In the course of the discussions, it was pointed out that there is a great leakage from schools of boys who are under the proper leaving age, and that such boys necessarily receive little scientific education. There was no lack of enthusiasm for science on the part of boys who fulfilled the course of instruction. The fact that boys were promoted in many schools without regard to their science work placed difficulties in the way, such as were met by re-arranging the schools in sets in the case of mathematics. The study of scientific mechanics might be postponed until boys had obtained some experience in general experimental physics; practical work in heat could be introduced earlier. Boys should be allowed to use modern electrical plant, such as the cheaper voltmeters and ammeters now available through being put on the market for motorists. Mr. Cross advocated the abandonment of the usual exercises in mensuration and Archimedes's principle, and the substitution of a course of experimental construction of working cranes, &c. He would devote the first two years to such work, which stimulates interest and leads to a grasp of principles, *e.g.* the inquiry into the transmission of power by belts leads to true notions about energy and friction. It is a pity that there was little criticism of this interesting and unorthodox paper, for there is no doubt that most boys want to know "how it works"; moreover, the course which Mr. Cross outlined can readily fulfil Prof. Miers's requirement that the application of the instruction to everyday life should be straightforward. The relative merits of working collectively or individually in the laboratory were discussed, and Mr. Cumming claimed that the former system proved successful at Rugby. In summing up the discussion, Prof. Miers remarked upon the extreme diversity of methods adopted in different schools.

The exhibition of apparatus attracted well-deserved attention. Several dealers in apparatus, and some of the leading publishers, sent extensive exhibits, but the most gratifying, and in many respects the most instructive part of the exhibition was the ingenuity of the home-made contrivances sent from a good number of schools. We must congratulate and thank those responsible, and particularly Mr. D. J. P. Berridge, to whose organisation much of the success of this feature of the meeting was due. There were so many items of interest that it is impossible to describe them all, and it seems invidious to select. On the score of daring simplicity, we may perhaps award the palm to a motor armature shown by Mr. C. J. L. Wagstaff, which consisted of a bottle-cork, a few turns of insulated wire, and a dozen pins. Dr. T. J. Baker reached the acme of simplicity in his supports for prisms, lenses, &c. These were mounted by being stuck in their appropriate positions into lumps of plasticine—*voilà tout*! We would suggest to the management the advisability of printing a large number of copies of the catalogue; they might be put on sale; in any case their wider diffusion would help to improve experimental teaching by simple apparatus of homely invention and make.

G. F. Daniell.

THE INTERDEPENDENCE OF MEDICINE AND OTHER SCIENCES.[1]

An historical sketch, necessarily brief and inadequate, of some of the principal phases in the reciprocal relations between medicine and the physical sciences, up to the time when the latter became fully independent at the close of the seventeenth century, will show with what propriety medicine has been called the "mother of the sciences."

Physical science has derived from the Greeks no such extensive records of sound observation and experience as those which medicine has inherited from the writings of Hippocrates and his followers. Physical theories embodied in the speculations of the nature-philosophers concerning the constitution and properties of matter furnished the

[1] From an address delivered by Dr. W. H. Welch, professor of pathology, Johns Hopkins University, Baltimore, as the retiring president of the American Association for the Advancement of Science, at Chicago, December 30, 1907.

starting point for the Hippocratic doctrine of the four humours and other generalisations, but these theories sat so lightly upon Hippocrates that his name is attached to that method of medical study which rejects dogma, authority, and speculation, and confines itself to the observation and record of clinical facts. As Gomperz in his admirable work on the "Greek Thinkers" has clearly pointed out, the age of enlightenment in scientific thought was inaugurated by Hippocrates and his medical contemporaries.

The influence of physical theories upon medical thought in antiquity can be traced, not only in the humoral doctrines of Hippocrates and of Galen, but also in rival schools, and especially in the so-called methodic school founded upon the atomistic philosophy of Democritus, which is so interesting in the history of scientific theories. As this school produced such admirable physicians as Asclepiades, Soranus, and Aretæus, it is to be regretted that their solidistic pathology was so completely displaced by the authority of Galen.

The large body of medical knowledge and doctrine which had grown up during the six centuries since Hippocrates was further developed and fixed by Galen at the end of the second century after Christ into a system not less complete in its field, nor less satisfying to the minds of men for nearly fifteen centuries, nor scarcely less remarkable as a product of the human mind than the physical and philosophical systems of Aristotle. Within their respective spheres the system of doctrine of each of these great men has exerted a similar dominating influence upon human thought, and has met a similar fate through influences almost identical.

The great awakening of western Europe, marked by the revival of learning and the Reformation, stirred the long dormant spirit of inquiry and led to revolt against authority, a fresh outlook upon a wider world, the study of original sources, the questioning of nature at first hand, and the search for new knowledge in all her kingdoms. The seat of learning was transplanted from the cloisters to the universities, which multiplied and flourished in the sixteenth and seventeenth centuries as never before.

In the sixteenth century practically all the valuable contributions to botany and to zoology were made by physicians, so that natural history scarcely existed apart from medicine. Of the medical contributors to botany, it must suffice to mention the names of Brunfels, Fuchs, Dodoens, Gesner, and, above all, Cesalpinus, who has been called "the founder of modern scientific botany," the most important name before John Ray in the history of systematic botany, and a distinguished figure likewise in medical history. Of names associated with the history of zoology in this century, the most important are those of the physicians, Conrad Gesner, a marvel of encyclopædic learning, and Aldrovandi, who ranks with the founders of modern zoology and comparative anatomy; of lesser lights Edward Wotton may be singled out for mention as the pioneer English zoologist. He was doctor of medicine of Padua and of Oxford, president of the Royal College of Physicians, and physician to Henry VIII.

A name of the first rank in the history of science is that of the physician, Georg Agricola, who founded before the middle of the sixteenth century the science of mineralogy, and developed it to a state where it remained for nearly two hundred years without important additions.

The student of medical history who takes up a history of physics will probably be surprised to find how many of the contributors to the latter subject in the sixteenth century were physicians, and that among these are such old friends as Fernel and Fracastorius, whom he has identified so intimately with the annals of his profession. It is to be presumed that he already knew that the most famous of all, Copernicus, was a doctor of medicine of Padua, and practised the medical art gratuitously among the poor in Frauenburg.

Far more important for the subsequent history of science than any relations between medicine and physics at this period was the union between medicine and chemistry effected by Paracelsus, and strengthened by van Helmont and Sylvius in the following century, a union so intimate that for nearly a century and a quarter chemistry existed only as a part of medicine until freed by Robert Boyle from bonds which had become galling to both partners. The story of this iatro-chemical period, as it is called, has been told by Ernst von Meyer in his fascinating "History of Chemistry" in a way not less interesting to the student of medicine than to one of chemistry, and should be there read by both.

William Gilbert, second in importance only to Galileo among the creators of experimental science, the founder of the science of magnetism, and a significant name in the history of electricity, was fully identified with the medical profession, being the most distinguished English physician as well as man of science of his day, physician to both Queen Elizabeth and James I., and president of the Royal College of Physicians.

Galileo's younger contemporary, William Harvey, the discoverer of the circulation of the blood, occupies in the history of experimental science an independent position quite unlike that of the other experimental physiologists of the century. These other physicians, as Sanctorius, Borelli, Lower, Mayow, consciously took possession of the method of experiment as a powerful and newly discovered instrument of research, and were swayed in all their physiological work by the discoveries of the physicists. Not so Harvey, who was influenced but little by contemporary physical science, and is linked on, not to Galileo or to Gilbert, as exemplars of experimentation, but in a very direct way to the experimental physiologist, Galen, and to Aristotle, as well as to the Italian anatomists of the preceding century. Harvey's genuinely scientific mind was in greater sympathy with Aristotle than with the essentially unscientific Lord Bacon, who was his patient, and of whom he said, "He writes philosophy like a Lord Chancellor."

Descartes was an anatomist and physiologist as well as philosopher, mathematician, and physicist, and John Locke, the other great liberator of thought in this century, was educated in medicine, practised it, and, like Boyle, accompanied Sydenham on his rounds. Kepler studied the pulse, contributed to physiological optics, and calculated the orbits of the planets. Borelli was an important mathematician, physicist, and astronomer, as well as one of the greatest physiologists and physicians of the century. Bartholinus was also professor of mathematics as well as of medicine, and discovered the double refraction of Iceland spar. His even more remarkable pupil, Steno, left a name memorable in geology and palæontology, as well as in anatomy and physiology, and died a bishop of the Roman Catholic Church. Mariotte, a pure physicist, discovered the blind spot in the retina. Boyle anatomised, experimented on the circulation and respiration, started chemistry on new paths, and perpetuated his name in attachment to an important physical law. Hooke, most versatile of all, claimed priority for a host of discoveries, and did, in fact, explore nearly every branch of science with brilliant, though often inconclusive, results. Malpighi was an investigator equally great in vegetable and in animal anatomy and physiology, and what a glorious time it was for the microscopists, like Malpighi, Leeuwenhoek, Swammerdam and others, who could immortalise their names by turning the new instrument on a drop of muddy water, or blood, or other fluid, or a bit of animal and vegetable tissue!

After the seventeenth century in Europe the natural sciences, though often cultivated by those educated in medicine and practising it, were independent, and followed their own paths, which, however, communicated by many by-ways with the road of medicine and with each other.

Botany and zoology acquired their independent position probably more through the work of Ray and Willughby than by that of any other naturalist. Botany, however, remained for more than a century still mainly in the hands of physicians. An interesting chapter in its history is the story of the various apothecaries' and other botanical gardens established through the efforts of physicians, and conducted by them primarily for the study of the vegetable materia medica. From such beginnings has grown the Jardin des Plantes in Paris, started by two physicians, Herouard and la Brosse, in 1633, into the great museum of natural history made by Buffon, Cuvier and others, as famous for the study of zoology as by the de Jussieus and by Brongniart and his successors for botany. Less humble was the foundation of the British Museum and its appanage, the great Museum of Natural History in South Kensington, the gift to the nation of his valuable collections in natural history and other departments by Sir Hans Sloane, a leading London physician in the first half of the eighteenth century.

Aspects of my subject, full of interest, which I can now barely touch upon, are the influence of previous medical or biological training upon the work of a physicist or chemist, and closely connected with this the extent to which purely physical problems have been approached from the biological side. Call to mind how the central physical and chemical problem of the eighteenth century, the nature of combustion, was throughout this period intimately associated with the identical physiological problem of respiration, and how John Mayow in the seventeenth century, approaching the subject from the biological side, reached a conclusion in accord with that fully demonstrated a century later by Lavoisier, who thereby opened a new era for physiology as well as for chemistry. For the first time clear light was shed upon the function of respiration, the nature of metabolism, and the sources of animal heat, and such physical interest was attached to the study of these physiological phenomena that physicists of the rank of Laplace, in association with Lavoisier, Dulong, W. E. Weber, Magnus, A. C. Becquerel, Hirn, Regnault, and of course Helmholtz, have all made valuable contributions to the elucidation of these subjects.

The study of electricity, especially after the physiologist Galvani's epochal discovery, more correctly interpreted by Volta, engaged the attention of physicians and physiologists scarcely less than that of physicists. The latter became greatly interested in animal electricity, a subject partly cleared up by the physicists Ritter and Nobili, but mainly by the physiologist Du Bois Reymond.

There is no more striking illustration of the correlation of two apparently distinct lines of approach to the same problem than the attack from the biological and from the purely physical sides upon the thermodynamic problem, which is as fundamental for biology as for physics. The conception of the principle of conservation of energy was supplied independently and almost simultaneously, on the one hand, by students of the conditions of mechanical work done by the animal machine, and on the other by investigators of technical machines. Much of the essential preliminary study was on the biological side by Boyle, Mayow, Black, and Lavoisier. Mainly from the same side the physician and physicist, Thomas Young, first formulated the modern scientific conception of energy as the power of a material system to do work. Davy and Rumford contributed, and from the physiological side Mohr, Mayer, and Helmholtz, and from the purely physical side, after preliminary work by Poncelet and Sadi-Carnot, Joule, Thomson, and Clausius reached the same grand conception. The first to enunciate clearly and fully the doctrine of the conservation of energy and to measure the unit of mechanical work derived from heat was the physician J. R. Mayer. Joule's work completed the demonstration, but Mayer's name is deservedly attached to this principle by Poincaré and others, as Lavoisier's is to that of the conservation of mass, and Sadi-Carnot's to the principle of degradation of energy. As regards this last principle, it is almost as interesting to biologists as to physicists that in the so-called Brunonian movement, discovered by the physician and more eminent botanist Robert Brown, and the subject of interesting physical investigations in recent years, we behold an apparent exception to the principle of degradation of energy, such as Clerk Maxwell pictured as possible to the operations of his sorting demon.

I must forego further citation of examples of this kind of correlation between the work of physicists and of physiologists, and leave untouched the chemical side, which is much richer in similar illustrations. The significance to organic chemistry of the synthesis of urea by Wöhler, and to agricultural chemistry of the bacteriological studies of nitrification in the soil and fixation of nitrogen in plants, will perhaps indicate how large and fascinating a field I must pass by.

The light which has transformed the face of modern practical medicine came, in the first instance, not from a physician, but from a physicist and chemist, Pasteur. The field of bacteriological study thus disclosed was placed on a firm foundation and thrown open to ready exploration by Robert Koch, and thereby that class of diseases most important to the human race, the infectious, became subject in ever-increasing measure to control by man. Thus hygiene and preventive medicine, through their power to check the incalculable waste of human life and health and activities, have come into relations, which have only begun to be appreciated, with educational, political, economic, and other social sciences and conditions, and with the administration of national, State, and municipal governments. It is an especial gratification to record the stimulating recognition of these relationships by the social and economic section of this association, in which was started a year and a half ago a movement for public health, particularly as related to the Federal Government, which has already assumed national significance.

To the marvellous growth of the medical and other sciences of living beings during the past century, and especially in the last fifty years, physics and chemistry and the application of physical and chemical methods of study have contributed directly and indirectly a very large and ever-increasing share. In many instances there is no telling when or where or how some discovery or new invention may prove applicable to medical science or art. Who could have dreamed in 1856 that Sir William Perkin's production of the first aniline dye should be an essential link in the development of modern bacteriology, and therefore in the crusade against tuberculosis and other infectious diseases? As Robert Koch has said, it would have been quite impossible for him to have developed his methods and made his discoveries without the possession of elective dyes for staining bacteria, and colouring agents of no other class have been discovered which can serve as substitutes for the anilines in this regard. And how much assistance these dyes have rendered to the study of the structure and even the function of cells! If we trace to their source the discovery of Röntgen's rays, which have found their chief practical application in medicine and surgery, we shall find an illustration scarcely less striking.

No important generalisation in physical science is without its influence, often most important, upon biological conceptions and knowledge. I have already referred to the great principles of conservation of mass and of energy which are at the very foundation of our understanding of vital phenomena. Although we cannot now foresee their bearings, we may be sure that the new theories, regarding the constitution of what has hitherto been called matter, will, as they are further developed, prove of the highest significance to our conceptions of the organic as well as of the inorganic world.

The ultimate problems of biology reside in the cell. Whatever the future may hold in store, at the present day only a relatively small part of these problems are approachable by physical or chemical methods, and the day is far distant, if it ever comes, when cellular physiology shall be nothing but applied physics and chemistry. We cannot foresee a time when purely observational and descriptive biological studies, which to-day hold the first place, shall not continue to have their value. They represent the direction which makes the strongest appeal to the great majority of naturalists. The broadest generalisations hitherto attained in biology, the doctrine of the cell as the vital unit and the theory of organic evolution, have come from this biological, as distinguished from physical, direction of investigating living organisms, and were reached by men with the type of mind of the pure naturalist, who loves the study of forms, colours, habits, variations, adaptations, inheritances of living beings.

It is well that the sciences of nature hold out attractions to so many different types of mind, for the edifice of science is built up of material which must be drawn from many sources. A quarry opened in the interest of one enriches all of these sciences. The deeper we can lay the foundations and the farther we can penetrate into the nature of things, the closer are the workers drawn together, the clearer becomes their community of purpose, and the more significant to mankind the up-building of natural knowledge.

RAINFALL AND WATER-SUPPLY.[1]

IT happens that rainfall is not only the most difficult of all the meteorological distributions to map accurately, it is also that one which is of the greatest importance, for by rain the rivers are fed, and the rivers both water and drain the land. Every year makes clearer the vast national importance of accurate knowledge of the rainfall of a county, for the problem of the rivers is becoming acute. The growing populations of the great towns are tapping the upper waters and diverting the water from its natural channels, and at the same time they are polluting the lower courses with the waste of the factories and the streets. Toll is taken all along the banks of industrial streams for raising steam and carrying on the multitudinous processes of manufacture. There is sometimes anxiety as to whether the waterways can be kept sufficiently supplied to float the water-borne traffic or to fight the silting action of the tides, and there is growing alarm as to the possibility of fish traversing the depleted and polluted streams to reach their spawning beds.

Of recent years, the value of the water-power which may be generated in the lonely and lofty places amongst the western heights of Great Britain, where the rainfall is large and unfailing, has been recognised, and chemical works for the production in electric furnaces of what a few years ago were rare substances are becoming familiar features in Wales and the Highlands. In Ireland, too, the rainfall is an unrecognised source of wealth which as yet has not been drawn upon to any appreciable extent. The increasing strenuousness of the struggle for the possession of large water supplies is producing in England, and especially in Wales, a great amount of local jealousy and strife, for the boundaries of parishes and counties coincide but rarely with water-partings, and the argument has been brought forward again and again that the rainfall of one county should not be diverted for the use of the inhabitants of another. The feeling is intensified when the boundary to be crossed is that of a historical division of national importance, like the boundary between England and Wales, but the map-study of rainfall can do something to suggest the lines on which such disputes should be settled.

Although the exceptional deluges of a thunderstorm or a great depression fall with equal and impartial heaviness on the hills of the west or the flat plains of the east, the common every-day rains are precipitated on the high lands and in the mountain valleys which cross the track of the prevailing wind in much greater abundance than on level and low stretches of country. Most of the rain is borne to our islands from the Atlantic, and when it comes torrentially it is of the air, and no boundary checks it; the largest annual falls come down on and near the watersheds, because there the land produces its maximum influence as a rain compeller.

From the high ground the rivers seek the plains, carrying off the excess of rainfall into the less liberally watered districts. The Dee, the Severn, the Wye, and the Usk restore to England part of the rains which the Welsh mountains have abstracted as the air passed over them. The high rainfall of the whole Pennine district, sometimes by circuitous routes across the comparatively dry plains of the east, swells the volume of fresh water that pours into the Humber. The Thames itself receives the comparatively high rains of the Cotswolds, the Chilterns, and the Downs, and forwards the water slowly through less and less rainy districts, until it reaches the sea in the driest part of England. Thus, I think, at least as good an argument can be drawn from this consideration of physical geography in favour of supplying the great towns of the east from the large precipitation of the west as can be drawn in the opposite sense from the artificial divisions of political geography. Care for the water supply of the country, coming as it does from the air that knows no bounds across the land, is by no means a parochial, but in the fullest sense a national matter, and should be dealt with in the interests of the nation as a whole, the units of subdivision, when such are required, being the natural units of river-basins.

[1] From the presidential address delivered before the Royal Meteorological Society on January 15 by Dr. H. R. Mill.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Senate has approved the affiliation of the University of Bishop's College, Lennoxville, Quebec, under the conditions laid down in the report of the council of the Senate dated November 25, 1907.

The Senate has assigned a site on the Downing ground, situate to the south of the botanical laboratory and parallel to it, for a building in connection with the Department of Agriculture.

Dr. James, Provost of King's College, has been appointed a member of the council of the National Trust for Places of Historic Interest or Natural Beauty.

The special board for physics and chemistry reports that the prize of 50*l.* from the Gordon Wigan fund for an investigation in chemistry was awarded in the year 1907 to F. Buckney, of Sidney Sussex College, for his essay entitled "A Study of some Quinquevalent Cyclic Nitrogen Compounds."

MANCHESTER.—A communication has been received from the Treasury intimating that to remove any uncertainty which may prevail in regard to the arrangements of the University during the current session, a special grant of the same amount as that paid before the proposed reduction, viz. 12,000*l.*, will be made to the University for the current year. The question of the future distribution of the Treasury grant is left open for decision after the Chancellor of the Exchequer has consulted the Advisory Committee which deals with grants to universities and colleges.

MR. F. M. SAXELBY, head of the department of mathematics at the Technical College, Belfast, has been appointed to a similar position at the Battersea Polytechnic.

IN the *Engineer* of January 17 is published the first instalment of a series of articles on the training of engineering apprentices, describing the methods followed at a number of works. The result of the inquiry has to a great extent been disappointing. No real general upward movement in the training of apprentices has been observed, and, with the exception of a few firms, the old indifferent method of training by hazard still obtains.

THE Government of Mysore has, the *Pioneer Mail* states, made public the new rules for regulating the grant of scholarships for scientific research and technical education from the Damodar Dass charities fund. The scholarships will be open to all Indians who have taken with credit a degree in arts, medicine, or engineering in an Indian or other recognised university. Each candidate selected will be given travelling allowance to England or elsewhere from Bangalore on the completion of his course of study or research. He will be allowed, during his stay in England or elsewhere, outside India, a sum of 200*l.* per annum, this allowance to be inclusive of college fees, cost of books, instruments, and boarding charges.

LORD AVEBURY was formally installed as Lord Rector of St. Andrews University on January 16, and delivered his rectorial address. Lord Avebury, during the course of his remarks, said there never was a time when St. Andrews was more adequately equipped, had a more distinguished list of teachers, and a curriculum more generous, wider, and less one-sided. The question is not, as is sometimes alleged, between a scientific and a classical education. No scientific man wishes to exclude classics. No degree should, in the opinion of scientific men, be given without demanding some classical knowledge. A man who is entirely ignorant of the classics, even if he is a profound mathematician, biologist, chemist, or geologist, is but a half-educated man. But the same is true even of the profoundest classical scholar who knows nothing of science. Science is of vital importance in human life; it is more fascinating than a fairy tale, more brilliant than a novel, and anyone who neglects to follow the triumphant march of discovery is deliberately rejecting one of the greatest gifts with which we have been endowed.

THE prospects of a university for Bristol were much discussed at the annual dinner last week of the Bristol University College Colston Society. The financial position was explained by Mr. J. W. Arrowsmith. Eight or nine years ago, about 400*l.* was collected yearly to forward higher education in Bristol, and the amount is now nearly 600*l.* per annum. In all, the society had collected a sum of 4732*l.* Speaking as to the University itself, Mr. Arrowsmith said the promise of Mr. H. O. Wills, announced in NATURE last week, was satisfactory to all, and all welcomed it very heartily and with deep gratitude to Mr. Wills. But the 100,000*l.* gift is not everything. The amount aimed at before the Privy Council is asked for the charter is 250,000*l.* The aggregate sum of 30,000*l.* was promised at the dinner a year ago. The sums were:—Lord Winterstoke, 10,000*l.*; Mr. J. S. Fry, 10,000*l.*; Mr. Frederick Wills, 5000*l.*; and Mr. F. J. Fry, 5000*l.* Adding for buildings and endowments in connection with University College the sum of 55,000*l.*, a total of 85,000*l.* is reached. Add to that the 100,000*l.*, and 185,000*l.* is obtained. Mr. Arrowsmith said that a friend, since he had been in the building, had added another 10,000*l.*, giving a total in hand or promised of 195,000*l.* It is obvious, therefore, that a sum of 55,000*l.* must be secured before the charter can be sought. Four sums each of 1000*l.* from Mr. Charles Thomas, Mr. Edward Robinson, Mr. Hiatt Baker, and an anonymous benefactor have also been offered. It should not be long, therefore, before the quarter of a million required for the university is raised by the men of wealth in Bristol who realise the value of higher education.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 12, 1907.—"The Effects of Temperature and Pressure on the Thermal Conductivities of Solids. Part ii. The Effect of Low Temperatures on the Thermal Conductivities of Pure Metals and Alloys." By Prof. C. H. **Lees,** F.R.S.

The object of the work described in the present paper was to extend the measurements of thermal conductivities of metals and alloys made by Lorenz, Jäger, and Diesselhorst and others at temperatures between 0° C. and 100° C. down to the temperature of liquid air, and thus provide a means of comparing the thermal and electrical conductivities of these substances over a much wider range of temperature than has hitherto been possible. The method adopted was a modification of that used originally by Wiedemann and Franz.

The results obtained are tabulated, together with those given for higher temperatures by Jäger and Diesselhorst, and they justify the following statements:—

(1) The thermal conductivities of most pure metals decrease as the temperature rises within the range −160° C. to 100° C.

(2) The thermal conductivities of all alloys tested increase as the temperature rises within the range −160° C. to 100° C.

Institution of Mining and Metallurgy, January 16.—Prof. William Gowland, president, in the chair.—The Vaal River diamond diggings: Mungo **Park.** A brief description of the diamondiferous terrace deposits flanking the course of the Vaal River. The author stated that the diamonds obtained from the river gravels are, taken collectively, probably the finest stones obtainable, averaging about 6*l.* per carat as sold to buyers on the diggings. Methods of working these deposits, and a few notes on the general conditions of digging, are dealt with in this short paper.—The eruptive diamond-bearing breccias of the Boshof district, South Africa: J. P. **Johnson.** A paper describing the three occurrences of diamond-bearing rock in the district, principally from a geological point of view. Special attention is directed to the lherzolite and eclogite boulders, which contain in proportionate abundance all the characteristic minerals of the eruptive diamond-bearing breccia, and which the author thinks are the more resistant portions of a rock which has gone to form the bulk of the breccia, and was the real home of the diamond. This lherzolite-eclogite rock may exist either as a widespread consolidated formation occurring at great depths or as a deep-seated molten magma, the former condition being more likely. The author can see nothing in the breccia other than a purely fragmentary formation, nor has he been able to detect traces of contact metamorphism either of the walls of the vent or of the included boulders. He concludes, therefore, that the type of volcanic phenomenon producing the peculiar features of these diamond-bearing vents would be a geyser rather than a volcano, more especially as there is not the least evidence of any molten rock or lava having passed through them.—The auriferous banded ironstones and associated schists of South Africa: Owen **Letcher.** Five principal mines working in the banded ironstone beds and associated schists are passed under review in turn under the following heads:—salient geological features; occurrence of gold in the formation; methods of mining and productive and economic values; and metallurgy of the series. The author points out that these banded ironstones are the oldest known auriferous sedimentary rocks in South Africa, lying between the basement schists and the conglomerate series, and he considers that on account of what is at present known as to the great width of the gold-bearing formation, the occurrence of gold in many places in payable quantities, and the amenability of the ores to a simple method of treatment, the exploitation of mines in the series is likely to assume considerable importance in future South African history.

PARIS.

Academy of Sciences, January 15.—M. Henri Becquerel in the chair.—Note on the density of graphite: H. **Le Chatelier** and S. **Wologdine.** On account of the wide range of densities which various experimenters have given for graphite, it has been assumed that graphite is not a single variety of carbon, although this is contradicted by the constancy of the heat of combustion of purified graphite. The authors have examined the following:—Acheson graphite (artificial); graphite from Ceylon, Australia, Bohemia (Mugrau and Scharzbach), Greenland, commercial graphite, and from cast iron. The method employed was flotation in a heavy liquid (mixtures of acetylene bromide and ether), care being taken to eliminate all air bubbles. The figures for the unpurified material from these sources varied between 1·62 and 2·66. Purification by Moissan's method was then tried, but the results were no more concordant, the deviations being finally traced to the imperfect removal of air. This was surmounted by removing the air by a vacuum, strongly compressing, breaking up again, placing a second time in a vacuum, and re-compressing. Under these experimental conditions all the natural and artificial graphites after complete purification gave the same density of 2·255 at 15° C. compared with water at 4° C.—The utilisation of turf for the purification of sewage: A. **Muntz** and E. **Lainé.** The experiments detailed show that natural turf is a highly satisfactory medium for forming sewage filter beds. The experimental filter has been at work for more than seven months, and its activity is still unimpaired. It is capable of treating a volume of from three to four cubic metres of sewage per square metre of surface per day. Figures are given of the chemical and bacterial purification effected, and fish live without inconvenience in the effluent. If loaded above this, the effluent is fair, but not so good, and it has been noted that on reducing the load to the normal figure the filter immediately recovers to original efficiency.—Observation of the transit of Mercury at the Observatory of Rio de Janeiro: M. **Morize.** The atmospheric conditions were unfavourable to good observations.—Observation of the transit of Mercury of November 13–14, 1907, at Schoi, Italy: Fr. **Faccin.** The atmospheric conditions were bad.—The summability of Fourier's series: A. **Buhl.**—The choice of the exponent of convergence for integral functions of infinite order: A. **Denjoy.**—The measurements of general movements of the soil by means of levellings repeated at long intervals: Ch. **Lallemand.** An analysis of the degree of exactitude practically possible in levelling operations shows that it is only in exceptional cases that a repetition of the measurements will permit the demonstration with certainty of gradual general movements under 1 decimetre.—The statics of a deformable surface and the dynamics of a deformable line: Eugène and François **Cosserat.**—The transformations of solutions of white phosphorus into red phosphorus: Albert **Colson.** Experiments with solutions of phosphorus in carbon bisulphide and in turpentine at various temperatures between 230° C. and 290° C. showed that the presence of the solvent causes the rate of transformation of the white into the yellow modification to be reduced.—The constitution of cast irons containing manganese: L. **Guillet.** Manganese displaces the eutectic point, which is produced for lower percentages of carbon than with the iron-carbon alloys. Other changes caused by the gradual increase of the percentage of manganese are noted.—Ammoniacal cuprous sulphate: M. **Bouzat.** The salt is formed by the interaction of aqueous ammonia, cuprous oxide and ammonium sulphate, and precipitated by alcohol. It is filtered off on asbestos, and washed with alcohol and ether. Great care has to be taken to exclude all traces of air, all reagents being freshly boiled, and the whole series of operations carried out in a current of pure hydrogen. Analyses of the precipitated salt show it to possess the composition $Cu_2SO_4.4NH_3$. The reactions are those of a cuprous salt, oxidising instantly when exposed moist to the air, and giving copper, cupric sulphate, and ammonium sulphate when treated with dilute sulphuric acid.—Syntheses in the camphor group. The complete synthesis of β-campholene lactone: G. **Blanc.** The starting point of this synthesis is $\alpha\alpha$-dimethyladipic acid, and this is converted successively into its sodium derivative, dimethyl-*cyclo*pentanone-acetic acid, and the ethyl ester of the latter. The bitertiary glycol obtained from this by Grignard's reaction forms a lactone identical with β-campholene lactone.—The constitution of the α- and β-methylsparteines and of isosparteine: Charles **Moureu** and Amand **Valeur.**—The synthesis of racemic dihydrocamphoric acid: L. **Bouveault** and R. **Locquin.**—The innervation of the sterno-mastoid and cleidomastoid muscles: F. X. **Lesbre** and F. **Maignon.**—The action of fresh kola nut on work: J. **Chevalier** and M. **Alquier.**—The apparent double refraction of vibratory cilia: Fred **Vlès.**—The action of choline on the arterial pressure: A. **Desgrez** and J. **Chevalier.** Choline furnishes the first example of a physiological substance of well-defined chemical composition, producing a marked lowering of the arterial pressure. It behaves as an antagonist to adrenaline, and it is possible to associate these two substances in such quantities that the one neutralises the effect of the other on the blood pressure.—Hexamer sea-urchins: Edouard **de Ribaucourt.**—*La graisse* in wine: E. **Kayser** and E. **Manceau.** The change in wine known technically as *la graisse* is complex, and is not caused by a single organism, but by the combined growth of several organisms.—The diminution of the salinity of sea water after filtering through sand: J. **Thoulet.** It is popularly supposed that the salinity of sea water is considerably reduced by filtration through sand. Direct experiments of the author have failed to confirm this.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 23.

ROYAL SOCIETY, at 4.30.—Report on the Eruptions of the Soufrière in St. Vincent in 1902, and on a Visit to Montagne Pelée in Martinique. Part II.: The Changes in the Districts and the Subsequent History of the Volcanoes: Dr. Tempest Anderson.—Petrographical Notes on the Products of the Eruptions of May, 1902, at the Soufrière in St. Vincent: Dr. J. S. Flett.—On the Intimate Structure of Crystals. Part VI., Titanic Oxide, its Polymorphs and Isomorphs: Prof. W. J. Sollas, F.R.S.—Dietetics in Tuberculosis; Principles and Economics: Dr. N. D. Bardswell and J. E. Chapman.—The Origin and Destiny of Cholesterol in the Animal Organism. Part I.: On the so-called Hippocoprosterol: C. Dorée and J. A. Gardner.

ROYAL INSTITUTION, at 3.—Recent Light on Ancient Physiographies: Prof. W. W. Watts, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Standard Performances of Electrical Machinery: R. Goldschmidt.

FRIDAY, JANUARY 24.

ROYAL INSTITUTION, at 9.—The Extinction of Malta Fever: Col. David Bruce, C.B., F.R.S.

PHYSICAL SOCIETY, at 5.—Recalescence Curves: W. Rosenhain.—An Experimental Examination of Gibbs' Theory of Surface Concentration Regarded as the Basis of Adsorption, and an Application to the Theory of Dyeing: W. C. M. Lewis.

INSTITUTION OF CIVIL ENGINEERS, at 8.—A Cost Theory of Reinforced-Concrete Beams: J. R. Wade.—The Neutral Axis in Reinforced-Concrete Beams: E. I. Spiers.

SATURDAY, JANUARY 25.

ROYAL INSTITUTION, at 3.—The Electrification of Railways: Prof. Gisbert Kapp.

MATHEMATICAL ASSOCIATION, at 2.30.—Address by the President, Prof. G. H. Bryan, F.R.S.—On the Teaching of Elementary Mechanics, with Special Reference to the Preparation and Use of Simple and Inexpensive Apparatus: W. J. Dobbs.—On the Teaching of the Elements of Analysis: C. O. Tuckey.—On the Geometrical Treatment of Series in Trigonometry, with Lantern Illustrations: F. J. W. Whipple.—On a New Treatment of Similarity in Elementary Geometry: W. E. Bryan.—Machine for Drawing Rectangular Hyperbolas: H. L. Trachtenberg.

ESSEX FIELD CLUB (at the Essex Museum, Romford Road, Stratford), at 6.—Report of Club's Delegate at British Association, Leicester, 1907: F. W. Rudler.—On Plant Distribution in the Neighbourhood of Felstead, Essex: J. French.

MONDAY, JANUARY 27.

SOCIETY OF ARTS, at 8.—The Theory and Practice of Clock Making: H. H. Cunynghame, C.B.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Exploration and Climbing in the Gurhwal Himalayas: Dr. T. G. Longstaff.

INSTITUTE OF ACTUARIES, at 5.—On the Construction of Mortality Tables from Census Returns and Records of Deaths: G. King.

TUESDAY, JANUARY 28.

ROYAL INSTITUTION, at 3.—Roman Britain: (*a*) Its Frontiers and Garrison: Prof. F. J. Haverfield.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.30.—Annual General Meeting.—President's Address: Anthropology in the Eighteenth Century: Prof. D. J. Cunningham, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Continued discussion*: Experimental Investigations of the Stresses in Masonry Dams subjected to Water Pressure: Sir J. W. Ottley, K.C.I.E., and Dr. A. W. Brightmore.—Stresses in Dams; an Experimental Investigation by Means of India-rubber Models: J. S. Wilson and W. Gore.—Stresses in Masonry Dams: E. P. Hill.

WEDNESDAY, JANUARY 29.

SOCIETY OF DYERS AND COLOURISTS, at 8. Colloidal Dyestuffs: Dr. E. Feilmann.—Notes on the Dyeing of Celluloid: Dr. J. N. Goldsmith.

BRITISH ASTRONOMICAL ASSOCIATION, at 5.

THURSDAY, JANUARY 30.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On the Observation of Sun and Stars made in some British Stone Circles. Third Note: The Aberdeenshire Circles: Sir Norman Lockyer, K.C.B., F.R.S.—On the Non-periodic or Residual Motion of Water moving in Stationary Waves: Mrs. W. E. Ayrton.—The Refractive Index and the Dispersion of Light in Argon and Helium: W. Burton.—On the Generation of a Luminous Glow in an Exhausted Receiver moving near an Electrostatic Field, and the Action of a Magnetic Field on the Glow so produced: Rev. F. J. Jervis-Smith, F.R.S.

FRIDAY, JANUARY 31.

ROYAL INSTITUTION, at 9.—Recent Researches on Radio-activity: Prof. E. Rutherford, F.R.S.

THE FUNCTION OF THE STAPES.

On the Impulses of Compound Sound Waves and their Mechanical Transmission through the Ear. By Sir Thomas Wrightson, Bart. Pp. 40, and portfolio of diagrams. (London: Thomas Kell and Son, 1907.)

LITTLE has been added to our knowledge of the auditory ossicles since the classical researches of Helmholtz, although the subject is of much interest. Sir Thomas Wrightson shows that, owing to the peculiar arrangement of the footplate of the stapes and the formation of the annular membrane, to and fro movements of the stapes are accompanied by vigorous transverse vibrations of its frame. These movements will be represented in any compound wave form by the points at which "the compound curve cuts across the average line representing the central or normal position of the membrane."

With the help of a very ingenious model, evidence is adduced that this complex of motions affords a reasonable basis for the analysis of compound notes, which is usually attributed to the fibres of the basilar membrane. Careful examination of the numerous wave forms reproduced by the author will, we think, make it clear that the theory advocated is worthy of attention. Sir Thomas Wrightson's criticism of the theory associated with the name of Helmholtz is not, however, entirely just. The statement that "In fact there is no intelligible explanation furnished by Helmholtz's theory why we can hear each note of a combination when all the component notes are sounded together" can be made with respect to any theory whatever. The real value of the hypothesis of Helmholtz is that it describes, not explains, a large series of phenomena which cannot easily be reconciled with rival theories. It remains to be seen whether Sir Thomas Wrightson's theory will better describe the facts. For example, the peculiar condition described by Jacobson under the name Diplacusis binauralis dysharmonica, in which the same note heard by the two ears simultaneously produces a dissonance, is most easily described by a theory of resonators in the cochlea. Again, if it be true that ossification of the fenestra ovalis is consistent with a partial preservation of hearing, as asserted by K. Schaefer (apparently on the authority of Frutiger), the function of the stapes would seem to be relatively unimportant; but evidence on this point is conflicting. The author assumes that an impulse is always imparted to the membrana basilaris by friction of the perilymph on its under surface; this is not necessarily the case. As Schaefer remarks:—

"It is conceivable that the fluid of the labyrinth, receding before the pressure of the stapes, flows from the Scala Vestibuli through the Helicotreme into the Scala Tympani, and conversely when rarefaction occurs in the auditory passage. But there is no time for this during the rapid sound vibrations, and it is far more probable that the membranous partition of the Cochlea bulges towards the Scala Tympani when the stapes moves inwards."

Whatever position may ultimately be assigned to the theory of stapedial analysis, Sir Thomas Wrightson and Dr. Arthur Keith, who is responsible for the anatomical part of the work, are to be congratulated on the performance of an interesting research which throws much light on the mode of action of a structure not readily accessible to the physiologist.

LIFE AND DEATH.

The Prolongation of Life. By Élie Metchnikoff. The English translation edited by P. Chalmers Mitchell. Pp. xx+343. (London: W. Heinemann, 1907.) Price 12*s.* 6*d.* net.

MOST people desire to live long, and hence Prof. Metchnikoff's book is sure to have many readers. He not only discusses the means by which life may be prolonged, but he also examines the question whether it is desirable to prolong it. About this he has no doubt; he is a confirmed optimist, and points triumphantly to celebrated men who have begun life as pessimists and have ended it as optimists. The chief of these is Goethe. Several chapters are devoted to the consideration of Faust, the sorrows of Werther, and Goethe's life. But this part of the book and that which treats of morality will probably appeal to fewer readers than the earlier part, for the subjects are so vast and so difficult that it is not easy to deal with them in the short space given to them by the author.

It is of interest to observe that Prof. Metchnikoff carries his optimism to the point of thinking that living has become easier from a moral point of view owing to the advances of science. For example, as science gets rid of or improves the treatment of plague and diphtheria, there will no longer be any need of the high moral courage of those who went freely among sufferers from these scourges in order that they might alleviate them. Life is already so difficult that this is a point of view we commend to the consideration of those who oppose scientific workers, and hinder them by vexatious restrictions.

"The Prolongation of Life" is a remarkable book in many ways. It and the "Nature of Man," of which it is an extension, treat of a subject about which little has been written. The whole range of literature is ransacked by the author, and the facts and opinions collected are discussed with an originality, a width of view, and knowledge that give the book an especial fascination and constantly arrest the attention.

Prof. Metchnikoff is of opinion that when old age approaches, the phagocytes, which have hitherto been man's friends, become his enemies, and hasten death by devouring the essential cells of the vital organs of the body, especially those of the nervous system.

These cells are rendered particularly vulnerable to phagocytes by the action of poisons manufactured by the bacteria of the large intestine, and Prof. Metchnikoff suggests that this might to a large extent be prevented by taking skimmed milk which has been boiled and rapidly cooled, and on which pure cultures of the Bulgarian bacillus have been sown. This produces a pleasant, sour, curdled milk containing about 10 grams of lactic acid per litre, the lactic acid of which prevents intestinal putrefaction.

The author is dependent mainly upon two kinds of evidence, experimental and numerical, and therefore his difficulties are chiefly two. Many experiments which might bear upon the prolongation of life must necessarily be observed for many years. For example, he devotes much space to the uselessness of the large intestine; so far as his facts go there is nothing to be said against them—indeed, from them and others we are probably justified in thinking poorly of the large intestine—but before we can certainly know much about this numbers of human beings who have been deprived of their large intestine will have to be observed for many years.

As the question is the prolongation of life, the numerical evidence as to how long certain animals and plants live is of the greatest importance, but the author has to depend largely upon hearsay. Very few of his statements are evidence in the technical sense of the word. We are more likely to be correct in our knowledge of very old human beings than very old animals, but even with regard to human beings the evidence of extreme old age—say over 100 years—often breaks down when carefully examined. Those in doubt on this point should read T. E. Young "On Centenarians." Sometimes the age is accepted because it is on the tombstone, but, as Johnson says, "In lapidary inscriptions a man is not upon oath." Prof. Metchnikoff is inclined to accept the commonly stated age of Parr, but there is no real evidence as to his age at death. Still, when we remember the extreme difficulty of getting suitable facts to support his views it must be admitted that the author has shown marvellous skill in the presentation of his case. No one can put down the book without feeling that it makes us think, will well repay careful critical reading, and induces gratitude to Dr. Chalmers Mitchell for his translation and excellent introduction.

PHILOSOPHICAL ESSAYS.

Proceedings of the Aristotelian Society. New Series, Vol. vii., 1906–7. Pp. iv+244. (London: Williams and Norgate, 1907.) Price 10*s.* 6*d.* net.

THIS volume contains the papers read before the society during the twenty-eighth session, 1906–7. The papers are eight in number, with titles and authors as follows:—(1) Nicholas de Ultricuria, a Mediæval Hume, by Hastings Rashdall; (2) on the nature of truth, by the Hon. Bertrand Russell; (3) on causal explanation, by T. Percy Nunn; (4) logic and identity in difference, by Miss E. E. Constance Jones; (5) Humism and humanism, by F. C. S. Schiller; (6) fact, idea, and emotion, by Shadworth H. Hodgson; (7) intuition, by A. T. Shearman; (8) philosophy and education, by Benjamin Dumville.

Both in the subjects chosen and in the standpoints adopted for their discussion, the series is quite representative of modern English philosophy. In the first paper, by the late president of the society, we find that element of historical appreciation, one might almost call it antiquarianism, without which English philosophy would be reft of half its distinctive charm. The second is virtually a criticism of Joachim's recent "Essay on Truth." The monistic theory championed in that book, viz. that "only the whole truth is wholly true," is shown to rest upon an assumed "axiom of internal relations," which may be formulated as follows:—"Every relation is grounded in the natures of the related terms." The arguments in its favour are shown to be fallacious, and the way is thus cleared for a return to the dualistic theory that facts are completely independent of our knowledge of them that experiencing does *not* make a difference to the facts. Finally, two theories, each admitting the possibility of a plurality of truths, are mapped out as tenable, between which the author prefers not to decide. The third paper is a very thorough and lucid treatment of the methods of explanation adopted in the various sciences, and should be found useful by those interested in the more concrete side of epistemology. Miss Constance Jones's paper is good, but too technical in nature to receive further mention here. In his paper, Dr. Schiller devotes many pages to the orientation of the pragmatic philosophy, defending it especially against the charge of kinship with the empirical scepticism of Hume. Particularly good is his exposition of Hume's theory of "activity," a portion of Hume's system unduly slurred over by the historian of philosophy. To his own panegyric of voluntarism the best antidote is to be found in the following paper (No. 6), by Dr. Shadworth Hodgson. This paper is excellent. However untenable one may feel some of his conclusions to be, one cannot but admire the clearness of conception and the feeling for reality which Dr. Hodgson displays. The analysis is carried out under the influence of the fundamental antithesis of "real conditions" and "conditionates." It is attempted to show that consciousness is a conditionate of which the real conditioning is to be looked for in something which is not consciousness. "This 'something' is known to us as matter and motions of matter"; *therefore,* says Dr. Hodgson, it is not a thing-in-itself. His argument takes no account of the alternative possibility that the reality of which matter is the phenomenon is itself mental, and that the efficiency of matter is really mental efficiency.

Mr. Shearman's paper is an attempt to map out the position of intuition in philosophy, and is extremely suggestive. In the last paper of the series we meet the well-needed reminder that philosophy is still indispensable in any theory of education. Philosophy alone is fitted to preside over the ideals which all educational systems must recognise.

W. B.

PRIMITIVE INTERPRETATIONS.

(1) *Ancient Egypt the Light of the World: a Work of Reclamation and Restitution.* In twelve books. By Gerald Massey. Two vols. Vol. i., pp. vi+544; vol. ii., pp. iv+545–944. (London: T. Fisher Unwin, 1907.)

(2) *Primitive Traditional History: the Primitive History and Chronology of India, South-Eastern and South-Western Asia, Egypt, and Europe, and the Colonies thence sent forth.* By J. F. Hewitt. Two vols. Vol. i., pp. xxviii+448; vol. ii., pp. viii+449–1024. (London: James Parker and Co., 1907.)

(1) ONE of the recreations of an archæologist is the reading of the various remarkable works that are produced by persons of untrained mind who know a little of the subject on which they write and are possessed of violent prejudices either for or against some particular form of religion. The latter element adds spice to the recipe. The peculiar nature of the late Mr. Massey's preface to his present "work of reclamation and restitution in twelve books," as he called it, disarms the critic, however, to some extent. He does not know what he ought to say in the circumstances. Mr. Massey had in the course of a long life read much and noted much. Unluckily he had not read deeply enough. He never attempted to get his own knowledge, but depended on what others said. Hence in any case his book would be of no value except as a compilation. But, further, he had little idea of what is and what is not permissible in logical argument; very few of his syllogisms are without a flaw; he had no perception of what is possible or impossible in respect of philological comparisons, and he was dominated by a fanatical belief with regard to the origin of Christianity which at once takes his book out of the realm of science.

It is no use collecting anthropological data if all that one wishes to do with it is to prove that Christ and the evangelists and disciples were ancient Egyptian gods, whose names are twisted to suit the argument. For Mr. Massey, Jesus Christ is the deified scribe Imouthes or Iemhetep (why, we are not told), Thomas is the god Tum, Matthew is Maati ("The two Truths"), while for John he makes out an Egyptian equivalent called Aan. "The Ritual," he says (p. 905),

"preserves the sayings of the Egyptian Jesus who was Iu the Su, or Sa of Atum-Rei [? meaning] and Iusaās [she was a goddess!] at Ou, and who was otherwise known as the Lord in different Egyptian religions. . . . This is the original *Evangelium Veritas* [*sic*: Mr. Massey's Latin was usually uninflected: cf. *jus prima noctis*]: the Gospel according to Mati = Matthew; to Aan = John; or Tum = Thomas," and so forth.

On p. 41 Mr. Massey says,

"In that [*i.e.* the Egyptian language] we find the word Ba signifies to be, Ba therefore is a form of to be. Also it is the name for the Ram and the Goat, both of whom are types of the Ba-er or Be-ing, both of whom say 'Ba.' The Cow says Moo. Mu (*e.g.*) means the mother, and the mythical mother was represented as a moo-cow."

Mr. Massey does not tell us the fact, which rather upsets his theory, that the Egyptians did not call a cow *mu*, but *ahu*. Apart from this, his statement that in Egyptian *ba* means "to be" is contrary to fact; in Egyptian "to be" is *un* or *iu*, and "to become" is *kheper*; there is no such word as *ba* meaning "to be." The word for mother was *m–t*: what the vowel was we do not know, probably *au* (*maut*). Mr. Massey goes on to say,

"The Ibis was one of the self-namers with its cry of 'Aah-Aah,' consequently Aah-aah is one name of the bird in the Egyptian hieroglyphics, and also of the moon which the Ibis represented."

Mr. Massey did not know that, though the word for "moon" (*not* for "ibis," which is *tekhen* or *hib*) is written conventionally *aah*, it was probably pronounced something like "*ioh*." Do ibises say "ioh-ioh"?

These are simple misconceptions as to matters of fact, and they give us reason to doubt whether Mr. Massey has any right to speak patronisingly of the work of an anthropologist like Mr. Frazer, as he does on p. 672:—

"Here we may say in passing, that the *Golden Bough* contains a learned, large, and serviceable collection of data, but the theories of interpretation derived from the writings of Mannhardt are futile. Besides which, mythology is not to be fathomed in or by a folk-tale, and the *Golden Bough* is but a twig of the great tree of mythology and sign language—a twig without its root. The reception of the work in England served to show how prevalent and profound is the current ignorance of the subject-matter. It was hailed as if it had plumbed the depths instead of merely extending the superficies."

The last remark may be rather a point, but we can assure the Gallio, who may say, "How these anthropologists love one another," that Mr. Massey was no anthropologist, but a somewhat peculiar kind of mystic, and had no right whatever to criticise Mr. Frazer.

(2) Mr. Hewitt has unaccountably omitted China, Mexico, Peru, and Australia from his title. His work is comprehensive: it covers the whole world. And what it is all about it is difficult to discover. "History" it is not; there is no history known to science in it. But doubtless there is much known to Mr. Hewitt, and his Indian confidants, alone. The fact that Mr. Hewitt regards avatars of the Buddha "about 10,700 B.C.," and from "about 6700 to 4500 B.C.," as historical personages (p. 45) is enough to stamp him as a peculiar "historian." His book is an *omnium-gatherum* of primitive traditions truly, and from them Mr. Hewitt, the believer in the historical character of avatars of Buddha, essays to disinter the early history of the human race by the help of an astronomical key. The astronomy we leave to the astronomers; of the "history" the following excerpt may suffice as a specimen:—

"The worship of the left thigh was succeeded by the worship of the right thigh of the independent sun-god, who took his own path sun-wise through the heavens, in whose ritual the right thigh of the sacrifice was given as their perquisite to the Jewish priests of the house of Kohath, the wearers of the inspiring Ephod, and sons of the almond-tree. This age is historically most remarkable as that of the great moral upheaval which gave birth to the wide-spread movement towards individual regeneration, and the attainment of sanctity in mind and deed, which characterised the history of the Buddha, born as the divine physician Osadha-Dhāraka, the medicine-child in the age of the Yama Devaloko, the twin-stars Gemini, when the sun entered the Ashvin constellation Gemini in January-February, about 10,700 B.C., and which continued through the next succeeding periods of his Vessentara birth in the Tusita heaven of wealth. . . . This age was, as I show, contemporaneous with that characterised in Persian and Zend history as the introduction of the religion of Zarathrustra . . . during this period a wide-spread *régime* of active trade, under the guidance of affiliated managers in touch with the Indian trade-guilds, was extended round the world from India as the centre, to the west of Europe under the Phœnicians, and to America. During this time of universal peace the world was governed by traders and was undisturbed by tribal wars. . . ." (pp. 45, 46).

This sort of "history" is worthy of a Mahatma. We have heard it from Indian and "theosophical" lips before, and we do not believe a word of it. This age of universal peace about 10,700 B.C. "under the guidance of affiliated managers in touch with the Indian trade-guilds" is as unknown to scientific historians as Mr. Ignatius Donnelly's story of "Atlantis." It will be news to them, also, to hear that Zoroaster lived about 10,700 B.C.!

OUR BOOK SHELF.

Cyclopedia of American Agriculture. Edited by L. H. Bailey. Vol. ii., Crops. Pp. xvi+690. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1907.) Price 21*s*. net.

THE second volume of Dr. Bailey's "Cyclopedia" deals with the field crops of North America, and opens with some interesting chapters on the economic side of plant life in general—the control of diseases, the principles of plant breeding and introduction, seeding, and the management and preservation of the crop. Though the plants dealt with in the main section of the book include the staple farm crops of this country, one cannot but be struck with the enormous diversity of the production of the United States. Its agriculture started practically on the basis of our own, with crops characteristic of temperate and humid climates, cotton being the only early addition on a large scale; but as population spread south and west, all the products of the Mediterranean region became included, and latterly the addition of the Sandwich Islands, Cuba, and Porto Rico to its territory has brought tropical and subtropical plants into the United States list. The valuable work done by the plant introduction division of the United States Department of Agriculture finds ample recognition here; the navel orange, Egyptian strains of cotton, with the date palm, the olive, and durum wheat for the arid regions, are striking examples of successful acclimatisation, and elaborate attempts are now being made to introduce tea.

The account of any individual crop is perhaps hardly full enough to be of much value to the farmer who is already engaged in that particular industry, and American conditions of climate and labour render much of the information inapplicable to British agriculture; but this volume of the "Cyclopedia" would be of the greatest service to any settler breaking ground in a new country, and looking round for profitable crops outside the accepted routine. As in all cyclopedias, many of the illustrations are rather trivial and pointless, but the full-page reproductions from photographs are of real value and often of beauty.

Penrose's Pictorial Annual, 1907–8. Vol. xiii. Edited by William Gamble. Pp. xvi+184. (London: A. W. Penrose and Co., Ltd., n.d.) Price 5*s*. net.

THIS annual has now reached its thirteenth volume, and although its predecessors have attained a very high order of excellence as regards text, illustration, and style, the present issue eclipses them all.

The volume before us is of perhaps more than usual interest, because a fundamental and important change has been made throughout the whole book. The editor, in his excellent and interesting summary of the year's work, tells us that on previous occasions the chief difficulty which became apparent in preparing these volumes was to present something conspicuously new in process work. The difficulty arose through the wonderful standard of excellence which had already been reached in photo-mechanical processes.

Owing to certain criticisms which indicated that the best effects from half-tones and three-colour blocks could only be obtained on highly-glazed paper, and with brilliant inks, and this did not comply with the canons of good art, an attempt has been made in the present volume to meet these views. The paper-maker has been asked to make a paper which should have a perfect surface without the gloss, and the ink-maker has been requested to prepare inks that would be suitable to the new kind of paper. To give the text illustrations a better chance, screens with 133 instead of 150 lines to the inch have been employed. The result of this combined effort, which is presented in these pages, is distinctly good, and throws great credit on all concerned in the endeavour. As in former years, the volume teems with a great number of excellent illustrations by various processes, and the text contains a wealth of information on allied topics.

The frontispiece is a fine heliotype reproduction from an old copper engraving, and the general appearance of the book leaves nothing to be desired.

The book should be found more useful than ever to anyone who wishes to seek the best process for book or catalogue reproduction, no matter whether the illustrations have to deal with the reproductions of oil paintings, photographs, black-and-white drawings, or such subjects as machinery, woodwork, or china.

The Education of To-morrow. By John Stewart Remington. Pp. 115. (London: Guilbert Pitman, 1907.) Price 2*s*. net.

"IT is my honest belief," says Mr. Remington towards the end of his book, "that at the bottom of almost all British failure in business or in industry is the nightmareish, unpractical nature of British education." Though he does not appear to be familiar enough with the progress which has been made during the last ten years in devising and introducing practical methods into our schools, Mr. Remington has much to say that deserves the earnest attention of schoolmasters and educational authorities generally. "The education of to-morrow will be an education for practical men, every branch of which will have to justify itself by ultimate usefulness." He combats successfully the common criticism that this would be to make education merely utilitarian and to ignore the need for culture. To foster in public schoolboys the belief that "the best people" cannot go in for trade, he describes as "suicidal." Altogether the little book provides much material for thought, and it may be commended to all who desire the welfare of their country. We hope, however, the education of the future will teach that it is unpardonable for a book of this kind to be published without an index.

Scouting for Boys. A Handbook for Instruction in Good Citizenship. By Lieut.-General R. S. S. Baden-Powell, C.B. Parts i. and ii. (London: Horace Cox, 1908.) Price of each part, 4*d*. net.

IN an earlier volume, "Aids to Scouting," Lieut.-General Baden-Powell has shown that the characteristics of the good scout are those which distinguish the successful man of science. In his appeal to headmasters in 1901, Prof. Armstrong pointed out how full of good advice in the training of children that book is. The present book, which is to be completed in six parts, two of which have now appeared, also may be recommended as likely to result in the development of faculties of observation, regard for accuracy, conscientiousness, and other desirable characters.

Photograms of the Year 1907. Text, pp. 48; illustrations, pp. 112. (London: Dawbarn and Ward, Ltd., 1907.) Price 2*s*. net.

BETWEEN the covers of the book we have a collection of reproductions of about 200 different pictures, about one-fourth of which are selections from the exhibitions held recently in London, while the remainder serve as examples of the pictorial work of the year, not only by home, but by colonial and foreign workers. The pictures are excellently reproduced, on stout paper, and every care seems to have been taken to ensure their being as true as possible to the originals.

In the text Mr. H. Snowden Ward gives us an interesting critique of the "Work of the Year," and contributions are included from the pens of various well-known colonial and foreign photographers.

Those who wish to make themselves acquainted with the main features of last year's work in pictorial photography will find much to interest them in the present issue.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Stability in Flight.

Now that two or three people have succeeded, by skilful manipulation, in travelling on a more or less determinate course in the air, it would be well that inventors should turn their thoughts to securing stability in flight without the demand of constant attention on the part of the aëronaut.

In a note written some years ago on this subject, I said:—"No flying machine will be satisfactory which does not contain some automatic device for securing stability. The principles which must be embodied in such a governor are in themselves simple, and may be realised in many ways.

"The principal axes of the flying machine have to be kept related in a definite way to the direction of the force of gravity and of the accelerations.

"To do this, the action of the governor must depend on the position of the axes of the machine in relation to the direction of two pendulums (or their equivalents), one having a very long and the other a very short period. In this connection, 'long' and 'short' have reference to what may be called the rate of instability." (A twenty-second period for the long, and a tenth of a second for the short pendulum, would be the sort of thing required.)

The long pendulum presents the greatest practical difficulties, but they can be met.

Until something of this kind is done, flying will remain a feat of personal skill. Probably most people could acquire this skill if they could practise when young, but, in learning to fly, any accident generally puts an end to the power of gaining further experience.

The Inheritance of "Acquired" Characters.

MAY I have space for a communication dealing, not with Mr. Spicer's letter (p. 247), but with some problems it suggests?

An individual develops from the germ-cell under the influence of various stimuli, of which the principal are nutriment, use, and injury. Nutriment supplies the material, but *not* the stimulus, for *all* growth. Up to birth, the human being, for example, develops wholly or almost wholly under this stimulus. Subsequently some of his structures continue to develop under it, for instance, his hair, teeth, external ears, and organs of generation, which grow whether or not they be used. But most of his structures now develop mainly, if not solely, under the stimulus of use, for example, his voluntary muscles, limbs, heart, and brain. Thus if the limb of an infant be paralysed it grows comparatively little, and the muscles atrophy. If the individual be injured, as by a cut, the injury supplies the stimulus for the growth (scar) which repairs the damage.

Scientific writers are accustomed to divide the characters of a living being into those which are "inborn" or "innate" and those which are "acquired," and are in the habit of declaring that the former tend to be "inherited" by offspring, but not the latter. I doubt if anything in science has been provocative of more confusion, misunderstanding, and futile controversy than this use of inaccurate terms. All our evidence indicates that the structures of the child are derived, not from the corresponding structures of the parent, but wholly from a germ-cell which dwelt as a parasite within the parent. Only in a purely metaphorical sense, then, does the child inherit from the parent. It resembles the parent merely because parent and child are derived from very similar germ-plasms which have been acted on to a very similar extent by very similar stimuli.

If we analyse the words of biologists carefully, we find that by an inborn character they imply one which has developed under the stimulus of nutriment, and by an acquirement one which has developed under the stimulus of use or injury. When they speak of the "transmission" of an "inborn" character, they imply that it has developed in both parent and child under the stimulus of nutriment; when they speak, as is still sometimes done, of the transmission of an acquirement, they imply that a character which developed in the parent under the stimulus of use or injury has developed in the child under the stimulus of nutriment. Apart from the immediate effects of injury (*e.g.* loss of tissue), I think it would puzzle anyone to indicate in what respects an "inborn" character is more innate and inherited than an acquirement. Obviously these vitally useful powers of growing, of developing in certain fixed directions under the stimulus of use and injury are just as truly inborn and rooted in the germ-plasm, just as truly products of evolution, as the power of growing under the stimulus of nutriment. It follows that the so-called acquirements are "innate" and "inherited" in precisely the same sense as the so-called inborn characters.

It is true that, since no character can be used or injured until it exists, all structures begin to develop under the stimulus of nutriment, and therefore that all acquirements are modifications of innate characters. But early development is no evidence of innateness, and most acquirements, like most of the growth made under the stimulus of nutriment, are nothing other than extensions of growth previously made. It is true also that innate characters arise inevitably as the child develops, whereas some acquirements are more or less rare. But this is only because the stimulus of nutriment is inevitably received, whereas the stimulus of a particular use or injury may not be received. If, however, the latter be received, the acquirement arises just as inevitably as the innate character. Thus if the child receives a like injury, it reproduces the scar on its parent's nose as certainly as the nose itself. If the nose is inborn and inherited, then the scar is inborn and inherited in the same sense.

Had the true nature of the distinction between innate and acquired characters been realised, had it been realised that the difference is one of stimuli, not of innateness or inheritability, and that acquirements are just as much products of evolution as innate characters, it is impossible that the controversy as to the alleged "transmission" of the former could have endured so long as it did. In effect, it was maintained by Lamarckians that a character (*e.g.* a scar) which the parent was able to acquire in a certain way (as a reaction to injury) because a long course of evolution had rendered such acquisition possible to the members of his race is reproduced by the child in a different category of characters, and in a way (as a reaction to nutriment) that no member of his race had ever acquired it before, and with which, therefore, evolution had nothing to do. An actual miracle was supposed to happen, the miraculous nature of which was concealed under a misuse of terms.

At the present day the majority of biologists are apt to regard "acquirements" as mere accidents, as things inferior to and less worthy consideration than "inborn" traits. Very little study has been given to the evolution of the power of making acquirements, especially use-acquirements, and hardly any attempt has been made to ascertain in what proportions the "normal" individual of any species is compounded respectively of innate and acquired traits. Lloyd Morgan, Baldwin, and Osborn have certainly dealt with this power under the name of "plasticity." But plasticity is not the same as growth, as development, and the fact that they have regarded acquirements as useful to the species mainly as affording time and opportunity for the evolution of corresponding inborn traits indicates an adherence, even if only a modified adherence, to the prevailing biological view. The evidence seems clear that animals low in the scale of life have little or no power of making use-acquirements, but that this power increases as species are more highly placed until in man the main difference between the infant and the adult is due to the use-acquirements made by the latter during development. The power of making use-acquirements is present only in structures where it is useful, and only to an extent that is useful. Great adaptability is thus conferred on the individual, for he develops only those traits which are useful to him in his particular environment, and is burdened with no others. We have a special name, memory, for the power of making mental use-acquirements. Memory is nothing other than the power or faculty of storing mental experiences, and so adding to the mental growth. It is strictly analogous to the faculty of storing physical experiences, and so adding to the physical growth. Without memory there could be feeling and (instinctive) emotion, but no thought, for the materials of thought would be lacking. Animals low in the scale of life appear to have little or no memory; they are guided more or less entirely by instinct. Man is intelligent and adaptable because he has a memory. He is the most intelligent of animals because he has the largest faculty for storing experiences. Memory, the *power* of learning, develops under the stimulus of nutriment, but intelligence and reason develop under the stimulus of use. They are amongst the *contents* of memory. We learn to think and reason just as surely as we learn the facts about which we think and reason. Reason, therefore, is an "acquirement."

Probably no problem in biology is of greater theoretical interest than that of the evolution of the power of making use-acquirements. Certainly no problem is of nearly such practical importance as that of determining the extent to which the individual develops, on the one hand, under the stimulus of nutrition, and, on the other, under the stimulus of use. From the times of Lamarck, Spencer, and Romanes, biologists have very generally assumed that use tends to cause development in all the structures of all animals, but that the amount of this modification is trivial. As a fact, use causes development in only some structures in some animals, and the major part of the development of the human being is due to it. If, for example, biologists had ascertained and were agreed as to the amount of this development, we should know to what extent races and generations of men differ "innately" and to what extent by acquirement, and therefore what effect could be produced by this or that system of mental training. Educationists could then apply this knowledge to the training of the young. At present the basis of bedrock fact is lacking, and biology is shorn of much of the practical importance which is its right.

I venture to write this letter in the hope of directing attention to one, at least, of the great problems of biology which are neglected under present fashions. Experiment itself, for example, loses much of its value unless the worker has clear and comprehensive notions concerning the subject with which he deals.

G. ARCHDALL REID.

The Melanic Variety of the "Peppered Moth."

MR. SPICER asks (January 16, p. 247), among other questions, "how does the 'peppered moth' contrive to appear in the black country hatched with sooty wings that harmonise with the now smoke-stained bark whereon he must rest?" His point, I conceive, is that the melanic variety is due in some unexplained way to the inheritance of acquired characters.

If Mr. Spicer found that an actor whom he had seen perform the part of Hamlet on Tuesday was cast for Macbeth on the Wednesday, he would not necessarily, I suppose, conclude that the actor had added the part of Macbeth to his repertoire during the intervening time. Now there is more than a possibility that the black coloration of the variety Doubledayaria may in like manner be a repertoire pattern of the "peppered moth" evolved in the remote ages of the history of the species. The dark form is not necessarily atavistic in the general acceptation of the term, as it may only have been developed by some stocks of the species in a more or less restricted portion of its range, the stocks in question having reverted when the factor that put a premium on blackness gave place to the original conditions of their habitat. The facts of mimicry prove that the germ plasm of the Lepidoptera can carry more than one distinctive pattern, and the temperature experiments of Standfuss and Merrifield suggest that such latency may extend over long periods of the insect's history.

Mr. Spicer has tacitly assumed that the variety is confined to the black country, but this is by no means the case. The dark form is, I believe, taken in the Black Forest in Germany; certainly it occurs in Denmark, and records from our own southern counties are not wanting. It is by no means uncommon in and round London, and has been taken as far out as Brentwood and Bexley, both of which are outside the smoke limit as regards soot-stained bark. In the last-named district, my friend Mr. Newman has taken melanic forms of several other Geometriid moths in addition to var. Doubledayaria.

There seems to be no doubt as to the increase of melanism among the tree-resting species of Lepidoptera in certain districts of England during the past fifty years, but this increase is apparent outside the actual smoke-stained area, though not perhaps beyond the range of darker bark owing to the destruction of the lichens—a cause that may have operated locally on more than one occasion during the life-history of the species quite irrespective of a sooty civilisation.

Apart from lichens, even a change in the species of trees composing a forest might have a marked effect on the cryptic coloration of the bark-resting species of moths in the locality. Birch would favour a pale coloration; oak, cherry, and especially the thorns, a darker one; beech, with its dense shade and wide range of bark coloration, a darker or lighter pattern, according to the dampness of the situation and whether the particular species emerged before or after its full leafage was attained.

The time during which the dark form could have been evolved from the normal coloration of the species by the action, direct or otherwise, of smoke is less than a century, say from fifty to seventy-five generations—presumably a quite inadequate period for the evolution *and fixing* of the form by the selection of small chance variations. Certainly, if the analogy of language in the human race is permissible, the number of generations is far short of what would be required to impress any character on the heredity of a species *by the inheritance of acquired characters*, even if we could find any reasonable connection between soot-stained bark and darkened wings for the purposes of the theory.

But gradual adaptation during the present epoch does not fit the facts for another reason. The darkening, if gradual, would have been noticed by entomologists, as is the case with *Aplecta nebulosa* in Delamere Forest and *Hybernia leucophaearia* in Epping Forest. The species would be a beautiful example of a mutation if it were not for the fact that intermediates, though rare, have a puzzling habit of turning up; and, what is more serious, a careful examination of the melanic forms reveals the fact that on the upper margin of the hind wings, where they are covered by the fore wings when the moth assumes its normal resting position, there is an area of the original pale coloration. As in the reverse case of the exposed tip of the underside of the fore wings of many butterflies being coloured quite differently from the rest of the wing area, in order that it may match the cryptic pattern on the underside of the hind wings, the retention of the pale area in var. Doubledayaria can only be accounted for by the supposition that the variability is the work of natural selection.

If the above reasoning be correct, the black variety must either be regarded as the recurrence of a pattern slowly evolved in some previous epoch, or we must consider it as an example of the working of Weismann's germinal selection. The needs of cryptic adjustment to environment having put a premium upon darker, but not necessarily black forms, the determinants of the darkened characters tend by the operation of selection within the germ to increase progressively to a point where they are cut off by the operation of natural selection upon the individual. As a consequence, a few rare examples will always be thrown having such a progressive character in excess, and should any rare and sudden chance such as is afforded to melanism by our smoky civilisation occur, an enormous premium is placed upon the survival of their offspring.

Inductance in Parallel Wires.

A problem of some considerable importance to the practical engineer or physicist is that of calculating the effective self-induction of a circuit consisting of two parallel wires, the one being the return of the other. When the wires are not very close together, and their current is either steady or only very slowly alternating, satisfactory results are known to be given by the formula

$$\frac{L}{l}=2\log\frac{c^2}{ab}+\tfrac{1}{2}(\mu_1+\mu_2),$$

where L is the self-induction of a length l, c the distance between the wires, which have radii a, b, and μ_1, μ_2 the permeabilities of their materials. But if the current oscillates rapidly, this formula fails to give even approximately correct results. Now in many practical problems, such, for example, as the measurement of small inductances not greater than 1000 microhenries, it is necessary to employ long leads to keep them at some considerable distance from bridge and other circuits. A knowledge of the self-induction of such leads is very desirable. Some results which I have recently obtained are capable of finding this quantity in most useful cases, and it may prove of use to give a short statement of them, pending more detailed publication.

The self-induction has a simple expression only if the two wires be equal in radius. In this case it takes the form

$$\frac{L}{l}=4\log\frac{c}{a}+\frac{4\mu}{x}\cdot\frac{\operatorname{ber}x\operatorname{ber}'x-\operatorname{bei}x\operatorname{bei}'x}{(\operatorname{ber}'x)^2+(\operatorname{bei}'x)^2},$$

where ber x, bei x are the functions introduced by Lord Kelvin, and subsequently tabulated (*vide* Presidential Address to the Institution of Electrical Engineers, 1889).

If $\frac{n}{2\pi}$ be the frequency of alternation per second, σ the specific resistance of a wire, μ its permeability, then

$$x=2a\sqrt{\frac{\pi\mu n}{\sigma}}.$$

This formula, passing naturally into the former when the frequency is small, becomes less accurate as c decreases and as the frequency or radius of a wire increases. So far as the first cause is concerned, it is subject to an error of not more than 1 per cent. when $c=10a$, and 4 per cent. if $c=5a$. If $c=3a$, which is the limiting closeness for most practical purposes, the error is about 10 per cent., which is not usually too great. The other causes of error may be considered together. The per cent. error they produce is of order $100.\frac{n^2a^2}{V^2}$, where $V=3\cdot10^{11}$. Practically, a is never more than about 2 millimetres, and thus, with a frequency of a hundred million per second, the error is not more than one-tenth per cent. The range of application of the formula is therefore extremely wide. A formula equally accurate may be given when the wires are unequal, but it is somewhat cumbrous.

Stock Frost or Ground Ice.

During the recent frosty weather the subject of what is locally called "stock frost" has been much to the front in this neighbourhood. This phenomenon is known to the scientific world, I believe, as "ground ice," and the circumstances in which it appears and disappears present to the ordinary observer a very great many puzzling features.

I should be exceedingly glad if some of your readers would kindly give me, through the columns of Nature, their opinion on several points which puzzle and interest me and others in connection with "stock" or ground ice.

(1) I wish to know, first of all, what are the *essential* conditions for the formation of ground ice on the bed of a river?

(2) Is it essential, or does it favour the formation of "ground" ice, that there should be no surface ice? We notice that when a very cold and very strong north-east wind is blowing, violently agitating the surface water, there is no surface ice, but a formation of ground ice at the bottom of the river.

(3) What are the circumstances to which is due the presence of ice-cold water at the bottom of a river, cold enough to be precipitated into ice?

This ice-cold water cannot reach the bottom of the river by gravitation, because its density is inferior to that of water at a higher level. To what, then, is due this cold temperature on the river bed?

(4) Can the bulk of water in the river bed be a conductor of cold from the surface to the bottom of the river in any other way than that of the mechanical action of running water? I assume that when ground ice appears in a river the whole of the water above it is of an ice-cold temperature, but it has not formed into ice because of the lack of the ice-precipitating conditions which exist on the bed of the river.

(5) Do the conditions necessary for the formation of ground ice operate more favourably in ice-cold still water or in that which is agitated, say, by passing through a mill? My own observation is that ground ice appears nearer to a mill on its upper side than on its lower side, and I want to know the reason of this.

There is quite a long list of questions which might be asked in connection with the formation of ground ice, but I fear that I have already trespassed too much upon your space.

John J. Hampson.

Costessey Vicarage, near Norwich, January 20.

THE PRODUCTION AND MANIPULATION OF INDIA-RUBBER.[1]

In this work the author gives a description of the various stages through which india-rubber passes from the time when it oozes out of the tree until it leaves the factory, a finished article, fashioned and fit for the service of man. The book is expressly designed for the general reader. It does not, except incidentally, deal with the chemistry of india-rubber, nor with the minute details of manufacture; the volume is neither a laboratory guide nor a factory handbook. There are, however, many people interested in india-rubber who are neither chemists nor manufacturers, and the author thinks that a volume conceived on broad general lines to expound the natural and commercial history of rubber cannot be deemed a superfluity. Similarly it may, perhaps, not be amiss to give here a short outline of the matter for the benefit of those readers of NATURE who, likewise, are neither chemists nor manufacturers.

Many species of plants are now known to yield marketable rubber. They range from the lofty *Hevea braziliensis* of the Amazon swamps to the Landolphia creepers of West Africa and the Clitandra shrubs, a foot or two high, the rhizomes of which yield the "root-rubber" of the Congo. The chief genera are Hevea, Manihot, and Micranda (Euphorbiaceæ); Castilloa and Ficus (Artocarpaceæ); Hancornia, Funtumia, and Landolphia (Apocynaceæ); and Callotropis (Asclepiadeæ). The bark of the trees yields a milky latex, which is obtained generally by "tapping," though sometimes by the wasteful process of felling the tree. In various ways the latex can be caused to coagulate, much as ordinary milk is made to "curdle"; and the separated coagulum, after undergoing a process of "curing," is the "raw" rubber of commerce. This raw rubber, which comes here in various forms—loaves, biscuits, balls, cups, sheets, lumps, and slabs—contains water, sand, woody fibre, and other impurities, ranging in quantity from 15 to 50 per cent., which are removed by washing and rolling; and there are also present resinous bodies, relatively small in amount, but important in their effect upon the quality of the rubber, that are not eliminated by washing. The cleaned rubber is "compounded" where necessary (*i.e.* having regard to the purpose it is destined to serve) by kneading it with various mineral ingredients, such as antimony sulphide, iron oxide, litharge, and barium sulphate, and is eventually vulcanised by treatment with sulphur before it emerges in its final form as motor-tyre, cable, or other article.

Smoking Para rubber with palm nuts by the method which has recently superseded the paddle to a great extent. From "India-Rubber and its Manufacture."

Mr. Terry writes on these subjects with the authority of personal knowledge, though perhaps without the lightness of touch desirable in a work of this character. Probably the second and fifth chapters of the book will be found of the most general interest. They treat respectively of "the production of raw rubber" and of "india-rubber plantations," giving as fully as the scope of the work allows a sketch of the present aspect of these matters.

Among points mentioned as calling for special attention, it is urged that more care should be given to the "tapping" operations, so that other juices in the trees shall not be allowed to mix with the rubber latex. Further, the exudations of other trees are sometimes mixed with the rubber latex for the purpose of increasing the bulk. The author mildly stigmatises this as an "injudicious" practice; it is surely a fraud. Another important point to which the attention of producers is directed is the desirability of removing or sterilising the fermentable albuminous substances present in the latex. They give rise to evil odours and become a nuisance, even if they do not injuriously affect the quality of the rubber itself—a point which is perhaps debatable.

As regards plantation rubber, an estimate of the area under cultivation about two years ago gave a total of some 150,000 acres, and this, no doubt, has now considerably increased. The chief regions concerned are Ceylon (40,000 acres), the Malay Peninsula (38,000), Africa (33,000), Mexico (10,000), and India (8000). Young plantations in a more or less experimental stage, covering in the aggregate some 20,000 acres, are also found in Borneo, Java, Brazil, Venezuela, Ecuador, Central America, and the West Indies. As to the quality of the plantation rubber, recent experiments seem to indicate that, judged by vulcanisation tests on a small scale, some plantation rubber at least is not inferior to the best "hard cure" Para. The author, however, remarks that up to the present there is a unanimous opinion amongst experts that plantation rubber is deficient in "strength" compared with the Brazilian forest product. Nevertheless, it commands a higher price, owing to its greater freedom from waste.

"Never before," say some recent writers, "have brokers or manufacturers had presented to them a raw rubber of the purity of the best plantation rubbers."

For this very reason, they urge, it may well be that the present rough practical tests applied to the raw rubber are insufficient for proper valuation. At present the question of the relative merits is an open one; we shall probably know much more about it during the next year or two, when larger quantities of the plantation product are expected to come into the market.

C. SIMMONDS.

SCENERY AND NATURAL HISTORY OF NEW ZEALAND.[1]

FEW countries enjoy so many natural advantages of scenery and climate as New Zealand, and none of similar extent can compete with this favoured land in the variety and interest of its indigenous fauna and flora. The scenery of the Southern Alps, with their snow-fields and glaciers, rivals that of Switzerland, and it may be doubted if the fjords of Norway can be compared in romantic beauty with the west coast sounds. The weird volcanic district of the North Island, with its hot lakes and geysers and the still smouldering fires of Tongariro and Ruapehu, stands in startling contrast to the peaceful forest-girt lakes of the south, with the snow-clad mountain peaks reflected in their clear waters. The luxuriance of the subtropical vegetation in the far north, with its kauri forest, tree ferns, and nikau palms, is only eclipsed by the still more luxuriant mixed forest of the wet west coast, with its gigantic evergreen beeches, conifers, and crimson-flowered ratas. The peculiar alpine and subalpine floras, again, with their beautiful Celmisias, their magnificent species of Ranunculus, their Ourisias, and, most interesting of all, the so-called "vegetable sheep" of the genera Raoulia and Haastia, are probably unsurpassed in botanical interest in any part of the world.

By far the greater number, at any rate of the flowering plants, are endemic, and even the outlying islands have many species absolutely peculiar to them. Some of the more striking plants, such as the cabbage tree (Cordyline, known to English horticulturists as Dracæna), the flax bush (Phormium, shown in the foreground of our illustration), *Olearia haastii* (one of the many beautiful species of this genus found in New Zealand), and some of the shrubby Veronicas, have already found their way into English gardens; but no one who has not been in the country can form any idea of the wealth and beauty of its native flora.

Along the Route of the North Island Main Trunk Railway: Ruapehu Mountains, from Raurimu. (Photo. C. Spencer.)

Associated with this striking vegetation is a no less unique and interesting indigenous fauna, in which the ancient tuatara and the numerous flightless birds of divers families—kiwis, kakapos, wekas, and Notornis—form the most conspicuous features, to say nothing of hosts of remarkable invertebrates, such as Peripatus, land planarians and nemertines.

It was inevitable that the process of settlement of the country by Europeans, with the consequent clearing of the forests and the introduction of carnivorous animals—dogs, cats, rats, weasels, and so on—should have a disastrous effect both upon the scenery and upon the plants and animals. Already much of the forest has been destroyed, and many of the unique native birds are almost extinct, especially those which have lost the power of flight, while the tuatara is no longer found on the mainland, having, it is said, been exterminated there by the pigs introduced by Captain Cook, though still surviving on some of the small islands.

In these circumstances any attempt to arrest the progress of destruction must be heartily welcomed, and the New Zealand Government is to be congratulated upon the vigorous efforts which it is making in this direction. The report on scenery preservation recently issued by the Department of Lands is a most interesting document, with a wealth of beautiful photographic illustrations, one of the most striking of which we reproduce. We learn from this publication that already nearly three million acres have been set aside as national parks, and since the Land Act of 1892 came into force "the protection and preservation of the beautiful natural scenery with which New Zealand is so richly endowed has been steadily kept in view, and when any portion of Crown lands has been opened for settlement, areas of specially attractive forest, or land surrounding waterfalls, caves, or thermal springs, have been excluded from sale and set apart for all time by permanent reservation." In 1903 a special Scenery Preservation Act was passed, dealing with the acquisition and reservation of all suitable lands, whether Crown, freehold, or native. A further Act provided for the formation of "The Scenery Preservation Board," which now acts as an advisory board to the Government, and reports on all cases of suggested reservations. That this board is no mere shadow but a really efficient instrument for the purpose in view is proved by the amounts which have been paid by way of compensation for land acquired during the three years of its existence. In 1904–5 the amount was only 216*l*. 4*s*. 10*d*., but in 1906–7 it had already risen to 7855*l*. 19*s*. 10*d*.!

No less important is the work which the Government has long had in hand in protecting the native animals and providing sanctuaries where they may remain unmolested, either by man or by the noxious animals which man has introduced. For this admirable purpose some of the small islands off the coast have been selected, such as Little Barrier Island in the north, Resolution Island in the south-west, and Kapiti Island in Cook Straits. These islands have been well chosen so as to give as great a range as

[1] (1) "Report on Scenery Preservation for the Year 1906–7." (Published by the New Zealand Government, 1907.)
(2) "Report on a Botanical Survey of Kapiti Island." By L. Cockayne. (Published by the New Zealand Government, 1907.)

possible in climatic conditions, nor has the purely scientific aspect of the question been neglected, for simultaneously with the document to which we have already referred, the New Zealand Government has just issued a detailed "Report on a Botanical Survey of Kapiti Island," by Dr. L. Cockayne, a botanist who is already widely known for his researches on the New Zealand flora. This exhaustive and painstaking piece of work deals with the physical geography and climate of the island, and with the introduced plants and animals, as well as with the indigenous flora. The latter is treated under the headings of the various plant-formations—classified as forest, shrub, coastal, meadow, and rock-formations—and much attention is devoted to ecological problems. The suitability of the island as a plant and animal sanctuary is discussed, and lists are given of the native and introduced plants. This report, again, is illustrated by numerous excellent photographs taken by the author.

The interesting monograph which we have thus briefly summarised is a good example of the activity and enthusiasm with which the representatives of natural science in New Zealand are carrying on the good work initiated by such pioneers as von Haast, Hutton, Hector, Kirk, Buller, and Parker, to mention only some among those who have already passed away from the scene of their labours.

ARTHUR DENDY.

LIEUT.-COL. R. L. J. ELLERY, C.M.G., F.R.S.

LIEUT.-COL. R. L. J. ELLERY, whose death we announced on January 16, was for many years the director of the Williamstown and Melbourne Observatories. To review his career is to recall the history of astronomy in Australia, so intimately was he connected with its progress. When he took up work as Government Astronomer in a rising colony, the instruments at his disposal were small, and the funds available for promoting astronomical research necessarily limited. The extension witnessed in the last forty years is due in no small measure to his initiative, and not the least of his services was to induce the colony to recognise the claims of science and to make more liberal provision for its needs. By his efforts arose the new observatory at Melbourne, and by his activity it became the centre for the prosecution of much useful work. There, too, at his instigation was mounted the four-foot reflector, at the time of its erection the most powerful instrument in the southern hemisphere. This instrument was much used for the examination of Herschel's nebulæ, but in a new society, intent upon material progress, such a telescope was perhaps of even greater use by the interest it aroused in science generally. It served as a permanent reminder of the progress of science, and of the necessity of meeting its demands. For as the colonies enlarged, the claims of science required increasing support. In climatology, Col. Ellery's powers of organisation were invaluable. Not only did he collect the necessary information which indicated the more valuable localities for settlement, but gradually issued isobaric charts and storm warnings, at first applicable to the coast, but afterwards, as other colonies joined in an uniform scheme, published daily weather charts extending over the whole continent. Terrestrial magnetism was another subject he pursued with great eagerness, and geodesy, including pendulum experiments and longitude determinations, also claimed the attention of the staff. In a word, the observatory was the centre of enterprise and activity, encouraging the scientific spirit in many directions.

Forty years ago, the condition of meridianal astronomy in the southern hemisphere was in a backward condition, and naturally much attention had to be paid to the determination of star places. Two standard star catalogues were issued from the Melbourne Observatory under Col. Ellery's direction, and, in addition to this special work, zone observations on a large scale were carried out. Taking part in the work of the International Star Chart has increased the meridian measures very considerably, since the observatory has loyally assisted others in providing the positions of guiding stars, where required, and for the final reduction of the measures on the photographic plates. Both in 1874 and 1882, Australia furnished a number of stations for the observation of the transit of Venus, and particularly on the former occasion the late director was instrumental in providing suitable equipment, and assisted the general programme very materially.

Col. Ellery retired from the office of director in 1895. Some portion of his leisure he devoted to the preparation of a history of the beginnings and growth of astronomy in Australia, and in various ways he was prominent in promoting scientific interests. He was elected a Fellow of the Royal Society in 1873, was a Fellow of the Royal Astronomical Society, and of many colonial societies for the promotion of scientific aims.

NOTES.

IN the Henry Sidgwick memorial lecture at Newnham College, Cambridge, on January 25, Mr. Balfour spoke on decadence, and remarked that progress is with the West and with the communities of the European type. "If our energy of development," he is reported to have said, "were some day exhausted, who can believe that there remains any external source from which it can be renewed? Where are the untried races competent to construct out of the ruined fragments of our civilisation a new and better habitation for the spirit of man?" He answered his own questions with the assertion that such nations do not exist. But Japan has been steadily assimilating what is most important in European civilisation for some years now, and her system of education is every year approaching in efficiency anything the West has to show. In the contingency of which Mr. Balfour spoke, it is easily conceivable that a people with a genius for development, such as Japan has shown, may take naturally the place of superiority and develop a system which is a distinct advance on any civilisation the world has yet known. Men of science will be pleased with Mr. Balfour's tribute, in the latter part of his lecture, to the achievements effected by science and to the extent science has assisted human development, but they will at the same time remember that the Government of which Mr. Balfour was the leader assisted scientific work no more than other Governments. Statesmen are eloquent in praising scientific work and methods, but few of them have sufficient courage of their expressed convictions to make adequate provision for the extension of natural knowledge which is the life-blood of the modern State.

WE regret to see the announcement of the death of Sir Thomas M'Call Anderson, regius professor of medicine in the University of Glasgow since 1900.

MR. MORRIS K. JESUP, who died last week, bequeathed 200,000*l.* to the American Museum of Natural History for its collections. Mr. Jesup was president of the museum for twenty-five years; his name is familiar to anthropologists, and naturalists generally, as that of one who gave generous assistance to various expeditions and other scientific enterprises.

LORD AVEBURY has been elected president of the Royal Microscopical Society, and will deliver an address on seeds, with especial reference to British plants, at the March meeting of the society.

WE learn from the *British Medical Journal* that the Secretary of State for the Colonies has appointed Dr. W. J. Simpson, professor of hygiene at King's College, London, to proceed to the Gold Coast to assist in combating the present outbreak of bubonic plague at Accra. Prof. Simpson left for the Gold Coast on January 18.

To the *Times* of January 22 Miss L. L. Veley contributes a letter on the subject of luminous barn-owls, in which it is suggested that the emanation is due to the feathers of the birds having come in contact with luminiferous decaying wood in their roosting-places. This suggestion, which has doubtless occurred to many naturalists, affords a probable and satisfactory explanation of the phenomenon.

THE Philosophical Society of Washington held its 643rd meeting at the Hubbard Memorial Hall, in the City of Washington, on January 18, the entire evening being devoted to commemorative addresses of the life and work of Lord Kelvin. Prof. A. G. Webster spoke of Kelvin's life and work, Prof. R. S. Woodward confined his address to Kelvin's contributions to geophysics, and Prof. Simon Newcomb devoted his remarks to Kelvin's character and personality, to which topic the British Ambassador also contributed some reminiscences. The president of the society, Dr. L. A. Bauer, presided.

DR. G. A. DORSEY, curator of anthropology in the Field Museum of Natural History, Chicago, has recently visited Cambridge before embarking on a protracted tour through the East Indian Archipelago, Australia, and Melanesia. After visiting the Philippines, where three of his students are engaged in ethnological researches, he will return to Chicago by way of China, Japan, and the Hawaiian Islands. He expects to be away from Chicago for about one year. This is merely a tour of inspection, but it may not unreasonably be expected that it will lead to future investigations by others in certain localities.

IN the Rev. Dr. Lorimer Fison, who died near Melbourne on December 29, 1907, Australian anthropology has lost one of its earliest scientific workers. He was born in England on November 9, 1832, and went up to Caius College, Cambridge, but never took a degree; after residing some time in Australia he became a Wesleyan missionary and went to Fiji, and it was from him that Lewis Morgan drew important information for his "Systems of Consanguinity." Returning to Australia, Dr. Fison met Dr. A. W. Howitt, and a joint work on Australian marriage customs, &c., "Kamibaroi and Kurnai," appeared in 1880. Whatever his views at that date, Dr. Fison subsequently dissented from Morgan's interpretation of the facts in favour of primitive promiscuity, for in an address to the Australasian Association for the Advancement of Science he took the view that the group marriage did not mean more than marital right or qualification by birth. Dr. Fison, unfortunately, found little time for writing; papers by him on Fijian customs and kinship systems appeared in the Journal of the Anthropological Institute; he dealt with Fijian land tenure in the *Expository Times* of 1905, and a year earlier he published in "Tales of Old Fiji" a small part of his great store of knowledge of that island. Some years ago he received a Civil List pension, but, to the loss of anthropology, broken health forbade him to do much literary work.

IN the *Engineer* and in *Engineering* of January 24 a large amount of space is devoted to the Board of Trade inquiry into the facts relating to a disastrous explosion of a thermal storage-drum in connection with a Babcock and Wilcox boiler at Greenwich. The explosion took place on December 20, 1906, and the inquiry (one of the longest on record) ended on January 22, 1908, when judgment was given by the commissioners. The finding was that the primary cause of the explosion was a crack which had been formed in the end plate, owing to the bad treatment to which the plate had been subjected while being fitted into the drum. Any fears that existed as to the peculiar liability of thermal storage-drums to fail were removed. Many points of scientific interest occurred during the inquiry, notably in the reports by Mr. W. Rosenhain and Dr. T. E. Stanton, of the National Physical Laboratory, showing from the results of chemical, microscopical, and mechanical tests that the plate in question was of good normal commercial quality, but that it had received severe treatment in the hands of the boiler-makers.

LAST spring Dr. J. Elberts, the German geologist, conducted an expedition to investigate further the fossiliferous deposits of the Bengawan River, near Trinil, in Java, rendered famous by the discovery of *Pithecanthropus erectus* by Dr. Eugene Dubois in 1891–2. Although extensive collections were made and fresh forms discovered, no trace of Pithecanthropus was found; but, according to the correspondent of the *Pall Mall Gazette* (January 17), Dr. Elberts found roughly fashioned implements of bone, "a fireplace, and the remains of extinct animals, from which he became convinced that the ape-man must have existed at a remoter period." Unfortunately, this statement is so vague that nothing can be accepted until more information comes to hand. The implication is that some beings made fires and cooked animals, now extinct, before the gravel beds were deposited which contain Pithecanthropus and other extinct forms. In the province of Madium a fireplace was discovered 20 feet below the surface containing stone arrow-heads and fragments of pottery, broken and partly burned bones, and charred teeth of a fossil buffalo, together with the bones of deer, pigs, and a fossil elephant (Stegodon); some of these bones had been split open in order to extract the marrow. Dr. Elberts computes that these people lived 20,000 years ago, but, as the correspondent of the *Pall Mall Gazette* does not give the data upon which this estimation is based, this date must await the publication of all the facts. It is evident that we may congratulate our German colleagues on having discovered remains of early inhabitants of Java who were apparently in their "Neolithic" stage of culture. It is to be hoped that when the finds are published in full it will be possible to learn what manner of men they were. We understand that the expedition is now in south Sumatra, where fossil plants will also be collected, in the hope of determining whether Sumatra had an Ice age.

THE correspondence on the winding of rivers in plains which followed the letter from Sir Oliver Lodge published in these columns on November 7 last (vol. lxxvii., p. 24), and to which Mr. J. Lomas contributed on December 5 (vol. lxxvii., p. 102), has led Dr. D. T. Smith, of Louisville, Ky., to remind us that the subject is discussed in a book of his entitled "Philosophy of Memory," which was reviewed in NATURE of May 18, 1899 (vol. lx., p. 51).

In his book a chapter on the laws of river flow is included, in which he expresses the opinions supported by Mr. Lomas. Dr. Smith's views were arrived at after many years of close observation of streams, ranging from rivulets to the Mississippi, on the banks of which he resides. As was said in the review of his book, his results merit careful consideration as an important contribution to the inquiry.

MR. R. I. LYNCH writes commenting on the review of "The Garden Beautiful" which was published (p. 217) in our issue of January 9. He takes exception to the remark:—"We cannot agree with the suggestion on p. 76 that trees growing in isolated positions on lawns have their roots robbed by the grasses! in anything like the measure that obtains when the trees are growing together in a plantation." Mr. Lynch reminds us of the experiments carried out at the Woburn Experimental Fruit Farm, and of the serious results that were found to follow when grass grows over the roots of a young tree. These experiments were personally inspected by our reviewer, who wrote with full knowledge of the results obtained. Mr. Lynch appears rather to have misunderstood the meaning of the sentence in the review. It was not intended to deny the deterring influence of the sward; the statement is that a tree growing on a lawn suffers less robbery at the roots from grasses than is suffered by a tree growing in a plantation, and therefore exposed to the competition caused by the encroachment of roots from adjacent trees, which in course of time must interlace. The question raised is, in fact, one of degree, and degree only.

IN the course of an article on the "Atlantic flora" of Scandinavia in *Naturen* for January, Mr. E. Jörgensen gives a figure, taken from a living specimen of the Lofoten variety of the fjord-horse, which affords a much better idea of this pony than does the one from a badly mounted skin in the Bergen Museum published last year by Dr. Stejneger in Smithsonian Miscellaneous Collections.

To the January number of the *Journal of Anatomy and Physiology* Dr. D. Forsyth contributes the first part of an important paper on the anatomy of the thyroid and parathyroid glands in mammals and birds, embodying the results of the examination of these organs in a large number of species. Since the conclusions are reserved for the continuation, a fuller notice of the paper may likewise be deferred. In the same issue Dr. W. L. H. Duckworth continues his account of the brain of native Australians, while Dr. Ramsay publishes additional observations on the dentition of the same race.

BULLETIN No. 56 of the University of Arizona Experiment Station is devoted to scale-insects infesting palms and the best means of exterminating these pests. One of the most troublesome, which much resembles the jujube-scale (*Parlatoria zizyphus*) commonly infesting oranges from the Mediterranean countries, and appears to belong to the same genus, was introduced on palms from North Africa. Unfortunately, it has been described independently by three different naturalists, in Italy, America, and New Zealand, under as many distinct names, of which *Parlatoria blanchardi* is entitled to stand.

To Dr. W. L. Abbott, who has previously done such good service to America by collecting in the Malay countries, the U.S. National Museum is indebted for a series of specimens of mammals from western Borneo, a notice of which is given by Mr. M. W. Lyon in No. 1577 of the Proceedings of that institution. The collection is noteworthy for the large number of skins of the proboscis-monkey. The animal referred to under the disguise of *Pongo pygmaeus pygmaeus* appears to be the orang-utan. Other recent issues of the same publication include an account of the North American parasitic copepod crustaceans of the family Caligidæ (No. 1573), by Mr. C. B. Wilson, and a list of the land-shells of the family Pyramidellidæ, with descriptions of new species, from the Oregon district (No. 1574), by Messrs. Dall and Bartsch.

A NOTABLE contribution to the botany of Texas is published in the eighteenth annual report of the Missouri Botanical Garden under the title of "Plantæ Lindheimerianæ, Part iii." Mr. F. Lindheimer was one of the early German pioneers in Texas, and from 1833 to 1851 made botanical collections that were to be named by Dr. G. Engelmann, of St. Louis, and Dr. Gray, and distributed among subscribers. Four fascicles were collected and distributed, and in the first two parts of "Plantæ Lindheimerianæ" determinations were given for the orders as far as Compositæ (Bentham-Hooker's sequence). The present part, prepared by Mr. J. W. Blankinship, contains a biography, the determinations for the remainders of the early fascicles, and for another series that may be regarded as fascicle v. Also the author has compiled a revised index of names for all the collections.

FERTILISATION in the genus Cypripedium forms the subject of a paper by Miss L. Pace published in the *Botanical Gazette* (November, 1907). The species *spectabile* and *parviflora* were examined, and the development of the embryo sac furnished results of peculiar interest. The original mother cell divides to form two daughter cells, one micropylar, the other chalazal. The nucleus of the micropylar cell rarely divides, but the nucleus of the chalazal cells divides, giving rise to two nuclei, so that three megaspore nuclei are usually produced. The chalazal cell becomes the embryo sac, in which two megaspore nuclei are used; another nuclear division completes development in the embryo sac, that contains then one egg cell, two synergids, and a polar nucleus. Fertilisation of the ovum is normal, and so-called double fertilisation is effected by the fusion of one synergid, the polar nucleus, and a male nucleus.

BOTANISTS, more especially those who favour the view that the derivation of the angiosperms should be traced through the gymnosperms, will be much interested in the theory with regard to the embryo sac advanced by Dr. O. Porsch in a small brochure published at Jena by Mr. Gustav Fischer. The original and essential points in the argument lie in the interpretation of the antipodal cells as an archegonial complex, and in homologising the polar nuclei with ventral canal cells. This postulates an archegonium consisting of an ovum and two neck cells, and a vestigial ventral canal cell nucleus at each end of the embryo sac. Dr. Porsch bases his arguments on a sequence starting from the condition of numerous archegonia found in Sequoia through types of the Cupressaceæ and Ephedra, where the archegonia are reduced in number and complexity, to a hypothetical case of two archegonia, at first juxtaposed, but subsequently located at the poles of the embryo sac.

IN the latest addition (No. 15) to the series of Bulletins issued by the University of Illinois, Mr. L. P. Breckenridge discusses the burning of Illinois coal without smoke. The fundamental principles that apply to smokeless furnace construction and working are enumerated, and, by means of units in actual operation, several ways are indicated in which these principles have been satisfactorily applied.

THE report of the Chief Inspector of Mines for the year 1904–5, issued by the Mysore Geological Department (Madras, 1907), has just been received. It contains the mineral statistics for 1904, and, as regards gold mining, is a record of steady progress. The value of the gold production in 1904 was 2,323,194*l*. The total value of gold produced from the commencement of mining operations up to the end of 1904 was 21,011,075*l*., and the total dividends paid amounted to 9,329,487*l*. In addition to gold, statistics are given of the production of salt, iron ore, corundum, soapstone, limestone, clays, laterite, granite, and other building stones.

IN a review of engineering in the United States last year, reference is made, in the *Engineer* of January 17, to the spectacular feature of building as an engineering work in the construction of the numerous steel-frame office buildings of enormous height in New York. The highest of these is the tower of the Manhattan Building, 75 feet by 85 feet, 660 feet high to the top of the cupola. This has forty-eight stories. Next to this is the tower of the Singer Building, forty-two stories, with a height of 612 feet. The main portions of these buildings are respectively eleven and fourteen stories high. On the other hand, the City Investing Company Building has the main building, twenty-five stories high, with a tower 70 feet square, having thirty-two stories, and rising to a height of 400 feet above the street. In all these cases the towers are used as offices, &c., like the main parts of the building. This requires very elaborate lift equipment, with high speeds. The city now has one building each of forty-eight, forty-two, and thirty-two stories; twenty buildings of twenty to twenty-six stories; fifty of fifteen to twenty stories; and 465 buildings of ten to fifteen stories in height.

WE have received from Dr. Eredia, of the Italian Central Meteorological Office, an article on the rainfall of the Ligurian Riviera, reprinted from the *Rivista Agraria* for October, 1907. This paper, like his other useful investigations of the meteorology of various Italian provinces, collects into convenient tables the most trustworthy data relating to the object in view, and discusses them in an interesting explanatory text, dealing with monthly and seasonal values. The latter clearly show that in all seasons of the year the rainfall along the eastern Riviera is greater than along the western, and that autumn is the wettest and summer the driest period. Next to the autumn season, winter is wettest at Genoa, Spezzia, and San Remo, *i.e.* near the centre and extremes of the province, but at other places the greatest fall occurs in the spring. The mean yearly values are 52·8 inches at Genoa, 57·7 inches at Spezzia, and 31·9 inches at San Remo; the period dealt with is 1880–1905.

THE Cantor lectures, delivered by Mr. Conrad Beck in November and December last, have been reprinted in recent numbers of the Journal of the Society of Arts (December 27, 1907, to January 17); they deal with the theory of the microscope, a subject of never-failing interest, whether it be considered from the theoretical or the practical standpoint. The first lecture deals with the problem of arranging lenses so as to obtain an enlarged view of an object; although most of the matter is well known, many points are considered in a most interesting and instructive manner, as, for instance, the interpretation of the Gauss surfaces for a thick lens or system of lenses. The second lecture is concerned with the quality of the image formed. The methods of correcting certain classes of lenses for spherical and chromatic aberration may be found in most books on geometrical optics, but the microscope objective is so complicated in its structure, and the conditions to be complied with in its design are so far different from those which determine the design of other lenses, that but scanty notice is generally given to this most important and interesting lens combination. Mr. Beck outlines the principles which must guide the designer of such a lens combination. The third lecture is devoted to the consideration of diffraction, so far as this applies to the microscope. The theory due to the late Prof. Abbe is outlined, and Mr. J. W. Gordon's criticisms of the theory are then explained; an experiment shown by Mr. Beck in his lecture proves conclusively that the Abbe theory is at fault in certain respects. The fourth lecture, which is concerned with the practical use of the microscope, should prove of great value to those who wish to employ that instrument to its greatest advantage.

MESSRS. E. B. ROSA and L. Cohen examine critically the formulæ given by different authors for the self-inductance of a circle in the Bulletin of the Bureau of Standards for December, 1907. They consider Wien's formula the most accurate, Maxwell's and Rayleigh's next, Minchin's, Hicks's, and Blathy's untrustworthy, and the simple formula of Kirchhoff, *i.e.* $L=4\pi a(\log 8a/r-1{\cdot}75)$, in which a is the radius of the circle and r the radius of its cross-section, as a very close approximation to the correct value.

THE *Journal de Physique* for December, 1907, contains Prof. Schuster's address to the Société française de Physique on some electrical phenomena of the atmosphere and their relations with solar activity. Prof. Schuster points out that the most important free periods of oscillation of the atmosphere of the earth are, according to the calculations of Lord Rayleigh and M. Margules, about twelve and twenty-three hours, and that in consequence the semi-diurnal motions are more pronounced than the diurnal. Assuming that the conductivity of the upper atmosphere is much greater than that of the lower, he shows that the electric currents produced in the atmosphere by its motion across the earth's magnetic field are capable of explaining the diurnal variations of terrestrial magnetism. The negative charges brought down by rain drops he considers account for the maintenance of the earth's negative charge. He points out that the evidence with regard to magnetic storms and sun-spots only establishes a general connection, and does not warrant us in attributing a particular storm to a particular spot. Finally, he urges the substitution of short organised attacks on definite problems for the present rather aimless accumulation of observations carried on for such long periods at so many places.

A COPY of the prospectus of Dr. J. W. Spengel's *Ergebnisse und Fortschritte der Zoologie* (see NATURE, January 16, p. 246), giving a sketch of the lines upon which that serial is to be conducted, and the names of the editors for special subjects, has been received from the publisher, Mr. Gustav Fischer, Jena.

GOOD pictures often serve to direct the attention of children to the beauties of nature and to encourage them to seek out the objects themselves in order to study them at first hand. A series of beautiful slides illustrating wild bird life, all of which have been made from photographs taken from nature, submitted to us for inspection by Messrs. Sanders and Crowhurst, should certainly succeed in attracting to the observation of birds in their natural surroundings those who are fortunate enough to see them.

MESSRS. MACMILLAN AND CO., LTD., have published a third edition of "Comparative Anatomy of Vertebrates," which has been adapted from the sixth German edition of Prof. R. Wiedersheim's work by Prof. W. N. Parker. The present edition has been almost entirely re-written, and with Prof. Wiedersheim's permission, alterations desirable in the interests of English students have been made. The general plan of the original has been retained, but some portions have been extended and others abridged. The second English edition was reviewed in the issue of NATURE of September 1, 1898 (vol. lviii., p. 409), when the characteristics of this widely known student's manual were described. The price of the new edition is 16s. net.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN FEBRUARY:—

Feb. 4. 4h. 11m. Moon in conjunction with ♀ and 3° 48′ S.
5. 6h. 22m. to 11h. 12m. Transit of Jupiter's Satellite IV. (Callisto).
,, 13h. 19m. to 17h. 1m. Transit of Jupiter's Satellite III. (Ganymede).
10. 7h. 50m. Venus and Saturn in conjunction.
11. 10h. 28m. Minimum of Algol (β Persei).
,, 12h. 22m. to 13h. 19m. Moon occults ζ Tauri (Mag. 3).
13. 2h. Mercury at greatest elongation (18° 9′ E.).
,, 11h. 45m. to 13h. 0m. Moon occults δ Geminorum (Mag. 3·6).
14. 7h. 17m. Minimum of Algol (β Persei).
15. 2h. 7m. Moon in conjunction with Jupiter and 1° 12′ N.
,, Illuminated portion of the disc of Venus = 0·797.
27. 12h. 48m. Moon in conjunction with Uranus and 0° 7′ N.

PHOTOGRAPHIC OBSERVATIONS OF ENCKE'S COMET (1908*a*).—Encke's comet was photographed at the Heidelberg Observatory on January 13, 14, 15, 18, and 19, and in No. 4229 of the *Astronomische Nachrichten* (p. 79, January 21) Prof. Wolf records the positions and magnitudes derived from the plates. On the first three dates the recorded magnitude was 12·0, on the last two 12·5. The observed positions have been compared with those given in the ephemeris, and corrections to the latter are appended; those for R.A. are fairly constant at +3m., but those for declination vary from −24′·0 (December 25, 1907) to +1′·4 (January 19).

SATURN, A NEW RING SUSPECTED.—Observing at an elevation of 1550 metres, at the Revard, Puy-de-Dôme, France, under exceptionally favourable conditions on September 5, 1907, M. G. Fournier suspected a faint, transparent, and luminous ring exterior to the principal rings of Saturn. On September 7 the same observer confirmed the presence of a very pale luminous zone sharply defined at its edges, but neither he nor M. Jarry-Desloges, who communicates the discovery to the *Bulletin de la Société astronomique de France* (p. 36, January), was able to find it on September 11. The latter observer suggests the possibility that the ring is subject to periodical fluctuations of brightness, and may, therefore, only become visible at certain intervals; he also suggests that observers situated in high altitudes, such as the Arequipa and Flagstaff stations, may, alone, be able to observe this difficult detail of the Saturnian appendage. A drawing accompanying the communication shows the nebulous ring, extending beyond the principal rings, as it appeared at 22h. 25m. on September 7.

DETERMINATION OF THE MOON'S LIGHT WITH A SELENIUM PHOTOMETER.—In a recent note in these columns (p. 258, January 16) reference was made to some results obtained by Messrs. Stebbins and Brown in a determination of the brightness of moonlight with a selenium photometer (*Astrophysical Journal*, vol. xxvi., p. 326). The result was given as 0·23 candle-power, but, as there seems to be some misconception as to the meaning of this, an explanation seems desirable. American observers state quantities of this kind in candle-metres, and thus interpreting the above result it means that the light of the full moon illuminates a white surface to the same extent as an illuminating source of 0·23 candle-power, placed at a distance of 1 metre, would illuminate it.

Owing to the colour-sensitiveness of the selenium cells being as yet unknown, this result must be accepted as purely preliminary; different cells gave results varying from 0·07 to 0·37, the mean being 0·22 candle-power, and very near to the 0·23 adopted by Müller ("Die Photometrie der Gestirne," Leipzig, 1897, p. 344) as the mean of several visual observations by different observers.

The method of observation adopted by Messrs. Stebbins and Brown was to determine at what distance from the selenium cell the standard candle would produce the same deflection as the light from the moon, and then to reduce this distance to terms of the standard candle-metre, afterwards applying the corrections for atmospheric absorption. The determinations of the variation of moonlight with the moon's phase gave consistent results for each cell, and forms the most valuable part of the work. The standard candle employed is by Max Kohl, and burns amyl acetate; the diameter of the round wick is 8 mm., and the height of the flame was regulated to 40 mm.

A USEFUL SUN AND PLANET CHART.—From the firm of Carl Zeiss we have received a copy of their chart for showing the position of the sun, or of any of the planets, at any epoch during the present year. The chart is constructed on a principle employed by Mr. R. H. Bow, of Edinburgh, and consists of two sets of curves and a star map. On the one set of curves, which is placed to the right of the star map, the declinations of the various bodies during the twelve months are shown, whilst the second set, placed directly below the star map, shows the right ascensions. To find the position of a planet on any date, the declination of the planet on that date is found on the former set of curves, and from the point thus determined a horizontal line is drawn across the star map. A vertical line is then drawn from the corresponding point on the right-ascension curve, and where these two lines intersect on the star map is the position occupied by the planet. A calendar of oppositions, quadratures, and conjunctions is also shown on the chart.

