpoint. Motor instruction conformed to natural methods, and the moment these methods were departed from the work of the teacher became a distortion of what it should be. The brain could only be built up properly through the action of the muscles. Dr. Slaughter, late assistant to Dr. Stanley Hall, read a paper on the need of manual training in the lower standards, in which he insisted on the idea of training all classes for citizenship. Scientific investigation showed that the human body was no longer to be regarded as separate from the human mind, and that thought was truncated action. He based his hopes for the future of education on manual training, although present methods were open to serious criticism. Perhaps their greatest fault was that they aimed too much at the acquisition of technique, whereas such training should be in daily use for its adaptive educational value. It should mean more than hand training, should make use of drawing, and should give knowledge about geography, animals, and plants. Mr. J. C. Hudson gave an account of manual work in American elementary schools, some making it merely supplementary, whilst others use it as a means of correlating all subjects. Perhaps the underlying idea may be indicated by the substitution of the terms "expression work" and "associative activities" for the term "manual training." Mr. P. B. Ballard considered the position of manual work in Standards I. to IV. of the senior departments of English elementary schools. As the result of a recent inquiry, he obtained replies from 120 educational authorities, which showed that only sixteen authorities adopted a systematic course of hand-work. As regards London, courses in brush-work, clay-modelling, &c., were rare, except in the special schools for the mentally and physically defective, so that in the matter of motor training the lost sheep was looked after and the ninety and nine forgotten. Mr. Ballard proceeded to advocate the application of hand-work to ordinary school subjects, and gave a series of illustrations of his ideas as applied to arithmetic, geography, and history. He wished to bridge the gap at present existing between the kindergarten occupations of the infants' department and the manual and domestic work of the senior standards.

During the sitting devoted to educational experiments in elementary schools, a paper was read by Mr. H. J. Hazlitt, in which the author described in detail how he had been conducting classes in open-air geography. By making previous provision of home-made survey maps and notes, the class was able to take an enlightened interest in an excursion to Crowhurst. Open-air work gives a genuine foundation to the study of geography, and thereby that essential factor, the map, can be properly understood.

Public Schools' Science Masters' Association.

The salient features of the annual meeting, held at Westminster School on January 14, were:—(1) the address from Prof. H. A. Miers, F.R.S.; (2) the instructive exhibition of apparatus; (3) the discussion on the position of mechanics in the physics course; (4) the repeated expression of the need for cooperation between the masters responsible for mathematics and physics respectively.

Prof. Miers took as his subject the order in which scientific ideas should be presented. He deprecated any rigid division of science into subjects, and believed that harm had resulted from attempts to keep mathematics, physics, and chemistry apart from each other, and to confine them to separate teachers. He desired to leave freedom to the individual teacher as regards method, but felt that as regards order there should be more system in our science teaching. In other subjects there was an advantage in having a recognised order based upon prolonged experience, and science should stand upon the same level as languages and mathematics in our schools, and should form an integral part of any liberal education. It was not easy to find out at the moment what the pupil understood of the instruction, and where he had succeeded in analysing the difficulty of a pupil he generally discovered that he himself was at fault in having presented ideas in the wrong order, and assumed something which was not yet familiar to the pupil. He found a useful guide to the proper order in the succession in which the ideas of a science had been developed in its past history.

Prof. Miers advocated nature-study in the wide sense; the boy should be taught to notice the ordinary objects and events of his own world, and to draw scientific nourishment therefrom, including in his intelligent observation all that was going on around, and not merely the processes of nature familiar in country life. If only the ordinary boy could get into his head the notion that science was the intelligent study of ordinary things, he would cease to regard it as a mere educational task. It was unwise, if not impossible, to teach chemistry and physics as independent subjects. In the preparatory school the boy should be trained in observational work, which would impart information useful in the experimental science that was to come next. The systematic teaching at a public school should from the outset be experimental, and the spirit of inquiry should be cultivated, and scientific dogmatism guarded against.

Coming to the university teaching of science, we had now to deal with mature minds, and the spirit of research should absolutely dominate the teaching. There was nothing better for encouraging research than natural history, which was admirably suited for advanced study at the university. Original papers were more stimulating than text-books, and there is need for an English series reproducing the original researches of highest importance, perhaps with the translation of archaic expressions into modern equivalents. Lectures should follow the historical order, laboratory work the method of research.

Prof. Armstrong felt it to be a deplorable fact that science had lost ground in public estimation. We felt the absence of Huxley and Playfair, and it rested with the public schools to carry the banner forward. The Davy-Faraday laboratory had, with one exception, failed to attract the gilded youth, fired with enthusiasm for science by their work in public schools. We must teach so as to excite more interest, so as to make that interest more continuous and permanent, and so as to cultivate, not powers of observation only, but the faculty of keen, intelligent criticism also. He held that Germany had achieved her position owing to the cultivation of originality by her universities.

The other papers read during the meeting were:—(1) the educational value of mechanics, by Mr. C. F. Mott (Giggleswick); (2) the teaching of practical mathematics, by Mr. H. Wilkinson (Durham); (3) scheme for laboratory work in physics, by Mr. Cumming (Rugby); (4) a suitable physics curriculum for the first and second years, by Mr. W. E. Cross (Whitgift); (5) the compulsory teaching of elementary physics to junior forms, by Mr. J. M. Wadmore (Aldenham).