CHICAGO MEETING OF THE AMERICAN ASSOCIATION.

THE fifty-eighth meeting of the American Association for the Advancement of Science and of its affiliated scientific societies was held at Chicago from December 30, 1907, to January 4, 1908, under the presidency of Prof. E. L. Nichols, professor of chemistry at Cornell University. The attendance was estimated at about 1400, the accurate registration of the affiliated societies having not been handed in at the time of writing. The programme was one of unusual interest, and a number of important measures were adopted.

The opening meeting of the association was held on the morning of Monday, December 30. Addresses of welcome were made by Dean G. E. Vincent, of the University of Chicago, in the enforced absence of the president, Dr. H. P. Judson, and by Mr. G. E. Adams, vice-chairman of the local committee for the meeting. The retiring president, Dr. W. H. Welch, of Johns Hopkins University, introduced the president of the meeting, Prof. Nichols, who replied to the addresses of welcome. The address of the retiring president, Dr. W. H. Welch, was given on December 30 before a large audience, and consisted of a masterly treatment of the subject of the interdependence of medicine and other sciences of nature (see NATURE, January 23). At the conclusion of the address a reception was given to the members of the association and affiliated societies.

The vice-presidential addresses, that is, addresses of presidents of sections, were distributed through the week at afternoon sessions. That before Section A (mathematics and astronomy) was delivered by the retiring vice-president, Edward Kasner, of Columbia University. Its title was "Geometry and Mechanics." The address of the retiring vice-president of Section B (physics) was given by Prof.

W. C. Sabine, of Harvard University, under the title of "The Origin of the Musical Scale." The address before Section C (chemistry) was given by Mr. Clifford Richardson, of the New York Testing Laboratories, on "A Plea for the Broader Education of the Chemical Engineer." There was no address before Section D (mechanical science and engineering). The address of the retiring vice-president of Section E (geology) was delivered by Dr. A. C. Lane, State Geologist of Michigan, at the summer meeting of the section held at Lake George. The address of the retiring vice-president of Section F, Dr. E. G. Conklin, of the University of Pennsylvania, was entitled "The Mechanism of Heredity." The retiring vice-president of Section G (botany), Dr. D. T. MacDougal, of the Carnegie Institution, Washington, D.C., discoursed on "Heredity and Environic Forces." The retiring vice-president of Section H (anthropology and psychology), Prof. A. L. Kroeber, of San Francisco, spoke on "The Anthropology of California." The address before Section K (physiology and experimental medicine) was given by retiring vice-president Simon Flexner, of the Rockefeller Institute for Medical Research, New York, on the subject "Recent Advances and Present Tendencies in Pathology." An address was given before the newly established Section L (education) by the Hon. Elmer Brown, United States Commissioner of Education, on "The Future of the Section of Education."

The character of the papers read before the different sections and the affiliated societies was of a very high order. A prominent feature of the meeting was the holding of joint sessions and symposiums on subjects of allied interest. The section on mathematics and astronomy, that on mechanical science and engineering, and the Chicago branch of the American Mathematical Society, for example, held an important joint session to consider the teaching of mathematics to engineering students, in which the present status in the United States was discussed by Prof. Edgar J. Townsend, of the University of Illinois, and in other countries by Prof. Alexander Ziwet, of the University of Michigan.

Section K held an important symposium on January 1 on the subject of immunity, in which the following papers were presented after introductory remarks by the vice-president of the section, Dr. Ludwig Hektoen, of the University of Chicago:—anaphylaxis and its relation to immunity, by Dr. M. J. Rosenau and Dr. John F. Anderson, of the United States Public Health and Marine-Hospital Service (paper read by Dr. Anderson); hyper-susceptibility and immunity, by Dr. Victor C. Vaughan, of the University of Michigan; the hæmolysins of animal toxins, by Dr. Preston Kyes; artificial immunity to glucosides, by Dr. W. W. Ford; the differentiation of homologous proteids by serum reactions, by Dr. S. P. Beebe; immunity in spirochætal infections, by Dr. F. D. Novey; immunity in Rocky Mountain spotted fever, by Dr. H. T. Ricketts and Dr. L. Gomez; virulence of pneumococci in relation to phagocytosis, by Dr. E. C. Rosenow; the mechanism of streptococcus immunity, by Dr. G. F. Ruediger; immunity in tuberculosis, by Dr. M. P. Ravenel; chemical aspects of immunity, by Dr. H. Gideon Wells.

The American Society of Naturalists, in the afternoon of January 1, held an important discussion on the topic of cooperation in biological research, in which Prof. F. P. Lillie, of the University of Chicago, Dr. W. Trelease, of the Missouri Botanical Garden, Dr. H. H. Donaldson, of the Wistar Institute, Dr. Simon Flexner, of the Rockefeller Institute, Prof. W. H. Howell, of Johns Hopkins University, and Prof. J. R. Angell, of the University of Chicago, took part.

Under the auspices of Section I an important symposium was held on the subject of federal regulation of public health. This session was held jointly with the National Legislative Conference of the American Medical Association and other interested organisations. Addresses were given by Dr. W. H. Welch, Hon. George L. Shiras, Dr. Charles A. Reed (president of the National Legislative Council of the American Medical Association), and Dr. F. F. Westbrook, of the University of Minnesota. There was also a lengthy prepared discussion by representatives of the various organisations concerned.

Section G and the Botanical Society of America held a symposium on the species question, in which the taxonomic aspect was discussed by Prof. C. E. Bessey and Dr. N. L. Britton, the physiologic aspect by Dr. J. C. Arthur and Dr. D. T. MacDougal, and the ecologic aspect by Prof. F. E. Clements and Prof. H. C. Cowles.

The American Chemical Society, as usual, held a very important meeting with a lengthy programme in joint session with section C of the American Association for the Advancement of Science.

As the result of a letter from the President of the United States, Mr. Roosevelt, to the president of the association, Dr. Nichols, concerning the necessity for active measures to conserve the natural resources of the United States, resolutions were adopted announcing the importance of such an effort, and appointing a standing committee of the association to consider plans and to forward the general movement. Resolutions were also adopted favouring an increase in the facilities given by Congress to the United States Bureau of Education. Further resolutions were passed urging the establishment of a research laboratory in tropical medicine in the Isthmian Canal zone; favouring the efforts to preserve from extinction the great sea animals of the waters adjoining the United States; and urging upon Congress the establishment of an Appalachian Forest Reserve, reiterating a recommendation urged at the last meeting of the association.

At the meeting of the general committee on the night of January 2 it was decided that the next regular meeting of the association be held in Baltimore during convocation week, 1908–9, and that a summer meeting be held in the week beginning June 29 at Dartmouth College, Hanover, N.H. A resolution was also adopted recommending that arrangements be made, if possible, for a meeting in the summer of 1910 in the Hawaiian Islands.

Officers for the present year were elected as follows:—president, Prof. T. C. Chamberlin, of the University of Chicago; vice-presidents, A, no election; B, Prof. K. E. Guthe, State University of Iowa; C, Prof. L. Kahlenburg, University of Wisconsin; D, Prof. G. F. Swain, Massachusetts Institute of Technology; E, Prof. Bailey Willis, U.S. Geological Survey; F, Prof. C. J. Herrick, University of Chicago; G, Prof. H. M. Richards, Columbia University; H, Prof. R. S. Woodworth, Columbia University; I, no election; K, Prof. W. H. Howell, Johns Hopkins University; L, Prof. G. Stanley Hall, Clark University; general secretary, Prof. F. W. McNair, president Michigan School of Mines; secretary of the council, Prof. D. C. Miller, Case School of Applied Science; treasurer, Prof. R. S. Woodward, Carnegie Institution, Washington, D.C. (as before); permanent secretary, Dr. L. O. Howard, Smithsonian Institution, Washington, D.C. (as before).

STRESSES IN MASONRY DAMS.

THE stresses in masonry dams, to which much attention has recently been devoted in our correspondence columns, formed the subject of three papers read before the Institution of Civil Engineers on January 21. In the first, Sir John W. Ottley, K.C.I.E., and Dr. A. W. Brightmore described some experiments, occupying about fourteen months, made with plasticine models of a dam of typical triangular section under perfect conditions. The height of the model was 30 inches, and the length of the dam 12 inches. From the results of the experiments the following conclusions were drawn:—(1) If a masonry dam be designed on the assumption that the stresses on the base are uniformly varying, and that these stresses are parallel to the resulting force acting on the base, the actual normal and shearing stresses, on both horizontal and vertical planes, would (in the absence of stresses due to such factors as changes in temperature, unequal settlement, &c.) be less than those provided for. There can be no tension on any plane at points near the outer toe. There will be tension on planes other than the horizontal plane near the inner toe, the maximum intensity of such tension being generally equal to the average intensity of shearing stress on the base, and the inclination of its plane of action being about 45°.

In the second paper Mr. J. S. Wilson and Mr. W. Gore gave the results of an experimental investigation by means of india-rubber models. The following are some of the conclusions given:—(1) Tensile stresses may exist at the up-stream toe of a dam, notwithstanding the fact that the line of resistance lies well within the middle third. The tension may be reduced by (*a*) making the up-stream face vertical, or by otherwise increasing the weight of the dam toward that face; this would have the effect of increasing the stresses in the dam when the reservoir is empty; (*b*) by a general increase in the dimensions of the dam; (*c*) by placing an earth embankment against the down-stream face. (2) The direct stresses at the down-stream toe are compressive in every direction, but reduce to zero in the direction normal to the face. (3) The maximum compressive stresses in a dam above its foundations are in a direction approximately parallel with the down-stream face, and generally some distance therefrom. In magnitude they are slightly greater than

$$\frac{P_T}{\cos^2\phi},$$

where P_T is the maximum normal pressure on a horizontal plane as determined by the trapezium law, and ϕ is the angle between the resultant and the vertical. (4) The shearing stresses are considerable at or near the up-stream toe. They are a maximum a short distance from the down-stream face, in a plane approximately at 45° to the face. The maximum shearing stresses are in magnitude equal to

$$\frac{P_T}{2\cos^2\phi}.$$

(5) The stresses in the foundations are of less consequence than in the dam above the base, because of the lateral support and the more extended distribution. (6) The stresses are considerable at the toes of a dam if they form sharp angles with the foundations. These stresses may be reduced by replacing the angles with curves of large radii. The curve at the up-stream toe may take the form of a rounded quoin, cut in large stones, so as to avoid joints, in the masonry, normal to the direction of the greatest tensile stress.

In the third paper Mr. E. P. Hill described a method of determining stresses based on the assumption that the vertical pressure on the base varies uniformly from one side to the other.

AUSTRIAN SCIENCE.

THE monthly parts of the *Sitzungsberichte* of the Vienna Academy of Sciences which appeared last year show that there is no falling off in the research work carried out at the Austrian universities in the fields of mathematics and natural philosophy. Prof. Lecher, of Prague, has verified Ohm's law by showing that there is no difference in the resistance of a silver or platinum wire when a small or a large electric current passes through it, provided its temperature is the same in both cases. Assuming that the current is carried by one type of free electron, he deduces a velocity of propagation of electricity in ordinary cases of the order of a few centimetres per second.

Prof. F. Exner and Dr. E. Haschek have been engaged in a search for the cause of the slight variability of wave-length of many of the spectral lines with the method of excitation. They are disposed to attribute it to the lines for which it has been observed being complex, with satellites of variable intensity or number which appear to be present more frequently on the red than on the blue side of the line. In an instrument of only moderate resolving power, the apparent effect of any cause tending to increase the intensity of such satellites with respect to the original line will be a displacement of the line towards the red end of the spectrum.

Dr. N. Stücker has investigated the sensitiveness of a great number of persons to small differences of pitch in different parts of the musical scale. He finds that in general the region of maximum sensitiveness is in the octaves c^1 and c^2, where about 1/20th of a tone can be detected. A few musical people were able to detect a difference of 1/200th of a tone in this region. The higher limits of audibility varied from about 40,000 in general to more than 60,000 in the case of musicians.

The meteorological side of the activity of the academy is well represented by Dr. F. M. Exner's outlines of a theory of variation of atmospheric pressure. The principal result of this investigation is that the pressure variations may be represented by the motion of a relatively permanent system of isobars over the surface of the earth from west to east with a velocity varying slightly with the season.

An important series of papers by Prof. Rudolph Wegscheider and Dr. Heinrich Walter, published in the *Sitzungsberichte* (vol. cxvi., pp. 443, 455, and 533), throws a great deal of light on the phenomena occurring when soda is causticised by means of lime. On the one hand, the conditions of equilibrium for the reversible change $Ca(OH)_2 + Na_2CO_3 \rightleftarrows CaCO_3 + 2NaOH$ have been ascertained at different temperatures; that the change is a reversible one is shown by the fact that the same condition of equilibrium is established at a definite temperature whether the lime acts on sodium carbonate or caustic soda on calcium carbonate. The change in the direction from left to right seems to be more complete at 80° than at 106°–110°, and to occur more readily in dilute than in concentrated solutions; the way in which it is influenced by concentration is considered at some length from the standpoint of the theory of mass action. The loss of sodium carbonate which may occur in the more concentrated solutions owing to the formation of the mixed carbonate, $CaCO_3,Na_2CO_3$, is also fully dealt with, the conditions under which gaylussite, $CaNa_2(CO_3)_2,5H_2O$, and pirsonnite, $CaNa_2(CO_3)_2,2H_2O$, are capable of existence in contact with solutions of sodium carbonate and caustic soda being defined for different temperatures. It is noteworthy that the decomposition of both of the double salts by water is retarded owing to the formation of a protective sheath of insoluble calcium carbonate on the surface of the particles, so that if the mixed salt is once precipitated owing to the concentration becoming too great, loss of sodium carbonate may occur even though the insoluble material be well washed. The whole investigation has a special interest as illustrating the applicability of recently developed views in pure chemistry to the elucidation of technical problems.

During several years past the study of the general laws of esterification, especially of the influence exercised by structural peculiarities on the phenomena, has formed a special feature of the research work carried out under the direction of Prof. Wegscheider in the first chemical laboratory of Vienna University. The results obtained have, in particular, thrown considerable light on the nature of the so-called "steric hindrance." In continuation of these researches a series of papers by Anton Kailan appears in the *Sitzungsberichte* of the academy dealing with the esterification of the dinitrobenzoic acids, of mono- and di-hydroxybenzoic acids, and of pyridinemonocarboxylic acids by alcoholic hydrogen chloride. Prof. Wegscheider and E. Frankel discuss in considerable detail the reasons for abnormalities which sometimes are found to characterise the action of alkyl haloids on metallic salts of organic acids. The peculiar influence exercised by the presence of a small proportion of water on the rate of formation of ethyl chloride from alcohol and hydrogen chloride is the subject of a paper by A. Kailan, in which it is shown that the velocity constants of the action are proportional to the concentration of the hydrogen chloride only in absolute alcohol. In alcohol containing water, even in 99·9 per cent. alcohol, an increase in the concentration of the hydrogen chloride is found to be accompanied by a considerably greater increase in the velocity constant.

To vol. cxvi. of the *Sitzungsberichte (mathematisch-naturwissenschaftliche Klasse)* of the academy Mr. F. Siebenrock contributes a monographic revision of the American tortoises of the family Cinosternidæ, in which several changes in the generally accepted classification are proposed. In the British Museum Catalogue of Chelonians the family is taken to include only the single genus Cinosternum, while Claudius and Staurotypus are included with Dermatemys in the family Dermatemydidæ. This the author regards as an unnatural arrangement, and he proposes to transfer Claudius and Staurotypus to the Cinosternidæ, in which they form the subfamily Staurotypinæ. Mr. Siebenrock goes, however, even further than this, and suggests that the Cinosternidæ should be brigaded with the Chelydridæ in one sectional group—the Chelydroidea; while the families Dermatemydidæ and Platysternidæ are regarded as more nearly related to the Testudinidæ, with which they should form the group Testudinoidea. For the structural details on which the author justifies this radical change in taxonomy, reference must be made to the paper itself.

Morphologists will find much to interest them in an article in the same volume by Mr. Max Holl, of Graz, on the anatomy of the hind portion of the cerebral lobes in man and apes. The author appears to have been led to undertake the investigation by finding one human brain which differed most remarkably in regard to the arrangement and complexity of the postero-lateral sulci from all others which had come under his observation. His studies have, however, shown that there is a great amount of variation in this respect in human brains, and he has in consequence been led to recognise two principal types. To the more primitive of these he gives the name pithecoid and to the other that of anthropoid, type. Between the two there exists, however, an almost complete gradation. By far the greatest degree of individual variation in the form of the postero-lateral region of the brains of Primates occurs in the case of the tropical American spider-monkeys of the genus Ateles.

Attention may likewise be directed to a paper by Dr. Karl Byloff in the same volume on the structure and life-history of the blood-parasites *Trypanosoma lewisi* and *T. brucei*. New methods of staining microscopic preparations have enabled the author to bring to light certain previously unknown features in connection with these organisms. The various developmental stages assumed by trypanosomes in mammalian blood are the result of division of adult forms. High magnifying power has revealed the presence of pseudopodia-like projections at the "hind extremity" of both species of trypanosomes, but whether these are constant morphological features or merely temporary developments has yet to be demonstrated.

THE CENTENARY OF DAVY'S DISCOVERY OF THE METALS OF THE ALKALIS.[1]

A HUNDRED years ago last October, there happened one of those events to which the term epoch-making may, without cavil or question, be fittingly applied.

As it was an occurrence with which the name and fame of the Royal Institution are inseparably bound up, the managers have thought it only proper that its centenary should not pass unnoticed here, and it is by their wish, therefore, that I appear on this the first possible opportunity after the actual date of its hundredth anniversary to give you some account of it, and to state, so far as I am able and within the limits of an hour, the fruitful consequences that have flowed from it.

Let me, in the first place, attempt to recall the circumstances which led up to that cardinal discovery of which to-night we celebrate the centenary. These are connected partly with the institution itself and partly with the state of science in the early years of the nineteenth century.

In the year 1807 this institution was entering upon the eighth year of its existence. As you doubtless know, the Royal Institution grew out of a proposal to deal with the question of the unemployed, namely, by forming in London by private subscription an establishment for feeding the poor and giving them useful employment, and also for furnishing food at a cheap rate to others who may stand in need of such assistance, connected with an institution for introducing and bringing forward into general use new inventions and improvements, particularly such as relate to the management of heat and the saving of fuel, and to various other mechanical contrivances by which domestic comfort and economy may be promoted. Such was the original prospectus, but, like many other prospectuses, it failed to equal the promise its projectors held out.

[1] A lecture delivered at the Royal Institution of Great Britain, on Friday, January 17, by Prof. T. E. Thorpe, C.B., F.R.S.

Eventually the promoters decided, on the initiation of Count Rumford, that the Associated Institution would, as they expressed it, be "too conspicuous and too interesting and important to be made an *appendix* to any other existing establishment," and therefore it ought to stand alone on its own proper basis.

Accordingly, the problem of the unemployed still remains with us, whilst the new institution took the form of converting Mr. Mellish's house in Albemarle Street into a place where, by regular courses of philosophical lectures and experiments, the applications of the new discoveries in science to the improvement of the arts and manufactures might be taught, so as to facilitate the means of procuring the comforts and conveniences of life.

The Royal Institution had a troubled infancy. Like the poor it was originally designed to succour, it suffered much in the outset from lack of nourishment. To add to its miseries, the little starveling was caricatured by Gillray, lampooned by Peter Pindar, and ridiculed by Lord Brougham, and it was literally in the throes of dissolution when new life was breathed into it by the opportune arrival, in 1801, of a small spare youth of twenty-two from Bristol, whom the managers had engaged at a salary of 100 guineas a year. The youth was Humphry Davy, who had acted as assistant to Dr. Beddoes, of the Pneumatic Institution, and who had already made some slight stir in scientific circles by his discovery of a characteristic property of nitrous oxide. In announcing his arrival to the managers, Count Rumford reported that he had purchased a cheap second-hand carpet for Mr. Davy's room, together with such other articles as appeared to him necessary to make the room habitable, and among the rest a new sofa-bed, which, in order that it may serve as a model for imitation, had been made complete in all its parts. Six weeks after his arrival Davy was called upon to lecture, and a descriptive paragrapher of the period thus chronicles his success in the *Philosophical Magazine* for 1801:—

"It must give pleasure to our readers to learn that this new and useful institution, the object of which is the application of Science to the common purposes of life, may be now considered as settled on a firm basis. . . .

"We have also to notice a course of lectures, just commenced at the institution, on a new branch of philosophy—we mean the Galvanic Phenomena. On this interesting branch, Mr. Davy (late of Bristol) gave the first lecture on the 25th of April. He began with the history of Galvanism, detailed the successive discoveries, and described the different methods of accumulating galvanic influence. . . . He showed the effect of galvanism on the legs of frogs, and exhibited some interesting experiments on the galvanic effects on the solution of metals in acids. Sir Joseph Banks, Count Rumford, and other distinguished philosophers were present. The audience were highly gratified, and testified their satisfaction by general applause. Mr. Davy, who appears to be very young, acquitted himself admirably well; from the sparkling intelligence of his eye, his animated manner, and the *tout ensemble*, we have no doubt of his attaining a distinguished eminence."

And what was of more immediate consequence, this confident assurance was shared also by the managers, for at a subsequent meeting they unanimously resolved "that Mr. Humphry Davy, director of the chemical laboratory, having given satisfactory proofs of his talents as a lecturer, should be appointed, and in future denominated, lecturer in chemistry at the Royal Institution, instead of continuing to occupy the place of assistant lecturer, which he has hitherto filled."

That such shrewd experienced men of the world as Sir Joseph Banks and Rumford, who were the moving spirits in the management of the institution and genuinely solicitous for its welfare, should thus entrust its fortunes, then at their lowest ebb, to the power and ability of a young and comparatively unknown man, barely out of his teens, seems, even in an age which was familiar with the spectacle of "a proud boy" as a Prime Minister, like the desperate throw of a gambler.

But Banks and Rumford had, doubtless, good reason for the faith that was in them. For a happy combination of circumstances had served to bring the Cornish youth within the range of many who could be of service to him in that search for the fame for which he hungered. His connection with the Beddoes brought him the friendship of the Edgeworths, and it is amusing to trace how the good-humoured patronage of the gifted Maria quickly passed into amazement and ended in awe as her acquaintance with him ripened. Living in Bristol, he was at once brought into that remarkable literary coterie which distinguished that city at the close of the eighteenth century. Southey spoke of him as a miraculous young man, whose talents he could only wonder at. Cottle, the publisher, on one occasion said to Coleridge, "You have doubtless seen a great many of what are called the cleverest men—how do you estimate Davy in comparison with these?" Mr. Coleridge's reply was strong and expressive. "Why, Davy can eat them all! There is an energy, an elasticity, in his mind which enables him to seize on and analyse all questions, pushing them to their legitimate consequences. Every subject in Davy's mind has the principle of vitality. Living thoughts spring up like turf under his feet."

Davy's experimental work on "the pleasure-giving air" had made him known to the Watts and the Wedgwoods. Priestley, then in exile, and Hope, of Edinburgh, were greatly impressed with the philosophical acumen of the author of phosoxygen, and he had a powerful friend in his own countyman Davies Gilbert, who succeeded him in the presidential chair of the Royal Society. We need be in no doubt, therefore, as to the influences which conspired to bring Davy into what he termed "the great hot-bed of human power called London."

The mention of Davy's first course of lectures in this institution brings me at once to the proper subject of this discourse.

The first year of the last century is memorable for the invention of the voltaic battery and for its immediate application by Nicholson and Carlisle in this country to the electrolytic decomposition of water.

Davy himself has said:— "The voltaic battery was an alarm bell to experimenters in every part of Europe; and it served no less for demonstrating new properties in electricity, and for establishing the laws of this science, than as an instrument of discovery in other branches of knowledge; exhibiting relations between subjects before apparently without connection, and serving as a bond of unity between chemical and physical philosophy."

We owe it to Sir Joseph Banks that Volta's great discovery was first made known to English men of science, and the study of the phenomena of galvanic electricity was at once entered upon by a score of experimenters in this country. Among them was Davy. Even before he left Bristol he was hard at work on the subject, sending the results of his observations to Nicholson's Journal in a series of short papers. He resumed his inquiries immediately on his arrival in London, and was doubtless well prepared, therefore, for his opening course of lectures.

In 1801 he sent his first communication to the Royal Society on "An Account of some Galvanic Combinations formed by the Arrangement of Single Metallic Plates and Fluids, Analogous to the New Galvanic Apparatus of Mr. Volta." Although the work was continually interrupted by requests made to him by the managers to carry out their own ideas of facilitating the means of procuring the comforts and conveniences of life, he never lost sight of the subject of voltaic electricity, and in spite of innumerable distractions due to the precarious position of the institution, he gradually accumulated the material out of which grew his first Bakerian lecture, "On some Chemical Agencies of Electricity," read before the Royal Society on November 20, 1806. I have ventured elsewhere to express my opinion of this paper. In my judgment it constitutes, in reality, Davy's greatest claim as a philosopher to our admiration and gratitude, for in it he, for the first time, succeeded in unravelling the fundamental laws of electrochemistry, and thereby imported a new order of conceptions, altogether unlooked for and undreamt of, into science.

I am only at the moment concerned with this memoir in its relation to the discovery of which to-night we celebrate the centenary. The isolation of the metals of the alkalis was unquestionably an achievement of the highest brilliancy, and as such appeals strongly to the popular imagination. But it was only the necessary and consequential link in a chain of discovery which, had Davy neglected to make it, would have been immediately forged by another.

The publication of Davy's first Bakerian lecture produced a great sensation, both at home and abroad. Berzelius, years afterwards, spoke of it as one of the most remarkable memoirs that had ever enriched the theory of chemistry. Very significant, too, of the impression it made on the world of science was the action of the French Institute. Bonaparte, then First Consul, had announced his intention of founding a medal "for the best experiment which should be made in the course of each year on the galvanic fluid," and a committee of the institute, consisting of Laplace, Halle, Coulomb, Hauy, and Biot, was appointed to consider the best means of giving effect to the wishes of the First Consul. To the young man, with the little brown head, like a boy (as Lady Brownrigg described him), now twenty-eight years of age, was awarded the medal. All the institute got from the founder of the medal was what Maria Edgeworth termed "a rating all round in imperial Billingsgate." There was no *entente cordiale* in those days; indeed, the feeling of animosity was intense. Of course, there were persons who said that patriotism should forbid the acceptance of the award. Davy's own view was more sensible and politic:—"Some people," he said to his friend Poole, "say I ought not to accept this prize; and there have been foolish paragraphs in the papers to that effect; but if the two countries or Governments are at war, the men of science are not. That would, indeed, be a civil war of the worst description; we should rather, through the instrumentality of men of science, soften the asperities of national hostility."

Thanks to the kindness of Dr. Humphry Davy Rolleston, the grandson of Dr. John Davy, the brother of Sir Humphry, who has also been so good as to lend me this admirable bust of the great chemist by Chantrey, and this charming portrait by Jackson, I am able to show you this evening this historically interesting medal.

What Davy looked like at this period of his life may be seen from the picture I now project upon the screen. It is a reproduction of the large portrait which hangs in the vestibule, and which the institution owes to the thoughtful kindness of the late Mr. Graham Young.

As the applications of voltaic electricity seemed in 1806 to have no immediate bearing on the comforts and conveniences of life, Davy, during the greater part of the following year, was required to direct his attention to other matters. But in the late summer of 1807 he was able to resume his work with the voltaic battery, and he commenced to study its action on the alkalis.

That the alkalis—potash and soda—would turn out to be compound substances was not an unfamiliar idea at the time, and it is significant that almost immediately after Nicholson and Carlisle had resolved water into its elements by the action of voltaic electricity, Henry, of Manchester, the friend and collaborator of Dalton, should have made the attempt to apply the same agency to the separation of the presumed metallic principle of potash. The conception that what the older chemists called "earths" might be made to yield metals was at least as old as the time of Boyle, and probably dates back from the earliest days of alchemy. The relation of the earths to the metals was part of the doctrine of Becher and Stahl; it was no less a part of the antiphlogistic doctrine of Lavoisier, although the points of view were diametrically opposed. Neumann attempted to obtain a metal from lime, Bergman considered that baryta was, like lime, a metallic calx, and Baron that alumina contained a metal. From their many analogies to these substances it was not unreasonable, therefore, to surmise that potash and soda might also contain metallic principles.

I have elsewhere pointed out that there is some evidence that whilst at Bristol Davy had already attacked the problem of the resolution of the alkalis by means of voltaic electricity. What precise idea he had in again attacking it, or what expectation he had of a definite result, is difficult to determine. In one of his lectures on electrochemical science, delivered some time subsequently, he said he had a suspicion at the time that potash might turn out to be "phosphorus or sulphur united to nitrogen," conceiving that, as the volatile alkali was composed of the light inflammable hydrogen united to nitrogen, so the fixed and denser alkalis might be composed of the denser inflammable bodies—phosphorus and sulphur—also united to nitrogen.

Davy once said that "analogy was the fruitful parent of error," and few more striking instances of perverted analogy are to be met with in science than this. In another of his lectures he said of the alchemists that "even their *failures* developed some unsought-for object partaking of the marvellous"; and if such had been his reasoning, the statement is no less true of himself.

So far as can be ascertained, it was on October 19, 1807, that he obtained his first decisive result. This is thus described in Davy's own handwriting in the Laboratory Journal, which has been preserved for us by the pious care of Faraday, and which is one of the most precious of the historical possessions of the Royal Institution:—"When potash was introduced into a tube having a platina wire attached to it, so [fig.], and fused into the tube so as to be a conductor—*i.e.* so as to contain just water enough, though solid—and inserted over mercury, when the platina was made negative, no gas was formed and the mercury became oxydated, and a small quantity of the alkaligen was produced round the platina wire, as was evident from its quick inflammation by the action of water. When the mercury was made the negative, gas was developed in great quantities from the positive wire, and none from the negative mercury, and this gas proved to be pure oxygen—a capital experiment, proving the decomposition of potash." On the 19th of the following month he delivered what is generally regarded as the most memorable of all his Bakerian lectures. It is entitled "On some New Phenomena of Chemical Changes produced by Electricity, Particularly the Decomposition of the Fixed Alkalies; and the Exhibition of the New Substances which Constitute their Bases; and on the General Nature of Alkaline Bodies."

Few discoveries of like magnitude have been made and perfected in so short a time, and few memoirs have been more momentous in result than that which, put together in a few hours, gave the results of that discovery to the world.

The whole work was done under conditions of great mental excitement. His cousin, Edmund Davy, who at the time acted as his assistant, relates that when he saw the minute globules of the quicksilver-like metal burst through the crust of potash and take fire, his joy knew no bounds; he actually danced about the room in ecstasy, and it was some time before he was sufficiently composed to continue his experiments.

The rapidity with which he accumulated results after this first feeling of delirious delight had passed was extraordinary, and he had obtained most of the leading facts concerning the physics and chemistry of the new substances before the middle of November.

He began his lecture with a felicitous reference to the concluding remarks of the one of the previous year, namely, "That the new methods of investigation promised to lead to a more intimate knowledge than had hitherto been obtained concerning the true elements of bodies. This conjecture, then sanctioned only by strong analogies, I am now happy to be able to support by some conclusive facts."

In the first attempts he made to decompose the fixed alkalis he acted upon concentrated aqueous solutions of potash and soda with the highest electrical power he could then command at the Royal Institution, viz. from voltaic batteries containing twenty-three plates of copper and zinc of 12 inches square, 100 plates of 6 inches, and 150 of 4 inches, charged with solutions of alum and nitric acid; but although there was high intensity of action, nothing but hydrogen and oxygen was disengaged. He next tried potash in igneous fusion, and here the results were more encouraging; there were obvious and striking signs of decomposition; combustible matter was produced, accompanied with flame and a most intense light. He had observed that although potash, when dry, is a non-conductor, it readily conducts when it becomes damp by exposure to air, and in this state "fuses and decomposes by strong electrical powers."

Let me state in his own words, for the words are classical, what followed:—

"A small piece of pure potash, which had been exposed for a few seconds to the atmosphere, so as to give conductive power to the surface, was placed upon an insulated disc of platina, connected with the negative side of the battery of the power of 250 of 6 and 4 [that is 100 plates of 6 inches square and 150 plates of 4 inches square] in a state of intense activity; and a platina wire communicating with the positive side was brought in contact with the upper surface of the alkali. . . . Under these circumstances a vivid action was soon observed to take place. The potash began to fuse at both its points of electrization. There was a violent effervescence at the upper surface; at the lower, or negative surface, there was no liberation of elastic fluid; but small globules, having a high metallic lustre, and being precisely similar in visible characters to quicksilver, appeared, some of which burnt with explosion and bright flame, as soon as they were formed, and others remained, and were merely tarnished, and finally covered by a white film which formed on their surfaces."

He goes on to say:—

"Soda, when acted upon in the same manner as potash, exhibited an analogous result; but the decomposition demanded greater intensity of action in the batteries, or the alkali was required to be in much thinner and smaller pieces.

"The substance produced from potash remained fluid at the temperature of the atmosphere at the time of its production; that from soda, which was fluid in the degree of heat of the alkali during its formation, became solid on cooling, and appeared having the lustre of silver."

It would seem from this description of its properties that the potassium Davy first obtained was alloyed with sodium owing to the fact that the potash contained soda. Potassium is solid up to 143° F., whereas, as Davy was the first to show, an alloy of potassium and sodium is fluid at ordinary temperatures.

On account of their alterability in contact with air, Davy had considerable difficulty in preserving and confining the new substances so as to examine their properties. As he says, like the alkahests imagined by the alchemists, they acted more or less upon almost every body to which they were exposed. Eventually, he found they might be preserved in mineral naphtha.

The "basis" of potash was described by him as a soft malleable solid with the lustre of polished silver.

"At about the freezing point of water it becomes harder and brittle, and when broken in fragments, exhibits a crystallised texture which in the microscope seems composed of beautiful facets of a perfect whiteness and high metallic splendour. It may be converted into vapour below a red heat, and may be distilled unchanged, and is a perfect conductor of heat and electricity. Its most marked difference from the common run of metals is its extraordinary low specific gravity." At the time of its discovery it was the lightest solid known.

The "basis" of soda was found to have somewhat similar properties. It was slightly heavier than the "basis" of potash, and fused at a higher temperature.

Davy next examined the behaviour of the new substances towards a large number of reagents, but as his observations are now the common property of the textbooks, it is unnecessary here to dwell upon them.

He then enters upon some general observations on the relations of the "bases" of potash and soda to other bodies:—

"Should the bases of potash and soda be called metals? The greater number of philosophical persons," he says, "to whom this question has been put, have answered in the affirmative. They agree with metals in opacity, lustre, malleability, conducting powers as to heat and electricity, and in their qualities of chemical combination.

"Their low specific gravity does not appear a sufficient reason for making them a new class; for amongst the metals themselves there are remarkable differences in this respect. . . . In the philosophical division of the classes of bodies, the analogy between the greater number of properties must always be the foundation of arrangement.

"On this idea, in naming the bases of potash and soda, it will be proper to adopt the termination which by common consent has been applied to other newly discovered metals, and which, though originally Latin, is now naturalised in our language.

"Potasium (*sic*) and sodium are the names by which I have ventured to call the new substances; and whatever changes of theory, with regard to the composition of bodies, may hereafter take place, these terms can scarcely express an error; for they may be considered as implying simply the metals produced from potash and soda. I have consulted with many of the most eminent scientific persons in this country upon the methods of derivation, and the one I have adopted has been the one most generally approved. It is perhaps more significant than elegant. But it was not possible to found names upon specific properties not common to both; and though a name for the basis of soda might have been borrowed from the Greek, yet an analogous one could not have been applied to that of potash, for the ancients do not seem to have distinguished between the two alkalies."

Such, then, are the more significant features of one of the greatest discoveries ever made by a British chemist, as these are set forth in one of the most remarkable papers in the Philosophical Transactions of the Royal Society.

The publication of Davy's discovery created an extraordinary sensation throughout the civilised world, a sensation not less profound, and certainly more general from its very nature, than that which attended his lecture of the previous year. But at the very moment of his triumph it seemed that the noise of the universal acclaim with which it was received was not to reach him. I have already made reference to the condition of mental excitement under which the discovery was made and prosecuted. Almost immediately after the delivery of his lecture he collapsed, struck down by an illness which nearly proved fatal, and for weeks his life hung on a thread. He had been in a low, feverish condition for some time previously, and a great dread had fallen upon him that he should die before he had completed his discoveries. It was in this condition of body and mind that he had applied himself to the task of putting together an account of his results. Four days after this was given to the world he took to his bed, and he remained there for nine weeks. Such a blow following hard on the heels of such a triumph aroused the liveliest sympathy. The doors of the Royal Institution were beset by anxious inquirers, and written reports of his condition at various periods of the day had to be posted in the hall. The strength of the feeling may be gleaned, too, from the sentences with which the Rev. Dr. Dibdin, who had been hurriedly engaged to take his place in the theatre, began the lecture introductory to the session of 1808:—

"The managers of this institution have requested me to impart to you that intelligence, which no one who is alive to the best feelings of human nature can hear without the mixed emotion of sorrow and delight.

"Mr. Davy, whose frequent and powerful addresses from this place, supported by his ingenious experiments, have been so long and so well known to you, has, for the last five weeks, been struggling between life and death. The effects of these experiments recently made in illustration of his late splendid discovery, added to consequent bodily weakness, brought on a fever so violent as to threaten the extinction of life. Over him it might emphatically be said in the language of our immortal Milton, that

"... Death his dart
Shook, but delayed to strike."

"If it had pleased Providence to deprive the world of all further benefit from his original talents and intense application, there has certainly been sufficient already effected by him to entitle him to be classed among the brightest scientific luminaries of his country."

After having, "at the particular request of the managers," given an outline of Davy's investigations, Dr. Dibdin proceeded to say:—

"These may justly be placed among the most brilliant and valuable discoveries which have ever been made in chemistry, for a great chasm in the chemical system has been filled up; a blaze of light has been diffused over that part which before was utterly dark; and new views have been opened, so numerous and interesting, that the more any man who is versed in chemistry reflects on them, the more he finds to admire and heighten his expectation of future important results.

"Mr. Davy's name, in consequence of these discoveries, will be always recorded in the annals of science amongst those of the most illustrious philosophers of his time. His country, with reason, will be proud of him, and it is no small honour to the Royal Institution that these great discoveries have been made within its walls—in that laboratory, and by those instruments which, from the zeal of promoting useful knowledge, have, with so much propriety, been placed at the disposal and for the use of its most excellent professor of chemistry."

And now, in the few minutes that remain to me, let me indicate what has been the outcome of this great and fundamental discovery. How far has the expectation of future important results been realised? Have sodium and potassium at all justified the hope that they would facilitate the means of procuring the comforts and conveniences of life?

I have not the time, even if I had the intention, to attempt to follow the many changes in the metallurgy of the metals of the alkalis of the past century. Let me at once proceed to show how the matter stands at the end of a hundred years.

The general properties and chemical activities of potassium and sodium are so very similar that, as a matter of commercial production, that metal which can be most economically obtained is necessarily the one most largely manufactured, and of the two that metal is sodium. To-day, sodium is made by thousands of tons, and by a process which in principle is identical with that by which it was first made by Davy, *i.e.* by the electrolysis of fused caustic soda. It is very significant that after a series of revolutions in its manufacture, sodium, having been produced from time to time on a manufacturing scale by a variety of metallurgical methods involving purely thermal processes of reduction and distillation, entirely dissociated from electricity, we should have now got back to the very principle of the process which first brought the metal to light. And that this has been industrially possible is entirely owing to another of Davy's discoveries—possibly indeed the greatest of them all—Michael Faraday. As we all gratefully acknowledge, it is to the genius and labours of Faraday—Davy's successor in this place—that the astonishing development of the application of electrical energy which characterises this age has taken its rise.

The modern method of production of sodium is based, therefore, as regards principles, upon the conjoint labours of Davy and Faraday.

These principles took their present form of application at the hands of a remarkably talented American—Mr. Hamilton Y. Castner—whose too early death, in the full vigour of his intellectual powers, was an incalculable loss to metallurgical chemistry. It is by Castner's process that all the sodium of to-day is manufactured.

In the Castner process melted caustic soda, produced by the electrolysis of a solution of common salt by a method also devised by Castner, is brought into an iron vessel shaped like a large cauldron, mounted in brickwork, and provided with an extension adapted to receive the negative electrode. Suspended directly above the kathode is an iron vessel attached to a lid; to its lower edge is secured iron wire gauze, which, when the receptacle is in position, completely surrounds the kathode. The positive electrode is connected with the lid of the vessel, which is provided with openings for the escape of the gases resulting from the electrolysis, and is suitably insulated.

As the electrolysis proceeds, the alkali metal, being much lighter than the molten caustic, rises from the negative electrode and passes into the receiver, the gases escaping around the edges of the cover. The molten metal collects on the surface of the caustic, and is removed by means of a large perforated spoon, the perforations enabling the melted caustic to flow out, while the metal remains in the spoon. As the several vessels are thus skimmed in succession, the fused sodium is collected into an iron vessel, whence it is poured into moulds, in which it congeals, forming blocks of the size and shape of an ordinary building brick. These, after being trimmed to remove adherent oxide, are immersed in paraffin oil, and are then packed into large iron drums holding about 6 cwt. or 7 cwt., capable of being closed air-tight, and protected in transit by an outer casing of wood.

The due regulation of the volume and intensity of the current is a matter of the greatest importance in order to obtain the most economical yield of the metal. No very high temperature is needed; indeed, the temperature of the fused caustic soda should not be much higher than that of its melting point. By suitably regulating the current, the soda, in fact, may be maintained at the proper temperature and in the proper degree of fluidity without extraneous heat. Fresh melted caustic soda is added to the vessel from time to time to replace the metal removed, and in this manner the process is made continuous.

The Castner process is now worked in England at Wallsend-on-Tyne, and at Weston Point, in Cheshire; at Rheinfelden, in Germany; at Clavaux, in France; also in Switzerland, and at Niagara, in America. The present yearly output amounts to about 5000 tons, but the plant already laid down is capable of producing at least twice this quantity.

The greater quantity of the sodium made in England is sent to Glasgow, where it is converted into sodium cyanide by the Cassel Cyanide Company for use in the extraction of gold. As gold is, I suppose, generally considered the principal material factor in procuring the comforts and conveniences of life, Davy's great discovery may be thus said to have secured the primary object which the projectors of the Royal Institution had in view. Other important uses of sodium are in the manufacture of peroxide for bleaching purposes, of artificial indigo, and of a number of other synthetic dye-stuffs and of drugs like antipyrin.

It need hardly be said that this extraordinary development of the manufacture has not been without its influence on the price of sodium. A quarter of a century ago it was a comparatively rare metal, and a stick of it was regarded as a chemical curiosity, to be handled with circumspection and care. Even as late as 1890 its selling price was as high as 8*s*. per lb. To-day it is 8*d*. Sodium now takes rank, therefore, with zinc, tin, copper, or aluminium as a common, ordinary metal of commerce.

I am indebted to the directors of the Castner-Kellner Company, and in particular to my friends Sir Henry Roscoe and Mr. Beilby, for affording me the opportunity, in connection with this lecture, of actually witnessing the modern process of manufacturing sodium as it is carried out at Wallsend, and I am further indebted to Mr. Beilby for the loan of the lantern-slides and specimens with which I have sought to illustrate that process.

And in concluding may I be permitted to recall here the feelings to which that visit to Wallsend gave rise? There, grouped together on the very spot where ended the old wall—the visible symbol of the power and might of a civilisation long since passed away—were some of the characteristic signs of another civilisation ampler and more beneficent. Before me, stretching down to the river, was the factory where a score of workers, clad in helmets and gauntlets, and swathed like so many Knights Templar, their visages lit up by the yellow soda flames, and their ears half-deafened with the sound of exploding hydrogen—a veritable inferno—were repeating on a Gargantuan scale the little experiment first made a century ago in the cellars of this building, turning out, day and night, tons of the plastic metal in place of the little pin-heads which then burst upon the astonished and delighted gaze of Davy. Behind me was the magnificent power-house—one of the most magnificent of its kind in the world—furnishing not only the electrical energy which transformed the soda into sodium, but diffusing this energy for a multitude of other purposes over an entire district—a noble temple to the genius and prescience of Faraday. Surely one might here say, if you desire to see the monuments of these men, look around! And to my right, and close at hand, was the huge building slip just vacated by the *Mauretania*, herself a symbol of the supremacy of an empire, far mightier, more world-wide, and more potent for good than that which massed its legions behind the old wall.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The electors to the Allen scholarship give notice that they are prepared to receive applications from candidates. Any graduate of the University is eligible for the scholarship provided that his age on the first day of the Lent term 1908 does not exceed twenty-eight years. This year the scholarship is open to candidates who propose to undertake research in any branch of study which comes within the department of any of the following special boards:—medicine, mathematics, physics and chemistry, biology and geology. The scholarship is tenable for one year, during which period it will be the duty of the student to devote himself to research in Cambridge or elsewhere. The emolument of the student is 250*l*., or such smaller sum as the fund, after payment of all expenses, shall be capable of providing. Every candidate must send particulars of his qualifications, &c., to the Vice-Chancellor, Gonville and Caius College Lodge, on or before February 15.

MANCHESTER.—The following brief summary of some recently published statistics serves to illustrate the development in the work of the University during the past eight years. The table not only indicates that a considerable increase has taken place in the numbers of students and staff, but also shows that the progress has been particularly marked in the fields of advanced study and research. The growing success of the honours schools in both science and arts is particularly worthy of notice:—

	End of 1899	End of 1907
Professors	30 ...	43
Total teaching staff...	98 ...	203
Students taking full day courses...	900 ...	1400
Science honours students	97 ...	180
Arts honours students	34 ...	106
Graduate and research students in residence	— ...	141
Research fellows and students pursuing original work	— ...	55

By the will of the late Mr. Basil McCrea, the Magee Presbyterian College, Londonderry, receives several substantial benefactions. Among these gifts occur 14,000*l*. for building and equipping a new lecture hall; a sum to endow two professorships, to be known respectively as the "Henry Wallace" and the "William Archer Butler" professorships, each professor to receive an annual stipend of 300*l*.; a sum to found and endow two lectureships in the science department of the college, each lecturer to receive an annual stipend of 150*l*., and to be known as the "McCrea lecturers"; such annual sum as may be necessary to make up the stipends of each of the professorships in the literary and science departments to 300*l*. per annum; 500*l*. each year to found and endow a "McCrea science scholarship" and a "McCrea literary scholarship," each of the value of 100*l*., to be competed for every third year, and any surplus to be used for "McCrea prizes" in the science and literary departments.

AT a recent meeting of the governors of the Glasgow and West of Scotland Technical College it was intimated that the Glasgow City Educational Endowments Board had made a further grant of 1000*l*. to the building fund of the college, and that the trustees of the Bellahouston Bequest Fund had promised a donation of 5000*l*. on condition that the governors raised a further sum of 45,000*l*. Including these grants, the building fund now amounts to 301,000*l*. The governors of the college have just resolved to raise the standard of the preliminary examination for admission to the course for the college diploma to that of the Leaving Certificate of the Scotch Education Department. The holders of this certificate are exempted from the preliminary examination of the Scottish universities. This raising of the standard of the entrance examination by the governors of the great technical college at Glasgow represents a new departure of high significance in technical education. Now that the courses will be based upon a preparatory training equal to that demanded by any British university, it will be possible to make substantial advance in the quality of the work undertaken.

A SCHEME to prepare girls better to undertake the duties of the home was described in a letter to the *Times* of January 24. The communication was signed by Prof. William Osler, F.R.S., Sir Henry Roscoe, F.R.S., and Prof. A. Smithells, F.R.S., with others. Instruction of the kind required is impossible without teachers capable of giving it, and the first step must be, the letter points out, to provide education of an advanced type for those who will hereafter conduct the work in its more elementary stages. It is therefore proposed to provide in London a course of post-graduate instruction in household economics. The course will be given at the women's department of King's College, and will begin next October. A college board, consisting mainly of the professors of the subjects germane to the course, with Prof. Smithells acting as honorary adviser, will control the educational side of the work. It is hoped that it will be found possible to include courses of training for the management of large educational and other institutions, for the duties of factory inspection, and for social work aimed at raising the standard of home life. Donations are asked for in order to raise 3000*l.*, the sum necessary for the effective organisation of the scheme, and may be sent to Miss Soltau, King's College (Women's Department), 13 Kensington Square, W.

THE best results are obtained in those technical schools where the students are encouraged to follow a suitable course of training extending over a number of years, and where the instruction provided is suited exactly to the industrial requirements of the district. The latest report of the Board of Education states in this connection:—"Well-considered programmes of instruction within schools and careful adjustment of the relation of school to school in populous areas have become more common. In an increased number of schools we find teachers at pains to urge continuity of study and to order their teaching so as to help towards this end. Opportunities for advanced work are provided more widely than before, and accordingly we find the period of study extending and the number of students of mature years increasing." To mark still more obviously the importance of continuity of study, the Board has given prominence to an arrangement by which the Board and the school authorities join in responsibility for the issue of "technical course certificates" affording suitable records of completed curricula. These certificates are to be given only in connection with courses each approved as providing such a technical education as will have a definite value in relation to the occupation to which it has regard. Each certificate as awarded by the local education authority or the managers of a school and endorsed by the Board will record continued attendance and satisfactory attainments in the several sections of the specified course of instruction. The system thus initiated appears to be capable of considerable development. It may become a valuable feature in the organisation of technical courses—standardising their aims and encouraging the students to persistent attendance and continuity of study. The statistics in connection with the examination of students in evening schools, too, the report points out, reflect both the improvement in the provision of more advanced classes and the increased regularity of the attendance of the students.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 7, 1907.—"The Electrical Discharge in Monatomic Gases." By F. **Soddy** and T. D. **Mackenzie.** Communicated by Prof. J. Larmor, Sec.R.S.

Helium and argon purified by volatilising calcium (Soddy, Proc. Roy. Soc., 1907, lxxviii., A, 429) from traces of common gases show a disinclination to conduct the discharge, and the question arises whether the monatomic gases in a perfectly pure state will conduct at all. The well-known phenomenon of "running out" or exhaustion of spectrum tubes filled with these gases with prolonged use might be due to absorption of the impurities only by the electrodes leaving the pure monatomic gases in a non-conducting state. This question has been exhaustively investigated, and the conclusion is drawn that the monatomic gases conduct in the same manner as common gases, but are relatively electrically, as well as chemically, inert. That is to say, the various stages of the discharge from the X-ray vacuum to the ribbon discharge when considerable quantities of gas are present are produced in the case of helium, for example, at pressures from five to ten times the pressure required to produce the same stage of the discharge in a gas like hydrogen or nitrogen.

The "running out" of spectrum tubes filled with monatomic gases under the discharge is due to absorption of the monatomic gas principally in the film of aluminium volatilised from the electrodes. In one series of experiments six tubes were filled with helium purified by calcium at the initial pressures 1·1 mm., 2·3 mm., 4·9 mm., 8·6 mm., 16·8 mm., and 31·2 mm. The first three became non-conducting—the discharge passing an alternative spark gap of an inch of air, and the tube fluorescing strongly—with less than an hour's running, and the fourth after sixty hours, the residual pressure of pure helium in each case being about 0·7 mm. This was determined by breaking the tube under mercury, and confirmed by the use of a specially designed form of McLeod gauge. In the first case the mercury rapidly liberated the greater part of the occluded gas by dissolving the film of volatilised aluminium. The occluded gases are also slowly evolved spontaneously in the cold, and practically completely when the tube is heated to its softening point for some time.

X-rays are given out in pure helium at pressures below 0·2 mm. in an X-ray tube 8 cm. diameter, while in hydrogen X-rays are not given out until the pressure is reduced below 0·1 mm. It is probable that the real pressure in an X-ray tube is in no case below 0·01 mm., and the general impression that the pressure is of the order of 0·001 mm. is due to a variety of misapprehensions regarding high vacua. The behaviour of argon, neon, mercury vapour, nitrogen, and carbon dioxide has also been investigated.

The behaviour of helium at low pressures, at which it conducts the discharge with abnormal difficulty, is strictly analogous to its behaviour at high pressures, when it conducts with abnormal facility (Ramsay and Collie, Proc. Roy. Soc., 1896, lix., p. 257). The curves connecting discharge potential and pressure were taken in the same tube for helium and hydrogen. Helium at 60 mm. showed the same discharge potential (7750 volts) as hydrogen at 12 mm. At a pressure of 30 mm. the potential in helium was 3400 volts, and in hydrogen 16,000 volts. Throughout the whole region, both of high and low pressure, one hydrogen molecule is electrically equivalent, so far as its effect on the character of the discharge is concerned, to several helium molecules.

The remarkable observation was made that some new spectrum tubes, as obtained from the maker, generated helium during preparation and the removal of the occluded gases. The only escape from the conclusion that helium was formed under the special conditions to which the tubes had been subjected was that the helium was derived from the aluminium electrodes. Experiments were made with old aluminium electrodes which had been exposed for months to the air after removal from old spectrum tubes in which they had been used with the rare gases. By the help of the calcium method it was proved that helium, neon, and argon can be obtained in this way in quantities sufficient to give a clear spectrum from old aluminium electrodes which have been used with these gases.

All the spectrum tubes used showed strongly Campbell Swinton's effect (Proc. Roy. Soc., 1907, A, vol. lxxix., p. 134) of developing minute bubbles when fused, usually in the areas exposed to the bombardment of particles travelling normally from the surface of the electrodes; but the argon tubes showed the effect to an extraordinary extent, the glass appearing to boil when fused. Experiments are described in which these glasses have been subjected to a temperature of 1300° C. in a vacuum furnace, and all but the inert gases absorbed by calcium. Only the minutest trace of rare gas is ever obtained in this way, and this is quite insufficient to produce the effect. In the case of the glass of a helium tube which showed Campbell Swinton's effect strongly, it was proved that after a preliminary heating in a vacuum, at a temperature below that necessary to produce bubbles, to drive off surface gas, not the faintest trace of helium was obtained. The view is put forward that the effect is due to a secondary decomposition of the glass under local heating during the bombardment, and that it is not due to the discharge gases being driven into the glass.

Royal Microscopical Society, December 18, 1907.—Mr. Conrad Beck, vice-president, in the chair.—Specimens of luminous bacteria: J. E. **Barnard.** On the room being darkened, the light given off by the bacteria was at once apparent, and the contents of the flask when shaken became very luminous. The light produced was nearly monochromatic, lying between the lines F and G of the spectrum. The whole energy of these bacteria seemed to be utilised in producing light, no heat whatever being detected.—Specimens of natural twin-crystals of selenite: E. **Large.** Specimens were also exhibited under special reflecting polariscopes; under some of these were also shown artistic subjects made from selenite, one representing a vase of flowers, and another flowers and fruits, with animals, such as parrots, chameleons, &c., which changed colour when a film of mica below the design was rotated. Mr. Large also exhibited a small double-image prism made from a fragment of Iceland spar and mounted on the nose of an objective, by means of which two images of a suitable object placed on the stage with a selenite plate were obtained in complementary colours.—Gregory and Wright's microscope: E. M. **Nelson.** This microscope was described and illustrated in an old and rare book published by Gregory and Wright in 1786, and was called a "new universal microscope, which has all the uses of the single, compound, opaque and aquatic microscopes." The illustration shows it to be very similar to one presented to the society in 1899 by Dr. Dallinger, which was then thought to have been made by Benj. Martin, but it now seems likely that it was made by Gregory and Wright, who were probably Martin's successors.—A correction for a spectroscope: E. M. **Nelson.** The paper described a device by which the object-glass of the telescope may be automatically rotated so as always to receive the rays from any part of the spectrum without obliquity.—Some African rotifers: J. **Murray.** The paper described about twelve species of Bdelloid rotifers from Old Calabar, Uganda, and Madagascar, among which were one new species and two new varieties.

January 15.—Mr. E. J. Spitta in the chair.—A new method of showing living bacteria by dark-ground illumination: C. **Beck.** The apparatus consisted of a modified parabolic illuminator, a Nernst lamp, and monochromatic blue light filter.—Some microscopes of new design made by Messrs. Leitz: J. W. **Ogilvy.** The instruments were fitted with Leitz's fine adjustment, the arrangement consisting of a worm wheel and heart-shaped cam, which gives an alternate rise and fall of 3 mm. to the body of the microscope. Mr. Ogilvy said an important feature in the arrangement was that, in the event of the objective being brought into contact with the cover glass when focussing, it simply rested upon the slide, no further downward motion being imparted to the body even if the observer continued to turn the milled head. The coarse adjustment was also provided with a safety arrangement.—The microscope as an aid to the study of biology in entomology, with particular reference to the food of insects: W. **Wesché.**

EDINBURGH.

Royal Society, January 6.—Prof. Crum Brown, F.R.S., vice-president, in the chair.—The chairman read a preliminary obituary notice of the late president, Lord Kelvin (see p. 253).—The fossil Osmundaceæ, part ii.: D. T. **Gwynne-Vaughan** and R. **Kidston,** F.R.S. The present part begins with a full account of the synonymy of scorral fern stems of osmundaceous affinity from the Permian of Russia. The internal structure of two of these, *Zalesskya gracilis* and *Z. diploxylon* (the latter a new species), is described in detail. They form a primitive genus of the Osmundaceæ, and are especially characterised by the possession of a broad and perfectly continuous ring of xylem, from which the leaf-traces depart in protostelic manner. The xylem is non-parenchymatous, and most of the tracheæ bear multiseriate pits. The protoxylems of the leaf-traces are shortly decurrent into the stele of the stem as mesarch strands dying out rapidly below. Two distinctly different regions are to be observed in the xylem, a peripheral zone of normal tracheæ and a central mass of short and wide elements with reticulate markings. In the living plant of *Z. diploxylon* the latter tissue occupied the whole of the centre of the stele, which therefore possessed a solid central mass of xylem. It follows that the central ground-tissue of the recent Osmundaceæ must be regarded as a true pith derived from the modified central xylem of such a stele. The phlœm consists of metaphlœm only, there being no protophlœm or porous layers.

PARIS.

Academy of Sciences, January 20.—M. Henri Becquerel in the chair.—The principal earthquake centres in France, and on the system of seismic stations that should be established: G. **Bigourdan.** Taking into account the stations already existing or now being established, further stations are suggested at Nice, Marseilles, Rennes, and Lille.—Concerning a tooth discovered by MM. Maurice de Rothschild and H. Neuville: Albert **Gaudry.** It is concluded that this tusk, found near Addis-Abeba, belongs to a large unknown African mammal, now existing or recently extinct.—Morphological variations, obtained artificially, of the tubercle bacillus of man and mammals: S. **Arloing.** An account, accompanied by reproductions of photographs, of the modifications produced in human and bovine tubercle bacilli by prolonged cultivation at either a high temperature (45°) or high pressure (2·5 atmospheres).—A differential system of the second degree: L. **Schlesinger.**—The periodic solutions of certain functional equations: Ernest **Esclangon.**—Methodical attempts at a cellular aëroplane: H. **Farman.** A detailed account of the steps by which the author constructed his aëroplane and learnt its use.—The efficiency of screws for propulsion in the air: Louis **Breguet.**—The study of radio-active lead: B. **Szilard.** Radium D, E, and F have been separated from radio-lead. The present paper is concerned with the best methods of effecting this separation.—An exceptional case of Zeeman's phenomenon: A. **Dufour.** It is shown that there exists at least one source of light, a flame in which calcium fluoride is volatilised, giving a spectrum attributed to a compound and not to an element, which, placed in a magnetic field, gives out circular vibrations the sense of which agrees with the hypothesis of the existence of positive electrons.—The calorimetric method applied to the study of slow reactions: Jacques **Duclaux.** A closed Dewar tube is used as the calorimetric vessel, the whole being placed in the water of a thermostat. As showing the accuracy obtainable, an example of the application of the method to the hydrolysis of ethyl acetate by potash is given.—The synthesis of ammonia: M. **Woltereck.**—The catalytic power of silica and alumina: J. B. **Senderens.** The catalytic effect produced by silica or alumina depends upon the state of division and also upon the temperature to which these substances have been raised. Thus precipitated silica, dried by a gentle ignition, at 280° acts upon alcohol giving 99·5 per cent. of ethylene. The same silica, calcined for one hour at a red heat, gives ethylene and 5·3 per cent. of hydrogen. After six hours' ignition, the decomposition takes place only at 390°, and the amount of hydrogen increases to 17 per cent. Alumina behaves in a similar manner.—Some compounds of terbium and dysprosium: G. **Urbain** and G. **Jantsch.** Salts of these elements having been recently isolated in a pure state by the authors, they have studied the properties of some of their compounds with the view of devising less tedious methods of separation. The present note contains an account of terbium peroxide, Tb_4O_7; nitrate, $Tb(NO_3)_3,6H_2O$; sulphate, $Tb_2(SO_4)_3,8H_2O$; and chloride, $TbCl_3,6H_2O$. Dysprosium does not form a peroxide, but the properties of the nitrate, $Dy(NO_3)_3,5H_2O$; sulphate, $Dy_2(SO_4)_3,8H_2O$; and chloride, $DyCl_3,6H_2O$, are described.—The heats of solution of the alkali metals and the heats of formation of their protoxides: E. **Rengade.** On account of the violence of the action of water upon these metals, especially cæsium and rubidium, the reaction was allowed to take place in a modified Berthelot bomb. The results are very concordant, and lower than those previously obtained by other methods.—The estimation of sulphide of carbon in benzenes: Isidore **Bay.** The carbon bisulphide is precipitated by phenylhydrazine, the precipitate washed with pure benzene, and dried *in vacuo*.—The transformation of the α-oxyacids into aldehydes by boiling their mercuric salts in aqueous solution; application to the preparation of *l*-arabinose by means of mercuric gluconate: Marcel **Guerbet.**—Some cases of the simultaneous production of the 1:6- and 2:7-dimethylanthracenes: James **Lavaux.**—Syntheses by means of ethyl and methyl adipates: L. **Bouveault** and R. **Locquin.**—The action of nascent hypoiodous acid (iodine and sodium carbonate) on some acids of the general formula $R.CH:CH.CH_2.CO_2H$, R being C_6H_5 more or less substituted: J. **Bougault.**—Some mineral salts which can act as peroxydases: J. **Wolff.**—A new type of polychætal annelid: Ch. **Gravier.**—The oculo-reaction in its relation to previous treatment with tuberculin: H. **Vallée.**—A bacilliform piroplasmosis observed in cattle in the neighbourhood of Algiers: H. **Soulié** and G. **Roig.**

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part iv. for 1907, contains the following memoirs communicated to the society:—

January 12.—Seismic waves. (1) Theory of the propagation of seismic waves; (2) seismic time-curves: E. **Wiechert** and K. **Zoeppritz.**

July 6.—The uniformisation of algebraic curves: P. **Koebe.**

July 20.—Researches from the Göttingen University chemical laboratory, xviii. (1) The synthesis from nopinone of a hydrocarbon related to β-pinene; (2) the synthesis of homologous compounds of the dipentene series; (3) syntheses in the terpinene series; (4) the synthesis of anethol from anise-aldehyde, and of isosafrol from piperonal; (5) the occurrence of sabinene in Ceylon oil of cardamoms and majorana oil; (6) isomeric camphenes and a new camphene-camphor acid; (7) condensation products of cyclic ketones with aromatic aldehydes: O. **Wallach.**

August 6.—A contribution to our knowledge of the light-sense in chickens: D. **Katz** and G. **Révész.**

The official communications (part ii., 1906), just published, include a report by E. **Klein** on the progress of the issue of Gauss's works.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 30.

TRANSPIRATION AND ANATOMICAL STRUCTURE IN TROPICAL PLANTS.

Der Einfluss des Klimas auf den Bau der Pflanzengewebe. Anatomisch-physiologische Untersuchungen in den Tropen. By Dr. Carl Holtermann. Pp. viii+249; plates. (Leipzig: W. Engelmann, 1907.) Price 12 marks.

DR. HOLTERMANN'S investigations, mainly carried out in Ceylon, include a long series of experiments on the transpiration of different tropical plants. His tables show great variations in the amount of transpiration for the same plant during the same hours of different days, and these are in many cases not explained by the differing temperature and relative humidity, which are the only other data given. Thus, for instance, in the case of *Canna indica*, between 9.40 a.m. and 5.40 p.m. on January 11 (with a relative humidity of 61 and a temperature of 25°·4 at 10 a.m.), the transpiration was 0·37 gr. per hour per sq. dm. of leaf surface, while on January 17, between 9.45 a.m. and 5.30 p.m. (R.H. 63, temp. 26°·2, at 11.15 a.m.), the transpiration was 0·92 gr. per hour per sq. dm., and on January 18 between 9.15 a.m. and 3.30 p.m. the transpiration was 2·60 gr. per hour per sq. dm. (no humidity or temperature data are given within the period of the experiment, but judging from the late afternoon figures the day did not differ much from the others). This, though an extreme case, is only one out of several similar ones, and the effect of such figures on the reader is decidedly bewildering, though the striking variations may be explicable by changes of insolation, or the irregular occurrence of drying winds. As they stand, the author's figures only demonstrate that the transpiration of the plants studied exhibited startlingly wide fluctuations which remain quite unexplained.

The author's general conclusion from his experiments is that while the highest transpiration figures per hour in the tropics are considerably higher than any north European ones, yet active transpiration begins later and stops earlier in the day in the case of a damp tropical climate, so that the daily average is no higher than in Europe, while in the wet season transpiration may cease for weeks at a time. He thus does not disagree with the conclusions either of Haberlandt or of Giltay on this question. Dr. Holtermann holds that water-tissue is essentially an arrangement to supply water to the transpiring tissues during these short periods of excessive evaporation, not a means of lessening transpiration, and this view he supports by showing that it is especially developed in actively transpiring plants liable to be subjected to these sudden demands. It is characteristic of the leaves of tropical plants growing in a climate which is neither quite xerophytic nor constantly moist, and this harmonises with the short daily period of very active transpiration already mentioned. The mangroves, which ordinarily possess characteristic water tissue well developed, form much less or none at all in the leaves of examples cultivated in garden soil, which transpire very much more freely than plants growing in the natural salty soil. If these plants cultivated without salt are now watered with 3 per cent. salt solution and placed in the sun, they show a wilting of the leaves, and the mesophyll becomes shrivelled. Mangroves growing in their natural habitat also show wilting on hot afternoons, but only the water-tissue is partially emptied and the leaves recover during the night. For the rest the author holds that the xerophily of mangroves and of other halophytes has been much overrated by Schimper and others. They are scarcely, if at all, more protected in this respect than many trees growing in similar situations but not in a salty soil.

Dr. Holtermann describes three other formations of strand-plants besides the mangroves, viz., first the plants of moist sand, which fall into two categories, (1) those growing on the edge of the sea, absorbing salt water, and possessing water-tissue; (2) those growing further from the sea, with fresh bottom-water, which have no special xerophilous adaptations. Secondly, the dune plants, a highly xerophilous type; and, thirdly, the plants growing on salty mud, which have internal water-tissue, and resemble succulent desert-plants in many anatomical features. These three formations have close parallels among the strand formations of temperate regions. This classification is good so far as it goes, but it ignores the beach-jungle (Barringtonia-formation of Schimper), which the author apparently includes with the damp lowland forest type. Yet this formation, though not well developed in Ceylon, certainly has an independent existence; it is much in need of exact study and delimitation.

The author goes on to describe the damp lowland woods, the dry plains of the north and east, and the upland vegetation, as also the epiphytes and parasites of Ceylon. Many interesting observations are contained in this part of the work. Dr. Holtermann also discusses at some length the question of leaf-fall in the tropics, and concludes that though it is a hereditary character, it is, in the endemic species, determined by the dry season, and, in general, leaves fall when their structure does not fit them to withstand the conditions prevailing during the time the trees are bare. A similar explanation is given of the occurrence of annual rings of growth in the wood, the author relating the renewed formation of wide xylem elements to the increased transpiration taking place when a crop of young leaves is produced.

The final section of the work is devoted to a discussion of "Direct Adaptation," in the course of which an account is given of many interesting experiments which add considerably to our knowledge of adaptive reactions under new conditions. The author rightly classes all these as phenomena of irritability, but draws the conclusion that such characters, acquired during the lifetime of the individual, can in process of time be fixed and inherited. This conclusion is, of course, wholly unwarranted; in fact, it is totally irrelevant. And meanwhile the mystery of adaptive reaction, so widespread a phenomenon in the biological world, remains unsolved. Until we know a great deal more than we do at present about the physico-chemical connection of stimulus and response it is likely to remain so. A. G. T.

CLIMATE AND MAN.

The Pulse of Asia: a Journey in Central Asia illustrating the Geographic Basis of History. By Ellsworth Huntington. Pp. xxi+416. (London: A. Constable and Co., Ltd.; Boston and New York: Houghton, Mifflin and Co., 1907.) Price 14s. net.

IN NATURE, vol. lxxii., 1905, p. 366, some account was given of the expedition of the Carnegie Institution of Washington to Eastern Persia and Turkestan. Mr. Huntington showed his descriptive power in the joint memoir issued in that year; and he dedicates his new book to Prof. W. M. Davis, his instructor in the "rational science" of geography, and his companion in arduous travel. Mr. Huntington states that, thanks to the help of Prof. Davis, he spent three years in Central Asia, in addition to four previously spent in Asia Minor. His study of languages has again and again been of service to him; and it is interesting to note at one point (p. 153) the struggle between his natural sympathy and the need for a little self-assertion, which, to the Oriental, is an outward sign of self-respect. His relations with the Khirghiz, and even with the feebler Chantos, were pleasant in the extreme; we fancy that something more fundamental than a training in geography gave him his thoughtful perception of the conditions and limitations of their lives.

The map of Asia, and no small part of it, is required to reveal the significance of the author's routes. The high passes of the Kwen Lun and Tian Shan ranges are mere incidents in these loops of travel, which lead us from Batum across Bokhara, and as far east as the shrinking salt-lake of Lop Nor.

Nine months were spent in the Lop Basin alone, and one of the finest things in the book is the general account of the succession of physical and climatic zones (chapter iv.), as one descends from the mountains across a ring of river-gravels to the edge of the region of desiccation. Here the fine sands and muds of old flood-plains are to-day whirled up before the wind, and are deposited as loess on the mountain-pastures to the south. The life of the nomadic inhabitants of the basin is practically limited by this pastoral land, which occupies all but the highest parts of the plateau-zone; and this zone terminates in steep slopes inwards, rising "like a continental ring around a sea forever dry." Down below, patches of forest-land are already poisoned by salt, and dying tamarisk bushes mark the spread and triumph of the desert.

All through Mr. Huntington's chapters we trace the same compelling influence. The desert, with its rippled and shifting dunes, its "hateful haze" swept onward by the wind, its inexorable hostility, demanding an inexorable endurance (p. 260), is driving man steadily before it, and has him, as it were, over leagues of country, by the throat. Old irrigation-channels have been abandoned, from failure at their source; old roads around lake-basins have given place to direct tracks across their floors. Even in mountain-gorges, streams have run dry, leaving the lower ground dependent on the sudden and dangerous torrents that follow on each melting of the snows. Springs may temporarily arise in desiccated areas, and may furnish real rivers as time goes on (p. 182); but such incidents only temporarily retard the retreat of man, who leaves lost cities behind him, still "beautiful in the clean, graceful shrouds of their interment in the sand." Archæological research, local legends, the experience of recent generations, all show that the drying up of Central Asia is a continuous phenomenon; yet a "climatic pulsation" in an opposite direction is traceable, both in the Caspian and Lop Nor Basins, in the "Middle Ages" following on 500 A.D.

The conditions of the still older dry or "interfluvial" epoch have not even now been reproduced, since (p. 351) there are places in the Tian Shan range, now too cold and wet for agriculture, where canals were once made to provide for irrigation. Mr. Huntington throughout acknowledges the work of Brückner and his other predecessors in these fields of travel, observation, and deduction, and has, in his later pages, urged the climatic aspect of human movements to an almost hazardous extreme. He set out (p. 6) to use Central Asia as a text "to show the immense influence which changes of climate have exerted upon history." In this respect his book does not quite rise to the anticipated level, which is reached more nearly in the memoir issued by the Carnegie Institution. But, with its simple record of perilous adventures, its excellent illustrations, and its clear devotion to science first of all, it forms a noteworthy and inspiring work of travel. Throughout it we feel, as the author means us to feel, the insistent pressure of natural law against the will and work of mortals—the helplessness of millions of men against the untimed pulse of Asia.

GRENVILLE A. J. COLE.

THE MODERN MICROSCOPE.

Microscopy: the Construction, Theory, and Use of the Microscope. By E. J. Spitta. Pp. xx+472; 16 plates. (London: J. Murray, 1907.) Price 12s. 6d. net.

MICROSCOPISTS are at present divided into two factions. There are those of the old school, who are content with the principles under the guidance of which such great improvements have been made in microscope construction since the earlier days of Abbe; and there are those whom we may call the "Gordon rioters," who hold that Abbe's experiments were inconclusive and even misleading, and have found a new prophet. The new theory—the adjective has at least some justification—has been duly set forth, with a mint of strange phrases, in Sir A. E. Wright's "Principles of Microscopy," already reviewed in these pages (vol. lxxv., p. 386, February 21, 1907). Mr. Spitta is of the older school. He is for "legitimate methods of observation." He casts an oblique and somewhat mistrustful glance upon the new practices, and hurries by to surer and more familiar ground.

Not so Mr. Conrady, who contributes to the present volume a couple of chapters on the undulatory theory of light, and on Abbe's diffraction theory of the microscope image. Mr. Conrady "has no use" for the new theory, propounded long since by Dr. Altmann, and only of value in that it called forth a complete and overwhelming reply from Abbe in his well-known paper "Über die Grenzen der geometrischen Optik." He urges strongly the adequacy of the diffraction theory to explain all the observed phenomena, and is emphatic as to the inapplicability to the microscope of the theory of the Airy diffusion-disc.

This, however, is not the place to enter on this much-discussed but fascinating topic, with which, indeed, Mr. Spitta's book, from its plan and object, is but little concerned. It is the practical rather than the theoretical to which attention is directed, to the intelligent handling of one of the most finished and delicate of optical instruments.

From this point of view, let us hasten to urge every student of the microscope who wishes to gain a thorough understanding of its principles and possibilities and its defects, and every user of the instrument who desires a work of reference to which he may turn for an explanation of some unexplained optical phenomenon, or for particulars of up-to-date apparatus, to procure a copy of Mr. Spitta's book without delay. It is a leisurely book—an unfriendly critic might even call it diffuse—but there is scarcely a chapter which will not repay careful reading; and when one comes to the chapter on "Testing Objectives," one can but feel grateful to Mr. Spitta for his admirable treatment of a difficult subject.

Mr. Spitta has called his work "Microscopy"; but it is only of one branch of microscopy that he treats. His subject is the theory and use of the microscope as an optical instrument; with the preparation of objects for the microscope he does not deal. The book will be of much interest and of great value to many who are in no sense "microscopists," but who use the microscope as an accessory in other physical investigation. The non-mathematician who desires to know the meaning of the terms "numerical aperture," the "sine-law," "resolving power," or to make himself familiar with the essentials of the Abbe theory, will find Mr. Spitta a satisfactory guide; and the microscopist proper will find innumerable useful suggestions as to the manipulation of his instrument.

It will be well to indicate shortly the ground Mr. Spitta covers. After a preliminary account of the elements of geometrical optics and the theory of the simple microscope, he proceeds to deal with the compound microscope in its modern form, fine adjustments, mechanical stage, substage, objectives—achromatic, semi-apochromatic, and apochromatic; dry and immersion—with details and illustrations of the work of the best makers. In connection with objectives the chief optical properties, spherical and chromatic aberration, the sine-law, &c., are discussed. Then follow chapters on numerical aperture, eyepieces, magnification—in which may be found the main principles of the Abbe theory—the substage condenser, and methods of illumination—critical light, monochromatic light, dark ground illumination, Rheinberg's multiple colour illumination, oblique light, illumination of opaque objects, polarised light. Then we come to "the use of the microscope," with which may be mentioned the valuable hints to workers with which the volume concludes. The binocular microscope and measurements with the microscope are treated, and a long chapter is devoted to the discussion and illustration of microscopes by different makers for various purposes, which is a feature of the book.

Then follows the excellent account of the testing of objectives already referred to. Mr. Spitta confines himself to the use of the Abbe test-plate, and of specified test objects, but within these limits he goes into the matter in detail and with admirable clearness, and this chapter alone is sufficient to justify the work. The section is illustrated in sixteen plates by a beautiful series of photomicrographs. Mr. Conrady's two chapters follow, with another on accessory apparatus. The usefulness of the book is completed by a satisfactory index.

We have said enough to commend Mr. Spitta's volume. It teems with "tips," and is likely to command an even wider popularity than his previous books on allied subjects.

MATHEMATICAL TEXT-BOOKS.

(1) *Easy Exercises in Algebra for Beginners.* By W. S. Beard. Pp. x+134. (London: Methuen and Co., n.d.) Price 1s. 9*d*.

(2) *Plane Geometry for Secondary Schools.* By C. Davison and C. H. Richards. Pp. viii+411. (Cambridge: University Press, 1907.) Price 4*s*.

(3) *Cartesian Plane Geometry.* Part i. By Charlotte A. Scott. Pp. xiv+428. (London: J. M. Dent and Co., 1907.) Price 5*s*.

(4) *A Sequel to Elementary Geometry.* By J. W. Russell. Pp. viii+204. (Oxford: Clarendon Press, 1907.) Price 6*s*.

(5) *Text-book of Mechanics.* Vol. ii. By L. A. Martin, Jun. Pp. xiv+214. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1907.) Price 6*s*. 6*d*. net.

(7) *Elementary Trigonometry.* With Answers. By C. Hawkins. Pp. xiii+310. (London: J. M. Dent and Co., 1907.) Price 4*s*. 6*d*.

(1) THIS book is a collection of 3500 examples in elementary algebra up to quadratic equations. It will prove useful to those teachers who dictate the bookwork instead of leaving their pupils to read it for themselves. The exercises are well arranged, and there is a good list of contents, so that the reader can at a moment's notice find a dozen or more examples of exactly the type he requires for class use. Answers and examination papers are given, and even though the book does suggest cramming, it has a practical value which will ensure it a welcome. The idea might with advantage be extended to other mathematical subjects.

(2) This book is written for schoolboys who have had a preliminary training in practical geometry, and is devoted almost entirely to theoretical work. The authors are not very fortunate in the first few pages, but when once the reader is fairly started, he will find very little to which he can take exception, provided he is in sympathy with the general arrangement of the book. The authors adopt a conservative point of view, and give a very strong Euclidean flavour to their treatise, but they show themselves capable of appreciating the chief lessons to be learnt from recent experiments in geometrical teaching. Hypothetical constructions are allowed if it can be proved that the construction is possible. The theory of parallels based on Playfair's axiom is deferred until after the principal properties of congruent triangles have been proved. The book covers the substance of Euclid i. to vi.; those of Euclid's theorems which are not included in the text are set as riders together with a large number of well-chosen examples. The treatise is very complete within the limits chosen, and contains sections on loci, geometrical dissections, the nine-point circle, inscribed and escribed circles, Ceva's theorems, &c. A teacher who has conservative views could, on the whole, hardly wish for a better text-book.

(3) The treatise on analytical conics in this series was undertaken by Mr. R. W. H. T. Hudson, and Miss Scott, while pursuing her own plan, has had at her disposal the outline he drew up before his death. The book will prove interesting to the teacher on account of the extreme novelty of the arrangement. The author claims to have shown deference to existing conventions, but it is not so easy to see where self-restraint has been exercised. Apart from the professed innovation of introducing line-coordinates concurrently with point-coordinates from the very first, we have the novelty that the circle is taken as a special case of the ellipse, change of axes is deferred until necessary for the tracing of conics, and so on.

The chief fault of the treatise is probably that the arrangement is far too confused. Properties of the circle are spread over three or four chapters in various parts of the book, interspersed with theorems on conics and straight lines, which theorems are in their turn introduced apparently incidentally, then recapitulated further on, only to be extended in a still later chapter. It seems very doubtful whether a pupil brought up on this method would be able in any way to systematise his knowledge.

Introductory remarks and definitions are apt to be a little obscure, but this is amply compensated by excellent diagrams and very intelligible examples worked at full length. It is a pity that no answers to the exercises are given.

(4) This book is somewhat on the lines of Casey's sequel to Euclid, and covers a good deal of the same ground. It is in many ways an improvement on that standard treatise, and will probably replace it with those students who are just beginning an honours course in mathematics. The chief criticism we have to make is that the contents are of too miscellaneous a character; no one subject is treated quite fully enough, and the reader is led from one idea to another with almost bewildering rapidity. Perhaps some improvement might have been effected by omitting the chapter on "recent geometry," which contains very little that is new except the nomenclature, and treating more important subjects at greater length.

In a book of this kind the chief danger lies in the insertion of artificial geometrical proofs of theorems best established by analytical or other methods. The author is to be congratulated in having avoided this danger, on the whole, with marked success, though perhaps it would be better to solve Fermat's problem and other examples in chapter xi. by the more instructive methods of chapter xii. The reasoning adopted is of a simple character, and in many cases alternative proofs of equal elegance and simplicity are given. There is a plentiful supply of well-chosen exercises; in many cases concise but useful hints are given in the text for their solution, and a key to the remainder of the examples is promised. The book will prove very inspiring to the beginner, and give pleasure to the more advanced reader.

(5) Mr. Martin's book is intended for readers who have a fair knowledge of differential calculus and are beginning integral, and it covers the more elementary portions of uniplanar dynamics of the particle and rigid body. There is room for such a treatise, but the present one is not entirely satisfactory. Much of it is carelessly worded, *e.g.* a movement is called the motion of a "point" and of a "particle" in the same section, the definition of a radian is unintelligible, &c. Some of the proofs, as in the case of normal acceleration, are far too cumbrous, while others are hardly rigid—an instance of this is the absence of any mention of D'Alembert's principle or a substitute therefor. The 420 examples will be useful, though no answers are given.

(6) In this treatise an attempt is made to cover the ground very thoroughly; for instance, three distinct proofs are given of the resultant of two parallel forces and the three requisites of a good balance are discussed, while chapters on work and energy, frameworks, virtual work, elasticity, &c., are given. The object aimed at is to include all that part of statics which can be profitably discussed without the use of the calculus. The result is a book which every teacher should possess; it contains all the bookwork he is likely to want and more, while it is a most useful mine of excellent examples. It is more doubtful whether the book is equally suited to class use; it is hardly simple enough for beginners, and the practical experiments are not described in sufficient detail to be of much use for such a purpose. Readers who have Borchardt and Perrott's "Trigonometry" will have a very fair idea of the style and aim of this "Statics."

(7) Mr. Hawkins's book is rather attractive; for a boy who was learning trigonometry in order to become a surveyor it would be ideal. It may be doubted, however, whether the ordinary pupil will take much interest in so many technical details of land-measurement, even granting that practical applications have a fascination for beginners. With a

little judicious skipping, however, the book may be suited to ordinary class use. It is well written, very intelligible, pleasant reading, and mathematically sound (except in § 88). An interesting feature is that the use of the sine and cosecant in solving triangles, finding areas, &c., is explained before the definition of the cosine and secant, and similarly the applications of the cosine are given before the tangent and cotangent are introduced. The contents of chapters ix. and x., with the exception of an isolated section on inscribed and escribed circles, might well be left to a more advanced treatise. The diagrams throughout are excellent. Demoivre's theorem and similar theoretical developments are not included.

OUR BOOK SHELF.

(1) *Mining Tables.* By Dr. F. H. Hatch and E. J. Vallentine. Pp. viii+200. (London: Macmillan and Co., Ltd., 1907.) Price 6s. net.

(2) *The Weights and Measures of International Commerce.* Tables and Equivalents. Pp. 59. (London: Macmillan and Co., Ltd., 1907.) Price 2s. 6d. net.

In the former of these works the authors give a comparison of the units of weight, measure, currency, and mining area of different countries, together with tables, constants, and other data useful to mining engineers and surveyors. In the second work, they reprint a selection of tables that appeal to others besides mining engineers. On the whole, the authors have carried out their difficult task in an admirable manner. It is customary for engineers to get together data for use in their professional work, and the reprint of the authors' collection cannot fail to be of service to other workers in the same field. All such collections have, however, their limitations, as the requirements of no two engineers are precisely the same. We miss, for example, information relating to the strength of materials, tables for converting kilograms per square millimetre into tons per square inch, and the like, and in the table of rates of exchange for money, any reference to Spain, Portugal, or the South American republics.

While it is easy to point to omissions, we have not been able to detect any errors in the figures given, notwithstanding a careful comparison, for example, of the tables for the calculation of heights and distances from tacheometer readings with the similar tables communicated by Mr. Neil Kennedy to the Institution of Civil Engineers in 1890. In the text, typographical errors are few. There is a little want of uniformity in the spelling of the names of metric weights and measures, grammes and grams, metre and meter, litre and liter being used indiscriminately. Barbados is spelt incorrectly; and Mohs, the inventor of the scale of hardness, appears as Moh. On the title-page, too, Dr. Hatch describes himself as member of the Institute, instead of Institution, of Civil Engineers, and Mr. Vallentine as member of the Federated Institute of Mining Engineers, a society which dropped the term Federated in 1897, and has since been known as the Institution of Mining Engineers.

Les Aciers spéciaux. By L. Revillon. Encyclopédie scientifique des Aides Memoires. Pp. 188. (Paris: Gauthier-Villars, n.d.) Price 2.50 francs.

To understand even the present state of general knowledge with regard to special steels a very large and difficult field must be traversed, and the task of condensation to a reasonable limit will be a heavy one, but, for those who are unable from various causes to enter the field and would like to know the kind of work that is being done, this book may be helpful. To compare the results given with one's own ascertained tests of materials made under known conditions would be a considerable task, but a few general matters taken at random are worth noting as examples.

On p. 99 we are told that chrome steels are chiefly made in the crucible, even when large pieces, &c. What can the author think would prevent them being made in the open hearth? They are so made in large quantities. On p. 154, the author permits himself to dream that nickel chrome steels may also be made in the open hearth (they are made extensively) as nickel steels and chrome steels are (which seems to contradict p. 99). P. 118, "Vanadium remains a scientific curiosity . . . excepting for steels of high price such as tool steels." It was a source of great pride to the late Auguste Wiener that he had obtained the recognition of vanadium as an element of practical industrial importance in the manufacture of special structural steels, and Kent-Smith's success in making vanadium chrome and vanadium nickel steels was the main reason why he was taken to America, undoubtedly to carry on similar work.

One regrets to find in a work on this subject, where names are freely used, that the only mention of Prof. Arnold, who has done so much in connection with nickel, vanadium, and chrome steels, is in chapter xv., on nickel vanadium steels:—"There exist also several tests by Prof. Arnold." Perhaps there is some kind of poetic justice in the fact that, to take one example only, the author's readers will not know that a nickel steel given by him at 61 tons per square inch, with an elongation of 3·5 per cent. on 100 mm., when properly made, gives the extraordinary test of about 90 tons per square inch and 10 per cent. elongation on 2″.

A. McW.

Voice Training in Speech and Song. By H. H. Hulbert. Pp. xii+83. (London: W. B. Clive, 1907.) Price 1s. 6d.

This book is primarily designed for the use of teachers, who, as the author points out, are probably the greatest voice-users, but it will interest all who speak or sing in public. Voice production is difficult to teach even when the pupil has the advantage of performing exercises under the personal supervision of the instructor, and it may be doubted if much improvement in the use of the organs of speech can be effected by reading text-books alone; but what is possible in the direction of describing suitable exercises appears to have been accomplished with success by the author. The book provides an account of the structure and use of the vocal organs, and the means of securing distinct articulation; it should be useful to all persons who are attending practical classes for the cultivation of the voice.

Revisio Conocephalidarum. By H. Karny. Pp. 114. (Jena: Gustav Fischer, 1907.) Price 4.50 marks.

This compilation dealing with a subfamily of the Locustidæ, was published in the Abhandlungen der k.k. zoologisch-botanischen Gesellschaft of Vienna, and provides a serviceable continuation of the monograph prepared by Redtenbacher that appeared in the Behandlungen of the same society in 1891. Revised analytical tables are given for several of the genera to include recent determinations by the author and other workers. Three genera are here described for the first time—Paroxyprora, Rhytidogyne, and Pœcilomerus. A considerable number of new species are made, principally additions to the tribe of Conocephalini; many were collected in South America, and six were obtained in New Guinea.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Cotton Plant.

ATTENTION has been directed in NATURE of January 16 to a work in which a writer on economic subjects deals with "The Wild and Cultivated Cotton Plants of the World." The subject is as difficult as it is important, and your reviewer, whose expert opinion is held in regard, shows that some of the questions involved may have two sides.

Your reviewer remarks that this work has been doomed to failure owing to the mode of study adopted by its author. If this means that the work is not without error and does not attain finality, the judgment has been anticipated by the author. But if this also means that the work adds nothing to what is known by those who do not happen to be experts in cotton, its readers will find that the verdict cannot be sustained.

The work is compared unfavourably with another on this subject by the late Prof. Todaro. Your reviewer attributes success to Todaro's book because Todaro dealt for the most part with living plants grown by him from seed. It is possibly true that the material studied by Todaro was, for the most part, obtained from the living plants the cultivation of which is related in the introductory fifth part of his monograph. But it is not the case that Todaro's revision of the cottons of the world was based for the most part on this material. Those who have studied Todaro's work know that, of the fifty-four species of Gossypium there enumerated, only eleven were certainly described from living plants, although it is possible that others may have been seen by him in the living state. In dealing with the remaining thirty-eight, Todaro has had to rely on the mode of study which your reviewer tells us is doomed to failure; indeed, as regards a considerable number of the species recognised, Todaro has had to depend on the accuracy of descriptions by other writers, because he did not have access to authentic herbarium specimens.

We are, however, less concerned with the work of Todaro than with the continuation and extension of that work which your reviewer says was needed, and which Sir G. Watt has tried to supply. A study of Watt's work shows that its chief merit and value lie in the exhaustive way in which it brings together references to all conceivable sources of information. On this account it will be indispensable to anyone who may hereafter be seriously at work on cotton, who will find it a comprehensive guide to the literature of the subject and to the whereabouts of authentic material. Its readers must follow the rule that applies to the study of subjects so critical, and reserve perfect freedom of judgment as regards the acceptance of Watt's conclusions. They are not bound to agree with Watt as to the provenance or the pedigree of any particular cultivated cotton, nor are they bound to adopt the advice Watt may give as to the kinds most suitable for a particular locality. But when, in deference to other views or on intuitive grounds, we question the validity of Watt's opinion, we are not entitled to do more than reserve our assent unless and until we have critically examined, and if need be supplemented, the material on which that opinion is based.

Believing, as he explains, that the work of Todaro does not require to be corrected, your reviewer is justified in refusing to accept any opinion expressed by Watt which is at variance with that of Todaro, and is free to imagine that, because Watt at times differs from Todaro, Watt's volume is rather a retrogression than an advance on Todaro's work. He is also entitled to assert the right to criticise details as to which he considers himself a competent judge. But his decision that when Watt differs from Todaro therefore Watt must be wrong does not prove this to be the case; his belief in the infallibility of Todaro does not establish that unusual quality; we know, indeed, that at least one of Todaro's species of Gossypium does not belong to the genus.

In exercising his right to criticise, your reviewer occasionally raises a doubt whether sound judgment as to the value of a cotton need include full appreciation of the difficulties connected with its botanical status, while his terminology does not make it clear that his conception of botanical characters, and his interpretation of words like "species" and "variety," accord with established usage. This prevents our commenting on his estimate of Watt's system of classification, which is based on those characters that Watt believes to be least subject to variation in truly wild cottons. That among cultivated forms even these characters prove unstable is only too true; but they may still be the best available, and the reviewer does not suggest an alternative method of arrangement.

In certain specific instances your reviewer directs attention to what he terms errors. Thus the treatment by Watt of *G. obtusifolium*, Roxb., and *G. Wightianum*, Tod., is cited as a case of "erroneous synonymy." The situation is this:—Todaro has shown that he only knew of *G. obtusifolium* from Roxburgh's description, and that he did not recognise Roxburgh's species in any of the plants he grew. Todaro has further concluded that a plant which most Indian botanists have treated as a form of *G. herbaceum* does not belong to *G. herbaceum*; this plant he has named *G. Wightianum*. Dealing anew with the subject, Watt has agreed with Todaro in considering *G. Wightianum* distinct from *G. herbaceum*. But Watt also thinks that he can recognise the plant which Roxburgh named *G. obtusifolium*, and believes that *G. Wightianum* is only a variety of *G. obtusifolium*. However the case may stand as to these conclusions, the synonymy they involve is accurate. Even if, as is possible, your reviewer by "erroneous synonymy" only implies that Watt differs from Todaro, the criticism fails. We are unable to say whether, if Todaro had been able to recognise *G. obtusifolium*, any difference of view would have existed. The subordinate questions as to whether Watt's limitation of *G. obtusifolium*, var. *Wightiana*, accords with natural facts, and whether *G. obtusifolium* proper and *G. Nanking*, var. *roji*, should be kept apart or united, are only differences of opinion between Watt and your reviewer on points as to which they are equally entitled to form a judgment.

Your reviewer cites two cases in which he believes that plants have been wrongly identified by Watt. He states that the figure of *G. microcarpum* given by Watt (plate 36) represents a plant other than the one figured by Todaro as *G. microcarpum*. He points out that Todaro describes the two lobes on either side of the central lobe as unequal, and states that the figure given by Watt does not display this peculiarity. On examining the figure of *G. microcarpum* given by Watt, we find that it does show this peculiarity, and on consulting the text we see that it is *G. microcarpum* of Todaro and no other species that is intended to be represented. There may be some mistake with regard to this species; if it be the case that the *G. microcarpum* grown by the reviewer is the true *G. microcarpum* of Todaro, and is at the same time the plant figured by Watt as *G. Schottii*, then the figure which Todaro has given of *G. microcarpum* can hardly represent his own species accurately; it is unlikely that a suggestion as to the identity of *G. Schottii* as figured by Watt (plate 35) and *G. microcarpum* as shown in Todaro's plate will be generally admitted. In the other case, your reviewer's conclusion as to misidentification rests partly on a statement that the name "Piura" indicates a cotton other than the one it connotes in Watt's book, partly on an assertion that Lamarck describes his species *G. vitifolium* as having the underside of its leaves glabrous. The incidence of vernacular names is not always so exact as to justify implicit confidence, but in this instance Spruce, who collected the Piura cotton in Peru and has described it with care, assigns the name to the plant with which Watt associates it. Finally, what Lamarck says with regard to the leaves of his *G. vitifolium* is:—"Elles sont glabres en dessus, un peu velues en dessous."

What we now await is a work on the cultivated cottons from the pen of your reviewer. D. PRAIN.

Kew, January 20.

The Inheritance of "Acquired" Characters.

I HAVE looked with much interest for some reply from your reviewer to the queries put to him in the letter of Mr. Spicer (January 16, p. 247).

But while he does not attempt to enlighten us, Mr. Archdall Reid, one of the principal exponents of "the infant science of heredity," seeks to show in your columns of January 30 (p. 293) that there is no real basis for this controversy—that Weismann and Herbert Spencer, and all others who have dealt with the question, are alike in error in supposing that there is any real difficulty to be solved.

Mr. Reid seeks to establish his position in this way. He objects to the distinction commonly drawn between "innate" and "acquired" characters; he says these are inaccurate distinctions, and that they have given rise to a long drawn but "futile controversy." He holds the peculiar view that "in man the main difference between the infant and the adult is due to the use acquirements made by the latter during development." Thus, he says:—"Nutriment supplies the material but *not* the stimulus, for *all* growth. Up to birth, the human being, for example, develops wholly, or almost wholly, under this stimulus. Subsequently some of his structures continue to develop under it, for instance, his hair, teeth, external ears, and organs of generation, which grow whether or not they be used. But most of his structures now develop mainly, it not solely, under the stimulus of use, for example, his voluntary muscles, limbs, heart, and brain." But surely the fact that use occurs during the development (and therefore, of course, has some share in promoting the growth) of some parts of the human body must not blind us to the probable fact that the post-natal growth is essentially due to the same inherent causes as pre-natal growth. That being so, is it not absurdly inaccurate to say that "in man the main difference between the infant and the adult is due to use acquirements"?

Then, again, Mr. Archdall Reid seems to assume (in the face of multitudinous difficulties) that the germs of all human beings are potentially alike. He says "innate characters arise inevitably as the child develops, whereas some acquirements are more or less rare. But this is *only* because the stimulus of nutriment is inevitably received, whereas the stimulus of a particular *use* or *injury* may not be received. If, however, the latter be received, *the acquirement arises just as inevitably as the innate characters.*"[1]

This may, and probably does, hold good for the result of injury and the production of scar tissue, but surely not in regard to the effects of use. No amount of use exercise could make a colour-blind man a good colourist, or enable many persons having, as it is commonly said, "no ear for music" to be good musicians. Thus in some persons what in the majority should be innate qualities are found to be wanting (owing to defects in organisation), while in other persons, wholly independent of any commensurate amount of use exercise, powers like those possessed by a Turner or a Watts, by a Mozart or a Beethoven, or such powers in the direction of mental arithmetic as were found in Bidder, Inaudi, and others. One person has highly developed auditory centres and cerebral regions in association therewith, another has a poor development of the same parts, and the same thing holds good for the visual centres and their associated cerebral mechanisms. Some of those having highly developed auditory centres may prove to have unusual musical abilities, while other persons, like Inaudi, may have marvellous powers in dealing with figures.

It is, in fact, notorious that the stimulus of nutriment and the stimulus of use being present, the results in the way of acquirement will vary *ad infinitum* in accordance with innate differences in individual germs. Yet it is upon the basis of such views as I have quoted that Mr. Reid strives to show that the controversy as to the alleged "transmission" of acquired characters is due to a misunderstanding. "Had the true nature of the distinction between innate and acquired characters been realised," he says, "had it been realised that the difference is one of stimuli, not of innateness or inheritability, and that acquirements are just as much products of evolution as innate characters, it is impossible that the controversy as to the alleged 'transmission' of the former could have endured so long as it did."

I venture to think that many will not be satisfied with Mr. Archdall Reid's doctrines, and will still consider that the controversy is not closed, as he seems to suppose, but that there is a real problem open to discussion; and certainly those who believe that the effects of use and disuse may be inherited will not find anything in Mr. Reid's letter to show that they are wrong.

In your pages in 1905 (June 15, p. 152) there was a brief communication on this subject from Mr. Woods Smythe which I take to be of considerable importance. He says:—"Lately I heard a missionary at a May meeting tell of the marvellous facility with which Chinese children memorise whole books of the Bible; the four Gospels, and sometimes the Acts also, being an easy feat for children of ten or twelve years. Having carefully sought information from other authorities, I find these facts confirmed, and that the same applies to Mohammedan children. We are aware that for ages their ancestors have been compelled to memorise long portions of their sacred books, and although occasionally we meet with a child of any nation with a gigantic memory, that differs widely from the case of a people where it has become a general characteristic."

Facts of this kind are very difficult, if not impossible, to understand except upon the supposition that use and practice carried on through many generations have led to the begetting of germs having modified developmental tendencies.

How would Mr. Reid explain such facts? In his letter he says:—"Memory, the power of learning, develops under the stimulus of nutriment, but intelligence and reason develop under the stimulus of use." Memory is, therefore, for him one of the so-called "innate" characters which develops independently of the stimulus of use and exercise. For him, therefore, there ought to be no such remarkable memorial powers as those which have been referred to by Mr. Woods Smythe.

H. CHARLTON BASTIAN.

The Athenæum, London, February 3.

The Nature of Röntgen Rays.

IN NATURE of January 23 (p. 270) Prof. Bragg defends his neutral pair theory of X-rays, and his explanation of scattering and polarisation on this theory, against a criticism which I made in a recent letter (NATURE, October 31, 1907). Though he appears to have enlarged his conception of the possible function of the ether pulse in X-ray phenomena, he contends that my one assumption is unjustifiable, consequently is of no value as a critical test. Prof. Bragg had assumed that a pair revolves in a plane containing its direction of translatory motion, that when incident on light atoms it is liable to be taken up only by an atom revolving in the same plane, sometimes to be ejected again, and that if ejected again it continues to rotate in the same plane. My assumption in calculating the distribution of intensity of secondary radiation was that after being *taken up* by an atom its liability to be ejected again is equal in all directions in that plane. This does not appear quite so unjustifiable as, from Prof. Bragg's letter, one would judge it to have been.

It is evident, however, that this assumption is not a necessary part of the argument against the neutral pair theory, though it appeared, and still appears, to me to be the nearest approximation one can make to the probable behaviour of a pair, if we accept Prof. Bragg's previous assumptions.

But to make calculation possible in place of such a definite distribution we may assume any one of a score of others, as Prof. Bragg does not suggest one. Still, experiments supply what appears to me to be absolutely conclusive evidence in favour of the ether pulse theory. For, after measuring the intensity of secondary radiation proceeding in a direction perpendicular to that of propagation of the primary beam from a substance of low atomic weight during the transmission of "soft" X-rays (conditions producing the most complete polarisation), I have found that the intensity of radiation in a direction opposite to that of propagation of the primary rays as experimentally determined is within 5 per cent. of that calculated on the ether pulse theory (see *Phil. Mag.*, February, 1908). If Prof. Bragg can suggest a distribution of ejected pairs that will produce such close agreement between the calculated and experimentally determined intensities, it will be time to consider the theory further.

My argument has not been concerned with γ rays, but with the type of radiation with which I am experimentally more familiar—X-rays of ordinary penetrating power.

University of Liverpool. CHARLES G. BARKLA.

The Wave-length of Röntgen Rays.

IN his theory of thermodynamical radiation, Planck has found the simple law $e=h_0n=h_0\frac{c}{\lambda}$, where e is an element of energy, $h_0=6.55\cdot10^{-27}$ a constant, n the frequency, λ the wave-length of an electromagnetic resonator, c the velocity of light; according to this "elementary law" the energy of an electromagnetic resonator changes during a period by a multiple of e.

Applying Planck's elementary law on the emission of Röntgen rays by stopped kathode ray particles, I have found the following (*Physik. Zeitschr.*, viii., 882, 1907). Let $e_k=\frac{m_0v^2}{2}$ be the kinetic energy of a kathode ray, ϵ its electric charge, V the freely traversed potential difference, the total kinetic energy may be, by stopping, transformed into energy of radiation. The smallest wave-length of the emitted Röntgen radiation is then $\lambda_k=\frac{2h_0c}{e_k}=\frac{2h_0c}{\epsilon V}$; for a working potential difference of 60,000 volts on a Röntgen bulb λ_k becomes $6\cdot10^{-9}$ cm. Haga and Wind (*Ann. d. Phys.*, x., 305, 1903) have found by their experiments on diffraction for the wave-length of the used Röntgen rays the value $\lambda=5\cdot10^{-9}$ cm.

It is clear that the reversed phenomenon—the transformation of Röntgen rays into kinetic energy of electrons—gives the emission of secondary kathode rays by Röntgen rays, or more generally by light. I have deduced from Planck's elementary law that the maximum of the velocity of secondary kathode rays is independent of the nature and temperature of the radiating body, but inversely proportional to the square root of the absorbed wave-length. This statement is in agreement with the observations of Innes (Proc. Roy. Soc., lxxix., 442, 1907); the observations cannot be explained by the hypothesis of J. J. Thomson and W. Wien that the emission of secondary kathode rays is produced by some radio-active process.

It may be added that Planck's elementary law is also confirmed by my observations on the Doppler effect on Kanalstrahlen; the simple or two-fold minimum of the intensity in this effect is explained by that law (*Physik. Zeitschr.*, viii., 913, 1907). Applying the law to a hypothesis of the origin of banded spectra, it is possible to calculate an inferior limit for the spectral position of the banded spectra of the saturated and "loosed" valencies in chemical compounds (*Physik. Zeitschr.*, ix., 85, 1908).

J. STARK.

The Orientation of the Avebury Circles.

IN Sir Norman Lockyer's notes on the orientation of stone avenues printed in NATURE, January 16, pp. 249–257, in dealing with Avebury, he founds his argument as to the existence and direction of the Beckhampton avenue upon Stukeley's statement as to the remains of it visible when he wrote in 1724. He then passes to the Kennet avenue, and says:—

"As will be seen from the map, this avenue apparently was connected with the southern circle as the Beckhampton one was with the northern one. If this were so, certainly the enormous bank, erected apparently for spectacular purposes, which is such a striking feature of Avebury, was not made until after the Kennet avenue had fallen out of any astronomical use."

In accordance with this statement, Sir Norman Lockyer marks on the map reproduced to illustrate his notes the course of the south-eastern or Kennet avenue as a straight line making directly for the centre of the southern circle *across the existing bank and ditch* well to the left of the present road leading to Kennet. In this he entirely ignores the fact that Stukeley (in the map given by Long, "The Temple at Abury surveyed by Dr. Stukeley in 1724") marks two prostrate stones of the avenue actually in the existing gap in the earthworks by which the Kennet road enters Avebury, and furthermore notes that they were "broke 1722." Aubrey, too, in his plan taken in 1663 (reproduced in Jackson's "Aubrey," p. 319), shows seven stones of the avenue as lining the sides of the existing road *immediately* on its leaving the gap in the mound. Lastly, there is standing at this moment a few yards on the right-hand side of the Kennet road a large stone which is the only one now remaining of those seen by Aubrey and Stukeley at the point where the avenue struck the earthwork circle. This stone was apparently not noticed by Sir Norman Lockyer.

Surely if anything can be said to be certain at all about Avebury, it is that the Kennet avenue joined the outer circle through the existing gap in the rampart by which the Kennet road enters it to-day, and did not make straight for the centre of the southern circle over the bank and ditch as shown in Sir Norman Lockyer's plan. Theoretically, perhaps, it ought to have done so, but as a matter of fact, if any weight is to be attached to the statements and plans of Aubrey and of Stukeley, and to the position of the one existing remnant of the avenue on the spot to-day, it did not. In the interests of accuracy it seems desirable to point this out. ED. H. GODDARD.

Stability in Flight.

MR. MALLOCK (January 30, p. 293) seems to presume, as a great many others do, that an apparatus on the aëroplane principle "demands constant attention on the part of the aëronaut" to maintain its stability in the air. We are apt to get ideas from watching the behaviour of little bits of paper floating in the gusts of wind, and to forget that the flying machine of the future may run into tons of weight. Though a frail canoe may easily capsize, the big ship seldom turns over even in the roughest of seas. Even so primitive a contrivance as we may presume that of Mr. Farman to be is some 33 feet across and weighs, complete, half a ton. Such a structure is not easily upset by mere puffs of wind. But it is also evident that a machine can be designed possessing nearly perfect automatic stability. Langley's model, away from all human control, flew steadily on over the billows of the air for a minute and a half. A well-designed and well-balanced machine is automatically stable without any pendulums or other appliances; in fact, it forms a pendulum of itself. B. BADEN-POWELL.

32 Princes Gate, S.W., February 1.

REFERRING to the letter which appeared under the above heading in NATURE of January 30, I have given some little attention to this subject for the past few years, and thoroughly endorse your correspondent's views.

Any balancing apparatus must be automatic in its action if it is to respond to the changes in the relative motion of the air without delay. It would seem to me that any such apparatus must, as is suggested in the letter referred to, depend on the conservation of angular momentum in a pendulum or fly-wheel. Such a pendulum (or system of pendula) or fly-wheel may operate directly or indirectly, *i.e.* the torque of resistance opposing change of angular momentum may be employed to right the aëroplane, or may operate mechanism to control the position of guide planes or jockey weights, or rotate the main planes in a suitable manner. The first case is analogous to the Brennan mono-rail system, the second to the Obry torpedo balance. HERBERT CHATLEY.

32 Britannia Road, S., Southsea, February 1.

The Stresses in Masonry Dams.

I DO not think that Prof. Pearson proves his point. Is it not an axiom of practical mathematics that nearly identical functions (within certain limits) may have widely different second differentials? Between o and π, for example, a parabola can be found differing but little from $\sin x$. To show that the stresses $\widehat{xx}$ and $\widehat{zz}$ are widely different in a plate dam and in a complete dam, it would therefore seem essential to integrate the two equations given by Prof. Pearson in his last letter, and to compare these integrals, or else to decide the matter on other considerations. The integration is, I understand, impracticable, and this being so, the argument in my letter of January 2 would seem to apply. It was to the effect that if in the case of a plate it is permissible to write $\widehat{xy}=\widehat{yz}=\widehat{yy}$ throughout, then to the same order of approximation the stresses $\widehat{zz}$ and $\widehat{xx}$ are the same in the plate dam and in the actual structure. If the stresses $\widehat{xy}$ and $\widehat{yz}$ are zero in the case of the plate, then the stresses $\widehat{yy}$ which are developed when the lamina forms part of the complete structure cannot, themselves, give rise to any such shears as $\widehat{xy}$, $\widehat{yz}$, or $\widehat{zx}$, and as the dam is not constrained at top or flanks, it is difficult to see how, in the absence of these shears, the stresses $\widehat{xx}$ and $\widehat{zz}$ can be affected. Certainly not by the 30 per cent. which Prof. Pearson gives as the order of the error.

83 St. James's Road, Croydon. H. M. MARTIN.

SOME SCIENTIFIC CENTRES.

No. XII.—THE BOTANICAL INSTITUTE OF THE UNIVERSITY OF BONN.

THE traveller visiting the well-kept Rhenish city of Bonn, on taking a stroll down the beautiful Poppelsdorfer Allee, finds at the end of this delightful avenue a large square building within an enclosure, the Poppelsdorfer Schloss. This building, which is two stories high, enclosing a circular court, bears no external evidence of containing within its walls a great centre of biological research, for the edifice was originally a palace, having been used up to the beginning of the last century as a summer residence of the electors of Cologne. The building is now owned by the university, and is occupied by the biological laboratories and the natural history museum. The rooms of the second floor on the north-east and south-east sides are occupied by the botanical laboratories and by the residence of the professor in charge, one of the greatest botanists of all times, Geheimrath Prof. Edouard Strasburger.

The young botanist who is familiar with the writings of Prof. Strasburger, and has formed some idea of this famous botanical institute, on entering the laboratories for the first time is only surprised and perhaps disappointed, for he sees little that suggests a modern and well-equipped laboratory. The fact that the building was erected in the first half of the eighteenth century, and for another purpose, explains why the rooms are not well adapted for their present use. However, the windows are large, and since there is ample room for apparatus and materials, the investigator has little cause for complaint.

The Botanical Institute includes an elementary laboratory, one for advanced students, a large lecture room, and rooms for assistants and the professor extraordinary. The lecture room is provided with a profusion of charts and diagrams for illustrative purposes. The rooms adjoining the laboratories on the south-east side of the building are occupied by the professor as a residence. Two rooms of his residence Prof. Strasburger devotes to his own work, one serving as a laboratory and the other as a library. In these rooms, which are plainly furnished, everything is orderly arranged and kept scrupulously clean. The library contains, in addition to files of periodicals, all the important works on morphology and cytology. Perhaps the most valuable part of the library is the series of reprints on histological subjects. A copy of almost every cytological paper published, whether treating of animal or plant, is to be found here.

The principal windows of the laboratories and of the residence overlook the palace garden, which has been the botanic garden since the founding of the university. The garden, though small in area, is well stocked and rich in flowering plants. The latter occupy the central part of the grounds, which are carefully laid out and arranged according to the system of Eichler. On either side of the central part is the arboretum, containing many fine specimens of European and some American trees. The arboretum is rich in conifers, one, a cedar of Lebanon, being unusually large and beautiful. A portion of the old palace moat is maintained as a pond for aquatics. The large palm house, the Victoria house, and other greenhouses contain many interesting exotics. The garden has also its special beds of poisonous, economic and medicinal plants, as well as one con-

Prof. E. Strasburger. From a photograph by K. Fujii.

taining plants, widely separated in relationship, but which have solved certain problems of adaptation in the same way. But it is neither the laboratories, the library, nor the botanic garden that has made the institute at Bonn famous; rather the enthusiasm, earnestness and profound resourcefulness of the master mind that directs it.

Prof. Strasburger began his notable series of investigations upon the conifers where Hofmeister left off. In 1872 appeared the large volume with numerous plates upon the morphology and fertilisation of conifers and the Gnetaceæ. This was followed in 1879 by another volume, dealing with the embryology of gymnosperms and angiosperms. His attention having been attracted by the nuclear figures in the endosperm during his earlier studies on gymnosperms, he soon brought to publication a series of observations upon nuclear and cell division. Just thirty-two years ago the nucleus was traced in continuous sequence from one cell-generation to another, thus establishing for the nucleus beyond all question of doubt the rank of morphological unity. The classic and path-breaking work, "Ueber Zellbildung und Zelltheilung," reached the third edition in 1880, while its author was professor at Jena.

Since going to Bonn, Prof. Strasburger's more important contributions, dealing chiefly with the division of the nucleus and of the cell, with the growth of the cell-wall, the structure of the vascular bundle, and with the process of fecundation, have appeared in five or six volumes, each bearing the principal title "Histologische Beiträge." The bulkiest of these volumes (No. 3), and probably one of the most noteworthy, is on the structure of the vascular bundle ("Ueber Bau und die Verrichtungen der Leitungsbahnen in der Pflanzen"). Apart from several other very important monographs, Prof. Strasburger has prepared the best and one of the most elaborate laboratory manuals and handbooks of microscopic technique known to biological science. "Das botanische Practicum" is now in its fourth edition. "Das kleine botanische Practicum," an abridged edition for the use of more elementary students, was also prepared. A translation of this volume by Hillhouse is still one of the very best botanical handbooks in the English language. With the aid of his former collaborators, the late Prof. A. F. W. Schimper, Prof. Fritz Noll, now of the University of Halle, and Prof. Heinrich Schenck, of the Technical University of Darmstadt, the text-book of botany was prepared, which has gone through several editions and has been translated into several languages.

In more recent years the results of certain important investigations carried on in the institute have been published conjointly by Prof. Strasburger and his students. The most important of these is the volume known as the "Cytologische Studien," which marked the beginning of the more modern phases of cytology. The especial value of this collection of papers consists (1) in the perfection of the best cytological methods known at present for a number of widely differing plants, (2) in the proof that no such structures as centrosomes or centrospheres exist in higher plants, and (3) in the complete establishment of true sexuality in the ascomycetes. Occasionally, Prof. Strasburger carries his private work into fields somewhat removed from the general subject of his life work, though such studies have been comparatively few. In this connection may be mentioned the elaborate study with diœcious plants, having for its object to determine, if possible, the effect of environmental conditions upon the control of sex. During the past few years the chief work of the institute has centred about problems relating to the physical basis of heredity, such as the individuality of the chromosomes, the transmission of characters in hybrids, &c.

A glance at the vast amount of literature issued from this most famous centre of cytological research is sufficient to convince one who is not a special student of cytology that the main object and life-work of its director is to understand the meaning of the cell by knowing in the most detailed manner its structure at every step of its activity in all kinds of plants, from the lowest to the highest, and that which has been discovered is only a fair index of what is still to be known.

Probably a summary of the day's programme at the institute will not be without interest to the reader. During the winter semester Prof. Strasburger lectures upon the morphology of the plant groups below the spermatophyta, four lectures being given per week. Once a week, on Fridays, the public lecture is given, which is open to all who wish to attend. The subject of these public lectures varies from year to year, but it usually pertains to some topic of general interest concerning plants, and is treated from a philosophical standpoint. In the summer semester the lectures deal with the anatomy and physiology of the higher plants. Before going to the lecture room, the professor makes his daily rounds in the advanced laboratories, visiting each investigator, making inquiries concerning the progress made during the past twenty-four or forty-eight hours, and at the same time offering suggestions and criticisms. A visit is frequently made to the laboratory after the lecture or in the afternoon, depending upon the interest in the particular line of study.

Prof. Strasburger's wonderful grasp of the whole field of morphology and physiology, as brought out in frequent discussions in the laboratory, increases daily one's admiration and quickens in one the consciousness of being in the presence of a master mind. When the marvellous results of this centre of scientific research are considered, and the relatively meagre equipment and lack of convenience, the success can only be attributed to the genius of the man who is the centre of its activity and the source of its inspiration.

D. M. MOTTIER.

EXAMINATION v. RESEARCH.

A UNIVERSITY is as much a place for compromise as a party caucus or a church. It has to provide for different needs and to satisfy conflicting interests. It has to preserve its corporate balance against the attacks of specialists and extremists who try to drag it on to a side-track. And it has to do all these things with limited means and limited wisdom. From time to time doubts may well arise as to how far it succeeds in steering the best course. Oxford at present is in the throes of such a discussion. Always critical, she is more critical of herself than of anything less near and dear, and is now enjoying a perfect orgie of self-criticism. But such emotional delights should not lead to oblivion of the fundamental facts of academic life.

Oxford has to find a working compromise between four distinct functions which lead up to four distinct ideals (or exaggerations) of a university. She has to educate, to teach, to examine, and to research, to say nothing of governing herself, which is not, perhaps, the supreme ideal, as our officials are apt to imagine.

(1) Educationally, Oxford is a place where those who can afford it, or are selected by private or public charity as fit recipients of scholarships, may obtain an intellectual training which will fit them (more or less imperfectly) for a number of professional pursuits, and are subjected to a moral discipline which (again somewhat imperfectly) induces them to do less harm to themselves and to create less disturbance in the community than similarly situated youths are wont to do in any other country. Thus Oxford is not an ideal university. But it is as incapable of being the university of Bohemia as of Utopia. Its educational ideal conducts to the perfect gentleman, or, if it fails, to the perfect snob.

(2) As a teaching institution Oxford is expensive, but (on the whole) efficient. It is expensive because it sacrifices the teacher to the taught, and leads the former to bestow upon the latter a great deal of individual attention, more, possibly, than is good for him, more, certainly, than is necessary or than he gets elsewhere. It is efficient because the college spirit is strong, and the competition between the colleges is keen. Wherever this inducement fails, *i.e.* wherever the university conducts the instruction or the college takes no pride in it (*e.g.* in the case of

the "pass" man), the tutor has *not* rendered the "coach" superfluous. Elsewhere the teaching is good of its kind. But since good teaching aims at enabling every fool to appear a genius, it is not an end in itself. The teacher's ideal therefore has to be controlled by a higher, the *examiner's*.

(3) These two functions are quite distinct. The good examiner is not necessarily a good teacher, nor *vice versâ*. The excellence of the teacher lies in his ability to instil knowledge and a desire for knowledge; that of the examiner is held to be the exposing of ignorance and pretence. Experience has shown, also, that competitive examinations are among those aids to learning which appeal most forcibly to the national character. They appeal strongly also to the critical faculties of the academic man, and to the love of power in a class which has naturally few occasions for gratifying this instinct. It has been discovered that though knowledge is power, yet the power of testing knowledge confers *superior* power. It is possible to control all knowledge by conducting examinations in it. This, therefore, is what we have set ourselves to do, and the regular genesis of a new branch of study is, first an examination, then students, and last of all the provision of teachers. This is distinctly suggestive of Looking-Glass Land, but to one who has grasped the rationale of examinations it will not be the paradox it seems.

Now it need not be wholly denied that examination has its uses. A certain amount thereof is necessary, and even beneficial to the soul of the examinee, promoting in him a willingness and capacity to absorb and reproduce teaching and to arrange his knowledge which are very conducive to mental efficiency. But the qualities which examination fosters and rewards are not the only qualities of value. Moreover, the benefits to the soul of the examinee are offset by grave dangers to that of his examiner; for the ideal examiner becomes one who is wholly devoted to the exercise of his function, and wholly critical. He can examine everything but produce nothing.

When, therefore, for these and other reasons which it would hardly be decorous to mention, a university sets up an examination system, and gives it power over the whole realm of knowledge, it runs a risk of sacrificing to this idol all its other functions. Teachers and taught alike are sacrificed to it at the annual holocausts, the results of which are contemplated with such reverence that their fame clings to their victims throughout life, and forms an important factor in their subsequent success or failure. Hence it is an ingenuous refinement of cruelty when professors of eugenics argue statistically that there is a "high degree of correlation" between success in examination and in life. Does it not follow rather that when a university conceives too great an admiration for its examinatorial function, it will grow a mental atmosphere which affects the national mind, and is deadly to all its other ideals? The "perfect gentleman" and the devotee of culture (mental or physical) will be forced by the menace of examination into undignified and banausic efforts to escape expulsion. The ideal of the perfect researcher will hardly be allowed to germinate; for such a university will have as little use and real regard for researchers as for "pass" men.

(4) Yet the Laputan ideal of an academic life of pure contemplation (or, in a more modern but lowered version, of scientific productiveness), exempt from the sordid duties of disciplining, teaching and examining, is in some ways the prettiest dream of them all. It is a sad pity that ever since the days of Dean Swift mankind has laughed at it. For there is some good in the researcher's ideal, even though in its extreme form it is absurd. In practice *no* seat of learning can be made up of professors who do not teach, and exist only as objects of distant contemplation by students fearful of perturbing their sacred meditations. Neither the country, nor our purses, nor our sense of humour, would stand it. Besides, it is a psychological fact that a certain amount of teaching is good for research, just as a certain amount of research is good for teaching. The one helps to clarify the worker's exposition, just as the other helps to imbue the teacher with a flavour of originality. Whether a similar connection could be traced between researching and examining seems more disputable.

But there can be no doubt that at present Oxford sets too low a value on research because it sets far too high a value on examination. This sterilises research both by the excessive selection of minds possessing the excellences of the examinee without possessing those of the real student or of the scientific originator, and by the enormous absorption of time and mental energy which our vast masses of examining exact. The wonder is that with such a system we produce anything at all. It is a still greater wonder that, despite contrary assertions based on our habits of self-depreciation, our scientific output, taking it all in all, is not inferior in quality or even in quantity to that of any other academic institution in the world. The explanation lies in the excellence of our recruiting system. We make ourselves so attractive that even the ablest will welcome an opportunity of joining our ranks. And then the perversity of human idiosyncrasy will divert some of this surplus ability into researches which we tolerate without encouraging. For genius, like murder, will out. But with the high average of ability we have in Oxford we could, and should, produce much more, if only more value were put upon productiveness and less store set by criticism.

Enough has been said, perhaps, to give an idea of the root of the evil. But it is not so easy to suggest remedies; for radical measures are Utopian, and ignore the psychological hold which the examination-system has over the national character. But the following suggestions at least seem wholly practicable. (1) In some subjects, *e.g.* natural science (but not, perhaps, in classics, mathematics, and philosophy), the lead just given by the modern historians might be followed, and a research thesis be permitted to form part of the undergraduate's examination. (2) Most of the university prizes, &c., should be awarded to the best researcher rather than to the best examinee. (3) There ought to be a great development of graduate study, and our teachers ought to be enabled, and even required, to acquire a greater initial superiority in knowledge over the taught than is compatible with a system under which most of them are appointed immediately after examination. It will be a red-letter day when an Oxford college elects a research student pure and simple, a mere B.Sc. or B.Litt., to a fellowship. (4) Fellowship examinations of the sort we now have ought to be abolished; for what is the use of deciding over again whether a man possesses the qualities of a good examinee? A college should ascertain rather whether he possesses also the capacity of working at his subject. And, as we saw, he is not the less likely to make a good teacher on this account. From this point of view it is to be hoped that our new Chancellor will give us at least an object-lesson in self-reform by inducing an alteration in the All Souls fellowship examination. (5) The university and the colleges should largely increase the inducements to their members to proceed to "superior degrees" and to undertake the researches which a doctorate ought to imply. At present only the "new" doctorates of Science and Letters connote any considerable intellectual achievement (though they all mean much spare cash), and so they are manufactured chiefly for export, and hardly half-a-dozen of the existing college tutors (of whom the present writer was unwise enough to become one) have found it desirable to take them.

There are, I know, difficulties of detail in the way even of these moderate suggestions; but even their partial and gradual adoption would abate the fascination of our examination system, and check the tendency to identify the good examinee, functioning as a good examiner, with the ideal of academic man.

F. C. S. SCHILLER.

PROF. C. A. YOUNG.

FEW astronomical books have acquired or have deserved a wider reputation than has been accorded to the "General Astronomy" of Prof. C. A. Young, and all who have profited by the accuracy and completeness of that work will regret to hear of the death of the distinguished author, who identified himself so closely with the progress of the Princeton Observatory (N.J.). Other popular works, such as "The Sun," have been well received, for Prof. Young's qualities as a writer and teacher were well known and acknowledged. But though accident may have given him distinction as a writer of elementary works, of which his long career as a teacher had shown him the necessity, he had far greater claims on our respect and gratitude. Son of a distinguished astronomer, Dr. Ira Young, of Dartmouth, he was early and severely trained in mathematics and astronomy, and for fifty years he gave of his best to forward the interests of the science he loved. Moreover, his activity synchronised with the recent development of physical astronomy; he was one of the pioneers of solar spectroscopy, and his continued and successful researches in various directions entitle him to ample recognition.

His first appointment was to the chair of mathematics in the Western Reserve College, a post from which he retired only to serve his country in a military capacity during the War of Secession. After the war, he succeeded his father as professor of astronomy at Dartmouth College, leaving that post in 1877 to accept a similar position at Princeton, where his energies found sufficient exercise during the remainder of his professional career.

Like most astronomers who have occupied themselves with solar phenomena, Prof. Young found it necessary to follow the track of many eclipses. The most famous of these is that of 1870, when he, for the first time, saw and described the now familiar appearance of the reversed Fraunhofer lines at the instant of the inner contact of the limbs of the sun and moon. Owing to the much-debated "reversing layer," which he suggested as the true cause of the flash, this eclipse has become historical. He took part in the observations of the solar eclipse of 1878 which passed over the American continent, and visited Europe in 1887 for the Russian eclipse, but without result, owing to bad weather. Onwards to 1900 he was a diligent observer of eclipses, and extended our knowledge of the sun's surroundings as well by his acute observation as by his luminous discussion of results obtained. His early explanation of the spectrum of the corona is now received practically as he gave it.

But Prof. Young's researches were not limited to exceptional opportunities. He gave constant and assiduous attention to the solar spectrum at all times, and was an indefatigable observer of the spectrum of sun-spots, repairing to favourable situations in order to secure good observing conditions. The chromosphere, no less than sun-spots, was the subject of his care, and his catalogue of chromospheric lines, begun so far back as 1872, is a memorable piece of work. Further, he was among the first to determine the velocity of the solar rotation at various heliographic latitudes by measuring the displacement of solar lines due to motion at the source of light. The spectra of planets and comets, of stars and nebulæ, were all made the subject of profound study, for his industry was as untiring as his resource was abundant. His work was recognised by the Royal Astronomical Society, which enrolled him among its associates in 1872, and many other learned societies paid him similar honours. He was the recipient of the Janssen medal of the French Academy of Sciences in 1891, but his great reward must have been the consciousness of the amount and variety of work he had accomplished for the promotion of astronomical science.

NOTES.

WE regret to announce that Prof. J. B. Pettigrew, F.R.S., Chandos professor of medicine and anatomy in the University of St. Andrews, died on January 29 in his seventy-third year.

WE observe with great regret the announcement that Mr. W. A. Shenstone, F.R.S., senior science master in Clifton College since 1880, died on Monday, February 3, at fifty-eight years of age.

A REUTER message from Brussels announces the death of M. A. Lancaster, director of the meteorological department of the Royal Observatory of Belgium at Uccle.

PROF. W. RIDGEWAY, professor of archæology in the University of Cambridge, has been elected president of the Royal Anthropological Institute.

THE French Physical Society has undertaken the publication of a collection of physical constants. The general secretary, M. H. Abraham, has issued an appeal to members of the society to assist in the collaboration.

THE King, who is patron of the Society of Arts, has granted permission to the society to prefix to its title the term "Royal," and the society will consequently in future be known as the "Royal Society of Arts."

ON Tuesday next, February 11, Prof. Stirling will begin a course of six lectures at the Royal Institution on "Membranes: their Structure, Uses, and Products." The Friday evening discourse on February 14 will be delivered by Dr. C. W. Saleeby on "Biology and History," and on February 21 by Sir Oliver Lodge on "The Ether of Space."

SIR PHILIP WATTS, K.C.B., F.R.S., Director of Naval Construction, has been elected a member of the Athenæum Club under the rule which empowers the annual election by the committee of three persons "of distinguished eminence in science, literature, the arts, or for public services."

THE annual general meeting of the Iron and Steel Institute will be held on Thursday and Friday, May 14 and 15. The annual dinner will be held—under the presidency of Sir Hugh Bell, Bart.—in the Grand Hall of the Hotel Cecil on Thursday, May 14. The autumn meeting will be held in Middlesbrough on September 29 and following days.

In *Engineering* of January 31 there is a sympathetic account of the career of Dr. Coleman Sellers, the eminent American engineer, who died on December 28, 1907, at his residence in Philadelphia in his eighty-first year. He was best known in connection with machine tools, but he will also be remembered for his scheme for utilising the water-power of Niagara Falls, and by his inventions in photography and microscopy.

A correspondent asks if the use of wires stretched horizontally at a height of 15 feet or 20 feet in concert halls, churches, and other buildings where the acoustic properties are of the first importance is not based upon erroneous ideas. He expresses the opinion that though the wires are supposed to remedy some fault in the acoustics, they do not produce any useful effect. We are informed that, theoretically, the wires absorb some of the energy and radiate it again in all directions, thus diminishing the amount of regular reflection, constituting echoes, from the walls. But the fraction of the vibrations thus treated is so small that it is difficult to believe the wires have any real, beneficial effect.

Mr. H. F. Witherby, editor of *British Birds*, informs us that an inquiry is being made into the nature and origin of the disease from which many wood-pigeons have died this winter. The subject is of considerable interest; moreover, possibly the disease, which is very infectious among wood-pigeons themselves, may also be contracted by other birds, and especially game birds. A systematic inquiry into the disease has therefore been undertaken, and schedules of questions have been posted to readers of *British Birds*, the editor of which will be glad to send schedules to anyone who may be in a position to give information on the subject. All the observations will be collated and studied by Dr. C. B. Ticehurst, of Guy's Hospital, who will draw up a full report at a later date.

The fourth International Congress of Mathematics will be held in Rome on April 6–11. The congress will be divided into four sections. The first section will be concerned with arithmetic, algebra, and analysis, and discussions will be inaugurated by Profs. Arzelà, Capelli, Pascal, and Pincherle. The second section will deal with geometry, and the work will be introduced by Profs. Bianchi and Segre. The third section, covering mechanics, mathematical physics, geodesy, and various applications of mathematics, will be addressed by Profs. Levi-Civita, Luiggi, Pizzetti, and Toja. The fourth section will take up philosophical, historical, and didactical questions, and addresses will be given by Profs. Enriques, Loria, and Vailati. Numerous lectures have been arranged, and among these may be mentioned that by Prof. Forsyth, F.R.S., on the present condition of partial differential equations of the second order, as regards formal integration. Other lectures will be delivered by Profs. Darboux, Hilbert, Klein, Lorentz, Mittag-Leffler, Newcomb, Picard, Poincaré, Veronese, and Volterra. Full particulars of the congress can be obtained from the general secretary, Prof. G. Castelnuovo, 5 Piazza S. Pietro in Vincoli, Rome.

Referring to the letter by the Rev. John J. Hampson in our issue for January 30 (p. 295) dealing with "stock frost" or ground ice, Mr. D. O. S. Davies, of the Norwich Technical Institute, reminds us of a volume on the subject of "Ice Formation, with Special Reference to Anchor-ice and Frazil," by Prof. H. T. Barnes, of McGill University, Montreal. Prof. Barnes provides information on the points raised by Mr. Hampson in his letter. The book, a descriptive review of which appeared in the issue of Nature for January 17, 1907 (vol. lxxv., p. 267), is published in this country by Messrs. Chapman and Hall, Ltd.

The *South-Eastern Gazette* of January 28 contains an obituary notice of the late Mr. Edward Bartlett, who from 1875 until 1890 occupied the post of curator and librarian of the Maidstone Museum. The deceased naturalist was a son of the late Mr. A. D. Bartlett, the well-known superintendent of the Zoological Society's menagerie in the Regent's Park. In his earlier years Mr. Bartlett travelled as a natural history collector in Upper Amazonia, where he obtained many valuable specimens. Later on, 1863–4, he accompanied the late Canon Tristram to Syria and Palestine, and in 1891 left Maidstone for Sarawak, to act as curator of Raja Brook's museum, a post which he occupied until 1897, when he returned home. Mr. Bartlett edited his father's well-known work "Wild Animals in Captivity," and was himself the author of several papers on natural history subjects.

No. 13 of the Bulletin of the Imperial Academy of Sciences of St. Petersburg for 1907 contains a paper, unfortunately in Russian, by Mr. D. Dejneka, on the nervous system of the nematode worms.

We have received copies of two papers published by the author at Lancaster, Pa., as Nos. 1 and 2 of a new serial, *Weber's Archives*, in which the author, Veterinary-Surgeon Weber, claims to have bred from the eggs of the ordinary gnat, *Culex pipiens*, two other species of gnats or mosquitoes, in addition to the normal progeny. "Mutation in Mosquitoes" is the title of the second and larger paper. The earlier one, which contains a preliminary account of the same alleged phenomenon, is a reprint of an article published two years ago in *Natur und Haus*, vol. xv., May, 1907.

Two papers on the reproductive organs of sharks have recently appeared within a short time of one another. The first, by Mr. Albert Krall, is published in vol. xxxvii., part iv., of the *Morphologisches Jahrbuch*, and devoted specially to the "claspers" on the pelvic fins of the male of *Hexanchus griseus*, and generally to the corresponding organs in other sharks. In the second, which appears in vol. xxxviii., part iv., of the *Zeitschrift fur wissenschaftliche Zoologie*, Dr. Victor Widakowich describes the uterus of the spiny dog-fish (*Squalus acanthias*), with remarks on the developmental history of allied species. The structure of the uterus is described in great detail, and a figure given of a portion of its wall containing an embryo.

Considerable interest attaches to an account by Mr. C. H. Danforth, published in vol. xxxiv., No. 1, of the Proceedings of the Boston Society of Natural History, of a new genus and species (*Paedoclione doliiformis*) of pteropod mollusc from Casco Bay, Maine. The new form, which was taken in plankton, "does not properly fall under any established family, although perhaps it approaches most nearly the Clionidae, from which it differs in having an odd number of cephalocones and the entire posterior part of the body filled by the viscera." In life the creatures swam for some time by means of their fins, and then sank for a time below the surface, after which the swimming was resumed. With the exception of numerous vacuoles in the integument filled with yellowish or yellowish-brown fluid, the body is transparent.

The distribution of the pine-marten in England and Wales forms the subject of an article by Mr. H. E. Forrest in the January number of the *Zoologist*. In the midland

and south-eastern counties of England the species, it appears, became rare during the first half of last century, and in most of these it was exterminated before 1860, although isolated occurrences have been recorded since that date in Hertfordshire, Surrey, and Sussex. In Lincoln, Norfolk, and Suffolk it survived until the 'eighties, and there have been recent occurrences in Leicestershire. The Lake District and the west of north and central Wales are, however, at present the sole strongholds of the species. Many of the isolated occurrences appear to be due to the remarkable degree to which the marten wanders.

IN addition to the well-known fishery of the pearl-oyster, Ceylon, it appears from an article by Dr. A. Willey in *Spolia Zeylanica* for November, 1907, possesses a source of pearl in beds of the "window-pane oyster" (*Placuna placenta*) in the backwaters of the eastern province. These beds occur in the backwaters of two neighbouring divisions of the Trincomali district, one of which includes Lake Tamblegam, the headquarters of the Placuna fishes. As the lease of this fishery recently expired, Mr. Willey was sent to the district to report on the best means of improving the product of oysters. These molluscs, it seems, are liable to be destroyed in large numbers by unusually heavy falls of rain such as took place a year ago; nevertheless, the species is in the main a hardy creature, capable of living for several hours out of water, and of surviving for long periods in earthenware vessels if the water be from time to time changed. No mention is made by the author of the annual value of the pearls yielded by the Placuna fishery. The paper includes an account of cysticercoid larvæ found parasitic in these oysters.

MR. W. TALIEW contributes to the *Bulletin du Jardin Impérial Botanique* (vol. vii., part iii.), St. Petersburg, a paper on the distribution of forests in the district of Starobjelsk, which furnishes evidence that the "steppes" were formerly wooded areas. Mr. A. A. Sapehin discusses the method by which water is absorbed by the sacs in such liverworts as Frullania.

LIEUT.-COLONEL F. BAILEY and Mr. R. C. M. Ferguson both contribute articles to the Transactions of the Scottish Arboricultural Society (vol. xx., part i.) on the Interliever State forest. The purchase by Government of this estate in Argyllshire affords great satisfaction to British foresters, but it is hoped that it is only the first step in the policy of acquisition by the State of land for afforestation purposes. The estate, consisting of 12,000 acres, carries very little timber, so that while it affords an opportunity for showing how timber crops can be scientificially grown and for recording data, it will not for many years provide a demonstration forest. It is urged that two wooded areas should be acquired for this purpose, one in the lowlands where hardwoods are cultivated, and one in the highlands stocked with conifers.

IT is a debated question whether it is preferable for science students to undertake practical experiments with instruments of their own construction or to make use of apparatus manufactured by instrument makers. Prof. F. W. Ganong, formerly an advocate of the former method in botanical physiology, now declares in favour of instruments of greater precision, and with this purpose has designed several pieces of apparatus that are being manufactured by Messrs. Bausch and Lomb; a descriptive catalogue can be obtained from their agents in London, Messrs. Staley and Co., Thavies Inn. Among the instruments are a transpiration balance, clinostat, autographic transpirometer, leaf-area cutter and leaf clasp, but the photosynthometer and respirometer will probably be found the most useful on account of the functions they record.

A BATCH of pamphlets issued from the Royal Botanic Gardens, Ceylon, as Nos. 2 to 5 of vol. iv. of the Circulars and Agricultural Journal, has been received. Mr. E. B. Denham, writing on the use and objects of agricultural societies, attaches much importance to the visits of travelling instructors and to the distribution of leaflets printed in the vernacular; also he suggests that the local societies should make it their business to collect agricultural data. In connection with camphor production, Mr. J. K. Nock has prepared a useful circular on propagation. Practical hints are given for preparing the seed beds and raising the seedlings. If good seed is not obtainable, it is recommended to propagate by means of root cuttings. The chief object of a circular by Mr. T. Petch is to direct attention to a stem disease caused by the ascus-bearing fungus *Massaria theicola*. The hyphæ of the fungus fill up the vessels of the wood and cut off the supply of water and salts. The disease can be traced by the discoloration of the wood. A catalogue of plants available for distribution from the gardens has been prepared by the curator, Mr. H. F. Macmillan. The economic list comprises certain spice, rubber, fibre, and drug plants.

WE have received the first number of the *Quarterly Journal of Experimental Physiology*, a new periodical issued under the editorship of Profs. Schafer, Gotch, Halliburton, Sherrington, Starling, and Dr. Waller. The four papers contained in it maintain a high standard; they are:—(1) on the time taken in transmission of reflex impulses in the spinal cord of the frog, by Florence Buchanan; (2) some comparisons between reflex inhibition and reflex excitation, by C. S. Sherrington; (3) the freezing of frog's nerve, with special reference to its fatigability, by John Tait; and (4) on protagon, by R. A. Wilson and W. Cramer. We could have wished that it had been possible to avoid the issue of a new journal, but with so distinguished an editorial committee we presume its appearance is necessary for the advancement of physiological science.

IN the third report to the Gas Engine Research Committee, presented to the Institution of Mechanical Engineers on January 17 by Prof. F. W. Burstall, the results were given of an interesting series of experiments carried out during the past two years on an adapted form of one of the Premier Company's existing types of gas-engine. The engine employed was capable of giving 150 horse-power at a speed of 170 revolutions per minute, the size of the cylinder being 20 inches in diameter with a 24-inch stroke. The diameter of the cylinder was reduced to 16 inches, and an entirely new breech end was constructed with the admission and exhaust valves horizontal. The tests were undertaken to determine the thermal efficiencies based on the indicated horse-power at various compressions, having regard to the richness of the mixture, and to formulate, if possible, the law connecting efficiency and compression. The results of the experiments appear to show that the most economical mean pressure is very considerably below the maximum that can be obtained, and that the highest economies are obtained with a comparatively low maximum temperature. Both these conclusions imply that the engine should not only be subjected to lower pressure, but to lower temperatures as well, and thus many of the difficulties that arise in large engines from rich charges might be avoided, and the maximum pressures kept down to quite reasonable limits. This applies only to the indicated power; the conclusions as to the brake horse-power would be widely different. If, however, the engine is constructed to work only with these moderate pressures and temperatures, the whole of the working parts might be very much lightened, and a good mechanical efficiency obtained with the very moderate mean pressures.

At the meeting of the Institution of Engineers and Shipbuilders in Scotland on January 21, two papers of considerable interest were presented. In the first Mr. J. J. O'Neill discussed the inter-relation of the theory and practice of shipbuilding, with special reference to the speed-power aspect of the question. He considered that the lengths of the present Atlantic liners warrant the belief that greater power can be obtained, providing that the power their dimensions invite is present. The curves of power also show that the present speeds can be attained on shorter lengths, and that the variations of form involve relatively small gains. The possibilities of the future of the steam turbine, the chief function of which is its capability to obtain greater powers on a given weight than its competitors, widen considerably the vista of engineering practice. With regard to the screw-propeller, the author is inclined to think that, had the same attention been devoted to the screw-propeller problem as has been bestowed on the form of the vessels, greater advantages than the slight variation of form effected would have been secured. In the second paper Mr. I. V. Robinson gave some comparative figures of the cost of power generated by gas and by water. The results show that power generated from blast-furnace gas costs about the same as water-power when the capital cost of the generating station, with or without transmission lines as may be required, is about 18*l.* per horse-power delivered at the consumers' boundary.

The new French ethnographical review, *Revue des Études ethnographiques et sociologiques*, under the editorship of M. A. van Gennep, starts its career in the number for last month with an excellent programme. Dr. J. G. Frazer contributes a chapter from the new forthcoming edition of the "Golden Bough" on "St. George and the Palilia." The Palilia is a Roman spring agricultural feast, at which the herdsman used to make a sacrifice to Pales and invoked his protection for the flocks, praying him to grant rain for the pastures and to protect the cattle from wolves. In Esthonia, about the same time of the year, a feast is held in honour of St. George, who grants fertility to women and flocks. In eastern Europe the saint seems to represent the old spring god of the Lithuanians, Pergrubius, and, further east, Tammuz or Adonis. With his wide knowledge of peasant rites and ceremonies, Dr. Frazer has no difficulty in establishing the connection between these varied cults of agricultural and pastoral life. This paper is followed by an elaborate sketch by M. M. Delafosse of the Siena or Senoufo tribe, who inhabit the French territory in West Africa in the region adjoining the British Ashanti frontier. M. C. Boreux discusses the decorated pottery of pre-dynastic Egypt. Some reviews and a bibliography complete a publication which promises to be of considerable value to ethnologists.

The current issue of the Journal of the Scottish Meteorological Society (No. xxiv., third series) contains memorial notices of Dr. Buchan from several men of science, including Prof. Hann (Vienna), Dr. Shaw and Dr. Mill (London), testifying to the enduring value of his numerous and "epoch-making" investigations. Mr. H. Bell contributes an article on thunderstorms at the Ben Nevis observatories and on the Scottish coasts, on which subject Dr. Buchan was recently engaged. Tabular statements show the cases of occurrence of thunder and lightning from 1884 to 1904, together with their seasonal and diurnal range. The atmospheric conditions which determined the displays were of a very complex character, and are not yet fully understood. The same journal contains (1) an interesting article, by Mr. R. G. K. Lempfert, on the present condition of telegraphic weather services in various countries; especial reference is made to the great importance of recent extensions of area due to the exertions of the Danish and Egyptian Governments. (2) Rain-producing east winds and their influence on the summer of 1907, by Mr. R. Richardson; the author considers that one of the principal causes of the phenomenally bad character of that summer was the frequent sudden shifting of the wind to the east.

MM. P. Weiss and V. Planer give the results of their comparison of the energy losses due to hysteresis in iron, steel, and nickel, in alternating and rotating magnetic fields respectively, in the *Journal de Physique* for January. As previous observers have found, the loss in a rotating exceeds that in an alternating field for comparatively weak fields, but the authors find that for electrolytic iron the loss in the rotating field reaches its maximum when the intensity of magnetisation is about 1200, and decreases to zero at intensity 1700. For steel, the maximum occurs at 1000 and the zero at 1600. For nickel the corresponding numbers are 300 and 500 respectively. The energy losses at the maxima are 17,000, 120,000, and 17,000 ergs per c.c. per cycle respectively.

The small intensity of the electric waves emitted by a sender consisting of a comparatively short vertical wire, to the top of which a long horizontal wire is attached, in the direction in which the latter points, and the great intensity of the waves sent in the opposite direction, was pointed out by Mr. Marconi in 1906, and in the *Physikalische Zeitschrift* for January 15 Dr. J. Zenneck works out the theory of a receiver of the same form. Such a receiver is most sensitive to waves coming from the direction opposite to that in which the horizontal wire points, for then both the vertical and horizontal components of the electrical field are utilised. The best ratio of vertical and horizontal lengths depends on the ratio of the corresponding components of the wave, and on the conductivity of the soil, but in any case the efficiency of the receiver may be increased by attaching a wire to the base of the vertical wire and extending it on or under the surface of the soil towards the arriving waves.

In a communication to the Royal Academy of Belgium (Bulletin, 1907, No. 6, p. 684) Prof. Walthère Spring gives an account of his further researches on the nature of the allotropic forms of sulphur. Whilst in a previous paper (see Nature, vol. lxxv., p. 182) he was able to show that the sulphur obtained on decomposing a solution of hydrogen sulphide with sulphur dioxide is a hydrate, S_8,H_2O, it is now demonstrated that the material precipitated by the action of ferric chloride on a solution of hydrogen sulphide is not hydrated, but is a new allotropic form of the element. The new variety has a density which is sensibly the same as that of orthorhombic sulphur, and like the latter dissolves in carbon bisulphide, but it differs from it and from all other known forms of the element in its specific heat. Precisely the same form, giving identical values for the density and specific heat, is also obtained on decomposing an alkaline polysulphide in solution by means of an acid.

IN a note published in the *Atti dei Lincei* (vol. xxvi., 2, p. 717) under the title "The Origin of Stereochemistry," Prof. E. Paternò points out that in 1869, five years prior to the publication by Le Bel and van 't Hoff of the doctrine of the asymmetric carbon atom, he suggested that if *three* isomeric forms of the compound $C_2H_4Br_2$ actually existed, the fact could be explained by assuming the four affinities of the carbon atom to be directed towards the corners of a tetrahedron. This was the first occasion on which the hypothesis of the tetrahedral configuration of the carbon atom was definitely formulated. Although the validity of Prof. Paternò's claim has already been admitted in some quarters, it is not generally known to chemists that the conception of a tetrahedral carbon atom, the basis of modern stereochemistry, had been proposed earlier than the year 1874, when it was brought forward simultaneously by Le Bel and van 't Hoff.

THE whole of the mathematical and physical library of the late Prof. A. S. Herschel, F.R.S., and also works from the library of the late Mr. F. Moore, author of books on the Lepidoptera of India and Ceylon, are included in a catalogue just issued by Mr. T. Thorp, Guildford, Surrey, who offers the books for sale.

AN enlargement by four diameters of a photograph of the moon taken by Mr. W. Rice with a Goerz telephoto lens, the exposure being three-fifths of a second, has been sent to us by Messrs. G. Philip and Son, Ltd. The photograph was taken twelve hours before the moon was full, and though the enlargement, which is 6 inches in diameter, is not remarkable for any details it shows of lunar features, it gives a real impression of our satellite as a ball in space, this appearance of relief being accentuated by the bright streaks radiating from the crater Tycho near the south lunar pole.

AT the anniversary dinner of the Royal Society on November 30 last, Lord Dunedin bewailed the fact that few men of science make any attempt to describe their investigations in language which can be understood by men of culture without special scientific knowledge. This speech, as was pointed out in NATURE (vol. lxxvii., p. 111), gave rise to a correspondence in the *Times*, in which the advantage of increasing interest in scientific work by making the results as widely known as possible was insisted upon in many quarters. A similar necessity has been recognised in America, and an attempt is being made at Columbia University to provide literature of the kind required. The Columbia University Press has arranged to publish in the form of pamphlets a series of twenty-two descriptive lectures in non-technical language of the achievements of science and modern scholarship. We have received copies of the first two pamphlets; the first, on mathematics, is by Prof. C. J. Keyser, and the second, on physics, by Prof. E. F. Nichols. A doubt may be expressed as to whether the language of these lectures will be simple enough for the public for whom they are intended. The pamphlets partake largely of the character of the Royal Institution lectures, reprints of which are often available in this country, and contain terms and ideas which, though simple enough to the reader with some training in science, present difficulty to the student whose education has been chiefly on literary lines. It will be interesting to learn later the extent of the encouragement received by the Columbia University Press. The price of the pamphlets is in every case to be 25 cents.

OUR ASTRONOMICAL COLUMN.

THE DISTORTION OF PHOTOGRAPHIC FILMS IN STELLAR WORK.—In No. 1, vol. i., of the Publications of the Allegheny Observatory (Pennsylvania), Dr. Frank Schlesinger discusses the possibilities of error introduced into photographic star-measures by reason of the distortion undergone by the film during the process of development. He further describes some experiments and measures he has made in order to determine the magnitude of this error. By developing, drying, and measuring a negative in the ordinary way, and afterwards putting it through the developing, fixing, washing, drying, and measuring processes again, he has obtained the data from which he draws his conclusions. Briefly, he finds that this error is much smaller than the error of bisection for good star images, being of the order of one one-thousandth of a millimetre for the kind of plate employed.

TWO HUNDRED NEW DOUBLE STARS.—Lick Observatory Bulletin No. 125 contains a list, and measures, of 200 double stars discovered by Prof. Aitken. This is the eleventh list of its kind, and the stars now announced bring the total of Prof. Aitken's published discoveries up to 1700. Nine fainter companions to previously known pairs are included in the present list, which also contains measures of the unusually bright and close pairs κ Ursæ Majoris and ν^2 Boötis (Aitken, 1585 and 1634) as follows:—

	Date	Angle	Distance	Mag.	Annual proper motion
κ Ursæ Majoris ...	1907·83 ...	283°·2 ...	0"·21 ...	4·0–4·2 ...	0"·079 in 211°·1
ν^2 Boötis	1907·55 ...	237°·0 ...	0"·09 ...	5·5–5·5 ...	0"·04 „ 246°

A NEW ASTRONOMICAL JOURNAL.—The members of the progressive astronomical society of Antwerp having expressed a desire for a publication which would give the various ephemerides, and a simple account of the astronomical phenomena to be observed from time to time, the council of the society has commenced the publication of the *Gazette astronomique*, which is to appear monthly, and is designed to fill the gap indicated; popular articles on astronomical subjects are also to appear. No. 1 (January 4) contains various ephemerides, notes on phenomena occurring during January, accounts of the recent transit of Mercury, and a series of notes dealing, respectively, with the planets, asteroids, meteors, comets, &c. The annual subscription for this useful publication is three francs, post free in all countries, and all communications should be addressed to "Gazette astronomique," Chaussée de Turnhout, 342, Borgerhout, Antwerp, Belgium.

THE STUDY OF METEOR TRAINS.—The *Monthly Weather Review* (U.S.A.), vol. xxxv., No. 9, contains a suggestive article by Prof. Trowbridge on the utility of the precise observations of meteor-train drifts for the determination of atmospheric currents at altitudes otherwise inaccessible. This altitude, of meteor trains seen at night, ranges from forty-five to sixty-five miles, and Prof. Trowbridge believes that the conditions of pressure and temperature at about fifty-five miles above the earth's surface are possibly peculiarly suitable for the production of trains; careful study may enlighten us as to these conditions. Several recorded trains are illustrated in the article and fully discussed, and the author suggests that valuable results may follow from an organised series of careful observations.

THE ACCURACY OF DOUBLE-STAR MEASURES.—A paper by Prof. Doberck, appearing in No. 4229 of the *Astronomische Nachrichten* (p. 65, January 21), should appeal to double-star observers. In it the author gives the probable constant errors, and the residuals after applying these constant, or the mean, errors to the observations, in position-angle and distance for some fifty past and present observers. The probable errors are based on the comparison of the results of the various observations with the positions calculated from the orbits of thirty double stars recently determined by Prof. Doberck. The effects of difference of colour, which, as Prof. Doberck remarks, must be considerable, are not discussed in the present paper, but the same worker expects to deal with them later. The variations of the probable errors caused by increase of the distance between the components, and by greater differences of magnitude, are well shown in some of the results, although in other cases magnitude appears to have made no difference. Thus Admiral Smyth's results show a probable error in angle of $\pm 0''.031$ below $3''$ and $\pm 0''.040$ above $3''$, but it is not certain whether the magnitudes have any influence; there is no evidence of systematic error in the distances, but an average constant error of $\pm 0''.073$ is indicated. Prof. Doberck states that these observations are of very great value. In the case of H. Struve the magnitude coefficient is probably considerable.

FORTY-ONE NEW VARIABLE STARS.—Circulars No. 134 and No. 135 of the Harvard College Observatory announce the discovery of forty-one variable stars. Of the sixteen announced in the former, two show remarkably large variations. One of these, D.M. $-30°.2883$, situated in Columba, decreases from magnitude 10·4 to below magnitude 15·0, whilst the other, D.M. $-46°.14688$, situated in Phœnix, ranges from 8·5 to less than the twelfth magnitude. The variations of a number of stars announced in Circular No. 129 have been confirmed visually, and of these TT Aquilæ is especially interesting on account of its brightness and probable colour changes. The second circular gives particulars of twenty-five newly discovered variables found in regions Nos. 24, 36, and 42 of the Harvard map. In this research the number of variables found to be of the Algol type has been a remarkable feature, and of the twenty-five now published, eight are probably of this, or of the β Lyræ, class. The large number of variables found in map 42 appears to be significant, and should be taken into account in any discussion of the region, which includes a large portion of the constellation Scorpio and the nebulous region in Ophiuchus.

AMERICAN ETHNOLOGY.

THE American Bureau of Ethnology, with its usual energy, has lost no time in extending its operations over the new colonial possessions, the Philippines, and some West Indian islands. The most important contribution to the twenty-fifth volume of its reports, for 1906–7, is an account of a preliminary survey of Porto Rico and the neighbouring islands, conducted by Dr. J. W. Fewkes.

Porto Rico, the smallest of the Greater Antilles, is naturally linked with Venezuela by the chain of the Lesser Antilles, which stretch southwards to the mouth of the Orinoco. It lies within a region of volcanic disturbance, and it is possible that when it was first occupied by man it may have formed part of an isthmus connected with the South American coast. A temperate climate and a productive soil naturally invited colonisation. The fauna and flora are of the South American type, and many considerations support the conclusion that Porto Rico and the adjoining islands were peopled from the valley of the Orinoco. Thus the houses of the people of both these regions are similar in type, and we find no traces of stone buildings which would naturally have been erected by emigrants from the Maya or other Yucatan tribes. The use of cassava, a South American product, and the care which the primitive inhabitants of Porto Rico, like those of the Orinoco, devoted to the preservation of the skeletons of their dead, are facts pointing in the same direction.

Except in the interior of the island, few traces of the aborigines survive. The inhabitants were massacred by the Spaniards, who re-peopled the island with slaves from the Bahamas and negroes from Africa. From the intercourse of these people with their rulers a half-caste population sprang up. Thus the island at present is occupied by a mixed race, and the absence of a collection of the skulls of the aborigines renders it difficult to decide what their race character may have been. The accounts of their physique and character given by the early Spanish writers do not, however, conflict with the theory of their South American origin.

The relics of this forgotten race are to be found in the dancing plazas, shell-mounds, and caves scattered over the island. The character of their stone carvings and pottery indicates that they had reached a high grade of culture. The plazas were stone enclosures in which ceremonial dances were performed with the object of securing abundant rain and plenteous harvests, success in war, the cure of the sick, for commemoration rites of the dead, initiation and other ceremonies. They often contain

FIG. 1.—Lateral and top views of a three-pointed stone of the second type (Latimer collection); length 3 inches.

water-worn stones, which Dr. Fewkes supposes to have been emblematic of flowing water, and to have been used in some form of mimetic magic to control the rain. Their religion was of the animistic and shamanistic type, and its ritual largely consisted in the worship of Zemis, a term which included their gods, symbols of deities, idols, bones, skulls of the dead—in short, anything supposed to possess magical power.

The most remarkable idols were those of the "three-pointed" anthropomorphic type (Fig. 1). The interpretation of these objects is obscure, and many theories of their origin have been suggested. Dr. Fewkes regards them as clan idols or tutelary totems, the difference in their form denoting different conceptions of the Zemi in the various clans. Equally curious are the zoomorphic or anthropomorphic pestles (Fig. 2), which were employed with mortars in the preparation of food, and the stone collars, which, according to one theory, were used in association with the "three-pointed" images, and with them formed a snake idol. This explanation Dr. Fewkes rejects; but, except that they must have been used for some religious or ceremonial purpose, their meaning is still uncertain.

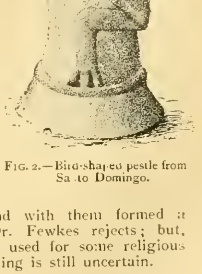

FIG. 2.—Bird-shaped pestle from Santo Domingo.

The rude pictographs or petroglyphs found in the island are equally remarkable. Some of the best specimens are engraved on boulders in rivers or in their vicinity, thus possibly indicating their use in some mimetic rain ceremony. Others, drawn with less care, differing from the river sculptures in size, shape, and apparently in significance, are inscribed in the caves so common in the calcareous rocks of the island. They represent in some cases a head furnished with horns, human faces, and rude representations analogous in type to the "three-pointed" images, with circles, spirals, and other symbols. Our knowledge of the aboriginal cults is at present too scanty for any attempt to explain their significance. That they represent objects of religious worship seems fairly certain.

Porto Rico is thus a most promising field for archæological investigation. The report of Dr. Fewkes suggests many interesting problems. It is well written, and, like other publications in the same series, is admirably illustrated.

Another article by the same writer describes a tour of exploration in eastern Mexico, undertaken with the object of ascertaining the relationship between the mound builders of the lower Mississippi and the people of the Mexican coast known as Totonac and Huaxtec. The Totonac metropolis, Cempoalan, was for the first time examined. From this investigation it seems probable that the mound builders of the southern States were more closely connected with the races of eastern Mexico than with those of the arid region of the south-west or even with the plateau tribes of eastern Mexico.

The third part of the thirteenth volume of the Journal of the Academy of Natural Sciences, Philadelphia, is devoted to a fresh exploration of Moundville, Alabama, and sites on the Crystal, Chattahoochee, and Lower Flint Rivers, and the Ten Thousand Islands of Florida, by Mr. C. B. Moore. The appearance of the Swastika symbol and other objects discovered at Moundville seems to indicate that this was an important religious centre, specially devoted to the worship of the sun, conducted in temples by an order of priests, who kept the sacred fire continually burning as an emblem of the luminary. The discovery at the Crystal River of an ear-ornament overlaid or covered with meteoric iron is an interesting proof of the skill of this race in metallurgy, and it seems to connect the races of Florida, who buried their dead in mounds, with the people of the Ohio valley region. This report also is provided with excellent illustrations of the remarkable series of finds which were secured by Mr. Moore's expedition.

THE NITROGEN PROBLEM IN AGRICULTURE.[1]

FOR many years what is known in agriculture as the nitrogen problem has received considerable attention both from men of science and from practical men. It has two aspects. Few soils contain nitrogen compounds in sufficient quantity for the needs of non-leguminous crops, and the application of nitrogenous manures is one of the commonest, as well as one of the more costly, operations of modern agriculture. On the other hand, leguminous crops not only need no nitrogenous manure for themselves, but actually increase the store of nitrogen compounds in the soil, and dispense with the necessity of adding more for the succeeding crop. The problem would obviously vanish if leguminous crops could be grown every other year, but unfortunately they are liable to "sickness," and can only be grown once in four or even six years. Even as it is, however, any method that increases the nitrogen-fixing power of a leguminous crop is a welcome addition to the resources of a farmer.

In 1886 Hellriegel and Wilfarth showed that nitrogen-fixation is the work of certain micro-organisms associated with the leguminosæ. It has since been shown that they can grow apart from the plant, and can be inoculated into soils, and also that an increased crop may follow such inoculation.

On three occasions cultures of these organisms have been widely distributed among farmers. In 1896 Nobbe sent out "nitragin"; in 1903 Moore's cultures were issued in America; and now we have Prof. Bottomley's cultures. Each time very great and widespread interest has been aroused, the matter has been discussed at length in the daily Press, and has even on occasion formed the subject of questions in the House of Commons. The subject appeals to almost everyone. Few scientific problems are more interesting than the wholly unparalleled synthesis of complex organic compounds from free nitrogen and other simple bodies effected by these micro-organisms at the low temperatures of the soil. The practical man sees in inoculation the possibility of increased leguminous crops and of less expenditure on nitrogenous manure for his other crops. The man in the street, who has always been ready to take an interest in nitrogen since Sir William Crookes's British Association address at Bristol in 1898, sees the threatened nitrogen famine averted and his food supply rendered secure for a long time to come.

Inoculation has proved very successful on virgin soils, or in dealing with new leguminous crops, but there is little or no evidence that it is effective when the soil is already in cultivation and the crop no longer new. Nobbe's cultures failed, and Moore's cultures were not particularly successful when applied in ordinary farm practice. Certain other less boomed cultures, *e.g.* Hiltner's, have done better, and have sometimes given 20 per cent. or 30 per cent. increases in crop. Prof. Bottomley tested his culture by distributing more than a thousand specimens; 80 per cent. of the reports received (unfortunately we are not told the actual number) showed an increase in crop. The pamphlet before us consists largely of extracts from these reports.

Experiments of this nature are very difficult to carry out. Great care is necessary in selecting the ground, proper control plots are needed, and the experiment must be continued for several years without essential modification. Under favourable conditions, the error of a field experiment lasting many years may be as low as 5 per cent., but for shorter periods it is much higher. We cannot find any evidence that these facts have been taken into account; on the contrary, most of the trials have obviously been made by novices. Only in a few cases have any weights been taken, and the results have usually been guessed. Here is an "experiment" with peas:—

"I planted the inoculated peas on land that had not been manured for many years, and had a crop of peas quite equal to those grown by a friend on manured soil" (p. 24).

Another:—"'Gradus' *without inoculation*, a fair crop, but they were soon over."

"'Sutton's A 1' *inoculated*, heavy crop, with abundance of well-filled pods" (p. 21).

Again:—"First sown peas, inoculated, a fine crop. . . . Second sowing, uninoculated, results very poor. . . . The ground on which first crop was sown had had no peas on it for several years, whereas the ground on which second crop was sown had had peas grown on it in the previous year" (p. 17)

It is scarcely necesary to say that statements of this kind are of no scientific value.

Fifty-two reports are quoted; fifteen must certainly be rejected, eighteen give no figures, thirteen give estimated figures, and six give weights. Confining our attention to the nineteen cases where figures are given, we find that in four the increased yield is 20 per cent. or less; this cannot be much greater than the magnitude of the experimental error. In nine cases the estimated increase is 30 per cent. to 50 per cent., and in five cases more than 50 per cent. A detailed discussion is obviously impossible; we can only point out that a few experiments properly made on sound lines would have been very much better than all these testimonials. So far as they prove anything at all, however, they go to show that the author has, like Hiltner in Germany, Moore in the United States, and Golding here, obtained cultures which may in suitable cases increase the yield of leguminous crops, and the increase seems to be estimated in the majority of cases at about 30 per cent. to 50 per cent.

Now if this turns out to be correct it will be a very useful result, but in ordinary farming it can only be

[1] "Seed and Soil Inoculation for Leguminous Crops." By Prof. W. B. Bottomley. (London: *Country Life* Office.)

looked for once every fourth or sixth year, for it is not claimed that inoculation cures "sickness" and increases the frequency with which leguminous crops can be grown. Even a 50 per cent. increase in crop, useful though it would be, would in these circumstances hardly effect any particular revolution in agricultural practice. We are therefore unable to follow the author when he remarks:—"For a few thousand pounds the 21 million acres of poor barren land in this country could be made productive and rendered capable of finding work for and supporting such a population that both the food problem and the unemployed problem would be easy of solution. . . . Waste land reclaimed and made fertile for 6*d*. an acre! . . ." It would have been better if the author had induced an agricultural friend to revise this estimate. We are told on pp. 8 and 10 that inoculation will be a failure when the soil is too acid and in need of lime, when it is deficient in phosphates and potash, when the physical conditions of the soil are unfavourable, or when drainage is needed. Barren land in England commonly suffers from several or all of these defects. How far would sixpence an acre go in putting them right?

At a time when the farmer needs, and is willing to accept, all the assistance the scientific investigator can give him, the fact that an enthusiastic worker like Prof. Bottomley has directed his attention to agricultural botany is a matter for congratulation, and we can only regret that in this, his first appeal to the practical man, his enthusiasm should have outrun his judgment. However, although we must regard the present production as unsatisfactory, we still look forward to sound work from the author on this subject, and we wish him success in his work on the numerous and difficult problems connected with soil inoculation.

E. J. R.

MATHEMATICAL EDUCATION AND RESEARCH.

THE annual meeting of the Mathematical Association was held at King's College, London, on Saturday, January 25. The proceedings bear abundant testimony to the great changes which are taking place in the methods of teaching mathematics, and show that these changes are not confined to the subject of elementary geometry. Mr. W. J. Dobbs showed what useful work could be done by means of simple home-made apparatus in the teaching of mechanics, his apparatus consisting merely of spiral springs with cardboard scales attached for illustrating applications of the parallelogram law, and suspended sticks for illustrating the principle of the lever and the balance. He further showed how the solution of problems on accelerated motion could be greatly simplified by the application of direct methods not involving such restrictions as to units as are necessary in working with "poundals" or "slugs." Mr. C. O. Tuckey made a distinct step in advance in his suggestions as to the methods of introducing the properties of convergent series to students who require these series principally in the study of the calculus, and it is interesting to compare his views with those which prevailed twenty or thirty years ago, when the calculus was regarded as something sacred which should not be handled by students until they had passed through a lengthy period of probation in working with algebraic series. Mr. F. J. W. Whipple's lantern-slides, showing how the convergency of certain trigonometric series could be illustrated by diagrams drawn by mere beginners, were a revelation to those who had approached the subject by the study of pages of long formulæ. Mr. W. E. Bryan suggested a very original way of introducing similar figures in geometry, a method which, however, may well form a basis of further discussion and criticism. An apparatus for drawing rectangular hyperbolas was shown by Mr. H. L. Trachtenberg.

In his presidential address Prof. G. H. Bryan, F.R.S., dealt with the uses of mathematics and the training of mathematical teachers. It was necessary that the public should be made aware of the important part which higher mathematical research had played, and was destined to play, in practical applications on which the prosperity of a nation depended. As an instance, Prof. Bryan referred to the seemingly unpractical and uninteresting study of the properties of imaginary quantities, without which modern applications of electricity to purposes of commerce, including wireless telegraphy, could never have reached their present developments. In order to overcome the existing lack of public interest in mathematical matters it was important that the university training of every mathematical teacher should afford him some insight into the research aspect of some one branch of the subject, and the experiments that had already been made in this direction in the university colleges of Wales showed that this ideal was quite capable of attainment. Turning to the teaching of mathematics in elementary schools, Prof. Bryan expressed the opinion that the children of the working man should learn to measure and calculate correctly in order that they might become more efficient and improve their positions in the labour market. If their teaching was conducted in such a way as merely to stimulate in them a spirit of luxury and discontent as distinct from a desire for self-improvement, the working classes had quite as much cause for complaint as the tax-payers. But in the training of elementary teachers, antiquated and unpractical methods are still prevalent, and are often greatly encouraged by examinational requirements.

RADIOGRAPHY IN PEARL FISHING.

THE products of the sea are commonly wasted to a very deplorable degree by those who gather and use them. In no instance is this waste more marked than in the search for pearls. By the old method, which is still in vogue as a general rule, an enormous number of the so-called oysters are taken from their habitat and destroyed without any thought of economy. It is said that only one pearl is found in 100 oysters, and only 1 per cent. of the pearls found are of any commercial value. Thus some 10,000 of the precious molluscs are sacrificed for every useful pearl obtained. Among these victims there must be a vast amount of immature pearls or seed, pearls *in posse*, which might grow and become valuable gems, which are deprived of that possibility by premature destruction.

In the year 1901 Prof. Raphaël Dubois took radiographs of pearls *in situ* within the shell of *Unio prolifera*, and obtained a clear view of their size and situation in spite of the thickness of the shell in which they were encased. He showed these radiographs at the Linnean Society of Lyons, and remarked that the X-rays might receive a novel application if used in the fisheries of Ceylon, and the destruction of a vast number of the prized molluscs might thus be avoided.

The difficulty of applying the X-rays to many thousands of shells *per diem* seemed sufficient to deter the ordinary person from such a laborious attempt. However, a few years later an electrical engineer of New York, Mr. John J. Solomon, who took an interest in the question of pearls, was struck by the same idea of using the X-rays to detect the existence of pearls within the shell of the living animal. He was then unaware of the earlier experiments of Prof. Dubois, but promptly set himself about the work from a commercial point of view.

He found that an exposure necessary to obtain a good picture did not in any way injure the animal, and even an exposure of ten times as long could be applied without causing its death from the effect of the rays. The dangers lay rather in the removal of the bivalve from its normal attachment and in the time required for its transit from its bed to the laboratory of the photographer: for the pearl oyster is really a kind of mussel, which holds on to some fixed object by a brush of fibrils (*byssus*) growing from its body

Thus the fundamental principle of Prof. Dubois, to save the life of unremunerative bivalves, bids fair to be carried out by American ingenuity and capital.

For practical purposes, where many thousands of shells have to be radiographed daily, a completely novel kind of plant had to be devised. This was done, and final success was considered to be well in view, when 100 clear radiographs could be taken on an average every fifteen seconds.

Mr. Solomon often succeeded in taking as many as 500 per minute. In this process some hundred shells are exposed at a time to the rays. The oysters, spread on trays, are carried under the specially constructed cylinders by means of an electric motor. These great cylinders are cooled by means of suitable water jackets, and can thus be kept working continuously.

The oysters in which there is no sign of pearl formation are put back to their beds. Those in which good-sized pearls are detected are removed and opened, and the pearls promptly utilised. Those showing no pearls of adequate commercial value, but containing promising seed or immature pearls, are carefully placed in hospital. This hospital has rather a novel object; not the cure of the pearl disease (for the much prized gem is but a pathological growth), but, on the contrary, everything is done to keep the mollusc in *statu quo ante* so that the disease may progress as rapidly as possible to the production of valuable pearls and to the death of the incurable patient.

The question seems to arise, can the normal, or perhaps we should say the abnormal, conditions of the pearl-producing bivalve be well enough imitated in captivity to ensure the continued growth of the pearls? May not the "change of water" (as they must be kept nearer the surface) secure for the sufferers immunity from their diseased process? One might have imagined that a greater amount of sunlight, more oxygen, altered temperature, different nutrition, lessened pressure, and other changed conditions we think not of, would so influence the life of the mollusc that it might depart from its pathological but useful habit of producing these valued round bits of shell material, and the hospital might thus prove a true *Kur-Anstalt* instead of a pearl-breeding depôt. But Mr. Solomon tested these points, and he has satisfied himself that, if he can be certain to transmit in all circumstances the oysters to and from his laboratory without injury to their well-being, all other difficulties have already been overcome. As to the lucrative commercial value of the undertaking, time alone can tell; sufficient has not yet elapsed to make it demonstrable by actual proof that pearls can thus be hatched *en gros*.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Two Graces will be offered to the Senate at the Congregation on Thursday, February 13; the first gratefully accepts the generous offer of the Drapers' Company to contribute a sum of 200*l*. a year until 1919 towards the stipend of a second professorship in the department of agriculture, and the second establishes in the University a professorship of agricultural botany.

The council of the Senate has reported that it is of opinion that the University should hold a Darwin celebration in the course of the year 1909. The council points out that Charles Darwin was born on February 12, 1809, and that the "Origin of Species" was published on November 24, 1859. The hundredth anniversary of the former event, and the fiftieth anniversary of the latter, will therefore fall in the course of the year 1909. It is suggested that representatives of universities and other learned bodies, together with distinguished individuals, should receive invitations to visit the University on the occasion. Should this report be confirmed by the Senate, the council will appoint a committee to consider the details of the proposed celebration. The week beginning June 20, 1909, appears to the council to be the most suitable time for the celebration.

LONDON.—The degree of D.Sc. has been conferred on Mr. H. B. Fantham for a thesis entitled "*Spirochaeta* (*Trypanosoma*) *balbianii* (Certes) and *Spirochaeta anodontae* (Keysselitz); their Movements, Structure, and Affinities," and other researches in zoology.

Dr. Otto Stapf has commenced a university course of ten lectures on "Grasses: their Structure, Biology, Distribution, and Classification," and Dr. Beddard, F.R.S., a course of four lectures on "The Circulatory System of Reptiles." Both courses are being delivered at University College on Mondays, the botany lectures at 4 p.m. and the zoology lectures at 5 p.m., admission to these lectures being free.

A university course of four advanced lectures in zoology on "Tooth Development and Morphology" will be given by Prof. H. W. Marett Tims, at Bedford College for Women, at 5 p.m. on Tuesdays, commencing March 3. Admission will be free.

Arrangements have been made for university courses in geology by Prof. Garwood, on "The Geology and Physiography of Arctic Europe" (in March); by Prof. Seeley, F.R.S., on "The Thames and its Tributaries" (in May); by Dr. Evans, on "Recent Advances in the Determination of Minerals by Optical Methods" (in June); and by Miss Raisin, on "The Geological Structure of the Area of the Vosges" (in October).

In future, a candidate for the D.Sc. degree may be required by the examiners, as an additional test, to submit within a given period a reasoned report on a subject prescribed by them. Candidates for the B.Sc. honours degree in mathematics as internal students are to be allowed, under certain conditions, to submit research work, and such work will be taken into account in estimating their qualifications.

THE Lord Alverstone, G.C.M.G., Lord Chief Justice of England, will present prizes and certificates to students of evening classes and the day college of the South-Western Polytechnic, Chelsea, on March 13.

THE Board of Education has issued a return (325) showing the application by local authorities of funds for higher education in England and Wales during the official year 1905–6. It appears that the total expenditure on account of education other than elementary during the year was 3,355,434*l*. Of this amount, 706,149*l*. was spent on secondary schools and 234,182*l*. on pupil-teacher centres. On behalf of evening schools and institutions for higher and technical education, 1,200,789*l*. was expended, and in day schools of similar scope 258,517*l*. Exhibitions and bursaries at secondary schools, pupil-teacher centres, evening and day technical institutions, accounted for 376,762*l*. The training of teachers cost 71,910*l*., the salaries of officers other than teachers 120,531*l*., and 150,660*l*. was paid on account of loans. The part of the total amount which was expended in Wales reached 214,185*l*., more than half of which was devoted to secondary schools.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 21, 1907.—"Note on the Sensibility of the Ear to the Direction of Explosive Sounds." By A. **Mallock**, F.R.S.

Soon after the introduction of modern rifles, which give their projectiles a velocity much higher than that of sound, the author noticed that when standing in a position in front of the gun, and not far from the line of fire, the sound seemed to come, not from the firing point, but from some point considerably in advance of the gun. The natural explanation seemed to be that the sound thus heard was not that of the explosion itself, but was caused by the wave-surface, which is generated in the air by the projectile moving at a velocity higher than that of sound. In 1898 the author made observations at the ranges at Browndown to see if the apparent directions agreed with this supposition; and in the present year he has again made similar experiments in much more favourable circumstances. It is clear (if the source of the sound is due to the wave caused by the projectile) that the apparent direction of the sound will be the normal to the wave-surface, and that if the direction of this normal is known, the velocity of the projectile, at the time that that particular portion of the wave-surface was generated which ultimately reaches the observer, can be calculated.

These observations are now recorded, not as giving a practical method of ascertaining the velocity of projectiles, but as showing that the ear can distinguish with considerable accuracy the direction of a sound which consists, not of a train of waves, but, at most, of two waves only. The figure gives the plan of the range and the stations at which the observations were made.

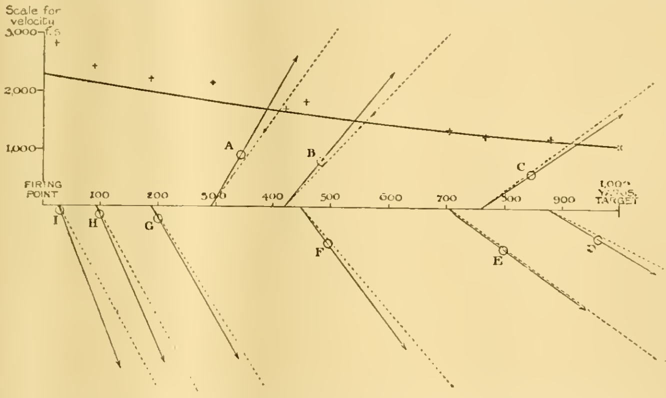
The arrows through these points show the direction of the sound as judged by ear. Each arrow is the mean of eight observations, which rarely differed among themselves by more than two or three degrees.

That portion of the wave-surface which passes the observer at any station was generated at the point where the apparent direction of the sound cuts the line of fire, and since the trace of the wave on the trajectory necessarily has the velocity of the projectile at the place where it was formed, and moves along the normal with the ordinary velocity of sound, it is plain that at those points the velocity of the bullet is the velocity of sound ÷ the sine of the angle which the tangent to the wave-surface makes with the trajectory.

The spots, +, show the velocities thus computed, and the full curve gives the actual velocity, as determined by firing, at various ranges up to 1000 yards, into a ballistic pendulum.

The agreement of the values of the velocities thus obtained with the true velocities shows the degree of accuracy with which the direction of the sound was estimated. In this case the difference between the true and observed directions was seldom more than a few degrees, and was generally in one direction.

A sound which is caused by the detached waves, such as those which accompany a bullet, can scarcely be said to have a pitch, but the wave-length is certainly small compared with the distance between the ears, and is, indeed, comparable with the dimensions of the bullet itself. It would seem, therefore, that the ears can determine the direction of a sound, not only by difference of phase, but by the actual difference in the times at which a single pulse reaches them.



The arrows show the apparent direction of the sound at the stations A B C . . . The dotted lines are the normals to the wave-surface, calculated from the known velocity of the projectile. The full curve is the velocity of the projectile, obtained from experiments with the ballistic pendulum. The spots, +, are the velocities of the projectile, as deduced from the observed direction of the sound.

"Results of the Interaction of Mercury with Alloys of other Metals." By Dr. J. W. **Mallet,** F.R.S.

It being well known that alloying metals with each other often modifies notably their relations to acids and other non-metallic reagents, it seemed desirable to ascertain what the behaviour would be of solid alloys to liquid metallic mercury.

In the experiments reported in this paper three alloys were used, namely, tin-platinum, silver-platinum, and copper-tin, approximately $PtSn_2$, $PtAg_{1}$, and $SnCu_{1}$. These were shaken up in a finely divided state with pure mercury in large excess. In the first case the tin was completely protected by the platinum from amalgamation, and neither of the solid metals was dissolved by the mercury. In the second case the presence of the silver brought about amalgamation of the platinum, which would not have been so affected if alone, and both metals were dissolved by the mercury, the platinum, however, in less proportion than that in which it was present in the solid alloy. In the third case, mere traces of the copper and tin were dissolved by the mercury, although each of the constituent metals of the alloy would by itself be readily taken up. A solid amalgam was, however, formed.

These experiments, which were interrupted by illness of the author, go to show that the relations of mercury to alloys are not the same—at any rate for those tried—as to the component metals taken separately.

December 5, 1907.—"The Reciprocal Innervation of Antagonistic Muscles. Note XI. Further Observations on Successive Induction." By Prof. C. S. **Sherrington,** F.R.S.

This communication announces that an essential part of the flexion-reflex of the limb is a contraction of the extensor muscles which sets in immediately the external stimulus which excites the reflex is discontinued. The external stimulus, it may be recalled, while exciting the flexor muscles to contraction, produces relaxation of their antagonists, the extensors. This latter it effects by quelling (inhibiting) all nervous discharge for the time being in the extensor moto-neurones of the spinal cord. The inhibition of the moto-neurones is on cessation of the stimulus followed by a superactivity in them accompanied by the discharge of impulses from them into the muscles they innervate, namely, the extensors. This tendency to motor discharge which follows on the inhibition had been noted in previous communications by Prof. Sherrington, but the evidence of it had hitherto been only indirect. It had been found that on withdrawing the inhibitory stimulus the inhibited part of the reflex arc showed itself more easily excitable by stimuli than it had been before the inhibition occurred.

In the present communication it is shown that the inhibited centre actually discharges spontaneously on withdrawal of the external inhibitory stimulus that depresses it. It is further shown that the inhibited centre will spontaneously discharge even in face of a weak inhibitory stimulus if that stimulus follows on a strong inhibitory one. The process in virtue of which inhibition of the arc leads to or induces a subsequent superactivity of the arc is called *successive induction*, because of its analogy to certain processes in the physiology of vision which are also called inductive. The intensity of the successive induction increases with increase of the intensity of the inhibitory stimulus and with increase—up to certain limits—of the duration of the inhibitory stimulus. In other words, the stronger and longer the inhibitory stimulus, the greater the contraction which ensues on the withdrawal of the stimulus.

The contraction of the extensors of the limb which thus follows on their relaxation by reflex inhibition is probably an important, perhaps the most important, factor in the extension phase of the reflex stepping of the limb. Its occurrence supplies an explanation for the relatively poor representation of extension as a primary movement in the motor area of the cortex cerebri. It may be fundamentally analogous to the excitation which occurs in a peripheral nerve at the site of the anode of a voltaic current when the passage of the current is broken. It is, at any rate, perhaps the most striking instance known of a depression which in Arnim v. Tschermak's terms is *allonomic*, being followed by a reverse condition the process of which is *autonomic*. In other words, an allonomic depression

(? assimilatory) of the nerve-centre induces an autonomic (? dissimilatory) excitation.

Geological Society, January 8.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—Chronology of the Glacial epoch in North America: Prof. G. F. **Wright.** In the case of Plum Creek, Lorain County (Ohio), the study of the activity of the stream and of the amount of work done since the Glacial epoch has yielded important results. This stream began erosion when the temporary lake, held up by the ice, was maintained at the level of its Fort Wayne outlet; it has never had anything more resistant than Till to act upon. From a section 5000 feet long it has excavated 34 million cubic feet of Boulder-clay, removing it from exposed banks 1600 feet long. Twelve years' erosion of a 500-feet length of a part of the trough of the stream gives a rate of 8450 cubic feet per annum. Therefore, the removal of 34 million cubic feet from the 5000-feet section would give a period of 2505 years. The erosion of the Niagara Gorge began later than that of Plum Creek, and dates from midway between the disappearance of the ice from northern Ohio and from Quebec. If conditions have been uniform, the age of the gorge would be 7000 years. The author concludes, with some confidence, that the gorge is less than 10,000 years old, and that the ice of the Glacial epoch continued down to that time to such an extent over the lower St. Lawrence Valley and Central New York that it obstructed the eastern drainage of the Great Lakes.—The application of quantitative methods to the study of the structure and history of rocks: Dr. H. C. **Sorby,** F.R.S. The angle of rest in the case of sand-grains of varying size and quality enables the velocity of current necessary to keep such sand drifting, and that needed to move it when at rest, to be ascertained approximately. The comparison of this angle with that in sedimentary rocks made of similar materials may be used to determine the vertical contraction of rocks since deposition, the average in cases studied in Tertiary and secondary rocks being from 100 to 57. The connection between the structure of "ripple-drift" and time is discussed. The connection between the structure of a deposit and depth of water is found to be difficult to study quantitatively. From the occurrence of "drift-bedding" the depth of water may be determined to within a few feet. The deposition of fine deposits, like clay, varies according to the amount of mud present and whether the grains subside separately or cohere together. When no pressure is applied, the amount of water included in the deposited clay may be 80 per cent., and when dry the empty spaces may still amount to 32 per cent. Many of the older rocks must now be only 20 per cent. of their original thickness. In the green slates of Langdale the volcanic eruptions sometimes occurred probably within a few weeks of one another, and at other times at more distant intervals. When deposited, part of the rock was probably analogous to fine, loose sand, and part to semi-liquid mud. In the Coal-measure sandstones deposition at the rate of 1 inch per minute was common, with intervals of little or no deposit. The volume of invisible cavities in rocks varies from 49 per cent. in some recent rocks to nearly 0 in the ancient slates. The packing of grains was discussed mathematically and experimentally. The methods of determining the volume of minute cavities in rocks were given. In some limestones the cavities have been reduced by pressure to close on the mathematical minimum, whereas in others the cavities are filled with carbonate of lime. Some oolites have had their cavities filled in a similar manner; in others most of the material of the original grain has been removed, and the present solidity is due to the filling-up of the cavities mainly by internal segregation. Among fine-grained rocks, the Chalk probably was originally a sort of semi-liquid with 70 per cent. of water, and in its present state is about 45 per cent. of its original thickness; the thickness of some clays must have diminished still more. By the measurement of green spots in slates it can be deduced that the rock before cleavage was more consolidated than rocks of the Coal-measures now are, and was then greatly compressed. The development of "slip-surfaces" in cleaved rocks is great, and furnishes additional proof that the cleavage is of mechanical origin. The volume of minute cavities in clay-rocks and their analogues of various ages were discussed. There is a distinct relation between it and the probable pressure to which the rocks have been exposed.

Zoological Society, January 14.—Prof. J. Rose Bradford, F.R.S., vice-president, in the chair.—Mammals obtained in the Shantung Peninsula, N. China, by Mr. M. P. Anderson, for the Duke of Bedford's exploration of eastern Asia: O. **Thomas.** No mammals had come from this region since the time of Consul Swinhoe, who visited it in 1866–8. The present series contained 106 specimens belonging to six species, of which one was new.—The musculature and other points in the anatomy of the engystomatid frog *Breviceps verrucosus*: F. E. **Beddard.**—The hermaphroditism of the amphipod *Orchestia deshayesii*, Audouin: C. L. **Boulenger.**

Linnean Society, January 16.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Stages of soil denudation and forest destruction in the Tyrol: A. P. **Young.** Slides were shown from photographs taken in two valleys, one north of the Brenner Pass, the Navistal, near Innsbruck, and one south of the pass, the Schaldarertal, near Brixen, illustrating various limits, commencing near the upper limit of the vine cultivation at about 700 metres to the snow limit at about 2800 metres. Great waste of soil is caused in forest land by the simultaneous felling of trees over single plots of ground, and in the higher levels by the encroachments of grazing animals. One effect of this waste is the recession, not only of the tree line, but also of the limit of continuous forests, which is generally considered as distinct from the tree line.—Notes on Brassica crosses: A. W. **Sutton.** The origin of some of the cultivated forms of Brassicas has been very obscure, and this has led to much confusion in their classification. It has naturally been supposed that by careful study of those types which intercross with one another, and of those which refuse to intercross, some light might be thrown upon the origin of many Brassicas which to-day form so important a portion of the plants used in agriculture and horticulture. Consequently, experiments were undertaken to investigate the tendency or otherwise to intercross. Various accepted forms of *Brassica oleracea* (such as kale, cabbage, savoy, and Brussels sprouts) were planted side by side and allowed to flower and seed. *Result*:—A large collection of nondescript plants, some of which, after selection, have been practically fixed as new and useful types. Some of the generally accepted types of *Brassica oleracea* were arranged in "sets" together with types of *Brassica campestris*, *B. rapa*, and *B. napus*, that is to say, swedes with rapes, cabbages with turnips, &c., and these were allowed to bloom in juxtaposition. *Result*:—Many hybrid plants resulted from certain "sets" where natural cross-fertilisation took place, and in other cases the pure parental types were reproduced when no cross-fertilisation occurred. The results were quite in accordance with what experience led the author to expect. As in the preceding experiments several types had been seeded together, the experiments were repeated under carefully controlled conditions in order to find by artificial cross-fertilisation to which of the types the resulting hybrid forms were due. Artificial crosses (about eighty-six) were attempted between many of the different types of Brassicas. As was expected, many attempted crosses failed to produce hybrid forms, no seed being developed, probably showing that in these cases crossing was impossible. Other crosses gave seeds, in some cases these being well developed, but in others small and immature. These seeds when sown produced intermediate or hybrid plants quite unlike the parental forms, thus showing that cross-fertilisation was possible and had occurred, confirming experience gained in the practical work of seed-growing.—Revision of the genus Illigera, Blume: S. T. **Dunn.**

Chemical Society, January 16.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—Colour and constitution of azo-compounds, part ii., the salts of *p*-hydroxyazo-compounds with mineral acids: J. J. **Fox** and J. T. **Hewitt.** The authors accept Tuck's statement that benzeneazonaphthol and its ethyl ether are similar in structure, but not his hypothesis that this structure is of the azo type. They also regard Baker's attempt to formulate these compounds as carbonium salts as unsatisfactory, since it would involve an assumption that *p*-bromobenzeneazophenol hydrochloride is identical with *p*-chlorobenzeneazophenol hydrobromide, and they suggest, instead of the formulæ hitherto proposed, the constitution of oxonium salts for these substances thus, $NHPh.N:C_6H_4:O(H$ or $Et)Cl$.—A new method of determining vapour densities, part i.: P. **Blackman.**—Studies in the camphane series, part xxv., action of diazomethane on the two modifications of *iso*nitrosocamphor: M. O. **Forster** and H. **Holmes.** Diazomethane produces with the stable *iso*-nitrosocamphor the N-methyl ether, whilst with the unstable modification isomerisation to the stable variety only takes place.—The oxidation of aromatic hydrazines by metallic oxides, permanganates, and chromates: F. D. **Chattaway.** Experiments on the oxidation of a number of hydrazines have afforded evidence of the correctness of the view already put forward by the author that an unstable hydroxyhydrazine is first produced, which, in presence of alkalis, breaks down into the hydrocarbon, nitrogen, and water.—Studies in fermentation, part ii., the mechanism of alcoholic fermentation: A. **Slator.** A number of conclusions are drawn as to the relative velocities with which the four principal hexoses are fermented by living yeast, and it is shown that the results can be explained on the assumption that the reaction, which mainly controls the velocity of fermentation, is the decomposition of a stable compound between the enzyme and the sugar. Yeast appears to contain *glucozymase*, fermenting dextrose and levulose; *galactozymase*, fermenting galactose; and *mannozymase*, fermenting mannose.—Organic derivatives of silicon, part iv., the sulphonation of benzylethylpropylsilicyl oxide and of benzylethyldipropyl silicane: H. **Marsden** and F. S. **Kipping.** The authors have prepared benzylethylpropylsilicyl oxide, and find that on sulphonation it furnishes a sulphonic acid identical with that previously resolved into optical isomerides, so that there can now be no doubt as to the constitution of this substance.—The formation and reactions of imino-compounds, part vi., the formation of derivatives of hydrindine from *o*-phenylenediacetonitrile: C. W. **Moore** and J. F. **Thorpe.**—Valency: J. A. N. **Friend.**—The esterification constants of the normal fatty acids: J. J. **Sudborough** and J. M. **Gittings.** The value $E^{15°}_{MeOH}$ for formic acid is 1124, acetic 104, propionic 92, and from butyric to stearic varies from 50 to 54.—The anomalous behaviour of the hydrogen electrode in solutions of lead salts and the existence of univalent lead ions in aqueous solutions: H. G. **Denham** and A. J. **Allmand.**—Amphoteric metallic hydroxides, part i.: J. K. **Wood.**—The use of pyridine bases as hydrogen carriers: W. E. **Cross** and J. B. **Cohen.** It is shown that pyridine facilitates the chlorination of benzene and toluene, and the bromination of the same hydrocarbons and of chlorotoluene and naphthalene.—Decomposition of hyponitrous acid: E. **Divers.**

EDINBURGH.

Royal Society, January 20.—Prof. J. C. Ewart, F.R.S., vice-president, in the chair.—The arterial pressure in man, i., methods: Dr. G. A. **Gibson.** A brief historic sketch of the methods used and instruments devised to measure the arterial pressure was followed by a demonstration of Dr. Gibson's own improved form of sphygmomanometer. The records of the pulsations were obtained in the usual way by pointers moving over a smoked surface rolled round a slowly rotating vertical cylinder. To estimate the pressure, the method introduced by Riva-Rocci was adopted. It consisted in compressing the brachial artery above the elbow until the radial artery ceased to beat. The compression bag was connected by flexible tubes with a mercury manometer, the pressure value of which was indicated by a float to which one of the recording pointers was attached. The radial pulsation was recorded by a transmission sphygmograph. As the pressure on the radial artery was gradually diminished by opening the valve the oscillations of the mercury began to increase in amplitude, and at a certain point the radial pulsations began to show themselves. The pressure in the mercury manometer, as given by the height of the record above the abscissa at the instant when the radial sphygmograph began to show distinct oscillations, was the measure of the systolic pressure. The gradual diminution in average pressure of the compressing bag as measured by the manometer was accompanied by an increase in amplitude of the oscillation until a certain average pressure was reached, followed by a decrease until the pressure was the ordinary atmospheric pressure. The lowest point of the maximum oscillation was taken to be the diastolic pressure. The two simultaneous records thus obtained gave all the data at a glance. Interesting examples of records were shown bearing upon various diseases and abnormalities.—Seismic radiations, ii.: Dr. C. G. **Knott.** On the assumption of a particular law of variation of the speed of propagation of elastic waves with distance from the earth's centre, the forms of the rays and the times of propagation along them were calculated and compared with the results of observation. The conclusion was that the observed facts of the transmission of the preliminary tremors could be co-ordinated on the assumption that throughout all but a comparatively thin crust of the earth the elastic waves of highest speed were transmitted with a speed of 12·23 km. per second, and that within this crust, of thickness equal to one-tenth the radius, the speed increased from the value 6 km. per second at the surface to the value 12·23 at the depth one-tenth of the radius. The second phase of the preliminary tremors was similarly transmitted, but with speed less than that of the first phase in the ratio of 18 to 31·3. The hypothesis that the two phases represented the compressional and distortional waves led to the conclusion that the interior of the earth satisfied the uni-constant elastic theory associated with the names of Navier and Poisson. The curving of the rays within the crust of variable speed of propagation led to a concentration of the energy towards the immediate neighbourhood of the epicentre, a result which had important bearings upon the interpretation of seismograms from distant stations.

PARIS.

Academy of Sciences, January 27.—M. Henri Becquerel in the chair.—The emission spectra of varieties of fluor-spar: Henri **Becquerel.** The peculiarities recently pointed out by A. Dufour in the spectra of fluor-spar as regards the Zeeman effect are probably due to the presence of rare earths in the spar.—Concerning a hitherto unknown fragment of the "Opus tertium" of Roger Bacon: P. **Duhem.** This manuscript, No. 10,264 in the Bibliothèque nationale, is headed "Liber tertius Alpetragii." M. Duhem surmises that it is really a portion of the "Opus tertium" of Roger Bacon, and points out that it indicates a clear knowledge of the composition and explosive power of gunpowder before the middle of the thirteenth century.—The geological history and phylogeny of the Anthracotherideæ: Charles **Depéret.**—A class of surfaces: M. **Tzitzéica.**—The equation $\frac{\partial^2 z}{\partial x^2} - \frac{\partial z}{\partial y} = 0$: Eugenio Elia **Levi.**—The definition of the area of a portion of a curved surface: E. **Cartan.** The author points out that his note of December 30 last on this subject has been anticipated by M. Schwarz.—The theory of thin bodies: Eugène and François **Cosserat.**—The action of the X-rays on the photographic plate: M. **Chanoz.** These experimental results show a parallelism between the successive aspects presented for increasing irradiation by radiographic and photographic negatives. It furnishes an argument in favour of the luminous nature of the X-rays.—The abnormal mobility of the ions of some rare earths: Jules **Roux.** With the exception of the samarium ion, the mobility of which is of the order of the usual monovalent ions, the mobilities of the other earths studied (lanthanum, yttrium, cerium, and gadolinium) are greater than those of monovalent and divalent ions. This difference may be of use in the separation of these metals, pointing to a possibility of effecting their separation by diffusion or by electrolysis.—The radio-activity of the waters at Plombières: André **Brochet.** These researches confirm a point already established, that, contrary to a view very commonly expressed, there is no relation between the radio-activity of a water and its temperature.—The dissociation by water of the double chlorides of dimercuriammonium and ammonium: H. **Gaudechon.** The compounds

$$NHg_2Cl.NH_4Cl, \quad NHg_2Cl.3NH_4Cl,$$

in presence of water at the ordinary temperature behave as true double salts. The establishment of the constitutional formula of fenone: L. **Bouveault** and M. **Levallois.** The authors regard their experimental work as definitely eliminating the formula suggested by Wallach, and giving great probability to that of Semmler.—The essence of *Magnolia kobus*: Eug. **Charabot** and G. **Laloue.** This essence consists chiefly of citral (15 per cent.) and anethol.—The volcano of Siroua, Moroccan Anti-Atlas: Louis **Gentil.**—Researches on the pulp called Netté flour: A. **Goris** and L. **Crété.** The name flour applied to this substance, which is obtained from the fruit of *Parkia biglobosa*, is a misnomer, as it contains no starch. It is rich in fatty matter, phosphates, and sugar (saccharose). As regards the latter, it contains about 25 per cent. of saccharose and 20 per cent. of glucose and levulose, and surpasses either the sugar beet or sugar cane.—The erythrolytic function of the spleen in fishes: Richard **Blumenthal.** In fish the spleen appears to be normally the place where the red corpuscles of the blood are destroyed.—Modifications of the blood caused by the injection of atropine or of peptone: MM. **Doyen** and Cl. **Gautier.**—Bovine bacilliform piroplasmosis observed in the neighbourhood of Algiers: H. **Soulié** and G. **Roig.**—An attempt at grafting articular tissues: Henri **Judet.** These experiments were made on rabbits, dogs, and cats, and show that it is possible to repair a loss of articular cartilage by the transplantation of fragments arising either from the costal cartilages of the same animal or the articular cartilages of an animal of closely allied species.—The nature of the urns of the Siphuncles: J. **Kunstler.**—*Bacillus endothrix*, a new bacterial parasite of the hair: Fernand **Guéguen.**—A Laboulbeniacieæ, *Trenomyces histophtorus*, an endoparasite of the lice (*Menopon pallidum* and *Goniocotes abdominalis*) of the domestic fowl: Édouard **Chalton** and François **Picard.**—The middle Lias in the Seybouse basin (Algeria): J. Dareste **de la Chavanne.**—A neotype of *Pinus* (*Pseudostrobus*) *Defrancei* in the Lutetian of the Trocadero (Paris): Paul **Combes,** jun.—Characteristics of the foliar trace in genera Gyropteris and Tubicaulis: Paul **Bertrand.**

IS MARS HABITABLE?

Is Mars Habitable? A Critical Examination of Prof. Lowell's Book, "Mars and its Canals," with an Alternative Explanation. By Dr. Alfred Russel Wallace, F.R.S. Pp. xii+110. (London: Macmillan and Co., Ltd., 1907.) Price 2s. 6d.

IN the year 1903 Dr. Wallace published an interesting and fascinating volume entitled "Man's Place in the Universe," a book which created quite a large perturbation in the thinking world. In it he marshalled together a great number of lines of astronomical research, pointed out the deductions which had generally been made from them, and by weaving them together in a masterly way, drew some very definite conclusions from them.

These conclusions he "claimed to have shown to have enormous probabilities in their favour," and two of them, which need only here be mentioned, were as follows:—

(1) That no other planet in the solar system than our earth is inhabited or habitable.

(2) That the probabilities are almost as great against any other sun possessing inhabited planets.

Not only, then, was a wet blanket thrown over many of our favourite dreams relating to the probable doings of living creatures in other worlds, but quite a shock was received when our near neighbour Mars was ruled out of court and declared to be uninhabitable!

We had all become accustomed to regard the changes of hue on the planet's surface as due to the varying tints of waxing and waning vegetable growth. We pictured to ourselves the great ice caps melting away under the heat rays of the approaching summer sun. The gemination of the canals and the later duplication of some of them were the means of making the best use of the water after its release from the poles, and the oases served as distributing centres. These and many other variations of absorbing interest all tended to indicate a world of change, very different from the serenity on, let us say, the moon, but more approximating to those of the earth when seen from afar.

If we are to take the view of the writer of this book, such changes must be looked on rather as signs of death than of life, since water, he says, there is none.

During the last decade or more the planet Mars has received a considerable amount of attention. By the energetic, persevering, and painstaking astronomer Prof. Lowell, every portion of the planet's surface has been under close observation, and the surface features have been chronicled on nearly every occasion when favourable opportunities presented themselves.

It is not too much to say that just as the name of Schiaparelli is now, and will always be, identified with the planet Mars, so will that of Lowell be handed down to posterity for his magnificent consecutive series of observations.

In the year 1905 Prof. Lowell published a very valuable volume describing in great detail, and copiously illustrated with sketches and charts, the observations made by him at the oppositions of 1894, 1896, 1898, 1901, and 1903.

In 1906 he published a volume which was intentionally devoid of technicalities. This was meant to contain a summary of the main results, derived from the discussion of all the data, and his own deductions as to the probable cause or causes of the surface features and their changes. He was led finally to make the following statement with regard to the habitability of Mars:—"That Mars is inhabited by beings of some sort or other we may consider as certain as it is uncertain what those beings may be."

This very definite statement, made after the issue of Dr. Wallace's book to which reference above has been made, has called into being the present small volume by the same author. Although, as we read in the preface, it was commenced as a review article on Prof. Lowell's recent book, it became so extended that it was considered expedient to publish a more detailed examination of the various physical problems involved in order to give a complete presentation of the opposite view held by Prof. Lowell.

In directing attention to the contents of this book it is not proposed to enter into each point of the arguments dealt with, but it will be sufficient to refer briefly to some of them.

The first two chapters are devoted to a general survey of the observations of Mars made by early workers, concluding with those made by Prof. Lowell. With regard to the last-mentioned, the author pays a high tribute to the technical skill and persevering labour of Prof. Lowell, and, while accepting all his observations as valid, only parts company with him "as regards the startling theory of artificial production which he thinks alone adequate to explain them."

The two main topics dealt with in chapter iii. are the questions of the elaborate system of the canals and the water supply. The author takes the view that if the surface of the planet is so wonderfully smooth and level as Prof. Lowell states it to be, then the great network of straight canals could possibly have been constructed by intelligent beings for irrigation purposes. But he points out emphatically here that, if it were so smooth, then such a system would be quite unnecessary, as the water would naturally irrigate as much of the surface as it could reach. If it be admitted for a moment that the polar caps are frozen water, he joins with the late Miss Clerke in the view that the excessively scanty supply of water, coupled with the loss through evaporation, could not possibly serve the innumerable canals.

As the habitability of Mars depends on the presence of water, the question of the evidence for the presence or absence of water vapour is dealt with in chapter iv. Dr. Wallace first directs attention to the observation of the melting polar caps, and the deduction made by Prof. Lowell that this melting and re-forming affirm the presence of water vapour in the atmosphere. It will be remembered that Prof. Lowell observed blue borders on the edges of the polar caps as they melted, and he stated that "water alone could do this." The author entirely disagrees with this interpretation, "the only proof," as he says, "he gives that the caps are frozen water." He points out that for water to be blue it must be deep, and this cannot be so on Mars because its surface is so level.

He finally indicates that there are two very important pieces of evidence which point to a lack of water vapour on the Martian planet—the spectroscopic evidence, which must be taken into account, entirely negatives the view of the presence of water vapour; and Dr. Johnstone Stoney's proof that aqueous vapour cannot exist permanently there, or on any planet, unless its mass is at least a quarter that of the earth. As the mass of Mars is only one-ninth that of our earth, the planet must have parted with its water vapour many, many centuries ago.

In the next chapter the important question of the probable temperature of the planet is taken in hand, and the author shows to his own satisfaction, and probably to that of the majority of his readers, that the temperature must be far too low for the possibility of any formation of a high form of organic life. He introduces also a note stating the view on this point given previously by Prof. J. H. Poynting, who showed that unless an assumption be made that there exists some quality in the atmosphere of Mars entirely different from any found in our own, the temperature of Mars cannot be as high as the value given to it by Prof. Lowell.

The author ingeniously considers the condition of the Martian atmosphere as being intermediate between that of the earth (a dense atmosphere) and that of the moon (practically no atmosphere). He then refers to many researches on lunar radiation as regards measurements made on portions of the surface exposed and unexposed to the sun's rays. He recalls the important function of a planetary atmosphere, like that, for instance, of our own earth, in retaining and cumulating solar heat and reducing radiation into space. He finally deduces that the Martian conditions of temperature must approximate more to those of the moon than to those of the earth. Further, he lays great stress on the impossibility of the seasonal change at the Martian poles being an apparent freezing and thawing of water, and he expresses his view in the following words:—

"If the moon, even at its equator, has not its temperature raised above the freezing point of water, how can the more *distant* Mars, with its *oblique* noonday sun falling upon the snow-caps, receive heat enough, first to raise their temperatures to 32° F., and then to melt with marked rapidity the vast frozen plains of its polar regions?"

In the chapters referred to above the author has presented his views as to the extreme probability of a very low temperature and of the absence of water vapour on Mars, and consequently replies to the question "Is Mars Habitable?" in the negative.

In the remaining portion of the book he makes an alternative suggestion as to the cause or origin of the surface markings and changes recorded on the planet. Just as he stated he had to part company with Prof. Lowell when he considered the latter's deductions drawn from the discussion of his facts, so we must part company with Dr. Wallace, and disagree with his views on the peculiar, and what seems unique, origin of the planet Mars.

It may be recalled that Prof. W. H. Pickering, next to Prof. Lowell, has made the most minute study of the Martian surface details during the last decade or more. Further, he had the advantage of making his observations under practically similar climatic conditions, and, in addition, he has also closely studied the lunar features under specially fine instrumental and atmospheric conditions.

Prof. Pickering's suggested origin of the Martian canals is that they, like the rifts and streaks on the moon, are caused by volcanic action due to internal stresses set up by the cooling of the planet's heated interior. Dr. Wallace refers here to Prof. Pickering's work, and, like him, looks upon the canals and oases as the results of cooling.

In order, however, to create conditions on a planet which, when cooling, should be capable of producing an enormous network of fissures of large dimensions, and thus give a representation of the chief surface markings as seen on Mars, he suggests the following very ingenious but very questionable mode of planetary formation, rather straining even the very flexible meteoritic hypothesis.

He supposes that the planet began to be formed on the principle of the meteoritic hypothesis, but that the aggregation of the meteorites involved in the process took place so slowly that the heat generated by the bombardments was lost equally quickly by radiation. So gradual, he suggests, did this state of things occur that the planet attained its present size, minus about 50 to 100 miles of the radius, having grown to this dimension "as a solid and cold mass."

He then tells us that this cold mass, in its revolution round the sun, at a later stage of its life, passed through at each revolution a large and dense mass of meteorites. So violent were the impacts that the "inpour of the fresh matter first heated and later on liquefied the greater part of it, as well perhaps as a thin layer of the planet's original surface."

In this way the author produces a thin shell of liquid or plastic material covering a solid and cold interior, which he requires for the explanation of the surface features of Mars. At the termination of this series of annual bombardments this thin shell of heated material would rapidly cool, and, as it is superimposed on a globe of cool matter, craterlets would first be formed, and subsequently large fissures due to contraction. The fissures would have no regard for the equator, but would cross from one hemisphere to the other, as the canals are recorded to do.

The superficial tensions would render the cracks eventually very broad and deep, and where they crossed each other, holes, giving the appearance of oases, would be formed. In time, both fissures and oases would gradually crumble away at their sides, in consequence of the alternate expansion and contraction of the material, due to the presence or absence respectively of the sun's heat.

Although the author accounts for many of the other surface features and changes as recorded on the Martian disc, he is unable to suggest any satisfactory explanation of the doubling of the canals.

Enough, perhaps, has been said to indicate that in these pages we have some very original ideas on a subject of all-absorbing interest. It must nevertheless be left to the reader to form his own judgment as to the probability of the views put forward when he has carefully read the book.

We can unhesitatingly recommend this book to a very large circle of our readers, and more especially to those who have followed the previous publications relating to this subject. The last word on this difficult question has not been said yet, and the present issue will very likely re-kindle the flame.

WILLIAM J. S. LOCKYER.

AGRICULTURE IN FRANCE.

(1) *Races bovines. France—Étranger.* Pp. 426. Price 5 francs. (2) *Races chevalines.* Pp. viii + 467. Price 5 francs. By Prof. Paul Diffloth. Encyclopédie agricole. Zootechnie. (Paris: J. B. Baillière et Fils, 1908.)

IN the first of these volumes of the Encyclopedia Prof. Diffloth claims that special attention has been paid to varieties, to methods of selection and to breeding, and the author is to be congratulated on the success of his efforts. The book is a very valuable contribution to our knowledge of domesticated cattle; it treats, with commendable breadth and sufficient detail, not only of the characteristics of a great number of breeds and varieties of those breeds, but of certain of the physical conditions under which they thrive and of their geographical distribution.

Part i., which occupies thirty-four pages, begins with a short description of external features, head, body, limbs, teeth, horns, coat and colour, followed by brief notes on some of the anatomical variations which are specially marked in different races.

Part ii. fills the remainder of the book. The classification adopted by the author is based partly on Sanson's scheme of skull measurement, by which all species are divided into two main groups in accordance with the angle formed by a line drawn across the forehead at the base of the horns and a line from the base of one horn to the outer edge of the eye of the same side. When the angle so formed is a right angle, the type is recognised as brachycephalic, when it is obtuse as dolicocephalic. It is pointed out, however, that such classification is by no means a sufficient guide, and that various other external features, such as the form of the crest between the horns, the curve of the horns themselves, &c., must also be taken into account for practical purposes.

Twelve main races are recognised, and these are again subdivided into eighty-five varieties, as follows: —

(1) Low countries, with fifteen varieties; (2) German, three varieties; (3) Irish, five varieties; (4) Alpine, eight varieties; (5) Aquitaine, eight varieties; (6) Scythian, eight varieties; (7) Vendéenne, seven varieties; (8) Auvergnate, three varieties; (9) Jurassic, fourteen varieties; (10) Ibérique, six varieties; (11) Asiatic, seven varieties; (12) Scotch, represented only by the breed of that country.

Each variety is described; its origin, relation to other breeds, and the effects of crossing are discussed; its special capabilities are examined; the physical conditions of the geographical area it inhabits are generally noted, and their possible effect upon the breed is referred to.

A series of seven maps is of special interest. They are designed to show the areas over which certain races and varieties range, and in some cases their special breeding area is further distinguished. With two exceptions these maps refer to French breeds, the Dutch and Austro-Hungarian races being the only others so treated. This scheme is a most suggestive one, and if consistently carried out would be a very valuable aid both to the student and the practical breeder.

The text is full of valuable information concisely and clearly presented, especially valuable to English readers where it treats of French breeds. Besides figures in the text, many of which leave very much to be desired, there are forty plates, photogravures of selected animals.

The space at our disposal allows of only a very brief notice of the second volume. This book is equally carefully compiled, and is a valuable aid to the student, especially in relation to the natural conditions under which the various races and varieties of the horse thrive.

The author's classification scheme will not, perhaps, satisfy many authorities, but his descriptions of the characteristics of the very numerous varieties he recognises are clear and unbiased, and the figures and plates are good.

His statistics regarding the horse population of the world are no doubt open to criticism, but they cannot be questioned in relation to the conclusion he draws that the advent of the motor-car and agricultural machinery has been followed by an increase both in the numbers and value of horses. The view that Government aid is necessary for the breeding of certain classes of horses in this country receives substantial support from the author's description of the results gained by the care given and the large sums expended by his own Government for this purpose. Short chapters on the ass and the mules conclude the volume.

CHEMISTRY IN THE SEVENTEENTH CENTURY.

Medico-Physical Works of John Mayow (1674). Pp. xxiii + 331; with 6 plates. (Edinburgh: The Alembic Club, 1907.)

ALTHOUGH the name of John Mayow is well known to chemists, there are few who are acquainted with his works. Even the majority of the historians of chemistry have been content to acquire their knowledge of him at second hand, so that his discoveries and views are generally stated with more or less inaccuracy. This becomes clear on perusing the present work, a translation from the Latin of Mayow's five treatises, for which we are indebted to the Alembic Club.

The basis of Mayow's work was his recognition of the existence in the air and in common nitre of extremely subtle particles to which he gave the name "nitro-aërial spirit." He did not, however, as is often supposed, regard air as a mixture of two gases, as we do to-day, but considered the nitro-aërial particles to be "fixed in the aërial particles themselves," and to be "torn from them by the burning of a lamp or the breathing of animals." They are, in fact, "neither air itself nor some material interspersed among its particles." Whilst the generally received opinion is correct that Mayow recognised that an increase of weight occurs when metals are burnt in air, it is also true that he made but little use of this fundamentally important observation; in the main his experiments were purely qualitative, and ingenious as they often were, they served in many cases to distract the attention from the real issue. Had it been otherwise the course of chemical history might have been different.

When it is remembered that, in Mayow's time, fire and air, mercury, sulphur, and salt were regarded as the fundamental elements, the clearness and originality of his views is very striking. He substitutes his nitro-aërial spirit (which we now call oxygen) for air and fire, and considers that out of the conflict of this spirit with "sulphur" (that is, the combustible constituent of substances) "all the changes of things arise." At each step he feels his way by new experiments, as, for example, when he shows that a mouse, in breathing, diminishes the volume of air like a burning candle, or that, when put in a glass vessel along with a lamp, it will not breathe much longer than half the time it would otherwise have lived. His views on respiration are quite correct; by way of the lungs "the aërial particles enter the mass of the blood and are there deprived of their nitro-aërial particles." The latter are indeed "the principal instruments of life and motion." He scoffs at the idea of a vital flame as a source of animal heat, accounting for the latter by "the nitro-aërial particles in the blood fermenting with its saline-sulphureous particles" (or, as we should say, by the oxidation of combustible material).

It was probably unfortunate that Mayow sought to explain by the aid of his nitro-aërial spirit the most diverse phenomena, such as the elasticity of solids, the nature of light and colours, of lightning and the transmission of nerve impulses, for in so doing the more important facts established were obscured in a haze of speculation which Mayow's early death prevented him from dispelling; thus it happened that exactly a century had to elapse before the work of Scheele, Priestley, and Lavoisier led to a re-discovery of principles already clearly enunciated as early as 1674.

W. A. D.

TOWN GAS.

Town Gas and its Uses for the Production of Light, Heat and Motive Power. By W. H. Y. Webber. Pp. vii+275. (London: A. Constable and Co., Ltd., 1907.) Price 6*s*. net.

THE opening lines to the preface of this book supply the keynote to all that follows—"This book is a summary of what I know, that appears to me to be likely to interest a generally well-informed but not technically instructed reader about the manufacture of town gas and its uses."

The author, who was for many years the subeditor of the chief organ of the gas industry, has brought to bear his wide knowledge and ripe experience of the subject, and has given us a book that will be welcomed by all consumers of gas who desire an insight into the mysteries of its manufacture, and the best way to consume it for either heat, light, or power. The term "town gas" is used in preference to coal gas in order to cover the admixture of carburetted water gas and coal gas now so often distributed as a town supply, and which was necessitated chiefly by the demand for high candle-power gas, whilst now that the incandescent mantle has rendered rich gas not only unnecessary but wasteful, it is to be sincerely hoped in the interests of the consumer that carburetted water gas will disappear, and that only unadulterated coal gas will again become the general supply.

Excellent as is the book as a whole, there are many points that invite criticism; it was to be expected that the author would be an ardent champion of the virtues of coal gas, but surely when (pp. 175, 176) he is comparing the relative cost of coal and gas as a fuel for domestic use, and debits the cost of coal with a servant's wages and keep at 4*l*. a month, so bringing the cost of the coal as a fuel to 5*l*. 15*s*. a ton, he is going too far, and is more likely to do his cause harm than good. Burnt in properly constructed gas stoves, so arranged that none of the products of combustion find their way into the air of the room, coal gas is an ideal fuel, and, taking into consideration the cleanliness, saving in labour, convenience, and the fact that it need only be used when wanted, it can be shown to be equal in cost at 2*s*. 6*d*. per 1000 cubic feet to coal at 24*s*. per ton, but beyond this its most ardent advocate would scarcely venture to go.

Again, in speaking of the smoke curse and its prevention, he says (p. 227), "Gas is the sole practicable cure for this crying evil"—a statement which would not be endorsed by the advocates of smokeless fuels, such an anthracite, coke, coalite, or its imitations.

Some small inaccuracies might with advantage be corrected in a future edition; for instance, no gas manager would be inclined to accept as an average example of the normal supply to "the British Metropolitan region" a gas containing 15·52 per cent. of carbon monoxide, 1·5 per cent. of carbon dioxide, and 5·31 per cent. of nitrogen (p. 5).

On p. 69 the author speaks of blue water gas being made by the "methane-hydrogen plant"; this form of apparatus, however, should be deleted from amongst the "blue" gas plants, as its value is dependent upon its producing a gaseous mixture in which methane plays an important part.

The chapters upon gas lighting and the arrangement of light for indoor and outdoor illumination are excellent, whilst the chapter upon the legal relations of gas suppliers, consumers, and the public should prove of the greatest value to those who desire to gain an insight into the intricacies of gas legislature.

OUR BOOK SHELF.

The Canterbury Puzzles and other Curious Problems. By H. E. Dudeney. Pp. xxiii+195. (London: W. Heinemann, 1907.) Price 3s. 6d.

The author of this little book is a well-known expert in the invention and solution of puzzles. Those which he presents to the reader are in the main entirely original; those which are not so are given in a new dress. Puzzles can be made, as the author says, out of almost any materials, and most people are familiar with specimens made out of matches, cards, coins, &c. Generally speaking, they are in essence either of an arithmetical or geometrical character, and involve, consciously or unconsciously, mathematical processes. An inferior class it is difficult to deal with except by some tentative process which involves no clear line of reasoning; such, for instance, are certain dissection problems which are of the nature of "patience," and are not good exercises for the intellect. Mr. Dudeney may be congratulated on having excluded these from his book.

It is no easy matter to invent a good puzzle; the simplest method would be to modify or generalise a known one; a really new idea is not likely to come from anyone who has not considerable knowledge and power of observation. The author gives shortly the solutions of the puzzles without, in the large majority of cases, explaining them. He recognises that the non-scientific solver is generally satisfied with knowing the solution, and is not curious about reasons; at the same time, he has known how to whet the appetite of more intelligent and curious persons for a knowledge of the principles which underlie the solutions. As an example may be noted the puzzle called "Lady Isabel's Casket." The square top of a box was inlaid with a rectangular strip of gold 10 inches by ¼ inch, and for the rest with square pieces of wood, no two of which were of the same size. The puzzle is to find out the size of the top of the box from these data. In his solution of this difficult question, Mr. Dudeney gives you the pattern, and states that the number, size, and order of the squares can be calculated direct from the given dimensions of the strip of gold, and that there is only one possible solution. He then leaves the mathematical reader with an interesting if difficult nut to crack.

The book is written in a popular manner, and is copiously illustrated so as to impart as much human interest as possible into the various questions. The puzzles are of great variety, and will be found interesting and alluring to persons of all kinds.

Matter and Intellect: A Reconciliation of Science and the Bible. By Andrew Allan. Pp. vi+224. (London: A. Owen and Co., n.d.) Price 5s.

This book has value from one point of view only; it is a series of unscientific statements of the very first water. "Now if we suppose that the oceans of the earth are represented by the bright sides of the discs of the radiometer, and the continents by the dark sides, we can understand how the sun attracts the water and repels the land, thus causing the earth to rotate upon its axis." Even Mr. Allan's more specific attempts to "reconcile Science and the Bible" will provide the average reader with amusement more often than they will scandalise him. "The serpent which tempted Eve was probably a dinosaurian, and may possibly have been the Iguanodon, a reptile which 'must have walked temporarily or permanently upon its hind legs,' thus presenting a human appearance, to which its magnificent skin or robe of feathers would add considerable beauty. Eve, therefore, seeing this human-like animal eating of the tree, and suffering no harm, would readily forget the prohibition, and be tempted to try the fruit for herself without any actual speech passing between the two."

Only one serious comment suggests itself when one's capacity for laughter is exhausted. This extraordinary work comes from a writer who has ability enough often to express himself clearly and forcibly, and quotes constantly from the pages of our more august popularisers of science. The schoolmaster admits at least a partial responsibility for the examination blunder. Is the blame here to be thrown entirely upon the pupil?

Leçons sur la Viscosité des Liquides et des Gaz. By Marcel Brillouin. Part i., Generalités. Viscosité des Liquides. Pp. vii+228. Part ii., Viscosité des Gaz. Caractères généraux des Théories moléculaires. Pp. 141. (Paris: Gauthier-Villars, 1907.) Price 9 francs and 5 francs.

Both the mathematical and experimental study of viscosity are admittedly of a high order of difficulty, and the author is to be congratulated on the clear and concise manner in which he has developed his subject. After summarising in the first chapter the early work on viscosity, the mathematical treatment of the subject is fully developed in the following four chapters. The second part of the first volume is devoted to a description of experimental work. Each of the principal memoirs is described and subjected to a careful criticism; this part of the book is very complete, and is absolutely free from the tendency to ignore work done outside France occasionally met with in French standard works.

In the second part the theoretical and experimental study are taken together, the relations between the viscosity and the dynamical theory of gases being fully discussed. The concluding chapters contain a general discussion of the molecular theories of liquids and gases.

The work as a whole is characterised by clear exposition, acuteness and fairness of criticism, and completeness. It will doubtless take its place as the standard work on viscosity.

Aphorisms and Reflections. From the works of T. H. Huxley; selected by Henrietta A. Huxley. Pp. vii+200. (London: Macmillan and Co., Ltd., 1907.) Price 2s. 6d. net.

To quote one of these aphorisms, "Time, whose tooth gnaws away everything else, is powerless against truth." There is garnered in Huxley's works so much truth worth wide dissemination that we echo heartily Mrs. Huxley's wish that this book will attract the attention of many persons who are yet unacquainted with her husband's writings. We trust also that this attractive volume, which can be carried in the pocket, will serve to make men of science and students turn oftener to the complete works of this master of lucid expression, who proved conclusively by his essays that it is possible to describe scientific achievements in a manner which will appeal to earnest readers of all classes.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Inheritance of "Acquired" Characters.

DR. BASTIAN is unaccountably mistaken. Nothing in my letter indicates that I "assume (in the face of multitudinous difficulties) that the germ cells of all human beings are potentially alike." I have no doubt that germ cells differ, and therefore that the individuals which arise from them would vary even were they reared under absolutely identical conditions. These germinal differences between individuals and species are rightly termed innate. Individuals differ also because they are exposed to unlike influences during development. These differences, due to the unequal play of stimuli, are rightly termed acquired. But in my letter I did not allude to differences between individuals, nor even to acquired differences between one side of the body and the other. I merely discussed the question whether the terms "innate" and "acquired" correctly distinguished between certain *classes* of characters. I gave reasons for believing that a nose is no more innate and inheritable than a scar on it. If Dr. Bastian thinks I am in error, will he indicate in what sense the scar is less inborn and more acquired than the nose?

Often we are able to express our meanings very well by inaccurate terms the use of which has been sanctioned by convention. If, then, by "innate" and "inheritable" we merely imply characters which arise under the stimulus of nutriment no great harm is done. But, unfortunately, the words are usually given their literal meanings. The nose is supposed to be more rooted in the germ-plasm, more a product of evolution, more truly inborn than the scar; use acquirements are treated as trivial accidents unworthy the attention of the student of evolution; as a result, a very important phase of evolution is obscured and the study of it neglected. Dr. Bastian treats as absurd the belief that the bulk of human development after birth is an "acquirement." But, suppose we supplied an infant with sufficient nutriment but denied its body the stimulus of use and its mind the stimulus of experience, what sort of physical and mental maturity would the individual achieve? Would he develop nearly as well as the fœtus in the uterus or the butterfly in the chrysalis? How many of his physical and mental parts would attain even the stage of development reached in a little child? Apart, however, from the precise degree in which the human being develops under the influence of use and experience, the points I wish to urge are:—(1) that a principal phase of the evolution of the higher animals is the evolution of a power of responding by growth to these stimuli; (2) that the characters which thus arise are in some species (*e.g.* man) of great magnitude; and (3) that they are just as much a part of "normal" development as the inborn traits. Variation renders a species adaptable. But the power of developing under the stimulus of experience confers adaptability on the individual as well. In his very interesting letter, Mr. A. Bacot refers to the "repertoire" patterns of "the peppered moth" (NATURE, January 30). Consider how many repertoire patterns are possessed by the human being, whom the environment may train to play the part of an acrobat or a clerk, a beggar or a king.

Dr. Bastian insists that "post-natal growth is essentially due to the same causes as pre-natal growth." His words sound well, but what do they imply in this connection—that use plays nearly as important a part in prenatal as in post-natal development?

He declares that the memories of Chinese and Mohammedan children are exceptionally good, and accounts for this circumstance by the hypothesis that the memory (the *faculty* of learning as distinguished from the things that are learnt which are only the *contents* of the memory) grows in the individual with use, and that this acquirement is transmitted. Animals which are not protected and trained by their parents have little or no memory. It would be of small use to them, for they must begin life fully equipped for the struggle by instinct. But in proportion as they are protected and trained, they are mentally immature on entrance into the world. The function of parental protection is to afford time and opportunity to make the acquirements without which they cannot attain maturity, and which in them in some measure take the place of instincts. The helplessness of the human being at birth, and the prolonged training necessary before he is able to maintain independent existence, is connected with the magnitude of his memory and the acquirements he makes by means of it. Now what is the evidence that memory (the faculty, not the contents) grows with use? So far as I am able to judge, memory, like the homologous power of growing physically, is greatest just when it is most useful—in the little child who has to equip himself with absolutely essential acquirements, and who, starting from a position of blank ignorance and incapacity, in a few months reduces the chaos of his world to order, and within two years even learns to walk and speak a language, as well as a vast deal more. Has Dr. Bastian any evidence that Chinese and Mohammedan adults are able to learn chapters of the Bible and the Koran more readily than their children? If, then, as seems probable, memory does not grow with use, how can the transmission of acquirements cause an increase of this faculty in a race?

Southsea, February 9. G. ARCHDALL REID.

MR. BACOT'S interesting letter (p. 294) on melanism in moths suggests that the moth I had seen in Yorkshire (though I knew it appeared elsewhere) has a "repertoire" of colours as an actor has a repertoire of plays, and each moth in his time plays many parts. But the actor learnt them all, and the moth apparently inherits them all, the result being the same, since each possesses them all, and according to environment each appears occasionally "in yellow stockings and cross-gartered," or "in customary suits of solemn black," so that while the actor's knowledge of Hamlet dies with him, the moth's repertoire is perpetuated by an ineradicable involution. The question that lies behind all this does not seem to be answered by reference to the operation of evolution in a "previous epoch," for evolution begs the question. If we say that evolution in the past packed the "germ plasm" with possibilities, and evolution in the present only unpacks here and there one as it is required, we seem to be illogical in the use of any argument founded upon such an uncertain term, for the evolution of an actor and the evolution of a moth are two totally and impossibly different things, yet the stimulus of environment produces the same results.

If we believe that the racial moth has plastic possibilities he may start with whatever form or colour you like, and he will, when it is good for him, become "peppered," and will continue peppered until it is bad for him, when he will become black or otherwise. But if he has to carry a whole load of inherent characters all the time, where, when, and how did his germ plasm "acquire" them? Is what was possible in the past impossible now? And, further, does not the geological statute of limitations forbid the possibility of "cramming" every plant and animal with all these inherent characters during the short time that most species exist?

Dr. Archdall Reid in his most thoughtful letter sends a breath of delightfully fresh air into the subject, for he suggests that, after all, the arguments on both sides of this fascinating subject are not about facts, but words, and suggests (p. 293) that "confusion, misunderstanding, and futile controversy" are due in this matter to the "use of inaccurate terms." The idea of his letter suggests the possibility of a complete explanation of this puzzling question.

If natural selection operated in the past by the slow development of racial possibilities until a fixed type was reached, and if "recapitulation" is established, the "adult" form at any stage short of the last must have had, like the imperfect individual, the power of somehow acquiring characters that it then passed on to its descendants; and if this be so it is difficult to believe that acquired characters are no longer transmitted, for in that case no new type can possibly arise, and every plant and animal in the world is an "end group," which is utterly inconceivable from the evolutionary hypothesis.

Sunlight is pure and colourless. Under the stimulus of a prism it becomes red, yellow, and blue. If animal form and colour are no more than the prismatic separation of inherent characters preexisting in the germ plasm, it seems to me that the theory of "Darwinian" evolution falls to the ground, and that it is not logical to use arguments founded on that hypothesis to establish conclusions that are fatal to its existence; but I write with a certain trepidation, remembering the fate of the earthenware pipkin that ventured into the stream amongst the iron pots.

E. C. Spicer.

Waterstock, Oxford, February 1.

The slightly dogmatic tone of my original article (January 2, p. 193) under the above heading has called forth quite a number of confessions of failure to understand the modern attitude towards this question. But, though we admire the generous spirit of those who have come forward and made a public exhibition of this failure, we consider that we have contributed our fair share by enticing them out into the open, and that they are asking too much when they try to relieve their very natural embarrassment by appealing to us to tell them what the modern attitude really is.

Ideally, of course, those who by inclination or accident are in touch with recent thought on these subjects ought to be only too glad to impart what they know to others less fortunate—to the aged and to the remote. But practically it cannot be done. The Editor of Nature would say, perfectly rightly, that the correspondence column of his journal was not the place for enlightening those who fail to keep abreast of modern biological thought.

Dr. Archdall Reid's statement of the real nature of the problem is not a final one of course (as he probably thinks it is), but it is undoubtedly an improvement on the chestnut-old one which asserts that acquired characters are inherited as well as innate ones—a statement which is meaningless, because all characters are both acquired and innate.

If Dr. Bastian and Mr. Spicer have read that part of Dr. Reid's book, "The Principles of Heredity," which deals with this subject, their letters show that they have been unable to understand it. If they have not, it does not seem to us to be profitable to discuss the matter until they have.

Atmospheric Electricity and Fog.

In view of the interest recently shown in the subject of the dispersion or prevention of fog, it may be opportune to direct attention to a recent remarkable example of an atmospheric electricity phenomenon which usually accompanies London fogs. I should first explain that the method adopted at Kew for determining the absolute value of the potential gradient—*i.e.* the increase in the voltage per metre of height above the ground—certainly does not err in the direction of overestimating it. Taking eight years, 1898 to 1904, I found in a recent paper[1] that the mean value of the potential gradient at Kew was 159, the mean value for January being 201. The phenomenon referred to above is the occurrence during fog of specially high positive potentials, values double or treble that appropriate to the season being not unusual. At such times, however, there are usually large and frequent oscillations in the value of the gradient, so that the maintenance of an exceptionally high value for a number of consecutive hours is comparatively rare. On the morning, however, of January 21, during an intensely thick fog, the potential gradient at Kew exceeded 730 *continuously* from 1 to 9.30 a.m. How much it may have exceeded this value it is impossible to say, as the trace was beyond the limits of registration during the whole of this time. Both before the trace left the sheet and after its return the oscillations in the potential gradient were large, so that the maximum value was probably at least 1000.

A question of practical interest is whether the steepness of the potential gradient near the ground during fogs serves, or may be made to serve, a useful purpose in helping to clear the atmosphere of dust and smoke. It would also be interesting to know whether these high potentials are wholly without physiological effects on the human body.

The Penetrating Radiation.

Many writers apparently assume that the penetrating radiation is due to γ-like rays coming from radio-active products in the ground, and is practically constant in amount. It seems probable, however, that the penetrating radiation comes largely from radio-active products in the air, and that it fluctuates greatly in value.

Taking the mean value found by Strutt and Eve for the radium content of sedimentary rocks as $0{\cdot}9(10)^{-12}$ grams of radium per gram of rock, one finds that it is the source of γ radiation which would produce an ionisation on the surface of the ground in air of less than 0·8 ion per c.c. per sec. Now the above value for the radium content is perhaps large for surface soils subject to constant erosion. The actual value found by Cooke for the ionisation in air as due to the penetrating radiation was 4·5 ions per c.c. per sec. McClennan takes the value as 9, and the writer has found a much larger value in the open country during the warm hours of the day. Assuming that the emanation of the radium differs from a depth of 50 cm. or 60 cm. of the ground, one gets a penetrating radiation that will produce a much greater ionisation.

If the penetrating radiation is due to radio-active products in the air, one would expect that it would vary very greatly in amount. The experiments of Jaffe, Campbell, Wood, Borgmann, the writer, and others would indicate this. On the other hand, if the penetrating radiation comes from radio-active products in the ground, its amount should be quite constant. Dike has found that the active deposit which gathers on a charged wire exposed to the air varies greatly with the time of day. Eve, by his charcoal method, has found widely different amounts of the radium emanation in the air at different times. The writer (*Science*, July 12, 1907) has found that during a heavy rain or snow the penetrating radiation decreases very greatly in amount. Rain and snow have been shown to carry down radio-active products, and if the penetrating radiation is due to radio-active products in the air, then its value should be less during a heavy rain or snow.

If the penetrating radiation is due largely to radio-active products in the air, its value in underground cavities should be less than on the surface of the ground. This is what Elster and Geitel found. The writer has found the ionisation in a closed electroscope to be approximately the same (*a*) in a cave; (*b*) in a cistern where there was 4 feet of water on all sides of the electroscope; and (*c*) inside a screen of lead and cast-iron blocks. In the open country during August and September (1907) this same electroscope showed an ionisation during the day some three or four times greater than during the night. In the cave and cistern the ionisation during the day and night was the same. It is natural to suppose that the penetrating radiation was greater during the day, and was due to radio-active products which had diffused out from the ground. During the night the ionisation was not much greater than for the electroscope in the cave or cistern.

Johns Hopkins University. W. W. Strong.

Classification of Secondary X-Radiators.

The relation between the character of secondary X-radiation emitted by elements when subject to the same beam of X-rays and the atomic weight of the radiating substance has been considered in various papers, but only brief reference has been made to the dependence of the character of the secondary on that of the primary radiation. We have recently made a more systematic study of the relation between the secondary and primary rays.

Although the behaviour of no two substances is exactly the same under the same conditions, yet substances may conveniently be divided into several groups, each consisting of elements which emit a radiation possessing many properties characteristic of that group.

H–S Group.—The elements of this group when subject to a very soft X-radiation emit an almost perfectly scattered radiation of intensity proportional to the mass of radiating substance traversed by a beam of definite intensity.

This conclusion has been based on observations of absorbability, ionising power, polarisation, and distribution of intensity of the secondary rays.

With a moderately penetrating primary the scattering becomes less perfect—as shown by the above tests—and with a very penetrating primary beam there is considerable difference in character between the secondary and primary rays. This is not due to a superposition of a second radiation on the purely scattered; the purely scattered disappears, and in its place is a radiation more absorbable than the primary producing it, one which is less completely polarised, possesses greater ionising power, and is distributed in a way which exhibits less perfect control of the primary pulses over the radiating electrons.

Cr–Zn Group.—A striking characteristic of this group is the enormous ionisation produced by the secondary beams—of the order of 100 times that produced by an equal mass of one of the (H–S) group. This radiation, though produced by a heterogeneous primary, consists almost entirely of homogeneous rays of a very absorbable type. For certain primary beams there appears to be a more or less perfectly scattered radiation (producing 1 per cent. or 2 per cent. of the total ionisation) mixed with this.

Some remarkable properties of these homogeneous radiations have been referred to in a paper published by us. Their intensity is for large ranges in the penetrating power of the primary proportional to the ionisation produced by the primary beam in a thin film of air, so that it is highly probable that the radiation is produced during the process of ionisation in the radiating substance.

This radiation has not been found to disappear with any changes we have made in the primary beam.

Ag–I Group.—This group is characterised by its sensitiveness to changes in the character of the primary rays when they are of ordinary penetrating power. Though for moderately penetrating primary beams the secondary rays are heterogeneous and do not differ in penetrating power very considerably from the primary, they do not exhibit the polarisation effect and are not distributed in the manner showing scattering as exhibited by rays from the H–S group. These rays are not superposed on a radiation which could be classified with that from the H–S group. We have recently found, however, that some of the group (if not all) may be reduced to order by using a very easily absorbed primary. In this case there appears by every test made to be almost perfect scattering. The intensity, however, appears to be several times as great as that from an equal mass of a substance in the H–S group.

W–Bi Group.—These substances much more closely resemble the Cr–Zn group in the intensity and constancy in character of the rays they emit. They have, however, not yet been examined carefully.

Substances with atomic weights between those in the above-mentioned groups possess some of the characteristics of the two groups between which they lie. It appears possible that similarity in behaviour of all the different groups will be discovered by great variation in the penetrating power of the primary beams—one group when subject to a certain kind of primary beam behaving as another group when subject to a primary of different penetrating power.

The above grouping has, however, been based on the behaviour when subject to beams of ordinary penetrating powers, and the generalisations hold with very few exceptions.

Auroral Characteristics of Clouds.

THE question has often been raised as to a possible connection between the aurora and the formation of clouds in the upper atmosphere. Observers in high latitudes have described cases in which, after a bright aurora, clouds have retained in some measure the forms of the previous light display. In other cases high clouds have been observed to arrange themselves in a formation very similar to the arch and streamers which are so characteristic of the aurora.

It may be of interest to those who have studied this question to record an exhibition of the latter kind which was observed here yesterday evening. During the greater part of the day the sky had been overcast with alto-stratus clouds, which, as usual, began to dissipate soon after sunset. Between ten and eleven o'clock (local time) the greater part of the sky was clear, but there remained in the south a mass of light cloud which formed an arch, from which bands spread out in all directions as if radiating from a point on the horizon under the middle of the arch. The effect was remarkably like an aurora except that there was no rapid motion of the bands or streamers. So far as I could judge from the Pole Star, the centre of the arch was due south, and its top about 5° above the horizon, but being on the river at the time in a native boat I had no means of making accurate measurements. Small masses of cloud in other parts of the sky exhibited wave lines, but they did not appear to be parallel to the main streamers, nor did the latter look like a wave formation. In about half an hour the outlines had lost their sharpness, and the whole effect became that of a light, diffuse mass of cloud.

The interest in this observation is two-fold. Those who hold that the clouds which take upon themselves the form of the aurora are due to the same causes as the aurora will be interested to know that this formation can be seen within 16° of the equator, and also that the centre of the arch appeared to be due south. Those, on the other hand, who hold that there is no connection between the two phenomena will feel their position strengthened in that an almost exact imitation of the aurora has been seen in the clouds in a region which is supposed to be almost entirely free from the aurora, thus lending support to the idea that such a formation is only one of the infinite number of possible cloud formations.

GEORGE C. SIMPSON.

Moulmein, Burma, January 13.

Reissner's Fibre in the Frog.

IN October last, at the suggestion of Prof. Dendy, I undertook an investigation into the structure known as Reissner's fibre, which, Sargent's work notwithstanding, is still regarded by many as an artifact or as a coagulum of cerebro-spinal fluid, Johnston even, in his recent work on the "Nervous System of Vertebrates," dismissing the subject with the briefest of notices.

As a more than ordinary interest attaches to the description of any hitherto unrecorded feature in such a well-known type as the frog (*R. temporaria*), I venture to direct the attention of anatomists and physiologists to the fact that this animal possesses a well-developed and easily demonstrable Reissner's fibre, although no reference to this structure can be found in Gaupp's exhaustive treatise, nor does Sargent include any Anuran form in the long list given by him of animals in which he has seen the fibre.

The whole or parts of the central nervous system of about a dozen frogs have been sectionised, the sections having been cut in the usual three planes, and the fibre has been found in all the series examined, showing very definite and constant relations to the various brain structures. In every case it may be made out, beginning anteriorly at the dorsal end of the deep and narrow ependymal groove on the anterior face of the posterior commissure, and, emerging from this groove ventral the commissure, lying freely in the iter spanning the cavity between posterior commissure and cerebellum. It is somewhat closely applied to the ventral surface of the cerebellum, but posteriorly it slopes steeply towards the floor of the fourth ventricle and continues backward, with a wavy course throughout its length, to the hind end of the spinal cord near the floor of the canal.

Beneath the posterior commissure, in one specimen at least, it may be observed dividing into two or more finer fibres, while in the posterior half of its length numerous fine fibre-like structures may be made out, apparently given off to enter the substance of the spinal cord (much as Sargent has described for other forms), but that these are truly given off by the fibre, and are not merely coagula, I have not yet been able to determine.

In transverse sections a definite sheath to the fibre can be seen, although the fibre itself is not readily made out in these sections until a certain familiarity with its course has first been obtained from an examination of sagittal sections. In the one fibre measured, the diameter was a little more than 6 μ.

I did not find in any of my preparations that the fibre curled up into the "tangle" or "snarl" as described by Sanders in Myxine, by Dendy in Geotria, and mentioned by Sargent as commonly occurring, but this may probably be attributed to the precaution that was taken in every case thoroughly to fix and harden the central nervous system before severing the spinal cord. (The brain and spinal cord of several of the smaller specimens were cut entire in sagittal sections.) In all cases the central nervous system was dissected out entire from the freshly killed animal, and, where practicable, under the actual preserving fluid. Zenker's fluid, which did not admit of this, gave less satisfactory results than Flemming's stronger fluid. The stain employed was a modification of Weigert's suggested by C. Judson Herrick.

I have compared the fibre seen in sections so prepared with that shown in sections of *Petromyzon fluviatilis* in the laboratory collection at King's College, and also with that shown in Prof. Dendy's Geotria sections, which were prepared by altogether different methods, and the comparison leaves no doubt in my mind that we have here to do with a perfectly normal structure, and one cannot but express wonder that an object so clearly defined should have for so long escaped notice in the frog.

King's College, London, February 6.

Rhynchobdella aculeata in Ceylon.

IT seems worth while to make a special note of the occurrence of the above-named food-fish in the inland waters of Ceylon. Its near ally, *Mastacembelus armatus*, has long been known to occur here. The general Ceylonese term for fishes belonging to the family Rhynchobdellidæ, commonly known as "spined" or "thorny-backed eels," though not nearly related to the true eels, is "telliya," but the natives distinguish between the "Gang-telliya" (river-telliya), which is *Mastacembelus armatus*, and the "Batakola-telliya" (alluding to the lanceolate form of the body), which is *Rhynchobdella aculeata*. The latter is reputed to grow to a length of 15 inches, and I recently examined one of 12 inches. In the former, commoner species, the vertical fins are confluent and the dorsal spines are numerous (about thirty-eight); in the second species, which has not previously been recorded from Ceylon, the dorsal and anal fins are separated from the caudal by a notch above and below; the dorsal spines are less numerous (sixteen), and the long, fleshy snout, which gives these fishes such a remarkable, antiquated appearance, is transversely ribbed below. The identification is therefore not open to doubt.

The Rhynchobdellidæ, as a family, are "excellent as food," to quote the words of the late Dr. Francis Day, and the hitherto unsuspected presence of an important member of the family in Ceylon affords an illustration of the incompleteness of knowledge concerning the biological conditions of the local inland fisheries. The batakola-telliya is stated to be absent from Malabar, a peculiarity of distribution which ranges it roughly in the same category with *Channa orientalis*, *Polyacanthus signatus*, and perhaps a few other fresh-water fishes.

ARTHUR WILLEY.

Colombo Museum, January 20.

Poseidonius on the Originator of the Theory of Atoms.

IN Strabo's "Geography," book xvi., chapter xi., § 24, in the description of Sidon, we find the following remark:—

"If we are to believe Poseidonius, the ancient opinion about atoms originated with Mochus, a native of Sidon, who lived before the Trojan times."

This tracing of the theory of atoms to an authority much more ancient than Democritus does not seem to be mentioned in any of the works on physics, but as it is from the usually accurate Strabo, and rests on the high authority of Poseidonius, it seems worthy of notice.

AGRICULTURAL AND HORTICULTURAL RESEARCH.[1]

NO better evidence can be adduced of the growing interest in agricultural education and research in this country than the support which has been given to them by the county councils of Surrey and Kent during the last few years. They have materially promoted the science of agriculture and horticulture by furnishing the necessary means for the annual publication of such valuable reports as the one which

FIG. 1.—Gooseberry shoot attacked by the American Gooseberry-mildew numerous dark scurfy patches of the spawn of the mildew can be seen on the stem.

has recently been issued from the South-eastern Agricultural College at Wye, Kent.

The report gives the results of an immense amount of painstaking investigation, and the exhaustive way in which the subjects are treated will be appreciated when it is realised that a bulky volume of 438 pages has been produced by the combined labours of the various members of the staff. The work is well written, and the different subjects are presented with pleasing freshness. Altogether we feel that it will prove a veritable mine of immensely valuable information, enhanced in no small degree by some of the most beautiful half-tone illustrations which we have yet seen in a work of this kind.

[1] University of London. "The Journal of the South-eastern Agricultural College, Wye, Kent." No. 16. Pp. ix+428. (London and Ashford, Kent: Headley Brothers, 1907.) Price 6s.; for Residents in Kent and Surrey, 3s.

Apart from the research work connected with the college, we gather that an increasing use is made of this institute "as an advisory centre on matters relating to agriculture and horticulture, so much so that in future years each department of the work of the college will have its special journal." In the section devoted to the report of the economic zoologist, Mr F. V. Theobald, no less than 119 pests are dealt with, chiefly under the following heads:—those injurious to man's domestic animals, to fruit trees, to pulse, hops, and vegetables, flowers, forest trees, food-stuffs, and those causing annoyance to man; and beside these are some replies to Extra-British inquiries. One of the more interesting portions, issued from this department, is that dealing with the habits of the woolly aphis (*Schizoneura lanigera*). The author has conclusively proved that the damage done by the root form of this pest is much more severe in this country than has been generally supposed. In view of this, Mr. Theobald attributes the failures in treatment because we have hitherto ignored the presence of the migrating ground form. An injection of carbon bisulphide is recommended for the terrestrial, and a caustic alkali wash for the arboreal form. In a short note on the habits of the house fly (*Musca domestica*), this insect is said to "have bred largely in rotting cow-dung mixed with vegetable matter." We may add, however, that in one of our largest cities, stable middens and ash-pits form the chief breeding places for this fly; anything in the form of decayed vegetable matter, such as the dung of pet animals, vegetables, or even paper, provides food for the larvæ, and more especially so where heat is engendered.

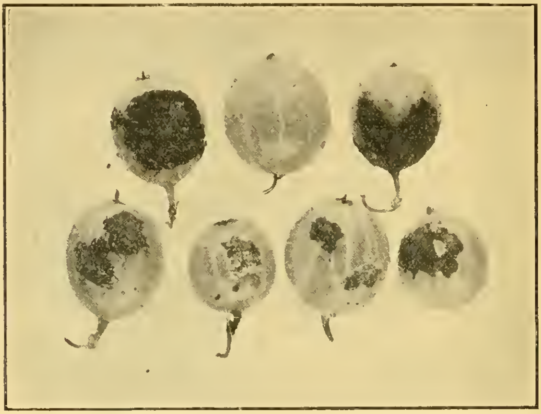

FIG. 2.—Six nearly ripe gooseberries which have been attacked by the American Gooseberry-mildew; one healthy berry is shown. (From Ireland.)

Messrs. H. E. Annett, F. V. Darbishire, and E. Russell furnish the report from the analytical laboratory, in which it is stated that 250 samples ot various substances were sent in for analysis during the past year. A detailed account is given of some of these; others are dealt with briefly. They are treated under the following heads:—Manures, feeding-stuffs, poisons, milks, waters and soils.

The reports from the botanical department are contributed by the four members of the staff. Mr. E. S. Salmon, the mycologist, has given evidence of his energy in turning his extensive knowledge of fungi to practical account for the benefit of fruit growers in this country. The detection of the outbreaks of American gooseberry mildew (*Sphaerotheca mors-uvae*) (Figs. 1 and 2) by him was followed by an energetic and tactful campaign to bring about the stamping out of the disease, and his efforts have been rewarded by the introduction of the Bill dealing with fungus attacks into the House of Lords. The Board of Agriculture and Fisheries has now made an order which may be cited as the Gloucestershire and Worcestershire (Gooseberry Mildew) Order of 1907. It came into operation on July 22. This constitutes the first legislative measure against fungus diseases put into force in this country. The fungoid disease of the gooseberry was discovered in the winter of 1906 in some commercial plantations in Worcestershire and Gloucestershire, but it had previously been introduced into Ireland on diseased stock imported from America. It is during the so-called "summer stage" that this mildew spreads most rapidly, as at this period the chains of Conidia are produced in continuous succession day and night. We gather that the cherry orchards in certain portions of Kent are still seriously affected by the fungus *Gnomonia erythrostoma*, which depends "absolutely for the continuance of its existence on fresh infection taking place in spring by means of the spores scattered from the fruit-conceptacles of the fungus on the dead leaves hanging on the tree." R. N.

THE GEOLOGY OF THE TRANSVAAL.[1]

THE most interesting features of the report of the Transvaal Geological Survey for the year 1906 are the excellent pieces of detailed mapping of the rocks of the Transvaal System, in the Lydenburg district, between Lydenburg and Belvedere, by Mr. A. L. Hall, and in the area immediately east of the Crocodile River and south of the Rooiberg by Mr. W. A. Humphrey. These two districts form parts of the same great synclinal trough; but while the Lydenburg district is at the eastern end of the trough, and is as remarkable for the simplicity of its geological structure as it is famous for the grandeur of its scenery, the area mapped by Mr. Humphrey lies 200 miles to the west and nearer the centre of the trough, and is characterised by an exceptionally complicated structure. Surrounded by the much later Red Granite formation, the isolated inliers of the Transvaal System in the latter area owe their position to faulting and folding on a large scale, an adequate explanation of which can only be forthcoming when the area to the west is mapped in detail.

In both districts the three members of the Transvaal System are developed—namely, the Pretoria Series, the Dolomite, and the Black Reef Series. The quartzites of the Black Reef Series, which form the lowest division, attain to an unusual development in the northern part of the Lydenburg district, where they form the main portion of the great escarpment of the Drackensberg, and play a considerable *rôle* in determining the wild character of the scenery.

[1] Transvaal Mines Department. Report of the Geological Survey for the Year 1906. (Pretoria, 1907.) Price 7s. 6d.

"No mere description," says the author, "can convey an adequate idea of the grandeur of the country between Belvedere and Blyde River Poort, where this stream enters the granitic Low Veld area." The escarpment of the Drackensberg "here forms a fine semi-circular curve, cut into by a number of spruits which give rise to precipitous and densely wooded kloofs. Immediately below the edge of this escarpment runs a massive kranz of quartzite nearly 500 feet in thickness." About a thousand feet below lies the great plain of the Low Country, beyond which, on a clear day, the distant chain of the Lebombo Hills can be discerned. The dip of the Black Reef Series being to the west, the escarpment rises eastward until it culminates in two magnificent bluffs, 3500 feet higher than the Belvedere (see Fig.). North of Belvedere the greater thickness of the quartzites produces, under the profound erosive action of the

Portion of the Great Eastern Escarpment of the Drakensberg, S. of Belvedere, formed by the Black Reef Series.

larger rivers, even more striking scenic effects. Thus the Blyde River is mentioned as having carved out a cañon in the quartzites to a depth of more than 2000 feet.

The Dolomite, owing to its more homogeneous composition and consequent absence of marked horizontal features, is characterised by a different type of scenery. Its vertical jointing, however, gives rise to peculiarly pointed kopjes, recalling portions of the dolomite area in the Tyrol. Northward, from Pilgrim's Rest to Hermansburg, the Blyde River flows in a gorge formed by precipitous walls of dolomite. It then travels in a more open valley; but on leaving the Dolomite it cuts its bed down into the Black Reef quartzites by a succession of cataracts and waterfalls until, joining forces with the Treuer River and the Belvedere Creek, it forms the deep cañon mentioned above.

The Pretoria Series presents in the Lydenburg district no feature, either topographical or geological, of especial interest; the same succession of shales, quartzites, and intrusive sheets is met with as in the country further south. The only noteworthy point is the marked thinning out of the series which is observable to the north of Lydenburg. The middle member of the system—the Dolomite—undergoes no great change in thickness, although a thick bed of quartzite (the "Blyde Quartzites") makes its appearance for the first time in the middle of the series; but while the upper member—the Pretoria Series—becomes much attenuated, the lower member—the Black Reef Series—rapidly assumes greater and greater proportions as it is traced northwards. In the extreme eastern portions of the Rand basin, near Springs, the boreholes put down through the Karroo Coal-measures and the Dolomite, to cut the underlying Witwatersrand Beds, showed that the Black Reef Series was represented at the base of the Dolomite by a bed of hard quartzite only 20 feet in thickness (see Hatch, Trans. of the Geol. Soc. of S. Africa, vol. vii., 1904, p. 63). At the Devil's Kantoor, in the Barberton district, it is 110 feet thick; at Mac-Mac, 700 feet; at Belvedere, 1260 feet; while near the northern termination of the Drackensberg, at Marieps Kop, the series reaches 2550 feet. The horizontal distance across the syncline formed by the beds of the Transvaal System, under the Waterberg and Red Granite formations, from Springs to the Drackensberg escarpment, is only about 160 miles, so that the conditions of sedimentation must have changed rather rapidly, the cause of which is not explained

It will be seen by the free use made of Boer topographical words in the sentence quoted above that the committee appointed by the British Association at its last meeting "to determine the precise significance of topographical and geological terms used locally in South Africa" should serve a useful purpose. The precise meaning of such words as *kranz, bult, vlei,* and *kloof* will not be known to the generality of English readers, although *kopje, veld,* and *spruit* may have been made familiar by the late war. The report is accompanied by excellent colour-printed maps, and illustrated by beautiful photographic reproductions; but, unfortunately, it lacks an index, and has not even a paged table of contents.

F. H. Hatch.

THE HISTORY OF ARITHMETICAL NOTATION.

The invention of the decimal notation, which involves the use of zero and the assignment of local value to digits, made such an immense alteration in the character of arithmetical calculations that it would be extremely interesting to know its origin. It became familiar in Europe mainly through Mohammedan sources; hence the term Arabic, as opposed to Roman notation. But the discovery of Sanskrit literature and of Indian works on mathematics led to the theory that the real inventors of the system were the Hindus. The object of Mr. Kaye, in the paper referred to below,[1] is to show that this conclusion has been based on insufficient evidence, and that the whole question requires further and more careful consideration, including a critical study of Indian texts, to avoid being misled by spurious documents. Mr. Kaye gives in the first place a series of arguments which go far to prove that there is no trustworthy evidence for the use of the new notation in India

[1] "Notes on Indian Mathematics.—Arithmetical Notation." By R. Kaye. (Journ. and Proc. As. Soc. of Bengal, new series, vol. iii., No. 7, 1907.)

before the ninth century A.D., and that, if a single inscription prove untrustworthy, we shall have to fix the tenth century as the earliest date attested. Another point on which there can be no doubt that he is right is that the Arabic epithet *hindashi*, applied to the decimal notation, certainly does not mean Indian, the word for which is *hindi*, and cannot be connected with *hindashi* by any regular Arabic method of word-formation; not to mention that *hindashi* usually means "geometrical," and was derived from a Persian word by the Arabic lexicographers themselves. There is no probability in favour of Colebrooke's conjecture that the Indian work translated by Alfarazi was entitled "Siddh'anta"; and it is clear enough that after Brahmagupta there was a decline in the study of mathematics in India.

As to Brahmagupta himself, Mr. Kaye points out that in his treatise, side by side with Hero's exact formula for the area of a triangle in terms of the sides, he gives the absurd rule that the product of half the base and half the sum of the other sides is the gross area of a triangle—a survival of a rough approximation similar to those used in Egypt more than two thousand years previously—and this without a word of warning as to when this method would give no approximation at all (though, of course, it should be remembered that in applying this rule, the side most unequal to the others would probably be taken as the "base"). Altogether Mr. Kaye's paper is well worth reading, although he refrains from advancing any definite conclusions of a positive character.

G. B. M.

PROF. J. B. PETTIGREW, F.R.S.

BY the death of Prof. Pettigrew another gap has occurred in the able band who, in the last three or four years of the "'fifties" of last century, studied at Edinburgh University. Born in 1834 at Boxhill, in Lanarkshire, young Pettigrew attended first Airdrie Academy and then arts' and a few divinity classes in Glasgow University. Proceeding to the University of Edinburgh as a medical student in 1856, he was first brought into notice in the senior anatomy class of Prof. Goodsir, for by devoting himself to a research on the arrangement of the muscular fibres of the heart he, with 125 marvellous dissections and 120 ingenious drawings, carried off the gold medal. By and by he became president of the Royal Medical Society in Edinburgh, and gave the "Croonian" lecture on the arrangement of the muscular fibres of the heart (after rehearsing it to his fellows in Edinburgh) to the Royal Society of London. He also won the gold medal in the class of medical jurisprudence for an essay on the presumption of survivorship. Next he carried on a research on the cardiac nerves and their connections with the cerebro-spinal and sympathetic system, for which a gold medal was awarded on graduation day, 1861.

After a brief period of office as house-surgeon in Prof. Syme's wards in Edinburgh Infirmary, Pettigrew was appointed assistant curator (under Prof. Flower) in the museum of the Royal College of Surgeons, London. There his remarkable skill in dissection, his stimulating enthusiasm, and his fine preparations of the muscular coats of the stomach, bladder, and other viscera—which he rendered so visible by distending them with coloured plaster of Paris—made his period of office memorable. He also published at this time his memoirs on the arrangement of the muscular fibres of the heart and on the muscular fibres of the stomach and bladder in the Philosophical Transactions; and another memoir on the relations, structure, and functions of the valves of the vascular system in vertebrates (Trans. Roy. Soc. Edin.). He further entered into another field, viz. the mechanism of flight, first prominently brought out in his lecture on the subject at the Royal Institution. This was followed by his elaborate and finely illustrated memoir in the Linnean Transactions, and, in 1879, by his volume on animal locomotion in the International Series.

His health, however, broke down in 1868, and as total blindness was feared he had to relinquish his post at the museum of the Royal College of Surgeons in London and take rest. Improving in health, he, in 1869, accepted the post of curator of the museum of the Royal College of Surgeons in Edinburgh. He held also the offices of pathologist to the Royal Infirmary, lecturer on physiology to the Royal College of Surgeons in Edinburgh, &c. He published in 1874 a volume on the physiology of the circulation in plants, in the lower animals, and in man. Unsuccessfully competing for the chairs of anatomy and physiology in Edinburgh University, his niche was found in the professorship of medicine and anatomy (Chandos chair) at the University of St. Andrews in 1875. His period of office in this chair soon became eventful, as he was appointed the university's representative on the General Medical Council, and in connection with the union of the university with Dundee College. To his labours, and those of one or two others, the university owes the Berry fund of 100,000*l*., the principal's residence of Scores Park, and the fine Bute Medical Buildings.

In recent years he published various general papers, gave the "Harveian" oration in Edinburgh in 1889, and continued his researches on the mechanism of flight in his private laboratory, where his remarkable machine with its gigantic wings exhibited all his recent experiences. Failing health lately much curtailed his labours, yet, under great weakness, he bravely elaborated a large illustrated work embodying the various researches formerly alluded to and evidences of design in animals. Besides other honours, he received the Godard prize of the French Academy of Sciences, and was made a laureate of the Institute of France.

W. C. M.

W. A. SHENSTONE, F.R.S.

"DISTINGUISHED for his skill as an experimenter, for his ability as a teacher, and for his zeal in the introduction of improved methods of teaching physical science as a branch of general education." Such was the statement of his qualifications for admission to the Royal Society, of which Shenstone became a Fellow in 1898. By his friends he will be remembered for his enthusiastic eagerness in the pursuit of science, by unselfish devotion to what he thought his duty, by his loyalty and good-fellowship, and by the indomitable cheerfulness with which he bore physical suffering.

I made his acquaintance in October, 1871, when, as one of the Bell scholars, Shenstone entered the laboratory of the Pharmaceutical Society in Bloomsbury Square, where I was then demonstrator. After my removal to Clifton College, and feeling the need of an assistant, I was led to think of the young student I had left behind. He accepted the proposal to live under my roof, and thus was laid the foundation of a friendship which persisted without a check to the end. In 1875 Shenstone left me on his appointment as science master at Taunton College, and after about two years removed to Exeter School to take up a similar appointment. Here he built and fitted up a school laboratory, which he described in NATURE (July 25, 1878), and which proved that, contrary to general belief, a place for teaching physical science practically was not necessarily a very costly affair. Shenstone while with me assisted in various lines of experimental research, and after leaving was good enough to return and devote a whole month of the summer holidays to work in the laboratory. In those days no science master who had ambition to be more than a teaching machine could refresh his own mind or take part in the advancement of his subject save at the sacrifice of recreation, health, and pocket; and the pity of it is that times are not greatly altered in this respect.

In 1880 Shenstone was appointed chief science master at Clifton, and, spite of heavy routine, he managed to carry out admirable and difficult work on ozone, and on the properties of certain highly purified substances, from which he drew the important conclusion that in certain cases two elements can unite together without the presence of that minute quantity of a third substance which had been supposed by some chemists to be invariably necessary.

Shenstone was a skilful glass-blower and an excellent popular lecturer. He was instrumental in introducing vitrified silica as a material for making tubes, flasks and other vessels for laboratory use which are now manufactured in a clear form by Messrs. Johnson and Matthey. The production of this material was described by Shenstone in a lecture at the Royal Institution in 1901.

He died on February 3, after a long illness, at Mullion, South Cornwall, aged fifty-eight; and there he lies in the old churchyard within sight of the Cornish sea, which he so much loved.

Shenstone married in 1883 Mildred, daughter of the late Rev. R. N. Durrant, of Wootton, Canterbury, who survives him, together with a son and daughter.

William A. Tilden.

NOTES.

At the annual general meeting of the Royal Astronomical Society to be held to-morrow (Friday) the president will deliver an address on presenting the gold medal of the society to Sir David Gill, K.C.B., F.R.S., to whom it has been awarded for his contributions to the astronomy of the southern hemisphere and his other astronomical work.

The Dublin meeting of the British Association will be held on September 2–9 under the presidency of Mr. Francis Darwin, F.R.S. The sectional presidents are as follows:—A, Dr. W. N. Shaw, F.R.S.; B, Prof. F. S. Kipping, F.R.S.; C, Prof. J. Joly, F.R.S.; D, Dr. S. F. Harmer, F.R.S.; E, Major E. H. Hills, C.M.G.; F, Lord Brassey, K.C.B.; G, Mr. Dugald Clerk; H, Prof. W. Ridgeway; I, Dr. J. S. Haldane; K, Dr. F. F. Blackman, F.R.S.; L, Prof. L. C. Miall, F.R.S. There will also be a subsection of Section F, to be concerned with agriculture, and the chairman will be Sir Horace Plunkett, K.C.V.O., F.R.S. The first evening discourse will be delivered by Prof. H. H. Turner, F.R.S., on "Halley's Comet," and the second by Prof. W. M. Davis, of Harvard University, on "The Lessons of the Colorado Cañon."

The death is announced, at the age of eighty-seven, of the Rev. F. Howlett, whose drawings and observations of sun-spots have appeared in various publications, and will be remembered by many students of solar physics.

The thirty-fifth annual dinner of old students of the Royal School of Mines will be held on Wednesday, March 18, at the Hotel Cecil. The chair will be taken by Dr. R. Pearce.

The Mary Kingsley medal, which was struck by the Liverpool School of Tropical Medicine for presentation to distinguished investigators and others who have aided the cause of combating disease in the tropics, has been presented to Lord Lister, who formally opened the school on April 21, 1899. The medal was forwarded to Lord Lister with a letter signed by Princess Christian (hon. president), Sir Alfred Jones (chairman), Sir Rubert Boyce (dean), and Mr. Alan Milne (secretary), in which it was stated:—"No words of ours are required to amplify the esteem in which your magnificent achievements are held throughout the world. The Mary Kingsley memorial medal has been founded for the purpose of recognising the work of those who have accomplished much in the cause of tropical medicine. No one has accomplished more for this cause, or, indeed, for the whole cause of medicine, than yourself. The school feel honoured that your lordship has consented to receive the medal."

We regret to learn from the *City Press* that Mr. R. J. Friswell, whose name is well known among analytical chemists, died on February 6 after a brief illness. Mr. Friswell studied at the Royal College of Chemistry under Sir Edward Frankland, and later acted as assistant at St. Mary's Hospital to Dr. W. J. Russell. Subsequently he engaged in research work at the Royal College, being appointed in that connection on the staff of the Indian Eclipse Expedition, and later, on his return to London, continuing to assist Sir Norman Lockyer in his spectroscopic researches. Afterwards, for many years, he was the chief chemist to the firm of Brooke, Simpson, and Spiller, leaving them to become the scientific adviser of the British Uralite Company, Ltd. For the last few years he had been in practice for himself as an analytical chemist in Great Tower Street. Mr. Friswell was elected a Fellow of the Chemical Society in 1871, and served on the council for several years; he was one of the founders of the Institute of Chemistry, and last year was chairman of the London section of the Society of Chemical Industry.

We notice with regret the announcement that Sir J. D. Macdonald, K.C.B., F.R.S., retired Inspector-General of Hospitals and Fleets, died at Southall on February 7 in his eighty-first year. Sir J. D. Macdonald entered the Royal Navy as an assistant surgeon in 1849, and was placed in charge of the Plymouth Hospital Museum. In 1852 he joined H.M.S. *Herald*, and from that date until July, 1859, when promoted to surgeon, he was employed on surveying and exploring service in the south-west Pacific. After many years of almost unremitting microscopic work on the products of the sounding-lead, dredge, and towing-net, he was elected a Fellow of the Royal Society. His next promotion came in 1866, and for nine years he held the post of professor of naval hygiene at the Netley Medical School. In the meantime he was awarded the Macdougal-Brisbane medal of the Royal Society of Edinburgh in 1862, and the Gilbert Blane medal in 1871. He was the author of numerous papers read before the Royal Societies of London and Edinburgh and other societies. His published works also included "A Guide to the Microscopical Examination of Drinking Water," "Analogy of Sound and Colour," and "Outlines of Naval Hygiene." He was made a Deputy-Inspector-General of Hospitals and Fleets in February, 1875, and five years later was again promoted, holding from 1883 to 1886, when he retired from active service, the charge of the Naval Hospital at Stonehouse. In 1902 he was made a K.C.B.

The February number of the *Strand Magazine* contains two articles of interest to readers of Nature. In the one, entitled "The Physiognomist at the Zoo," Mr. A. E. Johnson discourses pleasantly on the expression of animals as an indication of character, his points being brought out by four striking—if somewhat accentuated—portraits of the lynx, the chimpanzi, the mantled guereza monkey, and the loris. The second article, by Mr. D. M. Beddoe, is devoted to the recently discovered mummy believed to be that of Menephtah, the Pharaoh of the Exodus, and the son of the great Rameses. Photographs of the mummy illustrate the article, so that the reader may look on features familiar to Moses some three thousand or more years ago.

In the January number of the *Quarterly Journal of Microscopical Science* Mr. C. C. Dobell describes the life-history and development of a newly discovered genus and species of flagellate monad (*Copromonas subtilis*) inhabiting the fæces of frogs and toads. Starting with the adult monad, it appears that the organism undergoes two distinct phases or cycles of development, one asexual and the other sexual. In the former multiplication takes place by means of longitudinal division, with the eventual development of two flagellas and two nucleuses. In the sexual stage the monads conjugate in pairs, and thus eventually give rise to a dormant cyst, from which, when a suitable *nidus* is reached, a small hyaline monad is liberated, this in due course developing into an adult monad, when the whole cycle recommences. The cysts are swallowed by frogs or toads, and reach the rectum by the usual course.

The anatomy and histology of the alimentary tract of the dugong are described in detail by Mr. J. F. Gudernatsch in the fourth part of vol. xxxvii. of Gegenbaur's *Morphologisches Jahrbuch*. At the conclusion of the paper the author refers to some curious resemblances between the sirenian and the cetacean tongue. In that organ in the dolphin there have, for instance, been found certain peculiar pits occupying the position of the circumvallate papillæ in other mammals, while the author has discovered very similar pits in the dugong which occupy the position of the foliate papillæ. Whether these pits are connected with the sense of taste is, however, uncertain, although the occurrence in both cases of ganglionic cells in the pits is in favour of such a function. An important difference between the sirenian and cetacean mouth is the presence in the former of large salivary glands, which are totally wanting in the latter.

A series of "studies in adaptation" commences in the fifth volume of the *Baltimore Journal of Experimental Zoology* with an article by Dr. Alexander Petrunkevitch on the sense of sight in spiders, a subject discussed with great elaboration and in minute detail. This sense is of the greatest importance to certain species, those which obtain their prey by hunting depending entirely on sight during the chase. Nevertheless, the acuteness of vision even in the sharpest-eyed spiders is far inferior to that of man. An insect of about a square centimetre in size would, for example, be perfectly visible—even perhaps to the extent of specific recognition—to the human eye at the distance of a yard, whereas to a spider of the genus Phidippus it would appear as a tiny, ill-defined moving object, while to members of the genus Lycosa it would be invisible. The poor visual power of spiders is largely due to the peculiar form of the retina, while the inferiority in this respect of Lycosa to Phidippus depends on the fact that, while in the latter the retinal image covers the terminations of nearly seven nerve-rods, in the former it scarcely exceeds the diameter of a single rod.

The best mode of determining the age and rate of growth of eels forms the subject of a long article by Mr. K. J. Gemsöe in the report of the Danish Biological Station for 1906 (Copenhagen, 1908). By means of measurements, it has been ascertained that when eels attain a length of about 18 cm. and begin to develop scales, they have lived for two years in fresh water, that is to say, from the time of their arrival as larvæ or glass-eels. After this the age may be determined by the number of concentric zones or rings in the scales, which indicate annual periods of growth. The age of any individual eel is therefore the age of the scale +2. Judged by this test, it appears that in the case of males some assume the silvery breeding-dress (preparatory to descending to the ocean) in about $4\frac{1}{2}$ years after their arrival in fresh water, although the majority do not do so until from $5\frac{1}{2}$ years to $7\frac{1}{2}$ years. The females, on the other hand, assume the silver livery somewhat later, scarcely ever before $6\frac{1}{2}$ years, and in most cases not until $7\frac{1}{2}$ years, while many do not do so until they are $8\frac{1}{2}$ years old or even more, whereas only one male of that age was detected in the course of the experiments. It is during their fourth and fifth years that eels increase most rapidly in girth.

In an article on the evolution of life, published in the *Century Illustrated Magazine* for February, Dr. Percival Lowell asserts that life is an inevitable phase of planetary evolution, and consequently that every planet must be inhabited by living creatures of some kind during a certain stage of its existence. Mars is at present passing through this stage. The author also considers it demonstrated that in the case of our own planet life originated in the ocean. Very picturesquely does he describe the life of the deep sea. That a blind fauna, he writes, should inhabit the abyssal depths is of itself a sufficiently wonderful phenomenon; but that nature should undertake to light the region, and that by means of its inhabitants, is still more wonderful. And yet "this is precisely what she does, and with something akin to electricity, each animal carrying with it its own machine. Whole tracts are brilliantly lighted up, till they must resemble London or Paris by night, only that in these thoroughfares of the abysses of the sea the passers-by provide the illumination."

Prof. Dunbar, as the result of a series of experiments conducted over a long period and with every care, has come to the conclusion that the bacteria are not an independent group of organisms, but, together with some of the yeasts and moulds, are stages in the life-history of green algæ ("Die Entstehung von Bakterien, Hefen und Schimmelpilzen aus Algenzellen," published by R. Oldenbourg, Munich and Berlin). A pure culture of a single-celled alga belonging to the Palmellacia was obtained, but by modifying the culture medium by the addition of acid, alkali, or traces of copper salts, other organisms, generally bacteria, occasionally moulds and yeasts, and even spirochætes, made their appearance in the pure cultures. Granting there was no flaw in the experimental methods, and every care seems to have been taken to exclude contamination, the results are susceptible of another explanation, viz. that the secondary growths were derived by transformation of the algal cells, in fact, by the phenomenon of "heterogenesis," which has been claimed by Bastian to occur with certain organisms.

An editorial in the *Indian Forester* (November, 1907) on "Forestry and Agriculture," advocating the afforestation of some of the large areas of uncultivated or unculturable land in India, touches on a matter of great importance, seeing that so much timber is required as fuel.

It is suggested that the planting of such areas might be undertaken by district boards working in consultation with forest officers.

A PAMPHLET on the fibrous plants of the west coast of Africa, forming the subject of a paper read before the Liverpool Chamber of Commerce by Dr. E. Drabble, has been received from the Liverpool Institute of Commercial Research in the Tropics. The author treats his subject under the groups of leaf fibres, bast fibres, piassavas, and raffias. The first named include species of Agave, Sansevieria, and the oil palm Elæis; most of the bast fibres are derived from malvaceous plants; the greater quantity of both piassavas and raffias is obtained from the palm *Raphia vinifera*.

AN account of culture experiments undertaken with the object of studying the effect of organic matter on nitrification in impure cultures is contributed to the *Bulletin International de l'Académie des Sciences de Cracovie* (June, 1907) by Messrs. A. Karpinski and B. Niklewski. The authors come to the conclusion that weak solutions of various organic substances, especially humates, and to a less degree acetates, peptone, and sugar, do distinctly promote nitrification processes. Messrs. T. Koźniewski and L. Marchlewski communicate a paper on chlorophyll derivates, in which they indicate the spectra obtained with solutions of phyllotaonin and allophyllotaonin.

THE first number of the *Kew Bulletin* for the current year contains diagnoses of new flowering plants, "Decades Kewenses: XLV., XLVI.," by workers in the herbarium, and identifications by Mr. G. Massee of a set of fungi collected in Singapore by Mr. H. N. Ridley. The majority of the fungi are agarics, of which several are new species; a Calodon (Hydnaceæ) and a Geoglossum also furnish new species. An article on the fruit fly, *Ceratitis capitata*, refers to a pest that has caused serious damage to orange bushes and fruit trees in South Australia and other colonies. It has also been reported from the neighbourhood of Paris on apricots and peaches. Kerosene placed in shallow vessels is said to provide an attractive lure that has proved efficacious. Mr. T. A. Sprague contributes a synopsis of the prickly fruited species of Euonymus, of which three are new Chinese plants, and an article by Mr. F. Turner on Australian grasses is reprinted.

THE first of a series of contributions by Mr. T. F. Cheeseman to a fuller knowledge of the flora of New Zealand, constituting an addendum to the author's "Manual," is published in the Transactions of the New Zealand Institute (vol. xxxix.). As a guide for future work, the author indicates the regions that have been insufficiently explored. The notes refer chiefly to new varieties and specimens. The indigenous localities of the handsome shrub *Clianthus puniceus* and the myrtaceous tree *Metrosideros tomentosa* are collated. Illustrations are given of two unique specimens of branched "nikau" palms, *Rhopalostylis sapida*, one showing seventeen irregular branches. Separate papers are devoted to the description of a plant previously named *Trithuria inconspicua*, now transferred to Hydatella, another genus of the same order, Centrolepidaceæ, and to the discussion of the discontinuous distribution of *Pittosporum obcordatum*.

LAND erosion by storm water appears to be going on at a remarkably rapid rate in parts of Cape Colony, and to cause considerable loss to farmers and others. For the past three years the Irrigation Department has been collecting information on its bad effects and on possible remedies, and this is now summarised in the November (1907) number of the *Agricultural Journal of the Cape of Good Hope*. It is considered that two main causes operate—the burning of forest, of bush, and of grass has destroyed vegetation that used to hold back storm water, and the movement of cattle and waggons, &c., along definite paths tends to wear down tracks in which the water can start its course. Once erosion begins its progress is very rapid. Among the instances quoted we may mention the Ongers or Brak River. Sixty years ago there was no river, but for some cause erosion began, and it has since gone on so rapidly that the river channel is now generally 300 feet wide and 15 feet deep. In order to check the process it is suggested that small channels or "sluits" should be so obstructed by stones, bushes, &c., that the water must distribute itself over a wider area, and do correspondingly less damage. The subject is a very important one, and we trust that the Irrigation Department will not stop at collecting information, but will proceed to a sound and complete investigation of the whole matter.

THE Bulletin of the American Geographical Society, vol. xxxix., No. 11, contains an account of physiographical experiments on the aggrading and degrading stream, carried out at the Ohio State University during the past year. An initial valley of cement was constructed in a water-tight tank, the slope of which could be varied. Fire-clay of unequal fineness was placed above the upper end of the valley, and a fine spray of water turned on. During the aggradation process, the construction of systematic asymmetrical fans over previous flood plain deposits, and the formation and preservation of pits or depressions on the flood plain, were noticed. The latter is the probable origin of the so-called "kettles" of the Susquehanna. Conclusions were also arrived at concerning the relative importance of slope, water supply, and load as causes of the aggradation or degradation of streams, the influence of load being specially emphasised. Finally, Prof. Davis's explanation of alluvial terraces standing above existing flood plains was strikingly confirmed by the action of the experimental river as it carved out its series of terraces.

AN account of the astronomical and geodetical observations made in 1902–5 by the German Commission for fixing the boundaries of German East Africa appears in *Die Mitteilungen aus den deutschen Schutzgebieten*, vol. xx., part iv. The report is published in three divisions, the first containing particulars of the Lake Kivu Expedition under Captain Herrmann, with Prof. Lamp as astronomer, and the second and third giving the results of the Deutsche Uganda Grenz Expedition under Captain Schlobach. On the Kivu Expedition, Prof. Lamp established an astronomical station at Usambara, and determined a value for its latitude. Valuable geodetical results, of which full tables are given, were also obtained in this neighbourhood, and with the figures of Captain Schlobach furnish the data for triangulation of a map of the district west and north of Lake Victoria. East of the lake, triangulation was continued from a base at Port Florence, the work being carried as far as Kilimanjaro, and from thence connected with Zanzibar. A map is published showing the boundary line between British Uganda and German East Africa from Lake Victoria to Kilimanjaro. Captain Herrmann also gives an account of altitude measurements made by the Kivu Expedition, and Captain Schlobach a table of those made during the Uganda Grenz Expedition.

THERE are few regions in the world so rich in minerals as the State of Nevada. In addition to gold, silver, copper and lead, deposits of sulphur, zinc, bismuth, antimony, tungsten, nickel, iron, mercury, arsenic, salt, and gem-stones are being developed at the present time. The discovery of the great Tonopah gold mine in one of the barren mountains in the desert area of the State caused Nevada to awake from the economic lethargy into which she was plunged after the flooding of the Comstock mines in the early 'eighties, and the closing down of nearly every mine of importance on the other mining fields through the fall in the price of silver. In an interesting review of the recent mining developments in Nevada, Mr. A. Selwyn-Brown, in the *Engineering Magazine* (vol. xxxiv., No. 4), shows that since the Comstock rush in 1850 to the end of 1907 the gold and silver mines of the State yielded the enormous value of 206,670,000*l*. In the Journal of the Franklin Institute (vol. clxv., No. 1) Prof. O. C. S. Carter also deals with the mineral resources of Nevada, and describes the irrigation started by the Government Reclamation Service. The irrigation canal, thirty-one miles in length, to divert water from the Truckee River to the Carson River, together with 270 miles of lateral ditches, is completed, and is the first irrigation project carried out under the authority of the United States law of June 17, 1902.

In the December (1907) number of the *National Geographic Magazine*, the organ of the National Geographic Society of Washington, U.S.A., Mr. R. M. Brown describes an experiment intended to give practical proof of the curvature of the earth, carried out by him on Lake Quinsigamond, on the model of the well-known investigations of Mr. H. Yule Oldham on the Bedford Level in this country. The most interesting contribution is that of Hon. J. Wilson, Secretary of Agriculture, entitled "The Modern Alchemist," in which he surveys the multiform activity of his department in the introduction of new varieties of cereals and other useful plants, arboriculture, forestry, fisheries, and many other subjects.

Mr. F. Soddy is giving a course of six free public lectures at Glasgow University on "The Nature of Matter." He regards them as some slight return to the people of Glasgow for the help given to the University by prominent citizens, especially in the equipment of the department of physical chemistry with apparatus for research, and he believes it to be the duty of men of science who receive such help to place before the public from time to time, and in a manner to be readily comprehended, the principal results achieved. The first lecture, delivered on January 30, dealt with radium and atomic disintegration.

Sir Charles Todd has issued the meteorological observations made at the Adelaide Observatory and other places in South Australia and the Northern Territory during the year 1905. The section relating to rainfall gives the monthly and yearly totals at 517 stations, and compares the figures with the average for previous years wherever there are at least seven years' records. The year was a moderately wet one over the older established agricultural districts, but dry over the pastoral country, the interior, and the Northern Territory. From August to the middle of December the weather was very cold in the southern areas; the special meteorological feature of the year was the exceptionally cold spring; February was also the coldest month on record. The useful experiments on the exposure of thermometers have been continued; Sir Charles Todd observes that, as might be expected, the thermometers in the "Stevenson" screens as a rule read higher than those on the "Greenwich" stand during the night and lower during the day; the difference depends very much on the wind-force and the state of the sky. An interesting table shows the approximate mean rainfall for each month and year from 1861 to 1905, and the average yield of wheat per acre; wheat-growing can be successfully prosecuted only where the percentage of winter rains is largely in excess of that for the summer months.

M. L. Natanson has an article on the electromagnetic theory of dispersion in gases in the April (1907) number of the *Bulletin de l'Académie des Sciences* of Cracow. After working out the general theory of propagation of electrical disturbances in a medium composed of molecules which contain electrons or "corpuscles" having their own periods of oscillation, he limits his consideration to gases, and assumes the molecules to contain electrons of one kind only. He finds that in the cases of hydrogen, oxygen, air, and carbon monoxide, the values of the refractive indices calculated on this assumption agree fairly with the values found by experiment. In the case of carbon dioxide the agreement is poor, owing probably to the influence of the absorption bands in the infra-red. In the case of sodium vapour the assumption of two kinds of electrons fails to produce a satisfactory agreement between theory and experiment.

Prof. Cohen has made valuable additions to our knowledge of the allotropic states of the elements, notably in the cases of tin and antimony, and the current number of the *Zeitschrift fur physikalische Chemie* (January 31) contains two papers by him (in collaboration with Mr. J. Olie) on the so-called amorphous antimony and bismuth. These were described by Mr. F. Hérard in 1888 as resulting from the action of nitrogen upon these metals at a dull red heat. The experiments now described prove conclusively that neither pure antimony nor bismuth undergoes any change when heated in nitrogen which has been carefully purified from oxygen and oxides of nitrogen. If the nitrogen is not specially purified, however, Hérard's results are reproduced, the "amorphous" antimony (or bismuth) thus obtained consisting of a mixture of the metal and its oxide. These allotropic modifications of the two elements are therefore non-existent.

Under the title "A propos de l'État civil de Jean Baptiste van Helmont" the question of the correct dates of the birth and death of van Helmont is discussed by the Chevalier Edmond Marchal in a recent number of the Bulletin of the Royal Academy of Belgium (1907, No. 7, p. 732). The researches of M. G. Des Marez among the registers of the cathedral church of Ste. Gudule, Brussels, show that van Helmont was born, not in 1577, as has been generally supposed hitherto, but on January 21, 1579 (N.S.). The date of his death is somewhat less certain, being either November 16, 1635, or December 30, 1644; it appears to be clear, however, that he died in Brussels and not at Vilvorde, where he spent seven years of his life. It is an interesting fact that the bust of van Helmont at the Royal Belgian Academy of Medicine does not represent Jean Baptiste van Helmont at all, but his son François, whose likeness, appearing side by side with that of his father in the first edition of the "Ortus Medicinæ," was confused with it when the bust was carved in 1863.

Messrs. Longmans, Green and Co. have published a fifth edition of "The Old Riddle and the Newest Answer," by Father John Gerard, S.J. The price of the book is 6*d*.

The publishing firm of B. G. Teubner, Leipzig and Berlin, has just issued an authorised translation into German, by Dr. J. Friedel, of Prof. Horace Lamb's standard work on "Hydrodynamics." The second English edition was reviewed in Nature of November 21, 1895 (vol. liii., p. 49), and the third edition, carefully revised and largely supplemented, was published early in 1906. This is the edition of which a translation has now appeared in Teubner's collection of text-books of mathematical science.

THE fifth volume of the second series of the Proceedings of the London Mathematical Society has now been published by Mr. Francis Hodgson. The volume includes an account of the meetings held during the session November, 1906, to June, 1907, and many of the papers read before the society during the session. Obituary notices are included of the late Colonel Mannheim and Dr. E. J. Routh. As the meetings of the society are recorded from time to time among our reports of societies and academies, it is unnecessary to do more now than mention the publication of the volume containing records of papers presented.

OUR ASTRONOMICAL COLUMN.

OCCULTATIONS OF URANUS IN 1908.—From Dr. Downing we have received, as an excerpt from No. 2, vol. lxviii., of the Monthly Notices, a table showing the times and angles of immersion and emersion for the occultations of Uranus by the moon observable at British observatories during the present year. The places specifically named are Adelaide, Melbourne, Sydney, Wellington, Natal, Perth (W.A.), and the Cape, and the dates of the occultations are April 22, May 19, July 13, August 9, and October 3. Dr. Downing hopes that the publication of these data will enable astronomers favourably situated to observe some peculiarities in the appearance of the planet at the time of occultation.

OBSERVATIONS OF COMETS 1907*d* AND 1907*e*.—The results of the observations of comets 1907*d* and 1907*e*, made at the Vienna Observatory with the 6-inch refractor, are recorded by Dr. J. Holetschek in No. 4231 (p. 99, February 3) of the *Astronomische Nachrichten*. Some of them for 1907*d* are particularly interesting, as, in addition to the brightness of the nucleus and of the comet as a whole, the observer gives the length of tail and the times before sunrise up to which the comet was observable. Thus on July 18, when the brightness of the whole comet was of the fourth magnitude, the brightness of the nucleus being 7·5 mag., the object was followed until 15h. 33m. (Vienna M.T.), that is, until 46m. before sunrise. On August 26, mag. 2·0, it was seen until 20m. before sunrise. The greatest length of tail measured was about 8°, on August 18.

Signor Abetti also records, in the same journal, a number of observations, made at the Arcetri Observatory, of these two objects during November and December, 1907.

PLANETS NOW VISIBLE.—With Mercury at its greatest eastern elongation on February 13, it may be possible, during the next night or two, to observe, with the naked eye, five of the major planets at the same time. On February 13 Mercury will set about $1\frac{1}{2}$ hours after the sun, *i.e.* at about 6.30 p.m., some 10° south of west. Venus is still quite a bright object in the western sky, whilst Saturn sets, nearly due west, some three hours after sunset. Mars does not set until about 10.30 p.m., and is to be found in the constellation Pisces to the south-east of the Great Square of Pegasus.

At 6 p.m. Jupiter is now a striking object in the eastern sky, having risen some three hours earlier.

Mercury will, of course, be the most difficult object to locate, but, following the directions given in these columns on December 5, 1907 (p. 115, vol. lxxvii.), Mr. W. E. Rolston found the planet at 6.35 a.m. on December 6, and was able to follow it easily until 7.10 a.m. The observation was made at Wimbledon Park, the sky being clear and the sun rising at 7.51 a.m.

At present Uranus is in conjunction, and therefore invisible, but Neptune may be found, with a telescope, situated between the stars ϵ and ζ and near to η Geminorum.

ENCKE'S COMET, 1908*a*.—The following is a further extract from the ephemeris for Encke's comet given in No. 4222 (p. 363, December 18, 1907) of the *Astronomische Nachrichten* by M. Kamensky and Mdlle. Korolikov :—

Ephemeris oh. (M.T. Berlin).

1908	α (app.) h. m.	δ (app.)	1908	α (app.) h. m.	δ (app.) °
Feb. 12 ...	23 50·3 ...	+6 21·0	Mar. 3 ...	0 27·0 ...	+10 4·5
,, 20 ...	0 3·9 ...	+7 43·7	,, 7 ...	0 35·6 ...	+10 56·1
,, 28 ...	0 18·9 ...	+9 15·3	,, 11 ...	0 44·7 ...	+11 49·6

From this we see that the comet is apparently travelling in a north-easterly direction through the constellation Pisces, and should be sought, in the earlier part of the evening, some few degrees to the south of the Great Square of Pegasus. Its photographic magnitude on January 19 was 12·5, and its distance from both the sun and the earth is decreasing rapidly. According to Prof. Wolf's observations, the above ephemeris required corrections of +2·4m. and −24′ on December 25.

Some interesting notes on the successive reappearances of Encke's comet appear in No. 2 (February 1, p. 13) of the *Gazette astronomique*.

A CATALOGUE OF ZODIACAL STARS.—A catalogue of zodiacal stars, principally prepared for use in occultations of stars by the moon, appears as part iii., vol. viii., of the Astronomical Papers prepared for the use of the American Ephemeris and Nautical Almanac. This catalogue was prepared by Mr. H. B. Hedrick, and all the catalogues employed in the investigation were reduced to the same absolute system as Prof. Newcomb's Catalogue of Fundamental Stars, which appeared as part ii. of the same volume. The catalogue includes 1607 stars, and gives the definitive positions for the epochs 1900·0 and 1920·0. Centennial and secular variations and proper motions are also given.

METEORS OBSERVED ON JANUARY 2.—Observing at Hjörring, North Jutland, Herren P. Muusmann and H. Wanning saw a number of meteors in the region between Cygnus and Pegasus on January 2. The observations were made between 8.10 and 8.20 p.m., and during the last five minutes more than thirty meteors were counted. The position of the radiant is given as 300° + 61° (*Astronomische Nachrichten*, No. 4230, p. 95, February 1).

THE WINDS OF NORTHERN INDIA.[1]

THE phenomena of atmospheric motion may be considered and discussed from three main points of view. They may be (1) regarded in their relation to the general system of winds prevailing over a rotating earth unequally heated, and having an annual period of temperature variation; (2) considered in their dynamic relation to the synchronous distribution of the various other meteorological elements, more particularly the pressure and temperature, in their vicinity; (3) arranged in order to facilitate comparison with one another at different times and seasons, and to exhibit the connection between wind and climatic conditions in such a way as to enable account to be taken of this connection in a general survey of meteorological conditions and in relation to forecasts. In the memoir before us, the main feature is the development and discussion, from the third standpoint, of the results of anemographic records at Allahabad and Lucknow during the years 1890–1904 and 1878–1892 respectively. Sir John Eliot prefixes the discussion by a short account of the synchronous distribution of pressure and temperature at Lahore and Allahabad, which is very suggestive of the method to be adopted and the results to be used in a discussion from the second standpoint. The modifying influences of the orographic distribution are too considerable to admit of close connection between the results recorded and the general atmospheric circulation, and no attempt has been made to develop such connection.

[1] "Memoirs of the Indian Meteorological Department, being Occasional Discussions and Compilations of Meteorological Data relating to India and the Neighbouring Countries." Published under the direction of Dr. G. T. Walker, F.R.S. Vol. xviii., part iii. V. A Discussion of the Anemographic Observations recorded at Allahabad from September, 1890, to August, 1904. VI. A Discussion of the Anemographic Observations recorded at Lucknow from June, 1878, to October, 1892. By Sir John Eliot, K.C.I.E., F.R.S. (London: Harrison and Sons, 1907.) Price 2 rupees.

Allahabad is situated about 300 feet above sea-level at the junction of the Ganges and Jumna, where their general direction is changing from E.S.E. to E. The plain of these rivers forms part of a great plain 1300 miles long and about 200 miles broad, in no part of which does the height above sea-level exceed 1000 feet. On the north it is bounded by the Himalayas, which change their direction from N.W. to W. in passing from the Punjab to Assam. Near Allahabad the direction is approximately W.N.W.

To the south the ground rises gradually to the plateau of Central India, across which runs a low range of hills from Bombay in an E.N.E. direction, passing about 150 miles south of Allahabad.

Allahabad is therefore near to the south edge of the flat bottom of a trough with sides converging towards the east, the south side being very slightly inclined and of small elevation compared with the north. Lucknow is 110 miles N.W. of Allahabad, and lies at the centre of the flat bottom. The motion of the air in such a trough is complicated, but the general result is that air flowing in or out transversely is deflected towards the right in its course, the effect being in both cases to produce motion parallel to the trough. On these motions will be superposed the effect of the general circulation of the atmosphere, which is both actually and theoretically westerly in the upper regions so long as the trough is definitely north of the thermal equator, becoming easterly when the thermal equatorial region includes the trough.

The exposure of the anemometer at Allahabad was excellent, but at Lucknow was not so good, and at the latter place the instrument, during the later years, was not kept in proper working order. It is probably partly due to these causes that the records from Lucknow show winds considerably weaker than those from Allahabad.

The results of the records have been arranged in tables giving for each month for each hourly interval of the day (1) the mean movement of the air, irrespective of direction; (2) the number of winds recorded under each octant of the compass; (3) the number of miles recorded under each octant of the compass; (4) the mean coordinates of the resultant wind movement.

For exhibiting the leading features of the air movement these results have been charted, and a series of carefully drawn plates is given at the end of the discussion. In addition to wind roses, showing the amount of wind in each direction and the proportion of calms, there is an excellent set of diagrams showing for each month of the year the diurnal variation of the air movement and the mean monthly resultant velocity. The diurnal variation bears no direct relation to the ordinary diurnal pressure variation.

For the purposes of discussion, Sir John Eliot divides the year into two periods, the dry season extending from the middle of October to the middle of June, and the wet season during the remaining four months. The dry season is further subdivided into the dry cool season, November to February, and the dry hot season, March, April, May.

During the cool season, pressure gradients are small, and the main feature of the distribution is the persistent continental high pressure. Locally, the isobar through Allahabad at 8 a.m. in January runs nearly through Lucknow in a N.W. direction, becoming more northerly as the day advances, while the wind changes its direction from W.N.W. to N.N.W. Thus there appears to be a correspondence between the wind direction and the local pressure gradients similar to that noted every day on the synchronous weather charts for temperate latitudes. The variations are, however, too rapid for the development of the full effect of the earth's rotation in producing an approach to parallelism between the isobars and the wind direction.

It is important in considering this rotation effect to remember that it acts as a modifying influence in conjunction with the pressure distribution, and although the latter is in the end the outcome of the air motion and temperature variation, there is nothing to warrant the assumption that the combined effect on air motion is to produce always a veering in the wind. Air starting from rest and moving across a permanent system of isobars will veer as it progresses, but a change in the direction of the gradient may more than counteract this action of the earth's rotation.

Briefly, if the pressure fall in unit distance along two perpendicular straight lines, Ox, Oy, by amounts α, β, and if the resultant velocity due to the effects of the pressure gradient, friction, and the earth's rotation be proportional to the gradient and make a constant angle θ with the isobars, the components of velocity in the two directions Ox, Oy, will be $k(\alpha \cos \theta - \beta \sin \theta)$, $-k(\alpha \sin \theta + \beta \cos \theta)$.

If, now, $\bar{\alpha}$, $\bar{\beta}$ are the mean values of α, β deduced from mean pressure distribution, and if $\bar{u}$, $\bar{v}$ are the mean values of the components of wind velocity, we find

$$\bar{u} = k(\bar{\alpha} \cos \theta - \bar{\beta} \sin \theta), \quad \bar{v} = -k(\bar{\alpha} \sin \theta + \bar{\beta} \cos \theta)$$

and the same relation, therefore, holds for mean values as for synchronous distributions. The angle θ depends on friction and on the time the motion has been in progress; u and v will therefore vary between limits depending on these factors. The general relation is, however, simple, and it appears desirable to test its applicability to motion in the large unbroken plain, ample and suitable data for which are furnished by the present series of memoirs.

An examination of the diagrams shows that at both Allahabad and Lucknow the cold season has the greatest percentage of calms and the smallest air movements. The latter are, however, steadier than at any other season. Calms are $2\frac{1}{2}$ times more frequent at Lucknow than at Allahabad, the average number at the former place being 30 per cent. of the total number of observations. The mean direction of the air movement is slightly W. of N.W. at both places. The diurnal variations of magnitude are similar at both places, the maximum being reached about 3 p.m., when the average velocity is more than double that of the evening. The changes in direction at the two places are very different. The wind usually veers throughout the day at Allahabad, and backs during the night; at Lucknow the main feature is considerable, backing from 11 a.m. to 3 p.m., and slow veering for the remainder of the day, with slight and very irregular movements at night, the changes being much less than those at Allahabad.

In the dry season the winds are of maximum intensity at Lucknow and of mean intensity at Allahabad. At both places the actual resultant air movement is a maximum for the year. The winds are relatively very steady in March and April, and very unsteady in May. The mean direction changes from N.W. to N. at Allahabad, and from W.N.W. to N.W. at Lucknow during the course of the season. The diurnal changes are similar to those of the cold season, but are more marked, and in May the changes in direction are greater at Lucknow than at Allahabad, but still take place in the reverse direction.

The winds during the wet season are remarkable for their increased variability in direction. The actual amplitude of the diurnal variation of magnitude is considerably less than for the dry season, the winds being less feeble during the night and of average intensity in the day. At Allahabad the mean direction of air movement in July is from W.S.W., but during the early morning hours it is nearly S., and at 4 p.m. it is N.W. by N. At Lucknow the mean direction is N.E., and the variations are less marked, but there is a very remarkable change from E. by N. to N.E. by N. between 10 a.m. and 11 a.m. The motion is the same as if the places were in a trough of ascending motion the axis of which moved towards Allahabad in the course of the day.

Diagrams are also drawn to show the variations of air movement along, and perpendicular to, the axis of the trough, appropriately called the axial and transverse variations. The axial variation shows similar features throughout the dry season. There is a fairly rapid increase in the daytime until 4 p.m., after which there is a rapid decrease. During the night there is practically no change. In the wet season the increase is much smaller at both places. At Allahabad the maximum is reached at 11 a.m., and the decrease takes place slowly during the remainder of the day. There is a feeble secondary maximum at 2 a.m. At Lucknow the increase takes place slowly and irregularly from midnight to midday, while there is a similar decrease until 10 p.m. The transverse variation is throughout markedly different at the two stations. At Allahabad the northerly component *diminishes* during the dry season until midday, after which it increases until about 5 p.m., the epochs advancing two hours from November to April. At Lucknow the northerly component *increases* rapidly to a maximum at 11 a.m., and diminishes again to a minimum at 3 p.m., after which the changes are slow and irregular.

In the wet season there is an average increase in the northerly component at Allahabad from midnight until 4 p.m., and a corresponding decrease for the rest of the day. At Lucknow the main feature is a sudden increase in the northerly component between 10 a.m. and 11 a.m., after which there is a decrease with oscillations to the minimum at 10 a.m. on the following day, the rapid afternoon fall being absent.

These features of the transverse oscillation, together with the greater steadiness of the winds at Lucknow, appear to be partly due to its more central situation; but the backing of the wind during the day indicates that a longer period is necessary to produce the larger motion in the direction of the trough than is requisite for the smaller transverse variation. It is probable that for Allahabad the earlier transverse motion is modified by the effect of the Central Plateau; this effect diminishes in the afternoon, and is replaced by the influence of the Himalayas, which is, of course, weaker than at Lucknow. The nature of the transverse variation appears also to imply that the effect of the Himalaya range in constraining the air motion in the plain is actually produced dynamically through the medium of rotary motion transverse to itself rather than through a forcing of the stream lines to conform to parallelism with a rigid boundary.

The solution of the problems presented, and their connection with convective motion not shown directly by the winds, would be considerably advanced by a knowledge of the vertical temperature gradient in the free atmosphere over the plain.

A noteworthy feature is brought out in the auxiliary tables, representing the steadiness of the wind by the ratio of the resultant air movement to the total movement. The winds of the wet season are most steady near midnight, while in the dry season the epoch of maximum steadiness is about 4 p.m.

The accompanying tables exhibit the main features of the annual variation and the distribution of the wind.

We note that the winds were taken from the records of Beckley's anemograph, but there appears to be no statement regarding the factor used in the reduction to miles per hour. In any case, the winds are comparatively feeble, the maximum recorded in any single hour being thirty-five miles at Lucknow and forty-five miles at Allahabad. There appears to be an inconsistency between the statement on p. 320 of the years of maximum and minimum movement and the table on the preceding page, so that either the suggestion of periodicity or the table needs readjustment.

The arrangement of the memoir is excellent, and it is full of suggestiveness to the student of meteorology. It forms a valuable contribution to our knowledge of Indian meteorology.

E. G.

MEDICAL INSPECTION IN LONDON.[1]

DR. JAMES KERR, medical officer (education) to the London County Council, here adds another to the series of his admirable reports. These always contain much that cannot be neglected by the students of educational conditions, and this report is no exception. It consists of sixty-six pages crowded with new materials of the highest scientific and practical value. Administratively, probably the most important statement in the report is that "a point has now been reached, as to whether the greater part of the medical inspection shall remain fruitless, or whether the Council shall take steps which will justify its later interference to see that its younger dependents have a fair chance of benefiting properly by the education offered. Treatment as a public concern will have to be considered in respect to certain educational matters, such as visual troubles, discharging ears, ringworm, and the care of the teeth, in which neither the private practitioner nor the hospitals can give hope of either providing sufficient or satisfactory relief for most of the cases requiring it" (p. 3). A composite committee has been appointed to inquire into this serious problem, on which the circular recently issued by the Board of Education has a definite bearing. The report of this committee will be looked for with interest alike by the hospitals and the practitioners.

The general results of the medical inspection confirm the work of previous years. The medical officers are now coming to closer quarters with the children, and this report contains many careful pieces of special research. These it is here possible only to indicate. Emphasis is laid on the urgency of the inspection of infants, especially of infants of three to five years of age. Tubercular bone and joint disease can then be most readily prevented. In inspection of the secondary schools and training colleges there was noticed a "general ignorance of how to expand the thorax by deep inspiration" (p. 8). Among girls, "headaches were complained of by 20·5 per cent. . . . Exaggerated movements, corrugated foreheads, insomnia, and somnambulism were met with. Several cases of overstrain were specially reported" (p. 9). "The average standard of physique is low." There is a careful mathe-

[1] London County Council. Report of the Education Committee of the London County Council submitting the Report of the Medical Officer (Education) for the year ended March 31, 1907.

matical study (pp. 10–16) by Dr. Shrubsall of the statistics of growth. The general results might with advantage have been further elaborated on the practical side. As to teeth, there is a strong plea for school dental clinics on the model of Strassburg.

A special investigation as to tuberculosis of the lungs in school children was undertaken by Dr. Squire and Dr. Annie Gowdey. Of actual phthisis, only 335 cases (*i.e.* 0·55 per cent.) were found among 58,934 children. The sections on hearing and acuity of vision contain much fresh material. One of the most important sections deals with the "development of articulatory capacity for consonantal sounds" (p. 27). Considerable detail is given of the methods of testing, and 105,000 tests were made on some 3000 children. The results are given in an exact quantitative way, capable of analytical study. This department is of immense importance to the teacher, as the work already done in phonetics has abundantly shown. As to fatigue, some new curves from rifle-shooting are given. It is found that the curve improves with a little practice, co-ordination improving very rapidly. Cigarette-smoking was found to impair the capacity to shoot straight.

There are the usual sections dealing with the inspection of defective children and cripples, country homes, infectious diseases, adenoids, &c.; but two sections must be specially named, one on the artificial lighting of school-rooms and the other on the mental and physical effects of bad ventilation. In both researches the practical results are very definite, and ought to be driven home among teachers and architects alike. Of the ventilation research, some provisional conclusions are:—"Temperatures above 65° F. give rise to definite subjective symptoms, slackness and inattention in some, headaches in others. Although it is not easy to assert definite mental alteration till about 70° F." "Symptoms do not appear at 65° if the air is kept in gentle movement by a fan in the room. With temperatures 70° F. and above, other factors being normal, there are marked symptoms and very evident deterioration in mental alertness and accuracy." At low temperatures, relative humidity does not affect the mental capacity of children, but increase of humidity increases the effects of high temperatures. Carbonic acid gas in considerable excess increases markedly the fatigue of the children. Exact details are given of the methods used.

The London County Council is to be congratulated on the issue of this mass of original and important observations in so many departments of medical inspection. Dr. Kerr's reports show the great educational possibilities of the system, which, under his guidance, has revealed many new regions for clinical and scientific research.

THEORY OF THE MIRAGE.

THE theory of the mirage forms the subject of several recent papers by Prof. Antonio Garbasso. In notes contributed to the *Atti dei Lincei*, xvi. (2), 1, 8, the author discusses the propagation of light in a heterogeneous medium, making use of the principle of least time, and considering the case of space of any number of dimensions defined by curvilinear coordinates. The space in question is supposed to be subject to the usual assumption that the square of the line-element is a homogeneous quadratic function of the differentials of the coordinates. As might be expected from the principle of least action (an analogy the applications of which to the problem are probably already known), the equations of the path can be reduced to the form of the ordinary equations of dynamics by a suitable choice of the characteristic function. The applications to the mirage itself are discussed in a paper in the *Memorie* of the Turin Academy, 1907. Prof. Garbasso claims that while the phenomenon has been studied both experimentally and theoretically, his present work fills a gap in the literature by establishing agreement of a quantitative character between the results of calculation and those of experiment.

Two kinds of mirage are distinguished, one due to the variations of density caused by diffusion between two fluids of different refrangibility initially having a plane of separation; this is called the mirage of Vince. The second kind, called the mirage of Monge, depends on diffusion outwards from a plane boundary maintained indefinitely at the same conditions. The former condition gives three images, two direct and one inverted; the latter gives only the reflected image. Prof. Garbasso calculates the law of density from the equations of diffusion, and thus determines the equations of the trajectories of the rays of light and the form of the wave-front.

The final comparison with experiment is discussed in a paper by Luigi Rolla, also in the *Memorie* of the Turin Academy. In it the last-named author describes experiments showing how, not only has Wollaston's original artificial mirage of the Vince type been reproduced with its three images, but also the Monge mirage has been imitated, and in both cases the trajectories of the rays have been determined by observation and compared with results of theory. Moreover, a mirage with five images, observed by Parnell at Folkestone in 1869, was realised by placing over a layer of carbon bisulphide a mixture of equal parts by volume of alcohol and chloroform. Owing to the unequal rates of diffusion, the conditions give rise to five images, and this and other experiments are shown to be suitable for lecture-room demonstration.

By taking a block of gelatin containing a cavity filled with liquid which gradually diffuses into the gelatin, the corresponding images for a cylindrical or spherical distribution of density have been also produced and compared with the results of mathematical calculation.

The first and second figures show the mirages of a diaphragm somewhat in the shape of a ship produced by the medium formed by diffusion between alcohol and

FIG. 1. FIG. 2. FIG. 3.

bisulphide of carbon. Fig. 1 represents the appearance after a few hours, Fig. 2 after several days. Fig. 3 shows the five images obtained by diffusion between bisulphide of carbon and a mixture of alcohol and chloroform.

G. H. B.

A CONTRIBUTION TO THE HISTORY OF IRONCLADS.

LORD ROSSE has made an interesting contribution to the history of ironclads by placing at the service of the Institution of Naval Architects copies of letters written by his father to various distinguished men in the years 1854–5. From these letters it appears that the late Lord Rosse not merely appreciated the importance of armour protection against horizontal shell fire, but satisfied himself that it was possible by means of suitable proportions to secure ample stability in ironclad ships. Naval officers were then disposed to think that the "top-weight" inevitable with heavy loads of armour would make vessels unstable. Lord Rosse proposed the construction of ironclad floating batteries of moderate size; they were intended to fight in smooth water, and consequently were to carry their guns at a small height above water. The exposed sides were to be armoured with 5 inches of iron, and the upper decks to be covered with 2-inch plating.

In a letter to Sir John Burgoyne dated June 26, 1854, Lord Rosse proposed an armament of sixteen heavy guns; the draught of water was not to exceed 12 feet to 13 feet, and the vessel was estimated to be about 1500 tons. He added:—"All this is the roughest possible, but I think if worked out in detail the result would not be widely different. The greatest care would, of course, be necessary to guard against submarine explosives." To this letter Sir John Burgoyne replied that he doubted whether 5 inches of iron would answer its intended purpose and make a vessel practically impregnable. In this connection he remarked:—"Iron is very treacherous, and breaks, rends, and tears under very irregular effort. The Navy have a thorough dislike to it for the sides of ships, but then they have never contemplated, I believe, such thickness."

These remarks from so high an authority on ordnance as Sir John Burgoyne throw an interesting light upon opinions prevailing little more than fifty years ago in regard to naval construction. Lord Rosse was not discouraged, but proceeded to press his scheme upon the attention of the Duke of Newcastle and on Sir Baldwin Walker, who was then Controller of the Navy. In his letter to the Duke of Newcastle, Lord Rosse stated that he "had been considering, *no doubt in common with many others*, in what way the great mechanical resources of England could be brought to bear against the mechanical resources of St. Petersburg." In thus writing, Lord Rosse no doubt had in view the fact that iron-clad floating batteries had been decided upon. Five such vessels were commenced in France in September, 1854, and later on similar vessels were built here, but not from Lord Rosse's outline design.

In the publication of these letters a filial duty has been fulfilled. The late Lord Rosse is shown to have been one of the first to make a definite proposal for the construction of ironclad floating batteries, and his treatment of the subject is worthy of his scientific reputation. On the other hand, it cannot be doubted that the action taken in France was independent of the suggestions of the late Lord Rosse. The correspondence with Sir John Burgoyne, the Duke of Newcastle and others could not have been known to the Emperor Napoleon when he took action; the construction of the French floating batteries was commenced about the same time as these letters were written, but was preceded by experimental trials made to determine the thickness of the armour to be adopted. It may be added that General Paixhans, to whom the introduction of horizontal shell-fire was due, had proposed the use of armour protection for ships about 1820, and Mr. Stevens began the construction of a floating battery near New York many years before the Crimean War took place. Lord Rosse obviously had no knowledge of these facts when he made the proposals above described, and acted quite independently.

THE SMITHSONIAN INSTITUTION.

THE report of the secretary of the Smithsonian Institution for the year ending June 30, 1907, has been received. It serves admirably to show the great part taken by the institution in American scientific life. Full particulars are provided, not only of the explorations and researches inaugurated by the institution, but also of the work of the U.S. National Museum, the Bureau of American Ethnology, the International Exchanges, the National Zoological Park, the Astrophysical Observatory, the Regional Bureau of the International Catalogue of Scientific Literature, and the excavations on the Casa Grande Reservation—all placed by Congress under the direction of the institution.

Reference has already been made from time to time in these pages to the researches prosecuted in connection with the institution, but it will be of interest to refer to a few which are summarised in the report. In connection with the study of the older sedimentary rocks of North America, on which Dr. Charles D. Walcott, the secretary of the institution, has been engaged during the past twenty years, upwards of 20,000 feet of strata have been carefully examined and measured. The Cambrian section has been found to include more than 12,000 feet of sandstones, shales, and limestones, and the Lower, Middle, and Upper Cambrian have been found represented in the section of Bow River series and the Castle Mountain group. Characteristic fossils have been found in each division.

An expedition in April, 1907, to Alaska to collect the remains of large extinct vertebrates, particularly mammals, has already done good work. Dr. G. P. Merrill has examined the crater-form depression near Canyon Diablo, Arizona, to determine whether it was caused by explosive volcanic action or is due to the impact of a mass of meteoric iron; his observations are being collated and arranged.

In connection with the seismological investigations undertaken to compare the disturbance in Chile with that in California, it seems to have been determined that there has been some elevation of the coast of Chile, but no traces of a rift such as caused the earthquake at San Francisco. Numerous other researches were assisted during the year; these included the absolute measure of sound, the properties of matter at very low temperatures, the study of the upper air, the organs of flight, and others.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The council of the Senate recommends that the necessary steps be taken for altering Statute B, chapter vi., by the insertion of a paragraph giving the University power, upon the retirement of a professor, either at the date of his retirement or subsequently, to appoint him as a professor emeritus in the subject of the professorship previously held by him. A professor emeritus shall not as such receive any stipend, and shall be subject to no conditions as to duties or residence.

Dr. W. N. Shaw, of Emmanuel College, has been appointed to represent the University at the meeting of Imperial and colonial meteorologists, convened by the Royal Society of Canada, to be held at Ottawa in May.

Mr. J. S. Gardiner has been re-appointed demonstrator in animal morphology for five years as from October 1, 1907, and the appointment has been approved by the special board for biology and geology.

The special board for biology and geology reports that the Gordon Wigan income for biology and geology has been applied during 1907 as follows:—(*a*) a grant of 50*l.* a year to Dr. D. Sharp for a period of three years (1907–9), or such part of it during which he holds the curatorship in zoology; (*b*) a grant of 50*l.* a year for one year (1907) to Prof. Seward to enable the Botanic Gardens Syndicate to offer greater facilities for plant-breeding experiments; (*c*) a grant of 50*l.* out of the income for 1907 to Prof. Hughes, to enable Mr. E. A. N. Arber, of Trinity College, to continue his researches into the stratigraphical and geographical distribution of fossil plants.

LORD STANLEY OF ALDERLEY will distribute the prizes and certificates to evening students of the Battersea Polytechnic on Wednesday evening, February 19, and will deliver an address.

WE learn from the *Pioneer Mail* that the Maharaja of Darbhanga has made a gift of nearly 17,000*l.* to the Lieutenant-Governor for the purpose of constructing a library building in connection with the Calcutta University.

THE annual general meeting of the Association of Technical Institutions will be held on February 21 and 22 at the Drapers' Hall, Throgmorton Street, London. On the first day the association will be entertained at luncheon by the Drapers' Company, after which the new president, Sir Norman Lockyer, K.C.B., F.R.S., will deliver his presidential address. On the second day papers will be read on the best early training for a boy about to enter a technical institution or to take up a trade.

IN a recent report, the Director of Education for the United Provinces has, in accordance with the orders of the Government of India, described the progress of education in his district during the last five years. An abridgment of the report in the *Pioneer Mail* states that the attendance at the Thomason Civil Engineering College at Roorkee has increased from 336 to 495, and various improvements in and extensions of the curriculum have been effected. An agricultural college has been opened at Cawnpore. It is hoped that the medical college at Lucknow will be in working order soon. The Thomason College will, it is expected, shortly develop into a technological institute for engineering purposes, and a technological institute for chemical matters will be established at Cawnpore. Another matter of high importance referred to in the report is the change recently made with the object of introducing more practical work into the course for the degree of Bachelor of Science—a necessary step to meet the growing demand for good teaching in science, which is evidenced by the doubling, in five years, of the number of affiliated colleges preparing for science degrees, and a large increase in the number of undergraduates studying science.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 12, 1907.—"On the Scattering of the β Rays from Uranium by Matter." By J. A. **Crowther.** Communicated by Prof. J. J. Thomson, F.R.S.

The results of the experiments described are summarised as follows:—

(1) A parallel pencil of β rays is scattered in its passage through matter, the scattering being practically complete after the rays have traversed a thickness of material which varies from 0·015 cm. for aluminium to 0·0002 cm. for gold.

(2) The scattering, after correction for the loss of energy, due to the absorption of the rays may be represented by an equation of the form $I/I_0 = e^{-\sigma d}$, where d is the thickness of the material traversed by the rays, and σ is the coefficient of scattering for the rays, I_0 being the initial intensity of a narrow parallel pencil of β radiation, crossing a small fixed cross-section of the pencil, and I the intensity crossing the same cross-section when a thickness d of material is placed in the path of the beam at a considerable distance from the fixed cross-section.

(3) The ratio of the coefficient of scattering σ to the coefficient of absorption λ is approximately constant for all the substances measured, its average value being about 13. The values of the ratio σ/ρ, where ρ is the density, show similar variations to those for λ/ρ.

December 12, 1907.—"Preliminary Note on the Operational Invariants of a Binary Quantic." By Major P. A. **MacMahon,** F.R.S.

Mineralogical Society, January 21.—Prof. H. A. Miers, F.R.S., president, in the chair.—Zeolites from the neighbourhood of Belfast: F. N. A. **Fleischmann.** The author gave an account of a number of hitherto unrecorded zeolite localities near Belfast which he visited in November last. The localities described are quarries in the lower basalt of the neighbouring hills, the most important being two, the first situated on the north side of the hill, which is locally known as Cat Carne, the second on the north-east slopes of Collinward. The first quarry is the most prolific in zeolites in the neighbourhood, yielding fine specimens of apophyllite, analcite, chabazite, levynite, faroelite, &c. In the second quarry cavities are rare, but when they occur are, as a rule, large, and are usually lined with colourless tabular apophyllite crystals which reach sometimes an inch and a half across, and are associated with large hemispherical aggregates of natrolite.—Strüverite and its relation to ilmenorutile: Dr. G. T. **Prior** and Dr. F. **Zambonini.** The mineral was found in the pegmatite of Craveggia, N. Piedmont. In its crystallographic characters it is almost precisely similar to rutile, tapiolite, and ilmenorutile (F. Z.). Chemically (G. T. P.) it is closely related to ilmenorutile, and contains titanic, niobic, and tantalic acids with oxide of iron, in proportions corresponding approximately with the formula $Fe(TaNb)_2O_6.4TiO_2$. At first it was thought to contain zirconia as an essential constituent; the supposed zirconia, however, was shown on further examination to consist of niobic and tantalic acids, which, after the fusion of the mineral with $KHSO_4$ and treatment with water, had passed into solution with the titanic acid. In the presence of as much titanic acid as occurs in strüverite (40 per cent.) it was found that the greater part of the niobic and tantalic acids could thus pass into solution, and when a dilute solution of sulphuric acid (5 per cent. H_2SO_4) was used instead of water in treating the melt obtained with $KHSO_4$, the whole passed into solution. New analyses of ilmenorutile from the Ilmen Mountains and from Norway showed that the titanic acid has been previously much over-estimated, and is present, in the first case, only up to 53 per cent., and in the other to about 54½ per cent. The mineral from the Ilmen Mountains was also found to contain tantalic acid up to about 15 per cent. The most reasonable view of the composition of these minerals appears to be that they are solid solutions of tetragonal rutile (TiO_2) with the crystallographically similar tetragonal mossite or tapiolite, $Fe(TaNb)_2O_6$.—Twin structure: Dr. John W. **Evans.** The author adopts as a definition of a twin crystal that it is a crystal consisting of two component parts such that (a) parallel lines in general have not the same physical characters in the same direction in the two components; (b) one or more "twin-planes" exist such that all lines parallel to (1) any line in a twin-plane, or (2) the "twin-axis" normal to a twin-plane, have the same physical characters in the same or opposite directions in the two components. He shows that this definition includes all twins by reflection, rotation, or inversion (=reflection+rotation), and divides twin-axes into eleven classes according to the odd or even cyclic characters of the twin-axis, the relations between the terminations of the twin-axis, and the relations between the disposition in space of the structure of the two components. He describes twins as amphithetic, homothetic, or antithetic according as lines parallel to the twin-plane have in both components the same physical characters (1) in both directions; (2) in the same directions; or (3) in the opposite directions.—A simple method of drawing crystals of calcite and other rhombohedral crystals, and of deducing the relations of their symbols: Prof. W. J. **Lewis.** The author described a simple method of drawing crystals of calcite and other rhombohedral crystals, in which the principal axis and the twin-axis lie in the plane of the paper. The method is not well adapted for showing simple forms, but with combinations and twinned crystals the drawings closely resemble ordinary clinographic drawings, and are much more easily and rapidly constructed. The geometrical relations between the faces and the relations between the Millerian and Naumannian symbols are readily followed from these drawings. Some unusual twinned crystals of calcite were shown and described; one shows the form {91$\bar{7}$} twinned on {011}, and another {13.0.$\bar{1}\bar{1}$} twinned on the same law.—The structure of perowskite from the Burgumer Alp, Pfitschthal, Tyrol: H. L. **Bowman.** The examination of the optical properties and etching figures of transparent cubic crystals from this locality confirms the interpretation of the structure of perowskite proposed by Baumhauer from the study of crystals from the Ural Mountains and from Zermatt. The crystals are mimetic, and belong to the orthorhombic system, the "cubes" being formed by a combination of basal pinacoid {001} and a prism {110} with an angle of 90°, and having a lamellated structure due to twinning about faces of {110} and {111}.

Geological Society, January 22.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—The origin of the pillow-lava near Port Isaac in Cornwall: Clement **Reid** and Henry **Dewey.** The Upper Devonian strata around Port Isaac consist of marine slates, in which occurs a sheet of pillow-lava. The pillows measure usually from 2 feet to 5 feet in diameter, but range up to 8 feet. The individual pillows are disconnected. Their mutual relations seem to prove that they were soft when deposited. Each pillow shows internally a central vacant space or open sponge, succeeded by a thick shell of vesicular lava, followed by a shell of banded rock. The whole mass is so vesicular that it must have been very light. The association with fine-grained marine strata shows that this lava was probably submarine. The specific gravity of the whole mass must have been low, not greatly exceeding that of sea-water. The lava seems to have been blown out into thick-walled bubbles. The mass was for a time in the spheroidal state, and the sheet could flow like a liquid. This eruption seems to have been analogous to that of Mont Pelée, described by Dr. Tempest Anderson and Dr. Flett, except that it was submarine instead of subaërial.—The subdivision of the Chalk at Trimmingham (Norfolk): R. M. **Brydone.**

Royal Anthropological Institute, January 28.—Annual meeting.—Prof. D. J. Cunningham, F.R.S., in the chair.—Anniversary address, anthropology in the eighteenth century: Prof. **Cunningham.** The work of the period centres round five men, Camper, White, Blumenbach, Prichard, and Lawrence, of each of whom an interesting account was given.

MANCHESTER.

Literary and Philosophical Society, November 26, 1907.—Prof. H. B. Dixon, F.R.S., president, in the chair.—Demonstration illustrating the formation of acetylene from elementary substances: Prof. E. **Knecht.** On heating a small piece of calcium on charcoal before the blow-pipe, the metal readily took fire, and, after burning with a brilliant orange flame for about two seconds, sank into the mass of the charcoal. After the latter had been allowed to cool, it was broken up, when a hard lump was found which yielded acetylene on treatment with water.—New reactions for the characterisation of mercerised cotton: J. **Hübner.** The author has found that, on immersing mercerised and ordinary cotton in a solution of iodine in saturated potassium iodide solution for a few seconds, and afterwards washing with water, the colour of the mercerised cotton quickly changes to a bluish-black, whilst the ordinary cotton becomes lighter in colour and changes to a brownish-chocolate shade. After further washing the ordinary cotton becomes white, whilst the mercerised material remains a bluish-black colour, which fades very slowly on prolonged washing.—The direct combination of carbon and hydrogen: H. F. **Coward.** In experiments made with small quantities of highly purified carbon, the author has obtained from 0·1 gram of carbon, containing a maximum of 0·9 c.c. of hydrogen, 100 c.c. to 120 c.c. of methane by direct union with hydrogen.

December 10, 1907.—Prof. H. B. Dixon, F.R.S., president, in the chair.—Some notes on the mammals of Lundy Island: T. A. **Coward.** The notes were the outcome of a few days spent in trapping on the island; some of the specimens obtained were exhibited.—Notes on some destructive mites: C. G. **Hewitt.** The author described a new mite, *Lohmannia insignis*, Berl., var. *dissimilis*, n. var., which was found feeding on the scale-leaves of tulip bulbs. Two other mites which have occurred in the Manchester district were described, viz. *Rhizoglyphus echinopus* and *Glycyphagus spinipes*.

January 14.—Prof. H. B. Dixon, F.R.S., president, in the chair.—The atomic weight of chlorine: Dr. E. C. **Edgar.** The method used to re-determine this constant was to burn pure dry chlorine, at the tip of a quartz jet, in an atmosphere of pure dry hydrogen in a quartz "combustion vessel"; the hydrogen chloride formed was condensed in a limb of it by liquid air. As the mean of eight experiments, the atomic weight of chlorine calculated from the ratio weight of chlorine burnt/weight of hydrogen burnt is 35·194; from the ratio weight of hydrogen chloride caught − weight of hydrogen burnt/weight of hydrogen burnt it is 35·193 (atomic weight of hydrogen = 1). If the atomic weight of oxygen is taken as 16, that of chlorine becomes 35·462 and 35·461 respectively.—The production of photographs in the colours of nature: A. **Brothers.**

January 28.—Prof. H. Lamb, F.R.S., in the chair.—A new type of dynamical stability: A. **Stephenson.** A system in a position of equilibrium and capable of oscillation about that position may be acted on by periodic force in such a way that no oscillation is generated; thus the equilibrium of a pendulum is not disturbed by the action of vertical force. The object of the communication was to establish the remarkable property of this non-generating type of disturbance in maintaining an equilibrium which would otherwise be unstable.

PARIS.

Academy of Sciences, February 3.—M. A. Chauveau in the chair.—The existence of crystallised sodium fluoride as an element of the nepheline syenites of the Los Islands: A. **Lacroix.** These rock specimens were collected by M. Villiaume from Ruma. In order that unweathered material only should be obtained, the specimens were removed by blasting with dynamite, and about half a ton of rock was brought to Paris. One syenite was found to contain a new mineral, the mineralogical and physical characters of which are described in the present paper. It has a smaller refractive index ($n_D = 1·328$) than any other known mineral, and appears to consist of sodium fluoride, with traces of manganese, calcium, potassium, and possibly zirconia. The mineral is named villiaumite, and its mode of origin is discussed.—The heat of formation of the anhydrous oxides of strontium and barium: M. **de Forcrand.** Strontia and baryta cannot be purchased pure, but if the hydroxides are placed in a platinum boat and heated to 850° in a current of dry hydrogen, absolutely pure, white SrO and BaO can be obtained, the platinum boat not being attacked. The heats of solution found are higher than those of Thomsen, possibly on account of the greater purity of the material.—Observations of the sun made at the Observatory of Lyons during the third quarter of 1907: J. **Guillaume.** The results are summarised in three tables, giving the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude respectively.—The development of an arbitrary function according to the functions of Laplace: Léopold **Fejér.**—A new electric arc furnace applicable to laboratory researches: Louis **Clerc** and Adolphe **Minet.** For an E.M.F. of 50 or 60 volts, by suitably proportioning the area of cross-section of the furnace to the current, an arc of any length can be obtained. In the furnace figured, using from 1 to 2 kilowatts, any desired temperature from a dull red heat upwards can be obtained, and capable of dealing with from 2 to 40 grams of material.—The use of flames as valves for high-tension alternating currents: André **Cathiard.**—Some anomalous modifications of the band spectra of various compounds in the magnetic field: A. **Dufour.** M. Henri Becquerel has attributed the peculiar behaviour of the bands of calcium fluoride, previously described by the author, to the presence of impurities. This view would appear to be improbable, since similar phenomena are now shown to be exhibited by the chlorides and fluorides of all the alkaline earths.—The reduction of indigo by the electrolytic method: H. **Chaumat.** The method recently described by the author was anticipated by Goppelsröder in 1882.—Some complex salts of iron in which the iron is masked: P. **Pascal.** Recently precipitated ferric pyrophosphate is soluble in sodium pyrophosphate, the solubility being independent of the temperature and concentration of the sodium salt. When the solution is saturated, the constituents are in the proportion $Fe_4(P_2O_7)_3 : 3Na_4P_2O_7$, which may be written $Na_6Fe_2(P_2O_7)_3$, or sodium ferropyrophosphate comparable with the ferricyanide, and the behaviour of the salts, together with the isolation of the acid itself, confirm the view that such a complex acid exists.—Some new derivatives of camphenylone: its constitution: L. **Bouveault** and G. **Blanc.**—The order of addition of ammonia to organic α-oxides of asymmetrical structure: K. **Krassousky.** The reactions between ammonia and trimethylethylene oxide and *iso*butylene oxide have been studied, and the conclusion is drawn that in the combination of ammonia with asymmetrical α-oxides, the hydroxyl group is found attached to the carbon atom containing the least hydrogen.—The genesis of certain minerals of alumina and iron. Lateritic decomposition: Jean **Chautard** and Paul **Lemoine.**—The presence of scapolite gneiss and cipolin in Dahomey: Henry **Hubert.**—The origin of the fertile soils of western Morocco: Louis **Gentil.**—The solution of saccharose isotonic with the eggs of Strongylocentrotus: Jacques **Loeb.** The author contests that his experimental results are in strict agreement with those of M. Delage.—The morphology and evolution of the Sabellarians of Saint Joseph: Ch. **Gravier.**—Contribution to the study of the calorific solar radiation: C. **Féry** and G. **Millochau.** An account of work done in the observatory at the summit of Mont Blanc in 1907. The apparatus was standardised by pointing at an electric furnace, and gave an effective absolute temperature for the centre of the solar disc of 5555° C. The value found for this temperature in 1906 was 5620° C.

CALCUTTA.

Asiatic Society of Bengal, January 8.—Notes on Indian mathematics, ii., Āryabhata: G. R. **Kaye.** The most important part of this paper consists of a translation of Aryabhata's "Ganita," and a comment thereon. These are prefaced by brief notes which explain the position occupied by Aryabhata in the history of mathematics. The point of view of the writer differs from that of those who have previously treated the subject in that he holds that it is beyond all doubt that Aryabhata's work owes its origin to the Alexandrian school of mathematicians. Aryabhata does not claim to be the discoverer of the rules he gives, and it is thought that the "Ganita" was intended by him to be supplementary to the mathematical knowledge of the Hindus of his time. The "Ganita" is examined in close detail, and abundantly confirms this hypothesis. The claims that have been made for Aryabhata—that he was the inventor of our modern system of arithmetical notation; that he discovered a more accurate value for π than any of his predecessors; that he was the first to give a systematic solution for indeterminate equations of the first degree—are shown to be unsound (see also p. 347).—Studies in experimental breeding of the Indian cottons: an introductory note: H. Martin **Leake**. Breeding experiments have been undertaken at Cawnpur, and the third generation has now been reached. As a result of numerous measurements of the leaf it has been found that if narrow-lobed and broad-lobed leaved plants be crossed, the proportions of the leaves in the first generation (F1) approximate remarkably to the arithmetic mean of those of the two parents, and this appears to be true for all crosses, whether they be made between the extreme forms of *Gossypium neglectum* or between such divergent types as *G. arboreum* and *G. herbaceum*. In the F2 generation of crosses, plants with typical broad and with typical narrow-lobed leaves appear, just as ascertained laws of heredity teach us to expect. From the way in which intermediates such as have been artificially raised occur naturally in the fields of the United Provinces of Agra and Oudh, it is apparent that cross-fertilisation is common. Further, in illustration it is cited that a packet of seed of *G. arboreum* taken without precautions yielded two out of fourteen plants the parentage of which was obviously impure, and which therefore stand as evidences of natural cross-fertilisation of *G. arboreum* by some other species of Gossypium.

DIARY OF SOCIETIES.

CONTINUATION SCHOOLS.

Continuation Schools in England and Elsewhere. Edited by Prof. M. E. Sadler. Pp. xxvi+779. (Manchester: University Press, 1907.) Price 8s. 6d. net.

PROF. SADLER and his fellow-workers are to be congratulated on the production of a volume which is full of useful information and contains many valuable suggestions and expressions of opinion; moreover, it appears at a time when precise information of the kind given is urgently needed by educational authorities, merchants, manufacturers, workpeople, and teachers. For at the present moment two problems stand in urgent need of solution, and with both of them this volume is largely concerned. The first is how to meet the grave difficulty occasioned by the enormous development of machinery, which, though a good in itself, has brought in its train a grave loss, viz. the almost entire disappearance of the old apprenticeship system, which involved the careful training of the craftsman by his employer; and the second is how to deal with the large number of children who are employed as unskilled labourers at comparatively high rates of pay during their early years, who are subsequently replaced by similar children, and are then thrown on the labour market as unskilled labourers for whom there is not an adequate demand, and who go to swell the ranks of the unemployed.

Prof. Sadler and his colleagues give an account of the agencies which seek to solve these problems in this country and abroad, and of the legislative and administrative measures which we and other nations have adopted in order to cope with these difficulties. They show that, in so far as Great Britain is concerned, our success has only been partial, and, while giving full credit to all the improvements we have effected, they point out in what respects other nations are in advance of us; they instance, for example, the people's high schools in Denmark, and the enormous service they have done to the Danish nation, more particularly in so far as they have educated the agricultural population, and, *inter alia*, made possible cooperation among farmers, thus bringing about numerous improvements in Danish agriculture and conditions of rural prosperity which one would like to see in this country.

It is impossible to touch on all the various questions which the authors discuss; but there are four points which seem of more importance than the rest. In the first place there is the question of the "half-timer," which is dealt with by Mr. Sandiford in chapter ix., and by Prof. Sadler in the following chapter, which gives details as to the laws in regard to the employment of children in this country, Germany, and Switzerland. The evidence on both sides of the question is given in an impartial manner, and few unprejudiced persons will read it without being convinced that the continuation of the half-time system involves grave injustice to a not inconsiderable proportion of the child population of Lancashire and Yorkshire; for it is clearly shown that the mental, moral, and physical condition of the average half-timer is seriously injured by the large amount of overwork to which he is subjected. It is painful to read that these wretched children are awakened by the "knocker-up" between 4.45 and 5.30 a.m., that with short intervals for food they work until 12.30 p.m., and are then expected to learn something in the two and a-half hours which they spend in school in the afternoon. The result of this cruel treatment can readily be imagined; careful measurements have shown that the average half-time scholar between the ages of thirteen and fourteen is an inch less in height, and weighs more than 2 lb. less than the average full-time scholar of the same age. Moreover, the damage is not merely physical; we are told that the half-timers are undoubtedly duller than the full-time children, and that they rise less frequently to good positions in their industry.

Clear evidence is adduced to prove that the employment of half-timers is by no means necessary, as there are many successful mills in which no such persons are employed; it is to be hoped, therefore, that Parliament will soon awaken to this crying evil, and will absolutely forbid employment of this kind, which is sanctioned in scarcely any other civilised country in Europe.

The second question, concerning which this book provides valuable information, is the need for the improvement and development of our public elementary schools in directions likely to give a better preparation for industrial life in the case of boys, and domestic life in the case of girls. In the past, and to a large extent at the present time, the schemes of education set forth by the Board of Education have been devised, and their working inspected, mainly by persons trained on classical lines in the great public schools and at the older universities; the result has been that our elementary education has taken directions which are too bookish and not of a sufficiently practical character; if anyone doubts this, he need only examine, as a sample, the absurd questions in arithmetic set by the Board of Education for the so-called "Labour Certificate." As a consequence, our elementary schools have tended to encourage unduly the production of clerks, and to spread amongst the poorer classes the idea that manual labour is less honourable than clerical work. Experiments are being made to counteract this, experiments, unfortunately, in some cases, not too cordially assisted by the Board of Education.

In chapters xiii. and xiv. an account is given of certain trade schools and pre-apprenticeship schools, which shows the attempts that are being made to combine ordinary elementary instruction with the attainment of a reasonable amount of manual skill. The very few hours a week at present given to such work in our elementary schools are grossly inadequate, and a much better result would be obtained if boys between the ages of twelve and fourteen were allowed to devote a considerably larger fraction of their school time to practical training of a suitable character, and if, during the same period, girls were given a knowledge of domestic subjects much more substantial than the smattering which they now get in the very short periods devoted to this essential part of their education. The experiments in this direction which have been tried in Gloucestershire have shown that, while the amount of book knowledge which the children possess may be somewhat smaller, the larger amount of contact they have had with *things*, as distinguished from mere *words*, makes them, on the average, not less, but more intelligent.

In the third place, one of the collaborators, Mr. G. L. Bruce, deals in the third chapter with evening schools in London, and mentions incidentally the great drawbacks to evening work of a university character, which are unfortunately imposed by the new teaching university itself (see pp. 132 and 138). There is no doubt much truth in this complaint, and, if a consideration of the question leads us to be careful that, in the foundation and working of our newer universities, we do not hand over technical training too largely to the control of those whose experience in this kind of work is either wanting or small, we shall have learnt a good lesson. The most successful technical colleges in the world are probably the Technical High School at Charlottenburg (Berlin) and the Massachusetts Institute of Technology at Boston; neither of them is subordinate to an ordinary university, though in each case a flourishing university exists side by side in the same town. Both of them have the right to give degrees, but the basis on which these degrees shall be offered is determined by those primarily interested in technical education; this is by no means always the case in our English universities.

Lastly, the most important matter dealt with in the book is probably the problem as to whether or not the State ought to make compulsory further attendance in continuation schools after a child has left a public elementary school; and if so, whether it should require employers to offer facilities for such attendance so that the child can continue its education without undue pressure. The attitude taken by Prof. Sadler in regard to this matter is one which will commend itself to most thinking persons; he asks for no rapid or revolutionary change, but he indicates clearly that the time has come when a step should be made in the direction taken by our most successful Continental competitors; for he states:—

"I am convinced that in the end some form of compulsion to attend day or evening continuation classes between fourteen and seventeen years of age will be found desirable, not so much in the interest of the picked individuals as in that of the rank and file. Many of the present evils of unemployment may be traced to the lack of educational care and of suitable technical training during the critical years of adolescence. Compulsion, however, should be accompanied by reduction in the hours of juvenile and adolescent labour where those are now excessive."

A careful perusal of the facts and statistics given in this book ought to convince our legislators that a move forward should now be made. It is a well-known fact that many of the students attending our evening continuation classes are so tired when they arrive there that only very poor work can be obtained, or indeed expected, from them. No such classes are held in Prussia after 8 p.m.; many of them in this country only commence at this hour. Some wise employers (unfortunately comparatively few in number) allow their young people time in which to improve themselves, and so to become more useful citizens and better servants, but this practice is hardly likely to become general unless the State intervenes; that the employer and the nation would benefit in the end few can doubt.

No Government in this country is likely to attempt to deal with a matter of this kind until compelled to do so by public opinion. The volume under review should prove a powerful agency in stimulating the rapid growth of a healthy view of the matter; we therefore cordially congratulate Prof. Sadler on having once more taken a leading part in hastening an important educational and social reform.

J. WERTHEIMER.

ICELAND PAST AND PRESENT.

Island in Vergangenheit und Gegenwart. By Paul Herrman. Erster Teil, Land und Leute. Pp. xii + 376. Zweiter Teil, Reisebericht. Pp. vi + 316. (Leipzig: W. Engelmann, 1907.) Price, 2 vols., 15 marks.

THIS is an account of travel in Iceland in the summer of 1904 by a German schoolmaster. He made the journey in exceptionally favourable circumstances, for, in addition to four months' leave for the special purpose, and a Reise stipendium, the municipal authorities of Torgau provided a *locum tenens* at the gymnasium during his absence; while in Iceland he had the services of the guide who accompanied Thoroddsen on seventeen of his eighteen journeys.

A lover of Iceland and an ardent student of the mythology and folk-lore of northern lands, Herr Herrmann is rather inclined to dwell on the different parts of the country in their aspect as the scenes of this or that Saga. But beyond this, his observation is keen and thorough. Though the book claims to be "not a geological or geographical, but a popular work," we learn incidentally of the geology, geography, natural history, and botany of those parts of the island visited.

The work is divided into two volumes, the first dealing with "Land and People," the second being a full account of three months on the route along the south and east coasts, from Reykjavik to Akureyri. If the book is to be regarded as a "popular" work, it would be advisable to read vol. ii. first. Then, having gained from the detailed description of the journey through the most populous and typical parts of the country a clear idea of the land and its inhabitants, the reader can better follow vol. i., which deals with the land and people generally, and assumes some knowledge of them.

The voyage from Copenhagen to Reykjavik is described, mentioning, *en passant*, Edinburgh, the Orkneys and Shetlands, and the islands south of Iceland, with their myriad sea-bird life. From Reykjavik a trial expedition to Hvalfjördur, Reykholt, and Thingvellir was undertaken to prove the travellers' fitness for the longer distance along the south and east coasts, a route, travelled now for the first time by a German, that includes the passage of many dangerous glacial rivers.

In vol. ii. is the account of the principal journey. The party, consisting of the author, his guide, and a student from Torgau, left Reykjavik, passed again Thingvellir, and the Geysir district, and made the ascent of Hekla. Then across the Ranga to Oddi Storolfshvoll and the many scenes of the Gunnarr Saga, Bergthorshvoll—of the Njáll Saga—to Vestur and Austur Skaptafells Sysla—the most difficult part of the journey; it is here that the coast is so dangerous, and so many fishing smacks are wrecked. The inhabitants of this district have but little communication with centres of civilisation, and have preserved the ancient characteristics almost unchanged. The travellers then continued through the Mula Sysla (Sudur and Nordur), and Thingeyjar Sysla (Nordur and Sudur), to Akureyri.

Every part traversed is minutely described; there is a good deal of scientific matter for the lay reader; and here it may be remarked that the author has an irritating habit of interspersing his reading matter with references—in addition to the many footnotes—and of placing the Icelandic of so many words in italics and parenthesis. This is a great hindrance to easy reading, especially as the same translation is given many times as the word recurs, and items of information are often repeated.

Vol. i. deals with Iceland's geological origin and formation, its volcanoes and glaciers, its geographical exploration, and traces its history from the earliest colonisation in the ninth century, as a free State, under Norwegian and Danish government, to the present day's self-government under the Danish flag.

The study and practice of medicine, the system of education, which is praised as perhaps the best in the world's history, the language and literature, are all considered, as are the ancient and modern industries and arts—wood-carving, embroidery, sculpture, painting, music, and the drama.

Much space is devoted to agriculture, and eighteen pages treat exclusively of sheep. The varied efforts of the State to encourage the farmers to obtain practical knowledge and to provide schools for their training and assistance are noted. The fishing industry also receives State help, and many statistics of this important branch are given. Much is made of the piracy of foreign fishing boats in Icelandic waters, English trawlers being specially attacked. But the author seems to have a prejudice against everything English; the British tourist is unmercifully criticised, and his manners, clothes, and food unfavourably compared with those of the German traveller. The one of our countrymen who joined the party for a short time must have been a very bad example of his kind, or there is another side to the story, which is given—as all else in the book—in detail.

The descriptions of Reykjavik and Akureyri are very full and explicit, and during his visit Herr Herrmann made the acquaintance of many Icelanders, and so gained, at first hand, information regarding the hospitals, schools, and many public and private social institutions and customs.

He sees everything generally *couleur de rose*, and prophesies a bright future for the island, expressing, nevertheless, the fear that the people, who, more than any other nation, have through centuries of civilisation preserved their ancient manners and customs, their pure language and literature, will, with their advance, lose in primitive charm. He urges philologists, while there is yet time, to make a thorough study of Icelandic.

We can hope, with Herr Herrmann, that he may add later a third volume to his book, dealing with the other parts of the island. If, at times, the personal element is too obtrusive, still the book leaves a very clear idea of Iceland, land and people, past and present, a result due partly to the many and excellent photographs, and numerous references, with which the author fortifies or supplements his own observations.

M. G. B.

ADVANCED ORGANIC CHEMISTRY.

Organic Chemistry for Advanced Students. By Prof. J. B. Cohen. Pp. viii+632. (London: Edward Arnold, 1907.) Price 21*s*. net.

THERE are several very excellent text-books upon the subject of organic chemistry in the English language, but although these meet the wants of the average student, the want of a more comprehensive book has been long felt. The book before us is intended to supply this want, and to a certain extent it undoubtedly will do so. The book, according to the author, is a series of essays prepared from notes of lectures delivered to senior students. The work is perhaps best described as being a series of monographs upon different branches of chemistry; as a consequence certain subjects have been exhaustively dealt with, and other subjects have been entirely ignored. Some students will therefore find all they require within the covers of the book, and others will search in vain for the branch of chemistry with which they are familiar or desire to become familiar. Of course, a book written in this manner is bound to a certain extent to lack sequence, and one has practically to commence *de novo* with each section of the book, that is to say, every section has its own historical introduction. For example, the first chapter is a more or less general introduction, but when we come to chapter ii., dealing with isomerism and stereoisomerism, there is again a long historical introduction. We are not objecting to the author treating the subjects historically; in fact, it is probably best to deal with each branch in this manner in order that the student may get a thorough and comprehensive grasp of the subject. This method of introducing and showing the gradual development of the subject is more likely to stimulate originality than the simple setting forth of a number of cut-and-dried facts.

There is, of course, a danger in treating organic chemistry in the form of a series of monographs dealing with different branches, because of a tendency to detachment and to an unnecessary division of the subject. But in giving a series of lectures to advanced classes in organic chemistry, there is practically no other way open than thoroughly to exhaust certain branches, although at the same time it is well to connect and coordinate the groups as far as possible, just as examples in inorganic chemistry can often be made use of to elucidate certain facts in organic chemistry and *vice versâ*.

Chapter ii., upon isomerism and stereoisomerism, is written in a very interesting manner, and the subject can be made anything but interesting. The diagrams are good, and the explanations clear and not too overloaded with details. This chapter deals with isomerism of the lactic acids, van 't Hoff's and Le Bel's theories, mutarotation, &c., and the different action of dissolved substances, depending upon whether they are electrolytes or non-electrolytes. Certain of the sections, indeed, were it not for the full references, might be considered rather short. The next chapter treats of the stereochemistry of unsaturated and cyclic compounds (geometrical isomerism), and chapter iv. with the stereochemistry of nitrogen. The work of Pope and collaborators upon the optical activity of sulphur, selenium, and tin compounds is also included in this chapter, and also that of Kipping upon silicon compounds. It would certainly have been advantageous if this part of the section had been a little more fully gone into.

One of the best chapters in the book is that upon condensation. Here the various methods employed for condensations are elaborated and brought together in a manner which will be found extremely useful to students of chemistry and even to those who may consider themselves beyond the student stage. Not only are the methods themselves given, but the subject is also treated theoretically, as, for example, in the acetoacetic ester condensation and in Perkin's reaction. Another chapter is devoted to fermentation and enzyme action, which includes, beside an historical introduction, references to hydrolysis, oxidases, reductases, and the mechanism of enzyme action. The alkaloids, terpenes, camphors, proteins, and carbohydrates are dealt with in detail, but not colouring matters, either natural or artificial. Of course, the author does not pretend to cover all the branches of chemistry, and presumably his reason for omitting the colouring matters is that there is a special chair of chemistry dealing with this subject at the University of Leeds, and there are also other books on this theme.

As we have already stated, the book supplies a want, and we have pleasure in recommending it to all advanced students of chemistry; certainly all chemical libraries will require it.

F. M. P.

OUR BOOK SHELF.

The Geology of the Leicestershire and South Derbyshire Coalfield. By C. Fox-Strangways. Pp. vi+373. (London: His Majesty's Stationery Office, 1907.) Price 6*s*.

THIS latest memoir contains a description of the joint coalfields of Leicestershire and South Derbyshire, commonly known as the Leicestershire coalfield. It is one of the smallest coalfields of the Midland counties, and is cut off from the Warwickshire and Derbyshire coalfields by an uplift of older strata. It includes an area of about sixty square miles in Leicestershire, and about sixteen square miles in South Derbyshire. Its exact limit has, however, not yet been proved. A large portion of the area is covered by Triassic rocks, so that the Coal-measures only come to the surface over twenty-four square miles. Although one of the smallest coalfields, it is one of the most ancient, having been worked to some extent from time immemorial. The earliest mention of coals being worked in the district is in the reign of King John in 1204.

The author describes the Coal-measures and the surrounding strata as far as it is possible from the evidence afforded up to the present time. He gives full particulars with regard to the productive measures, remarks on their probable extent beyond present workings, and a general account of the physical history and structure of the area. Brief accounts are also given of the associated rocks, including those of Charnwood Forest, of the Carboniferous Limestone and shales, of the Millstone Grit, and of the Permian and Trias. A chapter is also devoted to the superficial geology. The water supply, saline springs, pottery clays, whinstone, ironstone, building stone, and lime are touched upon in a chapter on the economic geology of the area.

The final chapter on the palæontology of the coalfield has been written by Mr. A. R. Horwood, of the Leicester Museum, who has made a special study of the subject.

There are three appendices (1) a glossary of technical or local mining terms, (2) a bibliography extending from Camden's "Britannia" of 1607 down to publications in 1907, and (3) details of all the borings and pit sections accessible, covering 200 pages. Many of these sections were left in manuscript by the late Rev. W. Coleman many years ago, and it is gratifying to find the records of old workings, that would probably otherwise have been lost, thus preserved. The bibliography is very valuable and complete. In the list of authors, by an oversight, the titles of Sir William Fairbairn and Sir Arthur Rücker have been omitted. Sir C. Le Neve Foster's title, omitted in the index, is given correctly in the list of authors preceding the bibliography.

The value of the report is greatly enhanced by a small coloured map of the coalfield and six large folding plates of vertical and longitudinal sections.

Inorganic Chemistry. By E. J. Lewis. Pp. xxv+408. (Cambridge: University Press, 1907.) Price 5*s*.

THIS book, primarily intended for school use, deserves the widest recommendation as a sound and interesting introduction to the subject. It consists of a series of chapters or lessons in which the systematic part of the subject is happily blended with a considerable amount of theory. The treatment is thorough and painstaking without being dry. One is a little surprised, perhaps, after reading of the intended scope and purpose of the work, at the very large number of topics introduced which by tradition have come to be regarded as part of an advanced course. Thus, in part ii., the successive topics treated theoretically are mass action, thermochemistry, basicity of acids, relative strength of acids and bases, isomorphism, osmotic pressure, ionic theory of solution, and the periodic classification. The treatment, though simple, is satisfactory.

For the small number to whom chemistry is to become a life-study, there may be two opinions as to the wisdom of this brief inclusion at an early stage of so many topics of the advanced course, since thereby the latter is apt to be robbed of some of its freshness and novelty, and to lose in consequence its stimulus for the expanding intellect. But in so far as the course of instruction is intended to apply to those, the vast proportion, who will have no subsequent regular instruction in the subject, the method and mode of treatment of the author may be heartily commended. It is, we learn, the outcome of actual class work, modified by experience and the mutual play of the minds of teacher and taught. The author has a belief in the especial value of "outdoor chemistry" as appealing to the interests of the learner, and there is an excellent chapter towards the end on plant respiration and nutrition.

One notices a few important omissions and errors. The use of the spectroscope in chemistry is nowhere alluded to. The mention of argon and its companions in the air should be amplified or omitted. As it is, it contains one of the few mistakes, in the statement that the density of argon is forty times that of hydrogen. Helium is not even referred to by name, surely a remarkable omission for an author addicted to "outdoor chemistry." We read, "The exact specific gravity of oxygen . . . is 15·88 (H = 1). This makes the atomic weight of oxygen 15·88. . . ." But these few blemishes in no way detract from the general accuracy of the treatment.

It is a pleasure to notice a book of this description, for it indicates the serious and important place chemistry is taking in the school curriculum. It deserves a high place, not only in the school, but generally as an excellent introductory first course, understanding by this term not a mere smattering of the kind deemed sufficient only a few years ago, but a course in keeping with the true position of the science as a serious and profitable part of a good modern education.

Altitude Tables. Computed for Intervals of Four Minutes between the Parallels of Latitude 31° and 60° and Parallels of Declination of 0° and 24°, designed for the Determination of the Position Line at all Hour Angles without Logarithmic Computation. By F. Ball. Pp. xxxii+241. (London: J. D. Potter, 1907.) Price 15*s.* net.

THE main purpose of these tables is to facilitate the determination of the position line from an observation of any heavenly body and to eliminate, practically, the chance of errors of computation in the result. When the idea occurred to the Rev. F. Ball he consulted the Astronomer Royal, who consented to the employment of several of the Greenwich computers on the work, under the direction of Mr. Crommelin; the accuracy of the tables is therefore beyond suspicion. The tables are computed for intervals of every four minutes between latitudes 31° and 60° and parallels of declination 0° and 24°, and they enable the observer to determine the position line at all hour angles without having to solve any spherical triangle. This does away with the necessity for logarithmic computations, and so the probability of errors is eliminated. For altitudes less than 70° it is expected that the tables will give results accurate within 12″; for greater altitudes their use is not recommended. The author hopes soon to publish a companion volume for latitudes 0° to 30°.

Problems in Strength of Materials. By Dr. William Kent Shephard. Pp. vii+70. (London: Ginn and Co., n.d.) Price 6*s.*

Whittaker's Arithmetic of Electrical Engineering for Technical Students and Engineers. Pp. vii+159. (London: Whittaker and Co., n.d.) Price 1*s.* net.

To set students of applied science to work numerical problems involving thought in their subject is a good test as to whether they understand the principles involved. It is customary in many classes to associate the laboratory and lecture work with practice in solving such problems, and teachers will find in these volumes many examples suitable for the purpose. The first volume, in addition to 568 exercises, contains some useful tables, but little in the way of worked-out examples to guide the student is given and no answers are provided. The second book, on the other hand, contains seventy-two typical problems fully solved, and a set of answers.

An Essay upon Disease: its Cause and Prevention. By Dr. G. E. Richmond. Pp. 96. (London: H. K. Lewis, 1907.) Price 2*s.* net.

THE main object of Dr. Richmond's little book is to point out the large number of diseases either spread by food or directly due to impurities in food or articles in common use. It is surprising to find a confession in the preface to the effect that "the essay has been written rather hurriedly," and unfortunate that no index is provided.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Radium and the Earth's Heat.

IT has been shown by the Hon. R. J. Strutt and other investigators that the materials composing the surface of the earth contain on the average about 10^{-12} gram of radium per gram, while about one-twentieth of this amount is sufficient to account for the heat lost by the interior of the earth by conduction. Mr. Strutt has therefore suggested that the interior of the earth contains less radium per gram than the surface. It is interesting to calculate what would happen if the whole earth contained 10^{-12} gram of radium per gram. If the specific heat of the interior of the earth is taken to be 0·1, and 1 gram of radium is supposed to generate 100 calories per hour, then it is easy to show that the temperature of the interior of the earth would rise by 10^{-5} degree C. per year if all the heat generated by the radium were used up in raising the temperature.

If the temperature of the interior rose 100° C., it is probable that the rise near the surface would be too small to be detected, so that observations extending over at least ten million years would probably be necessary to detect the effect of the heat generated by radium even if the whole earth contained 10^{-12} gram of radium per gram and all the heat generated went to raise the temperature.

I understand that geologists are inclined to think that the temperature near the surface of the earth has not altered much for many million years, but this is not inconsistent with a rise of 10^{-5} degree C. per year in the interior. It is, of course, quite possible that the specific heat of the earth is considerably greater than 0·1. The high pressure in the interior probably makes the specific heat larger than at the surface.

HAROLD A. WILSON.

I MENTIONED the possibility which Prof. Wilson discusses in my original communication on radium in the earth's crust in the Royal Society's Proceedings; but he certainly shows that it is more worthy of attention than I then thought it.

On this theory it becomes necessary to suppose that the primary stock of radio-active material in the earth—uranium—has not been in existence for a longer time than is required for the attainment of thermal equilibrium by conduction, for we know that the uranium is wasting away, and unless the supply is replenished it is clear that the gradient of temperature must diminish, instead of increasing as Prof. Wilson supposes. We cannot at present form any notion as to how the uranium could come into existence, so that any further development of the idea would have too little contact with ascertained fact to be of much value.

I will take this opportunity of mentioning an alternative theory, which has the advantage of being amenable to experimental test. If we suppose that the rate of transformation of uranium is much diminished by increase of temperature, the quantity of radium and of all the other products will be diminished too, and with it the general rate of heat production inside the earth.

The effect of heat on radium and its products has no direct bearing on the problem. Everything is governed by the primary slow transformation—that of uranium.

There is no experimental evidence on this question so far as I am aware. It could probably be best attacked by comparing the ratio of formation of uranium X at various temperatures. The amount of uranium X which had grown in the course of a few days could be determined by β-ray measurements, which might be made after cooling. R. J. STRUTT.

Sunnyside, Cambridge, February 13.

Ground Ice.

I SEE in your issue of January 30, p. 295, a letter from the Rev. John J. Hampson asking some questions on the subject of ground ice. I should like to say that my father, the late Prof. James Thomson, read a paper on this subject at the Natural History and Philosophical Society of Belfast on May 7, 1862, and I think his paper answers most of the questions. Thus he writes, after reviewing and setting aside several older theories:—"My own view is that the crystals of ice are frozen from the water at any part of the depth of the stream: whether the top, the middle, or the bottom, where cold may be introduced, either by contact or radiation; and that they may also be supplied in part by snow or otherwise: and that they are whirled about in currents and eddies until they come in contact with some fixed objects to which they can adhere, and which may perhaps be rocks or stones or may be pieces of ice accidentally jammed in crevices of the rocks or stones: or may be ground ice already grown from such a beginning.

"That pieces of ice under water have the property of adhering to one another with a continually increasing firmness, and this even when the surrounding water is above the freezing temperature, has been shown in a set of very interesting experiments by Prof. Faraday. I think too that the ready adhesion to the bottom, or to ice already anchored there, may possibly be increased by the effects of radiation, but I am confident that the anchor ice is not formed by crystallisation at the place where it is found adhering."

This paper has never been printed *in extenso*, but I hope soon to bring it out in a volume of collected papers written by my father. JAMES THOMSON.

The Stresses in Masonry Dams.

MR. MARTIN at first asserted that my reasoning was wrong on some general principle which I failed to grasp, whereas he has now fallen back on the order of the approximation, and appeals to what he terms an axiom of practical mathematics, which he illustrates by the statement that between 0 and π a parabola can be found "differing but little from sin x." If by the method of least squares a parabola be fitted to sin x, it will be found to differ by more than 30 per cent. from the ordinate of sin x when $x=5^\circ$; whether that difference is material or not depends entirely on what use is to be served by the correspondence.

In the memoir which has led to this controversy I showed that the equation for the stress function V, *i.e.* $\nabla^2\nabla^2 V=0$, was the same for a thin[1] slab and an actual dam. Since writing the paper I noticed that the third equation for the stresses was *apparently* not the same. I now see that this is only in appearance, for the terms which have a coefficient involving different functions of Poisson's ratio for the two cases are

$$\left(\frac{d^2}{dx^2}+\frac{d^2}{dz^2}\right)\left(\widehat{xx}+\widehat{zz}\right),$$

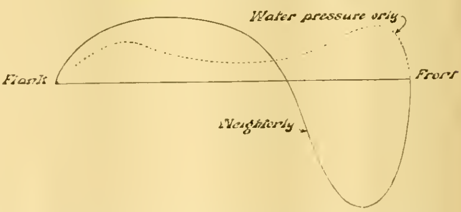
and I find that this vanishes by means of the differential equation for V. Hence, as I stated in my memoir, thin plates can be used to find experimentally the stresses. Mr. Martin is therefore quite correct in his views on this point, although I cannot still agree with his demonstration of the principle.

There are, however, far more vital criticisms to be made of the memoirs recently read before the Institution of Civil Engineers than the mere question of whether the stresses in a slab and an indefinitely long dam differ by 10 per cent. or 20 per cent. A very little experimenting will suffice to show that dams when they collapse go by *stretching*, and partly at points where there may be no tension at all. The strains measured by Messrs. Gore and Wilson are not those in a real dam at all, and if we now accept the view that the stresses are the same, then we must ask Mr. Martin to allow that their stretches differ by 30 per cent. from those in an actual dam.

It was this point which I endeavoured to bring out in the criticism of the paper to which Mr. Martin has referred. If their strains correspond to those of a real dam, then their stresses differ widely; if their stresses are correct, then their strains, upon which ultimately rupture depends, will be very different from those of the actual dam. I must leave Mr. Martin to choose his own horn of the dilemma.

Again, there is another point which is physically very obvious. If a dam, reservoir empty, were split up by a series of vertical divisions parallel to its length, each plate would be of different height, and compressed under its own weight would be subjected to a different squeeze at the base of the dam. To bring these vertical sheets into contact at the correct points it is needful to suppose shear over the vertical planes at the base of the dam. In other words, there must be a distribution of shear over the base of the dam due solely to its own weight. Since the total shear over the base is zero, this distribution of shear, if the extremity of the toes be vertical, must take some such form as is shown in the diagram. Our experiments at University College showed that this base shear due to the weight of the dam only was as important as, and probably more important than, the distribution of shear due to the water pressure.

SHEAR CURVE ON BASE



There is no evidence at all that I can see in Sir John W. Ottley and Dr. Brightmore's recent paper that they have paid attention to this point. They speak of the "original vertical lines on the model," and of measuring the displacement of these lines from "vertical lines on the glass." They speak of the return of the vertical lines on the model to the vertical lines on the glass on the removal of the water pressure. It would appear, therefore, that they have only measured the slide due to water pressure. But to deduce the stresses in the dam they must have the total shear, that due to the weight as well as that due to water pressure. I can find no evidence in their paper of any determination of the shear due to the weight of the dam. They say that the shear along the base is uniformly distributed. This, as Mr. Pollard and I showed in our memoir of last July, is *roughly*, but only roughly,

[1] Only thick plates can be properly used in dam experiments, for thin plates buckle and require a side support which destroys accuracy of experimental result. Even Messrs. Wilson and Gore's plates were at the toe as thick as they were broad.

true, if we confine our attention to water pressure. It is not true, and the base shear actually changes its sign, if the weight of the dam be taken into account as it must be. That there is no *tension* in dams of the Assuan and Vyrnwy types in the outer toe we showed in our memoir, but there is *stretch*, and on this final rupture in part depends. The existence of this stretch is also indicated, although not referred to, in the measurements of displacement given by Sir John Ottley and Dr. Brightmore. I may have misinterpreted these authors' mode of experimenting, but I can find no evidence in their paper of the manner in which they deduced the shear due to weight only, and without this knowledge I venture to think that the whole of the superstructure they base on a uniform distribution of shear fails to find any adequate foundation.

The Inheritance of "Acquired" Characters.

I am loth to take part in barren controversy on this subject again, but I feel it is really necessary to say a few words in reply to the letter of "A. D. D." in Nature of February 13. When that gentleman refers to the slightly dogmatic tone of his original article he is not doing himself justice; the article was as dogmatic as it could possibly be. Now he asserts that there is no sense in the distinction between acquired characters and innate ones with regard to inheritance, that all characters are both acquired and innate. This in the accepted meaning of the words is simply untrue. If a man takes a summer holiday and becomes sunburnt, the colour of his skin is an acquired character; a negro's colour develops without exposure to the sun; he is brown (not black) when he is born; that is an innate character. The supernumerary toe in a Dorking fowl is an innate character; it is not acquired in the accepted sense of that word. Acquired characters are those changes in the individual which are due to a change of external conditions, *i.e.* of stimuli; innate characters are those which develop without any stimulus, except what Dr. Reid calls the stimulus of nutrition.

When Dr. Reid says that a scar on the nose due to injury is as much innate as the nose itself he is merely quibbling; he means, I suppose, that the scar could not be formed if there was not an innate power of producing a scar in healing a wound. But the only important point is that the scar is the consequence of a wound as well as of the innate qualities; the nose is the consequence of innate qualities only. "A. D. D." appeals to Dr. Reid, but Dr. Reid has most distinctly recognised the distinction which "A. D. D." denies. They may be left to neutralise each other.

J. T. Cunningham.

Technical Research and the College System.

Since I made the proposal, some time ago (*Chem. News*, vol. xxxix., p. 2, and vol. xl., p. 230), that research boards should be instituted in our technical colleges, with the object of supplying the college departments with subject-matter for research of a more or less technical nature, and at the same time of keeping in touch with the old students, I have had the opportunity of discussing the matter with men who occupy important posts in the technical world. They generally hold the opinion that some such scheme is urgently needed.

Many observations are made in works and works' laboratories which for several reasons cannot be properly investigated within the factory, but are yet admirably adapted to serve as subjects for scientific investigation in the laboratories of our technical colleges. Research of such a character would be not only of real educational value to the students, but serve a special purpose in giving useful preliminary training in the investigation of problems such as they are likely to encounter in real life.

The attitude of teachers in our colleges towards such questions has been recently stated by Dr. M. O. Forster. He acknowledged that, as a teacher, it became more and more clear to him that professors ought to be educated in technology. As I previously pointed out, the suggestion, which he again brings to the front, that manufacturers should supply problems for the consideration of young chemists in the college, is one which can hardly be met in practice. The suggestion that manufacturers should supply raw materials for such trials is one that could easily be dealt with through ordinary channels if, and when, the subject-matter for research was available.

The suggestion that members of the college staff should enter the technical world for a time may be open to objection. Dr. Nichols, perhaps rightly, says that they could only return and "bring back to the students, and rehash to them, what was daily becoming obsolete." On the other hand, they would undoubtedly benefit from contact with the outside world, especially in acquiring broader ideas and in realising the way in which constant development occurs in technical processes.

I think it may be held that there is no training in our technical colleges, taken as a whole, which can compare with that given in the medical schools. Here the students actually come in contact with the work they will ultimately be engaged on in their daily routine, viz. the study of abnormal cases. Even in the departments of our more recently built colleges, which are almost small factories in their way, these necessary conditions are in the majority of cases still absent. The course simply deals with the routine work of the factory, as represented by everyday operations. This is equivalent to supplying medical students with a set of perfectly healthy men for examination, an example which well illustrates the point under consideration, for in both cases the students go out into the world to engage in actual practice. Medical men trained on these lines would hardly be tolerated by the public, yet the manufacturer is expected to receive students so trained with open arms.

To meet the conditions obtaining in the technical world, I have proposed that in every college of standing there should be constituted a research board composed of members of the staff, with possibly a few old students as advisory members.

Past students would have the opportunity to submit to these boards subject-matter for research arising out of their actual observations, and of such a nature that it can be freely investigated in a college laboratory by picked students, working under the supervision of the board. The results, if satisfactory, would be published under the names of the old and present students from the college address.

In this way colleges would be supplied with the subject-matter now so urgently needed, and the old students would be kept in touch with their college in the best possible way.

The college staff would at the same time be relieved to a great extent from the burden of supplying subject-matter of a semi-technical nature, which, to be of real value, can only be suggested by those who are acquainted with modern technical problems.

The results of some such scheme might form the basis for grants from the Government in aid of research, and also supply a rough means of testing the comparative value of the training of the colleges.

I venture to put this matter forward for discussion. It is vitally necessary that a link between the colleges in this country, and the technical world should be found. On this point everyone is agreed. I fancy that some such link may be found in the above scheme.

Occasional lectures by old students who have specialised should be given at intervals during the session with the object of interesting students in modern technical developments.

Such points as these might be brought forward, in a more prominent way, by a federation of old students' associations, which should accomplish good work in many directions.

W. P. Dreaper.

Quilter Road, Felixstowe.

A Variation in Amœba.

While looking at some *Amoebae proteus* received from Mr. Thomas Bolton, I noticed a condition of the protoplasm of several specimens which I cannot remember to have seen before. The ectosarc was deeply striated, the lines extending some distance into the endosarc, wherever pseudopodia were not being put forth. On the formation of the latter the striæ disappeared, but again became visible if the pseudopodia were withdrawn. Perhaps some reader of NATURE who has studied these protozoa may be able to tell me whether these striæ are commonly met with (in which case lack of power of observation has caused me previously to overlook them), or whether they may be pathological, resulting from some debility in the organism. Certainly the Amœbæ in which I noticed the striated protoplasm seemed to be as lively as any without it. Like all those whose business it is to teach elementary biology, I have examined hundreds of Amœbæ, but to-day for the first time I saw the condition described. No text-book in my possession refers to or figures it. I shall be happy to send a drawing to anyone who may wish.

Eton College, February 12. M. D. HILL.

An Alleged Originator of the Theory of Atoms.

MOCHUS OF SIDON, the alleged precursor of Demokritus, is not so unknown to historians of science as Prof. See seems to think (February 13, p. 345), nor is Strabo the only ancient writer who alludes to him; see, for instance, Josephus, "Antiquities," i., 3, 9. But nobody takes him seriously. The book of Mochus is one of the numerous literary forgeries which appeared in Alexandrian times. So far as I can find, it is not mentioned by any of the doxographic writers, so it is probably not much older than the time of Posidonius. J. L. E. DREYER.

Armagh Observatory.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

V.—*Avenues* (*continued*).

SO far I have not referred to the avenues at Shap. Mr. Lewis, in a memoir "on the past and present condition of certain rude stone monuments in Westmorland,"[2] gives extracts from several authorities showing that in the long past these avenues were not inferior to any in Britain.

Thus Camden (middle of the sixteenth century) writes:—"Several huge stones of a pyramidal form, some of them 9 feet high and 4 feet thick, standing in a row for near a mile, at an equal distance, which seem to have been erected in memory of some transaction there which by length of time is lost." Dr. Stukeley, writing about the middle of the last century, says:—"At the south side of the town of Shap we saw the beginning of a great Celtic avenue on a green common; this avenue is 70 feet broad, composed of very large stones set at equal intervals; it seems to be closed at this end, *which is on an eminence* and near a long flattish barrow with stone works upon it, hence it proceeds northward to the town, which intercepts the continuation of it and was the occasion of its ruin, for many of the stones are put under the foundations of walls and houses, being pushed by machines they call a 'betty,' or blown up with gunpowder; . . . houses and fields lie across the track of this avenue, and some of the houses lie in the enclosure; it ascends a hill, crosses the common road to Penrith, and so goes into the cornfields on the other side of the way westward, where some stones are left standing, one particularly remarkable, called the 'Guggleby' stone[3] . . . . I guess by the celebrity and number of the stones remaining there must have been 200 on a side" (he says the interval between the stones was 35 feet, which would give about 7000 feet, or nearly a mile and a third, or, allowing for the thickness of the stones themselves, a mile and a half, as the length of the avenue); "near them in several places are remains of circles to be seen of stones set on end, but there are no quantity of barrows about the place, which I wonder at." Gough, in his edition of Camden (1806), says:—"At the south end of the village, on the common near the road-side [on the east side thereof] is an area upwards of half-a-mile long and between 20 and 30 yards broad, of small stones; and parallel to the road begins a double row of immense granites, 3 or 4 yards diameter, and 8, 10, or 12 yards asunder, crossed at the end by another row, all placed at some distance from each other. This alley extended within memory over a mile quite through the village, since removed to clear the ground; the space between the lines at the south-east end is 80 feet, but near Shap only 59, so that they probably met at last in a point. At the upper end is a circle of the like stones 18 feet diameter." This description is evidently taken by Gough from the "History and Antiquities of the Counties of Westmorland and Cumberland," by Joseph Nicolson, Esq., and Richard Burn, LL.D. (London, 1777), an extract from which has been obligingly communicated to me by Col. Hellard, R.E., the director of the Ordnance Survey, and from which the remark enclosed in square brackets has been taken.

Mr. Lewis informs us that "Camden also mentioned an ebbing and flowing well, which Gough said was lost, and that its peculiarity was purely fortuitous; still it might have been used for the advantage of the priesthood who probably set up the stones. . . . From the descriptions already quoted it would seem that the avenue ran northerly or slightly north-westerly."

With such assiduity were these memorials of the past removed that when the Ordnance survey was made the final examiner recorded in the parish name-book for Shap (1858):—"No one person in the parish of Shap can point out the site of the old avenue of granite stones, or can tell whether the small spot well known as 'Karl Lofts'[1] is the S. or N. end of the Monument. It is most likely the N. end, as about ½ a mile S. is a portion of a circle still to be seen, composed of huge granite boulders, and which probably is the southern turning of the Avenue. It would appear to have been preserved in Doctor Burn's time, but except 2 or 3 boulders, itself and all recollection of it, have faded from Shap."

In spite of this, I think it has been possible to make out the position and direction of the avenues from the few stones shown on the Ordnance 25-inch maps which Col. Hellard has been good enough to send me. Taking the stones of which at least three are in the same straight line, we get two avenues crossing to the E. of the turnpike and to the south of the village, as stated in the preceding descriptions. As measured on the 25-inch Ordnance sheet, the azimuths are S. 19° E. and S. 40° E. From measurements of the contours on the 1-inch map, the elevation of the horizon is about 1° 10′ in each case.

These data give us declinations 32° 32′ S. and 25° 54′ S. respectively.

In bringing together the information available about avenues, I have been greatly struck by the existence of several with an orientation of S. 20°–30° E. The first of this series which I came across, on the ground, were those at Challacombe, an imposing monument once consisting of eight rows of stones with an orientation of N. 23° 27′ W., or S. 23° 27′ E. ("Stonehenge," p. 158). The rows might have been used in the south-east direction to observe the rising of a southern star; on the other hand, in the north-west direction, they might have been aligned on the setting of Arcturus, warning the summer solstice sunrise in 1860 B.C.

As this date was near to those suggested by the

[1] Continued from p. 251.

[3] Twenty-six chains S.W. of St. Michael's church. It is about 8 feet high, of a wedge-like or conical shape, placed upright with the heavy end uppermost. (Ordnance surveyor's note.)

[1] About 47 chains S. by E. of St. Michael's church.

other Cornish and Devon monuments, I thought the north-west use was more probable for these avenues and other less imposing ones on Shovel Down with nearly the same direction.

The more recent inquiries, however, suggest that in this I was wrong. In the first place, the evidence now afforded by Mr. Falcon regarding the Assacombe avenue shows that, like those at Merrivale, the look-out to the rising-place was up hill. Again, as at Merrivale, oriented to the rising of the Pleiades, the western end has two large monoliths, ending the two lines of stones, and a single sighting stone at the eastern end is placed *between* the lines.

Now these are the conditions at Challacombe if we assume a south-east use; the view is up hill, and the directing stone is at the eastern end.

I next proceed to give a list of the avenues at present known to me which are roughly parallel with those at Challacombe, and where, possibly, southern stars were in question; curiously enough, this condition applies to the Kennet avenue at Avebury, and to those at Borobridge and Shap.

Photo. by Prof. Thorpe.

(Other alignments at S. 22° E. and S. 28° E.)

Shap, Westmorland, lat. 54° 33′ *N.*
Direction of avenue S. 19° E., horizon 1° 10′, dec. 32° 32′ S.

Crug yr Avan Avenue, S. Wales, lat. 51° 40′ *N.*
S. 23° E. and S. 24° E., sea horizon.

With regard to this last avenue, the Rev. J. Griffith informs me that the "stone of honour" ("directing stone"), now recumbent, is at the southern end, and that the land rises in that direction; it would have been on the sky-line as seen from the north end of the avenue.

It is as well to point out at once that some of the monuments included in the above list are the most remarkable in Britain. Challacombe is the only multiple avenue that I have seen in these islands which approaches those in Brittany. The south-east avenue at Avebury was, I take it, the most important feature at one time of that elaborate temple; while, again, the stupendous stones which I think are the remains of an avenue at Borobridge are among the largest monoliths in Britain. The remains at Shap I have not seen, but an avenue nearly a mile long and 70 feet broad, according to Camden and Stukeley, is certainly out of the common.

What, then, might have been the use of these avenues? If they were erected to indicate the rising place of a southern star, the only important one they could have dealt with was α Centauri, and that between B.C. 3000 and B.C. 4000. I give approximate dates where the measures are sufficient to enable me to do so.

Challacombe	D.c. 31° 7′ S.	...	3600 B.C.
Avebury	31° 34′	...	3500
Borobridge	32° 15′	...	3400
Shap	32° 32′	...	3400
Shovel Down	34° 46′	...	2900
Crug yr Avan ...	36° 00″	...	2700

Now if we take 3500 B.C., that is some thousand years before the time I have suggested to be indicated by the stellar alignments connected with the Cornish circles. This raises several interesting questions. Why have we circles in Cornwall and practically no avenues? Why have we avenues practically without circles in Brittany?

Was there a swarm of avenue builders who preceded the swarm that built circles?

In this connection it is worthy of notice that in my "Dawn of Astronomy" I made out that there is a series of Egyptian temples oriented to α Centauri, one of them being the Memnonia at Thebes; and long avenues, generally of sphinxes, were associated with all these temples, while circles were unknown.

Another point is connected with the rise of the star and its use as a warner.

The rise of α Centauri would be preceded shortly by that of β, almost in the same azimuth.

At the time in question, 3500 B.C., they would serve as warners for the November sunrise, which was long afterwards accepted as the beginning of the year by the Celts.

Further, at the dates in question there were no first-magnitude stars rising near the north point of the horizon, as Arcturus and Capella did afterwards, by which the lapse of time during the night might be measured.

The two stars in the Centaur might have been used in this way, but their usefulness would be much restricted owing to the short time they would remain above the horizon.

It is well to note that while the nearly southerly avenue is accompanied at Avebury by a May-year alignment, the second avenue at Shap seems to have been a solstitial one, the sunrise at the Winter solstice being in question. This, however, cannot be considered certain until local observations of the height of the horizon have been made.

Mr. Goddard (NATURE, February 6) has raised objections to my statements concerning the Avebury avenues on the ground that in some of the old descriptions, given while many more stones were standing, some are indicated placed in relation to the road passing through the southern part of the bank, as it exists at present, and quite out of the line of the Kennet avenue indicated by the stones shown on the Ordnance map. If the stones once near the road were associated with those shown on the Ordnance map, there would be no avenue at all in the sense I have always used that word in these notes, but a twisty road having no possible astronomical significance, and, I may add, no resemblance to the Beckhampton avenue, of which all the recorded stones are in the same straight line as near as we can now say; or to any of the others in the table I have given above.

It may be, indeed, that Stukeley was led into his snake theory by attempting to marry these two sets of stones, for he sees a snake even at Callernish, the perfectly straight avenue of which fortunately remains.

"I saw another at Shap, in Westmorland. . . . There is another, as I take it, at Classeness, a village in the island of Lewis between Scotland and Ireland. I took a drawing of it from Mr. Lwydd's travels; but he was a very bad designer . . . a part of the snake remains going from it, which he calls an avenue. He did not discern the curve of it any more than that of Kennet avenue which he also has drawn in the same collection as a straight line."[1]

If the conclusions I have expressed above be confirmed, namely, that Avebury was a going concern a thousand years before anything that now remains of Stonehenge was set up in its present position, or the avenues laid out, the use of the Kennet avenue to watch the rise of α Centauri as a warner of the November festival (while the sunrise in May was provided for in the Beckhampton avenue) ceased at least 4000 years ago. There has been ample time, therefore, to build the bank, to leave openings for wheeled traffic and to set up stones in many places. Indeed, the stones may have been removed from the avenue when the bank was built. That the bank came long after Avebury was first in use was, I take it, well known to Stukeley, as the following extract shows:—

"When Lord Stowell, who owned the manor of Abury, levell'd the vallum on that side of the town next the church, where the barn now stands, the workmen came to the original surface of the ground, which was easily discernible by a black stratum of mold upon the chalk. Here they found large quantities of bucks' horns . . . there were very many burnt bones among them. They were the remains of sacrifices."[1]

Mr. Goddard does not seem to have read my previous notes carefully. I never imagined the Kennet avenue going "over the bank and ditch," but going to the southern circle *before the mound was built*, as the Beckhampton went to the other, as a *via sacra*, throughout the whole length of which the rising star could be seen. Of course, the existence of the bank would have prevented any star rise being seen from the circle along the southern horizon, and what often happened in Egypt suggests that the bank was built because the avenue had become useless.

That the Kennet avenue was once used as a *via sacra* to observe the rise of α Centauri as the morning star warner of the November sunrise is all the more probable since the avenue from the southern end of the Kennet avenue to the "sanctuary" was an alignment to the November sunrise itself so far as can now be made out.

Since writing the above I have received from Captain Devoir, of the French Navy, some admirable surveys of several of the Brittany monuments. In one

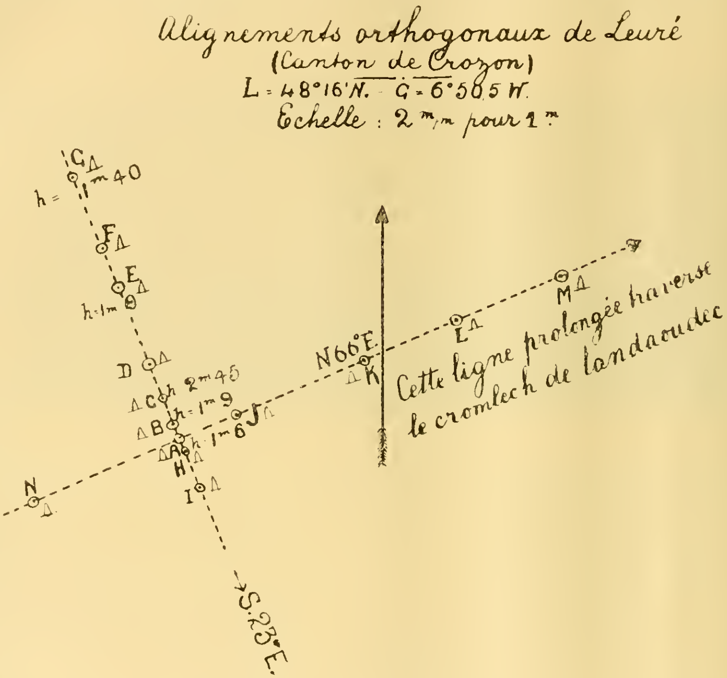

FIG. 17.—The alignments at Leuré from Captain Devoir's observations.

[1] Stukeley, "Avebury," p. 62.

[1] Stukeley, "Avebury," p. 27.

at Leuré we have two avenues, one S. 23° E. and another N. 66° E. (Fig. 17), avenues therefore practically parallel to the two at Avebury, and doubtless used for the same purposes.

NORMAN LOCKYER.

A STUDY OF THE RIVER TRENT.[1]

THIS little book is a clearly written popular account, in part amplified, and in part—rather unfortunately, we think—abbreviated, of the author's presidential address to the Lincolnshire Naturalists' Union. It deals with the geological structure and history of the Lindsey division of Lincolnshire, especially in relation to the vicissitudes, actual or supposed, of the river Trent.

The author is not the first, nor is he likely to be the last, to try conclusions with the intricate story of the Lincoln Gap, that sharp and sudden breach through the escarpment of the Lower Oolites by which the little strike-river, the Witham, abruptly doubles across into the fenlands of the Oxford, Ampthill, and Kimeridge clays, and so reaches the Wash.

Since the publication in 1862 of Jukes's epoch-marking paper on the river valleys of the south of Ireland, in which the cardinal principle of river-capture was enunciated, the Trent and its anomalous course has furnished a theme and an illustration to writers on our British rivers. Ramsey used it, Mr. Jukes Browne added much additional evidence and gave greater definiteness to our conceptions of the potentialities of river-adjustment, and Prof. Davis, in his splendid contribution to evolutionary potamology, adopted and amplified Mr. Jukes Browne's views. Still later Mr. Burton further extended the study of the Trent, and furnished data inaccessible except to a Trent-side resident. The earlier chapters of his book are devoted to an exposition of Prof. Davis's work, and his very convenient terminology is explained with all necessary clearness, though the general reader for whom the book is written will no doubt be puzzled by the reference without the necessary definition to a "peneplain."

The author attributes over-much of the levelling of the great plains of the Jurassic clays to the Trent, and seems to imply that while these valleys were in process of formation the escarpments by which they are bounded stood where we now see them, a confusion which he shares with many recent writers, who fail to recognise that escarpments are incessantly receding. On the other hand, it is satisfactory to find that he takes due account of the possibility that the Trent may have been captured by the Humber drainage in pre-Glacial times, have been restored to its primeval course through the Lincoln Gap in consequence of an ice-barrier across the Humber, and again in post-Glacial times re-captured by the Humber system, though not so decisively but that in seasons of flood it swept again across from the old elbow of capture at Newark and discharged its waters into the Wash. The Romans controlled this propensity by the erection of extensive floodbanks, but the degenerate moderns neglected to keep them in repair, so that in 1795, and twice in more recent times, the river has temporarily re-occupied its old course.

The Ægir, Gainsborough, October 12, 1904. Showing the after-waves, locally called "The Whelps." From "The Shaping of the Lindsey and Trent."

The later history and activities of the Trent are well described, and a special word of commendation must be bestowed upon the splendid half-tone illustrations, and in particular the two pictures of the bore or Ægir ("Sea-tempest is the Jötun *Ægir,* a very dangerous Jötun; and now to this day, on our river Trent as I learn, the Nottingham bargemen, when the river is in a certain flooded state . . . call it *Eager*; they cry out 'Have a care, there is Eager coming.'"—Carlyle). These are, we think, the finest pictures of this phenomenon that we remember to have seen. The excellence of the half-tone illustra-

tions stands in strong contrast to the very inadequate and unsatisfactory diagrams; that representing a section from the Trent valley to the coastal plain is about as misleading to the general reader as such a thing could be made; the vertical scale is nearly *one hundred times* the horizontal, and the dips are proportionately exaggerated, from the actual 2° or 3° to something like 65° or 70°. It is an aggravation of the offence to waste fine plate-paper on such a monstrosity.

Despite this and some minor blemishes the book is an interesting one, and should do something to stimulate an interest in the scientific study of the scenery of a region that is replete with beauty and charm.

THE SUN AND THE CLOCK.

LAST week a Bill was introduced into Parliament by Mr. R. Pearce, M.P., having for its object the better accommodation of the hours of business to the hours of daylight, to be accomplished by a device which, though simple in appearance, would in practice prove very troublesome. Custom and habit have so arranged the hours of the working day that the general tendency is to use more hours in the afternoon than in the morning. This unequal division is attended with many inconveniences, one of which is that we use artificial light for more hours than would be necessary if we would consent to divide our time more symmetrically with reference to the sun's meridian passage. It is not impossible but that greater economy and more healthy conditions for labour might follow, and so far as this is the purpose of the Bill, which owes its initiative to Mr. Willett, we can all sympathise. It would be an evident advantage to employ sunlight, which costs nothing, in the place of gas and electricity, which are expensive luxuries, and it is probable that it is this obvious benefit which has enlisted the good will of many well-known authorities to what on close examination seems to be rather a childish measure.

Mr. Pearce, who holds a brief for Mr. Willett, is anxious to begin the day earlier; he does not propose to curtail the hours of labour in any way, but simply to shift the hands of the clock so that for part of the year noon on the clock dial would not coincide with the transit of the mean sun. Since it is the clock and not the sun that regulates all affairs of business or pleasure, suitable arrangements could be made, but whether those proposed by the Bill are the most satisfactory is an open question. The Bill provides that on each of the first four Sundays in April standard time shall be advanced twenty minutes, making the clock gain on the sun eighty minutes in the course of the month. Ordinary office hours would therefore begin at 8.40 a.m. instead of ten o'clock, and, of course, end at 3.40 p.m. instead of five o'clock, as reckoned by the mean sun. In this way there would be approximately symmetrical distribution of the day on both sides of the meridian. In winter, when we use all the daylight available, nothing is gained by advancing the clock on solar time, and it is proposed to bring the clock and sun again into coincidence by putting standard time back twenty minutes on each of the first four Sundays in September.

This pushing the hands to and fro on the dial is, we are told, the whole cost of the scheme. Unfortunately, that statement is misleading. The hour chosen for this abrupt dislocation of continuity is two o'clock in the morning, an hour when very few people would care to make the necessary adjustment, and many a man on arriving at the station on Monday morning would find that his train had been gone twenty minutes, or that he had to wait twenty minutes before it was due, according as the time of the year was spring or autumn. This continual interruption of uniformity would be intolerable. One can more easily accommodate himself to a burden, however grievous, if the pressure be constant, than to the petty irritation arising from frequent change.

But we would seriously ask the supporters of Mr. Willett's scheme where is the necessity for this aggravating policy of perpetual alteration? We suspect, if we could get at the truth, that this constant interference is a concession to inherited instinct, and a desire not to depose the sun too hurriedly from that position of preeminence which he has hitherto enjoyed. The author of the scheme manifests a cautious hesitancy lest some mischief should arise from separating the clock and the sun by too great an interval, and thinks to appease the possible objections of more conservative minds by pointing out that it is only for half a year that the clock is wrong. It looks as though he were afraid of his own measure, for what possible advantage can accrue from putting the clock back in September? If the measure be wise and acceptable, why not boldly alter the time one hour by one and a final interruption? In summer we should get nearly the same advantage as that claimed for this policy of pin-pricks, and in winter we should be no worse off.

It is quite a different question to ask, is such a measure desirable? or, further, whether the proposed remedy is the most judicious? It might be more satisfactory to effect some change in our habits and customs more in line with those that obtain on the Continent or in India. The hours of business or of social functions may in those countries be dictated by a desire to avoid heat and glare, but the point is that we should do well to follow the example of those who have considered the sun as a factor in regulating their affairs. Such ends cannot, however, be accomplished by legislative action, but by the decision of Society with a big S. To ask a man to dine at six instead of at eight would be a drastic revolution that few would feel themselves competent to inaugurate.

The Astronomer Royal has raised a point of great importance, at the same time hinting that the authors of the scheme have thought too much of the convenience of their own order and too little of that of the great majority of the public, whose daily life begins far earlier than Mr. Willett seems to imagine. Where life is strenuous, in factory or workshop, in dock or on railway, toilers quit their homes soon after five o'clock by the sun. It is easy to conceive that earlier rising would entail a hardship. Those who minister to the comfort of Mr. Willett and his class accomplish much before the more leisured day begins. The handling of perishable articles and the distribution of food in great centres of population goes on all night. To shorten that night by an hour or more to get the same amount of work done in a shorter time would tax resources to breaking point.

There is, too, another consideration which is not without its weight. England has succeeded in securing the recognition of the Greenwich meridian as the origin of time throughout the world, and with something like uniformity time is reckoned from that meridian. Is it desirable to commence an agitation which involves a breach, though only nominal, of that uniformity? We have admitted that there are some advantages to be derived from the adoption of the scheme, but when weighed against the disadvantages arising from a fretful disorganisation, it may be "better to suffer the ills we have than fly to others we know not of."

IRISH FISHERY INVESTIGATIONS.[1]

THESE two volumes form the third and fourth reports upon the scientific investigations into fishery questions, which have been conducted for the Irish department responsible for the fisheries by Mr. E. W. L. Holt, the scientific adviser. They fully maintain the high standard set by their two predecessors both in the nature of their contents and in the manner in which they are printed and illustrated.

It is a matter for congratulation that the Irish Government has adopted so comprehensive and intelligent a view of the manner in which such investigations should be planned and carried out, and it is to be hoped that any narrow and uninstructed criticism, such as Mr. Holt appears to suggest has been made upon the work, may not be allowed to interfere in any way with its progress. "In my last report," says Mr. Holt in the volume for 1904, "I endeavoured to make it clear that the papers in the appendix, even if couched in unavoidably technical language, did actually contain information essential to the possibility of success in attack on practical fishery questions. The endeavour seems to have failed to some extent, but perhaps in the course of time it may be more generally surmised that if a due understanding of the minutiæ of habit and environment is of some use in agriculture, so may it also be in the direction of piscatorial enterprise, and that because an animal has an unfamiliar name it does not necessarily follow that it is of no importance."

The kind of criticism of which Mr. Holt here appears to complain would seem to be similar to that to which the work carried out by Prof. Herdman in the Irish Sea has recently been subjected. At a meeting last year of the Lancashire and Western Sea Fisheries Committee, a member of the committee, the Rev. J. E. Green, is reported by the *Liverpool Daily Post and Mercury* to have said "he thought they ought to manage to cut down the expense of the annual report. The printing came to about 70*l.* a year, and there was a quantity of verbiage in it which was not easily understood. For instance, they had a long list of Latin names which he had taken the trouble to try and translate, with the assistance of the latest work of Lewis and Short, but he had failed to do so. If the names were to be inserted, the translations should also be put by the side, for they were absolutely useless unless the Lancashire fishermen happened to be graduates of the Liverpool University."

The picture of the diligent committeeman seeking a translation of the specific names used by naturalists "in the latest work of Lewis and Short" has its humorous side. We fear his method might even be somewhat misleading in the case of such a simple specific name as *Homo sapiens*. Both Mr. Holt and Prof. Herdman must, however, take comfort from the fact that the difficulty of making the general public, or those who happen to occupy positions of authority, realise the importance of technical biological studies is one which most scientific investigators have to face, and for some unexplained reason is met with in a particularly aggravated form in the case of fishery work.

Mr. Holt's report for 1904 is followed by six, and that for 1905 by seven, appendices dealing with marine work, whilst in each case one appendix is devoted to inland fisheries. Of the former, one only deals directly with fishes, that by Holt and Byrne on the fishes of the Irish Atlantic Slope. This paper contains sixteen additions to the list of the fish fauna of the British-and-Irish area, which have resulted from the operations of the fishery steamer *Helga*.

The Crustacea, a group which is of such great importance from the point of view of the food of fishes, receive considerable attention. Dr. W. T. Calman records forty-eight species of Cumacea from the west coast of Ireland, of which nine are new to science. The latter are carefully described, and the details of their external characters are illustrated in eighty-six well-executed figures.

Mr. Tattersall treats in a similar way the Isopoda and pelagic Amphipoda from the same region, ten new species of Isopoda and four new species of Amphipoda being described and figured. Mr. Tattersall and Mr. Holt add a supplement to their former report on the Schizopoda, and Mr. Stanley Kemp contributes a useful review of the Decapod genus Acanthephyra. Miss Delap's notes on the rearing in an aquarium of *Aurelia aurita* and *Pelagia perla* are also of great interest.

The most important sections in the appendices on inland fisheries are Mr. Holt's reports on the artificial propagation of the Salmonidæ and Mr. Hillas's record of salmon-marking experiments.

The two volumes make it clear that a very large amount of most useful work is being carried out, the value of which will increase at a very rapid rate as the data accumulate from year to year.

NOTES.

In the House of Commons on Monday, Mr. Mallet asked the Secretary of State for War whether he was aware of the public service rendered by a commission of the Royal Society, at the request of the War Office and the Admiralty, in discovering the cause of Malta fever, from which many hundreds annually of our soldiers and sailors on that island until recently suffered; and whether, in view of the importance of this discovery in the annals of preventive medicine, inasmuch as at the present moment the disease had been entirely stamped out, he would consider the desirability of giving the thanks of the Government to the Royal Society for this instance of the successful application of British scientific research? In his reply to this question Mr. Haldane said:—"I am aware of the great service rendered by the commission in question. The commission's investigations and the adoption of preventive measures as the outcome of its recommendations have been followed by the practical disappearance of Malta fever from the garrison of the island. I think that the Royal Society is well aware how genuine is the appreciation of the Government. We owe much to the Royal Society's commission for the successful issue of this remarkable investigation, and for the excellent results which have followed. These results illustrate the enormous importance of bringing science into our business of government."

We announce with great regret that Lieutenant-General Sir Richard Strachey, G.C.S.I., F.R.S., died on February 12 at ninety-one years of age.

The following have been elected honorary and foreign members of the Chemical Society:—A. E. J. Gautier, Paris; A. Haller, Paris; J. W. Hittorf, Münster; J. A. Le Bel, Paris; H. L. Le Chatelier, Paris; T. W. Richards, Cambridge, Mass., U.S.A.; and O. Wallach, Göttingen.

The Paris Academy of Sciences has, says the *Revue Scientifique*, in cooperation with the Minister of Public Instruction, undertaken, at the invitation of Sir Norman

Lockyer, K.C.B., F.R.S., to form a committee of French men of science to assist in securing an important place for science in the forthcoming Franco-British Exhibition.

IT is stated in the *Pioneer Mail* that special subcommittees have been appointed by the Board of Scientific Advice for India to consider and report on proposals which have been submitted for the re-organisation of the Botanical Survey Department and the future organisation of the Economic Products Department.

WE learn from *Science* that Prof. W. Stratford, for forty-one years a member of the teaching staff of the New York City College, died on January 24. Prof. Stratford was a well-known member of the scientific organisations of New York, and was a recognised expert in biological microscopy. In his work in the City College he introduced laboratory methods and developed its museum, enriching it with the fruits of several palæontological excursions to the Rockies.

A ROYAL Commission has been appointed to consider, among other matters, the materials or the processes used in the manufacture or preparation of whisky and other kinds of potable spirits manufactured in or imported into the United Kingdom. The chairman of the commission is Lord James of Hereford, and the members are:—Mr. L. M. Guillemard, C.B., Dr. W. E. Adeney, Dr. J. R. Bradford, F.R.S., Dr. H. T. Brown, F.R.S., Dr. G. S. Buchanan, Mr. J. Y. Buchanan, F.R.S., and Dr. A. R. Cushny, F.R.S. The secretary to the commission is Mr. A. V. Symonds, of the Local Government Board. The appointment of this commission arises out of the difficulties described in an article on "What is Whisky?" which appeared in NATURE of March 8, 1906 (vol. lxxiii., p. 441).

AT a meeting of copper and brass manufacturers, engineers and others, held in Manchester on February 13 (Mr. W. H. Johnson in the chair), it was unanimously resolved to form a Copper and Brass Institute having similar objects to those of the Iron and Steel Institute. It is not the intention of the founders to limit the institute to the copper and brass trades, but to include all those connected with the commercially important non-ferrous metals and their alloys, as lead, zinc, tin, aluminium, nickel, silver, gold, platinum, &c., and their alloys. A further meeting will be held in the Midland Hotel, Manchester, on Tuesday, March 10, at 4 p.m., to which all those interested are most cordially invited. Prof. H. C. H. Carpenter, professor of metallurgy, The University, Manchester, will receive the names of any persons who propose to attend or are interested in the formation of the institute.

THE meteorological observatory on Ben Nevis was again the subject of a question in the House of Commons on Monday, when the Chancellor of the Exchequer was asked whether he could hold out any prospect of a grant towards its upkeep. In the course of his reply, Mr. Asquith said that the only scheme which has up to the present been placed before him is one under which the whole cost of the re-equipment and maintenance of the observatories would be thrown upon public funds, and to this he does not feel justified in assenting. He is, however, quite prepared to consider the question of renewing the Government grant, which was for many years given to the Ben Nevis observatories through the Meteorological Council, provided that an adequate contribution towards their re-establishment and maintenance is forthcoming from other sources.

AT a meeting held in the Transvaal Museum, Pretoria, on January 13, it was resolved to form an association, to be called "The Transvaal Biological Society," with the object of promoting the discussion of scientific problems by biological investigation, to arrange for regular meetings for this purpose, and to publish the proceedings of the meetings. All persons are eligible for membership who are actually engaged in biological investigations and have published at least one scientific paper, or are working on such. Every member is expected to furnish at least one paper each year. The committee for the current year consists of Dr. Theiler, C.M.G., president; Mr. Burtt-Davy, vice-president; and Dr. L. H. Gough, secretary and treasurer. The new society will fill a long-felt want in Pretoria.

PROF. G. K. GILBERT, in his recent report to the United States Geological Survey, stated that the conditions of flow and erosion at Niagara Falls would soon cease to be natural, owing to the large amount of water diverted for industrial purposes. The correspondent of the *Times* at Washington, as we note in that journal for February 14, gives an abstract of the views of Dr. Spencer, of the Canadian Survey, which are far more specific and alarming. Dr. Spencer, it appears, looks forward to the practical disappearance of the American falls, through the utilisation of water-rights already conceded; and the correspondent suggests that Congress would be favourable to the incorporation of an agreement for the regulation of the waters of the Niagara River in the general treaty respecting questions pending between the United States and Great Britain.

IT was suggested by Mr. R. Pohl in a paper read before the German Physical Society in June last that the formation of gas bubbles in the glass of vacuum tubes, described by Mr. A. A. Campbell Swinton in a paper before the Royal Society (see NATURE, April 4, 1907, p. 550), is due to a metallic film caused by disintegration of the internal aluminium electrodes, and that if the aluminium be first completely etched away, then no bubbles are formed in the glass when it is subsequently heated. Mr. Swinton writes, however, to say that these conclusions are disproved by some further experiments recently carried out by him, in which a plentiful supply of bubbles was easily obtained in the glass of tubes which had been excited over prolonged periods by electrostatic induction from outside, and in which there were no aluminium or other internal electrodes to disintegrate and cause the metallic film to which Mr. Pohl attributes the effect.

SEVERAL interesting speeches were made at a dinner of the Physical Society held on February 11 at the Hotel Cecil, when the chair was taken by the president, Prof. J. Perry, F.R.S., and a number of distinguished guests and fellows of the society were present. In the course of some remarks, Sir William Ramsay dwelt on the relations of physics and chemistry. He pointed out that one of the chief difficulties of the chemist at the present time is the solution of the mathematical problems involved in chemistry, and there is a great opening for "tame mathematicians" who will hold themselves at the disposal of the chemist. In response to the president, Prof. E. B. Rosa, of the National Bureau of Standards, Washington, stated that he had been greatly interested in visiting the National Physical Laboratory, and observing the progress that had been made since his last visit five years ago. At the National Bureau of Standards satisfactory headway is being made, and it is hoped that the laboratory will shortly be equal to any national laboratory in the world. In the United States much money is being spent on the science of agriculture, because agriculture is a national asset. Prof. Rosa suggested that England similarly would find it a profitable investment to devote the money spent in constructing one battleship per annum to the National Physical Laboratory instead of preparing for war. In responding to the toast of "The Physical Society," the president dwelt on the importance of research. At the present day there are many science teachers and many compilers of books who do no research. They are well up in the letter of science, but not in the spirit thereof, with the result that their writings lack a most essential quality which can be gained only by actual research. He appealed to the leaders of physical science to attend the meetings of the society, not for their own benefit, but from a sense of duty, for there is nothing so inspiriting to the younger members as contact with men who have carried out important work.

From Mr. F. L. Dames, of Berlin, we have received a catalogue of books and papers on entomological subjects (No. 96, *Bibliotheca Entomologica*).

No. 7 of Irish Fisheries Scientific Investigations for 1906 (1907) contains a report on artificial salmon and trout breeding for the season 1906–7, from which it appears that the total for salmon comes within about 500,000 of that of the previous season, and therefore is by about that number in excess of any previous year.

Two papers on regeneration are included in vol. lxxxix., part i., of the *Zeitschrift für wissenschaftliche Zoologie*. In the first of these Mr. J. Nusbaum describes the processes occurring in one of the polychæte worms of the genus Nereis, while in the second Mr. J. Grochmalicki discusses the regeneration of the lens of the eye in bony fishes. In the case of one particular fish from which this organ had been extirpated, a new lens, differing slightly in form from the original, was developed in 187 days.

In the course of an article on hermaphroditism in echinoderms, published in Nos. 6 and 7 of the *Travaux de la Société Impériale des Naturalistes de St. Pétersbourg* for 1907, the author, Mr. G. Gadd, argues that since this phenomenon is not uncommon in sea-cucumbers, more rare in star-fishes, and almost unknown in sea-urchins, we have a confirmation of the view that it is an attribute of the less highly organised members of the groups in which it occurs.

To the *Museums Journal* for January Dr. H. C. Sorby contributes a paper on the best means of preserving marine invertebrates for museum purposes in such a manner that their natural colouring will be retained. As regards his own private collection, the author finds anhydrous glycerin —covered, when necessary, with a layer of almond oil— the most satisfactory medium, some specimens which have been preserved in this manner for fully five years displaying their tints with even more than normal brilliancy. The chief difficulty in the case of museum specimens would be in the use of large rectangular vessels, owing to danger of leakage.

The *Lyttelton Times* (New Zealand) of December 3, 1907, contains a long summary of the results of the recent scientific expedition to Auckland, Campbell, and other islands lying to the southward of New Zealand. Mr. Speight, geologist to the expedition, claims to have discovered in Auckland, Campbell, Snares, and Disappointment (not apparently the island of the same name in the Low Archipelago, but one somewhere near the others) rocks indicating that these islands once formed a part of the Antarctic continent. The islands have also been extensively glaciated. Of insects, flies and tipulæ are the most numerous, but beetles and dragon-flies were also observed. A linnet-like bird from Campbell Island has not yet been identified; and successful photographs have been obtained of the skua, shag, mollymawk, gull, albatross, and penguin rookeries. On Snares Island the stench from the birds and seals is stated to have been almost intolerable, and the members of the expedition who visited the Campbell group suffered severely from the colds and wind.

A special paragraph in the issue quoted above is devoted to Disappointment Island, which was visited by Dr. L. Cockayne, who devoted special attention to the vegetation. Although the number of species is small, the vegetation as a whole is comparatively luxuriant. Very striking is the large *Aciphylla latifolia*, a member of the carrot tribe, while the male flowers of the orange lily, *Bulbinella rossi*, are conspicuous "The most interesting feature of all is the natural rejuvenation of the vegetation that is going on. Cast your eye over the landscape, and you will see brown meadow dotted with white birds, which slowly but surely kill out all the plant-covering, and patches of vivid green. This latter arises from the presence of the Antarctic burr, or piri-piri, in enormous quantities; and it, a quite rare plant in a virgin meadow, has spread from thence and occupied the new ground, thanks to its colonising power, its spiky fruits adhering to the feathers of the young birds and so being spread broadcast. Here there is a splendid example of a plant of little importance becoming virtually a weed in a virgin vegetation. But finally tussock will resume the sway, and a gradual destruction and rejuvenation of the vegetation must go on, thanks to the mollymawks."

In the February number of *British Birds* the editors discuss certain allegations against the black-headed gull which formed the subject of notice in the previous issue. Without entering into the controversy, we may notice that the allegations have induced two county councils in Scotland to strike gulls of all kinds out of the protected list. In another paragraph the editors refer to the subject of "luminous owls." In their opinion, the luminosity is most probably to be attributed to phosphorescent bacteria derived from decaying wood. It may, however, be due either to a phosphorescent feather-fungus (akin to one known to occur in geese) or to a diseased condition of the oil-gland, whereby the oil is more abundant than usual, and so abnormal in its nature as to become luminous on exposure to the air. Whatever be the true explanation, it is evident that the phenomenon is abnormal, and almost certainly due to the presence of foreign matter on the feathers.

The reports on the botanic and experiment stations and agricultural education in St. Kitts-Nevis for 1906–7, besides reviewing the work for the year, summarise the progress made since the institution of the Imperial Department of Agriculture for the West Indies. The sugar industry has benefited by the introduction of the seedling canes B. 147 and B. 208; cotton cultivation has been developed since 1901, when trial plots were started, until an area of 5000 acres is now planted in the three islands St. Kitts, Nevis, and Anguilla. The cultivation of cacao proceeds more slowly, but gives promise of success. Rubber planting, chiefly with *Castilloa elastica*, is also receiving attention. The records of the experiment plots provide useful data with regard to growing tobacco, varieties of potatoes, cassava, yams, sweet potatoes, and other minor products.

Acting upon the advice of Prof. H. J. Hamburger, it was decided to publish in the *Recueil de l'Institut botanique de Bruxelles* (vol. vii.) the course of lectures on molecular physiology delivered by the late Prof. Errera to students taking the botanical degree in the University. It is primarily a physicochemical course dealing with the properties of fluids and solids, and the special application of the laws regulating their action to various botanical problems. Surface tension of liquids, viscosity, properties of emulsions, circulation of gases and liquids in narrow tubes, and similar phenomena are treated with regard to their bearing in plants, and especially with reference to the two important subjects of osmosis and the ascent of sap in trees. Practical examples of calculations in connection with osmotic problems are given, and the discussion of the various theories put forward to explain the ascent of sap is illustrative of Prof. Errera's lucid exposition.

The *West Indian Bulletin* (No. 3, vol. viii.) contains summaries of several of the papers presented to the famous agricultural conference of 1907. Mr. Gossett points out how valuable Indian cattle have proved in Jamaica; they are said to surpass all others as workers, and to be so remarkably hardy in constitution that they withstand the effects of the climate, of insects, and other pests, besides being able to subsist on coarse grasses and shrubs that other cattle would refuse. Another paper deals with the suitability of Jamaica for breeding horses, mules, and polo ponies. Mr. Cox discusses the prospects of tea production, and concludes that tea is a safe crop for a settler who lives within reach of a factory. Mr. Cousins contributes two papers, one on cassava starch and the other on agricultural education in Jamaica. He finds that cassava starch of high quality and commanding a good price can be produced in Jamaica at a cost which allows a very handsome profit. Other papers deal with Jamaica ginger and with the native timbers. The standard of the papers is very good, and all the authors are very hopeful about the future. They have good reason, for few of our possessions have better agricultural departments than the West Indies.

The second number of the Bulletin of the Imperial Central Agricultural Experiment Station of Japan is to hand, and is in every way an excellent production. One paper deals with the behaviour of nitrate of soda in paddy soils. Nagaoka found some years ago that this fertiliser actually depressed the yields of rice, Sagittaria, and *Juncus effusus* when cultivated, as is usual in Japan, on swampy soils. He considered that the effect was due to denitrification, a process which would give rise, among other things, to poisonous nitrites. It is now shown that this view is correct. Another paper, by Uchiyama, deals with the influence of stimulating compounds such as manganese and iron salts, sodium fluoride and potassium iodide on crops, a subject to which considerable attention has been devoted in Japan. The general conclusion is that manganese sulphate at the rate of 20 kilos. to 50 kilos. per hectare increases the crop, but the actual amount of the increase depends on a variety of factors. The most favourable ratio of lime to magnesia in soils forms the subject of several papers. There is also an important synoptical list of Coccidæ of Japan, with descriptions of thirteen new species by Kuwana. The bulletin is profusely illustrated, and the illustrations are unusually good.

The report of the chief of the U.S. Weather Bureau for the fiscal year ended June 30, 1906, has just reached us. In the department dealing with weather prediction, the distinctive work of the year was the study of atmospheric movements in the United States with the additional light afforded by reports from the Azores, western Europe, Honolulu, and other places, the result of which has been sufficiently encouraging to warrant a still further extension of area. The amazing figures connected with the receipt of telegraphic reports and the distribution of meteorological information were referred to in Nature, vol. lxxvi., p. 300. There has been considerable increase of observing stations of various classes; the number now amounts to more than 4500. The report contains, *inter alia*, observations or summaries for a large number of selected places, and monthly and annual rainfall values for all stations, for the year 1905, the whole occupying 405 quarto pages. At Mount Weather Research Observatory systematic work is carried on in connection with the international kite experiments; the institution possesses a very complete instrumental outfit for the purpose. Among various other useful operations of the bureau, we may mention that efforts are being made to correlate and reduce to a uniform system the teaching of meteorology in the numerous colleges and schools; circular letters on the subject have apparently been addressed to a large number of educational establishments.

An important paper on the smoke from metallurgical works, by Mr. W. D. Harkins and Mr. R. E. Swain, is contained in the Journal of the American Chemical Society (vol. xxix., No. 4). The work which led to the publication of the paper was the estimation of the amount of arsenic expelled from the greatest of the world's smelting works, a plant which has a capacity of 10,000 tons of ore per day, and a production estimated at $11\frac{1}{2}$ per cent. of the world's output of copper. It has been found that not only are the trees and grass in the vicinity of works injured by the sulphur dioxide and sulphuric acid of the smoke, but the grass is also rendered poisonous by arsenic. By the erection of new works with huge settling chambers in place of the long flues of the old works, the loss of animals in the valley became very much greater than before. The velocity determinations and analyses of smoke set forth in the paper were undertaken with a view to determine the real efficiency of the great flues and stack, 300 feet high, built in order to prevent damage to the forests and crops. The velocity determinations were made with a Pitot tube, modified by Captain D. W. Taylor, which was found to give much more trustworthy results than the wheel anemometer. The results of the investigation show that while the great flue may be fairly efficient in causing the copper from the smoke to settle, a considerable amount escapes, while the amount of arsenic given off is very great. The arsenic is chiefly in the form of trioxide, but a small amount exists in the form of trisulphide and in the form of complex minerals containing iron. The dust from the flue near the stack or in the stack itself contains a considerable amount of concentrated sulphuric acid, while that from near the furnaces contains much less. To this sulphuric acid, together with the arsenic with which it is associated, is probably due much of the spotting of leaves which is so common in the vicinity of the works. The action of the flue dust is of far less importance than that of the sulphur dioxide in affecting the growth of plants, but the arsenic of the dust may affect to a greater degree the value of the grasses, since it renders them poisonous.

Messrs. C. Woolliscroft and Son, Ltd., Hanley, Staffs, ask for information as to an electrostatic separator for the purpose of extracting iron pyrites. An expert to whom we referred the inquiry has been good enough to reply that the latest type of electrostatic separator is the Blake-Morscher, which was described in a paper read before the Institution of Mining and Metallurgy by E. A. Weinberg (Transactions, 1905, vol. xiv., p. 169). It is of American manufacture, and can probably be obtained from Fraser and Chalmers, of Erith. Earlier forms are exhaustively described in a paper read by H. C. McNeill before the Iron and Steel Institute (Journal, 1899, vol. lvi., p. 18). Machinery for the extraction of iron pyrites is made by the German "Humboldt Company," of Kalk, near Cologne.

THE *Verhandlungen der deutschen physikalischen Gesellschaft* for December, 1907, contains a communication from Prof. E. Wiedemann, in which he directs attention to two Arabic books of the thirteenth and fourteenth centuries, in the former of which the method of magnetising a steel needle by rubbing it on a natural lodestone is described, while in the latter instructions are given for mounting a needle so magnetised within a wooden fish, which when placed on water heads always to the north. This appears to be the first known mention of the compass, although the matter is treated as if it were common knowledge at the time.

VOL. iv. of "Contributions from the Jefferson Physical Laboratory of Harvard University" contains thirteen memoirs, five of which are from the pen of Prof. B. O. Peirce. Most of these memoirs are reprinted from vol. xlii. of the Proceedings of the American Academy of Arts and Sciences, 1906. There is one, on architectural acoustics, by Prof. W. C. Sabine, reprinted from the *American Architect* for 1900, which well deserves close attention from architects in this country. It is a thoroughly scientific attack on the problem of determining the acoustical properties of a room before it is built. The author describes his measurements of the absorbing powers of walls, screens, furniture, and audience, and shows how the constants thus determined can be used in calculating the amount of reverberation to be expected in a large number of cases. In each case direct measurement confirmed the result of the calculation.

THE report for 1908 of the International Committee on Atomic Weights is printed in No. 335 of the Proceedings of the Chemical Society. From the data here given, and from those cited in previous reports, it is concluded that the entire table of atomic weights is in need of revision. The values assigned to potassium and sodium are too high; those given to chlorine and sulphur are too low, and these constants affect the determination of many others. They depend, however, on the atomic weight of silver, which is probably, but not certainly, as low as 107·88. It is well known that work upon these fundamental constants is now nearing completion in several laboratories, and within a few months it should be possible to enter upon a satisfactory revision of the table, a task which would be unsatisfactory if undertaken now. It is true that the present table contains inconsistencies, but they are small in amount, and are due to inconsistencies in the original data from which the values are derived. Since issuing the last report Prof. Moissan has died, and has been succeeded on the committee by M. G. Urbain. The report being drawn up in November last does not deal with the striking result obtained by W. Marckwald in the case of tellurium, which has been published since; this element has long held an abnormal position in the periodic arrangement owing to its appearing to have an atomic weight greater than that of iodine. According to Marckwald, its correct atomic weight is 126·85, that is, 0·12 unit less than the atomic weight of iodine, so that it now falls into line with the rest of the elements.

A SECOND edition of Mr. Arthur Whiting's "Retouching" has been published by Messrs. Dawbarn and Ward, Ltd.

A SECOND edition of the useful "Handbook to the Vivaria and Fresh-water Aquaria" at the Horniman Museum, Forest Hill, S.E., has been issued by the London County Council. Copies may be obtained through a bookseller, or directly from Messrs. P. S. King and Son, of Westminster; the price of the catalogue is one penny.

MESSRS. CROSBY LOCKWOOD AND SON have published a fifth edition of Dr. Bernard Dyer's "Fertilisers and Feeding Stuffs: their Properties and Uses," which contains also the full text of the Fertilisers and Feeding Stuffs Act, 1906, the regulations and forms of the Board of Agriculture, and notes on the Act by Mr. A. J. David. The new edition has been revised, and its price is 1*s*. net.

OUR ASTRONOMICAL COLUMN.

THE RECENT SPECTRUM AND MAGNITUDE OF NOVA PERSEI NO. 2.—The results of Prof. Hartmann's more recent investigations of the spectrum of Nova Persei No. 2 (1901) appear in No. 4232 of the *Astronomische Nachrichten* (p. 113, February 8). Finding that when the magnitude of the star became less than 10·0 he was unable to photograph the spectrum with the large instrument used in the previous investigation, Prof. Hartmann devised a new spectroscope in which the collimator objective, of 40 mm. aperture and 60 cm. focal length, was made of U.V. glass, and the camera objective was made of quartz, having an aperture of 40 mm. and a focal length of 32 cm.; quartz prisms were employed, and the distance between Hβ and Hδ on the plate was 4·6 mm. This spectrograph was used in conjunction with the 80-cm. refractor, and a good spectrum was obtained with $8\frac{1}{4}$ hours' exposure on October 15 and 18, 1907, when the Nova's magnitude was 11·4. The main feature of this spectrum is its similarity to the spectrum of the Wolf-Rayet star B.D. 35°.4001. In both spectra the brightest line is at λ 4688, whilst Hβ, Hγ, and Hδ are more faintly shown. The fairly strong line in the spectrum of the W.-R. star at λ 4618 is comparatively faint in that of the Nova, whilst the trace of a line in the latter at λ 3890 is not to be found in the Wolf-Rayet spectrum. The chief nebula lines at $\lambda\lambda$ 5007 and 4959 are apparently absent from both spectra or are very faint.

Determinations of the magnitude of the Nova gave the following results:—1905, November 1, 11·2; 1906, November 24, 11·3; and 1907, October 13, 11·44.

THE HELIUM LINE, D_3, AS A DARK LINE IN THE SOLAR SPECTRUM.—In No. 393 of the *Observatory* (p. 94, February) Mr. A. A. Buss discusses the article by Father Cortie, which appeared in the January number, anent the presence of the dark, D_3, line of helium in the solar spectrum. From our previous note (No. 1995, p. 281, January 23) it will be remembered that Father Cortie discussed a photograph obtained by Mr. Nagaraja, on which both the dark and the bright line of helium, D_3, were supposed to be represented, and came to the conclusion that the identification was, possibly, a mistaken one. Mr. Buss now advances a number of arguments upholding the original view. In the first place, he points out that any arguments on this question suffer considerable uncertainty owing to different values being given for the principal lines under discussion. Thus Runge and Paschen give 5875·870 as the wave-length of the laboratory emission line, whilst in Young's revised list the wave-length of the chromospheric line is given as 5876; that the latter, compared with the laboratory line, suffers displacement towards the red is indicated by several different observations. Mr. Nagaraja's dark line lies almost exactly mid-way between the two, at λ 5875·930, therefore Mr. Buss considers that it is, probably, the helium line. Other evidence and his own observations of the dark D_3 line in active areas outside the umbral regions of spots support this view.

A DETAILED STUDY OF THE PHOTOSPHERE.—In No. 1895 of NATURE (vol. lxxiii., p. 401, February 22, 1906) we published an article dealing with Prof. Hansky's study of the size and movements of the granules comprising the solar photospheric surface. Mr. Chevalier, of the Zô-sé Observatory, China, has for some time been engaged on a similar study, and publishes some very interesting results, with photographs, in No. 1, vol. xxvii., of the *Astrophysical Journal* (January, p. 12). The principal conclusions deduced from the results show that on comparing photographs taken at one minute or half-minute intervals the same photospheric granules may be easily recognised, although their shapes and brilliancies undergo considerable changes. A more detailed comparison shows changes in their relative positions, the magnitude of the changes differing greatly both in direction and velocity. The velocities obtained range from 0 to 30 or more kilometres per second, and, in the mean, are much lower than those obtained by Prof. Hansky.

SECTIONAL ADDRESSES AT THE CHICAGO MEETING OF THE AMERICAN ASSOCIATION.

BY the courtesy of Dr. L. O. Howard, permanent secretary of the American Association for the Advancement of Science, we have been favoured with copies of several addresses delivered by chairmen of sections of the association at the recent Chicago meeting, of which an account was given in NATURE of January 30. Subjoined are summaries of some of the points of interest in these addresses. A summary of the president's address appeared in NATURE of January 23.

Music and Melody.

In his address to Section B (physics) Prof. W. C. Sabine chose as his topic "Melody and the Origin of the Musical Scale," the discourse being a critique of views published fifty-five years ago by Helmholtz in his "Tonempfindungen." It is pointed out that in part ii. of that work Helmholtz gave a physical and physiological explanation of the harmony and discord of *simultaneous* sounds, and Prof. Sabine briefly quotes Helmholtz's description of the structure of the human ear, so far as it is required to explain why overlapping tones produce a sense of discord, thus leading to the necessity of a musical scale with regular intervals for the building up of harmonies. But in applying this principle to account for the origin of such a scale, Helmholtz was met by an apparent anachronism.

Up to the eleventh or twelfth century only homophonic music existed, this consisting merely in the progression of single-part melody. The existing music of the Oriental and Asiatic races belongs to this type, and Helmholtz, admitting that between sounds which reach the ear in discrete succession there could be neither harmony nor discord, nor beats, sought another explanation for the fact that musical scales were existent long before the introduction of polyphonic and harmonic music. Prof. Sabine now offers a new explanation of this particular point. When sounds are produced inside a closed space such as a building, they continue to reverberate for a certain interval after the exciting source has ceased to exist. In this connection Prof. Sabine gives (without, however, specifying the units) a list of the absorbing powers of different substances. It follows that as soon as melodies were performed inside buildings such as temples of worship, the consecutive notes became blended, and this overlapping produced all the conditions necessary for the production of the harmonies and discords discussed by Helmholtz in explanation of the chordal use of the musical scale. This proposed theory of Prof. Sabine's would (so it is claimed) account for the absence of a musical scale among the native tribes of Africa.

The Problem of Heredity.

It is a sign of the times that the addresses delivered before the American Association by Dr. D. T. Macdougal, a botanist, and by Dr. E. G. Conklin, a zoologist, are not about botany and zoology respectively, but that both deal with heredity; and it is evidence of the vastness of the topic with which they deal that, though they both treat of the mechanism of heredity, their two addresses do not overlap. Both addresses are admirable examples of what such addresses should be. Their opening sentences exhibit a breadth of view which, if we may say so, has not been a distinguishing feature of a great deal of recent American biological literature; and both addresses contain such a wealth of references to, and accounts of, new observations and experiments which bear on the interpretation of fundamental problems that the earnest biologist will do well to read them both.

Dr. Macdougal opens his address on "Heredity and Environic Forces" with some well-needed remarks on the assumption that the changes which ensue when a plant is transported to a violently different environment—as, for example, when a mesophyte is grown as a xerophyte—are adaptive changes. According to Dr. MacDougal, these are not only assumptions, but unwarrantable ones. Certain of the changes which accompany the transportation do undoubtedly benefit the plant in its new surroundings, "but results of the opposite character are encountered. Thus in my experiments with Roripa, the American watercress, it was seen to bear filiform, dissected leaves when submerged, linear dissected leaves when emersed, but when acclimatised at the Desert Laboratory developed broadly ovate, almost entire laminæ." Similarly etiolation, usually regarded as an adaptive change which enables the plant to lift its head above objects which keep the light from it, was found to occur in less than half the species tested, the majority "showing thickened organs and other useless alterations." Lastly, he cites the proof given by Lloyd that the movements of stomata are *not* adaptive or regulatory with respect to transpiration. We can heartily endorse Dr. Macdougal's conclusion on this part of his subject (as he happily phrases it in his native tongue), "that the entire matter of causal adaptations is in need of a basal re-investigation from an entirely new view-point."

But the most interesting part of this address is that which deals with the author's successful attempts to modify permanently the germ-plasms of plants by subjecting them to the influence of various chemicals. "It was found that the injection of various solutions into ovaries of Raimannia was followed by the production of seeds bearing qualities not exhibited by the parent, wholly irreversible, and fully transmissible in successive generations. One of the seeds produced by a plant of *Oenothera biennis* which had been treated with zinc sulphate differed so widely from the parental form that it could be distinguished from it by a novice. This new form "has been tested to the third generation, transmits all its characteristics fully, and does not readily hybridise with the parent even when grown so closely in contact with it that the branches interlock." Results as remarkable as this need confirmation, and it is to be hoped that similar experiments will shortly be undertaken in this country.

In his address on "The Mechanism of Heredity," Dr. E. G. Conklin suggests an answer to the question which always puzzles the philosophical biologist, "What exactly is the problem of heredity? How does it differ from that of development?" Dr. Conklin's answer is what at first sight would seem to be the natural and logical consequence of the acceptance of Weismann's doctrine of the continuity of the germ-plasm; it is, in fact, that there is little difference between the two problems. "Indeed, Heredity is not a peculiar or unique principle; for it is only similarity of growth and differentiation in successive generations. . . . In fact, the whole process of development is one of growth and differentiation, and similarity of these in parents and offspring constitutes hereditary likeness. The causes of heredity are thus reduced to the causes of the successive differentiations of development, and the *mechanism of heredity is merely the mechanism of differentiation.*" Having reduced the problem of heredity to this, Dr. Conklin goes on to consider the evidence for the view that the chromosomes are solely concerned in the process of differentiation, and expresses himself as definitely opposed to that view. He is not content with holding that the phenomena of differentiation may be the result of the interaction of nucleus and cytoplasm, but he goes on to assert that, as the animal pole of the egg becomes the animal or sense pole in all animals, and the cytoplasm in this region gives rise to the ectoderm of the developing animal, and as this polarity can be traced far back into the ovarian history of the egg, and in some cases is probably continuous from generation to generation, that "we have here an important character which is inherited through the cytoplasm and not through the nucleus." Dr. Conklin's final conclusion is that at the time of fertilisation the hereditary potencies of the two germ cells are not equal, because all the "early development, including the polarity, symmetry, type of cleavage, and the relative positions and proportions of future organs," are determined solely by the cytoplasm of the egg-cell.

Anthropology of California.

In his address as president of Section H (anthropology) of the American Association, Prof. A. L. Kroeber reviewed the progress of anthropology in California. Commencing with language, he pointed out that Powell's arrangement of about twenty linguistic stocks had not been disturbed by later investigations. The loose statements formerly made that the number of unrelated dialects of each stock was often very great, and that these dialects showed a gradual continuous change from one end of the territory occupied by a stock to another, have been found to be entirely erroneous. There are some loan-words common to contiguous stocks, but these are few, and the peculiarity of the linguistic problem lies in the fact that each form of speech occupies a well-defined area. So far, three great groups—north-western, south-western, and central—have been clearly traced, and the similarities between them, which up to the present have been ascertained, are not of such a nature as to be of bearing on the consideration of their genetic unity. Some progress has been made towards explaining this remarkable distribution of languages. In some cases it appears to have originated from mere divergence, continued until practically all traces of original relationship have become obliterated. At any rate, nothing has ever been discovered to support the so-called "fish-trap" theory, according to which the multiplicity of languages in California is due to the successive crowding, into this more desirable habitat, of waves or bands of unrelated immigrants from less favoured regions, to which none of them ever desired to return. This differentiation of speech, again, seems to be casually related to other factors, cultural and historical, and only indirectly physical and environmental.

Much the same is true of the relations of culture and environment, but the latter has been influenced by a long historical development. While, as compared with the rest of America, California forms a well-marked region, on a broader view its distinctive characters largely disappear, or are seen to coincide with such as are typical of the whole of the northern continent. In the north-west the culture seems to be an extension of that of the Pacific coast, while that of the centre and south is of a diverse type.

Archæological investigation, so far as it has been pursued, does not establish the origin of this culture in Quaternary times or the geological antiquity of those finds which are unquestionably of human origin. The civilisation seems to have remained practically unaltered for some thousands of years; but, at the same time, owing to the prevalence of the practice of cremation, the record of physical anthropology is very incomplete. In the domain of culture much remains to be done, particularly in tracing the relationship of analogous rites among the local tribes. What is needed in all branches of the anthropology of this region is more knowledge, and this can be gained only by more work on the lines of linguistic and anthropological investigation, which it is the main object of this address to illustrate and define.

Progress in Experimental Medicine.

An address on "Tendencies in Pathology" was given by Dr. Simon Flexner, chairman of Section K (physiology and experimental medicine). Dr. Flexner pointed out that the causation of disease is manifold, the reaction to abnormal influences is varied. The forces which divert the normal functions and bring disease into being are only in part external at the time of their operation. All parasitic plants and animals are essentially extrinsic agents of injury. Occupation diseases, so-called, are at present only slightly understood, and probably act, not only by increasing susceptibility to infections, but also through direct chemical and physical mal-influences. There is, however, a class of diseases which results, in part at least, from errors and disturbances of balance in the development of the animal organism or in the correlation of its functions. The peculiar control which the adrenals exercise over the tone of the vascular system, the degeneration of the aorta in rabbits produced by injection of adrenalin, and the association between sclerosis and atrophy of the kidneys and arterial hypertension and degeneration, suggest that the renal and the arterial disease are parts of one pathological complex. Other instances might be given, *e.g.* the association of disease of the pancreas with diabetes.

Lately an experimental method has been devised whereby portions of organs and tissues may be transferred from one animal to another, and thus the influences exerted by a new environment on certain organs, or of the transplanted organ on a new host, investigated. For example, it has been found that arteries may be successfully transplanted even after keeping aseptically in a refrigerator for twenty or thirty days after extirpation.

The phagocytic function of the leucocytes, whereby infecting microbes or worn-out somatic cells are ingested and disposed of, is well known, but this function of the living leucocyte is supplemented by its power to yield upon dissolution active proteolytic enzymes of considerable potency, which may have a considerable influence on various pathological processes, *e.g.* inflammation.

Until recently little progress had been made regarding tumour formation, and we are still ignorant of its cause, but the study of transplantable tumours of mice and rats has already yielded important results concerning the biological conditions underlying tumour growth. Such tumours are highly specific; they are transplantable only to individuals of the same species and race, never to animals of another species, and often not to those of another race of the same species. The existence of a form of immunity to tumour cells has been demonstrated, which may be restricted to one region of or may be general to the whole body. This immunity Ehrlich terms *atrepsy*, and he conceives it to be an expression of deprivation of the peculiar nutritive stuff required for tumour growth.

As regards bacteriology, one important phenomenon of recent recognition is that of the *microbe carrier*, an individual who harbours disease germs while himself apparently suffering no ill effect. This has been known for some time in the case of the diphtheria bacillus, but has recently been found to hold good for the typhoid bacillus, and for dysentery, plague, cholera, and a host of protozoan infections.

We are now learning, too, that while the forces of immunity may be in active operation, so far as tests made outside the body with the blood indicate, the very bacteria from and against which they have developed may still be surviving in the body.

The discovery of the opsonins in the normal blood, and their increase in states of induced immunity to bacterial and other infections, has added greatly to our knowledge of some of the complicated phenomena of the immune state.

The body infected with bacteria or other pathogenic micro-organisms, although it may survive the infection, may not be rendered more resistant—it may even be rendered more susceptible to the infecting agent or its products. From the diverse reactions of the body to foreign substances and parasitic organisms, phenomena have been discovered, some desirable and beneficial, others objectionable and injurious, and it becomes the quest of the future to secure for medical practice those effects that may be beneficial, and to eliminate those that may be injurious.

COPPER MIRRORS.

METALLIC mirrors have been known from very early times, and references to them are scattered through ancient literature. They were frequently elaborately decorated, and many of them possess the greatest interest as objects of art. Looking-glasses coated with an amalgam of quicksilver and tin came into use about the middle of the fifteenth century, but it is not known by whom they were originally invented. The details of their manufacture were, for long, carefully guarded as trade secrets, and were not made public until about a hundred years later. The process then described is in all essentials that still employed, wherever it has not been abandoned on account of the danger to workers from mercurial poisoning. Tin amalgam mirrors were most extensively used during the latter half of last century, but at the present time in England and Germany they are no longer made, as mirrors obtained by the actual deposition of metallic silver upon glass have displaced them.

This gradual but complete transformation of an important industry had its origin in an observation made by Liebig when investigating the properties of aldehyde, which he had recently discovered. He found that if a solution of silver nitrate to which some drops of ammonia had been added was warmed with the new compound, the silver oxide was immediately reduced, and that the reduction was accompanied by a peculiar phenomenon, the metal attaching itself to the glass in the form of a thin reflecting layer.

Liebig apparently did not at the time realise the importance of his discovery in relation to mirror making. This was first done by Thomas Drayton, of Brighton, who eight years later, in 1843, patented a process for manufacturing looking-glasses by a similar reduction of a silver solution by oil of cloves. His process did not prove a commercial success, and was soon abandoned in favour of one worked out by Liebig, in which milk-sugar was used as the reducing agent, and by various modifications of which all mirrors are now made.

Drayton's method at the time, however, excited widespread interest, and Faraday lectured upon it at the Royal Institution, silvering a number of large glass vessels during the lecture, to the great delight of his audience.

Faraday about this time made the interesting observation that a mirror-like deposit of copper upon glass could be obtained by heating plates of glass in a liquid made by dissolving a little oxide of copper in olive oil. Copper mirrors obtained thus are generally lacking in brilliancy, and if of any size are liable to be stained and discoloured in patches by decomposition products of the oil. Further, as the deposition of the metal only takes place at a temperature above that at which the oil decomposes, the process is excessively disagreeable to carry out, and as the oil is spoiled it is somewhat costly.

The writer has recently discovered[1] that copper can be deposited upon glass from aqueous solution in a film as brilliant as a similarly deposited silver one if a suitable reducing agent be employed. Such a reducing agent is found in phenyl hydrazine, which has the power of readily abstracting oxygen from copper oxide, leaving the copper in the metallic state, and being itself oxidised to benzene, nitrogen, and water.

To obtain a copper mirror by this process it is best to heat a mixture of one part of freshly distilled phenyl hydrazine and two parts of water until a clear solution is obtained, and to add about half its bulk of a warm saturated solution of cupric hydroxide in strong ammonia. Nitrogen is freely evolved during the addition, and the cupric is reduced to cuprous hydroxide, which remains dissolved in the ammoniacal liquid, and does not undergo any appreciable further reduction until heated. A hot 10 per cent. aqueous solution of potassium hydroxide is next to be added until a slight permanent precipitate of cuprous hydroxide is produced. If the colourless or pale yellow liquid thus made be cautiously heated in contact with a perfectly clean glass surface, metallic copper is deposited upon it in the form of a thin, coherent, perfectly reflecting lamina.

[1] "A Method of Depositing Copper upon Glass from Aqueous Solutions in a Thin Brilliantly Reflecting Film, and thus producing a Copper Mirror." Read before the Royal Society, November 21, 1907

As nitrogen is evolved during the reduction, and as tarry bye-products are formed in small quantity and float with the benzene produced to the surface of the liquid, if flasks or tube are to be coppered, devices must be adopted to keep the inner surfaces completely covered by the liquid from which the metal is being deposited, whilst allowing the gas to escape.

To obtain a film of sufficient thickness to be permanent, it is best to allow it to remain for an hour or so in contact with the warm reducing fluid, and not to pour off the latter until it has cooled to the temperature of the air. The surface of the deposited copper should then be well washed, first with water and afterwards with alcohol and ether, and finally should be protected from the slow oxidising action of the air by one or two coats of some quick-drying varnish.

The mirrors thus formed are very beautiful, for they show the splendid red colour of copper, and are more perfect in reflecting surface than the most highly polished metal. They are, moreover, if properly protected from the air, absolutely permanent. It is interesting to note that the copper is in the monovalent or cuprous state in which it is analogous to silver when it shows a similar capability of being deposited upon glass.

The surface on which the metal is deposited undoubtedly plays an important part in the process, since both silver and copper are deposited much more easily upon surfaces which have not been exposed for any length of time to the action of air or of water, and upon blown than upon polished glass.

It seems probable that the glass surface itself acts as a catalyser, and locally accelerates the reducing action.

F. D. CHATTAWAY.

GEOLOGICAL SURVEY OF CANADA.

SEVEN reports just received from the Geological Survey of Canada afford evidence of the valuable work that is being done in investigating the mineral resources of the Dominion. In Report No. 949 Mr. D. B. Dowling describes the Cascade coal basin, Alberta. He gives an outline of the geology and topography of the coalfield, and a detailed account of the character of the coal, thickness of seams, and extent of the measures. The report is accompanied by eight folding maps. The area illustrated on the map sheets lies within and to the east of the summit of the Rocky Mountains, the formations exposed giving a continuous section from the highest remaining beds of the Cretaceous down to the bottom of the Carboniferous. The coal is of Cretaceous age. In the hills south of the Bow River ten or eleven seams, more than 4 feet thick, have been found, while north of Bankhead, on the slope of Cascade Mountain, fourteen possibly workable seams occur. At the Bankhead colliery the coal is an anthracite, admirably suited for domestic purposes. A screening plant handling 1000 tons a day has been erected. In Report No. 953 Mr. H. S. Poole describes the barytes deposits of Lake Ainslie and North Cheticamp, Nova Scotia, and gives notes on the production, manufacture, and uses of barytes in Canada. Report No. 958 is devoted to Dr. G. C. Hoffmann's review of the work done in the laboratory of the survey during the year. It covers seventy-one pages, and contains a large amount of material of chemical and mineralogical interest. In Report No. 968 Mr. D. D. Cairnes gives an account of the geology of the Moose Mountain area of the disturbed belt of southern Alberta. Coal has been found in several places within this district, and natural gas has been found to the north, south, and east of this area in the same formations as those within it. In Report No. 977 Mr. R. W. Ells gives an account of the geology and natural resources of the area included in N.W. Quarter-sheet No. 122 of the Ontario and Quebec series, comprising portions of the counties of Pontiac, Carleton, and Renfrew. A lengthy list of fossils from the Chazy, Black River, Trenton, and Pleistocene formations comprised within the area, compiled by Dr. H. M. Ami, is appended. The minerals of economic value met with include iron ore, of which there is a workable deposit at Bristol mines, galena and zinc blende, mica, asbestos, gold, building stone, molybdenite, brick clays, ochre, and shell-marl. Report No. 971 is devoted to Mr. E. D. Ingalls's statistical review of the mineral industries of Canada for 1905. Although, unfortunately, somewhat belated, this report, which covers 174 pages, gives complete and revised information for the year 1905, advance provisional mineral statistics of which were issued on March 2, 1906.

The grand total of the mineral production of Canada is valued at 13,905,034*l*. The most valuable mineral product is coal, which accounts for 25·2 per cent. of the whole. Metallic minerals contributed together 54 per cent., structural materials 14 per cent., and other non-metallic minerals 5 per cent. Compared with the previous year, substantial increases are shown by all the leading industries, except in the case of gold, due to the continuous decrease of the Yukon placers. An interesting feature is the remarkable increase in the output of cobalt. The large supply of this metal rendered available as a result of the discoveries at Cobalt, Ontario, had, however, a depressing effect on the market, and caused a very marked decrease in price. Lastly, Report No. 1017 is devoted to a summary of the work done by the department of mines, Geological Survey, during the year 1907. It covers 132 pages, and its prompt publication deserves special commendation. There were in the field twenty parties, and the summary reports indicate that a large amount of valuable work was carried out, one of the chief results being the determination of enormous quantities of available bituminous coal in the Yukon region.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

ST. ANDREWS.—After a delay of more than a quarter of a century, at last, by the munificence of Mrs. Bell Pettigrew, the widow of the late professor of medicine and anatomy, a sum of 6000*l*. has been generously offered for the new museum of natural history of the University in which her husband laboured so long. The present museum was erected by the Government in 1846, and whilst its exterior is in keeping with the other substantial buildings in the quadrangle, its mode of lighting and its cases are far behind date. Moreover, its crowded shelves not only render proper exhibition of the specimens impossible, but interfere with classification. In all probability a new lecture-room, a practical class-room, and rooms for curator and workers will be attached to the museum.

CAMBRIDGE.—The essays for which the Smith's prizes are adjudged are as follows (the names are arranged in alphabetical order):—"Problems in the Wave-motion of Viscous Liquids," W. J. Harrison, Clare College; "On the Asymptotic Behaviour of Integral Functions of Zero Order, and Allied Problems," J. E. Littlewood, Trinity College; "On the Solution of Ordinary Linear Differential Equations having Doubly Periodic Coefficients," J. Mercer, Trinity College. The adjudicators are of opinion that the following essays are deserving of honourable mention, viz.:—"On Energy Accelerations and Partition of Energy," C. W. Follett, Trinity Hall; "On some Problems in the Theory of Metallic Reflection," H. R. Hassé, St. John's College; "The Geometry of Apolar Triads," W. P. Milne, Clare College; "Perpetuant Syzygies of the *n*th Kind," H. T. H. Piaggio, St. John's College; "The Reflection of Plane Waves of Light at the Surface of a Medium of Special Periodic Character," C. J. T. Sewell, Trinity College.

J. B. Hubrecht, Christ's College, has been elected to the Isaac Newton studentship, tenable from April 15, 1908, to April 15, 1911. The student will carry on a course of research in solar physics.

H. H. Arnold-Bemrose, Clare College; W. F. Sheppard, Trinity College; J. R. Sutton, Sidney Sussex College; and A. Young, Clare College, have been approved by the general board of studies for the degree of Doctor in Science.

The Vice-Chancellor has announced to the Senate that donations of 1000*l*. each, in memory of the late Mr. Walter K. Foster, have been promised towards the building fund of the new museum of archæology and of ethnology by Mrs. Walter K. Foster, Mr. E. Bird Foster, Mr. C. F. Foster, and Mrs. E. Rawlings. Mr. Foster, in whose memory this munificent gift has been made, bequeathed to the University in 1891 an extensive collection of prehistoric and Anglo-Saxon antiquities.

LONDON.—Dr. H. T. Bovey, F.R.S., has been appointed Rector of the Imperial College of Science and Technology at South Kensington. Dr. Bovey was educated at Cambridge. He was twelfth wrangler in 1873, and was elected a fellow of Queen's College. Before going to Canada in 1887 as professor of civil engineering and applied mechanics in McGill University, Montreal, he practised as a civil engineer, being engaged on important works on the Mersey. Under Dr. Bovey's direction the civil engineering department at McGill University acquired a considerable reputation both for undergraduate and research work. Recently a course of study in transportation was added to the seven other engineering courses. The work in this subject is liberally supported by the great Canadian railway companies. In 1888 Dr. Bovey was appointed dean of applied science in McGill University. It is well known that McGill University is excellently equipped both for engineering and applied science. In the chemistry department, for example, there are special laboratories for organic chemistry, physical chemistry, electrolytic analysis, iron and steel analysis, fire assaying, water analysis, determinative mineralogy, petrography, and photography. Dr. Bovey's experience both in engineering and science is therefore exceptionally wide. His literary output includes works on applied mechanics, theory of structures and strength of materials, and hydraulics, in addition to a number of scientific papers. He was elected a Fellow of the Royal Society in 1902.

The London County Council proposes to make a grant of 5000*l*. for the current year to the Imperial College, without, however, pledging itself to contribute 20,000*l*. a year in the future, as was intended if the original scheme for the college, by which it was proposed to establish a well-equipped institution for higher work in applied science and technology, independent of other institutions at South Kensington, had been carried out.

BY the will of the late Mrs. Rylands, the Victoria University, Manchester, will receive the sum of 50,000*l*.; Owens College, Manchester, 25,000*l*.; and Mansfield College, Oxford, 10,000*l*.

THE *British Medical Journal* announces that Prof. Wilhelm Erb has given the University of Heidelberg a donation of 5000*l*., one half to be applied for the benefit of students and assistants and their maintenance in hospital when required, the other towards the promotion of scientific research by students.

WE have received from Messrs. Swan Sonnenschein and Co., Ltd., copies of the 1908 issues of "The Public Schools Year-book and Preparatory Schools Year-book" (price 3*s*. 6*d*. net), and "The Schoolmasters Year-book and Directory" (price 7*s*. 6*d*. net). Both books have become well known to educational workers as useful volumes of reference. The annual dealing specifically with the public schools, those, that is, which are connected with the Headmasters' Conference, provides details concerning the public schools which a parent seeking a school for his boy wishes to know. But the book contains much other useful information about preparatory schools, scholarships available, and the public examinations which qualify for entrance into the professions. There is, in addition, a section dealing with the various professions themselves which should prove invaluable to fathers whose sons have completed their school careers. The second volume appeals more directly to schoolmasters and others concerned in the administration of education. The extensive organisations throughout the country for the administration of secondary education are summarised; there is a chronicle of educational events during 1907; and particulars are given about educational societies and publications, examinations and inspecting bodies, and miscellaneous matters. More than half the volume is devoted to a very complete directory providing detailed information concerning the qualifications and experience of masters teaching in secondary schools.

MANY of the numbers in the "Statistics of Public Education in England and Wales, 1905–6–7," recently published (Cd. 3886) by the Board of Education, give useful information as to the condition of our national education during the year 1905–6 and the years immediately preceding. On August 1, 1906, accommodation was provided in the public elementary schools of all grades for 7,068,641 children, of which number of places 3,543,760 were in "council" schools, or, as they were formerly called, "board" schools. In ordinary elementary schools, that is, omitting every kind of "special" school, there were 5,994,490 pupils on the registers and 5,303,229 in average attendance. These children were taught by 31,893 head teachers, 93,130 assistant teachers, and 49,056 "other" teachers. The Government grant to meet expenditure in respect of elementary education during 1906–7 reached 11,248,794*l*., and in 1905–6 was 10,829,396*l*. In addition, 92,328*l*. was paid in 1906–7 on account of allowances and pensions for teachers, and 552,894*l*. for the training of teachers and pupil-teachers. In secondary schools in receipt of grants from the Board of Education, which in 1905–6 numbered 689, there were in that year 65,994 boys and 49,694 girls, and on 66,014 of these pupils—for grants were only paid on children between twelve and sixteen years of age taking an approved course of work—the sum paid in grants amounted to 246,220*l*. A serious falling off in the number of pupils in secondary schools between the ages of twelve and sixteen years is shown in the statistics. To take one example, the number of boys (about twelve to thirteen years of age) taking an approved course and doing the work of the first year was, in 1905–6, 12,238; doing the second year's work, 9,924; the third year's work, 4,907; and the fourth year's work, 2,397. It would seem that less than 20 per cent. of the boys who at twelve years of age begin the approved course of work remain at school until sixteen years of age, and the same proportion seems to be true in the case of the girls.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 14, 1907.—"On the Result of Crossing Round with Wrinkled Peas, with Especial Reference to their Starch-grains." By A. D. **Darbishire.** Communicated by Prof. J. Bretland Farmer, F.R.S.

The facts so far brought to light are:—

(1) That, although roundness is dominant over wrinkledness in peas, the starch-grain of the F_1 generation (the round or *r*-grain) is a blend between the type of grain of the round pea (the potato-shaped or *p*-grain) and the type of grain of the wrinkled pea (the compound or *c*-grain) in respect of three characters:—

(*a*) It is intermediate in shape as measured by its length-breadth index—that of the *p*-grain being 66, that of the *c*-grain 92, and that of the *r*-grain 85 (neglecting decimals).

(*b*) It is intermediate in the distribution of compoundness, inasmuch as some of the *r*-grains are compound and some single.

(*c*) It is intermediate in the degree of compoundness, inasmuch as amongst those *r*-grains which are compound the most usual number of constituent pieces is three, whereas in *c*-grains it is six.

(2) In a subsequent generation—F_3—the homozygote round peas contain *p*-grains; the heterozygote round peas contain *r*- or intermediate grains. But both *r*- and intermediate grains may be associated either with a high or with a low degree of compoundness.

(3) *p*-Grains occasionally occur in wrinkled peas in F_2, and the evidence suggests that the existence of these grains in wrinkled peas tends to make them less wrinkled.

(4) A wrinkled pea takes up more water when it germinates than a round one. The hybrid between a round and a wrinkled pea is intermediate in respect of this character between its two parents.

(5) But this intermediateness of the hybrid in absorptive capacity is not occasioned by the intermediateness of the starch-grain of the hybrid, because, in F_2, peas containing *r*-grains *and peas containing* p-*grains* both have the same absorptive capacity as the F_1 pea.

(6) When, therefore, we cross a round with a wrinkled pea, we are dealing with *four* separately heritable characters:—

(i) The shape of the pea—whether round or wrinkled.

(ii) The absorptive capacity of the pea—whether low or high.

(iii) The shape of the starch-grain—whether long or round.

(iv) The constitution of the starch-grain—whether single or compound.

"On the Inheritance of Eye-colour in Man." By C. C. **Hurst.** Communicated by W. Bateson, F.R.S.

An examination of the eye-colours of a number of parents and their offspring in a Leicestershire village shows that there are at least two discontinuous types of iris in man:—

(1) The duplex type, with both anterior and posterior pigments, as in ordinary brown eyes.

(2) The simplex type, with posterior pigment only, the anterior pigment being absent, as in clear blue eyes.

In heredity the simplex type behaves as a Mendelian recessive to the duplex type, which is dominant. The unit characters concerned are evidently presence (duplex) and absence (simplex) of anterior pigment on a basis of posterior pigment, presence being dominant.

The duplex and simplex types can be distinguished at any age. Various pigmental and structural changes take place in the iris during childhood and youth, the extent of which is not yet known. Few families with living parents and offspring, all adult, are to be found in one village. Consequently, it has not yet been possible to determine the genetic relations between the various shades of the duplex type.

Mathematical Society, February 13.—Prof. W. Burnside, president, in the chair.—A proof that every algebraic equation has a root: Dr. H. A. de S. **Pittard.**—Note on *q*-differences: F. H. **Jackson.**—An extension of Eisenstein's law of reciprocity (second paper): A. E. **Western.**—Conformal representation and the transformation of Laplace's equation: E. **Cunningham.**—The uniform approach of a continuous function to its limit: Dr. W. H. **Young.**

Physical Society, January 24.—Prof. J. Perry, F.R.S., president, in the chair.—Observations on recalescence curves: W. **Rosenhain.** Referring to the importance of the accurate study of recalescence phenomena in metals and alloys, the author describes the two principal methods employed for obtaining recalescence curves. These are known as the "inverse rate" and "differential" methods respectively. In the former method the times occupied by successive equal decrements of temperature are observed and plotted against the temperature of the cooling body, thus giving a curve the ordinates of which are temperature (t) and dT/dt (T = time) respectively. In the differential method the difference of temperature between the body under observation and a neutral or "blank" body cooling under approximately the same conditions is observed and plotted against the temperature of the body. The physical interpretations, in terms of quantity of heat evolved and of rate of evolution of heat of these two kinds of curves, are discussed by reference to the fundamental curve representing the time-temperature relations of one or two cooling bodies. Finally, the author describes a recalescence first observed to occur somewhat mysteriously in the body of certain furnaces at a temperature of 580° C. This was ultimately traced to a transformation occurring in crystalline silica, whether free or in admixture with porcelain or fire-clay. The author points out that this recalescence in crystalline silica coincides with certain points in the iron-carbon diagram of Roberts-Austen and of Carpenter and Keeling, and suggests that the recalescences observed by those workers may have arisen from silica in their furnaces.

Society of Chemical Industry, February 3.—Dr. J. Lewkowitsch in the chair.—Nitroglycerine and its manufacture: Lieut.-Colonel Sir F. L. **Nathan** and W. **Rintoul.** The discovery and properties of nitroglycerine were described, and particulars were given of improvements which have been effected in methods of manufacture.

Chemical Society, February 6.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—The metallic picrates: O. **Silberrad** and H. A. **Phillips.** The water of crystallisation and properties of the commoner picrates have been definitely established.—Some physicochemical properties of mixtures of pyridine and water: H. **Hartley,** N. G. **Thomas,** and M. P. **Applebey.**—The constitution of umbellulone, part iii.: F. **Tutin.** A refutation of Semmler's recent statements (*Ber.*, 1907, xl., 5017) respecting the constitution of umbellulone.—Colour and constitution of azomethine compounds, part i.: F. G. **Pope.** The nitrohydroxyazomethine compounds show an entirely different absorption spectrum from that of their alkali salts when the nitro- and hydroxyl groups are in the *para* position to the azomethine group, and from the similarity of the .N : CH. grouping to the .N : N. grouping it would seem that the alkali salts of these compounds could be formulated on a di-quinonoid basis, the free hydroxyl compounds being represented thus:—

and the alkali salts as

(compare Hewitt and Mitchell, Trans., 1907, xci., 1251).—The preparation of *l*-benzoin: A. **McKenzie** and H. **Wren.**—Organic derivatives of silicon, part v., benzylethylsilicone, dibenzylsilicone, and other benzyl and benzylethyl derivatives of silicane: R. **Robison** and F. S. **Kipping.** Descriptions of these silicon derivatives are given.—The residual affinity of the coumarins and thiocoumarins, as shown by their additive compounds: A. **Clayton.** The coumarins and thiocoumarins combine with mercuric chloride, forming compounds of the type $R,HgCl_2$, where R is a coumarin or a thiocoumarin.—The influence of foreign substances on certain transition temperatures, and the determination of molecular weights: H. M. **Dawson** and C. G. **Jackson.** The changes investigated were:—

(1) $Na_2S_2O_3,5H_2O \rightarrow Na_2S_2O_3,2H_2O$ at 48°·1;
(2) $NaBr,2H_2O \rightarrow NaBr$ at 50°·67; and
(3) $CaCl_2,6H_2O + 2MgCl_2,6H_2O \rightarrow CaCl_2,2MgCl_2,12H_2O$ at 22°·4.

Constants representing the depression of the transition temperature when one gram-molecule of the foreign substance is contained in 100 grams of the saturated transition solution have been calculated. From a knowledge of these constants, the corresponding invariant points may be utilised for the purpose of obtaining the molecular weights of dissolved substances.—The bromination of *p*-hydroxydiphenylamine: Miss A. E. **Smith** and K. J. P. **Orton.**—The decomposition of ammonium dichromate by heat: W. M. **Hooton.** If the salt is decomposed slowly by heat, the final product is hydrated chromium dioxide, $2CrO_2,H_2O$, a glistening black powder which when heated yields oxygen, water, and chromium sesquioxide. If ammonium dichromate is heated in absence of oxygen, the final product is a dull, greenish-black powder having the composition $H_2Cr_2O_4$.—The effect of constitution on the rotatory power of optically active nitrogen compounds, part ii.: H. O. **Jones** and J. R. **Hill.**—Malacone, a silicate of zirconium: A. C. **Cumming.** The author finds that the formula ZrO_2,SiO_2 corresponds more closely with the observed composition of malacone than does the formula $3ZrO_2,2SiO_2$ assigned to it by Kitchin and Winterson (Trans. Chem. Soc., 1906, lxxxix., 1568).—The reducibility of magnesium oxide by carbon: R. E. **Slade.** The isolation of magnesium by direct reduction of the oxide by carbon has been effected at temperatures above 1700°. Rapid evacuation of the vessel in which the reaction occurs, absorption of the magnesium by molten copper, and reduction of magnesia in presence of aluminium or in a swift stream of hydrogen have all proved useful in preventing the reverse reaction, which occurs between magnesium and carbon monoxide.—The crystal form of halogen derivatives of open chain hydrocarbons with reference to the Barlow-Pope theory of structure: F. M. **Jaeger.** In accordance with the theory of Barlow and Pope, it is found that tetrabromo-ββ-dimethylpropane, 1 : 3 : 5-hexatriene, di- and tetra-bromide, and tetraiodoethylene exhibit a close morphotropic relationship.—The determination of the rate of change by measurement of the gases evolved: F. E. E. **Lamplough.**—The temperatures of spontaneous crystallisation of mixed solutions, and their determination by means of the index of refraction. Mixtures of solutions of sodium nitrate and lead nitrate: Miss F. **Isaac.**—Contributions to the chemistry of the terpenes, part iii.; some oxidation products of pinene: G. G. **Henderson** and I. M. **Heilbron.**—A β-lactonic acid from acetone and malonic acid: A. N. **Meldrum.** When malonic acid and acetone are mixed with acetic anhydride and a little sulphuric acid, the β-lactone of β-hydroxy*iso*propylmalonic acid,

$$\begin{array}{l} CMe_2 . CH . CO_2H \\ | \qquad\quad | \\ O \text{——} CO \end{array},$$

is formed.

PARIS.

Academy of Sciences, February 10.—M. H. Becquerel in the chair.—The spectra of non-dissociated compounds: Henri **Becquerel.** A reply to a recent note of M. A. Dufour, and pointing out the connection between the results of M. Dufour and certain phosphorescent and absorption spectra.—The alcoholysis of linseed oil: A. **Haller.** The author has applied his method of saponification with alcoholic hydrochloric acid to the preparation of the methyl esters of the fatty acids contained in linseed oil. These methyl esters were submitted to fractional distillation under reduced pressure, and the distillates caused to crystallise at −7° C. In this way the methyl esters of stearic, palmitic, and arachic acids were separated in a pure state.—Parthenogenesis at Roscoff and at Berkeley: Yves **Delage.** A controversial paper in reply to Loeb.—The dispersion of light in interstellar space: Charles **Nordmann.** A sketch of a new method for determining if rays of different wave-lengths all travel in interstellar space with the same velocity, based on the monochromatic photometry of a variable star. The experimental results will be given in a later paper.—Observations of the transit of Mercury of November 14, 1907, made at the Royal Observatory of Belgium: M. **Lecointe.** Results are given for the observations of the contacts, the form of the disc, and observations of position and of physical appearance.—Theorem on Taylor's series: Michel **Petrovitch.**—The approximate integration of differential equations: Émile **Cotton.**—The diminution of the rolling of ships: V. **Crémieu.**—A new series of ammoniacal ferric salts in which the iron is masked: P. **Pascal.** A description of some complex salts formed by the addition of ammonia to solutions of sodium ferripyrophosphate.—The silicide of magnesium: Paul **Lebeau** and Robert **Bossuet.** Alloys of magnesium and silicon containing from 0·38 per cent. up to more than 50 per cent. of silicon were examined micrographically. From the results of this examination it appeared that there exists only one magnesium silicide containing less than 40 per cent. of silicon. Aqueous solutions proved to be useless for the isolation of the silicide from the ingot, and the excess of magnesium was removed by the action of ethyl iodide and ether. The compound thus isolated was $SiMg_2$, and gives hydrogen free from hydrogen silicide when acted upon by water. Hydrochloric acid attacks it energetically, a mixture of hydrogen and spontaneously inflammable hydrogen silicides being produced. The compound is completely dissociated in a vacuum at 1100°–1200° C., the magnesium being volatilised.—The colloidal properties of starch, and on the existence of a perfect solution of this substance: E. **Fouard.** The starch solution was filtered through a membrane of collodion, and its properties were totally different from ordinary starch solutions. The strength of the solution was 2·74 per cent. of starch; it was clear and perfectly transparent, and an intense light bundle after passing through the solution showed no trace of polarisation. The viscosity of a 1 per cent. solution was of the same order of magnitude as water or 1 per cent. sugar solution, and only one-twelfth that of a 1 per cent. starch solution made in the ordinary way.—The state of the camphocarbonates of the fatty and aromatic amines in solution, as shown by the rotatory power: J. **Minguin.**—Researches on the physical modifications of gelatin in presence of electrolytes and non-electrolytes: J. Larguier **des Bancels.** In presence of certain salts gelatin dissolves in water at the ordinary temperature. At equal concentrations, salts of divalent metals exert a more powerful solvent action than salts of monovalent metals. For the same metals nitrates exert a more energetic action than chlorides. Certain non-electrolytes, such as alcohol or acetone, also attack gelatin more easily than pure water.—The rapid estimation of potassium bichromate in milks: M. **Gouère.**—The preparation of dithymol: the action of bromine on dithymol. H. **Cousin** and H. **Hérissey.** The oxidation of the thymol is carried out with ferric chloride in aqueous solution; the yield is from 25 per cent. to 30 per cent.—γ-Oxytetrolic acid: MM. **Lespieau** and **Viguier.** This is prepared by the interaction of propargyl alcohol and ethylmagnesium bromide, the reaction product being treated with carbon dioxide. The addition products with bromine have been studied.—Researches on a method of preparing the cyclic aldehydes: M. **Savariau.** Phenylmagnesium bromide reacts with chloral hydrate to give the compound $C_6H_5.CH(OH).CCl_3$, and this is converted into benzaldehyde by boiling with a solution of an alkaline carbonate. The method appears to be general, and may be useful in preparing small quantities of rare cyclic aldehydes.—The action of alcohols upon sodium benzylate: Marcel **Guerbet.** The action of sodium benzylate upon benzyl alcohol at 225° C. gives rise to stilbene, dibenzyl, toluene, and benzoic acid.—The chemical constitution and biological properties of the protoplasma of Koch's bacillus: Jules **Auclair** and Louis **Paris.**—Tyrosinase and racemic tyrosine: Gabriel **Bertrand** and M. **Rosenblatt.**—The genus Seuratia and its connections with Capnodium: Paul **Vuillemin.**—The intramolecular respiration of the aërial vegetative organs of vascular plants: G. **Nicolas.**—The multiplication *in vitro* of *Treponema pallidum*: C. **Lebailly.**

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 20.

ROYAL SOCIETY, at 4.30.—Notes on the Application of Low Temperatures to some Chemical Problems. (1) Use of Charcoal in Vapour Density Determination. (2) Rotatory Power of Organic Substances: Sir James Dewar, F.R.S., and Dr. H. O. Jones.—On the Osmotic Pressure of Compressible Solutions of any Degree of Concentration. Part II. Cases in which both Solvent and Solute are Volatile: A. W. Porter.—Effects of Self-induction in an Iron Cylinder when traversed by Alternating Currents: Prof. Ernest Wilson.—(1) On the Refractive Indices of Gaseous Nitric Oxide, Sulphur Dioxide, and Sulphur Trioxide. (2) On the Dispersion of Gaseous Mercury, Sulphur, Phosphorus, and Helium: C. Cuthbertson and E. Parr Metcalfe.

ROYAL INSTITUTION, at 3.—Wood: its Botanical and Technical Aspects: Prof. W. Somerville.

INSTITUTION OF MINING AND METALLURGY, at 8.—The Alloys of Gold and Tellurium: Dr. T. K. Rose.—A Method of Settling Slimes, as applied to their Separation from Solution in Cyanide Treatment: H. G. Nichols.—Two Deterrents to the Dissolution of Free Gold in the Cyanide Process: D. Simpson.—A Rapid Method for the Estimation of Arsenic in Ores: H. E. Hooper.—The Indian Mint Assay of Silver Bullion: F. T. C. Hughes.

LINNEAN SOCIETY, at 8.—Experiments with Wild Species of Tuber-bearing Solanums: A. W. Sutton.—The Life-history and Larval Habits of Tiger Beetles (Cicindelæ): Dr. V. E. Shelford. On a Possible Case of Mimicry in the Common Sole: Dr. A. T. Masterman. *Exhibit*: Stereoscopic Photographs of Alpine Plants in Natural Colours: T. Ernest Waltham.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electrical Power in Railway Goods Warehouses: H. Henderson.—Electric Power in Docks: C. E. Taylor.

CHEMICAL SOCIETY, at 8.30.—The Action of Thionyl Chloride and of Phosphorus Pentachloride on the Methylene Ethers of Pyrocatechol Derivatives: G. Barger.—The Preparation of Conductivity Water: H. Hartley, N. P. Campbell and R. H. Poole.—Derivatives of *para*-Diazoiminobenzene: G. T. Morgan and Miss F. M. G. Micklethwait.—A Study of the Diazo-reaction in the Diphenyl Series: G. T. THURSDAY, FEBRUARY 27, 1908.

MAN AND NATURE IN SOUTH-WEST AFRICA.

Aus Namaland und Kalahari. By Prof. Leonhard Schultze. Pp. xiv+752. (Jena: Gustav Fischer, 1907.) Price 60 marks.

THE scope of this admirable work on Namakwaland and the Kalahari has not any knowledge of political boundaries. Neither is it confined to ethnology or biology. Its range extends over a portion of British Bechuanaland and northern Cape Colony, and it deals slightly with the northern parts of German South-West Africa—Damaraland and the Ovambo countries. It is such a book as can as yet only be published in Germany. The reproduction of Dr. Schultze's photographs of human types, landscapes, birds, and beasts is simply perfection, the photographs themselves being without blemish. Where it has been necessary to make and reproduce drawings in lieu of photographs, these are of great beauty and accuracy, and their reproduction is of a quality apparently unattainable in England.

To summarise the principal subjects of the book. The geological features of the south-west coast of Africa are illustrated with many photographs, diagrams, and a careful verbal description. This, though thoroughly scientific, may appeal likewise to the eyes and intelligence of the unlearned. The set of the currents, the growth or diminution of the sand-bars along the coast, the caves (once, perhaps, inhabited by the primitive tribes of Strandloopers), the barren, rocky coast, with its beaches strewn with whalebones, the rocky capes with great maned sea-lions *in situ*, the islets, thick with cormorants, gannets (literally in millions), and penguins, are graphically depicted. An interesting record of the species of whales recorded on this coast, as well as of the principal sea fish, molluscs, and other water animals, is given on pp. 30 to 41. The author supplies the Hottentot names for all creatures or features recognised by the natives.

Though vegetation is not the strong point of this desolate region, such as is found there is of great interest to the botanist owing to its special adaptation to arid conditions of life. The Zygophyllums (characteristic of the northern desert from Senegal to Scinde), the soap bushes (Salsola), the Mesembrianthemums, with their cactus-like flowers and thick segmented stalks, the stumpy euphorbias, gouty, branched aloes, and that extraordinary plant the *Welwitschia mirabilis*—almost every example of this strange desert vegetation is represented by photographs of remarkable clearness and beauty. The camera also shows us the large-eared, chamois-like Raphicerus antelopes, perched on the jagged summits of honeycombed gneiss; vast river plains surrounded by monotonous ranges of table-top mountains, but exhibiting some relief from the universal desert in the acacias, Boscias, Bauhinias, Baphias, Combretums, gourds, lilies, rushes, and euphorbias they nourish. (One exquisite picture opposite p. 604 shows an erstwhile desolate stretch of the Kalahari Desert temporarily lovely with thick masses of the Brunsvigia lilies.) The black-backed jackal, the Chakma baboon, the ostrich, Cape hartebeest, porcupine (the South African species), the steenbock (Raphicerus), the white-tailed gnu, zebra, springbock, giraffe, lion, and all important members of the mammalian fauna, past and present, are illustrated by photographs from the living animal. From p. 268 to p. 288 a great deal of information is given about the existing mammalian fauna of the interior. The elephant is included, though it is practically extinct in this region, and only remains in the traditions of the Hottentots. The white rhinoceros is known by name, but is now extinct. The same fate has also probably reached the common black rhinoceros, and the quagga likewise only lingers in traditions. (The last quagga of South-West Africa appears to have been killed in 1880.) The strangely archaic dog form—Otocyon—with its four molar teeth on either side of the lower and sometimes of the upper jaw, is fairly common in Namakwaland and the Kalahari Desert. Dr. Schultze observes that it never goes in packs, but leads a solitary existence. The brown hyæna (*H. brunnea*) is apparently found in South-West Africa, as well as the spotted hyæna, but the Hottentots do not seem clearly to distinguish in nomenclature between the two forms.

The supreme interest of this work lies in the descriptions and illustrations of the Hottentot, Bushmen, and Berg-damara peoples. Portraits of the Herero and of the Barolong-Bechuana are also given to contrast the Bantu type with the very distinct Hottentot and Bushman. There are also pictures and descriptions of the Masarwa Bushmen, which would suggest that these last are due to some slight intermixture with the intruding Bantu.

Opposite p. 420 there are two photographs of the Berg-damara. This is a mountain people found in the northern part of Namakwaland. They speak a language which is obviously Hottentot, but in physical type they are entirely unlike the Hottentot, except that both are widely divergent forms of the negro species. The Berg-damaras are a tall people compared to the Hottentots, and hairy about the body, with abundant head hair, and, in the males, full beard and moustache. In shape of head and degree of prognathism they exhibit a good deal of variety. There are old photographs in the possession of the Royal Geographical Society (dating from the Palgrave expedition of 1873) which exhibit types of Berg-damara of quite a simian aspect, strongly reminiscent of the most primitive tribes of forest negroes in the Congo basin. On the other hand, the Berg-damara people seen by the writer of this review in South-West Africa in 1882, and illustrated in this book, represent a fairly good-looking type of Bantu negro, and might be matched easily among the Bantu tribes of the southern and eastern Congo basin.

Any doubt as to the ape-like faces of the pure-blood Bushmen is dispelled by a glance at the pictures opposite p. 322. On the other hand, some of the Hottentot types herein illustrated suggest what is no doubt the obvious solution of their origin—an ancient hybrid between the pure Bushman stock and some Nilotic negro race in the east of Africa, with a dash

S

here and there of the forest negro. There has also been an obvious intermixture of blood between the eastern Hottentots and the incoming Bantu, and some of the pictures of Hottentot boys are singularly reminiscent of the Nyanja populations of western and southern Nyasaland, regions that certainly once possessed a Hottentot or Bushman population. The extraordinary steatopygy developed by the Hottentot women, and occasionally the men, to a degree not met with in any other part of Africa (though by no means unknown among Nilotic or Sudanese negroes, and apparently characteristic of a primitive negroid population of Egypt and the Mediterranean basin) is also illustrated by photographs and verbal description.

What strikes one markedly in the Bushman types and some of the Hottentots is the superficial resemblance they bear in features to the peasant population of parts of central Europe, eastern France, and—if one may dare to say so—some parts of Ireland.[1] It is quite possible that the Bushman type of negro once ranged from central and western Europe, across the Mediterranean, and down the east side of Africa to his present habitat. It is curious that these types do not recall any reminiscences of the Congo pygmy or the West African negro. One is only able to match them in the eastern Sudan and in Europe. The author directs attention to the fact that the Bushmen and Hottentots, where they are uninfluenced by the Bantu, do not practise circumcision.

They are scarcely in an age of stone; indeed, Dr. Schultze does not seem to record the use of any stone implements. But they are living in an age of bone, wood, and skins. The arrow-heads of the Bushmen are usually made of bone. So are many other implements of Bushman and Hottentot. Wood and leather, gourds, thorns, and sticks are the materials out of which utensils, ornaments, and receptacles are made.

Among the many aspects of the life of these primitive peoples so completely illustrated in this work are the domestic animals—sheep, goats, and cattle. The dog no doubt migrated south with the Bushman and Hottentot, after a previous sojourn in the Mediterranean basin. But obviously, the goat first, then the ox and the sheep, were brought to them from the north by Bantu or Nilotic negroes. The Hottentot root word to express cattle (*goma-*) is probably derived from the southern Bantu *-komo*, and *biri-*, for goat, may be the early Bantu *buri*, *budi*. Even the vocable for sheep, *gu-*, can be traced to a Bantu source.

The cattle of these regions, whether belonging to Hottentot or Bantu peoples, are apparently a mixture between breeds introduced two and three hundred years ago by the Portuguese and the Dutch and the two more or less indigenous breeds of Central Africa, that is to say, the humped ox (*Bos indicus*) and the Gala or Egyptian ox (*Bos aegyptiacus*), with its enormous horns. Nowhere amongst the herds of any of the southern Bantu or of the Hottentot does one meet with the typical African ox that formerly ranged from Egypt across the Sudan to Senegambia, and which has penetrated to the mountain regions of the Nile and Congo basins. In this ox of pure breed the horn cores are never set horizontally and curved forward over the face; they grow out at right angles from the frontal line, and then upwards and backwards. It is evident that the cattle introduced from western and northern Europe considerably modified the stock of the South and South-West African breeds.

The Hottentot language is profoundly studied in the volume under review. There is a vast deal of information about folklore, rainfall, and temperatures, lists of plants, the musical notation of Hottentot songs, chemical analyses of Hottentot medicines, and a bibliography.

If this is the way in which Germany is going to illustrate her colonies, the world of science would gladly install her in possession of all the backward and little-known regions of the world.

H. H. JOHNSTON.

[1] Anthropologists hardly need to be reminded that Ireland contains at least half-a-dozen distinct anthropological types, ranging from the handsomest to the ugliest of European peoples.

ALCOHOL AND ITS EFFECTS.

Alcohol and the Human Body. By Sir Victor Horsley, F.R.S., and Dr. Mary D. Sturge, with a Chapter by Dr. Arthur Newsholme. Pp. xvi+370. (London: Macmillan and Co., Ltd., 1907.) Price 5s. net.

THE importance of the alcohol question to the well-being of the race can scarcely be exaggerated, and in many respects this book will be very useful, but it is questionable whether the authors do not go too far in ascribing to alcohol ill effects only and no useful properties. The book, in fact, is a partisan one, and any evidence favourable to alcohol has been completely suppressed.

In the first chapter the action of alcohol as a drug is considered, and it is shown how the use of alcohol has declined in hospitals. The chemistry of alcoholic beverages is then briefly discussed. The effects of alcohol on protoplasm, on the various tissues of the body, and on mental and physical work, are subsequently described in language which can be understood by all, technical terms being avoided, and in the final chapter Dr. Newsholme discusses statistically the influence of the drinking of alcoholic beverages on the national health and wealth.

In venturing to make some criticisms on the book as a whole, we would remark that we are in complete sympathy with the object of the authors, which is, we take it, to emphasise the disastrous consequences which may result from indulgence in alcohol.

The first criticism we would offer is that no distinction is made between alcohol and alcoholic beverages. It may be true that alcohol, as alcohol, does not possess all the virtues and properties which are so often attributed to it; but surely there is a consensus of opinion that the moderate use of good, well-matured spirit or wine is frequently beneficial in some disease conditions, and many of the ills attributed to alcohol may well be due to the by-products present in cheap beverages. Alcohol has been shown to occur in small quantities in the tissues; it is a result of normal metabolism; and we therefore question whether the moderate use of alcoholic beverages does any harm. The difficulty is, of course, to define what is meant by "moderate use"; probably a quantity of a beverage equivalent to 1 to $1\frac{1}{2}$ fluid ounces of absolute alcohol is as much as can safely be consumed *per diem*. If this be admitted it must be confessed that a large proportion of so-called moderate drinkers exceed the mark; the man who takes four or five whiskies a day is probably consuming 2 to 3 ounces of absolute alcohol *per diem*, and is therefore exceeding what may be considered to be a safe limit. The experiments quoted, in which even weak solutions of alcohol are shown to be protoplasmic poisons, are hardly convincing as to the deleterious action of alcohol on the organism as a whole, for are not distilled water, 3 per cent. salt solution, and beef-tea similarly protoplasmic poisons? A good deal is made of the supposed disastrous effects of alcohol on the nervous system, and it is stated that alcohol is accountable for 20 per cent. of the cases under care in our asylums. Dr. Mott,[1] however, says—and he has made the subject one of special study—that "alcohol does not *per se* produce a permanent mental derangement, such as constitutes our definition of insanity," and he points out that in an American inquiry into the subject, total abstinence was found to be more frequently an antecedent of insanity than was intemperance. These quotations show how difficult it is to associate cause and effect.

Dr. Newsholme deduces from the statistics of the consumption of alcoholic drinks in 1904 that each adult of the working class spends 2*s*. $2\frac{1}{2}$*d*. a week on alcoholic beverages; and, assuming that each family spends 5*s*. a week, this, if placed as an insurance premium, commencing at the age of 25, would mean that the husband would have saved the sum of 422*l*. at the age of 55, which, invested as an annuity, would yield 12*s*. 6*d*. a week. These are certainly figures of grave import, and we would commend them to the politicians, for here surely is the basis for a scheme of old age pensions!

We doubt, however, if there would actually be anything like this saving, for a majority would certainly spend the money on substitutes for alcoholic beverages—tea, coffee, cocoa, milk, and temperance drinks—on better food and clothing, and on amusements, and the actual gain would principally be in the well-being of the people. Finally, incidence of sickness and the percentage death rate among abstainers and non-abstainers is contrasted; among the former the death rate is 3·557, among the latter 6·532. Dr. Newsholme remarks:—"We are compelled to conclude that what is commonly described as moderate drinking has a most injurious effect on health and life." We feel convinced that the whole story is not told by these figures. No doubt many drunkards were included among the moderate drinkers (as Dr. Newsholme suggests), and probably a large proportion were not moderate drinkers according to our definition; and may it not be that a considerable proportion of naturally delicate persons, persons whose stamina is poor and who suffer from various ailments and tend to die young, are moderate drinkers, while the abstainers include a large proportion of robust individuals who do not feel the need for any alcohol?

[1] *British Medical Journal*, 1907, ii., p. 797.

On the other hand, a number of so-called abstainers are certainly really moderate drinkers, for many temperance drinks contain some alcohol. Thus, in the year ending March 31, 1907, of 1133 samples of beverages sold as temperance drinks examined in the Government Laboratory, 71 contained 3 per cent. of proof spirit, 37 contained 4 per cent., and 8 contained 6 per cent. or more. Herb beer and dandelion stout contained respectively 10·5 per cent. and 12·3 per cent. of proof spirit. That is to say, 10 per cent. of temperance drinks contain nearly as much alcohol as a mild ale!

The book is well got up, and contains a number of coloured and black-and-white illustrations and diagrams.

VAN DER WAALS AND HIS SUCCESSORS.

Die Zustandsgleichung der Gase und Flüssigkeiten und die Continuitätstheorie. By Prof. J. P. Kuenen. Pp. x+241. (Brunswick: F. Vieweg und Sohn, 1907.) Price 6.50 marks.

PROF. KUENEN'S monograph will be welcomed by a large circle of readers who have felt the fascination of van der Waals's equation in its simple but marvellous exposition of the critical phenomena, and who desire to become acquainted with the results of recent investigations in this important field of work.

As the author is able to show in his first four chapters, the equation of state affords a complete qualitative explanation of the behaviour of gases under varying conditions of temperature and pressure, including those which cause liquefaction. The whole description is admirably clear, but it may be permitted to direct special attention to three points which are not usually discussed; these are (1) the demonstration of the way in which the labile equilibrium (in which pressure and volume increase together) must collapse in such a way as to give rise to two layers of different density (p. 24); (2) the fact that in the metastable region the *pv* curves for low temperatures intersect and cross the axis of volume, corresponding with the experimental observations of Helmholtz and others that liquids may exist under considerable negative pressures without vaporisation (p. 28); and (3) the fact that the liquid in a capillary tube out of contact from air is under a pressure less than the normal vapour pressure, and is therefore metastable, and might even become labile if the capillary height were sufficiently great.

In spite of its wonderful qualitative accuracy, van der Waals's equation almost invariably breaks down when accurate quantitative tests are applied (chapters vi. to ix.). Thus, if the values of the critical constants are filled in, the expression RT/PV should have the value 8/3=2·67 for all gas; actually argon appears to give a normal value, and hydrogen the value 2·94, but a group of eighteen hydrocarbons and simple derivatives gave values ranging from 3·4 to 3·9 (p. 60), whilst polymerised liquids gave values between 4 and 5. Similar results are observed in reference to the ratio of the temperature of inversion to the critical temperature; in a number of cases the ratio has the value 2·98, but this figure, though substantially constant, differs considerably from the theoretical value $27/8 = 3·37$ (p. 68). In a third table (p. 83) are given the minimum volumes for a series of gases under extreme pressure and at low temperatures, as compared with the volumes at the critical point of each gas; the actual values:

O_2	Cl_2	CO_2	SO_2	C_2H_4	CCl_4	$C_4H_{10}O$	C_6H_6
0·278	0·282	0·269	0·243	0·243	0·260	0·255	0·258

are nearly constant at 0·26, but differ widely from the theoretical value $1/3 = 0·33$. A fourth table (p. 71), in reference to the minima in the pv/v curves, shows a precisely similar result—the four constants which are given for each of three gases agree closely together, but differ widely from those calculated from the equation of state.

In view of the failure of van der Waals to give an exact quantitative explanation of the behaviour of liquids and gases, it is natural that many attempts should have been made to correct and improve the original equation. These attempts are described in chapters xii. and xiii., but the fact that the author has found it necessary to discuss something like a dozen different equations is in itself sufficient evidence that the goal has not yet been reached.

A part of the difficulty which arises in applying equations such as that of van der Waals is due to the fact that in compounds such as water and the alcohols liquefaction is accompanied by the formation of molecular aggregates (chapter xi.); attention has therefore been directed in recent years mainly to the study of hydrocarbons and similar substances in which this tendency is at a minimum. In most cases the polymerisation is instantaneous, but the author is incorrect in supposing (p. 52) that this is always the case; thus the recent observations of Bamberger and Seligman have shown that in the case of nitrosobutane the association and dissociation (unlike those of nitrogen peroxide) proceed quite gradually. There can be little doubt, however, that he is right in attributing the anomalous densities observed by de Heen and others to the presence of impurities rather than to slow changes of molecular aggregation as postulated by Traube; on this point the evidence afforded by the author's own experiments, supplemented by the recent discussion of Verschaffelt, appears to be conclusive.

T. M. L.

AMERICAN FORAGE CROPS.

Forage Crops for Soiling, Silage, Hay and Pasture. By Dr. Edward B. Voorhees. Pp. xiii+384. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1907.) Price 6s. 6d. net.

THIS book is one of the Rural Science Series, edited by L. H. Bailey, and designed to give the American farmer simple but accurate instruction in scientific agriculture. Some of the series, *e.g.* King's "Soil," are of general interest, and are well known here; the others refer mainly to American conditions, and appeal less to English readers.

Forage crops are those which are fed in the green state to animals instead of being left to ripen and produce seed: turnips, mangolds, and "temporary" grass are all examples. They play a highly important part in every scheme of general farming; indeed, their introduction into England in the seventeenth and eighteenth centuries not only revolutionised our agricultural practice, but had a considerable indirect effect on the social life of our ancestors.

The author deals with practically all the fodder crops grown in the United States, giving details of cultivation and manuring, and, in some cases, summaries of the results obtained with the crop at the various experiment stations. These summaries are perhaps the best part of the book, and will be appreciated both by the student and the farmer; we should like the author to have extended them by including short descriptions of the soil and climatic conditions. The cultivation and manurial details are treated mainly from the empirical standpoint, and here we cannot help feeling that the author has missed an opportunity. Details are of very great importance in agriculture, but they should hardly be given the chief place in a text-book like the present one. Neither the student nor the practical man can make much of them; there is an endless variety about them, and a scheme that works well on one farm may not prove suitable on another close by. What is wanted is a clear statement of the general requirements of the crop, followed by a few well-chosen detailed illustrations. In this way the student gets a real picture that will be of service to him, and the practical man is put in a position to see whether or not he can profitably grow the crop. Unfortunately, the author does not quite give us this, and if the schemes he suggests fail, the farmer is not in possession of the principles which would aid him to frame a modification suited to his land.

A perusal of the book brings out very clearly the differences between English and American practice in regard to fodder crops. The difference depends not only on climate, but also on labour supply, for in the latter respect the American farmer is worse off even than his English cousin. We learn, for instance, that one of our best root crops, the mangold, is not widely grown because of the labour required. Its place is taken by green maize, which is partly fed green and partly made into silage.

The author also deals with the different ways of using fodder crops—soiling, ensilage, and conversion into hay. Soiling was introduced into the States from Europe in the middle of the last century by Josiah Quincy, whose writings on the subject are so good that it is a pity the author makes no mention of him. The practice consists in cutting and carrying green crops to the animals, which are kept in stalls all the year round instead of going out to grass in summer. It has proved to be economical in places where land is dear and labour cheap, but is not likely to displace ensilage in America, notwithstanding the prominent place assigned to it in the book. Indeed, one hardly sees how silage could be improved upon for the American farmer; he has learnt how to make it, and as a labour-saving device for the dairyman it has been ranked with the separator.

Certain statements will want correction in a future edition. We are told, for instance, that "the covering of land in summer prevents the temperature from rising so high as to destroy the organisms of the soil."

E. J. R.

OUR BOOK SHELF.

Astronomischer Jahresbericht, Vol. viii. Die Literatur des Jahres 1906. By A. Berberich. Pp. xxxvi+671. (Berlin: Georg Reimer, 1907.) Price 21 marks.

ASTRONOMERS are fortunate in the matter of having their literature catalogued, for, in addition to the volume published by the Royal Society for the International Council, we have this very excellent annual, instituted by the late Dr. Walter F. Wislicenus, which has now reached its eighth volume.

The contents of the present issue deal with the literature of the year 1906, and it only requires a cursory glance to indicate how important it is that such a catalogue is in existence, considering the great mass of work that is being turned out every year and published, not only in all sorts of journals, but in various languages.

The very arduous task of collating and cataloguing is now annually being successfully accomplished by Dr. Berberich and his co-workers, and an important feature about the publication is its early issue.

In the present volume, which contains no less than 1961 separate brief abstracts of published papers, accompanied by a complete name-index, some minor changes have been made.

Thus all references to publications with regard to minor planets are brought together under one section number, and the tabular statement of their observation is here omitted, as it appears in full in the Berlin Astronomical Year-book.

The literature relating to comets is now divided between two sections, while one section includes the whole of meteor-astronomy.

In spite of the above and other alterations, the volume is not reduced in size, for longer abstracts are given of works of greater importance.

The value of this publication to astronomers cannot be overestimated, and it behoves everyone interested in this science to support it, so that the continuation of future issues may be assured.

Lehrbuch der theoretischen Elektrochemie auf thermodynamischer Grundlage. By J. J. van Laar. Pp. xii+307. (Leipzig: W. Engelmann; Amsterdam: S. L. van Looy, 1907.) Price 6 marks.

THE present volume differs greatly in character from those to which we are accustomed from the pen of Dr. van Laar. His "Thermodynamik in der Chemie" and his "Lehrbuch der mathematischen Chemie" are so formal in their nature, so mathematical in their dress, and so slightly connected with the facts of observation, that the majority of chemists can have derived little benefit from them, excellent though they may be of their kind. Here the author adopts a different method; the mathematical deductions have the clearness and conciseness which might be expected, but everywhere the experimental data are brought into the foreground, so that the electrochemist with a modest mathematical equipment may hope to gain a clear view of the thermodynamical theory of his science.

The book is divided into twelve chapters, of which the first deals with electrical units, chapters ii.–iv. with conductivity, chapter v. with diffusion, chapters vi.–x. with electromotive force, chapter xi. with polarisation, and chapter xii. with capillary electric phenomena.

A good account of the work of Kohlrausch is given in chapter iii., and the recent researches of Walden and others on the conductivity of non-aqueous solutions, and of Lorenz on fused electrolytes, are well summarised in chapter iv. Chapter vii., on the partition equilibrium of electrolytes, contains much that is novel.

Altogether it may be said that the book is readable, original, and suggestive.

Coal. By James Tonge. Pp. vii+275. (London: Archibald Constable and Co., Ltd., 1907.) Price 6s. net.

THE author recently published an excellent little work on coal-mining for the use of students. It is disappointing, therefore, to find that in writing a book on coal for the general reader he has been less successful. The work appears to have been hastily compiled, and the proofs carelessly revised. For example, the Ruhr appears as "Rurh," Courrières as "Courrieries," Anzin as "Auzin," Resicza as "Kesicza," and Karwin as "Kirwin."

There is a useful chapter on the preparation of coal for the market; and the chapter on the botany of the Coal-measure plants is excellent, though somewhat technical for the general reader. Both these chapters are admirably illustrated. The chapters on the British and foreign coalfields, on the valuation and uses of coal, on the production of heat from coal, and on the waste of coal, contain, however, little that is not better set forth in the report of the Royal Commission on Coal Supplies, in the valuable digest of that report published by the *Colliery Guardian*, in Prof. Flux's revised edition of Jevons's work, or in other works dealing with coal. Of such works many have recently been published, for we cannot agree with the author that "it is now many years since a work on coal was presented to the public."

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Speed of Racing Animals.

IN NATURE, March 14, 1907, p. 463, there is an article giving the results obtained by Prof. Kennelly, of Harvard, from an examination of racing records. There is no harm in again directing the attention of your readers to these results. Prof. Kennelly's paper was sent July 6, 1906, to the American Academy of Arts and Sciences, and published in the Proceedings in December, 1906. It is entitled "An Approximate Law of Fatigue in the Speeds of Racing Animals." His general result is given in a question set by me in an examination in practical mathematics, January, 1907. Here is the question:—

If t seconds is the *record* time of a race of y yards; the law $t=cy^n$ seems to be wonderfully true for all record races of men and animals excepting men on bicycles; n is the same number in all cases. c has a special value in each case, men walking, running, skating, swimming, or rowing; horses trotting or galloping or pacing.

(1) For any particular kind of race it is found that when y is increased by 100 per cent., t is increased by 118 per cent.; find n.

(2) For men running, when $y=600$, t is 71; find c in the above formula. Express s, the average speed of each race, in terms of y.

(3) Assume that an animal has a certain amount of endurance E which is exhausted at a uniform rate during

the race, and that $E = E_0 + kt$, where E_0 and k are constants. Calling E/t the rate of fatigue f, express this in terms of s.

Assuming that an animal going at s_0 miles per hour feels no fatigue, or when $s = s_0$, $f = 0$; find f in terms of s.

(1) Contains the general result; the law is that t is proportional to $y^{9/8}$ or $y^{1 \cdot 125}$. It may be stated in various other ways; for example, that the average speed in each race is inversely proportional to the eighth root of y, or a race 256 times as far is done at half the average speed.

In short races there is increase of speed at the beginning and almost always increase near the end; and it may be that there is continuous change of speed during all record races. We have only average speeds recorded, unfortunately, but still I must consider this wonderful general law to be worthy of the attention of biologists. (3) Contains a poor speculation of my own, good enough for such an examination; the answer to it is that f is equal to $E_0 c^8 (s^9 - s_0^9)$. There is nothing extraordinary in the fact that record bicycle races do not follow the law; they have been run on machines of varying quality.

The values of c found by Prof. Kennelly are, his distances y being in metres:—trotting horse, 0·0295; pacing horse, 0·0291; running horse, 0·0236; man running, 0·0588; man walking, 0·0861; man skating, 0·0385; man swimming, 0·381. Men rowing, four oars, 0·0628; two oars, 0·0768; singles, 0·0824. JOHN PERRY.

Royal College of Science, S.W.

The Isothermal Layer of the Atmosphere.

THE investigation of the upper air which has been in progress during recent years has revealed conditions for which it is very hard to find an explanation. When Mr. Rotch first inaugurated observations on temperature and humidity by means of kites, it was hoped that the results obtained would solve many problems connected with meteorology, and this hope was strengthened when M. Teisserenc de Bort greatly extended the height to which observations could be made by his system of *ballons sondes*. It has not, however, been realised, and we seem to be as far as ever from knowing the cause and mechanism of the cyclonic storms that are so common in the oceanic parts of the temperate latitudes.

Since last June some forty balloons have been sent up in Great Britain, carrying with them a small instrument which draws automatically a pressure temperature diagram, and of these more than thirty have been recovered. The results confirm those previously obtained on the Continent, and no doubt can now remain about the existence of the curious isothermal layer in the atmosphere.

Briefly, the more important phenomena are these. As we ascend the temperature of the air decreases, at first often irregularly, with breaks and inversions, but after the first 10,000 feet (3 kilometres) have been passed with fair regularity, the usual decrease being about 3°·3 F. per 1000 feet (6° C. per kilometre). This continues to a height that varies, as a rule, from 30,000 feet to 40,000 feet. Nearly always at somewhere about this height the decrease suddenly ceases. Above this point the air in most cases gets a little warmer; occasionally, however, it continues to get cooler, but at a totally different rate, and we may take the remaining air to be at one practically uniform temperature in so far as change of height is concerned. This isothermal layer, as it has been called, has been reached in England more than thirty times. On the average its height is about 35,000 feet (10·7 kilometres), but the extreme values found were 25,500 feet and 49,000 feet. As a rule, it is higher than the mean when the barometer is high, and conversely. Its mean temperature was found to be $-53°·6$ F. ($-47°$ C.), and the extremes were $-22°$ F., at Ditcham Park, Hants, on July 24; $-24°$ F., at Crinan, on July 26; $-78°$ F., at Pyrton Hill, Oxfordshire, on September 12, 1907, and also on February 5, 1908; and $-74°$ F., at Manchester, on November 7, 1907.

This mean value is considerably higher than the Continental one for previous years, but as thirty observations do not suffice to give a true mean, this may be accidental. Balloons have been sent up from five stations on the same day, and the temperatures over the stations have been found to differ widely. Thus on November 11 Mr. Cave's balloon from Ditcham Park reached the isothermal layer at 36,000 feet, and its temperature was $-42°$ F. Over Oxfordshire the height was 38,500 feet, and the temperature $-58°$ F., while at the same time, which was a little after sunset, Mr. Petavel, at Manchester, found it at 37,000 feet, with a temperature of $-74°$ F. This is not an isolated instance, and although the heights given may be uncertain to an extent of perhaps 5 per cent. or even more, it is very unlikely that the error in the temperature can exceed three or four degrees F. It may be accidental, but the temperature over Ditcham Park, which is near the sea, shows a tendency to exceed that over the Midlands. The balloons mostly drift to the eastward, the centre of their falling points being thirty-four miles E., 23° N., of the starting point. Doubtless several of the unfound balloons fell in the North Sea, as some have been returned from France and Holland.

Various suggestions have been made to account for these results. There is, of course, no difficulty about the general decrease of temperature with height, but why should the fall suddenly cease when from one-third to one-fourth of the mass of the atmosphere remains above? In general, the transition point is perfectly sharp and distinct. It is said that the vertical circulation ceases at this point, and no doubt the statement is true, but why should it cease? There is a further difficulty. The absence of vertical motion implies a condition of equilibrium, but how can there be equilibrium with such large horizontal differences of temperature? At the height of 40,000 feet the pressure is small, and therefore trifling changes of pressure produce large changes of volume and temperature; hence large changes of temperature might be expected if we could assume some horizontal force, comparable with gravity, and capable of producing changes of pressure without producing vertical motion. The horizontal acceleration due to centrifugal force in a curvilinear path and that produced on a moving body by the earth's rotation are too small; also it seems to me that these forces, being due to motion of the air, must produce some vertical circulation, which apparently does not exist.

The problem is one of the most interesting presented at the present time to physical science, and it is not unlikely that its solution might clear up many other puzzling questions. W. H. DINES.

The Inheritance of "Acquired" Characters.

MR. ARCHDALL REID in his previous letter said (p. 293) "innate characters arise inevitably as the child develops, whereas some acquirements are more or less rare, but this is *only* because the stimulus of nutriment is inevitably received, whereas the stimulus of a particular *use* or *injury* may not be received. If, however, the latter be received, *the acquirement arises just as inevitably as the innate characters.*" This latter statement seemed to me particularly incorrect for the reasons which I stated; and now Mr. Reid practically admits (p. 342) that it cannot be accepted as it stands, in face of the fact that the inherent tendencies of the germs of different human beings vary so much, and must therefore react variously to the stimulus of use.

My chief objection, however, to Mr. Reid's view was that contained in his statement that "in man the main difference between the infant and the adult is due to use acquirements made by the latter during development." His whole case in the discussion hinges upon this statement, by which he seeks to establish a purely arbitrary distinction between the causes leading to the development of the human being anterior to birth and subsequent to birth—the stimulus in the one case, he says, being nutriment, and in the other use. As an illustration of his position, Mr. Reid said (p. 293):—"Thus, if the limb of an infant be paralysed it grows comparatively little, and the muscles atrophy." But this is by no means to be taken as a simple illustration of the fact that the muscles will not develop except under the stimulus of use, because the illustration ignores the fact that what happens in the way of retarded growth of the paralysed limb, together with actual atrophy of muscles, is, quite apart from the lack of use, largely due to a severance of the normal relations between the limb and the great nerve centres, and the consequent cutting off of the "trophic influence" exercised by the latter.

Again, it is a part of Mr. Reid's doctrine, as he tells us, to regard the power of walking and the power of speaking as use acquirements, while I, on the contrary, hold that the effects of use-exercise *seem* to be predominant in these cases simply because the efforts made to walk or to talk take place *pari passu* with the development of the nerve centres concerned with such accomplishments.

As I have said elsewhere ("The Brain as an Organ of Mind," p. 562), "the helpless condition of the infant monkey and of the human infant at birth are similarly to be ascribed, in great part, to the immature condition of their great nerve centres. Many of the movements which they slowly learn to perform are doubtless rendered possible by, and acquired coincidently with, *the actual development of those nerve cells and fibres in the spinal cord and medulla which are instrumental in the execution of such movements.* Thus, when we say that the young child 'learns' to perform these movements, it should be understood that this word is here applicable only in a very qualified sense. . . . But for the existence of this organic *nisus* (in the form of an inherited tendency to develop in certain modes and directions) the human infant could never so readily as it does acquire the power of executing the excessively complex movements which are concerned in standing, in walking, or in articulate speech."

In illustration of these views I have cited cases in which walking was an untaught act in a child at the end of her second year, as there had been no previous trials and failures; and also a case (*loc. cit.*, p. 607) in which a child who had been absolutely dumb up to the end of his fifth year suddenly began to speak under an emotional stimulus. Another very similar modern case, as well as two cases recorded by ancient writers, of untaught acts of speech are also cited in my work on "Aphasia and other Speech Defects" (1898, pp. 6–8).

No explanation of such facts seems possible except on the supposition that speech has now become a truly automatic act for human beings. Such untaught acts of speech would not, however, be possible unless cerebral development had been taking place in a normal manner, and unless the auditory sense and intelligence were unaffected.

These are some of the reasons why I dissent from Mr. Reid's view that "in man the main difference between the infant and the adult is due to use acquirements made by the latter during development," and why I say that post-natal growth and development are essentially due to the same inherent causes as pre-natal growth, notwithstanding the fact that use-exercise comes in as a powerful aid during the former period.

As to the extraordinary power of memorising shown by Chinese and Mohammedan children to which I referred Mr. Reid, in accordance with his views he would deny that any influence is to be ascribed to the practice in memorising carried on by ancestors of the children through very many previous generations; and in that case he must suppose that English children, as a class, should be capable of showing similar feats of memory, even though their ancestors had not been accustomed to any extraordinary exercise of their memorial faculty.

For the rest, that Mr. Reid's views do not suffice to close the controversy as to the inheritance of "acquired" characters may be easily seen by any of your readers who will refer to Herbert Spencer's "Principles of Biology," revised edition, 1898, App. C, pp. 692–695, and to his "Facts and Comments," 1902, pp. 92–96. I might even venture to refer your reviewer, "A. D. D.," to a consideration of the facts and arguments set forth in these works.

H. Charlton Bastian.

The Athenæum, London, February 15.

I said that acquirements are just as "innate" as "inborn" characters. Dr. Bastian read this—I am sure I cannot imagine why—as implying a denial of the occurrence of variations. I repudiated his interpretation, and this he now terms an admission! The muscles of a limb atrophy equally when they are rendered useless by joint disease as when there is "severance between the limb and the great nerve centres."

The Lamarckian doctrine is founded on two unproved assumptions:—(1) that use causes development in all characters, and (2) that parental acquirements tend to affect the germ-cells in such a way that the traits which arise in the parent under the stimulus of use are reproduced by offspring under the stimulus of nutriment—that is, when the parent acquires one thing the child is supposed to "inherit" something inherently different and much less useful. The second assumption was formerly universal, but has now been abandoned by the vast majority of biologists. Most of us know, or think we know, how great an obstacle it was to the attainment of truth and how much deeper and clearer has become our knowledge of nature since its abandonment. We suppose it was held merely because men tend to accept current beliefs without bestowing on them that critical and sceptical thought which is one of the essentials of real scientific work.

The first assumption is still very generally made, and I think for the same reason. Unsupported by an iota of evidence and obscuring the fact that a principal feature of the evolution of the higher animals has been the evolution of a power of developing under the stimulus of use, it is as great an obstacle to the recognition of truth as the other. Many human structures are plainly incapable of developing under the stimulus of use, for example, hair, teeth, external ears, and memory. These are wholly "inborn" (*i.e.* developed under the stimulus of nutriment). The evidence seems massive that many lower animals, for example, the Coleoptera and Lepidoptera, owe little or no part of their physical and mental development to use. Hence their lack of individual adaptability. But higher in the animal scale, memory (the power of profiting by mental experience, of growing mentally under the stimulus of use) becomes apparent, and increases until it bestows on man all that makes him preeminently the educable, rational, and adaptable being. *Pari passu* with this increase of the power of growing mentally under the stimulus of use has occurred an equally great evolution of the power of growing physically under the same stimulus. In my view, then, (1) while memory and the homologous power of growing physically are "inborn," all that arises from the exercise of them is "acquired"; (2) not all human characters are capable of developing under the stimulus of use, but only a majority of them; and (3) in the case of the latter all, or nearly all, that separates the infant from the adult is due to the stimulus of use.

Either Dr. Bastian is putting the cart before the horse or I am. I believe, for example, that use develops body and mind until we are able to walk, talk, and so forth. He believes, apparently, that we would develop physically and mentally into mature men, and would walk and talk and get a knowledge of Latin and so on even if we never used body and mind. The blessed words "trophic influences" and "organic nisus" afford him complete satisfaction. Surely his assumption is made "in the face of multitudinous difficulties." To him man's adaptability, the vastness of his memory, the great development in him of the instincts of sport, curiosity, and imitativeness, which impel him to make precisely the physical and mental acquirements which bring him into harmony with his own individual environment, tell no tale. He is in a position as unhappy as those investigators who, before defining what they mean by "inheritable," spend years of labour in ascertaining exactly what is "inherited."

Mr. Cunningham says, "innate characters are those which develop without any stimulus except what Dr. Reid calls the stimulus of nutrition," or nutriment as I prefer to term it. But is not nutriment "external"? A scar cannot develop under this stimulus, and I imagine it would puzzle Mr. Cunningham to explain in what sense nutriment is more innate than injury or use. Obviously all characters develop under the influence of some *external* stimulus, and the distinctions between characters are due, not to greater or lesser innateness, but to the kinds of stimuli that cause them to appear. Acquirements arise for precisely the same reason that all inborn characters arise—because evolution has created the power of responding in quite definite ways to quite definite external stimuli; clearly, then, they are innate in precisely the same sense as inborn characters.

February 21. G. Archdall Reid.

MR. CUNNINGHAM says (p. 367) that my article was as dogmatic as it could possibly be. It was meant to be. It was meant to stir up those who continue to use the old terms "acquired" and "innate" without really bothering much about their signification. It has achieved its object admirably.

He also says that I assert that there "is no sense in the distinction between acquired characters and innate ones with regard to inheritance" [which I did not say], "that all characters are both acquired and innate" [which I did]; he continues:—"This in the accepted meaning of the words is simply untrue." Well, of course it is. My point was that the accepted meaning of the terms was vague, that it had led to confusion, and that it ought to be dropped.

Mr. Cunningham does not follow me. I am willing to admit that that may be my fault. I fully recognise, as he does, that the characters of organisms may be divided into two big categories, which have for a long time been called "acquired" and "innate." But I hold that the difference between these two classes of characters is very inadequately expressed by the terms "acquired" and "innate," and that a much better, though, of course, provisional, classification of characters is into (*a*) those which owe their existence to the interaction between some innate factor and the stimulus (for want of a better term) of nutrition, and (*b*) those which owe their existence to the interaction between some innate factor and the stimulus of use or injury.

The view that all characters are acquired during ontogeny as the result of a definite stimulus acting on an innate factor was expressed by Weldon (*Biometrika*, vol. i., p. 367), who has also described (*loc. cit.*) how he succeeded in preventing the appearance of the amnion in the hen's egg by withholding the necessary stimulus.

A full answer to Mr. Cunningham's letter is quite out of the question, because it would involve a discussion on all the meanings of the terms "innate" and "acquired" and a history of their use, which could not be compressed within the limits of a single number of NATURE. But reference must be made to one of the things "innate," as opposed to acquired, certainly does not mean. Whatever it means, it does not mean what it literally means. It does not mean the kind of character one is born with. Before it was known that all organisms develop from a single cell it may have meant that, but now that we know that they do, we regard classifications of characters into those which appear before the act which separates intra-uterine from extra-uterine, and those which appear after it, as interesting from a historical point of view only. Yet in this year 1908 we actually read in a letter to NATURE (I am not quoting from memory) that a Negro "is brown (not black) when he is born; that is an innate character." The facts are true, of course, but not relevant. The fact that a negro is brown when he happens to be born does not matter. The fact we have to face is that the ovum which gave rise to Booker T. Washington was probably not browner than that which gave rise to George. The statement that the colour of the former is innate does not in the least help us to understand the causes to which the difference between the colours of the two men is due. A. D. D.

[FURTHER space cannot be devoted to this correspondence.—ED.]

The Possibility of Life in Mars.

THE perseverance with which Prof. Lowell has prosecuted his investigation of the surface markings of Mars compels admiration; the evidence he has brought forward for the objective reality of much of the detail he has shown in his sketches serves to convince many reluctant minds; but the interpretation he has put upon these markings, in terms of phenomena associated with life as we know it on our own planet, requires stronger evidence than he has yet brought forward in view of the considerations that follow.

The blue-green coloration he attributes to vegetation; its change to chocolate-brown to the fading of verdure with the change in the season. If we grant that the conditions on Mars have been possibly such as to allow of the development of living organisms from inorganic matter, is it likely that the course of evolution has been so exactly similar to that on the earth that a chlorophyll-bearing organism has resulted? Like conditions produce like results—granted; but when one considers the quasi-fortuitous nature of the conditions determining the characters of those organisms that survive in the process of evolution, the remoteness of the probability that the development of the power of forming chlorophyll should happen twice, in two independent evolutionary systems, seems overwhelming.

Again, Prof. Lowell attributes the markings which he considers irrigation systems to intelligent beings. It is possible that that high degree of adaptability to environment, which we call intelligence, might have evolved independently on two planets, but it seems in a very high degree improbable.

Similarly, other points in his scheme of interpretation may be conceivable, but highly improbable. But the probability of the whole is the continued product of all the independent probabilities! The evidence, then, in favour of Prof. Lowell's views will require to be of a much more overwhelming character to claim the assent of those who appreciate their extreme improbability.

Opposition to the views of Prof. Lowell has generally been based on difficulties regarding the physical condition of Mars. It is the object of this letter to emphasise the far greater improbabilities involved in the biological aspect.

Prof. Lowell attributes the reluctance of many to accept his position to the emotions of men. I venture to think that emotions are in his favour; it is the human desire for an anthropomorphic interpretation of nature—in this case perhaps one should rather say a geomorphic interpretation—that has prompted his views, and but for which they would receive small consideration. C. O. BARTRUM.

12 Heath Mansions, N.W., February 17.

IN Dr. William Lockyer's review of Dr. Russel Wallace's book on the habitability of Mars he refers to Dr. Johnstone Stoney's contention that aqueous vapour cannot exist on a planet of that size because the velocity of the molecules would be too great for its attraction to retain them. I do not know what temperature was assumed in the calculation, but a dozen miles above the surface of the planet the temperature of its atmosphere must approach absolute zero—a condition of things in which even hydrogen would not have the necessary velocity to escape.

The question is an important one for those who are interested in the history of the earth, for, whether we choose the nebular or planetesimal view of its origin, there must have been a time when the attraction it exercised on the outer portion of its atmosphere was far less than at present, and if Dr. Johnstone Stoney were right there would be some difficulty in understanding how any water vapour remained. J. W. EVANS.

Imperial Institute, S.W., February 15.

The Stresses in Masonry Dams.

PROF. PEARSON's letter in NATURE of February 20 requires little in the way of reply from me, since my essential point is now admitted, viz. that the stresses $\widehat{xx}$ and $\widehat{zz}$ are practically the same in a slab, whether it be free or form part of a complete dam. I should, however, like to point out to Prof. Pearson, *re* his comparison between a parabola and an equivalent sine curve, that at 5° the ordinate is only one-twelfth the maximum ordinate, so that an error of 30 per cent. in this ordinate is one of but $2\frac{1}{2}$ per cent. on the maximum, which would be, accordingly, absolutely negligible in practical engineering. As regards the remainder of his letter, engineers have the support of many eminent elasticians in their refusal to accept his and St. Venant's dictum that the maximum stretch is the proper criterion of the safety of a structure. In any case, the true criterion is a question for the engineer and the physicist, and not for the mathematician. The most recent experiments, I may add, negative Prof. Pearson's views on this head. H. M. MARTIN.

83 St. James's Road, Croydon.

THREE ANIMAL BIOGRAPHIES.[1]

MR. LONG is always interesting and original, and he is especially so in the daintily illustrated little volume standing first on our list, of which individuality in animals seems to be the keynote. Premising that no species breeds true in all its individuals, the author urges that analogous differences in temper, disposition, and mind reveal themselves to those who take the trouble to observe closely. All who make pets of cats, dogs, horses, and other domesticated animals are fully convinced of the existence in them of individual traits and idiosyncrasies; and the apparent absence of these in wild species seems due merely to the want of careful and minute observation of their habits. That such individualities do exist the author demonstrates, for example, in the case of the American lynx, which, although normally a cowardly and slinking creature, will on occasion follow the trail of a hunter with as mischievous intent as a panther. As usual, Mr. Long discusses members of widely different groups, and in the present volume we have delightful peeps into the life-histories of the black bear, the wolf, the wild goose, the trout, and other denizens of the forest and the stream. Where all is good, it is difficult to make a selection; but we have personally found special interest in the chapter on the bear. Describing the actions of a bear when ant-hunting, the author tells us that "he just knocks the top off the hill, stirs up the nest, and lies down quietly, placing his fore-paws where the ants are thickest. At first he makes no effort to pick up the hurrying insects, workers and fighters, which swarm out of their tunnels. . . . 'Moorween' waits till they crawl over the big black object that rests over the nest, and then he begins to lick his paws more and more greedily as he tastes the acid things. . . . So he gets all he wants, cleanly from his own paws, instead of filling his mouth with dust and chaff, as he must do if he attempted to catch them in any other way." Many other passages in this attractive volume bear equally eloquent testimony to the closeness with which its author has observed the habits of the creatures he loves so well and describes so graphically.

In the volume standing second on our list, Mr. Graham Renshaw brings to a close his long series of articles on mammals, interesting either from their rarity or from peculiarities in their structure or habits. The four-and-twenty species here discussed include a very varied selection, ranging from the musk-ox and the European bison to the Pacific walrus, the Tasmanian devil, and the platypus. As in the case of the earlier essays, the author deals specially with the historical aspect of his subject, and furnishes his readers with a large amount of detail connected with specimens exhibited in menageries and museums. Several of the illustrations are taken from specimens in the British Museum, and among these special attention may be directed to the one of the Congo buffalo, as an example of what may be accomplished in the way of photographing animals as they stand in the cases of the exhibition galleries. We may, however, venture to take exception to the photograph of a very tame-looking park bull being made to do duty for the extinct aurochs; and we should also like to know why the author, in defiance of Herberstain's evidence, states that the latter animal was mainly white. The assertion that all typical sheep have a lacrymal gland (p. 114) seems also to be contrary to fact, while the statement (p. 105) that two Greenland musk-oxen exhibited in 1900 were the first examples of their race known to science is contradicted on the following page by a reference to calves received in England in 1899.

Bearded Titmouse and Young. From "Home-Life of some Marsh Birds.

The author has evidently devoted a large amount of time to working out the history of the various species, and he has certainly succeeded in producing a very attractive volume.

[1] (1) "Whose Home is the Wilderness; some Studies of Wild Animal Life." By W. J. Long. Pp. xxi+230; illustrated. (Boston, U.S.A., and London: Ginn and Co., 1907.) Price 5s. net.

(2) "Final Natural History Essays." By Graham Renshaw. Pp xii+225; illustrated. (London and Manchester: Sherratt and Hughes, 1907.) Price 6s. net.

(3) "Home-Life of some Marsh-Birds." By Emma L. Turner and P. H. Bahr. Pp. 62; 32 plates. (London: Witherby and Co., 1907.) Price 2s. 6d.

One of the objections to the employment of photography as a means of illustrating natural history books is that very frequently the animals are taken in postures which do not display their leading characteristics, and thus render the pictures more or less completely useless for the purpose of specific identification. The same thing applies in the matter of characteristic attitudes and the nature of the habitat; and, in the case of birds, to the form of the nest and the appearance and growth stages of its occupants. To remedy these shortcomings in the case of the feathered denizens of British marshes has been the main object of the authors of the charming little volume standing third in our list. They have set themselves the task of portraying marsh-birds in positions and attitudes which will render the pictures of real service to the scientific ornithologist; and we venture to think that the verdict of their readers will be a pronouncement of unqualified success in this respect. As a specially good example of their work we may cite Miss Turner's photograph of a bearded titmouse, showing the black face-marks of the cock from which the species takes its name. This would not print satisfactorily in the pages of NATURE, but we are able to give another illustration showing the bird feeding its young. The book does not, however, depend entirely on its illustrations, and even in such a hackneyed subject as the life-history of British birds, the reader will find much of interest in the brightly written biographies which accompany the plates.

R. L.

STUDIES IN NATIONAL DEGENERATION.[1]

THE several aspects of study which the statistics deal with in this memoir are chiefly parental and fraternal heredity, the fertility of tuberculous stocks, and the distribution of pulmonary tuberculosis in tubercular families. Prof. Pearson's observations are admittedly, from a numerical standpoint, wholly insufficient, but if his deductions are thereby rendered inconclusive, he has pointed the way and laid the foundation for further study of an all-important subject.

Prof. Pearson discusses only pulmonary tuberculosis, that is, phthisis, or, as it is popularly termed, consumption; yet even with this limitation it is uncomfortable reading that about 10 per cent. of the inhabitants of the British Isles are affected by pulmonary tuberculosis. Unfortunately, other organs besides the lungs become the seat of tuberculosis, and their disorganisation is attended by as serious results as when the lungs alone are considered. It may be that tuberculosis of the lung is, from the point of possible national deterioration, not the most deadly form of the ailment. Tubercular diseases of the bones of the joints, of the lymphatic system, and of several of the organs other than the lungs, prevail to an extent little appreciated as being of an equally deadly nature, with the more evident lesions in the lungs. They all indicate a diathesis, and give rise to types of infirmities well known to medical men. These evils of tuberculosis, therefore, are much more widely spread than pulmonary tuberculosis or consumption would give us to understand, and being less manifest to the public scrutiny are more insidious and more apt to be neglected in the reckoning of tuberculous disease generally.

That heredity plays an important part in tuberculous disease is, in Prof. Pearson's opinion, undoubted. Recent beliefs point rather to infection as being the major element in rendering the disease so prevalent, and it is noteworthy that Prof. Pearson inclines to the older belief of heredity. He finds that tubercular lung trouble is chiefly prevalent amongst those who inherit a predisposition, that is, a phthisical or consumptive diathesis. It is impossible, however, owing to insufficient data, to assume that the tendency to any disease is inherited in the same sense as are physical and mental characteristics, but did inheritance not explain the matter it is difficult to understand how anyone escapes the disease, seeing that, in urban districts especially, the tubercle germ is so prevalent that "few individuals who lead a moderately active life can escape an almost daily risk of infection."

Such being the case, the tubercle germ can thrive best in the suitable soil to be met with in lung tissues which are prepared by hereditary predisposition, or, in some cases, by what may be termed accidentally acquired predisposition in the lung tissues themselves, by previous local lesions. That the predisposition to the lung becoming the seat of tuberculous disease is to be statistically ranged alongside well-established inherited characteristics, such as physical and mental traits are known to be, can only be proved by obtaining complete histories of multitudes of families and family stocks. This, however, is at present a long way off being established, and until this gap is filled any deductions we make at present can only be speculative for the most part.

The period of life during which tuberculosis is most likely to show itself in the lungs is between the ages of twenty and thirty. The mean age of onset in men is set down at the twenty-ninth year, and in women at the twenty-fifth year. The actual danger zone cannot, however, be said to be passed until the fortieth year, or perhaps the forty-third year, is passed.

The observation that there is but an insignificant difference between the time of onset of the disease when some member of the household is the subject of tuberculosis and when no member is thus afflicted is rather against the infection theory pure and simple; for with the constant possibility of infection in the immediate environment, phthisis should, according to infection beliefs, appear at an earlier age than statistics seem to show.

After discussing the part played by parental and fraternal heredity, Prof. Pearson concludes that the tuberculous diathesis is inherited in the same way and with the same intensity as the physical characters are inherited in man.

Concerning the fertility of tuberculous stocks, Prof. Pearson shows that the pathological conditions do not tend to reduce fertility, but, on the other hand, that such stocks appear to be quite as fertile, and in all probability are more fertile, than normal stocks of the same class in the community at large. The fact, however, that tuberculosis is a disease of youth and early middle life distinctly lowers the marriage rate and limits the child-bearing period of such stocks, and thus reduces the total number of offspring born to tuberculous people; there can be no doubt that by the inbreeding of purely tuberculous persons the stock would become in time extinct.

The question of order of birth, that is, whether the child belongs to the early or late portion of a given tuberculous family, is of considerable interest. Are the elder or the younger members of the family the more liable to develop tuberculosis and to possess a tuberculous diathesis? The children of old people, of, say, a man over sixty and a woman of forty-seven, are popularly believed to be handicapped in the struggle for life owing to inherited physical defects. There is no

[1] Drapers' Company Research Memoirs, II. A First Study of the Statistics of Pulmonary Tuberculosis. By Prof. Karl Pearson, F.R.S. Pp. 26. (London: Dulau and Co., 1907.) Price 3s.

real evidence that this is the case, as many instances for and against the contention can be given. Whether the child of elderly parents is healthy or not depends not so much upon the age as upon the health of the parents; for a man with, say, Bright's disease—the prevalent ailment of men over sixty—will certainly not beget a healthy offspring. It would seem, however, from a general study of constitutional defects which are inherited, that the elder members of the family are more liable to suffer than the younger. In the case of tuberculous families, as well as with stocks giving no parental tuberculous history, the elder offspring, especially the first and second, appear subject to tuberculosis at a very much higher rate than the younger members.

This observation is of especial interest when the modern notion of the limitation of families is considered. There are few "younger members" to the small and limited families of to-day. The two or three children born to a couple of parents would represent the elder branches only of the "old-fashioned family" of a dozen of some fifty years ago. We have just seen that Prof. Pearson declares that the first and second child are endowed with all forms of pathological heritage, and if there are only two children in the family, the limited family of the present day is producing a community of persons highly endowed with a pathological heritage, uncorrected in its national deteriorating effect had there been later children of the marriage—that is, children less likely to have inherited in a marked manner the pathological tissues or diathesis of their parents.

If we are to believe the above statement, and there is no evidence against its being logically acceptable, we are brought face to face with the question of the benefit or otherwise of the law of primogeniture which so largely obtains all the world over. From a racial standpoint the first and second children, as we have seen above, are the worst members of the family to beget a stock free from pathological taints; yet it is to the eldest son that the preservation of the family, and its possessions, its titles, or its wealth, is entrusted. To push this point to its seemingly logical conclusion, it would come about that the eldest son of one family marrying the eldest daughter of another family would in time lead to an effete progeny and the extinction of the power of rearing children. As a prophylactic agency in this scheme of pathologic inheritance, it would appear essential, to correct the deteriorating effects of intermarriage between elder members of different families, that the eldest child of one family should marry with a younger child of another family.

The limitation of families to one or two children is therefore a highly detrimental factor in national eugenics, for not only is there no allowance for what appears to be the inevitable waste attaching to child life, but the progeny, if thus produced only during the early years of married life, is calculated to add in time more affected individuals to the community, seeing it is the first-born children especially that inherit family traits of physique and diathesis.

The predominance of race depends on the preservation of the mentally and physically fitter stocks. In the struggle for existence amongst primitive peoples this is "naturally" provided for by the exigencies of life, but amongst a highly civilised race, such as our own, the fitter stocks appear likely to be weakened "by the lessened intensity of the intraracial struggle and the differential limitation of the family."

It is scarcely necessary to state that Prof. Pearson has handled this subject, as he handles all the problems he deals with, in a manner at once logical, unbiased and rigidly scientific. We are willing to accept Prof. Pearson's conclusions from the basis he starts from; but until the basis is widened a hundred fold it would be rash to formulate definite and incontrovertible deductions in regard to the effects of the inheritance of any pathologic diathesis for any given ailment.

SIR RICHARD STRACHEY, G.C.S.I., F.R.S.

On Wednesday, February 12, there passed away, at the advanced age of upwards of ninety years, a distinguished son of a distinguished Anglo-Indian family, Lieutenant-General Sir Richard Strachey, R.E., G.C.S.I., LL.D., F.R.S. To give any adequate impression of a career which extended from 1836, when Richard Strachey left Addiscombe to join the corps of engineers of the East India Company, to 1907, when he retired from the chairmanship of the East Indian Railway Company, would be in any case a difficult task, and when, as in this case, a life of nearly ninety-one years is more remarkable for the versatile activity of the spirit that animated it than for its length the task becomes insuperable.

He was elected a Fellow of the Royal Society in 1854 for scientific work in botany, geology and physical geography, carried out while he was stationed at Nani Tal, in the Kumaon Himalayas, whither he was transferred from engineering work in connection with the Ganges canal on account of repeated attacks of fever. In 1897, the year in which he was appointed Knight Grand Commander of the Star of India, a Royal medal was conferred upon him for his investigations in physical and botanical geography and meteorology. "Two of the most recent of these," quoting from the award, "are recorded in his report, published in 1888, on the barometrical disturbances and sounds produced by the eruption of Krakatoa and in his paper in the *Phil. Trans.* of 1893, entitled 'Harmonic Analysis of Hourly Observations of the Temperature and Pressure at British Observatories.' These, while important in themselves, are but the last of a long series of valuable memoirs. He was the first to treat scientifically of the physical and botanical geography, geology, and meteorology of the Western Himalaya and Tibet. He also first observed the occurrence of a regular series of fossiliferous rocks, from the Silurian upwards to the north of the great snowy axis of the Himalaya. His numerous papers on these subjects, dating from the year 1847, are published in the Journals of the Royal Asiatic, Geological, and Royal Geographical Societies' Proceedings, and in the reports of the British Association."

In 1873 he had returned home and was appointed a member of the meteorological committee of the Royal Society which controlled the Meteorological Office, established in 1867; he was a member of Sir William Stirling Maxwell's committee which revised the constitution of the governing body of the office, and was a member of the council which replaced the committee in 1876. After a further period of absence in India on special duty, he resumed his place on the council; in 1883, upon the death of Prof. H. J. S. Smith, he was appointed chairman and filled the office for twenty-two years. He was president of the Royal Geographical Society from 1887 to 1889. He received the Symons medal of the Royal Meteorological Society in 1906.

His scientific activity, although closely interwoven with the rest of his work, was only a part of his life. He won distinction as an engineer in the conduct of irrigation works and as a soldier in the Sutlej campaign. His greatest claim to remembrance is based upon his achievements as head of the Indian Public

Works Department, and the various successful organisations which he initiated in that capacity. It is not too much to say that he and his younger brother John, who died about two months ago, were for many years the principal figures in the administration of the Indian Empire. "The Finances and the Public Works of India," the title of a book which they published, is not inapt as a description of the position of the two brothers under Lord Mayo. Between 1871, when Richard Strachey returned to England, and 1879, when he finally retired from India to resume his place on the Indian Council, he held various appointments in connection with the India Office or in India, including the chairmanship of the Madras Famine Commission of 1878. In 1889 he became chairman of the East Indian Railway Company, and added to his reputation for business capacity by the successful administration of that undertaking. As a financier he represented India at the Monetary Conference at Brussels in 1892, and as a geographer he was one of the delegates of Great Britain at the Prime Meridian Conference at Washington in 1884.

My personal recollection of Sir Richard Strachey goes back to 1880, when I was engaged upon some work for the Meteorological Council. He was keenly interested in questions about the distribution of water vapour in the atmosphere. The vertical distribution was the subject of a paper in the Proceedings of the Royal Society in 1862. My recollection is that he had a good deal to do with disposing of an idea that I have seen attributed to Herschel, that in reckoning the pressure of the atmosphere, water vapour did not count. I write vaguely on this point, because to reconstitute the physical conceptions upon which meteorology was based before the 'sixties is to place oneself in the age when heat was still regarded as material, and the conservation of energy was an imperfectly formulated idea.

As president of the Royal Geographical Society he endeavoured to promote the teaching of geographical science, and he came to Cambridge to give lectures on geography, a missionary effort undertaken to show that geography was not really beneath the attention of a university. The distribution of vapour pressure in the atmosphere as determined by his own observations up to 18,000 feet in the Himalaya was again discussed. At that time the university recognised his contributions to the advancement of science by conferring the LL.D. degree. He returned to the subject of aqueous vapour in the atmosphere again in the determination of the heights of clouds by photographic observations at Kew, a preliminary report on the measurements was contributed to the Proceedings of the Royal Society in 1891, and there still exists a great store of unworked material.

From 1897 onwards I was closely associated with Strachey in the management of the Meteorological Office, and I speak without hesitation for his colleagues, Galton, Wharton, Buchan, Darwin, Field, and Scott, in saying that association with him was not the least among the privileges which attached to membership of the council. His clear insight into the questions at issue, his perfect lucidity in thought and expression, the logical marshalling of facts in the official documents which he wrote as chairman, will always be memorable. He had not much patience with people who were imperfectly acquainted with the facts of a case under discussion, and he never cared to argue with them, but difference of opinion on lines of policy, even when ill expressed, never ruffled his serenity in the conduct of business. From time to time while he was chairman, the office was subject to criticism, which was not always fair, but he never complained. He was always content to attribute the criticism to want of knowledge of the facts. He would not even let us indulge in the semi-official pastime of abusing the Treasury. Their responsibility had to take account of an aspect of the matter with which we were not cognisant, namely, where the money was to come from, and we must be content to accept a judgment that had to reckon with public opinion in its executive form as well as with scientific aspirations. Speaking for myself, as one accustomed for many years to the details of business of college meetings and university syndicates, Strachey's methods of transacting corporate business were a revelation.

As regards his later contributions to the science of meteorology, some words of explanation are necessary. He had watched, and indeed had been largely instrumental in providing the facilities for, its study both in India and in this country, on the new lines of the comparison of results for different parts of the country or of the world. He was conscious that the new science required a new method, that the method of the physical laboratory, which aims at elucidating a physical process by experiments specially directed thereto, was inapplicable to the case of the free atmosphere. Those who are critical of the vast accumulation of meteorological data which is going on are apt to be unaware of the fact that data have to be collected in advance, and that, to this day, nearly every attempt to deal with a meteorological problem of any importance is baffled by the want of data; they are equally unmindful of another noteworthy fact, namely, that in meteorology comparison is of the essence of the science. The meteorologist is absolutely dependent upon other people's observations; his own are only useful in so far as they are comparable with those of others. Thus the time, trouble, and money spent upon organisation are not the expressions of limited scientific ambition, but a primary condition for securing indispensable facilities. Strachey's scientific judgment was extraordinarily acute. He was quite prepared to carry on investigation to a speedy issue when circumstances permitted, as in the investigation of the Krakatoa eruption already alluded to, which led to the recognition of a drift from east to west in the upper air of the equatorial regions as a primary meteorological datum. In dynamical meteorology he was convinced that the most promising mode of attack was not to look for a direct dynamical explanation of the striking features, the eccentricities of the day's weather, which are the almost fortuitous result of many causes combined in various phases, but to seek for the relations between regular sequences and their causes underlying the apparently arbitrary variations. For this reason the methods of harmonic analysis specially attracted him, and he was disposed to regard anything less general than five-day means as unmanageable. He never completed the work on harmonic analysis that he had in hand. He attached particular importance to the third Fourier component of diurnal variation, because the length of the day in these latitudes oscillates between one-third and two-thirds of the twenty-four hours. A few years ago he took up again the investigation of the question, and he has left a considerable amount of unfinished material.

He was not to be driven from a position of modest optimism about such matters, and always explained that for a new science the progress made in the last fifty years is quite as great as could fairly be expected.

But he was no friend of the unnecessary compilation of data or of the unlimited extension of mean values. Almost the last contribution that he gave me was a computation of the number of years necessary to reach a mean value for temperature within the limits of the probable error of the mean value for a single year, based upon some tables published in 1902 for the extrapolation of mean values. He was always more concerned to present meteorological data in a form amenable to computation than to increase their volume or detail. When the weekly weather report was initiated in 1884, he provided formulæ for computing the true daily mean from the maximum and minimum temperatures for the day, and for computing the amount of effective and ineffective warmth as referred to a base temperature of 42° F., which are still in use. He once astonished me by pleading for graphical representation as being easier to read than columns of figures, for he could extract the meaning of a page of figures with a facility that made the discussion of results with him an indispensable part of any piece of work that was in hand. Yet he was more than eighty years of age when we had to transact this kind of business together. He never lost his appreciation of new methods which were sound, or of new projects which were promising. Throughout his administration of the office he held to a high scientific ideal while maintaining the efficiency of such daily work as was required for public use and for international cooperation. His scientific horizon was a wide one. With Stokes and Balfour Stewart, he was largely instrumental in providing means for the organised study of the sun, which had been commenced in this country and in India by Sir Norman Lockyer, in order to trace the primary causes of those great meteorological fluctuations which exhibit themselves in alternations of drought and plenty in India, a study which, pursued for many years at the Solar Physics Observatory at South Kensington and at Kodaikanal, in India, has recently taken its place among the greater international organisations. As head of the Public Works Department in India, he transferred meteorological work in that dependency from a provincial to an Imperial basis under Blanford and Eliot, and laid the foundation for the admirable organisation of which the Government of India and its scientific staff now enjoy the advantage. At the same time, he initiated the forestry department and the application of botanical science to the service of the public in that department.

Probably no single person had clearer views of the future that lies before meteorological work as a matter of practical influence upon everyday life, or was more fully conscious of the long years of observation, organisation and study that are necessary to secure the advantages which will ultimately more than reward the long years of patient inquiry.

Above the mantelshelf of the unpretentious room over a piano shop in Victoria Street, which for more than forty years has been the chief centre of meteorological work in this country, there is a clear-cut profile of an old but by no means aged man, giving an unmistakable presentment of intellectual strength altogether undisturbed by side-issues and petty difficulties. Such indeed was Strachey. Beneath the portrait over his characteristic signature are the last words of a letter written about an office balance sheet that I thought more than usually depressing. "On the whole there is nothing to complain of." For meteorologists this is, at times, a hard saying; but to me at least it is entirely characteristic of the spirit with which he insisted upon meeting the difficulties that confronted us. "A heart that is established and will not shrink," a keen appreciation of the practical services which science can render in the present and in the future, a simple determination to regard the whole, to make the most of the means at his disposal without grumbling—these are the abiding recollections of the ten years of our association at the close of a long life devoted, with untiring energy, to the service of his country.

W. N. Shaw.

NOTES.

Dr. C. Chree, F.R.S., has been elected president of the Physical Society of London for the ensuing year.

The annual congress organised by the Prehistoric Society of France will be held this year at Chambéry from August 24 to August 30.

M. Bouquet de la Grye has been elected president of the Bureau des Longitudes for 1908, M. Poincaré vice-president, and M. Bigourdan secretary.

Prof. W. J. Sollas, F.R.S., was elected president of the Geological Society of London at the anniversary meeting on February 21.

The director of the Royal Meteorological Observatory at Agram, Hungary, informs us that the founder and former director, Prof. Ivan Stožir, died on February 12 after a short illness.

Dr. H. F. Osborn, one of the vice-presidents of the American Museum of Natural History and curator of vertebrate palæontology, has been elected president of the museum in succession to the late Mr. Morris K. Jesup.

It is reported from Berlin that Mr. Andrew Carnegie has given half a million marks (25,000*l.*) to the Robert Koch fund for the campaign against tuberculosis. The amount collected so far for carrying out research work in connection with the disease amounts to 800,000 marks (40,000*l.*).

An exhibition and sale of farm and garden produce, organised by the Women's Agricultural and Horticultural International Union, will be held in the gardens of the Royal Botanic Society, Regent's Park, N.W., on Wednesday, July 15. All communications should be addressed to the secretary, Miss Eileen Johnson, c/o Mrs. T. Chamberlain, 5 Priory Mansions, Drayton Gardens, S.W.

The American Society of Naturalists has made arrangements to celebrate the one hundredth anniversary of Charles Darwin, in cooperation with the American Association for the Advancement of Science, on the occasion of their meetings in Baltimore in 1908. The Society of Naturalists, we learn from *Science*, will be represented on the committee of arrangements by the president, the secretary, and several members.

On Thursday next, March 5, Sir John Rhys will begin a course of two lectures at the Royal Institution on "Early British History and Epigraphy," and on March 7 Prof. J. J. Thomson will commence a course of six lectures on "Electric Discharges through Gases." The Friday evening discourse on March 6 will be delivered by Prof. John Milne on "Recent Earthquakes," and on March 13 by Chevalier G. Marconi on "Transatlantic Wireless Telegraphy."

Replying to a question in the House of Commons on Tuesday, Mr. Churchill said:—"It is impossible to obtain accurate statistics regarding the mortality from sleeping sickness in Uganda, but, in a recent despatch, the Governor has estimated the number of deaths at 200,000 during the past seven years. Every effort is being made by the

Government to combat the disease by scientific investigation under the direction of the Royal Society, by local administrative measures, and by international cooperation with the other Powers whose possessions in Africa are similarly afflicted."

THE council of the Royal Society of Arts has awarded the gold medal offered by the society, under the Shaw trust for industrial hygiene, to Prof. W. Galloway, "in recognition of his valuable researches into the action of coal dust in colliery explosions, the outcome of which researches has been the provision of means by which the risk of such accidents is materially diminished, and a consequent great saving of human life effected."

IN connection with the International Congress on Tuberculosis, which will be held in Washington on September 21 to October 12, a prize of 300*l.* is offered for the best treatise that may be submitted to the congress on the relation of atmospheric air to tuberculosis. The prize is offered by the Smithsonian Institution out of the Hodgkins fund. The treatises may be written in English, French, German, Spanish, or Italian. They will be examined, and the prize awarded, by a committee appointed by the secretary of the Smithsonian Institution in conjunction with the officers of the International Congress on Tuberculosis.

WE learn from the Berlin correspondent of the *Times* that on February 20 the Reichstag passed the second reading of the Bill for the regulation of wireless telegraphy, in accordance with the decisions of the International Congress in Berlin in 1906, and conferring a monopoly of wireless telegraphy upon the Government. The German Government desires to maintain an attitude of neutrality towards all systems of wireless telegraphy, and in particular to secure intercommunication on the part of ships and land stations without regard to the system employed. Germany has accordingly declined to bind herself to any one system, upon the ground that the efficiency of the system adopted is of far greater importance than its technical character. The special committee of the Reichstag to which the Bill was referred was informed that messages by the Marconi system would be accepted by German ships and stations if the company conformed to the obligation to exchange communications with other systems.

LAST year some opposition was shown in the American Congress to the usual vote of funds to the Biological Survey, certain members of the committee on agriculture suggesting that this branch of the agricultural department was more ornamental than useful. Accordingly, a paragraph was inserted in the Appropriation Bill directing the Secretary of Agriculture to investigate the work of the survey, and particularly to inquire into the value of the work done by the Government ornithologists. A report of this investigation has now been issued, and a whole column of the New York *Evening Post* is occupied by a summary of the services which Secretary Wilson finds that the Biological Survey has rendered to American farmers and horticulturists. Not only has this bureau issued valuable bulletins and other publications, but it has prepared the way for important legislation for protecting useful birds and for preventing the importation of such as would be injurious. A typical example is the success of the bureau in preventing the importation of the kohlmeise, the introduction of which was advocated through misapprehension in the apple-growing districts of the Pacific Coast and the North-West, where it might have done enormous damage.

TWO striking examples of the best style of modern taxidermic art are displayed in the central hall of the natural history branch of the British Museum in the shape of a male and female Californian sea-elephant from Guadalupe Island. The specimens are the gift of the Hon. Walter Rothschild, and probably represent some of the last survivors of their species. They have been mounted by Rowland Ward, of Piccadilly, in whose establishment may now be seen a walrus set up for the Edinburgh Museum, which is likewise practically a revelation in the matter of mounting as compared with the bloated mummies by which the species has hitherto been represented in our exhibition galleries.

A DISCOVERY of exceptional interest is announced in vol. vi., part iii., of *Annotationes Zoologicae Japonenses* (December, 1907), namely, the occurrence of a fresh-water medusa, referred to the genus Limnocodium, in the Yang-tsi-kiang about 1000 nautical miles from its mouth. Limnocodium, it will be remembered, has hitherto been known solely by *L. sowerbyi*, discovered in 1880 in the Victoria water-lily tanks at the London Botanical Gardens, and subsequently observed in similar tanks at Lyons, but never yet found in its native home. According to its describer, Dr. Asajiro Oka, the new Chinese species, for which the name *L. kawaii* is proposed, differs from *L. sowerbyi* in certain points, which are, however, insufficient to admit of its generic separation, although rendering necessary some slight modifications in the definition of the genus. The home of the typical species is generally supposed to be Amazonia (not the West Indies, as Dr. Oka states), and it is hence possible that the genus may have a distribution analogous to that of tapirs, alligators, or spoonbill-sturgeons. It may, however, be found that Limnocodium is widely spread in the rivers and lakes of Asia. The Yang-tsi species was discovered in April last by Captain Kawai, of the steamboat service, near Ichang, in the province of Hupi, ten specimens having been obtained. The muddy condition of the waters of the river accounts for the medusa having previously escaped observation.

MR. JOHN BROGDEN, of 28 Colville Square, London, has sent us a copy of a catalogue of natural history specimens, in which is included biological material of almost all kinds other than skins of vertebrates. Among the specimens catalogued we notice a series of models of whales and dolphins, on a scale of 1 inch to the foot.

LANCELETS and lampreys form the subject of a paper by Mr. H. W. Fowler in the issue of the Proceedings of the Academy of Natural Sciences of Philadelphia for December, 1907. Of lampreys, the author describes, under the name of *Oceanomyzon wilsoni*, a new genus and species on the evidence of a specimen a foot in length from the Atlantic. It is regarded as connecting the true lampreys, Petromyzon, with the deep-water Bathymyzon; it may occur at some depth.

THE first part of *Sitzungsberichte Natur. Verein der preuss. Rheinlande und Westfalens* for 1907 contains an account of the scientific results of a journey recently undertaken by Dr. Borgett to East Africa and the Nyanza. Although the expedition was mainly undertaken for the purpose of studying the plankton (of which certain new forms are described), the author furnishes some interesting information with regard to the big-game fauna of the Athi Plains and Nairobi, where he is of opinion that the protective laws enforced by the British Government are working satisfactorily. Giraffe, kudu, and eland were seen in numbers in several places, while hartebeest, gnu, water-buck, Thomson's and Grant's gazelles, and, above all, bonte-quagga, occurred in enormous herds, and rhinoceroses and hippopotamuses were by no means uncommon. The extinction, or decimation, of the fauna is, according to the author, not likely to occur for many a long day. Such testimony from an impartial and unprejudiced observer is as satisfactory as it is valuable.

For some years a difference of opinion has prevailed among palæontologists with regard to the systematic position of the group of Upper Tertiary mammals typified by the European genus Chalicotherium. In these mammals, it may be mentioned, the cheek-teeth are of the general type of the Perissodactyla, whereas the feet are of an unguiculate character, the latter feature having long led to the belief that these mammals were members of the Edentate order. Since the date of the association of the teeth with the foot-bones (when the ungulate affinities of the group could no longer be doubted), Mr. Lydekker has persistently maintained that there is no justification for separating the chalicotherioids from the Perissodactyla, whereas American palæontologists have with equal confidence asserted that they should form a subordinal (or ordinal) group by themselves. In an article contributed to the *American Naturalist* for December, 1907, Mr. O. A. Peterson, from the evidence of specimens referable to the genus Moropus, concludes "that Moropus is, excepting its unguiculate feet, essentially a perissodactyle in structure. That the laterally compressed and cleft condition of the terminal phalanges is quite distinct in some of the early Perissodactyla, and that by adaptation . . . the unguals of Moropus were specially modified, and should not . . . be regarded as of ordinal importance."

M. Gaston Bonnier records in the *Comptes rendus* of the Paris Academy of Sciences (vol. cxlv., No. 27) some interesting observations on what he terms the *raisonnement collectif* of bees. In one of his experiments he placed in his garden several lumps of sugar; these were visited by bees, which, however, were unable to bite off its particles on account of the weakness of their mandibles. The bees were marked by the experimenter, and were seen to fly off to their hive; in one to two hours they returned with other workers, but this time they flew, not from the hive, but from a fountain of water. On settling on the sugar they were seen to pump water from their crops on to the sugar, and then suck up the syrup so formed, finally flying back to the hive. Other observations convinced M. Bonnier that individual bees were able to communicate news of their discoveries of fresh sources of honey to the colony, and he has reason to believe that the number of workers summoned is always proportional to the supply of honey that has been found.

The *Bio-Chemical Journal* for January (iii., Nos. 1 and 2) contains several interesting papers, notably one by Prof. Moore and Dr. Roaf on the equilibrium between the cell and its environment in regard to soluble constituents, with special reference to the osmotic equilibrium of the red-blood corpuscles, in which the conclusion is formulated that the difference in composition of the electrolytes within and without the cell, and the physiological effects of perfusion or irrigation of cells by media defective or excessive in certain electrolytes normally present in the cell receive a simple explanation, on the basis of the formation of adsorpates or chemical combinations between cell protein (or protoplasm) and other constituents.

There are two essential factors with others required for the success of a nature-study course, the one that the course should be seasonal, the other that the instructor should manifest a continuous and keen interest in his subject. The first point has been effectively brought out in a pamphlet by Prof. J. A. Thomson, issued from Aberdeen University, wherein he indicates suitable lines of study for various courses. The notes refer to physical, botanical, and zoological studies. A careful perusal of the pamphlet cannot fail to supply teachers with suggestions and stimulate interest.

The January number of *Tropical Life* contains information with reference to a rubber exhibition that is already arranged to be held at the Royal Horticultural Hall in September this year, and an International Rubber Exhibition that it is proposed to hold in London a year or two hence. In the same journal useful information with regard to methods of cultivating and curing tobacco in Porto Rico is contributed by Mr. D. W. May, and the value of manures for cacao plantations forms the subject of one of a series of articles dealing with the cultivation of cacao.

A contribution by Mr. F. Ramaley on the silva of Colorado, dealing with the woody plants of Boulder County, is published in vol. v., No. 1, of the University of Colorado Studies. The flora provides an interesting study in altitudinal distribution, since the elevation of the county varies from about 5000 feet to 10,000 feet at the foot of the main range, while the highest peak exceeds 14,000 feet. Grass lands rise up to 6000 feet, when open forest of rock pine, *Pinus scopulorum*, and Douglas spruce, *Pseudotsuga mucronata*, is found. A zone of lodge-pole pine, *Pinus murrayana*, mixed with rock pine and limber pine, *Pinus flexilis*, reaches to 10,000 feet, above which the Engelman spruce is dominant. Higher again in the Alpine zone, the only woody plants are dwarf willows.

A number of the *Philippine Journal of Science* (vol. ii., No. 5), devoted to the descriptions of commercial Philippine woods, has been prepared by Mr. F. W. Foxworthy. It contains a general discussion of their structure and properties, a key for their identification, and notes on the species. The key is elucidated by means of a series of fifty-five photographs representing transverse sections. Of timbers well known on the European market, only teak and ebony are found; the former is very scarce, and the ebony is chiefly derived from *Maba buxifolia*, with less valuable timber from *Diospyros pilosanthera* and other species. "Narra" is a first-class timber yielded by *Pterocarpus indicus* and allied species, therefore related to Indian "padouk"; also the tree known in India as "poon," *Calophyllum inophyllum*, provides a timber that is employed for construction and furniture. Other valuable species are *Homalium luzoniense*, *Illipe betis*, *Pithecolobium acle*, species of Lagerstroemia, Intsia and Vitex, and *Pahudia rhomboidea*.

A pamphlet on the geology of the Roberts-Victor diamond mine has been published by Mr. J. P. Johnson (Johannesburg). This mine, which is situated in the Boshof district, Orange River Colony, presents many points of geological interest, and the author's observations lead him to believe that kimberlite, the rock in which the diamonds occur, is not an igneous rock, but a purely fragmental one, simulating in parts an igneous structure owing to changes induced by hot water or steam, and that it is to these factors that the extreme alteration of the mineral constituents of both the peridotite and pyroxenite boulders and of the matrix in which they lie is due.

A DETAILED description of the geology and mineral resources of Lawlers, Sir Samuel, and Darlot (East Murchison goldfield), Mount Ida (North Coolgardie goldfield), and a portion of the Mount Margaret goldfield is given by Mr. C. G. Gibson in Bulletin No. 28 of the Geological Survey of Western Australia. The report, which covers seventy-three pages, and is accompanied by three large folding maps and five mining plans, shows that rocks of the district comprise granites and greenstones, the payable gold quartz veins occurring in the latter. The granites are seen almost everywhere to be intrusive into the greenstones. The quartz veins appear to be of later origin than the granite, and in most cases they occur at no great distance from its junction with the basic rocks. The district under review had returned, up to the end of 1906, 581,104·61 ounces of gold.

THE Records of the Geological Survey of India (vol. xxxvi., part ii.) contain the report on the mineral production of India during 1906 compiled by Mr. T. H. Holland, F.R.S. Compared with the previous year, there was an increase of 10·9 per cent. in the value of the total production. The production included 581,545 ounces of gold, 9,783,250 tons of coal, 140,553,122 gallons of petroleum, 495,730 tons of manganese ore, and smaller quantities of salt, saltpetre, mica, ruby, sapphire, jadestone, graphite, iron ore, tin ore, chromite, diamonds, magnesite, and amber. In the same issue Mr. E. W. Vredenburg describes the ammonites of the Bagh beds, and there are several interesting brief miscellaneous notes. Amongst these there is a description of the occurrence of wavellite, which has apparently not been previously recorded from India, in the Singhbhum district, Bengal.

DR. GUSTAV BRAUN, of the Geographische Institut, University of Greifswald, announces that he is anxious to collect information as to "Bodenbewegungen," which he defines as movements taking place on restricted areas of the earth's surface as the result of gravitation (*Jahresbericht der geographischen Gesell. zu Greifswald*, 1908). He does not propose to include mountain-folding, though this might attract Herr E. Reyer and Dr. Ampferer, to name no others; but he seeks cooperation from those who have the opportunity of observing slow or sudden movements of the soil, landslides and rock-falls, flows of peat, and all kindred superficial phenomena. The results of human operations are to be included. Dr. Braun issues forms to those who can assist him, on which exact details of each case studied can be entered, and he is even willing to collect extracts from newspapers. Surely he cannot be acquainted with the reckless treatment of natural phenomena by the popular American and English Press. Yet his circulars will probably bring to his notice certain carefully studied examples of rock-creep, bog-sliding, and so forth, which will afford material for comparison with those examined by himself.

IN part i. of *Aus dem Archiv der deutschen Seewarte* for 1907, Mr. A. Paulus discusses the duration of the passages of German sailing vessels in 1893–1904. This laborious investigation, which should be of practical utility as well as interesting from a general point of view, deals with the three large oceans (the outward and homeward voyages being separately discussed), and shows the average duration and the times of the longest and shortest passages in the period mentioned. The tables also give the duration of the shortest passages from about 1870, including the results obtained from a somewhat similar discussion by Dr. Schott prior to 1893, and observations from other sources. From the latter it is seen that a fair number of the shortest voyages has occurred in the more recent period, and this result, we think, may be reasonably ascribed to the dissemination of useful information in American, English, and German charts. We note that Mr. Paulus is able to say that there are only a few German sailing vessels which do not keep a meteorological log for the Seewarte.

THE hydrographical researches carried on in connection with the international fishery investigations continue to lead to the issue of a number of useful monographs and reports. Amongst those now before us are the current issues of the *Bulletin des Résultats acquis pendant les Croisières periodique*, which has recently been enlarged in scope, with great advantage, to include observations taken during three-monthly periods, as well as those taken on the regular quarterly cruises. The number of charts and sections illustrating the results arrived at has also been increased. In *Publications de Circonstance*, No. 40, issued by the International Council, Mr. Johan Gehrke discusses the mean velocity of the Atlantic currents running north of Scotland and through the English Channel. These two currents constitute the sources of supply of Atlantic water to the North Sea. Mr. Gehrke calculates that the whole water volume that yearly passes round the north of Scotland (within certain defined limits) is about 61,000 cubic kilometres, and has a mean salinity of 35·15 °/₀₀, whilst the annual water supply to the North Sea through Dover Straits is 2036 cubic kilometres, and its mean salinity 35·07 °/₀₀. In *Publications de Circonstance*, No. 38, Mr. Martin Knudsen points out that in certain areas the determination of the salinity of the surface water may be of very great service to the navigator in helping him to fix the position of his vessel at sea.

A NOTE on certain Maori carved burial-chests, by Mr. T. F. Cheeseman, is published in the Transactions of the New Zealand Institute, vol. xxxix. Although it had been recorded that manoa trees, *Dacrydium colensoi*, were reserved by the Maoris for making coffins, there is little or no information regarding such coffins in which the bones were placed. The burial-chests recently discovered, and now stored in the Auckland Museum, are carved into the rough similitude of a human figure, except two of a different shape. So far as evidence is forthcoming, they may be two hundred years old.

To the January number of the Journal of the Gypsy Lore Society Mr. A. B. Sinclair contributes an article on the Oriental Gypsies. His view that there are no Indian Gypsies, that the recent find of Oriental books at Turfan, with other evidence, shows that the civilisation and phonetics we have been wont to consider special to India flourished at one time north of the Himalaya, and that therefore there is no need to seek the origin of the Romani speech in India, is startling, and not likely to be accepted without further proof than that furnished in the present article. The revived society, which has its headquarters at 6 Hope Place, Liverpool, deserves the support of all who are interested in this remarkable race.

TWO papers, one by Mr. Edgar Buckingham in the Bulletin of the Bureau of Standards (U.S.A.), iii., 2, and another by Mr. J. D. Hamilton Dickson in the *Philosophical Magazine* for January, show that there is still material for discussion in the already much discussed "Joule-Kelvin" experiments on the determination of absolute temperature by the flow of gases through a porous plug. Mr. Buckingham introduces the subject with a short discussion of the fundamental equation, which, as he points out, affords a direct comparison between the constant pressure scale of any gas and the absolute scale, but which cannot be applied directly to the constant volume temperatures without knowing the isothermal equation of the gas. He discusses the various empirical assumed formulæ for the "cooling effect," and the conclusions deducible from them. The relations of actual gas scales to the thermodynamical scale are set forth, but the author considers that the time is approaching when a mere reference of temperatures to "the gas scale" will be insufficient. Mr. Dickson's paper deals with the inversion temperature of the Joule-Kelvin effect both for small and for finite differences of pressure, with special reference to Olszewski's experiments.

THE *Physikalische Zeitschrift* for February 1 contains a description, by Dr. C. W. Lutz, of the filament electrometer invented by himself and Dr. M. Edelmann, jun. The filament consists of a Wollaston platinum wire of about 0·001 mm. diameter suspended vertically between two narrow vertical plates, one of which can be put into electrical connection with the wire, while the other may be connected either to earth or to some source at constant potential. The repulsion of the filament from the former plate when both are charged is observed through a small microscope magnifying eighty times, and by suitably adjusting the tension of the filament the range of the instrument may be made to extend from 2 volts to 1000 volts. It is very compact, and its electrical capacity is less than 10 cm.

MR. C. W. BURROWS, of the United States Bureau of Standards, after extensive experiments on the various methods in use for demagnetising iron in magnetic testing, comes to the conclusion that the following is the best method of procedure:—the current should be reversed about twice a second, and diminished at such a rate that the decrease of induction is as nearly as possible the same each second, the process to last about ninety seconds. In obtaining the magnetisation curve of the specimen, the magnetisation current should be reversed about the same number of times, and near the end of the series two throws of the ballistic galvanometer about twenty-five reversals apart should be observed. If they agree, they may be taken as representing the normal induction. The next observation may be made by this method without its being necessary to again demagnetise the specimen (Bulletin for January).

A NEW and cheap edition (price 5s. net) of Mr. Benjamin Kidd's "Principles of Western Civilisation" has just been published by Messrs. Macmillan and Co., Ltd. The original work was reviewed at length in NATURE of April 24, 1902 (vol. lxv., Supp., p. vi). In a long introduction, which appears for the first time in the new edition, Mr. Kidd replies to points raised by his critics, and refers to some differences between the evolution of the individual and of a social organism. Mr. Kidd has been appointed to deliver the Herbert Spencer lecture for 1908 before the University of Oxford in May or June next. Three lectures have already been given, namely, in 1905 by Mr. Frederic Harrison, in 1906 by Mr. Auberon Herbert, and in 1907 by Mr. Francis Galton, F.R.S.

OUR ASTRONOMICAL COLUMN.

SATURN'S RINGS.—The January number of the *Astrophysical Journal* (vol. xxvii., No. 1, p. 35) contains an article by Prof. Barnard in which he describes and discusses his recent observations of Saturn's rings with the 40-inch refractor of the Lick Observatory. On July 2, 1907, Prof. Barnard found that, although no direct sunlight was falling on its earthward side, the entire surface of the ring was distinctly visible. On each ansa were two prominent condensations symmetrically placed with respect to the ball. On October 4—when the earth again passed back to the shadow side of the ring—and for some days after, the ring was perfectly linear, and the condensations, which, if they were real masses on the ring system, should then have been best seen, had disappeared.

From his observations Prof. Barnard concludes that it is not merely the illuminated edge of the system which we see when the earth is on the shadow side, but the feebly luminous surface of the ring itself viewed very obliquely. The luminosity is caused by the transmittance, by repeated reflections from the particles comprising the ring, of sunlight. Adopting this interpretation, the condensations are produced by the outer brighter part of the inner ring, the higher illumination of which, as seen ordinarily by directly reflected light, or, as during these observations, by light which had by successive reflections passed through the ring, is probably due to the denser agglomeration of its particles.

THE OBJECTIVE PRISM IN SOLAR SPECTROSCOPY.—A device by which double equatorial refractors, as employed for stellar photography, may be adapted to serve as objective-prism spectroscopes in solar observations, is described by M. E. Schaer in No. 4233 of the *Astronomische Nachrichten* (p. 137, February 15). The solar rays, passing through the first objective, are, by two reflections by plane mirrors, projected along the axis of the second telescope. Before reaching the second tube the reflected image is, however, intercepted by a slit plate, so that only the narrow beam which passes through the slit traverses the tube to the object glass. On passing through the latter the light falls upon the objective prism, which is silvered on the posterior face, so that after two dispersions and one reflection it passes again through the object-glass and down the tube. The solar spectrum thus produced may be viewed with an ocular, or an arrangement for photographing it may be substituted. By the interposition of a second slit in front of the photographic plate and mechanical movements this instrument may be used as a photospectroheliograph.

UNIFORMLY DISTRIBUTED DARK SPOTS ON JUPITER.—In an article which appears in the January number of the *Bulletin de la Société astronomique de France*, Mr. Scriven Bolton describes a number of Jovian phenomena observed by him in recent years, and pays particular attention to a series of dark markings which are symmetrically distributed along the northern edge of the south equatorial and the southern edge of the north equatorial bands. As these spots occur in the same longitudes on each band and partake of a common motion, Mr. Bolton concludes that they have an objective existence. Generally, the alternate spots on the opposite bands are joined by festoons of dark material which cross the equatorial regions obliquely at angles of 45°. The spots on the southern band present the more marked uniformity, there being twenty-four of them at regular intervals throughout the whole length of this band. Drawings made on June 15, 1899, November 4, 1903, and February 23, 1907, respectively, are reproduced to illustrate Mr. Bolton's description.

DOUBLE-STAR OBSERVATIONS.—Finding that the published magnitudes of the components of double stars are generally only given approximately, Dr. Joel Stebbins, director of the Urbana Observatory, Illinois, U.S.A., decided to make a number of systematic photometric observations of them, and he now publishes the results in the Bulletin of the University of Illinois (vol. iv., No. 25, 1907). After describing the instruments employed and the system of observation, Dr. Stebbins gives a catalogue of the 107 double stars which he observed, and discusses the probable errors and the differences from the Harvard observations of the same objects. On comparing the results with other available observations, no evidence of variability could, with certainty, be detected, and in the case of θ^1 Orionis —the Trapezium stars—it appears certain that no change greater than 0·08 magnitude has taken place since the Harvard observations were made in 1878.

PLANETARY PHOTOGRAPHY.

THE recording on photographic plates of the canals of Mars is as significant from a technical point of view as it has proved of widespread interest in its result; for the method which alone rendered success possible had first to be developed, previous celestial photographic processes being inadequate to the task. At the request of the editor of NATURE, I propose to give some account of the method pursued, and the more gladly in that it is evident from attempts to follow it that its principles are as yet as much a *terra incognita* as have for so long remained the canals themselves. The process is the outcome of four years' study by Mr. Lampland, who, to a knowledge of the end desired, acquired from visual work on the planet, added experimental research on the means to attain it. Of the difficulty of the subject the best testimony are the words Schiaparelli wrote the writer on receiving in 1905 the first prints from the plates:—"I would never have believed the thing could be done."

The fundamental distinction between planetary photography and photography of the stars is that with the former definition, not illumination, is the primary point. To imprint upon the plate such delicate tracery as the canals of Mars requires a definition so far beyond celestial photography in general as to constitute a class of work by itself. For one is here concerned with quantities of the second order of minuteness.

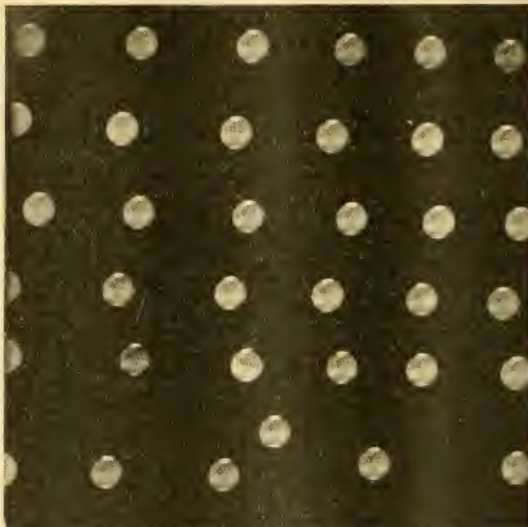
Definition, therefore, had to be studied. The chief disturber of the image is the atmosphere. A knowledge of how this conditions the seeing is, then, the first requisite to success. Living as we do under a gaseous ocean in constant turmoil, no image from beyond it stays perfect for long, soon being either distorted or displaced by the shifting refraction of differently dense layers of air. The effect we notice every day in the twinkling of the stars. To educate the eye to sift the fleeting impressions it receives is thus the first step to becoming an observer of Mars. Distrust of its own revelations because of their short-livedness is one chief cause of failure to see the canals More, not less, is a like handicap true of the camera; for the eye is some thousands[1] of times as sensitive as the films we can employ. So that at first it would seem hopeless to attempt to part the good moments of definition from the bad, and thus to prevent the superposition of a poor or shifted image upon a clear-cut one, to the resulting disheartenment of a general blur.

To catch the planet's fugitive expressions of itself, speed of exposure becomes imperative; and that as many such as possible might be seized, a special camera had to be devised, something which should realise the demon-machine of Clerk-Maxwell for images in place of molecules, to let the good ones through and stop the bad. The mechanical part of this Mr. Lampland contrived by a plate-holder fitted with a lateral ratchet motion worked by a bulb, and capable of being pushed up and down after each line of images had been secured. At the opposition of 1905 this camera was worked without guiding, as the exposure time seemed not to necessitate it, but for that of 1907 Mr. Lampland suggested the use of, and fitted on, the 6-inch as a finder. In spite of the very short exposure possible, the guiding thus introduced turned out an improvement.

The next difficulty in definition lies with the glass. In spite of its name, no achromatic lens is achromatic. Though the departure from perfection is practically imperceptible to the eye, such is not the case with the sensitised film; for the rays of different colours form their images in different focal planes. Of these, the eye selects what it will attend to, while the camera cannot, and so, on the plate, if an image made by one colour be in focus, it must perforce be surrounded by others that are not. A reflector, of course, avoids this blur of superposition, since all the rays are brought to one focus, but, on the other hand, it introduces more serious errors of spherical aberration; for not only does any want of figuring or of sag in the mirror, but any disturbance in the air produces three times the distortion it does in the glass. It is thus problematic whether a reflector can ever be used for such fine work, though we intend to give it a trial with a 3-feet mirror.

To secure approximate monochromatism, and thus a more clear-cut image, a screen or filter of coloured glass, or of a coloured solution between glass, had to be used to cut off certain of the rays. This device is the same that was used visually by Schiaparelli, and that has been used at Flagstaff in like research, though it has not been found there so effective as a neutral-tinted glass, because, as mentioned above, the eye does its own sifting for the rays it elects to observe. Photographically it was first employed by Ritchey in his photographs of the moon, and here its value is inestimable. The general method of making the screens is to determine first the colour-curve of the objective, that is, the curve in which the abscissæ represent the wave-lengths of the rays of differing refrangibility and the ordinates their focal lengths. From this curve it becomes possible to select what rays shall be allowed to pass to secure a sufficient approximation to monochromatisation, and the screen is then coloured to attain the result. In the construction of such screens Mr. R. J. Wallace is preeminent, and by him in this manner were made those for the Flagstaff glass.

The next crux entered with the plates. In consequence of the greater relative deviation in focal length suffered by the blue rays, which are the ones most actinic, and those to which the ordinary plates are sensitised, such plates cannot be used for interplanetary photography. To get enough light with them to approach instantaneity the



Photographs of Mars; Ganges region. Taken by Prof. Percival Lowell at Flagstaff, July 28, 1907.

[1] With the Flagstaff objective diaphragmed down to 12 inches, and with a power of [illegible] further weakened by a screen that takes off at least three-quarters of the light the eye sees on Mars' canals in less than the twentieth of a second which it takes the plate two seconds to register with a magnification of 150 and under the full aperture of the 24-inch glass.

blue rays would have to be made use of, and they would irretrievably blur the image. Plates sensitised to other parts of the spectrum must be employed, and as it has not been possible to make such adapted only to the yellow and orange rays, a coloured screen must be used in connection with them. Only when more restricted emulsions shall have been produced will it become feasible to dispense with the sifter.

The plates most nearly giving us what we wanted proved to be Cramer's isochromatic instantaneous plates. They are neither instantaneous nor isochromatic, but their two negatives nevertheless combine to the best affirmative it is now possible to obtain; for beyond their mountain mass of reaction in the violet and blue, to speak figuratively of their curve of sensitiveness, they have a hillock in the yellow with sides of great abruptness. By Mr. Lampland, who carefully experimented with every kind of plate, these were found, and for the above reason, to yield the best results in the way of speed *with* definition. Their chief drawback consists in their not being so finely grained as one could wish.

This brings us to another difficulty that had to be encountered. In the sensitising of plates speed is inevitably associated with coarseness of grain, and *vice versâ*. Finely grained emulsions are necessarily slow. To avoid the Scylla of over-exposure is to fall into the Charybdis of under-definition. As speed must be got at all hazards, the images of Mars are not so fine in texture as those securable of earthly scenes, as, for example, by lantern-slide plates. This is to be remembered in scanning the images. Anything beyond a slight magnification of the original negatives results in perceptible, though not always perceived, blurring of the details due to the showing of the grain. Photographic experts will thoroughly appreciate this, and trace the linearity of the canals clearly through its partial disguise.

After all other points have been attended to, there still remains the question of aperture; for the smaller the aperture the sharper the definition for the same sized magnification, the gain from the point of view of the air-waves vastly exceeding the loss due to a larger spurious disc. Thus with an image magnified to four hundred diameters, a 12-inch gives ninety-nine times out of a hundred more clear-cut detail than a 24-inch. This, which is so decided a gain in visual work, is partially offset in photographic work by the necessary increase in exposure time, and the consequent greater chance of mixing poor moments with the good. As the exposure time decreases inversely as the square of the radius of the glass, while the improved definition increases inversely as that radius, Mr. Lampland, in 1907, used only the full aperture of the 24-inch. In this decision I quite concur from the results at the last opposition, merely adding the gloss that with the larger aperture one is more certain of a good image; with the smaller, one will score an even greater success on exceptional occasions. This, of course, is to be taken within limits.

By the general method I have outlined Mr. Lampland secured the first photographs of the canals at the opposition of Mars in 1905. Some fifty of the canals show upon his plates. This success was entirely due to his exhaustive study and attention to all the factors I have formulated. During the time between 1905 and 1907 Mr. Lampland continued his research, and in June, 1907, took his first plates at the opposition just passed. The images showed a marked advance. In 1905 he had registered the Nilokeras double (12° apart). In June, 1907, the Gihon (5°·0 apart) stood duplicate in his photographs, while the Euphrates (4° apart) pretty certainly showed in the same manner, though from principles of conservatism I was not willing to commit myself to its announcement. At the same time plates were taken by me showing in like manner a great number of single canals, and the double Gihon and almost unquestionably the double Euphrates appear. For the same opposition an expedition was undertaken by the Lowell Observatory to the Andes under the charge of Prof. Todd, Mr. E. C. Slipher, of the Lowell Observatory, being detailed upon it armed with a duplicate of our apparatus, and thoroughly coached beforehand by Mr. Lampland in its employ. Mr. Slipher, by whom all the work of the expedition on Mars, both photographic and delineatory, was done, secured plates in July at Alianza, Chile. The place had been chosen primarily because of its lying in the solar eclipse belt, Prof. Todd being desirous of observing the annular eclipse there, but it proved, although but 4000 feet above sea-level, probably the best locality that could have been selected. By a skill and assiduity deserving of the highest praise, Mr. Slipher obtained some 10,000 images of the planet in the course of a couple of weeks. Owing to the remarkable steadiness of the air and the high altitude of the planet, his plates show a wonderful amount of detail. The doubling of the Gihon and of the Euphrates previously registered at Flagstaff were also exhibited on them, besides canals and oases in profusion. As an instance of the latter I may mention the distinct showing of the two little oases in the Trivium. His drawings were no less remarkable. As an example, the double Ganges, which for two oppositions now the writer has observed stronger on its right or western side than on its eastern, appears with this same differentiation in Mr. Slipher's picturing, although he had no previous acquaintance of the fact. Having discovered that he has an eye for planetary detail, he is to continue such study in the future.

The future promises even more than the past has fulfilled. Several improvements have been effected, or are in contemplation, which were not put into operation at the opposition of 1907. One of them is a new screen devised by the writer. Though both conceived and constructed before the opposition, it was only tested this last summer, but enough to show an improvement in definition from its use. Its basic principle was the integration of the greatest amount of illumination with the least focal difference of wave-length. To explain the idea, suppose that the light reaching the plate for each ray be weighted according to its proximity for focal length to a given focal distance by an inverse function of such departure, the function becoming negative after a certain discrepancy because the inclusion of the ray then does more harm than good. Suppose this light summed for all the rays between certain limits. The most effective screen will be that for which the integral is a maximum. The point up to which the rays should be cut off, as indicated by an examination of the colour curve of the 24-inch glass, seemed to lie at $\lambda = 5000$, and for this, accordingly, I asked Mr. Wallace to construct a special screen. The result, though for some reason not so effective practically with bathed plates as was theoretically to be expected, proved successful with Cramer's isochromatic instantaneous plates, owing to the insensitiveness of the plate for the red and ultra-red rays, and to the fact that $\lambda = 5000$ marked a minimum in its action followed by a rise.[1]

Other devices which should improve the process are also to be practised, and these, with the increased presentation of the planet's disc, should result in another decided advance in photographic presentment; for the planet will in 1909 be more advantageously placed for Flagstaff on three counts:—

(1) A larger disc.
(2) A greater altitude.
(3) A more developed condition of the canals due to the advance in the Martian season.

In spite of the interest which the taking of such photographs has caused, it must be remembered that after all the eye remains our most potent instrument of research. So thoroughly was this realised at Flagstaff that the photographs were originally undertaken simply with a view to their educational value. Inasmuch as these photographs in good air are superior to untrained eye observations in a poor one, they serve to dispel directly a modicum of doubt, though they cannot at present equal what the trained eye can see under similar conditions. But indirectly they do more; for they corroborate completely, so far as they go, visual observations which have been so extensively denied, and establish, therefore, a very strong presumption that those visual detections are true also beyond what the photographic plate has power to portray. In this connection it is interesting to note that more than one astronomer who has seen the canals from a middle ground of definition neither good nor bad has

[1] For a more detailed account of the device, see the Lowell Observatory Bulletin, No. 31.

adduced the photographs as he interprets their features as corroborating his own observations, forgetting that this implies that he sees the originals only a fraction as well as he should.

Yet even so the photographs have surpassed our hopes, for they disclose more than one could have ventured to imagine. An eye versed in photographic perception and interpretation will easily see in them the canals as lines and the little spots, the oases, at their junctions. Indeed, the camera has shown itself capable of rising beyond the confirmatory into the discovery stage; for one of the plates of the writer was instrumental in the detection of a new canal. A stranger appeared on the plate which when searched for visually in consequence proved to be there. At the next opposition, with our newly devised improvements and with the planet so much nearer the zenith for northern observers, it is confidently to be expected that we shall do still more.

Percival Lowell.

HYDROLOGY IN THE UNITED STATES.

In some of the more recent reports on the hydrology of the United States, the book is prefaced by a general statement as to the intention and scope of the surveys that are being carried out by the geological department of the Government relating to the water resources of the country.

Water supply is regarded as one of the principal national assets, and of more importance to the life and pursuits of the people than any other natural resource. In the arid States the limit of agricultural development is determined by the amount of water available for irrigation. In other States, where the rainfall is greater and more evenly distributed throughout the year, the lack of rain at the proper season often reduces a crop to one-half what it would have been with one additional wetting at the time most needed. Storage, providing water for use when most wanted, will in such a case be as beneficial as where irrigation has to be depended on exclusively. This is especially the case in those districts where market gardening is one of the most profitable agricultural pursuits. Here irrigation is a necessity for making the business profitable.

The increase in the population of cities and towns makes necessary additional water supplies for domestic and industrial uses, in procuring which both the quantity and quality of the water that can be obtained must be considered.

The location of manufacturing plants may depend largely on the water-power facilities and the character of the water. Electric transmission of power has led to the utilisation of water-power for the operation of manufacturing establishments and lighting plants. Water-power is also largely used in some States for log driving, lumbering, and saw-mills, and also for the manufacture of paper from wood pulp and straw.

For all or any of these purposes a knowledge of the flow of the streams and of the conditions affecting that flow, based on trustworthy data, and of the underground resources is essential. For the want of this many schemes for water supply have ended in failure, the plans being made without sufficiently trustworthy information.

The United States Geological Survey has therefore, by means of appropriations by Congress, for several years systematically been engaged in obtaining records of stream flow, the number of stations at which streams were under observation in 1906 being 700. Records are also obtained in regard to floods, precipitation, the relation of the rainfall to run-off of water, evaporation, water pollution, the flow of underground streams, the use of artesian and surface wells, and generally all matters relating to water supply.

The reports relating to the above matters, and also as to the water resources of different States and districts, are issued from time to time, upwards of 200 reports having already been issued.

Notices of these reports, directing attention especially to those papers which are of general interest, have appeared in Nature at various times.

The most recent reports of which we have received copies,[1] eleven in number, relate to the water resources of Georgia, New England, and other districts, the information contained in them being principally of local interest, except Paper No. 201, which has an introduction dealing with the system followed in obtaining the discharge of streams.

THE TESTING OF MATERIALS.

The official report of the proceedings of the fourth Congress of the International Association for the Testing of Materials was recently issued. The congress was held at Brussels in September, 1906, and the report contains a condensed account of the reports presented and a summary of the discussions upon the reports and papers. The congress met in three sections, one dealing with papers on metals, another with papers on cement and artificial stones, and the third dealing with miscellaneous investigations, such as protection of metals against rust, testing of timbers, rubber, &c. Before the sections began their proceedings, Prof. Schüle delivered an address dealing with the life and work of the late president and founder of the association, Ludwig von Tetmajer.

One of the most important matters discussed in the metal section was the method of testing notched bars; after a lengthy discussion the congress eventually adopted the following resolution:—"The congress recognises that the method of testing notched bars appears capable of giving extremely interesting results." The congress did not, however, adopt a resolution which was moved to the effect that the method should be experimentally introduced into certain specifications.

In regard to the subject of ball-pressure tests, the congress eventually adopted the following resolution:—"The present congress desires that in the acceptance of metallic materials tests of tenacity should be supplemented as often as possible by a determination of the Brinell hardness number, the latter test being performed for the object of collecting information."

During the meeting of the association a metal-testing laboratory was installed at Brussels in order to show in action the various modern processes employed in the testing of materials. The tests made were micrographic, determination of the critical points, impact tests on notched bars, Brinell ball tests, and shearing tests. The congress has published a small illustrated pamphlet descriptive of the various testing appliances which were at work in this metal laboratory, with a brief note on the results obtained.

T. H. B.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The Vice-Chancellor gives notice that the election of a professor of agricultural botany will take place on Monday, March 16. Candidates for this professorship are requested to communicate with the Vice-Chancellor on or before Wednesday, March 11.

Sir Ernest M. Satow, G.C.M.G., has been appointed to the office of reader on Sir Robert Rede's foundation for the present year. The lecture will be given in the Senate house on Saturday, June 13.

London.—In connection with the supplementary vote of 6000*l.* for the Imperial College of Science and Technology at South Kensington, being part of the annual Government subvention of 20,000*l.* to the college, Sir Philip Magnus inquired last Friday in the House of Commons whether the 20,000*l.* was in excess of the cost of maintenance of the Royal College of Science and the Royal School of Mines, which had been incorporated in the Imperial College. In reply, Mr. Lough explained that the grant of 20,000*l.* was arranged by the Board of Education under the late Government; in addition, the Imperial College would have the fees paid by students, including fees paid by the Board of Education for scholars nominated by the Board. In reply to a further inquiry by Sir Philip

[1] Water Supply and Irrigation Papers. (Washington: Government Printing Office.)

Magnus whether the Government intended to appoint a Royal Commission in reference to the relation of the Imperial College to the University of London, no information appears to have been forthcoming.

OXFORD.—The annual report of the delegates for instruction in forestry shows that the average number of forestry students in 1907 was fifty-seven. The forest garden and experimental plantations in Bagley Wood have been much increased during the year, and the lack of accommodation is about to be met by the generosity of St. John's College. A block of buildings for the accommodation of the professor of rural economy was erected in Parks Road during the years 1906–7. It is now proposed to add further accommodation for the forest branch, consisting of a lecture theatre, a class-room, a museum, a library, and a professor's room. The new buildings will be ready by the end of 1908.

The degree of Doctor of Science has been conferred on Mr. E. H. J. Schuster, New College, for his contributions to biometrical science.

WE learn from the *Revue scientifique* that by a decree of February 10, inspectors of technical instruction are to be appointed in France. Ordinary inspectors will be chosen from among the directors and teachers of technical schools, and district inspectors will be selected from competent leaders of industrial or commercial enterprises.

THE Secretary of State for India has appointed a committee to inquire into and report upon the present system of selecting, and of training after selection, candidates for the Indian Forest Service, and to make recommendations. The committee is constituted as follows:—Mr. R. C. Munro Ferguson, M.P., chairman; Sir John Edge, K.C., member of the Council of India; Sir W. T. Thiselton-Dyer, K.C.M.G., F.R.S.; Mr. E. Stafford Howard, C.B.; and Mr. St. Hill Eardley Wilmot, Inspector-General of Forests in India.

THE London Inter-Collegiate Scholarships Board will hold in May a combined examination for twenty scholarships and exhibitions tenable at University College, King's College, and the East London College. Candidates must have matriculated at the University of London or have passed an equivalent examination, and be under the age of nineteen years on October 1 next. The total value of the scholarships offered exceeds 1700*l*. Full particulars may be obtained from the secretary to the Board, Mr. A. E. G. Attoe, University College, Gower Street, London, W.C.

WE learn from the *Times* that at the meeting of the council of the University of Paris on February 24, the Vice-Rector presented to that body a loving cup, a gift made by the University of London to the University of Paris as a souvenir of the hospitality it received last summer. The cup is silver-gilt, repoussé and chiselled, and is nearly 3 feet high. The lid is surmounted by an allegorical figure, while the body of the cup bears on its outside the arms of the Universities of Paris and London, two escutcheons emblematic of the French Republic and Great Britain, and three figures symbolic of science, letters, and art.

THE Calcutta University will celebrate its jubilee this year by conferring the following honorary degrees at the Convocation to be held on March 14:—*D.Litt.*, the Hon. Sir A. H. L. Fraser, K.C.S.I., Lieut.-Governor of Bengal and Rector of the University. *D.L.*, the Hon. Sir Subramaniya Aiyar, K.C.I.E., Vice-Chancellor of the Madras University; the Hon. Mr. Justice Chatterjee, C.I.E., Vice-Chancellor of the Punjab University. *D.Sc.*, the Hon. Dr. Justice Mukerjee, Vice-Chancellor of the Calcutta University; Prof. A. Schüster, F.R.S.; the Rev. Father E. Lafont, S.J., C.I.E., late Rector of St. Xavier's College, Calcutta; Mr. T. H. Holland, F.R.S., director of the Geological Survey of India; Dr. G. Thibaut, C.I.E. *Ph.D.*, Dr. R. G. Bhandarkar, C.I.E., late Vice-Chancellor of the Bombay University; Sir Gooroo Das Banerjee, D.L., late judge in the Calcutta High Court; Sir H. H. Risley, K.C.I.E., C.I.E., secretary to the Government of India; Prof. P. C. Rây. *M.D.*, Surgeon-General G. Bomford, C.I.E., Director-General of the Indian Medical Service.

AMONG the gifts to colleges and other institutions of higher education announced in *Science* during the past few months, the following, of 10,000*l*. or more, may be mentioned. By the will of the late Mr. D. Willis James 20,000*l*. was bequeathed to five separate institutions, including Columbia and Yale Universities. Prof. J. H. Hammond, by an additional 1000*l*., has brought his gift to the Hammond Metallurgical Laboratory of Yale University to 25,400*l*. By the will of Mrs. Sarah E. Potter, of Boston, Harvard University received a bequest of 10,000*l*., to be used in connection with the Gray herbarium. Columbia University has received an anonymous gift of 20,000*l*. Yale University has benefited to the extent of 10,000*l*. by the will of the late Mr. Silliman Bladgen. Mr. John D. Rockefeller has added 438,200*l*. to his previous gifts to the University of Chicago, making the total amount of these nearly 5,000,000*l*. Colorado College has completed an addition of 100,000*l*. to its productive funds, towards which Mr. Andrew Carnegie contributed 10,000*l*. According to the daily papers, Bradley Polytechnic, of Peoria, Ill., benefits to the extent of nearly 600,000*l*. by the will of the late Mrs. Lydia Bradley. Mr. Andrew Carnegie has also given 40,000*l*. to Berea College and 15,000*l*. to Illinois College, at Jacksonville.

ANOTHER attempt at a settlement of the controversy relating to religious instruction in public elementary schools was introduced in the House of Commons on Monday in the form of a Bill brought in by Mr. McKenna, President of the Board of Education, "to regulate the conditions on which public money may be applied in aid of elementary education in England and Wales, and for other purposes incidental thereto." The Bill proposes that in future there should be but one type of public elementary school, provided, controlled, and managed by public authority, and the teachers to be appointed without religious tests. Every public elementary school receiving rate aid would thus be of the type of Board or County Council schools, and no child would be compelled to attend any other kind of school. The religious instruction given in these schools would be the same as that given in Board and county schools for the past thirty-eight years. Voluntary or Church schools would not have the support of public money in single-school parishes, for there the State would not recognise any other school than a public elementary school. In other cases, voluntary schools, when recognised as providing efficient instruction in secular subjects, would receive State aid in the form of grants, but no rate aid, the amount of the Government grant in both county and recognised voluntary schools being 47*s*. per annum for each child in attendance. The Bill was read a first time, after it had been vigorously condemned by Mr. Balfour and other members of the Opposition.

AT the prize distribution to students at the Battersea Polytechnic on Wednesday, February 19, Lord Stanley of Alderley remarked that when the polytechnic movement was first started it was a general idea that the work in the institutions was to be largely recreative. But though the importance of the social side and of its influence for the good of the students was recognised, in course of time the educational work asserted itself and became predominant. In the more modern institutions, the value of the day work with its regular courses is being more fully recognised. While the evening work is kept up to as high a standard as possible, the work done in the day classes is more thorough; the students obtain a greater mastery of their subjects, and therefore it is of greater importance than that of the evening side. Remarkable advances have been made in this direction in the great technical institutions, such as those at Sheffield, Bristol, and Manchester. In the management of institutions like the Battersea Polytechnic, there should be a strong local element which knows what are the requirements of the particular districts. It is necessary to separate what may be called the common work of education from that of the particular work of technical instruction as applied to arts and crafts. A comparison between the requirements for domestic economy training a few years ago and those which are now considered necessary to have any influence on the home life and habits of people shows that a much higher standard has been reached. The work carried on at the polytechnics will bear good fruit, and it is to be hoped that the London County Council will see its way clear to provide the means so that the polytechnics of London may furnish an example to every town in the United Kingdom and in all parts of the world.

THE fifteenth annual general meeting of the Association of Technical Institutions was held on Friday and Saturday last at the hall of the Drapers' Company. Sir Horace Plunkett, the retiring president, occupied the chair during the early part of the proceedings, and was succeeded by Sir Norman Lockyer, K.C.B., who was unanimously elected president for the ensuing year. Sir Norman Lockyer in his address referred to the progress that has taken place in educational methods in recent years, but pointed out that there is a lack of coordination between primary and secondary schools or technical schools. We have now a good system of elementary education, but there is a terrible wastage after the primary school. He pleaded for a fuller recognition of continuity in education and of the high standing of technical institutions in an organic system. At the second day's meeting there was a discussion on trade or craft schools, and eventually the following resolution was adopted:—"That this association, fully recognising the necessity for a comprehensive and graded scheme of technical education, embracing all sections of the community, request the council to make an inquiry with a view to ascertaining the best conditions for the development of technical education in relation to the training of workmen." In opening the discussion, Prof. W. M. Gardner, of Bradford, said that of 1000 boys passing through elementary schools, and ultimately taking positions as industrial workmen, foremen, or managers, probably not more than forty pass through a secondary school and not more than three or four attend a day technical school. The great problem is, therefore, that of the boys who leave the primary schools at thirteen and fourteen, or even earlier, and who constitute 950 out of every 1000 boys of that age. Three courses seem to be open, namely:—(1) to provide specialised technical instruction during the latter portion of the primary-school course, combining it with the general subjects in the time-table; (2) to pass the lads forward from the primary school to specially arranged trade schools for one or two years; and (3) to rely, as hitherto, on evening schools for technical instruction. How far the first plan is practicable, or even desirable, appears doubtful. It is educationally unsound to give technical instruction in a trade without first dealing with the underlying sciences in an elementary manner. The provision of special trade schools seems, the speaker said, to offer a more likely solution of the problem.

SOCIETIES AND ACADEMIES.

LONDON

Geological Society, February 5.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—Antigorite and the Val Antigorio, with notes on other serpentines containing that mineral: Prof. T. G. **Bonney**. It is not certain that the first described specimen of antigorite was really found in the Val Antigorio. The rock probably does not occur there *in situ*, though it is found in pebbles, &c., from tributaries. Other specimens of antigorite-serpentine were described. The origin of the mineral is discussed. Pressure is essential; it can be formed from augite, and there is evidence of its coming from this mineral.—The St. David's Head "rock series" (Pembrokeshire): J. V. **Elsden**. These intrusions are of complex composition. There is a high magnesia percentage. There is no evidence of differentiation *in situ*, but the facts suggest a common origin from a differentiated magma basin. The rocks afford facilities for the study of both rhombic and monoclinic pyroxenes. Rhombic pyroxene generally crystallised earlier than the monoclinic pyroxene. There are two varieties of augite. The relation of these types lends support to the perthitic theory. The probable age of the intrusions is not greater than that of the earth movements which folded the Arenig shales in this district.

Linnean Society, February 6.—Dr. A. B. Rendle, vice-president, in the chair.—Specimens and lantern-slides of leaf impressions from the Reading beds: H. W. **Monckton** and O. A. **Shrubsole**.—Fruits and seeds from the pre-Glacial beds of Britain and the Netherlands, especially the Pakefield specimens from the neighbourhood of Lowestoft (Cromer forest bed), and from Tegelen, near Venloo, in the province of Limburg, Netherlands: Clement **Reid**. The use of large quantities of commercial concentrated soda carbonate when boiling refractory deposits: Mrs. E. M. **Reid**.—A botanical expedition to Central Fokien: S. T. **Dunn**. In April, May, and June, 1905, a botanical expedition was undertaken, with three native collectors and one Chinese herbarium assistant, to the centre of the province of Fokien. The difficult journey from Foochow to Yenping was successfully accomplished, and enough stores deposited at that town to enable a large collection of plants to be made. The central portion of this province, which is as large as England and Wales combined, had never previously been visited by a botanist, and, as might be expected, many novelties were discovered, and are here described, amounting to at least forty new species.—Some new Alcyonaria from the Indian and Pacific Oceans: preliminary notice: Ruth M. **Harrison**.

Royal Anthropological Institute February 11.—Prof. W. Ridgeway, president, in the chair.—An additional note on New Guinea games: Dr. A. C. **Haddon**. The games were of various descriptions, and included a series of string figures.—A new instrument for determining the colour of the hair, eyes, and skin: J. **Gray**. The instrument was a simplified form of Lovibond's tintometer, by means of which hair-, eye-, and skin-colours could be classified by comparison with a series of standard coloured glasses. These standard glasses can be reproduced an indefinite number of times with the greatest precision by Lovibond's method, so that any number of observers can be provided with identical colour-scales. A series of locks of hair, arranged by the naked eye, from blonde to jet black, was exhibited, and curves showing the colour-elements of this series, as obtained by Lovibond's tintometer, were shown on the screen. The curves showed that the locks contained two coloured pigments, namely, orange and a yellow, and a black pigment. The black pigment increased uniformly in amount from blonde to black, and evidently formed the basis of the arrangement of the series by the naked eye, because the amount of orange and yellow pigment was practically constant throughout the whole series. A second series of locks of red hair was exhibited, arranged by the naked eye from light to dark red or auburn. Analysis showed that the orange pigment was predominant, and formed the basis of the classification. A diagram, exhibited to show the correlation between orange and black in the two series of locks, pointed to the conclusion that red hair was derived from dark hair by the conversion of more or less of the black pigment into an equal amount of orange pigment, while fair hair was derived from dark hair by a reduction of both the black and the orange pigments.

Institution of Mining and Metallurgy, February 20.—Prof. W. Gowland, president, in the chair.—The alloys of gold and tellurium: Dr. T. K. **Rose**. An examination of the mixtures of gold and tellurium by means of the Roberts-Austen recording pyrometer, and observing polished sections under the microscope. The main conclusions arrived at were:—(1) A compound, $AuTe_2$ or Au_2Te_4, containing 43·59 per cent. of gold, and corresponding in composition to sylvanite or calaverite, is formed when gold and tellurium are melted together in certain proportion; this compound fuses at 452°. (2) Two eutectic mixtures are formed, containing 60 per cent. and 20 per cent. of gold respectively. These alloys correspond in composition to the formulæ $AuTe$ and $AuTe_6$. Under the microscope they do not show the characteristic banded eutectic structure, but there are certain indications that they are true compounds. (3) All the alloys of gold and tellurium are brittle. (4) All those containing less than 60 per cent. of gold fuse at temperatures between 397° and 452°.—A method of settling slimes, as applied to their separation from solution in cyanide treatment: H. G. **Nichols**. The principle involved is that of removing the solid matter as it reaches the bottom of the tank in which it is settled by means of a conveyor belt. This process was found by repeated tests to give remarkable results both in the completeness of the separation effected and in the small proportion of liquid carried off by the solid matter.—Two deterrents to the dissolution of free gold in the cyanide process: Duncan **Simpson.** These deterrents are oil and lime, and the author gave examples showing their influence and the method adopted for counteracting it.—A rapid method for the estimation of arsenic in ores: H. E. **Hooper.**—The Indian mint assay of silver bullion: F. T. C. **Hughes.** A description of the methods employed in the Indian mints for the assay of the varying qualities of bullion received for coinage purposes. This process has been in vogue for upwards of fifty years, and has given satisfactory results, being specially suited to the condition of labour, &c., existing in India, and to the varied nature of the bullion operated upon.

Dublin.

Royal Dublin Society, January 21.—Prof. A. W. Conway in the chair.—The lines of flow of water in saturated soils, especially peat-mosses: L. F. **Richardson.** The author shows by means of experiments on "Bog of Allen" peat that the general velocity with which the water passes through the peat is proportional to the pressure gradient, and by utilising this fact he deduces the differential equations for the flow of water through peat saturated with water, neglecting capillarity, and assuming the peat to be isotropic in order to facilitate the mathematical treatment of the problem. The differential equations are solved by a freehand graphic method, and the form of the saturated water surface determined, when the tubes of flow are somewhat horizontal. From the diagrams thus obtained it is possible to calculate in a simple manner—the rainfall being given—how far apart drains must be cut in a bog so as to remove just the right amount of water, and conversely what will be the effect of a given cutting. The paper concludes with the description of another method for determining the conductivity of peat for water.—A simple form of apparatus for observing the rate of absorption of oxygen by polluted waters and by other fermenting liquids: Dr. W. E. **Adeney.**

Edinburgh

Royal Society, February 3.—Prof. Andrew Gray, F.R.S., vice-president, in the chair.—Sensitive state induced in magnetic materials by thermal treatment: J. G. **Gray** and A. D. **Ross.** When steel is cooled from a high temperature, the first measured susceptibility in a given field is much higher than later measured values after the specimen has been subjected to cyclic magnetisations. This phenomenon, first noticed by Ewing, was studied in detail for steel, cast iron, cobalt, and soft iron. In soft iron the phenomenon is absent or present only to a small degree. In certain specimens of steel the effect was induced to a slight degree when the substance was raised to as low a temperature as 100° C. and then cooled; it increased with increased temperatures to about 700° C., but further increase of temperature had little influence. Mechanical vibrations considerably reduced the effect. The phenomenon was most marked in fields which gave large values of the susceptibility, tending to zero as the saturation point was approached.—The growth and development of the limbs of the penguin: Dr. D. **Waterston** and A. C. **Geddes.** The material had been brought home by Dr. W. S. Bruce, leader of the Scottish Antarctic Expedition. A comparison of the stages of development with the corresponding stages of development of the chick of a duck showed that the limbs of the penguin began at a fairly early stage to diverge in mode of growth from those of the duck, indicating that the adaptation of the fore-limbs for swimming purposes did not imply a degeneration from a form suitable for flight.

Paris.

Academy of Sciences, February 17.—M. H. Becquerel in the chair.—The properties of pure starch: L. **Maquenne.** Referring to a note by M. Fouard at the last meeting of the academy on the isolation of a new soluble form of starch, the author points out that this soluble starch is in all respects identical with that described by him, in conjunction with M. Roux, in the *Comptes rendus* two years ago. The name amylose was given to this soluble form of starch, and ordinary starch solution consists of a clear solution of amylose thickened with amylopectose.—Isotonic solutions and isoosmotic solutions: Yves **Delage.** A continuation of the controversy with J. Loeb. The author concludes that it is impossible to doubt that the parthenogenesis of the eggs of the sea-urchin can be brought about in solution isotonic with sea-water.—The visibility of Saturn's ring on the side not lighted by the sun, and its reappearance in January, 1908: M. **Amann.** A detailed account of the appearances presented by the ring between October 4, 1907, and January 14, 1908.—The relation between flying shadows and scintillation: Cl. **Rozet.** A definite relation has been established between the shadow bands and the phenomenon of scintillation. The effects have been observed, not only with the sun, but also with Venus, Jupiter, Mars, and some stars of the first magnitude.—A theorem in the theory of integral equations: E. **Goursat.**—The electrolysis of solutions of hydrochloric acid: E. **Doumer.** In the electrolysis of hydrochloric acid, oxygen always accompanies the chlorine, the proportion of oxygen to the hydrogen set free at the other electrode depending on the concentration, and increasing with the dilution of the acid. With an anode of silver or mercury, capable of combining with the chlorine, the proportion of oxygen for the same intensity of current is increased. The author concludes that the electrolysis of both the acid and the water takes place simultaneously. The amount of oxygen produced is not negligible, and must be taken into account in the determination of the transport factor of the ions and in the measurement of the conductivity of these solutions.—Lithium in radio-active minerals: Mlle. **Gleditsch.** Determinations of the copper, lithium, and the radio-activity compared with uranium have been made for the minerals thorite, Joachimsthal pitchblende, Colorado pitchblende, carnotite, chalcolite from Cornwall, and autunite. Lithium was found in all these minerals in amounts varying from 0·00017 per cent. to 0·03 per cent., and copper in all but autunite. These results prove that there is no simple relation between the amounts of copper and lithium in radio-active minerals.—A new method of estimating sulphur in organic substances: Isodore **Bay.** The substance is mixed with sodium carbonate and magnesia, and ignited in a current of oxygen. Test analyses are given showing the accuracy obtainable.—The separation of chloride and iodide of silver: H. **Baubigny.** A solution of ammonium carbonate can be used to effect the quantitative separation of silver iodide and chloride in the absence of bromide.—A method for the complete analysis of vegetable materials: J. M. **Albahary.**—The hydrolysis of perchloride of iron. The effect of the valency of the negative ions: G. **Malfitano** and L. **Michel.**—The reciprocal displacement of hydrocarbon groups in the Friedel and Crafts reaction: H. **Duval.**—The reducing properties of organo-metallic compounds: M. **Letellier.** By the action of ethyl-magnesium bromide upon ethyl oxypivalate, besides the glycol

$$CH_2(OH).C(CH_3)_2.C(OH)(C_2H_5)_2$$

expected, the compound $CH_2(OH).C(CH_3)_2.CH(OH).C_2H_5$ was obtained as a by-product. This is formed by the reduction of the ketone $CH_2(OH).C(CH_3)_2.CO.C_2H_5$, ethylene being evolved. Other instances of the reducing action of alkyl-magnesium compounds are cited.—The simultaneous production of the 1:6- and 2:7-dimethyl-anthracenes in the action of CH_2Cl_2, of $CHCl_3$, or of $C_2H_2Br_4$ upon toluene in the presence of aluminium chloride: James **Lavoux.**—The essence of *Tetranthera polyantha*, var. *citrata*: Eug. **Charabot** and G. **Laloue.** The essences from the bark, leaves, and fruits were examined. That from the bark contained citral, citronellal, and an alcohol, possibly geraniol; the essence from the leaves contained citral, cineol, and the same alcohol as the bark; the essence from the fruits consisted of citral, an ester, and possibly geraniol.—The possible presence of microscopic diamonds on the sea floor and in a specimen of vegetable earth: J. **Thoulet.** The mechanical analysis of a deposit obtained from the sea floor in the Bay of Biscay furnished some minute crystals many of the characters of which corresponded to those of the diamond, and similar crystals were obtained from a specimen of vegetable earth from the forest of Haye, near Liverdun. The quantities obtained were too small to admit of complete identification.—Contribution to the study of the alkaline rocks of Central Africa: L. **Gentil** and M. **Freydenberg**.—New observations on the anatomy and affinities of the Malpighiaceæ of Madagascar: Marcel **Dubard** and Paul **Dop**.—The formation of the notochord in some larvæ of the Tunicates: Louis **Roule**.—The mechanism of variations in height of the human body and some pathological variations: R. **Robinson**.—The statistical proof of Mendel's law: Angel **Gallardo**. An answer to some criticisms of Prof. K. Pearson.—The reproduction and the variations of development in *Glossina palpalis*: E. **Roubaud**.—The fixation of zinc by *Sterigmatocystis nigra*: M. **Janvillier**. A small proportion of zinc is favourable to the growth of this mould, and in solutions containing four parts per million of zinc or less the whole of the zinc present is fixed by the mould. With increasing proportions of zinc in the culture solution increasing amounts of zinc are found in the mycelium, but the whole of the zinc present is not taken up. The Sterigmatocystis is capable of fixing without injury 1/100th of its weight of zinc.—The purgative action of phenolphthalein and its disodium derivative: C. **Fleig**. The frequency of intestinal ulcerations in the course of an attack of influenza: Gabriel **Arthaud**.—Contribution to the study of the calorific radiation of the sun: G. **Millochau** and C. **Féry**.—The predominance of the erosion of the river Sarine on its right bank: Jean **Brunhes** and Cesare **Calciati**.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 27.

ROYAL SOCIETY, at 4.30.—The Influence of Temperature on Phagocytosis: J. C. G. Ledingham.—The Glycogenic Changes in the Placenta and the Fœtus of the Pregnant Rabbit. A Contribution to the Chemistry of Growth: J. Lochhead and W. Cramer.—On the Maturation of the Ovum in the Guinea pig: Prof. J. E. S. Moore and Miss F. Tozer.

ROYAL INSTITUTION, at 3.—Wood: its Botanical and Technical Aspects: Prof. W. Somerville.

SOCIETY OF DYERS AND COLOURISTS, at 8. The Deterioration of Modern Dyed Leathers: M. C. Lamb.—A Note on the Germicidal Value of Petroleum Benzine: F. J. Farrell and F. Howles.

FRIDAY, FEBRUARY 28.

ROYAL INSTITUTION, at 9.—Explosive Combustion, with Special Reference to that of Hydrocarbons: Prof. W. A. Bone, F.R.S.

ROYAL SOCIETY OF ARTS, at 8.—The Removal of Dust and Fumes in Factories: Dr. J. S. Haldane, F.R.S.

PHYSICAL SOCIETY, at 5.—Contact Potential Differences Determined by Means of Null Solutions: S. W. J. Smith and H. Moss.—An Experimental Examination of Gibbs' Theory of Surface Tension as the Basis of Adsorption with an Application to the Theory of Dyeing: W. Lewis.

SATURDAY, FEBRUARY 29.

ESSEX FIELD CLUB (at the Essex Museum of Natural History, Stratford), at 6.—Artesian Wells on Fowlness Island, Essex, Ancient and Modern: W. H. Dalton.—On some Unexplored Fields of Essex Archæology: John French.—Note on a Post-Glacial Deposit on Mersea Island, Essex: W. H. Dalton.

MONDAY, MARCH 2.

VICTORIA INSTITUTE, at 4.30.—The Atlantic Islands, and Origin of Their Fauna: Prof E. Hull, F.R.S.

ARISTOTELIAN SOCIETY, at 8.—The Idea of Totality: Dr. S. H. Hodgson.

TUESDAY, MARCH 3.

ROYAL INSTITUTION, at 3.—Membranes: Their Structure, Uses and Products: Prof. W. Stirling.

ZOOLOGICAL SOCIETY, at 8.30.—A Comparison of the Neotropical Species of Corallus, *C. cookii*, with *C. madagascariensis*; and on some Points in the Anatomy of *Corallus caninus*: F. E. Beddard, F.R.S.—On a Young Female Kordofan Giraffe: Dr. P. Chalmers Mitchell, F.R.S.—Description of a New Species of Monkey of the Genus Cercopithecus: R. I. Pocock.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Notes on Engineering Works in Austria and Bosnia: A. S. E. Ackermann.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Further discussion:* The New York Rapid-transit Subway: W. B. Parsons.

WEDNESDAY, MARCH 4.

ROYAL SOCIETY OF ARTS, at 8.—Modern Dairy Practice: Loudon M·Douglas.

GEOLOGICAL SOCIETY, at 8.—On *Metriorhynchus brachyrhynchus* (Deslong.) from the Oxford Clay near Peterborough: E. Thurlow Leeds.—The High-Level Platforms of Bodmin Moor, and their Relation to the Deposits of Stream-tin and Wolfram: G. Barrow.

ENTOMOLOGICAL SOCIETY, at 8.—Descriptions of New Species of *Lepidoptera heterocera* from South-east Brazil: E. Dukinfield-Jones.

SOCIETY OF PUBLIC ANALYSTS, at 8.—The Volumetric Determination of Reducing Sugars: Part II. The Limits of Accuracy of the Method under Standard Conditions: A. R. Ling and G. Cecil Jones. Part III. The Influence of Cane Sugar: A. R. Ling and T. Rendle.—(1) The Composition of Milk; (2) The Nitrogen Factor for Casein: H. D. Richmond.

THURSDAY, MARCH 5.

ROYAL SOCIETY, at 4.30.—*Probable Papers:*—On the Atomic Weight of Radium: Dr. T. E. Thorpe, C.B., F.R.S.—On the Electrical Resistance of Moving Matter: Prof. F. T. Trouton, F.R.S., and A. O. Rankine.—On the Nature of the Streamers in the Electric Spark: Dr S. R. Milner.—The Relation between Wind Velocity at 1000 Metres Altitude and the Surface Pressure Distribution: E. Gold.

ROYAL INSTITUTION, at 3.—Early British History and Epigraphy: Sir John Rhys.

CHEMICAL SOCIETY, at 8.30.—The Solubility of Iodine in Water: H. Hartley and N. P. Campbell.—Traces of a New Tin-group Element in Thorianite: Miss C. de B. Evans.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Fuse Phenomena: Prof. A. Schwartz and W. H. N. James.

LINNEAN SOCIETY, at 8.—On the Morphology of Stigmaria in Comparison with Recent Lycopodiaceæ: Prof. F. E. Weiss.—On *Trichoniscoides albidus* and *T. sarsi*: Alexander Patience.—*Exhibits:* Fruit Destroying Flies: W. W. Froggatt.—Mimicry in the Common Sole: Dr. A. T. Masterman.

FRIDAY, MARCH 6.

ROYAL INSTITUTION, at 9.—Recent Earthquakes: Prof. John Milne, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Surveying on Thunder Bay Branch of the Grand Trunk Pacific Railway, Canada: R. V. Morris.—British Practice in Railway Surveying: W. Graham. Railway Surveying in Great Britain: W. C. Crawford.

SATURDAY, MARCH 7.

ROYAL INSTITUTION, at 3.—Electric Discharges through Gases: Prof. J. J. Thomson, F.R.S.

THE EVOLUTION OF ASTRONOMICAL INSTRUMENTS.

Zur Geschichte der astronomischen Messwerkzeuge von Purbach bis Reichenbach 1450 *bis* 1830. By Joh. A. Repsold. Pp. viii+132. (Leipzig: Wilhelm Engelmann, 1908.) Price 16 marks.

IN all that relates to the mounting of telescopes or the construction of instruments intended for accurate measurements, in all that increases their convenience or adds to their efficiency, the firm of Repsold has won a world-wide reputation, and the book before us indicates in some measure the reason for this marked success. The head of the firm has been a keen and interested student of the history of past construction. For more than forty years, the author reminds us, he has been engaged in furthering the progress of instrumental construction, and in this time he has given close study to all that has effected the gradual development of this branch of engineering technique. He has assimilated all that experience can teach, has learnt the strength and the weakness of the work of past masters, and has profited by their example and their attainments. We now in our turn have the opportunity of benefiting by the results of this close study, perfected by much examination and sifting, and in addition to tracing the evolution of modern instruments we get glimpses of the history of astronomy, viewed from a new and interesting standpoint. Obviously, the connection between the progress of astronomical science and the improvement in instrumental equipment must be continuous and intimate, but how close the tie is can hardly be apprehended until we make a historical survey of the principles of instrumental construction, on a plan which reveals the part played by successive makers, and makes us understand to what extent astronomy has been forwarded by their endeavours.

Although the author limits his review from 1450, when Purbach strove to give expression to his mechanical ideas, to 1830, when Traughton in England and Gambey in France were representatives of the art of instrument making, the survey cannot be restricted to precise dates. At one end we listen again to the description of the contrivances of Ptolemy, which served for models through so many centuries, and at the other we are permitted to see the beginnings of the famous house of Repsold, destined to influence the methods of future artists.

The author passes in review the mechanical efforts of the Arabians, whose claims to consideration have been extravagantly championed by Sédillot and as stoutly disputed by Delambre. He acknowledges the skill of the devices which enabled them to solve approximately a particular class of problems by mechanical means, but cannot find much to praise in their measuring instruments. The astrolabe and the so-called "sextant" meet with adequate recognition, but a careful consideration of the facts, which are set out with the clearness bespeaking the practical expert, leaves the impression that the Arabians did very little to advance the means for making accurate observation. They imitated, they did not invent, and none of the generic improvements which have facilitated the subdivision of small intervals of time and space—the main problem which has engaged the attention of successive generations of instrument makers—on which accurate astronomy depends, can be placed to their credit.

Frequent reproduction has made us familiar with the forms of the instruments used by Copernicus and Tycho, who with Hevel may be regarded as the last representatives of a pre-telescopic age. But here, in addition to very complete illustration, we have from the pen of a competent authority a full technical description of those contrivances, accompanied by acute and illuminating remarks on the adequacy of the design to secure the end contemplated, the faults of construction, and oftentimes the reason for the adoption of particular methods. Down the stream of time this discriminating but generous criticism is pursued, necessarily affording a clearer insight into the difficulties and successes of individual artists.

The introduction of the telescope offered a new set of problems for solution. The continual increase in focal length compelled makers to abandon the sector form of instrument, such as the quadrant, and forced upon them the necessity of devising more appropriate means for measurement, though Halley and Bradley both used 8-feet quadrants. The employment of complete circles and the designing of instruments of greater symmetry in their several parts were the consequence, and no one displayed more ingenuity or foresight than did Römer. With justice, the author carefully discusses the work of this astronomer, whose claims to recognition have been very tardily admitted, mainly owing to Delambre's jealous partisanship of Picard. But Dr. Repsold has known how to do justice to the one without injury to the other. Römer in various ways anticipated modern design. His *machina domestica* was the prototype of the present transit instrument, his *rota meridiana* of the meridian circle, while his azimuthal instrument foreshadowed the introduction of the convenient universal instrument. The use of two bearings to carry a long axis of rotation, increased symmetry of structure, the adaptation of the reading microscope, the practice of determining instrumental errors by suitable mechanical means, were all as fully appreciated by Römer as they are to-day.

Considering how indispensable a micrometer is to a telescope, and how materially it increases the scope and usefulness, its evolution proceeded slowly, but the study of its many transformations is of singular interest. The urgency of the demand for the means of measuring the diameter of a planet seems out of proportion to its importance, but the solution of the general problem, containing as it does that of the accurate and convenient subdivision of small spaces, taxed the ingenuity of instrument makers severely. Huyghens proposed a thin wedge, which could be moved in the focal plane until the planet was exactly occulted, when the measurement of the breadth of the wedge at that point gave the diameter. A net-

T

work of small squares in the focus of the eyepiece was another favourite device which might have answered very well if the object to be measured exactly fitted the side of the square. Picard seems to have first imagined the use of the screw to move two plates of metal, similar to the slit of a spectroscope, but to measure the distance, if we correctly understand the description, he had to detach the micrometer from the telescope and place it under an ordinary microscope. Hooke supplied the movable wires as an improvement to Gascoigne's micrometer, and Auzout introduced the divided head. Römer gave us the spring to take out the "loss" of the screw, Traughton added the position circle, and so the tale goes on, showing the variety of processes and the slowness of growth necessary to ensure the perfected form that receives general acceptance.

The processes followed in dividing the limbs of graduated instruments is another subject which the author's practical knowledge and great experience can render peculiarly interesting, but we can say no more than that in this treatise, with its admirable illustrations, will be found a valuable collection of facts from which one can trace that growth of mechanical skill and improved technique, which have ministered so materially to the progress of astronomical science.

NATURE AND NURTURE OF THE CHILD.

An Introduction to Child-study. By W. B. Drummond, M.B., C.M. Pp. iii+348. (London: Edward Arnold, 1907.) Price 6*s.* net.

The Child's Mind: its Growth and Training. By W. E. Urwick, M.A. Pp. xi+269. (London: Edward Arnold, 1907.) Price 4*s.* 6*d.* net.

MR. DRUMMOND, who is already well known as the author of a useful primer on the nature and nurture of the young child, has written a more ambitious book, which "aims at supplying a fairly comprehensive introduction to child-study." His work, therefore, necessarily covers a wide field, ranging from facts of growth, defects of the special senses, and school hygiene, by way of the instincts, habits and interests of children, to their forms of expression and their moral and religious characteristics. On all these he writes interesting chapters prefaced by sections dealing with methods of investigation and other introductory topics.

On p. 87 the student is wisely warned against the over-enthusiasm exhibited by "a number of workers especially in America," some of whom "start with no definite object in view and not unnaturally arrive nowhere." It would doubtless be unfair to suggest that this severe criticism applies not inaptly to the child-study movement as a whole. Nevertheless, on turning the last page of this book one is tempted to ask whether it is possible to secure "the chief end of child-study," which is, we are told, "not only to collect facts about children," but also "to formulate them in such a way as to make them available for science and for the use of those who need them for application to practical problems," so long as even such able exponents as Mr. Drummond give us little more than a mass of materials of widely different values, not always submitted to adequate criticism, and illuminated from no general point of view. This complaint should, however, be qualified by recognition that the author can scarcely fail to encourage sympathetic observation of children—a result with which he would, apparently, be satisfied.

By contrast with Mr. Drummond's book, the systematic unity of treatment that follows from adherence to a clearly conceived point of view is the most prominent characteristic of Mr. Urwick's. The author of "The Child's Mind" sees clearly that:—

"It is not sufficient for the purpose of education merely to collect and state facts drawn from these sciences [Biology, Physiology and Psychology] which seem to be relevant. . . . The rays of light coming from the different sciences must be focussed, passed, as it were, through a common lens, in order that the light thrown may be cumulative and concentrated rather than sporadic."

It may be said at once that he has performed the task thus indicated in such a way as to make his modestly announced "study" one of the most useful pedagogical treatises of recent years. He has given what is much more helpful than the best "psychology for teachers"—a consistent interpretation of the educative process as a whole as it presents itself under the more or less conventional conditions which actually determine it.

Mr. Urwick's treatment is based upon the modern concept of connation. Human behaviour can be analysed largely into connative processes which set towards or away from objects of positive or negative "immediate value." In relation to these immediate values other objects of perception or thought may have "final value." Education consists in the (indirect) teaching of a certain range of immediate values and the (direct) teaching of final values with reference to these. Thus immediate and final value replace in Mr. Urwick's scheme the Herbartian notion of interest. His treatment is in a sense complementary to the older doctrine, of which he gives fragmentary but interesting criticisms. The student will find it a valuable exercise to study "The Child's Mind" together with a representative exposition of the Herbartian psychology such as that of Prof. Adams.

T. P. N.

OUR BOOK SHELF.

The Essentials of Cytology. An Introduction to the Study of Living Matter. With a Chapter on Cytological Methods. By Charles Edward Walker. Pp. viii+139. (London: Archibald Constable and Co., Ltd., 1907.) Price 7*s.* 6*d.* net.

THE need for an elementary text-book on cytology has been felt for some years, and Mr. Walker has sought to meet it in the volume before us. There is much in the book that is good. The details of nuclear division in the higher forms are clearly presented, and the student is enabled to gain a clear idea of the process by means of the admirable and ingenious stereoscopic photographs which accompany the volume.

A considerable space is devoted to a consideration of the reduction phenomena which form such a striking feature in the cellular life-cycle of the great majority of animals and plants. But we cannot forbear from protesting against the introduction of what seems to us to be a totally unjustifiable confusion into current terminology. The term "meiotic phase," used to cover the processes connected with "reduction," was introduced to embrace the *two* mitoses which are intimately connected. In the course of the first of these the reduction in the number of the chromosomes is accomplished. Mr. Walker, however, speaks of the second meiotic division as post-meiotic, thus obscuring the close relationship that exists between the heterotype and homotype division, a relationship that is, partly at least, due to the fact that in the prophase of the first meiotic (heterotype) division, a fission in the chromosome rudiments takes place which will be consummated during the *second* (homotype) mitosis; this explains the common, though not invariable, absence of the spireme from the second division, and probably is connected with the rapidity with which the two mitoses usually follow on each other. The term post-meiotic should be (as it hitherto has been) reserved for those mitoses, if any, which occur after the completion of the meiotic phase.

The description given of polar bodies is made, doubtless by inadvertence, to read as though these structures only represented nuclei and not cells, whereas, of course, they are each severally homologous with the egg.

The book would be improved by the substitution of a more comprehensive account of the nuclei of the lower organisms for the matter contained in chapters x. and xi., which seems to us to be somewhat out of place in a work of this kind, as well as open to criticism on other grounds.

The addition of an introductory chapter dealing with the development of our knowledge of the cell, and the recognition of its paramount importance, would be useful when there is a demand for a second edition, and at the same time the references which appear at the foot of some of the pages might also be completed.

We have criticised the work somewhat frankly, perhaps, but this has been done not with the intention of condemning it. On the contrary, it possesses many very good qualities, and with some little modification and correction, it will easily rank as an extremely useful text-book of elementary cytology. J. B. F.

Immune Sera. By Dr. C. F. Bolduan. Second edition, re-written. Pp. viii+154. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1907.) Price 6*s*. 6*d*. net.

THIS book has its origin in a monograph by Wasserman, a translation of which was published by the author in 1904. This second edition has been re-written by the translator. The original chapters are dealt with more fully, and the scope of the book has been widened by the addition of chapters on venins and antivenins, agglutinins, opsonins, and serum-sickness.

The antitoxins are first dealt with, and brief outlines are given of the history of the subject and of the methods of preparing and testing antitoxins. Ehrlich's views on the origin of antitoxin, on the constitution of diphtheria antitoxin, and on the nature of the combination between toxin and antitoxin, are treated in a lucid manner. The views of Arrhenius and of Bordet receive less adequate treatment.

In handling the subject of the agglutinins, the bacteriolysins, the hæmolysins, and the precipitins, much discrimination has been shown in avoiding a discussion of the more difficult theoretical considerations, and in selecting the fundamental facts and experiments for exposition.

A good account is given of the application of hæmolytic and precipitin methods to practical purposes. Among these may be mentioned methods of great importance in medico-legal work, viz., the biological tests for bloodstains by means of which it is possible to differentiate human blood from the blood of other animals.

The least satisfactory chapters in the book are those on serum sickness, snake venoms, and opsonins. In regard to the last, the author states that the results obtained by most workers in America fail to bear out Wright's claims for his method.

On the whole, this is an excellent little book, and ought to be of service both to those who wish to keep abreast of the main advances in the subject and to those who are attacking these questions for the first time.

A Guide to the Study of Australian Butterflies. By W. J. Rainbow. Pp. 272; illustrated. (Melbourne: T. C. Lothian, 1907.) Price 3*s*. 6*d*.

THIS is a useful little book intended for beginners taking up the study of Australian butterflies, with special reference to their life-history. Indeed, the author not only tells us in his preface that "much of the material in the way of life-histories is now published for the first time," but also, "Only those species of which something is known of their life-history are included in the present volume." Surely this last resolution is a double mistake. On the one hand it will be a great disappointment to any collector who meets with one of the purposely omitted species not to be able to discover from this book (perhaps the only one on the subject to be found within hundreds of miles) whether his find is known, or probably new; and, on the other, if attention had been directed to imperfectly known species, it would have largely conduced to efforts being made to supply the deficiencies in our knowledge. The book otherwise, however, seems to be very well executed, and is remarkable for being written almost entirely from Australian sources.

The classification followed is taken from Mr. G. A. Waterhouse's "Catalogue of the Rhopalocera of Australia." The frontispiece represents two handsome species of Delias and two of Papilio, while most of the species mentioned in the book are excellently figured, figures of the earlier stages being frequently added. The introductory chapters deal with transformations, parasites, collecting and preserving, &c., and are also freely illustrated, the figures of wing-neuration on p. 23 being particularly good. Ninety species are included in this little volume, distributed among six families as follows:—Nymphalidæ (sens. lat.), 35; Libytheidæ, 1; Lycinidæ (*sic*), 16; Pieridæ, 12; Papilionidæ, 9; Hesperidæ, 17.

We notice a few peculiarities in the spelling of some of the names, which appear to be not misprints, but intentional, such as *Xenica kluggi*, and Lycinidæ.

W. F. K.

The Theory and Practice of Perspective Drawing. By S. Polak. Pp. viii+184. (London: University Tutorial Press, Ltd., 1907.) Price 5*s*.

THIS volume of the "Organised Science Series" has been specially compiled to meet the requirements of the Board of Education's syllabus in perspective, and covers the ground of both sections A and B of that syllabus with their direct and inverse problems.

The method of treatment adopted by the author is one likely to be very effective in teaching; new principles and processes, as they arise in the natural development of the subject, are illustrated and driven home by the use of models, diagrams, and repeated applications to suitable problems, so that the conscientious student is always fully conversant with the reasons for his geometrical constructions. The very excellent and suggestive questions from the examination papers of the Board of Education for the last five or six years are freely employed, both in the text and as sample test papers, affording a good criterion of progress.

In addition to the ordinary geometrical solids, many familiar objects the forms of which can be dissected into simple geometrical figures are used as examples. After the student has thoroughly mastered the fundamental principles as set forth in part i., he should experience comparatively little difficulty with the three succeeding parts, which extend the subject to lines and planes obliquely situated, to shadows by parallel and divergent rays, and to reflections in horizontal and vertical mirrors. The book will be very acceptable both to teachers and students of this interesting branch of applied geometry.

Strength of Materials. By W. C. Popplewell. Pp. x+180. (Edinburgh and London: Oliver and Boyd, 1907.)

This text-book, which is based on the notes of lectures given by the author to day and evening students at the Manchester Municipal School of Technology, deals with the fundamental principles which must be mastered by every student who wishes to have a sound knowledge of machine and structural design. Special attention has been devoted to the effects of unequal distribution of stress, and in chapter vii. the author gives details of his own experimental work in connection with this branch of the subject. The last three chapters give an account of the methods adopted and appliances required in making tests of the various materials used in constructional work, and the important subjects of limit of elasticity and of the influence of previous loading, &c., upon the limit are discussed. In an appendix is given a table of strengths and weights of a large number of different materials, and there is a collection of useful examination questions for each chapter.

LETTERS TO THE EDITOR.

Lithium in Radio-active Minerals.

The recent results of Mlle. Gleditsch (*Comptes rendus*, cxlvi., p. 331) corroborating those of Prof. McCoy, viz. that lithium is generally, but not always, a constituent of radio-active minerals containing copper, and that there is no fixed proportionality between the copper and the lithium in these minerals, must not be taken to have the exclusive significance which their authors attribute to them. As explained in our original communication to the Chemical Society, we are inclined to believe that sodium, and perhaps also potassium, are products of the degradation of copper salts when in contact with radium emanation. As both these metals are constituents of ordinary glass, and as the experiments were carried out in glass vessels, the only argument which was used was that the weight of the residue from the treated was greater than that from the untreated copper salt. Lithium was mentioned because it is an unlikely constituent of dust, glass, copper, &c., which were tested specially to prove its absence; it was certainly contained in the treated residue. Inasmuch as the emanation in contact with water yields neon, on the probable supposition that monatomic gases are produced from the emanation, it would follow that the production of any particular one is dependent on surrounding conditions. It will be remembered that the gases from the action of the emanation on a solution of copper sulphate contained no helium, but probably argon. As sodium and potassium are much more widely distributed than lithium, it is more likely that they are the chief products from copper, and that some modifying circumstance has determined the formation of a trace of lithium. Experiments now in progress in silica vessels will settle this point. Numerous chemical analogies might be adduced in favour of this view. For example, the action of bleaching powder on ammonia solution is to give nitrogen for the most part; if much ammonia be present, and if glue or some other colloid be present, hydrazine is the chief product. One can only be guided by such analogies in determining the lines of future experiments.

W. Ramsay.

Formation of Ground-ice.

In Canada we have made an extended study of the formation of ground-ice, or anchor-ice as it is called here, and consequently I was interested to see a letter in Nature of January 30 from Mr. Hampson asking for information as to its origin.

May I at the outset refer Mr. Hampson to four papers published many years ago which are wonderfully interesting to anyone studying the formation of ground-ice? Two of the papers appeared in the *Edinburgh New Philosophical Journal*, one by M. Arago, vol. xv., p. 123, 1833, and the other by the Rev. Mr. Eisdale, vol. xvii., p. 167, 1834. The two other papers were published in the *Phil. Trans.*, vol. cxxv., p. 329, 1835, and vol. cxxxi., p. 37, 1841, by the Rev. James Farquharson, of Alford.

In reply to the questions raised by Mr. Hampson, I may say that (1) the essential conditions for the formation of ground-ice on the bed of a river are clear weather conditions at night with the water at or near the freezing point, excessively low air temperatures by day, with no sunshine and no surface ice or other cover such as overhanging weeds or a bridge to check the nocturnal radiations. The answer to (2) is covered by the above. (3) A flowing river becomes stirred by eddy currents, and hence the cold surface layers find their way to the bottom. We notice many of our large rivers flow with a rolling motion. (4) The water is such a bad conductor of heat that it is only by the mechanical action that the bed of a river becomes cold enough to form ice on it when aided by radiation, or, as I have shown, by a slight supercooling in the water. (5) Ground-ice will form in water of any degree of agitation provided either or both of the causes mentioned in (4) are operating. In the case Mr. Hampson cites of the mill, I should say the heat generated by the water flowing through the mill would tend to prevent the formation of ice on the lower side.

In Canada we have anchor-ice formed in very large quantities in all the waterways flowing too swiftly for surface-ice to form. In some parts of the St. Lawrence it grows 5 feet or 6 feet in depth, forming very rapidly during the periods of intense cold and clear nights. On bright days the sun's radiant heat brings large quantities of it to the surface with much noise and disturbance. The buoyancy of large masses of the ice is often great enough to raise huge stones and boulders and carry them along in the current, depositing by this means portions of the river bed further down stream in the quieter waters. Boatmen are very careful not to cross the river when anchor-ice is rising, for fear of having a large mass come up under them and carry the boat helpless into the rapids. Under surface-ice, with its covering of opaque snow crystals, anchor-ice does not form, and hence it causes no trouble under these conditions.

Anchor-ice is known and studied in every country in the world where ice is formed, and there is much that might be written about it. In Nature of January 17, 1907, a careful review of my book on "Ice Formation," with special reference to anchor-ice and frazil, was given, and may help to answer some of the questions in the "long list" mentioned by Mr. Hampson. My paper read before Section G at the Leicester meeting of the British Association, and published with illustrations in *Engineering* for August, 1907, will convey some idea of the ice problem as presented to the users of "white coal" in Canada. In Russia, M. Wladimirop has published several important papers on his studies of the ice conditions on the Neva, in connection with the Waterworks Commission of St. Petersburg. One thing is well established, and that is that the formation of natural ice such as ground-ice, whether in Great Britain, Canada, Russia, France, Germany or elsewhere, conforms to the known laws of nature. Not a single known case of natural ice formation has ever come under my notice which has not its possible duplication in a laboratory experiment. The two differ only in the magnitude of their effects.

The Possibility of Life on Mars

MR. DINES's important letter on the "Isothermal Layer of the Atmosphere" has obviously an important bearing on the question of the gases that have been retained or lost by the atmosphere of Mars. If the temperature of our atmosphere ceases to decrease when a height averaging 35,000 feet is reached, and then remains practically constant at an average temperature of -47° C. whatever height be attained, we may expect somewhat similar conditions to prevail in the atmosphere of Mars, and naturally ask what are the temperatures which will allow of the escape of the different gases.

This question can be easily answered by a brief calculation from the data furnished on pp. 113 and 325 of Jeans's "Dynamical Theory of Gases" (1904). We find that at a temperature of -175° C. hydrogen will be "certainly retained," while at -65° C. it will be "certainly lost." The corresponding temperatures for helium will be -81° C. and 136° C., and for water vapour 599° C. and 1583° C. From these figures it results that if the temperature of the isothermal layer of Mars be the same as the temperature of that of our atmosphere, hydrogen will be lost, helium probably retained, and water vapour clearly retained. I should imagine that in the case of Mars the isothermal layer will be much colder, especially as the carbonic acid that is present in the atmosphere of that planet will be concentrated in the lower levels.

Neither Prof. Lowell nor Dr. Russel Wallace appear quite to have realised the importance of the influence of carbonic acid on the atmospheric temperature at the surface of the planet.

It is now a commonplace of geology that a variation in the small percentage of carbonic acid in the earth's atmosphere will have an important effect on the temperature of the latter, though authorities differ as to the numerical amount of the variation required to produce a given change of temperature under given conditions. If the atmosphere contains a relatively large amount of carbonic acid, a correspondingly greater proportion of the heat received will be retained, and the temperature will be higher. Such conditions will be marked by luxuriant vegetation, and at the same time rapid formation of carbonates by the action of water containing carbonic acid on silicates and other minerals. This will eventuate in a period when there is less carbonic acid in the air, and colder conditions will prevail. The growth of vegetation and the decomposition of minerals will be checked and confined to the warmer portions of the earth's surface. The supplies of carbonic acid from intratelluric sources will then gradually add to the amount of carbonic acid in the atmosphere, bringing an increase in temperature with it.[1] There are features in the geological record which lend support to the view that such a cycle of changes has occurred more than once in the earth's history.

If, now, we make the very reasonable assumption that the crust of Mars is composed of the same minerals as those with which we are familiar, and its atmosphere of the same gases as ours, and that accessions of carbonic acid are received from the interior of the planet, we may expect a similar automatic adjustment of the temperature so that it is never too cold for the chemical reactions of carbonic acid in solution to take place, and for vegetation, such as that believed to exist by Prof. Lowell, to maintain itself somewhere on the surface of the planet. The amount of carbonic acid required for the purpose will, of course, be greater than that in our atmosphere, but there is no reason to believe that it would reach an amount which would be injurious to the life of plants or animals, even if such were similar in nature to those on the earth.

Whether Prof. Lowell can be considered to have established his views is a question on which I do not feel called upon to express an opinion, but I confess that the arguments advanced against them do not strike me as convincing. They remind me of those of the engineers who satisfied themselves that a locomotive could not draw a train of trucks on smooth rails, and were not persuaded to the contrary until they saw that it did so.

Imperial Institute, February 28. J. W. EVANS.

[1] I have stated the theory in its simplest terms. There are other circumstances that affect the amount of carbonic acid in the air. Prof. Chamberlin believes that the sea plays an important part in absorbing or giving out the gas according to the conditions that prevail.

A Fundamental Contradiction between the Electrical Theory of Dispersion and the Phenomena of Spectrum-series.

THE electrical theory of dispersion is based on the hypotheses (1) that electric waves are due to motions of electric charges, and waves of light in particular to vibrations of charges inside the atom; and (2) that these vibrations are governed by linear equations. On this basis we obtain the usual dispersion formulæ, *e.g.* that of Drude:—

$$n^2 - 1 = \sum \frac{N_h e^2_h}{\pi m_h} \frac{\lambda^2_h}{1 - \lambda^2_h/\lambda^2},$$

where n is the refractive index for wave-length λ, λ_h one of the free periods of a set of electrons in the atom, e_h the charge, m_h the mass, and N_h the number per c.c. of the electrons of the set, while the summation is for all possible free periods of the atom. In particular, if λ be greater than every one of the free wave-lengths of the atom, we get

$$n^2 - 1 > \sum \frac{N_h e^2_h \lambda^2_h}{\pi m_h}.$$

Consider the contribution of all the lines of the well-known Balmer series to the dispersion of hydrogen; for this series

$$\lambda_h = \lambda_\infty \frac{m^2}{m^2 - 4}, \; m = 3, 4, \ldots \infty,$$

where

$$\lambda_\infty = 3646{\cdot}13 \text{ A.U.}$$

Its contribution exceeds

$$\sum_{m=3}^{m=\infty} \frac{N_h e^2_h \lambda^2_\infty}{\pi m_h} \frac{m^4}{(m^2-4)^2}.$$

If the theory is to account for the lines of the series at all, the factor $N_h e^2_h \lambda^2_\infty/\pi m_h$ cannot vanish for any line; let A be its least value. Then the contribution exceeds

$$A \sum_{m=3}^{m=\infty} \frac{m^4}{(m^2-4)^2}.$$

The sum is obviously infinite; but all experience shows that for long waves the refractive index of hydrogen is nearly unity, and finite even for *luminous* hydrogen.

The same result follows for any series formula which implies that a series has (1) a tail; (2) an infinite number of lines the wave-length of which exceeds that of the tail, that is, for all known formulæ which agree with measurements either of line or of band series.

Thus we must either reject the usual notion of a series, and with it all the formulæ which represent our experience best, or we must reject the hypothesis that series lines are due to small vibrations of electric charges governed by linear equations, and with it the usual theories of dispersion and absorption, of the Zeeman effect and of magnetic rotation for series lines. G. A. SCHOTT.

Physical Institute, Bonn, February 17.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

VI. DOLMENS.

In some previous notes I have given an account of some measurements of the so-called "cromlechs" of Cornwall. In referring to this subject in a more general manner, it will be well, I think, *pour préciser les idées,* to refer to the word itself. In English works on archæology it is used as a variant for dolmens, chambered barrows, chambered cairns, and kistvaens, while in France it is applied to the more or less irregular circles and groups of stones associated with avenues; and there the equivalents of the Cornish "cromlechs," which exist in great numbers, are invariably called dolmens.

FIG. 18.—Devil's Den, Avebury, looking towards November sunrise.

It is convenient, therefore, to use the word dolmen when such structures are considered separately from the circles.

With regard to the examples available for measurement in Cornwall, the important, and indeed striking, conclusion was arrived at that almost all those given by Lukis were erected so that the sunrises at the May-year or solstitial festivals could be plies to other localities, and referred to other similar structures in S. Wales which gave the same results.

I now propose to go further afield, with the view of inquiring whether this law applies to other localities, and I will begin with one I have myself measured, the Devil's Den at Avebury.

The conditions at Avebury are as follows:—Lat. N. 51° 25′. Magnetic variation, 16° 40′ W., 1906.

Theoretical value of May-year azimuths.

	May True	May Magnetic	November True	November Magnetic
$1\frac{1}{2}$° hill: refraction and semi-diameter	N. 64 26	... 81 6	... S. 61 50	... 134 50

My wife and I visited the Devil's Den, in company with Mr. R. H. Caird, in July, 1906, and again in August, 1907. The compass bearing was N. 134° E. looking eastward through the aperture formed by the three stones, and the height of the horizon in this direction was 1° 25′, thus agreeing with the value of the November sunrise given in the table.

Here then, as in Cornwall, the November and February sunrises, when the sun has a S. declination of 16° 20′, are in question.

It is well known that two of the most famous long barrows in England with their included dolmens are close to Avebury; one of them, the "West Kennet Long Barrow," is described in Smith's "British and Roman Antiquities of N. Wiltshire," p. 154. I condense his reference:—

"The 'West Kennet Long Barrow,' indeed, is one of the most notorious, as well as one of the largest of the Long barrows in the kingdom; and although it is much cut about, with a waggon-track passing over the centre of it, a confusion of large sarsens tumbled together at the east end, and several big trees occupying its sides,

FIG. 19.—Devil's Den, looking towards May sunset.

it is still of imposing appearance. Let us first see what our old Wiltshire antiquaries thought of it, and then what it proved to be, when opened by Dr. Thurnam. Aubrey gives but a brief and very inaccurate description: 'On the brow of the hill, south

[1] Continued from p. 371.

from West Kynnet, is this monument, but without any name: It is about four perches long, but at the end only rude grey-wether stones tumbled together. The barrow is about half a yard high.'" [1]

Stukeley says of it [2]: "The other Long barrows are much exceeded by South Long Barrow, near Silbury Hill, south of it, and upon the bank of the Kennet. It stands east and west, *pointing to the dragon's head on Overton Hill.* A very operose congeries of huge stones upon the east end and upon part of its back or ridge, pil'd one upon another, with no little labour. . . . The whole tumulus is an excessively large mound of earth 180 cubits long, ridg'd up like a house."

Sir R. Hoare's account of it [3] is as follows:—"There are several stupendous Long barrows in the neighbourhood of Abury: one of the most remarkable has been recorded by Stukeley as situated south of Silbury Hill. It extended in length 344 feet: it rises, as usual, towards the east end, where several stones appear above ground: and here, if uncovered, we should probably find the interment, and perhaps a subterraneous kistvaen."

Dean Merewether states [4]:—"At the east end were lying, in a dislodged condition, at least thirty sarsen stones, in which might clearly be traced the chamber formed by the side uprights and large transom stones, and the similar but lower and smaller passage leading to it: and below, round the base of the east end, were to be seen the portion of the circle or semi-circle of stones bounding it."

I have given this somewhat long account because it shows that all information relating to orientation is omitted from it; it is generally, indeed, neglected by modern archæologists. Even Stukeley himself, though he was thoroughly acquainted with magnetic variation and at times used a theodolite, is caught napping in the case of this barrow. Fortunately, however, the apparently useless statement that the barrow points to the dragon's head on Overton Hill helps us, as this was a circle the site of which is known, though the stones have disappeared. This bearing (true) is N. 64° E. as determined from the 6-inch Ordnance map.

Here again, then, we deal with the May year and the May and August sunrises, still another argument in favour of Avebury and its region being connected with the May year.

I may next refer to some cromlechs near Dublin (lat. 53° 20′ N.), which were described by Prof. J. P. O'Reilly.[5] I give the results of his stated amplitudes in tabular form:—

Cromlech	Value given	Azimuth	Hill	Declination
Glen Druid...	E. 24 30 N. ...	N. 65 30 E. ...	½ (assumed)	... 14 20 N.
Howth...	... E. 27 0 N. ...	N. 63 0 E. ...	½ (assumed)	... 15 44 N.
Mount Venus	E. 23 28 N. ...	N. 66 32 E. ...	0	... 13 5 N.
Shankill ...	,, ...	,, ...	,, ...	,,
Larch Hill ...	,, ...	,, ...	,, ...	,,

It will be seen that here again we are in all probability dealing with the May and August sunrises, when the sun has a declination of 16° 20′ N.

It is to be regretted that in Borlase's fine book on the dolmens of Ireland, the lack of all accurate statement touching the lie of the monuments renders its thousand pages and hundreds of illustrations quite useless for my purposes.

[1] From MS. in the Bodleian Library at Oxford, quoted in "Archæologia," vol xxxviii., p 407.
[2] "Abury Described," p. 46.
[3] "Ancient Wilts, North," p. 96.
[4] Proceedings of Archæological Institute, Salisbury volume, pp. 97, 98.
[5] Proc. R.I A., iv., pp. 589–605 (1896–8).

After what I have suggested as to the probable use of dolmens, namely, that they were useful among other things as look-out places, it is not to be expected that only the rise of the sun would be found provided for. They should follow the precedent of the avenues, and be presented to star as well as to sun rise.

In two instances known to me the information is complete enough to enable a stellar use to be traced.

The first is at the Hurlers. Full details have been already given in my "Stonehenge."

The second is at Callernish (Turnsachan, lat. 58° 12′ N.). A good description of the stone monuments there, which include a circle, avenue and cromlech, is given in Anderson's "Scotland in Pagan Times" ("The Bronze and Stone Ages," p. 119).

They were, fortunately, also carefully surveyed by Sir Henry James.

We learn from Anderson that:—

"In 1858, Sir James Matheson caused the peat which had grown on the site of this monument to be removed. The average depth of the peat from the surface to a rough causewayed basement in which the stones were imbedded was 5 feet. In the process of the removal of this accumulation, the workmen uncovered the remains of a circular cairn, occupying the space between the centre stone and the east side of the circle. In the centre of the cairn was a chamber with regularly built internal walls, and a passage leading from it to the outside of the cairn, the opening being placed between two of the stones of the circle. The chamber was divided into two compartments by slabs placed across the floor, leaving an opening between their edges a little less than 2 feet wide. Beyond these slabs the inner compartment was formed of dry-walling in the sides, and a long slab set on edge at the back. The passage was about 6 feet in length, and 2 feet wide, entering the chamber between two slabs set on end facing the two on each side of the entrance to the inner compartment. The first compartment was 6 feet 9 inches from side to side, and 4 feet 3 inches from front to back, the second, 4 feet 4 inches from side to side, and 2 feet 1 inch from front to back on the floor, widening upwards in consequence of a slight inclination of the slab at the back. With the exception of a single stone, which was supposed to have been a lintel, there was no appearance of a roof, and there is nothing on the record of the excavation to show whether the roof of the chamber had fallen in, or whether it had been removed. It is not even stated what was the height to which the side-walls were found standing. But it is obvious at a glance that here we have a very peculiar construction,—a cairn containing a chamber divided into compartments, and furnished with a passage opening to the outside of the cairn."

From Sir H. James's plan we get the data necessary for orientation purposes. They are as follows for the sight-line from the chamber:—

Az	Horizon (1″ map)	Decl.	Star	Date
N. 74 30 E. ...	1 18 ..	8 54 N. ...	Pleiades ...	1330 B.C.

In 1330 B.C. and lat. 58° 15′ N. the Pleiades warned the May sun by about 1¼ hours; in 1901 B.C. the warning was of about 1 hour duration. Thus, taking into account the high latitude, with the consequently extended dawn, the Pleiades warning was more effective in 1300 B.C. than it would have been at the earlier epoch, at which, as I have previously shown, the stones of the long avenue were probably erected.

Prof. Morrow has recently sent me measures of the side walls of the curious structure on the N.E.

side of the circle of Keswick. These are doubtless to be considered in relation to the direction of the chambered cairn at Callernish. The rising of the Pleiades seems to have been in question.

Still another stellar dolmen I measured in S. Wales has already been referred to.

NORMAN LOCKYER.

EXPERIMENTS ON SCREW PROPELLERS.[1]

THE screw-propeller was practically applied to steamships by John Ericsson and Francis Petit Smith about seventy years ago. It speedily became a formidable rival to the paddle-wheel. Long ago it entirely superseded the latter for ocean navigation, and in more recent years it has to a large extent taken the place of the paddle, even in river steamers of the shallowest draught. Accumulated experience over this long period has proved of great advantage, and has enabled naval architects and marine engineers to meet new conditions in ships of much larger dimensions and higher speed; but notwithstanding this wealth of experience—largely based upon "progressive trials" of steamships and the analysis of the results—it is still true that we are on the threshold of exact knowledge in regard to the principles underlying the efficiency of screw-propellers.

Even in recent years, when the limits of experience have had to be surpassed, there have been many proofs of imperfect knowledge. On the whole, it is true that success has been achieved, but not infrequently as the result of numerous and sometimes costly experiments on propellers of different forms. Perhaps the most striking example of this general truth is to be found in the case of torpedo vessels and motor boats, driven at extraordinarily high speeds in proportion to their dimensions; it is also true that, in vessels of large size and of less speed in proportion to their dimensions, remarkable results have been obtained by a simple change of propellers. For instance, the *Drake* class of cruiser in the Royal Navy, which are the fastest cruisers afloat, had a guaranteed speed of twenty-three knots on an eight hours' trial. The guarantee was slightly exceeded in the first trials, but there was evidence that the propellers became relatively inefficient as the highest speeds were approached, and that the blade-area was insufficient. New propeller blades were made with greater blade area, and with these the ship was driven at a speed exceeding twenty-four knots, representing a gain of about 25 per cent. in efficiency. Obviously, incidents of this nature point to the possibility of very large economies if our knowledge of screw-propeller action and efficiency could be made more definite as well as more extensive. Trials in actual ships, especially those of large size, are necessarily costly, and are often impossible to make because the vessels are required on service. Hence, at a very early date, attempts were made to introduce a system of experiments with model screw-propellers, and from these useful information was obtained. It was left for the late Mr. William Froude to perfect the method of experiment in connection with his well-known system of "tank" experiments on models of varying ship forms; and his son, Mr. R. E. Froude, superintendent of the Admiralty experimental tank at Haslar, has carried on and developed the investigation so far as the pressure of other and more urgent experiments connected with the construction of ships for the Royal Navy has permitted.

The model propellers used by Prof. Durand were forty-nine in number, of 12 inches diameter, with bosses of uniform diameter (2·4 inches); all the models had four blades, and all the blades were elliptical in shape. Blade-areas and pitch-ratios were varied over wide limits, going beyond the range of variation occurring in actual practice. For example, the pitch-ratios tried extended up to 2·1 from 0·9 by differences of 0·2, and the blade-areas were carried down to unusually small proportions of the disc area. Great care was taken to shape the model screws truly and to measure the pitch accurately. For each propeller there was a determination of the power absorbed and the thrust developed for a given number of revolutions per minute, and a corresponding record of the speed of advance in undisturbed water. Practically uniform motion was ensured, and accurate measurements were made of time, distance and force. From these experimental data the actual and comparative efficiencies of the model-screws were ascertained, and the percentages of "slip" could be estimated. The facts are tabulated and graphically illustrated in the memoir. They require and deserve detailed study. In this brief notice it is not possible even to mention the most striking features. Prof. Durand briefly summarises his conclusions in regard to the character of the efficiency-curves of the different model screws, and supplements this section by a description of the method he recommends for applying experimental results to propeller design for actual ships.

One cannot peruse this memoir without regretting that, as yet, no British university, or public institution primarily devoted to scientific work, possesses an experimental tank such as is attached to Cornell University, the University of Michigan, and to the Technical High School at Charlottenburg. Its value for purposes of instruction is great; but its importance as a means of research can hardly be overestimated. When tanks are closely associated with the detail-work incidental to the design of actual ships, the opportunities for research are less, and the interruptions of research-work more numerous and serious when undertaken in the intervals of ordinary employment. In other words, research has to give way to urgent demands connected with ship-designs, and the special apparatus required for research has to be removed or dismantled at short intervals. This has been the experience at the Admiralty tank, and at the two tanks attached to the shipbuilding yards at Dumbarton and Clydebank. A great need exists, therefore, in this the greatest shipbuilding and ship-owning country in the world, for an experimental tank in which research work on ship-forms and propellers can be undertaken systematically and uninterruptedly. This need has been recognised for a long time. The Institution of Naval Architects has made efforts to interest ship-owners and ship-builders in the establishment of such a tank at the National Physical Laboratory. Considerable support has been obtained from ship-builders and from a few ship-owners, but hitherto it has not been possible to secure the whole amount needed for the construction and equipment of the tank, estimated at 15,000*l.*, or for its maintenance, estimated at 1500*l.* a year. This failure is greatly to be regretted, and is not creditable to the community interested in shipping. It is certain that the investigations made at such an establishment would secure large economies and enable great advances to be made in the construction and propulsion of ships. In connection with screw-propellers alone there is a great opportunity for economies in coal-consumption, the benefits of which would be secured by ship-owners, and the amount of which in a single year's operations of our immense mercantile marine would far exceed the cost of the research-tank. Seeing that the United States and Germany already have a

[1] "Researches on the Performance of the Screw Propeller." By Prof. W. F. Durand. Pp. 61. (Washington: Carnegie Institution, 1907.)

distinct lead in this matter, it may be hoped that the scheme, which has been long delayed, will be realised before long, and the reproach wiped away that the country which equals all the rest of the world in its shipping and shipbuilding lags behind other countries in utilising the experimental methods due to that great English man of science William Froude.

Until recent years work done by the Froudes and published by permission of the Admiralty furnished the best information available for guidance in propeller design, especially when associated with progressive trials of steamships. The experimental methods introduced at Torquay and Haslar have been adopted and extended of late by other workers having command of specially equipped hydraulic laboratories or tanks. Amongst these the Washington tank, belonging to the United States Navy Department, has taken a leading position under the able superintendence of Naval Constructor Taylor, who received his training as a naval architect at the Royal Naval College, Greenwich. In addition to this establishment, the United States has the great advantage of possessing experimental tanks attached to universities; these tanks are necessarily more available for research-work than any establishment can be which is created primarily and regularly employed for experimental work bearing directly on actual ship-construction. Prof. Durand whose investigations on screw-propellers specially claim attention in this notice—for ten years past has closely studied the screw-propeller problem. His later experiments have been made at the hydraulic laboratory of Cornell University; they are systematic and thorough within the limits of the scheme laid down. The method and results have been admirably described and summarised in a memoir of about sixty pages. The Carnegie Institution of Washington made a grant in aid of the experiments, and has published the memoir, thereby conferring great benefit on all who are concerned in the propulsion of steamships, and furnishing a fresh illustration of the encouragement given to scientific research in the United States.

NOTES.

THE following fifteen candidates have been selected by the council of the Royal Society to be recommended for election as fellows of the society:—Mr. W. Barlow, the Earl of Berkeley, Mr. Dugald Clerk, Prof. A. Dendy, Prof. H. H. Dixon, Mr. J. Stanley Gardiner, Prof. W. Gowland, Mr. J. H. Grace, Prof. D. J. Hamilton, Mr. C. I. Forsyth Major, Mr. E. N. Nevill, Mr. W. H. Rivers, the Hon. Bertrand Russell, Dr. Otto Stapf, and Dr. J. F. Thorpe.

A SPECIAL general meeting of the Geological Society will be held on April 1 to consider a resolution relating to the admission of women to full fellowship of the society.

IT is reported by The Hague correspondent of the *Globe* (March 3) that Prof. Kamerlingh Onnes, professor of physics in the University of Leyden, has succeeded in liquefying helium.

SIR OLIVER LODGE will deliver his presidential address to the Faraday Society on Tuesday, March 24. The subject of the address will be "Some Aspects of the Work of Lord Kelvin."

THE Paris correspondent of the *Times* reports that Prince Roland Bonaparte has placed at the disposal of the Academy of Sciences a sum of 100,000 francs (4000*l.*) to be employed in promoting discoveries by facilitating the task of investigators who have already given proof of their ability by original work, but who may lack the resources necessary for undertaking or pursuing their investigations.

PROF. J. R. BRADFORD, F.R.S., Sir T. H. Holdich, K.C.M.G., and the Duke of Northumberland, F.R.S., have been elected members of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

DR. ARTHUR KEITH, lecturer on anatomy at the London Hospital Medical College, has been appointed conservator of the museum of the Royal College of Surgeons, in succession to the late Prof. C. Stewart.

PROF. MILNE'S discourse at the Royal Institution on "Recent Earthquakes," announced for Friday next, March 6, has been postponed until March 20. The discourse on Friday next will be delivered by Prof. Love on "The Figure and Constitution of the Earth."

IN a footnote to Cowper's poem (Magnet edition, 1834), a remarkable meteor, August 18, 1783, and a fog which covered Europe and Asia during the summer of 1783 are mentioned, as well as an earthquake in Sicily of unusual severity. A correspondent asks for details of these occurrences, or a reference to records of them.

THE following officers of the Asiatic Society of Bengal have been elected for the ensuing year:—*President*, the Hon. Justice Asutosh Mukhopadhyaya; *vice-presidents*, Dr. T. H. Holland, F.R.S., Dr. G. Thibaut, Mahamahopadhyaya Haraprasad Shastri; *general secretary*, Lieut.-Colonel D. C. Phillott; *treasurer*, Mr. J. A. Chapman.

WE learn from the *Times* that the Russian Government is dispatching a research commission to investigate some recent discoveries of mammoth remains in the Yakutsk province of north-east Siberia. The commission consists of a doctor of zoology, of the Academy of Sciences, the senior curator of the zoological department of the academy, and six junior laboratory students. The expedition, which is expected to be absent for a year or more, is supplied with a grant of 10,000 roubles (1600*l.*).

THE report of the committee appointed by the Treasury to inquire generally into the work now performed at the National Physical Laboratory has been published as a Parliamentary paper (Cd. 3926), which also includes a Treasury minute recording the approval by the Treasury of the recommendations contained in the report of the majority of the committee. The opinion of the 1898 committee, that the work proper for a National Physical Laboratory to undertake should include not only physical research directly or indirectly bearing on industrial problems, and the standardisation and verification of instruments, but also—under proper restrictions—the testing of materials, is in the first place endorsed. The committee then distinguishes "commercial testing" into "contractual" and "investigatory" testing—"contractual" testing being the ordinary testing of materials to ascertain whether their quality and behaviour are in accordance with the requirements of contracts; "investigatory" testing the investigation for commercial purposes of various substances in which no question of contract arises. To place restrictions upon "investigatory" testing would, it is pointed out, hinder the advance of knowledge. The committee thinks that the laboratory should remain entirely free with regard to "investigatory testing," and, as a rule, be debarred from undertaking "contractual testing"—though electrical, thermal, optical, and other physical tests are to be regarded as exceptional, and such as the laboratory may undertake. In the second place, no restriction should apply, the committee reports, to "reference" testing wherever, in cases of dispute, the parties concerned agree to refer their differences to the authoritative decision of the laboratory, or where the laboratory is called in by a Court of law or of arbitration. Lastly, in view of the character of the laboratory as a public institution, the laboratory is to be free to accept any work which any Government department may desire to commit to it. Subject to these observations, the committee does not consider that any alteration is required in the scope of the work of the National Physical Laboratory as defined by the committee of 1898. In a note added to the report Sir Andrew Noble and Sir J. Wolfe-Barry express the opinion that the restriction recommended in respect of "contractual testing" should come to an end after a definite time—say ten years.

IN the report of the Maidstone Museum, Library, and Art Gallery for 1907, attention is directed to the unprecedentedly large number of visitors during the year. It is satisfactory to notice that special attention is being concentrated on the local collection in the Kent county room, for which a special subscription list has been opened.

WE have received from Messrs. Cassell and Co., Ltd., the first part of a revised and enlarged edition of Mr. R. Kearton's "British Birds' Nests." It is to be completed in sixteen fortnightly parts at the price of one shilling each. When the beauty and number of the illustrations—inclusive of coloured plates of eggs—are taken into consideration, the new issue is a marvel of cheapness, and should command a large sale.

IT is announced in the January issue of the *Emu* that active steps are being taken by the Australian Ornithologists' Union to make more effective the laws for the protection of egrets and birds-of-paradise, groups which are specially persecuted for the sake of their plumage. The union is likewise encouraging lighthouse keepers to record observations with regard to the birds that strike against the lighthouses on the Australasian coasts on migration.

ACCORDING to Mr. T. Southwell's notes in the February *Zoologist*, the Arctic whaling voyage of last year, so far as the prime object of pursuit is concerned, was a disastrous failure. The seven vessels which left Dundee captured, in fact, only three right-whales among them, one being little more than a "sucker," which yielded only half a hundredweight of whalebone. This juvenile was taken in Davis Strait, while the two larger whales were captured in Greenland waters. The two latter yielded 32 cwt. of "bone," the price of which is now about 2400*l*. per ton. It is noteworthy that during the last two seasons most of the few whales taken were from Greenland waters, where the species was supposed to be practically exterminated.

THE biting flies of India form the subject of Bulletin No. 7 of the Agricultural Research Institute at Pusa. The account, which is drawn up by Mr. H. M. Lefroy, the Government entomologist, is intended to pave the way for a full investigation into the natural history of these insects, and has been published to a great extent with the view of stimulating the collection of specimens all over the country. If such collection be carried out systematically, there is little doubt that a number of new species will be brought to light, especially among groups like the sand-flies, represented by species of minute size. The Bulletin contains two coloured plates of horse-flies and cattle-flies, with, in some instances, their larvæ and eggs as an aid to the identification of species.

WE have received copies of four papers recently issued by the Entomological Bureau of the U.S. Department of Agriculture. The first of these, by Dr. W. E. Hinds, is devoted to further investigations with regard to the capability of natural agencies for holding in check the ravages of the pernicious cotton-boll weevil. On the whole, a hopeful view of the matter is entertained. The factors in question are conditions of temperature and moisture, predaceous and parasitic foes, and food-supply. While it may be impossible to increase the effectiveness of these agencies, there is reason to believe that others may be caused to lessen materially the weevil's power of mischief. A second paper treats of the ravages of the caterpillars of the catalpa hawk-moth (*Ceratomia catalpae*) on catalpa trees, which are sometimes completely stripped of their foliage. The two remaining papers deal respectively with the lesser apple-worm and wax-moths in connection with bee-keeping. In the case of the latter it is shown that the idea that the larvæ of wax-moths are beneficial to bee-keepers is erroneous.

A REPORT on marking and transplantation experiments with plaice in Danish waters, by Mr. A. C. Johansen, has recently been issued by the Danish Commission for the Study of the Sea (*Medd. Kommiss. for Havundersøgelser. Ser. Fiskeri*, Bd. ii., No. 5). The report contains an account of experiments made by the Danish Government in connection with the international fishery investigations. It is shown that the rate of growth of plaice varies in different districts, a result which confirms the conclusions which have been arrived at by English fishery investigators. Considerable light is also thrown by the experiments on the migration of plaice in Danish waters. Much importance is attached by Johansen to the facts that in the experiments in the Horns Reef area the value of the recovered specimens surpasses the value of all the liberated ones, and that in the Kattegat experiments the size at which the value of all the recovered specimens is equal to the value of all the liberated ones is higher than the present Danish size limit for Kattegat plaice (*ca.* 25·6 cm.) From the latter result it is suggested that a size limit for plaice in the Kattegat somewhat higher than that now enforced by Denmark might be considered by the international authorities with advantage.

MR. S. YAMANOUCHI contributes to the *Botanical Gazette* (January) an account of sporogenesis in the fern genus Nephrodium, dealing with nuclear changes in *Nephrodium molle*. The author comes to the conclusion that in the normal life-history of the genus there is a reduction of chromosomes in sporogenesis, and that the first nucleus which contains the reduced number of sixty-four or sixty-six chromosomes is the spore; further, that the first division of the spore is heterotypic, but the reduction is only completed in the second homotypic division.

THE economic value of the sunflower plant as a source of oil yielded by the seeds not infrequently forms the subject of inquiry. From the account of the plant that is provided by Mr. D. Hooper in the *Agricultural Ledger* (No. 1, 1907), issued by the Government of India, it is evident that as a crop it offers little inducement to planters except in southern Russia—possibly also in China—where there is a local consumption of the kernels roasted or salted, and the oil is in request for culinary or edible purposes. The pamphlet contains information with regard to experimental cultivation in India and the United States of America.

An article communicated by the chief conservator of forests in Burma, Mr. F. B. Bryant, is published in the *Indian Forester* (December, 1907), in which a strong case is made out against continued fire conservancy in certain of the moist teak forests. The policy of fire conservancy continued over a period of years has resulted in excessive development of the bamboos *Bambusa polymorpha* and *Cephalostachyum pergracile*, which smother the young teak and other light-demanding trees. It is also pointed out that, owing to the presence of the latter bamboo, extensive regeneration of teak when the Bambusa flowers gregariously is likely to be frustrated. The sanction of the Government of Burma to the abandonment of fire conservancy in selected areas has already been granted.

An important article on the Douglas fir as a commercial timber tree is contributed to the Transactions of the Royal Scottish Arboricultural Society (vol. xx., part i.) by Mr. J. D. Crozier. Owing to the difference in the rate of growth, it is essential to distinguish between the "green" Oregon variety and the slower growing "glaucous" Colorado variety. The author alludes to the excellent results shown by pure plantations on the Grampians, but expresses the opinion that the Douglas fir is not adapted to mixed plantations unless with the Norway spruce. As a suitable crop for poor and exposed ground, Sir John Stirling-Maxwell recommends the mountain pine, *Pinus montana*. Three varieties are specified, the upright, the intermediate, and the dwarf forms. The first is the more valuable, and grows at high elevations, notably in the Pyrenees. The intermediate is principally useful for afforestation of heaths; the dwarf form has no sylvicultural interest.

The Director-General of Indian Observatories has issued a memorandum (dated December 6, 1907) on the meteorology of October and November, 1907, with a discussion of the conditions affecting the precipitation during the cold weather of 1907–8. These seasonal forecasts, although at present only general opinions based on past experience, are of very great importance both to the Government and to agriculturists. On the mean of the whole country, the rainfall in October was 52 per cent. and in November 31 per cent. in defect. The records of the last thirty years, including some selected from places outside India, show that conditions like those of the past season have been followed by a deficiency of precipitation in January more often than by an excess. The data then available for February throw very little light upon the probable rainfall of that month.

A touch of wintry weather has spread over the whole country during the past week, and somewhat heavy falls of snow have occurred over a large part of Great Britain, whilst the temperature has been lower than for some time past. Strong winds and gales have been experienced in many places, and since March set in our weather has been under the influence of cyclonic disturbances passing down the North Sea. The Summary of the Weather issued by the Meteorological Office shows that for the winter season December to February—the mean temperature over the United Kingdom was nowhere very different from the average. The heaviest rainfall for the three months occurred in the north of Scotland, where the aggregate measurement was 17·19 inches, whilst the least aggregate fall was 5·21 inches, in the north-east of England. The winter rainfall was generally in excess of the average over the northern portion of the kingdom, but in defect elsewhere. The greatest excess was 1·61 inches, in the north-west of England, whilst the greatest deficiency was 2·65 inches, at the English Channel stations. The number of days with rain ranged from seventy-one in the north of Scotland to forty-seven in the south of England and the Midland counties. The greatest duration of sunshine for the winter was 203 hours, in the Midland counties, which is twenty-nine hours more than the average. The least duration was ninety-five hours, in the north of Scotland.

At the instance of Prof. Ricchieri, of the Accademia Scientifico-Letteraria, Milan, the reader of a paper on the spelling of place names at the sixth International Geographical Congress, held at London in 1895, the organising committee of the ninth International Geographical Congress, which is to meet at Geneva on July 27 to August 6, has placed on the list of agenda of the congress the following question:—What are the principal difficulties in the way of arriving at an international agreement on the transcription and orthography of geographical names, and in what manner can they be surmounted? Prof. Ricchieri, believing that if this problem is to be solved at all it can only be by slow stages and methodical procedure, proposes that all that should be aimed at in the first instance should be a preliminary understanding among a few men of different nationalities interested in this question as to the fundamental points on which it is necessary that a final agreement should, if possible, be reached, and that a statement of those points should be laid before the congress at Geneva, which should then be asked to appoint a small committee to study and procure the discussion of those points, and ultimately to draw up proposals and resolutions thereon. He further suggests that this committee should be expected to publish its proposals at least one year before the meeting of the next International Congress, which, it is hoped, might then be in a position to draw up final resolutions on the subject. This scheme of operations has received the support of Prof. Henri Cordier, of the École spéciale des langues orientales, Paris; Prof. Robert Sieger, of the University of Graz; and of Mr. G. G. Chisholm, Birkbeck College, University of London, who have agreed to cooperate with Prof. Ricchieri in drawing up the preliminary statement of fundamental points requiring solution to be laid before the Geneva congress. Mr. Chisholm will be glad to forward to Prof. Ricchieri any suggestions on this question sent to him at his private address (59 Drakefield Road, Upper Tooting, London, S.W.).

The curious phenomenon of a soft steel disc revolving at a high speed cutting hard steel has attracted the attention of numerous observers, and Mr. F. W. Harbord has endeavoured to throw light on the subject by publishing in the *Engineer* of February 21 the results of a microscopic examination of the revolving disc and of the material subjected to its action. He finds that the material acted upon is heated at the point of contact to a temperature approaching, if not equal to, the melting point of steel, and that this high temperature is confined practically to the surface in contact with the disc.

In the *Engineering Magazine* (vol. xxxiv., No. 5) attention is directed by Mr. Clarence Hall and Mr. W. O. Snelling to the waste of life in American coal-mining. Four recent mine disasters in the United States, with the loss of nearly one thousand lives, emphasise the urgent importance of the theme. Statistics show in regard to deaths per million tons of coal that the United States not only occupies a position worse than that of European countries, but also exhibits a general increase in the rate, whereas every other country has shown a decrease. The situation is still worse when it is considered that the natural conditions in America for raising coal with the minimum amount of danger to the workmen employed are as favourable as in any other country in the world. The natural result of the working of the thinner and less favourably mined seams will be greatly to increase the death-rate unless regulations based on careful investigations are rigidly enforced.

Egypt furnishes a region of great scientific interest which is as yet almost unexplored in many branches of knowledge, and it often happens that observations which seem commonplace to those resident in the country are of great value to workers elsewhere. The success which attended the periodical *Survey Notes* during the fifteen months it has been in existence has suggested that its scope might be extended with advantage, and with that object it has been decided to include communications on all branches of science. The magazine, which will in future be entitled the *Cairo Scientific Journal*, makes, in its January issue, a good start. The principal contents are papers on an expedition to Addis Abbaba, by Mr. J. I. Craig; on the underground waters of Egypt, by Mr. H. W. Beckett; on the use of the slide-rule in surveying, by Dr. J. Ball; on azimuth checks on traverse work, by Mr. M. Villiers Stuart; on upper air research at Helwan, by Mr. B. F. E. Keeling; and on temperature and constructional stability, by Mr. J. I. Craig.

On February 18 Mr. J. J. Prest read before the Institution of Civil Engineers a paper describing a remarkable achievement in mining engineering, the shaft sinking at the Horden colliery, south-east Durham. The work was of exceptional difficulty owing to the large volumes of water encountered in sinking through the magnesian limestone and sands of Permian age. In view of possible legislative interference with the hours of underground labour, it was decided to sink three shafts, two 20 feet and one 17 feet in finished diameter. The north shaft was begun on November 6, 1900, and was finished at a depth of 419 yards on July 23, 1904. The south shaft was begun on February 28, 1901, and was finished at a depth of 302 yards on September 1, 1905. The east shaft, 17 feet in diameter, was begun on September 3, 1900, and was finished at a depth of 406 yards on November 6, 1905. The maximum feeders of water pumped simultaneously at any one period amounted to 9230 gallons per minute, from the east and south shafts, from September 23 to November 26, 1903. The production of coal from this colliery is now averaging a million tons per annum.

The annual report of the council of the Institution of Mechanical Engineers, presented at the annual meeting of members on February 21, summarises the progress and work of the institution during the past year. The council has accepted from Mr. Charles Hawksley an offer of 1000*l.* for the foundation of a scholarship or premium in connection with the institution, to commemorate the centenary of the birth of his father, Mr. Thomas Hawksley, past-president. In connection with the alloys research committee it is noted that sea-water corrosion tests on copper-aluminium alloys are being carried out at Portsmouth Dockyard by the National Physical Laboratory. A systematic investigation of the ternary alloys of copper and aluminium with other metals, in the first place with manganese, zinc, and nickel, has been begun, and the preliminary investigation of the copper-aluminium manganese alloys is approaching completion. The council has made a small grant to Dr. H. C. H. Carpenter to investigate at the Manchester University the conditions which have to be observed if metal castings are to be capable of being gas-tight and steam-tight. Some further experiments on the large gas engine at the University of Birmingham are to be carried out by Prof. F. W. Burstall with a water-brake and with both optical and string indicators. The research committee on the value of the steam-jacket has met twice during the year, and designs are being prepared by Prof. T. Hudson Beare for carrying out jacket experiments with a larger apparatus than that formerly used by the committee. Information on the present state of knowledge on the following subjects is also being collected, previous to the appointment of research committees for prosecuting further inquiries:—(1) the features of refrigerating machinery in which further investigation is needed; (2) the transfer of heat across metallic surfaces in contact with water and with gases; (3) the action of steam passing through nozzles and steam turbines.

The *Physikalische Zeitschrift* for February 15 contains an account of Dr. H. W. Schmidt's experiments on the effect of high temperatures on the disintegration of radium C. The work was undertaken to decide between the conclusion of Messrs. Makower and Russ, that high temperature diminished temporarily the activity of radium, and that of Mr. Bronson, who denied the existence of such an effect. Dr. Schmidt's experiments were made on radium C prepared by von Lerch's method. The preparation was enclosed in a quartz tube which could be heated to 1300° C. in an electric furnace. The activity was measured by the fall of the leaves of a gold-leaf electroscope placed close to the furnace. The author concludes that at 1300° C. the preparation behaves exactly as at ordinary temperatures.

The theory of the radiation of the Auer incandescent gas mantle is discussed by M. M. Foix in the February number of the *Journal de Physique*. It is generally admitted that the mantle owes its brilliance to its selective radiation, which appears, according to the researches of Prof. Rubens, to be brought about by the addition of a little oxide of cerium to oxide of thorium. M. Foix now comes to the conclusion that the luminous efficiency of the mantle can be increased by carrying the dilution of the oxide of cerium in the oxide of thorium a further stage, the result being brought about by the diminution of the infra-red radiation of the mantle and a consequent increase of its temperature. The best proportion of the oxides appears to be 1 of cerium to 100 of thorium.

The attention of those of our readers who practise photography is directed to the catalogue of photographic dry plates, filters, and safelight screens recently issued by Messrs. Wratten and Wainwright, Ltd., of Croydon. The particulars provided are practical in character, and the tables of sizes and prices conveniently arranged.

The March issue of the *National Review* opens a new series, printed in larger type and provided with a different cover. Among its varied contents we notice an appreciation of the late Lord Kelvin by Sir William Ramsay, K.C.B., F.R.S., in which a delightful picture of Kelvin as a teacher is drawn, and a popular account given of some of his contributions to natural knowledge.

MESSRS. JOHN J. GRIFFIN AND SONS, LTD., have issued an illustrated and descriptive catalogue of apparatus suitable for demonstration purposes in the teaching of physiography, physiology, and hygiene. The information included respecting globes and lantern-slides should be particularly useful to teachers of geography who follow modern methods of presenting their subject.

A SECOND edition of Prof. G. S. Boulger's "Wood: a Manual of the Natural History and Industrial Applications of the Timbers of Commerce," has been published by Mr. Edward Arnold. The first edition was reviewed in NATURE of January 15, 1903 (vol. lxvii., p. 245), and it will be sufficient here to say the work has been revised and enlarged, and that its price is now 12s. 6d. net.

THE National Home-Reading Union, with the cooperation of the Library Association, has arranged to publish a penny monthly magazine for the guidance of readers in public libraries in the choice of books and other reading. The first issue, that for February, is now available, and among its principal contents may be noticed articles by Prof. H. H. Turner, F.R.S., on books about astronomy; books about Australia, by Sir John Cockburn, K.C.M.G.; and the literature of the sea, by Mr. Frank T. Bullen. The *Reader's Review*, as the guide is called, is intended primarily for localisation in the various libraries by means of the insertion of additional pages containing local literary notes, lists of recent additions, and so on. The idea of assisting readers in their choice of books is excellent, and it is to be hoped that the efforts of the editorial board will prove successful. The paper is published by Messrs. Sherratt and Hughes.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MARCH:—

March 5. 1h. Venus in conjunction with Moon. Venus 5° 49′ N.
,, 8h. 59m. Minimum of Algol (β Persei).
6. 3h. Mars in conjunction with Moon. Mars 5° 26′ N.
8. 10h. 10m. to 10h. 32m. Moon occults δ^2 Tauri (Mag. 4·2).
9. 11h. 42m. to 16h. 31m. Transit of Jupiter's Satellite IV. (Callisto).
10. Pallas (Mag. 8·04) in opposition to the Sun.
12. 6h. 12m. to 9h. 54m. Transit of Jupiter's Satellite III. (Ganymede).
13. 4h. Jupiter in conjunction with Moon. Jupiter 1° 7′ S.
19. 9h. 47m. to 13h. 28m. Transit of Jupiter's Satellite III. (Ganymede).
20. 12h. Sun enters Aries, Spring commences.
21. Venus. Illuminated portion of disc = 0·677.
26. 22h. Mercury at maximum elongation West (27° 49′).
28. 7h. 30m. Minimum of Algol (β Persei).
31. Ceres (Mag. 7°·36) in opposition to the Sun.

MICROMETER OBSERVATIONS OF PHŒBE.—During the period July 24 to October 16, 1906, Prof. Barnard made a number of observations of Phœbe, Saturn's tenth satellite, of which he now publishes the results in No. 4234 of the *Astronomische Nachrichten* (p. 145, February 22). A variation of brightness, amounting to half a magnitude or more, is indicated by the fact that while the object was usually a difficult one, of magnitude 16·0 or 16·5, it was found to be comparatively easy during October, and was perhaps brighter than the sixteenth magnitude. On several occasions the satellite presented a hazy appearance, and Prof. Barnard suggests that, should future observations confirm this nebulous or cometary character, the solution of the question of Phœbe's origin in the Saturnian system will be simplified.

EPHEMERIS FOR DANIEL'S COMET, 1907*d*.—The following is an extract from Herr Kritzinger's ephemeris for comet 1907*d*, published in No. 4234 (p. 150, February 22) of the *Astronomische Nachrichten*:—

Ephemeris 12h. (Berlin M.T.).

1908	α (1908·0) h. m.	δ (1908·0) ° ′	1908	α (1908·0) h. m.	δ (1908·0) ° ′
Mar. 5 ...	15 4·4 ...	−6 44·0	Mar. 21 ...	14 53·6 ...	−5 6·9
,, 13 ..	14 59·7 ...	−5 57·0	,, 29 ...	14 46·5 ...	−4 15·5

The computed magnitude of this object is 10·6, and the comet is now apparently travelling eastwards through the constellation Libra towards Virgo, rising a little south of east at about 10.30 p.m. On March 17 it will be about $2\frac{1}{2}$° north of δ Libræ.

THE SPECTRUM OF THE AURORA BOREALIS.—An exhaustive summary and discussion of the results hitherto obtained from spectroscopic observations of the aurora appears in No. 9, vol. xxxv. (September, 1907), of the *Monthly Weather Review* (U.S. Weather Bureau), from the pen of Dr. W. Marshall Watts. All the recorded visual and photographic observations made since the time of Ångström's observations in 1867 are analysed and compared, and the most probable values for the wave-lengths of the principal lines are tabulated; for the chief green line this value is 5571·6, and for the red line 6303·4. Various observations suggest that the spectrum varies at different times, and Dr. Watts urges that far more numerous and continuous observations should be made. With the apparatus which he describes, such observations could be made at a very small cost by any qualified observer.

SUN-SPOT SPECTRA.—No. 1, vol. xxvii., of the *Astrophysical Journal* (January) contains two papers which should prove of interest to all workers in solar physics. The first of these is by Prof. W. S. Adams, and really consists of a preliminary catalogue of lines affected in sun-spots. The photographs on which these lines were detected were taken with a Littrow spectrograph, used in conjunction with the Snow telescope of the Mount Wilson Solar Observatory, and give a linear dispersion of 1 mm. = 1·5 Å. The present catalogue includes a list of the lines affected in sun-spots in the region λ 4000 to λ 4500, and is to be followed by other lists giving the results obtained in other parts of the spectrum. The lines, their behaviour, and their origins are not discussed now, the discussion being reserved until the catalogue is complete; the present list includes nearly 900 lines, for each of which the probable origin, the intensities in Rowland's table and in the spot, together with remarks on its behaviour in the spot, are given.

In the second paper Mr. Charles M. Olmsted, of the Mount Wilson Observatory, announces that he has succeeded in identifying certain bands in the sun-spot spectrum with similar bands in the spectrum of the calcium arc burning in an atmosphere of hydrogen. There are two main groups of these bands, the stronger one at λ 6385, the weaker running through the B group, and the comparison with the spot spectrum leaves no doubt as to their identity.

ASTRONOMY IN WALES.—The *Cambrian Natural Observer* (January) contains several papers on astronomical subjects read before the Astronomical Society of Wales last year. Among others may be mentioned a paper by Mr. T. E. Heath on star clouds and nebulæ, another dealing with transits past and present, and an abstract of a paper by the Rev. John Griffith on the astronomy of the stones, delivered in November last before a crowded meeting of the Cardiff Archæological Society and the Astronomical Society in Wales. Sir Norman Lockyer's method of investigation of stone monuments was explained, and the audience was urged to aid in the accumulation of the orientation data which is apparently so abundant in Wales.

The periodical is again to be issued as a quarterly.

RECENT ADVANCES IN RADIO-ACTIVITY.[1]

In 1904 I had the honour of giving an address at the Royal Institution on the subject of radio-activity. In the interval steady and rapid progress has been made in unravelling the tangled skein of radio-active phenomena. In the present lecture I shall endeavour to review very shortly some of the more important advances made in the last few years, but as I cannot hope to mention, even briefly, the whole additions to our knowledge in the various branches of the subject, I shall confine my attention to a few of the more salient facts in the development of which I have taken some small share.

In my previous lecture I based the explanation of radio-active phenomena on the disintegration theory put forward in 1903 by Rutherford and Soddy, which supposes that the atoms of the radio-active bodies are unstable systems which break up with explosive violence. This theory has stood the test of time, and has been invaluable in guiding the experimenter through the maze of radio-active complications. In its simplest form, the theory supposes that every second a certain fraction (usually very small) of the atoms present become unstable and explode with great violence, expelling in many cases a small portion of the disrupted atom at a high speed. The residue of the atom forms a new atomic system of less atomic weight, and possessing physical and chemical properties which markedly distinguish it from the parent atom. The atoms composing the new substance formed by the disintegration of the parent matter are also unstable, and break up in turn. The process of degradation of the atom, once started, proceeds through a number of distinct stages. These new products formed by the successive disintegrations of the parent matter are in most cases present in such extremely minute quantity that they cannot be investigated by ordinary chemical methods. The radiations from these substances, however, afford a very delicate method of qualitative and quantitative analysis, so that we can obtain some idea of the physical and chemical properties of substances existing in an amount which is far below the limit of detection of the balance or spectroscope.

The law that governs the breaking up of atoms is very simple and universal in its application. For any simple substance, the average number of atoms breaking up per second is proportional at any time to the number present. In consequence, the amount of radio-active matter decreases in a geometrical progression with the time. The "period" of any radio-active product, *i.e.* the time for half the matter to be transformed, is a definite and characteristic property of the product which is uninfluenced by any of the laboratory agents at our command. In fact, the period of any radio-active product, for example, the radium emanation, if determined with sufficient accuracy, might well be taken as a definite standard of time, independent of all terrestrial influences.

The law of radio-active transformation can be very simply and aptly illustrated by an hydraulic analogy. Suppose we take a vertical cylinder filled with water, with an opening near the base through which the water escapes through a high resistance.[2] When the discharge is started the amount of water escaping per second is proportional to the height of water above the zero level of the cylinder. The height of water decreases in a geometrical progression with the time in exactly the same way as the amount of radio-active matter decreases. We can consequently take the height of the column of water as representing the amount of radio-active matter A present at any time. The quantity of water escaping per second is a measure of the rate of disintegration of A and also of the amount of the new substance B formed per second by the disintegration of A. The "period" of the substance is controlled by the amount of resistance in the discharge circuit. A high resistance gives a small flow of water and a long period of transformation, and *vice versâ*. By a suitable arrangement we can readily trace out the decay curve for such a case. A cork carrying a light vertical glass rod is floated on the water in the cylinder. A light camel's hair brush is attached at right angles, and moves over the surface of a smoked-glass plate. A vertical line drawn on the glass through the point of contact of the brush gives the axis of ordinates, while a horizontal line drawn through the brush when the water has reached its lowest level gives the axis of abscissæ. If the glass plate is moved with uniform velocity from the moment of starting the discharge a curve is traced on the glass which is identical in shape with the curve of decay of a radio-active product, where the ordinates at any time represent the relative amount of active matter present, and the abscissæ time. With such an apparatus we can illustrate in a simple way the increase with time of radio-active matter B, which is supplied by the transformation of a substance A. This will correspond, for example, to the growth of the radium emanation with time in a quantity of radium initially freed from emanation. Let us for convenience suppose that A has a much longer period than B. In the hydraulic analogy A is represented by a high head of water discharging at its base through a circuit of high resistance into the top of another cylinder representing the matter B. The water from the cylinder B escapes at its base through a lower resistance. Suppose that initially only A is present. In this case the water in the cylinder B stands at zero level. On opening the stop-cock connecting with A, water flows into B. The rise of water with time in the cylinder B is traced out in the same way as before by moving the glass plate at a constant rate across the tracing brush. If the period of A is very long compared with that of B the water is supplied to B at a constant rate, and the water in B reaches a constant maximum height when the rate of supply to B equals the rate of escape from the latter. The curve traced out in that case is identical in shape with the "recovery curve" of a radio-active product supplied at a nearly constant rate. The quantity of matter reaches a maximum when the rate of supply equals its own rate of transformation. The relative height of the columns of water in A and B represents at any time the relative amounts of these substances present.

If the period is comparable with that of B, the height of water in B after reaching a maximum falls again, since as the height of A diminishes the supply to B decreases. Ultimately, the height of B will decrease in a geometrical progression with the time at a rate corresponding to the longer period of the two. This is an exact illustration of the way the amount of a radio-active substance B varies when initially only the parent substance A is present. By using a number of cylinders in series, each with a suitable resistance, we can in a similar way illustrate in a quantitative manner the variation in amount with time of a number of products arising from successive disintegrations of a primary substance. By suitably adjusting the amount of resistance in the discharge circuits of the various cylinders, the curves could be drawn to scale to imitate approximately the variation in amount of the various products with time when the initial conditions are given.

During the last few years a very large amount of work has been done in tracing the remarkable succession of transformations that occur in the various radio-active substances. The known products of radium, thorium, actinium, and uranium are shown graphically below, together with the periods of the products and the character of the radiations they emit. It will be seen that a large list of these unstable bodies are now known. It is probable, however, that not many more remain to be discovered. The main uncertainty lies in the possibility of overlooking a product of rapid transformation following or succeeding one with a very slow period. In tracing out the succession of changes, the emanations or radio-active gases continuously evolved by radium, thorium, and actinium have marked a very definite and important stage, for these emanations can be easily removed from the radio-active body and their further transformations studied quite apart from the parent element. The analysis of the transformation of the radium emanation has yielded results of great importance and interest. After passing through three stages, radium A, B, and C, of short period, a substance, radium D, of long period, makes its appearance. This is transformed through two stages E and F of short period into radium G, of period 140 days. Meyer and Schweidler have conclusively shown that radium D is the primary

[1] A discourse delivered at the Royal Institution on Friday, January 31, by Prof. E. Rutherford, F.R.S.

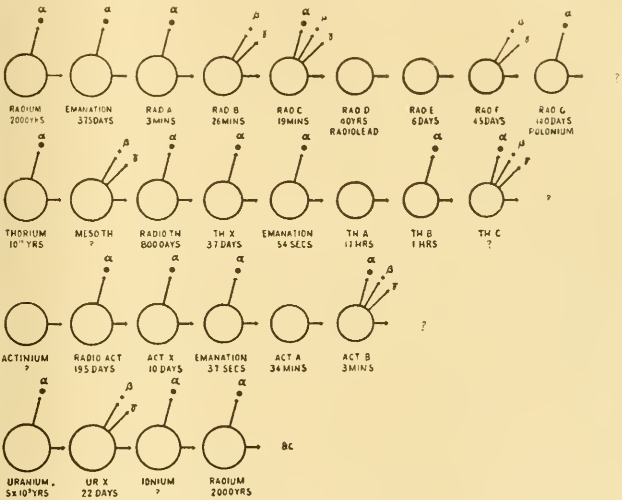
[2] A short glass tube in which is placed a plug of glass wool is very suitable.

constituent of the radio-active substance separated by Hofmann and called by him radio-lead. Radium G is identical with the first radio-active substance separated from pitchblende by Madame Curie, viz. polonium. We are thus sure that these bodies are transformation products of radium. It will be seen that I have added another product of period 4·5 days between radium D and polonium. The presence of such a product has been shown by Meyer and Schweidler.

In the case of thorium, a very long list of products is now known. For several years thorium X was thought to be the first product of thorium, but Hahn has recently shown that at least two other products of slow transformation intervene, which he has called mesothorium and radiothorium. The radiothorium emits α rays, and has a period of more than 800 days. Mesothorium apparently emits β rays, and has a still longer period of transformation, the exact value of which has not yet been accurately determined. Since thorium is used commercially on a large scale, there is every prospect that we shall soon be able to obtain considerable quantities of very active preparations of mesothorium and radiothorium. The separation of these bodies from thorium does not in any way alter its commercial value. It is to be hoped that if these active preparations are separated in quantity, the physicist and chemist may be able to obtain a supply of very active material at a reasonable cost, and that there will not be an attempt to compete with the ridiculously high prices charged for radium.

From the radio-active point of view, the radio-elements are only distinguished from their families of products by their comparatively long period of transformation. Now we have reason to believe that radium itself is transformed according to the laws of other radio-active products with a period of about 2000 years. If this be the case, in order to keep up its supply in a mineral, radium must be produced from another substance of relatively long period of transformation. The search for this elusive parent of radium has been one of almost dramatic interest, and illustrates the great importance of the theory as a guide to the experimenter. The view that radium was a substance in continuous transformation was put forward by Rutherford and Soddy in 1903. The most probable parent of radium appeared to be uranium, which has a period of transformation of the order of 1000 million years. If this were the case, uranium, initially freed from radium, should in the course of time grow radium, *i.e.* radium should again appear in the uranium. This has been tested independently by Soddy and Boltwood, and both have shown that in carefully prepared uranium solutions there is no appreciable growth of radium in the course of several years. The rate of production of radium, if it occurs at all, is certainly less than 1/1000 of the amount to be expected from theory. This would appear at first sight to put out of count the view that uranium is the parent of radium. This, however, is by no means the case, for such a result could be very easily explained if one or more substances of very slow period of transformation appeared between uranium and radium. It is obvious that the necessity of forming such an intermediate product would greatly lengthen the time required before an appreciable amount of radium appeared.

There is, however, another indirect but very simple method of attack to settle the parentage of radium. If radium is derived from the transformation of uranium, however many unknown products intervene, the ratio between the amount of radium and uranium in old minerals should be a definite constant. This is obviously the case, provided sufficient time has elapsed for the amount of radium to have reached its equilibrium value. The constancy of this relation has been completely substantiated by the independent work of Boltwood, Strutt, and McCoy. It has been shown that the quantity of radium corresponding to 1 gram of radium is $3\cdot8\times10^{-7}$ gram, and is the same for minerals obtained from all parts of the world. Since the radium is always distributed throughout the mass of uranium, we cannot expect to find nuggets of radium like nuggets of gold, unless by some chance the radium has been dissolved out of radio-active minerals and redeposited within the last few thousands of years. To those who had faith in the disintegration theory, this unique constant relation between the amounts of two elements was a satisfactory proof that radium stood in a genetic relation with uranium. A search was then made for the unknown intervening product which, if isolated, must grow radium at a rapid rate. A year or so ago Boltwood observed that a preparation of actinium separated



Succession of Substances produced by the transformation of radium, thorium, actinium, and uranium. The period of transformation of each substance is added below.

from a uranium mineral did grow radium at a constant but rapid rate. It thus appeared as if actinium were the long-looked-for parent of radium, and that actinium and its long family of products intervened between uranium X and radium. I was, however, able to show that actinium itself was not responsible for the growth of radium, but another unknown substance separated with it. These results were confirmed by Boltwood, who finally succeeded in isolating a new substance from uranium minerals, which was slowly transformed into radium. This substance, which he termed "ionium," has apparently chemical properties similar to those of thorium, and emits α rays of penetrating power less than those of uranium.

The main previsions of the theory have thus been experimentally verified. Radium is a changing substance the amount of which is kept up by the disintegration of another element, ionium. In order to complete the chain of evidence, we require to show that uranium grows ionium, and it is probable that evidence in this direction will soon be forthcoming. We thus see that we are able to link uranium, ionium, radium, and its long line of descendants, into one family, with uranium as its first parent. As uranium has a period of transformation of more than one thousand million years, it will not be profitable at the moment to try and trace back the family further.

It appears almost certain that, from the radio-active point of view, uranium and thorium must be considered as two independent elements. The case of actinium is different, for Boltwood has shown that the amount of actinium in minerals, like the amount of radium, is proportional to the amount of uranium. This indicates that actinium stands in a genetic relation with uranium. Unless our experimental evidence is at fault, it does not appear probable that actinium belongs to the main line of descent of uranium, for the activity of actinium separated from a mineral compared with radium is only about one-quarter of what we should expect under such conditions. I think that a suggestion which I put forward some time ago may account for the obvious connection of actinium with uranium, and at the same time for the anomaly observed. This supposes that actinium is a branch descent from some member of the uranium family. It does not appear improbable that at one stage of the disintegration two distinct substances may be produced, one in greater quantity than the other. After the expulsion of an α particle, it may happen that there are two possible arrangements of temporary stability of the residual atom. The great majority of the atoms may fall into one arrangement, and the remainder into the other. Actinium in this case would correspond to the substance in lesser quantity. It would act as a distinct element, and would break up in a different way from the main amount. It is probable that a large amount of accurate work will be required before the position of actinium in the scheme of changes can be fixed with certainty. It is a matter of remark how closely actinium resembles thorium in its series of transformations. It would appear that the atom of actinium has many points in common with thorium, or rather with its product, mesothorium.

The recent observations on the growth of radium offer a very simple and straightforward method of determining experimentally the period of radium. Suppose that we take a uranium mineral and determine by the emanation method the quantity of radium contained in it. If the immediate parent of radium (*i.e.* ionium) is next completely separated from the uranium and radium, it will begin to grow radium at a constant rate. Now the rate of growth of radium observed is a measure of the rate of breaking up of the radium parent in the mineral, since before separation the rate of production was equal to the rate of breaking up. Now the growth of radium observed for a short interval, for example, a year, divided by the quantity present in the mineral, gives the fraction of the radium breaking up per year. Proceeding in this way, Boltwood found that the fraction breaking up per year is about 1/3000, and that the period of radium is about 2000 years —a value which lies between the most probable values deduced from quite distinct data.

From an inspection of the radio-active families, it will be seen that out of twenty-six radio-active substances that have been identified, seventeen give out α rays or α and β rays, four give out only β rays, and five emit no rays at all. The rayless and β-ray products are transformed according to the same law as the α-ray products, and there is the same sudden change of physical and chemical properties as the result of the transformation. In the case of the substances which throw off atoms of matter in the form of α particles, there are obvious reasons for anticipating a change in properties of the substance, but this is not the case for the rayless or β-ray products. We must either suppose that the mass of the atom is not appreciably changed by the transformation, which consists in an internal rearrangement of the parts of the atom, or that the atom expels a particle at too low a velocity to be appreciated by the electrical methods. Unfortunately, it is very difficult to study the rayless products with care, as in practically every case they are succeeded by a ray product of comparatively rapid transformation. The rayless products are of great interest as indicating the possibility of transformations which can occur without any detectable radiation.

In the course of the analysis of radio-active changes, special methods have been developed for the separation of the various products from each other. It is only in a few cases, however, that we can hope to obtain a sufficient quantity of the substance to examine by means of the balance. It should be possible to obtain workable quantities of actinium, radium D (radio-lead), and radium G (polonium), but the isolation of these substances in any quantity has not yet been effected. Sir William Ramsay and Mr. Cameron have made a number of important investigations of the properties and volume of the radium emanation, freed so far as possible from any traces of known gases. The remarkable initial contraction of the volume due to the emanation shows that there is still much to be done to obtain a clear understanding of the behaviour of this intensely radio-active gas when obtained in a pure state.

Simultaneously with the work on the analysis of radio-active changes, a large number of investigations have been made on the laws of absorption by matter of the three primary types of radiation from active matter, viz. the α, β, and γ rays, and the secondary radiations to which they give rise. It has generally been accepted for some years that the γ rays are a type of penetrating X-rays. The latter are supposed to consist of electromagnetic pulses in the ether, set up by the impact or escape of electrons from matter, and akin in many respects to very short waves of ultra-violet light. Recently, however, Bragg has challenged this view, and has suggested that the γ rays (and probably also the X-rays) are mainly corpuscular in character, and consist of uncharged particles or "neutral pairs," as he terms them, projected at a high velocity. Such a view serves to explain most of the experimental observations equally well as the pulse theory; Bragg has recently brought forward additional evidence, based on the direction of the secondary radiation from the γ rays, which he considers to be inexplicable by the pulse theory. We must await further data before this important question can be settled definitely, but the theory of Bragg, which carries many important consequences in its train, certainly deserves very careful examination.

From the radio-active point of view, the α rays are by far the most important type of radiation emitted by active matter, although their power of penetration is insignificant compared with the β or γ rays. They consist of veritable atoms of matter projected at a speed, on an average, of 6000 miles per second. It is the great energy of motion of these swiftly expelled masses that gives rise to the heating effect of radium. In addition, they are responsible for the greater part of the ionisation observed near an uncovered radio-active substance. On account of their importance in radio-active phenomena, I shall devote some little attention to the behaviour of these rays. The work of Bragg and Kleeman, of Adelaide, first gave us a clear idea of the nature of the absorption of these rays by matter. The α particles from a very thin film of any simple kind of radio-active matter are all projected at an identical speed, and lose their power of ionising the gas or of producing phosphorescence or photographic action after they have traversed exactly the same distance, which may conveniently be called the "range" of the α particle. Now every product emits α particles at an identical speed among themselves, but different from every other product. For example, the swiftest α particles from the radium family, viz. that from radium C, travels 7 cm. in air under ordinary conditions before it is stopped, while that from radium itself is projected at a slower speed, travelling only 3·5 cm. We may regard the α particle as a projectile travelling so swiftly that it plunges through every molecule in its path, producing positively and negatively charged ions in the process. On an average, an α particle before its career of violence is stopped breaks up about 100,000 molecules. So great is the kinetic energy of the α projectile that its collisions with matter do not sensibly deflect it, and in this respect it differs markedly from the β particle, which is apparently easily deflected by its passage through matter. At the same time, there is undoubted evidence that the direction of motion of some of the α particles is slightly changed by their passage through matter.

The sudden cessation of the ionising power produced by the α particle after traversing a definite distance of air has been shown by Bragg to be a powerful method of analysis of the number of α-ray products present in a substance. For example, suppose the amount of ionisation in the gas produced by a narrow pencil of α rays is examined at varying distances from the radium. At a distance of 7 cm. there is a sudden increase in the amount of ionisation, for at this distance the α particles from radium C enter the testing vessel. There are again sudden changes in the ionisation at distances of 4·8 cm., 4·3 cm., and 3·5 cm. These are due to the rays from the radium A, the emanation and radium itself respectively entering the testing vessel. The α-ray analysis thus discloses four types of α rays present in radium in equilibrium—a result in conformity with the more direct analysis. This method allows us to settle at once whether more than one α-ray product is present in a given radio-active material. For example, an analysis by Hahn by this method of the radiation from the active deposit of thorium has disclosed the existence of two α-ray products instead of one as previously supposed. We can consequently gain information on the complexity of radio-active material, even though no chemical methods have been found to separate the products concerned. The range of the α particle from each product is a definite constant which is characteristic of each product.

The α particle decreases in velocity as it passes through matter. This result is clearly brought out by photographs showing the deflection of a homogeneous pencil of α rays in a magnetic field before and after passing through an absorbing screen. The greater divergence of the trace of the α rays on the plate, after passing through the screen, shows that their velocity is reduced, while the sharpness of the band shows that the α particles still move at an identical speed.

In order to make an accurate determination of the constants of the α particles, it is necessary to work with homogeneous rays, and we consequently require to use a thin layer of matter of one kind. For experiments of this character, a wire coated with a thin film of radium C by exposure to the radium emanation is very suitable. The velocity of the α particle and the value e/m, the ratio of the charge carried by the α particle to its mass, can be deduced by observing the deflections of a pencil of α rays exposed in a magnetic and in an electric field of known strengths. The deflection of a pencil of α rays in an electric field is small under normal conditions, and special care is needed to determine it with accuracy.

In this way I have calculated the velocity and value of e/m for a number of α-ray products. The velocity of expulsion varies for different products, but is connected by a simple relation with the range of the α particle in air. The value of e/m has been determined for selected products of radium, thorium, and actinium, and in each case the same value has been found. This shows that the α particles expelled from radio-active substances in general are identical in constitution. They have all the same mass, but differ from one another in the initial velocity of their projection. Although we are sure that the α particles, from whatever source, are identical atoms of matter, we are still unable to settle definitely the true nature of the α particle. The value of e/m found by experiment is nearly 5×10^3. Now the value of e/m for the hydrogen atom in the electrolysis of water is 10^4. If the charge carried by the α particle and the hydrogen atom is the same, the mass of the α particle is twice that of the hydrogen atom, *i.e.* a mass equal to the hydrogen molecule. But we are not certain that they do carry the same charge. Here we are, unfortunately, confronted by a number of possibilities, for the magnitude of m for the α particle is conditioned by the value assumed for e. If the charge of the α particle is assumed to be twice the value of the hydrogen atom, the mass comes out four times the hydrogen atom—the value found for the helium atom. The weight of evidence still supports the view that the α particle is in some way connected with the helium atom. If the α particle is a helium atom with twice the ionic charge, we must regard the helium produced by radio-active bodies as actually the collected α particles the charges of which have been neutralised. This at once offers a reasonable explanation of the production of helium by actinium as well as by radium. In addition, Strutt has recently contributed strong evidence that helium is a product of thorium. Such results are only to be expected on the above view, since the α particle is the only common product of these elements.

The determination of the true character of the α particle is one of the most pressing unsolved problems in radioactivity, for a number of important consequences follow from its solution. Unfortunately, a direct experimental proof of its true character appears to be very difficult unless a new method of attack is found. We have seen that if the charge carried by the α particle could be experimentally determined, the actual value of m could be determined in terms of the hydrogen atom, since the value of the charge carried by the latter is known. This could be done if we could devise a method of detecting the emission of a single α particle, and thus counting the number of particles expelled from a known quantity of a radio-active substance, for example, from radium. In considering a possible method of attack of this question, the remarkable property of the α particles of producing scintillations in zinc sulphide at once suggests itself. Apart from the difficulty of counting the scintillations, it is very doubtful whether more than a small fraction of the α particles which strike the screen produce the scintillations. Viewed from the electrical side, a simple calculation from the data at our disposal shows that the ionisation produced in a gas by a single α particle should be detectable. The electrometer or electroscope used for measurement would, however, require to be extremely sensitive, and under such conditions it is known that small electrical disturbances are very difficult to avoid.

In order to obtain a reasonably large effect, we require some method of magnifying the ionisation produced by the α particle. In conjunction with Dr. Hans Geiger, I have recently developed a method whereby the electrical effect produced by the α particle can be magnified several thousand times. From the work of Townsend it is known that if a strong electric field acts on gas at low pressure, any ions generated in the gas by an external agency are set in motion by the electric field, and under the proper conditions produce fresh ions by collision with the gas molecules. The negative ion is the most effective ioniser in weak fields, but when the voltage is increased near the point at which a discharge passes, the positive ion also produces fresh ions by collision. In the experimental arrangement the α particle from the active matter is fired through a small opening about 2 mm. in diameter, covered with a thin layer of mica, into a cylinder 60 cm. long and 2·5 cm. in diameter, in which the gas pressure is about 3 cm. of mercury. A thin insulated wire connected to the electrometer is fixed centrally in the cylinder. If the outside cylinder is charged negatively, for a difference of potential of about 1000 volts any ionisation produced in the cylinder is increased about 2000 times by collision. This can be simply illustrated by using the γ rays of radium as a source of ionisation. When a difference of potential is applied to the cylinder, the ionisation produced by the γ rays only causes a slight movement of the electrometer needle. By applying, however, a voltage nearly equal to that required for a discharge through the gas there is a very rapid movement of the needle. On removing the radium there is no appreciable current through the gas. On placing a source of α rays near the small opening in the cylinder so that some of the α particles can be fired along the axis of the cylinder, the electrometer needle does not move uniformly, but with a succession of rapid throws with a considerable interval in between. Each of these throws is due to the discharge produced by a single α particle entering the cylinder, increased several thousand times by the intermediary of the strong electric field. If a sheet of paper which stops the α rays is placed before the opening, the electrometer needle at once comes to rest. The interval of time between the throws is not uniform. This is exactly what we should expect if the number of α particles entering such a small opening is governed by the law of probability. On the average, a certain number of α particles are fired through the opening per minute, but in some cases the interval is less than the average, in others much greater. In fact, by observing the intervals between the entrance of a large number of α particles, we should be able to determine accurately the "probability" curve of distribution of the α particles with time. For purposes of measurements, the active material, in the form of a thin film covering a small area, is placed in an exhausted tube connected in series with the ionisation cylinder, and at a considerable distance from the hole. The number of α particles entering the opening per minute is counted, and from this the total number expelled can be calculated. Preliminary measurements show that the number of α particles expelled from a known weight of radium is of the same order as the calculated value. When the measurements are completed it should be possible to determine the charge carried by each α particle, since the total charge carried by the α particles from 1 gram of radium is known. In this way it may be possible to settle whether the α particle is a helium atom or not. In any case, it is a matter of some interest to be able to detect by its electrical effect a single atom of matter, and so to determine directly with a minimum of assumption the magnitude of some of the most important quantities in radio-active phenomena.

MEDICAL INSPECTION OF SCHOOL CHILDREN.[1]

THE memorandum issued by the English Board of Education on the medical inspection of children in public elementary schools is a statesmanlike document. It propounds a policy; it indicates a method, and the method, no less than the policy, takes full account of conditions, difficulties, and obstacles. The memorandum gives body to the provisions of section 3 of the Education (Administrative Provisions) Act, 1907. This section confers three broad powers on education authorities, first, to provide special environments for special children, *e.g.* vacation schools, vacation classes, play centres, &c.; second, to establish a medical inspection of the individual children; thirdly, "to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of the children educated in public elementary schools." These three powers may be exercised in cooperation with voluntary agencies, of which, it is needless to say, there are many. But the point of importance is that the powers may now be exercised by the education authorities, and practically, since grants may be made to depend on their exercise, the education authorities are now placed under obligation to carry them into full effect. The memorandum proceeds on this assumption; but it aims rather at sketching a process of natural administrative growth than at imposing an imperative system to be immediately realised. Accordingly, it starts from what is already being done in several localities to supervise the hygiene of schools and scholars. The sanitary authorities are in possession. This Act does not supersede, it expands and supplements, their work. Here emerges the cardinal principle of the memorandum, namely, the extension of the conception of public health to include, not merely the environmental sanitation considered apart, but the individual child's health as it is affected by his environment in the widest sense—physical, educational, &c.

The purpose of individual inspection, no less than of the general inspection of the hygienic conditions, is "to secure ultimately for every child, normal or defective, conditions of life compatible with that full and effective development of its organic functions, its special senses and its mental powers which constitute a true education." Unfortunately, owing to accidents of administrative convenience or development, there has arisen within the medical profession an acute difference of opinion as to the relative advantages of a special school medical service and an expanded public health service. Dr. Newman's appointment implied that the Board of Education favoured the idea of an expanded public health service, and this memorandum sketches in firm outline what this view implies. Incidentally, it shows that there is no opposition between the two views. On the one hand, it puts upon the medical officer of health the organising of the system of medical inspection, but on the other, it provides that "its actual execution" shall be "deputed wholly or partly to suitable colleagues or assistants (men or women)." The two factions are thus reconciled in the one administrative organisation.

The memorandum in more than one place emphasises in a way that it is impossible to controvert the primary importance of the home and its hygiene in the school-life of the child, and the absolute necessity for maintaining continuity of inspectorial interest between the home and the school. Medical inspection will thus work backwards to the home and forwards to the after-school life of the child, so covering the entire period between birth and the entry on industrial life. When this conception of continuity is fully grasped, there will be no further theoretical dispute between the medical factions concerned.

The British Medical Association has issued a memorandum dealing in a thoroughly practical spirit with the proposals and suggestions of the Board of Education. It is of immense importance that the medical profession should thus declare itself at the beginning. The differences between the association and the Board are essentially differences of detail. The association is quite frank in its acceptance of the general positions. The association's memorandum states that "these duties could not, having regard to the nature and extent of the duties already required of Medical Officers of Health, be efficiently discharged by them personally." This is not inconsistent with the Board's suggestions on the same point. The association also states that "part-time" medical officers, paid as for work done, could appropriately undertake medical inspection. This comes naturally from the profession, and there is much to say for it; but again there is nothing here inconsistent with the Board's views. But just as in the earlier, so in these later expansions of preventive medicine, the tendency will be towards "whole-time" specialists. In England many of the counties have not yet appointed whole-time or even part-time medical officers—so differing from Scotland, where every county is obliged to appoint a medical officer, and all except five have appointed whole-time men.

The association's memorandum is emphatic on another point, namely, that treatment of disease and visitation of the homes of the children shall be excluded from the scope of the medical inspector's duties. The full bearing of this suggestion will require very careful consideration. The Education Board's memorandum contains a very judicious discussion of the implications of the Act as to treatment, and it is difficult to reconcile the Act with the letter of the association's decision. The schedule proposed by the association is very well drawn, but it makes no provision for any record as to home conditions or occupation of parents, &c., which are insisted on in the Board's memorandum.

The Board of Education has followed up its memorandum by a detailed schedule, with full directions for the medical inspection. In most respects, this schedule meets all the proposals of the British Medical Association. From the tenor of the memorandum on the clear necessity for recording the home conditions and the occupational condition of the parents, we naturally expected that these points would be explicitly provided for in the schedule. In this we are somewhat disappointed; for all that we find is a heading for "Directions to Parent or Teacher." It would have been much simpler to have specified what details are wanted for every child—number of rooms in house, number of persons, occupation of father or mother, pre- and post-school labour of the child. These are all primary factors in the mental state of the child at any one time, and practically all these data are already in possession of the school authority. In other respects, the schedule is very comprehensive. Indeed, this is the one real criticism offered by medical critics. But when it is closely scrutinised, it will be found to contain only the bare essentials of a real inspection. The order of the schedule is simple, and the directive notes are models of lucidity. The anthropologist may regret that his special point of view is not as such provided for, but there is nothing

[1] (1) Memorandum on Medical Inspection of Children in Public Elementary Schools, under Section 13 of the Education (Administrative Provisions) Act, 1907 (Board of Education; Circular, 576).
(2) Memorandum by British Medical Association on the Circular of the Board of Education (*British Medical Journal*, Supplement, December 21, 1907).
(3) Schedule of Medical Inspection (accompanying Circular 582).

antagonistic to this either in the memorandum or in the schedule. Though not aiming directly at scientific facts, the medical inspection will certainly accumulate a vast number of facts that will form material of the first value for the anthropologist's methods.

We congratulate both the Board of Education and the British Medical Association on the practical sense displayed in these documents, and the general regard paid in each to the claims of science as well as to the claims of medicine. The great movement is now effectively inaugurated. Many points will emerge for adjustment, but these only experience can reveal. The main thing is that the work should now proceed on approximately uniform lines, and the Board of Education has given an effective lead.

FORTHCOMING BOOKS OF SCIENCE.

FOLLOWING our usual custom, we give the titles and names of authors of works relating to science which are to be found in the spring announcement lists of various publishers:—

Mr. S. Appleton:—"Minerals," by L. J. Spencer, illustrated; and "The Life and Habits of the Ants," by Dr. L. I. Dublin, illustrated.

Mr. Edward Arnold:—"Power Gas Producers, their Design and Application," by P. W. Robson.

Messrs. A. and C. Black:—"A Treatise on Zoology," edited by Sir E. Ray Lankester, K.C.B., F.R.S., part i., first fascicle, "Introduction and Protozoa," by Prof. S. J. Hickson, F.R.S., Dr. F. W. Gamble, F.R.S., J. J. Lister, F.R.S., Dr. H. M. Woodcock, and the late Prof. Weldon, F.R.S., illustrated; part vii., "Crustacea," by W. T. Calman, illustrated; part ix., "Vertebrata Craniata," by E. S. Goodrich, F.R.S., illustrated; "The Science and Philosophy of the Organism," the Gifford Lectures delivered before the University of Aberdeen in the Year 1907, by Dr. H. Driesch; "Cancer: Relief of Pain and Possible Cure," by S. and G. E. Keith; "Analytical Geometry of the Conic Sections," by the Rev. Dr. E. H. Askwith; "A Plant Book for Schools, being an Easy Introduction to the Study of Plant Life," by O. V. Darbishire, illustrated; "Descriptive Geography of the British Isles," by F. D. Herbertson, illustrated; "Man: his Manners and Customs," by Prof. L. W. Lyde, illustrated; "School Text-book of Geography," by Prof. L. W. Lyde: and new editions of "Studies in Fossil Botany," by Dr. D. H. Scott, F.R.S., illustrated; "An Introduction to Structural Botany," by Dr. D. H. Scott, F.R.S., part ii., "Flowerless Plants," illustrated; and "Totemism," by Prof. J. G. Frazer.

Messrs. W. Blackwood and Sons:—"Stephen's Book of the Farm," by J. Macdonald; "Forest Entomology," by A. T. Gillanders; "Significant Etymology," by J. Mitchell, and "Through the Depths of Space: a Primer of Astronomy," by H. Macpherson.

Messrs. Cassell and Co., Ltd.:—"The Complete Farmer—Soils: their Nature and Management," by P. McConnell; "Cassell's ABC of Gardening: an Illustrated Encyclopædia of Practical Horticulture," by W. P. Wright, illustrated; "The Townsman's Farm," by "Home Counties"; "Familiar Swiss Flowers," by F. E. Hulme, illustrated; "Gardening for Women," by the Hon. F. Wolseley; "Structural Engineering," by Prof. A. W. Brightmore, illustrated; and "Tinplate Work," edited by P. N. Hasluck, illustrated.

Messrs. Chatto and Windus:—"A History of Babylonia and Assyria from the Earliest Times until the Persian Conquest," by L. W. King, illustrated; vol. i., "A History of Sumer and Akkad, being an Account of the Primitive Inhabitants of Babylonia from the Earliest Times to about B.C. 2000"; vol. ii., "A History of Babylon from the Period of the First Dynasty, about B.C. 2000, until the Conquest of Babylon by Cyrus, B.C. 539"; vol. iii., "A History of Assyria from the Earliest Period until the Fall of Nineveh before the Medes, B.C. 606"; "The Open Air," by R. Jefferies, illustrated; and "Nature near London," by R. Jefferies, illustrated.

Messrs. Archibald Constable and Co., Ltd.:—"The North-West Passage: being the Record of a Voyage of Exploration of the Ship *Gjöa*, 1903–1907," by R. Amundsen, with a supplement by First Lieut. G. Hansen, 2 vols., illustrated; "Ice-bound Heights of the Mustagh: being an Account of Two Seasons of Pioneer Exploration and High Climbing in the Baltistan Himalaya," by F. B. and W. H. Workman, illustrated; "Electrical Measuring Instruments, Recorders and Meters," by K. Edgcumbe; "Heavy Electrical Engineering," by H. M. Hobart, illustrated; "Steam Electric Power Plants and their Construction," by F. Korster, illustrated; "Text-book of the Steam Engine," by J. Richardson, illustrated; "Boiler Construction," by F. B. Kleinhans, illustrated; "Hydraulics and its Application," by A. H. Gibson, illustrated; "Cranes," by A. Böttcher, translated from the German, enlarged, and edited with a complete description of English and American practice by A. Tolhausen, illustrated; "Sewage Disposal Works," by H. P. Raikes, illustrated; "Economics of American Railway Operation," by M. L. Byers, illustrated; "Railway Shop Up-to-date: a Reference Book of American Railway Shop Practice," compiled by the editorial staff of the *Railway Master Mechanic*; "Patents, Trade Marks and Designs," by K. R. Swan, illustrated; "The Manufacture of Paper," by R. W. Sindall, illustrated; "Wood Pulp and its Applications," by C. F. Cross, E. J. Bevan, and R. W. Sindall, illustrated; "Steam Engines," by J. T. Rossiter, illustrated; "Electric Lamps," by M. Solomon, illustrated; "Steam Locomotives," by V. Pendred, illustrated; "Gold and Precious Metals," by Dr. T. K. Rose; "Photography," by A. Watkins, illustrated; "Commercial Paints and Painting," by A. S. Jennings, illustrated; "Brewing and Distilling," by J. Grant, illustrated; "Specifications and Contracts," by Dr. J. A. L. Waddell and J. C. Wait; and a new edition of "Railway Tracks and Track Work," by E. E. R. Tratman, illustrated.

Mr. H. Frowde and Messrs. Hodder and Stoughton:—"A System of Medicine," edited by Prof. W. Osler, F.R.S., and Dr. T. McCrae, 7 vols., illustrated, vols. iv. and v.; "The Collected Papers of Lord Lister," with an introduction by W. W. Cheyne, F.R.S., 2 vols.; "A System of Diet and Dietetics," under the editorship of Dr. G. A. Sutherland, introduction by Sir Lauder Brunton, F.R.S.; and "Diseases of the Eye," by S. Mayou, illustrated.

Messrs. Gauthier-Villars (Paris):—"Leçons sur les Fonctions définies par les Équations différentielles du premier Ordre," by P. Boutroux; "Œuvres complétes," by A. Cauchy, Ière. Série, Tome II., Mémoires extraits des Mémoires de l'Académie des Sciences; "Leçons élémentaires sur le Calcul des Probabilités," by de Montessus, illustrated; "La Terre et la Lune: Forme extérieure et Structure interne," by P. Puiseux, illustrated; "Précis d'Arithmétique des Calculs d'emprunts à Longterme et de Valeur mobilière," by H. Sarrette; and a new edition of Villard's "Rayons cathodiques," illustrated.

Messrs. Harper and Brothers:—"Hypnotic Therapeutics," by Dr. J. D. Quackenbos; "Worlds in the Making: the Evolution of the Universe," by Prof. S. Arrhenius, translated by Dr. H. Borns, illustrated; and a new edition of "The History of Science," by Dr. H. S. Williams, 5 vols., illustrated.

Messrs. G. G. Harrap and Co.:—"Manual of Clinical Chemistry," by Prof. A. E. Austin, illustrated; "A Text-book of Topographical Drawing," by F. T. Daniels, illustrated; "Feathered Game of New England," by W. H. Rich, illustrated; and "The Teaching of Practical Arithmetic to Junior Classes," by J. L. Martin, illustrated.

Mr. W. Heinemann:—"The Natural History of Cancer," by W. R. Williams.

Messrs. Hutchinson and Co.:—"The Naturalist in West Cornwall," by W. H. Hudson, illustrated; "The World's Peoples," by Dr. A. H. Keane, illustrated; and "The World's Birds, a Simple and Popular Classification of the Birds of the World," by F. Finn, illustrated.

Messrs. Longmans and Co.:—"Refrigeration: an Elementary Text-book," by J. W. Anderson, illustrated; "The Life and Work of George W. Stow, South African Geologist and Ethnologist," by Prof. R. B. Young; and "A Practical Guide to School, Cottage, and Allotment Gardening," by J. Weathers, illustrated.

Messrs. Sampson Low and Co., Ltd.:—"Mosses and Liverworts," by T. H. Russell, illustrated.

Messrs. Macmillan and Co., Ltd.:—"African Nature Notes and Reminiscences," by F. C. Selous, with a foreword by President Roosevelt, illustrated; "A Text-book of Botany," by Drs. E. Strasburger, F. Noll, H. Schenck, and A. F. W. Schimper, revised with the eighth German edition by Dr. W. H. Lang, illustrated; "Origin and Development of the Moral Ideas," by Dr. E. Westermarck, vol. ii.; "Cotton Fibre," by F. H. Bowman, illustrated; "General History of Western Nations from 5000 B.C. to 1900 A.D.," by Dr. E. Reich, vols. i. and ii.; and "Atlas Antiquus: Forty-eight Maps in Colours, on a New Graphic Plan, with Explanatory Text in English; the Names of Places, Countries, &c., on the Maps themselves being in Latin; with a full Alphabetical Index," by Dr. E. Reich.

Messrs. Methuen and Co.:—"Diseases of Occupation," by Dr. T. Oliver, illustrated; "The Causation and Prevention of Tuberculosis (Consumption)," by Dr. A. Newsholme; "Folk-lore as an Historical Science," by G. L. Gomme, illustrated; "The Alps," by W. A. B. Coolidge, illustrated; "The Lore of the Honey Bee," by T. Edwardes, illustrated; "Examples in Elementary Mechanics, Practical, Graphical, and Theoretical," by W. J. Dobbs; "Outlines of Physical Chemistry," by Dr. G. Senter, illustrated; "A Health and Temperance Reader," by H. Major; "An Organic Chemistry for Schools and Technical Institutes," by A. E. Dunstan, illustrated; and "First Year Physics," by C. E. Jackson, illustrated.

Mr. Murray:—"Handbook of Commercial Products of India," by Sir G. Watt, C.I.E.; "From Peking to Mandalay: being the Account of a Journey from North China to Burma through Tibetan Ssuch'uan and Yunnan," by R. F. Johnston, illustrated; "Pearls and Parasites: a Series of Essays on Scientific Subjects," by Dr. A. E. Shipley, F.R.S.; "The South African Natives: their Present Condition and Progress," edited by the South African Native Races Committee; "Heredity," by Prof. J. A. Thomson, illustrated; "Therapeutics of the Circulation," by Sir T. Lauder Brunton, F.R.S.; and "Educational Woodwork on Scientific Lines," by J. T. Baily and S. Pollitt, illustrated.

Messrs. Kegan Paul and Co., Ltd.:—"Introduction to the Science of Electricity," lectures by B. Kolbe, authorised translation by J. Skellon, illustrated; "The Steam Engine and other Steam Motors," by R. C. H. Heck, illustrated; "The Evolution of Modern Physics," by Prof. L. Poincaré; "The Evolution of Forces," by Dr. G. Le Bon; "The Radio-active Substances, their Properties and Behaviour," by W. Makower; "Music: its Laws and Evolution," by J. Combarieu; "The Transformations of the Animal World," by M. C. Depéret; "Practical Dairy Bacteriology: for Students, Dairymen, and all interested in the Problems of the Relation of Milk to Public Health," by H. W. Conn; "Insects Injurious to Vegetables," by F. H. Chittenden, illustrated; "First Principles of Soil Fertility," by A. Vivian, illustrated; "Farm Machinery and Motors," by B. Davidson and L. W. Chase, illustrated; and a new edition of "Alternating Current Engineering, Practically Treated," by C. B. Raymond, illustrated.

Messrs. George Philip and Son, Ltd.:—"A Rational Geography," by E. Young; part ii., "Tides, Winds, Currents, Latitude and Longitude, and Geography of America and Africa," part iii., "Map Drawing, Map Projection, Surveying, and Geography of Asia and Australasia"; and "A Guide to the Choice of Geographical Text-books."

Sir Isaac Pitman and Sons, Ltd.:—"Notes of Lessons on Science"; "'The Teacher' Certificate Science"; "Notes of Lessons on Hygiene and Temperance," 2 vols.; "Notes of Lessons on Arithmetic," 2 vols.; and "Notes of Lessons on Geography," 2 vols.

Messrs. G. P. Putnam's Sons:—"Elements of Plane and Spherical Trigonometry," by Prof. J. H. Gore; "Alpine Flora of the Canadian Rocky Mountains," by S. Brown, illustrated; "Mosquitoes: the Habits and Life Cycles of the known Mosquitoes of the United States; Methods for their Control; and Keys for easy Identification of the Species in their Various Stages," an account based on the investigations of the late James William Dupree, Surgeon-General of Louisiana, and upon original observations by the writer, by E. G. Mitchell, illustrated; "The Muscles of the Eye," by Dr. L. Howe, 2 vols., illustrated; and a new edition of "Thinking, Feeling, Doing: an Introduction to Mental Science," by Dr. E. W. Scripture, illustrated.

Messrs. Watts and Co.:—A sixpenny edition of Prof. Huxley's "Man's Place in Nature."

Messrs. Williams and Norgate:—"The Surgical Anatomy of the Horse," by J. T. S. Jones, part iii., illustrated; and a new edition of "Principles and Practice of Agricultural Analysis: a Manual for the Study of Soils, Fertilisers, and Agricultural Products," by H. W. Wiley, vol. ii.

Messrs. Witherby and Co.:—"Three Voyages of a Naturalist: being an Account of many Little-known Islands in Three Oceans visited by the *Valhalla*, R.Y.S.," by M. J. Nicoll, with an introduction by the Right Hon. the Earl of Crawford, K.T., F.R.S., illustrated.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—There is a desire on the part of the biologists of Cambridge to celebrate in 1909 the centenary of Darwin's birth and the jubilee of the publication of the "Origin of Species" by endeavouring to found a chair of biology, the occupant of which shall devote himself to those subjects which were the chief concern of Darwin's life-work. It is probable that this will be accomplished; for the council of the Senate has had under consideration a generous offer of support made by a member of the University who wishes to remain anonymous.

Convinced of the great importance of the subjects with which such a professorship would be concerned, the benefactor offers to pay to the University 300*l*. a year for five years, provided that the University establishes for that period, and before June 30, 1908, a professorship of biology of the minimum annual value of 500*l*.

The donor also offers to increase the 300*l*. to 400*l*. for any portion of the five years during which the professor may be holding a professorial fellowship. The further condition is made that it shall be the duty of the professor or professors elected during the period of five years above mentioned to teach and make researches in that branch of biology now entitled genetics (heredity and variation).

The author of this offer further suggests, though he does not make it a condition, that the proposed temporary professorship, if established, should be entitled the "Darwin Professorship of Biology." The council of the Senate, while giving full weight to this suggestion, inclines to the view that it would be more expedient to reserve such a title until it shall have become clear that the professorship can, from whatever source, be placed on a permanent footing.

The council is of opinion that the generous offer anonymously made should be accepted, and that a professorship of biology of the value of 700*l*. per annum should be established, which will terminate at the end of the Easter term, 1913, unless the University shall previously have otherwise determined. The electors to the professorship shall, so long as the professorship is only temporary, be the council of the Senate, but if the professorship shall be made permanent a board of electors shall be constituted.

It is proposed to make a grant of 30*l*. from the Worts fund to Mr. A. R. Hinks, of Trinity College, towards defraying his expenses in travelling on the continent of Europe with the view of investigating the methods used in the study of astronomy and geodesy in certain observatories and institutions.

It is proposed to continue for a further period of five years, from Michaelmas, 1908, the Caley and Stokes lectureships in mathematics, the annual stipend of 200*l*. being attached to each lectureship. The general board is of opinion that, should the endowments for these two lectureships prove to be insufficient to provide these stipends, the University should undertake to make up for the five years any deficiency which may result from this insufficiency. This may involve a contribution from the University of 80*l*. a year.

Mr. C. A. Barber and Mr. A. W. Rogers have been approved by the general board of studies for the degree of Doctor in Science.

The syndicate appointed to obtain plans and estimates for the extension of the chemical laboratory has issued a second report, in which it is stated that last August a contract was signed by the builder for erecting the building, which is now rising in Pembroke Street, at a cost of 13,750*l*. The syndicate now asks leave of the Senate to expend a sum of 485*l*. for extras in the building, 2455*l*. for benches, lecture tables, and other fittings, and 700*l*. for instruments and apparatus.

LONDON.—The degree of D.Sc. in chemistry has been granted to Mr. R. J. Caldwell, an internal student of the Central Technical College. Mr. Caldwell presented a thesis entitled "A.—Studies of the Processes Operative in Solutions, part i., the Sucroclastic Action of Acids as influenced by Salts and Non-electrolytes; B.—The Hydrolysis of Sugars," and other papers.

The degree of D.Sc. in zoology has been granted to Mr. D. H. de Souza, an internal student of University College. Mr. de Souza presented a thesis entitled "The Activation of Pancreatic Juice."

THE death is announced of Prof. Laurent, professor of mathematical analysis in the Paris École polytechnique and Institut national agronomique.

MISS E. N. THOMAS, assistant in the department of botany, University College, has been appointed lecturer and head of the department of botany, Bedford College for Women.

M. CAMILLE MATIGNON has been appointed professor of mineral chemistry at the Collège de France in succession to M. H. Le Châtelier, who recently accepted the chair of general chemistry at the Sorbonne.

THE governing body of the Imperial College of Science and Technology has appointed as secretary Mr. Alexander Gow, formerly scholar of Gonville and Caius College, Cambridge, who for the last four years has occupied the position of director of education and principal of the Technical School, Blackburn.

IN the House of Commons on Monday Mr. Ramsay Macdonald asked the President of the Board of Education whether he proposed to appoint a Royal Commission to inquire into the constitution of the University of London, with a view to the University taking over the Imperial School of Science and Technology, or whether, in the event of no such commission being appointed and the school being in consequence maintained as a separate foundation, he would reconsider the constitution of the governing body of the school so as to strengthen it on its industrial side with the view of establishing a connection between it and technological institutions of lower grades. In reply, Mr. McKenna said that no representations had reached him from the bodies principally concerned leading him to suppose that the consideration of this question is urgently desired, and that no commission would be appointed unless these representations were made.

THE thirtieth annual meeting of the Institute of Chemistry was held on Monday, March 2, Prof. P. F. Frankland, F.R.S., president of the institute, being in the chair. In the course of his address the president dealt with the difficulties of students in deciding the most advisable method of preparing for admission to the profession of chemistry. He is convinced that the usual three years' curriculum is wholly inadequate, for whilst the ground to be covered in the study of chemistry has attained colossal dimensions compared with what it was twenty-five years ago, and is continually being extended, the student's time is no more protracted than before. The limited time at the disposal of the student gives him little opportunity to take proper advantage of the excellent equipment now to be found in the universities and colleges, and teachers are aware of the urgent necessity of increasing the minimum length of the curriculum prior to graduation, but no university appears to have the courage to initiate this reform. In the matter of students, it is quality, not quantity, that universities require, for every science student is a net loss financially, and the work of the classes is too often hampered by a large proportion of undesirables.

THE Board of Education has published (Cd. 3885) the reports from those universities and university colleges in Great Britain which participated during the year ended March 31, 1907, in the annual Parliamentary grant, now amounting to 100,000*l*. The reports deal with the work of the colleges during the year 1905–6, and appear to be reprinted just as they were received by the Board of Education. The information is arranged, it is true, under headings prescribed by the Board, such as land and buildings, staff and educational work, students, fees, finance, and so on, and it is possible with much labour to institute comparisons between the various institutions. The usefulness of the Blue-book would be increased greatly if, following the practice adopted in many other of the Board's publications and the custom which is fairly general in American volumes of a similar kind, the statistics relating to the various colleges were summarised and the totals obtained for the different institutions classified and compared. It would then be possible to coordinate the facts, and to say, for instance, how the interest in higher education in the north of England compares with that in the Midlands or in Wales. If some such plan were adopted much greater use would be made of what would then be an interesting and serviceable volume.

THE interim report for the period January 1 to September 30, 1907, submitted on February 25 last to the trustees by the executive committee of the Carnegie trust for the universities of Scotland, gives information concerning the allocation of grants during that period. The publication of this interim report, dealing only with nine months, was necessitated by an alteration of the financial year of the trust to bring it into line with the academic year of the universities. Sums amounting to 22,000*l.* have been handed over to the four Scottish universities during the nine months, bringing the total expenditure in this direction, since the inauguration of the first quinquennial scheme of grants in January, 1903, to 156,489*l.* The conditions which will regulate the second quinquennial distribution are under the consideration of a special sub-committee, and will, it is hoped, be published shortly. The total expenditure for 1906–7 under the scheme of endowment of post-graduate study and research was 7004*l.*, and the estimated expenditure for the current academic year is 7615*l.* The expenditure upon fees for the summer session, 1907, amounted to 11,685*l.* The proposed scheme of inclusive fees, that is, that in each faculty a beneficiary of the trust should be granted all such instruction as it is desirable for him to receive in his course for a degree on the payment of one fee for each academic year, is still under discussion. Numerous appendices to the report provide detailed information as to the different items of expenditure.

SOCIETIES AND ACADEMIES.

London.

Royal Society, December 12, 1907.—"Further Consideration of the Stability of the Pear-shaped Figure of a Rotating Mass of Liquid." By Sir G. H. **Darwin,** K.C.B., F.R.S.

In vol. xvii., No. 3 (1905), of the Memoirs of the Imperial Academy of St. Petersburg, M. Liapounoff has published an abstract of his work on figures of equilibrium of rotating liquid. In this paper he explains how he has obtained a rigorous solution for the figure and stability of the pear-shaped figure, and he pronounces it to be unstable. In a paper in the Philosophical Transactions (vol. cc., A, pp. 251–314) the present author arrived at an opposite conclusion.

The stability or instability depends on whether the sign of a certain function is negative or positive.

M. Liapounoff attributes the disagreement to the fact that the author only computed a portion of an infinite series, and only used approximate forms for the elliptic integrals involved in the several terms. He believes that the inclusion of the neglected residue of the infinite series would lead to an opposite conclusion.

In the author's computation the critical function is decisively negative, whilst M. Liapounoff is equally clear that it is positive. The inclusion of the neglected residue of the series, which forms part of the function, undoubtedly tends to make the whole function positive, but after making the revision it remained incredible, at least to the author, that the neglected residue should amount to the total needed to invert the sign.

The analysis of his former investigation was re-examined throughout, and the computations were repeated by improved methods. The same method was also applied to the investigation of Maclaurin's spheroid, where the solution could be verified by the known exact result.[1]

Dissent from so distinguished a mathematician as M. Liapounoff is not to be undertaken lightly, and therefore especial pains were taken to ensure correctness. The author states his conviction that the source of the disagreement is to be found in some matter of principle, and not in the neglected residue of this series.

Entomological Society, February 5.—Mr. C. O. Waterhouse, president, in the chair.—*Exhibits.*—Dr. T. A. **Chapman**: A collection of butterflies made last summer at Gavarnie, in the Pyrenees, including a number of specimens of *Erebia lefebvrei*, with *E. melas* from south-east Hungary, for comparison.—H. St. John **Donisthorpe**: Eleven species of ants taken in the hot-houses in Kew Gardens in December, 1907, and January, 1908, eight being new to the published Kew list, and six species not before recorded as introduced in Britain.—J. E. **Collin**: Microscopically mounted specimens of the gnat *Epidapus scabiei*, Hopk., a potato pest in the United States recently discovered in England attacking narcissus bulbs.—A. H. **Hamm**: Very young larvæ of *Bitaris muralis*, hatched in captivity, the natural place of deposit of these eggs being at the entrance to the burrow of the bee, *Anthophora pilipes*, in stone walls near Oxford.—Commander **Walker**: Two specimens of the rare *Pyralis lienigialis*, Zell, ♀, taken at light in his house at Summertown, August, 1906, and 1907.—R. E. **Turner**: A box of Thynnidæ from South America, mostly from Chile, with several new species from Mendoza and the Peruvian Andes.—Prof. T. Hudson **Beare**: A specimen of *Trachyphlaeus scabriculus* taken at St. Margaret's Bay in August, 1907, with the two deciduous mandibles still in place.—Lieut.-Colonel **Manders**: The ♀ of *Papilio phorbanta* from Bourbon, an aberrant member of the Nireus group of Papilios, compared with the other members of the same group from the African mainland, Madagascar, and Mauritius. It was pointed out that whereas in all the other species the ♀♀s were some shade of green similar to the ♂♂s, the Bourbon insect was more or less uniformly brown. It was suggested that this was due to mimicry, *Euplaea goudoti*, a species strictly confined to Bourbon, being the model.—Hon. Walter **Rothschild**: Interesting papilionids; (1) *Troides alexandrae*, Rothsch., remarkable for the beauty of the ♂ and the gigantic size of the ♀, a new discovery by A. S. Meek, who found this fine insect in the north-eastern portion of British New Guinea at some distance inland from the coast; (2) a gynandromorphic specimen of Troides, the only one known of this genus, obtained by Dr. L. Martin in South Celebes. It belongs to *T. haliphron*, the left side being ♀ and the right side ♂.—R. **Adkin**: Bred specimens of *Tortrix pronubana*, Hb., to demonstrate that the species is continuously brooded.—L. W. **Newman**: Long series of *Melitaea aurinia* and *Notodonta chaonia* from various localities in the United Kingdom to illustrate the wide superficial variation of the respective species.—Dr. F. A. **Dixey**: Specimens of *Nychitona medusa*, Cram., and *Pseudopontia paradoxa*, Feld.—*Papers.*—(1) Two diplopterous Hymenoptera from Queensland; (2) notes on Thynnidæ, with remarks on some aberrant genera of the Scotiidæ: R. E. **Turner.**—Diaposematism, with reference to some limitations of the Müllerian hypothesis of mimicry: G. A. K. **Marshall.**

Zoological Society, February 18.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—A series of specimens of internal parasites obtained from animals recently living in the society's gardens: Dr. L. W. **Sambon.** Stress was laid on the important additions to knowledge to be derived from an adequate investigation of such material, and on the practical results to the health of the animals in the gardens that might be expected.—The inheritance of colour in domestic pigeons, with special reference to reversion: R. **Staples-Browne.** A series of skins was exhibited illustrating some experiments upon which the communication was based. Crosses had been made between black barbs and white fantails. The F1 generation was black with some white feathers. In the F2 generation, among other forms, blacks and whites were obtained, and also some blues. Blues were found to be dominant to whites, but blacks were dominant, or rather "epistatic," to the blues, which accounts for the fact that the reversionary form does not appear until the F2 generation. When two blues of the F2 or later generations were mated together blacks were never obtained again. A white in F2 mated to a fantail gave whites only. A second series of skins illustrated a cross between a white tumbler and a white fantail. Some white birds splashed with red had figured in the ancestry of the tumbler, although the bird itself showed no trace of colour. In the F1 generation such splashed kinds occurred, which, when mated together, gave in F2 birds which were red and white with some distinct blue feathers. Possibly the white tumbler was a dominant white.—Mammals collected by Mr. M. P. Anderson during a trip to the Mongolian Plateau, N.W. of Kalgan: O. **Thomas.** Nine species were mentioned, of which two were described as new. The paper formed the

[1] Amer. Math. Soc. Trans., 1903, vol. iv., p. 113, on "The Approximate Determination of the Form of Maclaurin's Spheroid," and a further note on the same [illegible] recently sent to the same society.

eighth of the series on the results obtained by the Duke of Bedford's zoological exploration in eastern Asia. No properly collected material from the Mongolian plateau had been previously available to students, and these specimens, representatives of its comparatively poor fauna, were therefore of much interest.—Butterflies of the division Rhopalocera from Africa and from New Guinea: G. T. **Bethune-Baker.**

Chemical Society, February 20. Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—Organic derivatives of silicon, part vi., the optically active sulphobenzylethylpropylsilicyl oxides: F. S. **Kipping.** The sulphonic acids obtained by resolving *dl*-sulphobenzylethylpropylsilicyl oxide have been further studied, and the two acids are shown to be optically active, enantiomorphously related compounds having the constitution

$$(SO_3H.CH_2.C_6H_4.SiEtPr)_2O.$$

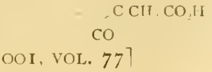
—The preparation of conductivity water: H. **Hartley,** N. P. **Campbell,** and R. H. **Poole.** A still has been constructed which in one operation gives a fair yield of water with a conductivity 0·75 gemmho at 18°, starting from ordinary distilled water with a conductivity of 5 gemmhos.—Derivatives of *para*-diazoiminobenzene: G. T. **Morgan** and Miss F. M. G. **Micklethwait.**—The affinity constants of bases as determined by the aid of methyl-orange: V. H. **Veley.** Results were given for the hydrochlorides of (1) bases not containing an alkyl grouping; (2) aliphatic amines; (3) amino-acetic acids; and (4) uric acid derivatives.—The action of thionyl chloride and of phosphorus pentachloride on the methylene ethers of catechol derivatives: G. **Barger.**—A study of the diazo-reaction in the diphenyl series: G. T. **Morgan** and Miss F. M. G. **Micklethwait.** The arylsulphonylbenzidines, $RSO_2.N\overset{*}{H}.C_6H_4.C_6H_4.NH_2$, furnish yellow crystalline diazonium salts giving rise on treatment with aqueous sodium acetate to dark brown crystalline compounds, which are either monohydrated nitrosoamines,

$$R.SO_2.NH.C_6H_4.C_6H_4.NH.NO,H_2O,$$

or dihydrated diazoimides, $\begin{array}{l} C_6H_4.N_2 \\ | \qquad | \\ C_6H_4.N.SO_2R,2H_2O \end{array}$. The diazonium salts of the arylsulphonylalkylbenzidines,

$$RSO_2.N(C_2H_5).C_6H_4.C_6H_4.NH_2,$$

although distinctly less coloured than those of the unalkylated bases, have nevertheless not been obtained in a colourless condition. There is accordingly no reason for supposing that the diazonium salts of the alkylated bases are differently constituted from those which still contain the labile acidic hydrogen atom (*).—A simple manometer for vacuum distillation: N. L. **Gebhard.**—Researches on the anthraquinones: W. H. **Bentley** and C. **Weizmann.** The condensation products of phthalic and hemipinic anhydrides with veratrole and pyrogallol trimethyl ether are described.—The formation of 4-pyrone compounds from acetylenic acids, part i.: S. **Ruhemann.**—The action of mustard oils on the ethyl esters of malonic and cyanoacetic acids: S. **Ruhemann.**—The triazo-group, part ii., azoimides of propionic ester and of methyl ethyl ketone: M. O. **Forster** and H. E. **Fierz.** On comparing the behaviour of the α- and β-triazo-derivatives of ethyl propionate towards alkali, it was found that, whilst the first-named resembles triazoacetic ester, ethyl β-triazopropionate rapidly parts with hydrazoic acid.—Brazilin and hæmatoxylin, part viii., synthesis of brazilinic acid, the lactones of dihydrobrazilinic and dihydrohæmatoxylinic acids, anhydrobrazilic acid, &c. The constitution of brazilin, hæmatoxylin, and their derivatives: W. H. **Perkin,** jun., and R. **Robinson.** Further confirmation of the constitution (Proc., 1907, xxiii., 291) of the members of this group is afforded by the synthesis of anhydrobrazilic acid, which has been proved to possess the formula



EDINBURGH.

Royal Society, February 17.—Dr. John Horne, F.R.S., vice-president, in the chair.—The systematic motion of the stars: Prof. **Dyson.** A careful study of 1500 stars having large proper motions corroborated Kapteyn's hypothesis that the stars moved in two well-defined streams crossing each other in space.—Preliminary note on *Lepidophloios Scotti*, a new species from the Calciferous Sandstone series at Pettycur, Burntisland: W. T. **Gordon.** Some of the diagnostic features of this new species named after Dr. D. H. Scott are:—(1) the short straight ligular canal the opening of which is protected by the overlying leaf base, and which opens far back from the leaf scar; (2) a marked concavity of the leaf base from half-way between the opening of the ligular canal and the leaf scar to the leaf scar itself; (3) the comparatively long course of the parichnos before it forks.—The middle cells of the grey matter of the spinal cord: Dr. J. H. Harvey **Pirie.** The description of the anatomical arrangement of these small cells showed that Argutinski was wrong in ascribing a segmented character to the group, and that the cells extended throughout the whole length of the cord, being specially numerous in the two enlargements.—*q*-Functions and a certain difference operator: Rev. F. H. **Jackson.**

PARIS.

Academy of Sciences, February 24.—M. H. Becquerel in the chair.—M. B. Baillaud was elected a member of the section of astronomy in the place of the late M. Lœwy.—Results of the measurements of the diameters of Mercury during its transit of November 14, 1907: Robert **Jonckheere.** The mean diameter is 9″·10, higher than the figure usually accepted, 8″·68. A table of results is given.—Observations of the sun made at the Observatory of Lyons during the fourth quarter of 1907: J. **Guillaume.** The results are summarised in three tables showing the number of spots, the distribution of the spots in latitude, and the distribution of the faculæ in latitude.—Researches on the dispersion of light in celestial space: Charles **Nordmann.** From measurements on two fixed stars by the photometric method previously described by the author, the conclusion is drawn that light undergoes a dispersion in space. These results can be applied to give new indications of the parallax of variable stars.—The congruences of plane curves: C. **Popovici.**—Remarks on a communication of M. E. E. Levi: E. **Holmgren.** A question of priority.—The singularities of differential equations of the first order: Georges **Rémoundos.**—Images the appearance of which changes with a projection screen ruled as a grating: E. **Estanave.** The influence of sunlight on the disengagement and on the orientation of the gaseous molecules in solution in sea-water: Raphael **Dubois.** If test-tubes containing various coloured solutions are plunged into sea-water and the whole exposed to the sun, it is noticed that bubbles of gas are deposited on the outside wall of the tube. If the solution in the tube is green, the evolution of gas, which is rich in oxygen, is much greater than with the other colours. That this is not due to the selective absorption of calorific radiations was shown by substituting water charged with carbon dioxide for the aërated sea-water; the increased effect with the green tube was not observed. The curves of induced radio-activity obtained by MM. Sarasin and Tommasina: J. **Danne.** An explanation of the results of these authors, by considering the distribution of the field in the different parts of the measuring apparatus.—The method of working of the electrolytic detector: the influence of temperature: Henri **Abraham.** The change in capacity and resistance of the electrolytic detector caused by raising the temperature to 120° C. gives several advantages in practical working.—The atomic weights of nitrogen, oxygen, and carbon: A. **Leduc.** The International Committee on Atomic Weights has now lowered the atomic weight of nitrogen from 14·044 to 14·01. Using this figure and the ratio of the densities of carbon monoxide and nitrogen, as determined experimentally by Lord Rayleigh and by the author, it is shown that the atomic weight of carbon must lie between 12·011 and 12·016.—Phosphorus oxybromide: E. **Berger.** Phosphorus pentabromide heated with phosphorus pentoxide gives a good yield (85 per cent.) of phosphoryl bromide. This forms crystals, melting at 56° C. and boiling at 189°·5 C. under 774 mm. Its vapour density is normal. The heat of formation has also been determined.—The essentially chemical causes of the allotropic transformation of white phosphorus dissolved in essence of turpentine: Albert **Colson.**—An isomeric modification of hydrated hypovanadic acid: Gustave **Gain.** The acid $V_2O_4,2H_2O$ exists in two forms, one green and the other rose colour. The change from one of these isomers to the other is accompanied by a thermal change, and this has been measured in the calorimeter.—Lutecium and neoytterbium: G. **Urbain.** The fact that Marignac's ytterbium can be separated into two elements differing in atomic weight by more than three units was briefly described by the author three months ago. The present communication contains fuller details of the methods and results. These results have been confirmed by Auer von Welsbach, who has described the two elements thus separated under the names of aldebaranium and cassiopeium. The former of these is identical with lutecium, and the latter with neoytterbium.—The action of sulphosalicylic acid upon borax: L. **Barthe.**—The action of nascent hypoiodous acid (iodine and sodium carbonate) upon some acids of the general formula

$$R—CH=CH—CH_2—CO_2H,$$

R being the phenyl group more or less substituted: J. **Bougault.** The product of this action is an acid of the general formula $R—CO—CH=CH—CO_2H$.—Antiamylasic serum: C. **Gessard** and J. **Wolff.** Quantitative studies on an enzyme preventing the action of malt extract upon starch.—The action of amylase of the pancreatic juice and its stimulation by the gastric juice: H. **Bierry.**—Note on the existence of products of cellular degenerescence recalling Negri's bodies: Y. **Manouélian.**—The measurement of the ventricular wave in man: Gabriel **Arthaud.**—The fixation, multiplication, and mode of attack of pathogenic trypanosomes in the proboscis of the tsetse-fly: E. **Roubaud.**—The genus Doliocystis: L. **Brasil.**—Stratigraphical researches in eastern Morocco: Louis **Gentil.**—Primary strata of Morvan and the Loire: Albert **Michel-Lévy.**—The extension of the Oligocene depressions in a part of the central *massif*, and their *rôle* from the hydrological point of view: Ph. **Glangeaud.**—New researches on the rare gases of thermal springs. Yields of gas in certain cases: Charles **Moureu** and Robert **Biquard.** The gases from nine springs have been examined. The proportions of the rare gases, taken together, vary from 1·24 per cent. to 6·39 per cent., the helium from 0·097 per cent. to 5·34 per cent. The total quantity of helium thus obtainable is very large, a spring at Bourbon-Nancy giving 10,000 litres per annum. The helium was separated by means of charcoal at the temperature of liquid air boiling under reduced pressure, and contained only a trace of neon as impurity.

DIARY OF SOCIETIES.

THURSDAY, MARCH 5.

ROYAL SOCIETY, at 4.30.—On the Atomic Weight of Radium: Dr. T. E. Thorpe, C.B., F.R.S.—On the Electrical Resistance of Moving Matter: Prof. F. T. Trouton, F.R.S., and A. O. Rankine.—On the Nature of the Streamers in the Electric Spark: Dr S. R. Milner.—The Relation between Wind Velocity at 1000 Metres Altitude and the Surface Pressure Distribution: E. Gold.

ROYAL INSTITUTION, at 3.—Early British History and Epigraphy: Sir John Rhys.

CHEMICAL SOCIETY, at 8.30.—The Solubility of Iodine in Water: H. Hartley and N. P. Campbell.—Traces of a New Tin-group Element in Thorianite: Miss C. de B. Evans.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Fuse Phenomena: Prof. A. Schwartz and W. H. N. James.

LINNEAN SOCIETY, at 8.—On the Morphology of Stigmaria in Comparison with Recent Lycopodiaceæ: Prof. F. E. Weiss.—On *Trichoniscoides albidus* and *T. sarsi*: Alexander Patience.—*Exhibits*: Fruit Destroying Flies: W. W. Froggatt.—Mimicry in the Common Sole: Dr. A. T. Masterman.

FRIDAY, MARCH 6.

ROYAL INSTITUTION, at 9.—The Figure and Constitution of the Earth: Prof. Love.

THE FIRST NILE CATARACT.

A Description of the First or Aswan Cataract of the Nile. By Dr. John Ball. Pp. 121; with 13 maps and plates, and 20 illustrations in the text. (Cairo: National Printing Department, 1907.) Price 200 milliemes.

AMONG the numerous valuable memoirs that have issued from the Egyptian Survey Department under the energetic administration of Captain Lyons, none is likely to prove of greater general interest to the public than this work of Dr. Ball. The easy accessibility of Aswan to visitors sojourning at Cairo, the wealth of objects of antiquarian interest in its neighbourhood, and the existence of that great engineering feat—the Nile dam—ensure the result of a constantly increasing stream of tourists to the district; and although the English, German and French guide-books to Egypt, published by Murray, Baedeker and Hachette respectively, have such a well-deserved reputation, yet the complete topographical and geological survey of the district, made by so competent an official as the author, has enabled him to supply many precise data and new observations not hitherto accessible to the writers of these guide-books. Dr. Ball, indeed, comes with excellent qualifications to the task before him; a good geologist, with special knowledge of petrography, he is at the same time skilled in surveying and engineering matters, while the account which he gives of the literature bearing on the district (pp. 15–20) shows that he has not been unmindful of the importance of this branch of knowledge in connection with a country having such a past as Egypt.

At the outset, the author has to correct the popular misconceptions concerning the nature of the Nile "cataracts." He writes:—

"There is nothing about a Nile cataract in any way resembling Niagara, nor even the Falls of the Rhine at Schaffhausen. The total fall of the water-surface at the First Cataract (between Philæ and Elephantine) is only about 5 metres in a length of about 9 kilometres; and although the greater part of the fall is concentrated within a fraction of this total length, it is only sufficient to give rise to rapids, and not to a waterfall in the ordinary sense of the term. The obstruction to navigation offered by a Nile cataract is in fact due, not so much to the velocity of the water, as to the irregularity and conflicting nature of the currents caused by the narrowness, winding nature and rocky state of the channels."

Aswan was always a place of great importance. Under its ancient name of "Syene," it is constantly mentioned by the writers of antiquity, including the prophet Ezekiel, and many of the Greek and Roman authors. It formed the limit between Egypt and Ethiopia (Nubia), and observations made on the shadows cast by gnomons erected at Syene and Alexandria respectively were employed by the early geographers in determining the size of the earth and the obliquity of the ecliptic. Although Syene was regarded as situated on the tropic of the Cancer, yet, as Dr. Ball points out, Aswan is really 37′ 57″ (71 kilometres) north of the tropic; and the period at which, by the secular variation of the obliquity, the site of Aswan coincided with the tropic was about 3500 B.C. Besides the gnomon, there were deep vertical wells sunk at Syrene, the bottoms of which were illuminated by the sun at midday at the summer solstice. These wells are mentioned by many ancient writers, including the geographers Strabo, Pliny, and Ptolemy.

The geological survey of this very interesting district was, of course, facilitated by the numerous excavations made during the construction of the great dam. But, on the other hand, the non-existence of any accurate topographical map of the district presented a difficulty which could only be got over by a complete survey of the whole area round the cataract. The line laid out for the dam by the engineers afforded Dr. Ball an excellent base-line, and from this a network of triangles was measured with a good theodolite, the details being filled in with sufficient accuracy by means of the plane-table. Heights were measured from the mean Nile level by the theodolite. This map, which is in six sheets, is a great improvement on any previous one, and has been issued by the Survey Department, its scale being $\frac{1}{10000}$, but a reduced copy forms plate i. of the work before us.

The geological formations present in the district as shown by the geological map (plate ii.) are:—

(3) Recent deposits, including those formed by the wind (desert sands) and those deposited by the river (Nile muds and sands).

(2) Nubian sandstones and clays, which cap many of the hills.

(1) Metamorphic and igneous rocks, constituting the foundation of the whole country.

The observations of the author on the chemical composition of the Nile muds and sands, and on the nature and form of the mineral particles present in them, are of great value and interest, and are illustrated by some excellent drawings, reproduced in collotype in plate iii. It appears both from recent analyses made in Cairo, as well as from the earlier work of Hofmann, that the Nile sands contain only small amounts of the hydrated aluminium silicates (kaolin, &c.), but consist mainly of finely comminuted felspars and other minerals, but little altered.

The work of the geological survey seems to have demonstrated that the Nubian sandstones in this district are wholly of Cretaceous age, although in the Sinaitic Peninsula there are Carboniferous sandstones of very similar appearance.

In opposition also to earlier statements made to the contrary, it is shown that the igneous intrusions are confined to the metamorphic rocks and that they are all older than the Nubian sandstone.

Aswan, or Syene, is of interest to petrologists from the circumstance that a large and important class of rocks derives its name from this locality. The name "Syenite" was first applied to the granitic rocks which were so familiar to the ancients from the circumstance that they were the materials of the great Egyptian monoliths (obelisks, statues, &c.). In 1788,

 U

Werner restricted the use of the term by making the hornblende-orthoclase rock of the Planenschen-grund, near Dresden, the type of the class; and now geologists are agreed in retaining the term for rocks with granitic structure but of intermediate composition, containing little or no free quartz, and having orthoclase as their predominant felspar. Rocks of this class do occur at Aswan, as shown by Dr. Ball, but they appear to be in all cases subordinate to the true granites with which they are associated.

The chief rocks quarried at Aswan, both in ancient times and also recently, for the construction of the dam, are these granites, sometimes coarse-grained and porphyritic, at other times fine-grained. Both hornblendic varieties and types of these rocks rich in mica occur, and by the diminution of proportion of the quartz and the increase in abundance of the subordinate plagioclase, the rocks pass locally by insensible gradations into syenites and diorites.

Full descriptions with excellent figures (plates iv. to xi.) are given by Dr. Ball, not only of these plutonic types, but also of the various metamorphic rocks, and of the rocks that form dykes cutting through both metamorphic and plutonic masses. The survey has, of course, given the author abundant opportunities for collecting specimens, of which he has made ample use. Like Prof. Bonney, who examined a series of the Aswan rocks collected by the late Principal Dawson in 1886, Dr. Ball is struck with the general resemblance of the metamorphic and igneous rocks, both of Upper Egypt and the Sinaitic area, to the Archæan rocks of North America, and he suggests that they may not improbably be of the same great antiquity. The crushing and faulting of these rocks with the intrusion of various dykes took place, the author of this memoir argues, at a date long subsequent to their formation, and this action continued quite down to Cretaceous times, when the Nubian sandstone was deposited quite unconformably on their greatly denuded surfaces. Near the cataract of Aswan no remains of the Eocene clays and limestones, found in other parts of Upper Egypt, occur—they have probably been removed by denudation. Subsequently to the Eocene period, there has been elevation and great denudation. At this period of elevation most of the faults which play such an important part, as shown in this memoir, in producing the general features of the cataract area were formed. By the denudation the older metamorphic and igneous rocks were exposed, and the escarpments and outliers of Nubian sandstone formed.

In the concluding pages of this interesting memoir the author adduces evidence to show that the ancient course of the Nile lay in a broad valley east of the present river, and he discusses the problem of the causes which have led to important changes in the course of the river and the effects of these changes on the character of the country. We must wait for the extension of the geological survey of Egypt, to districts which at present remain untouched, for a full solution of these problems. It is interesting to learn that, although the site of the great Nile dam was determined prior to the execution of the geological survey, Dr. Ball is of opinion that the line actually chosen for it was a satisfactory one, and that the results of the survey do not indicate that any better site could have been selected for it; and, further, that the straight form, finally adopted for the dam, has been at least equally successful in avoiding the difficulties presented by crushed and decayed rocks as would the curved form originally suggested.

J. W. J.

THE "HISTOIRE INTIME" OF NITROUS OXIDE.

Das Lachgas: eine chemisch-kultur-historische Studie. By Prof. Ernst Cohen. Pp. iv+99. (Leipzig: W. Engelmann, 1907.) Price 3.60 marks.

HABITUÉS of the Royal Institution, and especially those who have interested themselves in its early history, are aware of the existence of a characteristically coarse caricature of Gillray's entitled "Scientific Researches! New Discoveries in Pneumaticks! Or an Experimental Lecture on the Powers of Air," which first appeared in 1802, and is stated by Wright and Evans, who published in 1851 a descriptive account of Gillray's cartoons, to represent Dr. Garnett, the first professor of chemistry in the Royal Institution, administering, with the aid of his assistant, Humphry Davy, what is presumably laughing-gas to Sir John C. Hippesley, a noted patron of the Institution and prominent as a manager, with results disquieting to his "internal economy," and disastrous to "That garment 'twere rude to do more than allude to," as Thomas Ingoldsby says.

This print is hardly so rare as Prof. Cohen would seem to imply, and it has already done duty in connection with the early history of the Royal Institution. It—or rather what Prof. Cohen styles the *right* half of it—is reproduced in Thorpe's biographical account of Davy, published some years ago by Messrs. Cassell. Prof. Cohen, apparently on the sole authority of Pictet, who visited London in 1801, and contrary to all contemporary evidence and the testimony of the editors of Gillray's works, inclines to the opinion that the person administering the nitrous oxide is Thomas Young, who is styled professor of chemistry in the Royal Institution, a position he never held. Of course, a caricaturist like Gillray, who allowed himself unlimited licence, and was bound by no rules either of decorum or probability, might, in portraying a wholly imaginary incident, commit any anachronism he pleased. But there was no reason at the moment why Gillray should be guilty of the anachronism of putting Young into a position he never occupied, since Garnett was the actual professor of chemistry when Davy was assistant, and the humour of the incident—such as it is—is in no wise dependent upon what lecturer is behind the table. Pictet was certainly present at a symposium on a certain Saturday evening at the Royal Institution in the early summer of 1801, when, to quote from a letter from Davy to his friend King at Bristol, "there was respiration, nitrous oxide, and unbounded applause. To-morrow, a party of philosophers meet at the Institution to inhale the joy-inspiring gas. It has produced a great sensation

Ça ira." It was no doubt this "great sensation" that provoked Gillray's cartoon.

But who the lecturer may be would be a matter of small importance except for the circumstance that Prof. Cohen devotes much of his space to a somewhat laboured commentary on the print.

The caricature constitutes, in fact, as he explains in his preface, the *motif* of his little book—a fascimile reproduction of it is given as the frontispiece—and it was the chief inducement which led him to put together at such length the *histoire intime* of laughing-gas.

Such a book is probably not intended to be a serious contribution to historical chemistry. From the fact that it is dated from Zandvoort-Bad in the August of last year—that "summer of drear and dour, implacable rain"—we incline to the opinion that it was a holiday occupation imposed by the tedium of a particularly dolorous time.

With the aid of much "process work" and a wealth of classical allusion, Dr. Cohen has managed to pack within the compass of 100 pages the results of a considerable amount of bibliographical research on matters of no very great importance. Like the famous Cid Hamet, he is the most diligent searcher after the minutest circumstances, "even to the very atoms of his true history," and everything relating to laughing-gas—at least as regards its *histoire intime*—is set down with the most painstaking particularity. The history opens with Mitchill in America and his "oxide of Septon," passes on to Beddoes of Bristol and his Pneumatic Institution; the engagement there of Davy, and his discovery of the physiological effect of the respiration of nitrous oxide, which he prepared by the decomposition of ammonium nitrate in the manner first described by Berthollet and La Place, and, apparently independently, by Deiman and Paets van Troostwijk. There is, of course, no reason why chemistry should not have its Captain Gronow or its Greville memoirs, and, incidentally, Prof. Cohen has much to say of the personal history of certain of those whose names are connected, however slightly, with the *histoire intime* of nitrous oxide. The manner, for example, in which he runs his countryman Adriaan Paets van Troostwijk to earth is characteristic of your born commentator.

Davy's rhapsodical description of his sensations on breathing nitrous oxide is naturally given at length. Next we have a series of portraits, with here and there slight personal touches, of distinguished individuals who have breathed nitrous oxide, or who have seen others breathe it. They range from Southey and Coleridge in England to Fourcroy, Vauquelin, Thénard, Orfila, and Proust in France, and Pfaff and Wurzer in Germany. Indeed, the wealth of pictorial illustration of the *histoire intime* of nitrous oxide which Dr. Cohen's industry and perseverance have enabled him to accumulate is quite remarkable. The only omission we have been able to discover is a representation of a dentist's chair.

Davy's connection with the place, together with Gillray's caricature, is, of course, the main reason why Prof. Cohen devotes so much of his space to the early history of the Royal Institution, which *pace* Gillray and the symposium already referred to had very little to do with laughing-gas. To what extent the gas entered into its history may be seen from Pictet's lively account, published in 1802. Dr. Cohen, as becomes the true commentator, displays much erudition and no small amount of acumen in expounding the true inwardness of Gillray's drawing. The meaning is not very cryptic, after all. According to our author, the caricature must be regarded as directed against Rumford; it is, in fact, a satire on the Count, and incidentally on the Institution which he founded. Possibly this surmise is true, but the manner in which it is reached is even more humorous than the cartoon itself. So far as we are aware, no one has been at the pains to put forward any other interpretation—certainly none which would conflict with the view which Prof. Cohen has taken, and we are therefore content to be of his opinion, since "'tisn't worth while, it would seem, to dispute, when we know the result immaterial."

We congratulate Prof. Cohen on his interesting brochure. It is an elaborate trifle which may serve to beguile and amuse the tired researcher in his hours of ease. But if the *histoire intime* of chemical compounds, in general, say even of such things as arsenic, prussic acid, calomel or Epsom salts, were to become fashionable, what a literature we should have!

TRITUBERCULISM.

Evolution of Mammalian Molar Teeth, to and from the Triangular Type. (Biological Studies and Addresses, vol. i.) By H. F. Osborn; edited by W. K. Gregory. Pp. ix+250; illustrated. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1907.)

A QUARTER of a century ago next April, the late Prof. E. D. Cope, struck by the remarkable fact that the molar teeth, both upper and lower, of all the mammals from the Puerco or lowest Eocene horizon of North America carry three cusps arranged in triangular form, proposed what was practically the germ of the now well-known tritubercular theory. Briefly stated, this theory is to the effect that in the ancestors of all existing mammals each upper molar carried a triangle of cusps with the apex pointing inwards, while the corresponding lower teeth had a similar triangle with the apex directed outwards; and that from this primitive type have been evolved all the various modifications of molar structure, in most cases by the addition, but in certain instances by the subtraction, of cusps. The exponent, and to a great degree author, of the theory in its present form is Prof. Osborn, who has done well in laying before the scientific world the evidence for and against this fascinating doctrine.

For it has to be acknowledged that while the tritubercular theory was received with acclamation when first promulgated in its full development by the author of the volume now before us, there has of late years been a certain reaction in this respect as the result of hostile criticism and alternative hypotheses furnished by anatomists and microscopists of great scientific repute. Prof. Osborn is, however, fully convinced of the ultimate triumph of the theory; and, indeed, goes so far as to state that, in his opinion, "the evidence in favour of it is so overwhelming that primitive trituberculy is no longer an hypothesis or a theory, but an established fact."

That a theory, although established on what appears to be a firm basis of fact, may require revision in certain details is a matter of everyday experience, and our author is fully prepared to admit such emendations in this particular case so soon as the necessity can be proved to be imperative. One of the points against which criticism has been concentrated is the author's view that the apex of the triangle in both the upper and the lower molars represents the single cone of the ancestral reptilian tooth. In the case of the lower teeth, embryological evidence coincides with Prof. Osborn's theoretical view; but as regards the upper molars the testimony of embryology points to the conclusion that, at least in many groups, the antero-external, in place of the internal, is the primitive element. The author meets this and other objections by the candid statement that the five great principles on which the theory was originally based "do not stand or fall together"; one or more may go, or have to be modified, without imperilling the hypothesis as a whole; and even if the cusps ultimately prove not to be strictly homologous with one another in different groups, "the homological nomenclature should be retained for convenience because it has found its way so largely into literature."

The homology and origin of the cusps are, however, by no means the sole object of attack on the part of critics. Among other objections, reference may be made to the multitubercular theory, according to which molars have tended to simplify rather than to grow more complex. This hypothesis is met by the author, and we think rightly, with a direct negative, and certain other objections receive equally summary treatment.

As regards the plan of the work, it is important to notice that the contents are in the main formed by separate papers on trituberculism, which have been arranged in chronological order, and, where necessary, brought up to date by intercalary notes. This plan has its advantages and disadvantages. Its advantages are that the history of the controversy is easy to follow, while the disadvantages are manifest in the shape of a considerable amount of repetition. We are also left in doubt at the end of the volume as to what the author's present views really are with regard to several points on which his theory has been challenged.

To do anything like justice to the work demands much more space than can be given to it in this notice. All that can be done is therefore to direct attention to its importance and interest, and at the same time to express the opinion that the author has succeeded in placing trituberculism on a much more secure and unassailable basis than it ever previously occupied.

R. L.

OUR BOOK SHELF.

Nature and Development of Plants. By C. C. Curtis. Pp. v+471. (New York: Henry Holt and Co., 1907.)

THE author of this book has set himself a definite task, namely, to give an account of plant life, with special reference to that aspect which presents it as a working organism. Dr. Curtis is to be congratulated on the success with which he has achieved his object, for he has produced an excellent and readable book which may be confidently recommended for the use of junior classes in this country. Naturally, some of the actual examples may prove unfamiliar to the student, but the majority of the plants chosen for illustration are readily accessible to all.

The "nature of the plants" occupies the first part of the book, and it is this portion which strikes us as especially good. The second part is devoted to the development, meaning thereby the phylogenetic classification of the vegetable kingdom; and here again Dr. Curtis has, we think, contrived to sustain the interest in a branch of botany which, as treated in elementary works, is often intolerably dull. He has introduced a certain amount of advanced work in this part of the book, though with a judicious absence of unnecessary detail.

Perhaps a degree of emphasis, rather greater than is warranted by our knowledge, is laid on the relation between alternation of generations and chromosome reduction. The discussion also as to the meaning of unit characters and the method of their inheritance strikes us as too formal and dogmatic to be very useful. But these are small blemishes in a work where there is so much that merits praise.

The numerous and excellent illustrations form a distinct feature of the book, but we note two amongst them which might well be replaced. Fig. 43, and the text which accompanies it, represent a very diagrammatic and not very normal mode of secondary thickening, whilst Fig. 85 certainly ought to be redrawn. A seedling castor-oil plant is not the furry object there represented.

J. B. F.

The Diseases of Animals. By Nelson S. Mayo. Third edition. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1907.) Price 6*s*. 6*d*. net.

THIS work, which purports to be one of popular advice on the care and common ailments of farm animals, is written entirely from the American point of view, and deals with American methods principally, in most distinctly American orthography. It cannot be doubted that its usefulness to the British rural public, not less than the pleasure of reading it, are considerably lessened thereby. It is decidedly irritating to readers on this side of the Atlantic to see such abominations as "sulfur," "esophagus," "sulfate," "mold," and others of a similar kind. There is, nevertheless, a good deal of useful and practical information on the care of animals and farm stock which the farmer would do well to know, no matter in what part of the world he carries on his occupation. In fact, that portion of the book which deals with feeding, watering, exercise, and the hygienic care of domestic animals, both stock and pets, is in our opinion by far the most useful to the general reader. In this section dogs, cats, rabbits, hares, guinea-pigs, and poultry are dealt with, in addition to the farm animals proper.

The photographic illustrations of the animals themselves are good, but some of those representing morbid conditions are of little value, for example, that of tuberculosis of the lung (p. 380), which could give no assistance to the non-expert.

In a work of this kind it is doubtless difficult to deal satisfactorily with the pathological side, and it is a question whether such morbid processes as those of tumours would not be better omitted. In any case, we cannot agree with such statements as:—"True cancers are not common to animals," and, further, that cancers "are most frequent on the head and lower part of the legs." In the section on tuberculosis, the author is satisfied to leave the question of the identity or otherwise of human and bovine tubercle with Koch's original statement of non-communicability, ignoring all that has been done on the subject since that statement was made. Some other conditions, for example, rickets, are very inadequately described.

So far as this country is concerned, there is still room for a good up-to-date popular scientific work which will give the farmer such simple knowledge of the breeding, accidents, and diseases of his animals as will show him the occasion and the wisdom of consulting the skilled veterinarian. G. L.

Traité de Chimie analytique qualitative, suivi de Tables systématiques pour l'Analyse minérale. By Louis Duparc and Alfred Monnier. Second edition. Pp. viii+374. (Paris: Félix Alcan; Geneva: Librairie Kündig, 1908.)

THE first edition of this book on analytical chemistry appeared in 1900. In the present, second, edition there has been added a preliminary theoretical portion with the object of giving an insight into the reactions which take place during the analytical operations; this new portion gives an account of the atomic theory, the theory of solutions, and the theory of chemical equilibrium. Then follows the usual description of apparatus, reagents, and methods of manipulation. The main portion of the book is occupied by an enumeration of the reactions of the bases and acids, including the more common organic acids, and more briefly of the rare metals and alkaloids. In each case the reactions which take place are expressed by chemical equations. The book is intended to be a laboratory companion and work of reference not only for the student but also for the analytical chemist. Its value, however, for reference purposes is much lessened by the want of an index, though a full table of contents is given at the end of the volume.

Actualités scientifiques. By Max de Nansouty. Pp. 316. (Paris: Schleicher Frères, 1907.) Price 3.50 francs.

THIS volume is the fourth issue of an interesting and useful annual publication which on previous occasions we have commended to the notice of science students. Now that ability to read French is expected of science graduates in the University of London, books which provide means for a student to enlarge his vocabulary and at the same time to improve his knowledge of science should be very popular. The selection of subjects is very wide; *e.g.* articles are included on colour photography, the extraction of gold from the sea, spontaneous combustion, laughing, and artificial flowers.

(1) *California and the Californians.* Pp. 48. (2) *The Alps of King-Kern Divide.* Pp. 22. By President D. S. Jordan, Stanford University. (San Francisco: A. M. Robertson, 1907.)

THESE are two readable essays, the first of which appeared in the *Atlantic Monthly* ten years ago, while the other is reprinted from "Out West." The booklets should be read by visitors to California, and they may be commended also to the general reader, to whom the excellent illustrations will be an interesting feature.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Isothermal Layer of the Atmosphere.

THOSE who, like myself, have followed with interest, but at a distance, the attempts made during recent years to obtain direct information as to the meteorological conditions of the upper atmosphere, cannot but have felt a curiosity on some points which Mr. Dines's letter in NATURE of February 27 serves to deepen. To one who has had experience of the vagaries of self-recording instruments, the first question that suggests itself is what degree of reliance can be placed on the results obtained during *individual* ascents, whether of kites or of balloons. Supposing a temperature of −70° F. recorded, the total range of temperature between the ground and the "isothermal layer" will usually have exceeded 100° F.; thus a 3 per cent. or 4 per cent. error in the scale—an amount not infrequently exceeded in ordinary thermographs limited to ordinary surface temperatures—would suffice to give an uncertainty of 3° F. or 4° F., which seems all that Mr. Dines is prepared to allow. But, apart from mere scale errors, is it certain that there are no other sources of uncertainty in meteorograph records from kites or balloons even when these are sent up after nightfall?

Before attempting to explain such large differences as Mr. Dines mentions between the temperatures in the "isothermal layer," shown by meteorographs sent up on the same day from stations only a few hundred miles apart, one would like to know exactly what the evidence is that the temperatures recorded differ at most only 3° F. or 4° F. from the true ones. The following questions naturally suggest themselves:—

(1) Are the instruments tested over the whole range encountered in the atmosphere, both before and after an ascent?

(2) Has it been a frequent practice to send up two or more thermographs with the same balloon, or with separate balloons, but at the same station and at the same time, and if so, have they always given closely accordant results?

(3) Has it been established by actual trial that the different types of meteorographs, English and foreign, when sent up at the same time from the same station, give a satisfactory agreement?

Mr. Dines mentions a case when the temperatures found for the "isothermal layer" at three English stations on the same day varied from −42° F. to −74° F. An uncertainty of ±4° F. could account for only a quarter of this, but an uncertainty of ±8° F. might account for a half, and an uncertainty of ±16° F. for the whole. Now is there conclusive evidence that uncertainties of the order ±10° F. are quite out of the question?

March 3. CHARLES CHREE.

The Solidification of Helium.

IN the telegram from Prof. Kamerlingh Onnes announcing the solidification of helium, the statement is made that "the last evaporating parts show considerable vapour pressures as if liquid state is jumped over"—in other words, it apparently sublimes.

I have for a long time expected that this would be the case. When the boiling points and melting points of the non-valent elements are plotted against their atomic weights the curves nearly meet, the two points for argon being very near to one another. By a slight extrapolation they may be made to meet, and they then do so for an atomic weight much higher than that of helium. Now if an element corresponded to the meeting point its triple point would be given by the temperature at the join. Elements of lower atomic weight would sublime instead of melting. This is apparently the case for helium, and it is a moot point whether or not it will be found to be also so for neon. The uncertainty arises from the rapid drop in the curves in passing to the row of elements N, O, Fl, to which neon belongs. Each curve can be represented very nearly by a parabola. ALFRED W. PORTER.

University College, London, March 6.

Disease-resisting Sugar-canes.

It is observed in your issue for November 7 last in the article entitled "Immunity to Disease among Plants," being an abstract of a letter delivered before the British Pharmaceutical Conference at Manchester by Prof. F. E. Weiss, that the following statement occurs:—

"In the West Indies, the Bourbon cane has been given up on account of disease, but very useful and disease-resisting hybrids have been produced by crossing the valuable but easily attacked Tjeribon cane with the resistant Indian Tschan cane."

The latter canes are not known in the West Indies, and it is desirable, therefore, that the actual facts be placed on record.

When the Bourbon sugar-cane had to be abandoned in the West Indies on account of its susceptibility to fungus disease, its place was generally taken by the White Transparent—an introduced variety. Since then the latter is being largely replaced by seedling canes. These seedlings have been produced in some instances from the Bourbon cane, and, recently, almost entirely from the better of the newer seedling varieties under experiment. It may be of interest to mention that in British Guiana the area under cultivation with varieties of sugar-cane other than Bourbon is about 30,000 acres, and the greater portion of this area is occupied by seedling canes. In the island of St. Kitts about 71 per cent. of the sugar-cane acreage is occupied by seedlings. Seedling canes are also being largely planted at Barbados, Antigua, St. Lucia, and Jamaica. Many of the newer seedlings appear to be immune to some of the fungus diseases that affect the sugar-cane in these colonies, and the efforts in the direction of producing seedling canes by artificial cross-pollination give promise of success.

In Java the circumstances are also somewhat similar. The Cheribon cane had to be abandoned on account of its being liable to the "sereh" disease, and amongst the foreign varieties introduced to take its place was the East Indian cane Chunnee. In 1894 it was found that the Cheribon cane bore a large proportion of infertile pollen with a normal ovary, while the Chunnee produced a very large quantity of fertile pollen. Advantage was taken of this to plant the two varieties side by side in the hope of producing hybrids by natural means. Considerable success has been attained, for a very large number of seedlings was obtained by sowing seeds from the "self-sterile" arrows of the Cheribon, many of which combine the high sugar content of the Cheribon with the disease-resisting power of the Chunnee. Other introduced canes have also been used in these experiments, and somewhat similar experiments are in progress in the West Indies.

A *résumé* of the "Improvement of the Sugar-cane by Selection and Hybridisation" (with coloured plates) was presented by Mr. F. A. Stockdale and myself at the conference on genetics held in London in August, 1906, under the auspices of the Royal Horticultural Society. The society issued a full report of the conference in February, 1907. The paper referred to has since been reproduced in the *West Indian Bulletin* (vol. vii., No. 4).

Barbados, February 14. D. Morris.

Modern Views of Electricity.

To avoid misunderstanding, I write to say briefly, in connection with a review by "N. R. C." on p. viii of the supplement to Nature of March 5, that I have never supposed space to be a conductor, but have always taught the opposite view; and that I have never imagined unmodified ether to be subject to gravitation, or to be other than the vehicle of that property of matter. If any phrases in my book suggest the contrary they are examples of faulty expression. But I would add, parenthetically, that I should not scruple to speak, untechnically, of the centre of gravity of a surface. Oliver Lodge.

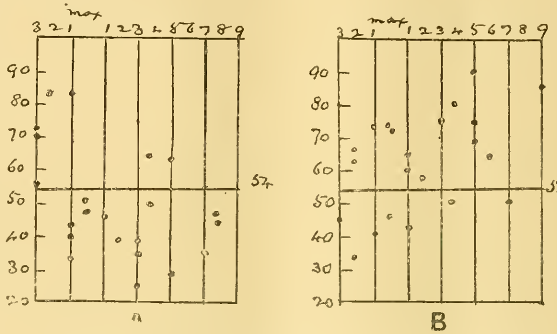
Rothesay Summers and Greenwich Winters.

Last summer at Rothesay (N.B.) was very wet, with 14·8 inches (average, 11·3 inches). The current winter season at Greenwich may now be pronounced a mild one.

It is a curious fact (whatever the explanation) that a very wet summer at Rothesay tends to be followed by a mild winter at Greenwich, and a very dry summer by a severe winter. This is connected, I believe, with the fact that the rainfall of Scotland and the winter cold of Greenwich both exhibit pretty clearly the influence of the sun-spot cycle.

Suppose we pick out the twenty-two wettest and the twenty-two driest summers at Rothesay in the sixty-six years 1841–1906 (*i.e.* a third in either case). The former group range from 19·1 inches down to 12·6 inches; the latter from 5·9 inches up to 10·7 inches. Next, consider what sort of winter at Greenwich followed each of these (say, how many frost days in the period September to May).

These winters may be represented as in diagrams A and



The scale of frost days at Greenwich is shown on the left, and that of the sun-spot cycle at top of each diagram. A, Winters after very wet summers. B, Winters after very dry summers.

B, where a dot indicates by its position both the number of frost days of one winter and its position in the sun-spot cycle.

It will be seen that the twenty-two "very wet" Rothesay summers were followed by fifteen mild and seven severe winters at Greenwich (A), and the twenty-two "very dry" Rothesay summers by fifteen severe and seven mild winters at Greenwich (B). The contrast is still more pronounced if we confine attention to the period of *decline* of the sun-spots.

These diagrams seem to warrant two practical rules, which may be thus stated:—

During decline of the sun-spots, if summer rainfall at Rothesay exceeds 12·6 inches, a mild winter at Greenwich is highly probable (say, 6 to 1), and if during the same period the Rothesay summer rainfall is under 10·7 inches a severe winter is highly probable (say, 3 to 1). In the former case a very severe winter, and in the latter a very mild winter, would seem to be excluded.

We are at present close to a maximum (1905 or 1907?), and have to do with diagram A, which shows no severe winters for the corresponding position in the cycle.

Alex. B. MacDowall.

The Possibility of Life in Mars.

At the risk of being thought by your correspondent, Mr. C. O. Bartrum, an "anthropomorphist," I consider that Prof. Lowell in his admirable investigations of the markings of Mars is quite reasonable in ascribing the change of colour to the presence of a vegetation containing a substance allied to, if not identical with, chlorophyll. I do so because the spectroscope has shown that, not only the solar system, but the whole universe, is built up of inorganic elements similar to those found on the earth. If we find unity of plan pervading the structure of the most distant stars, surely it is not beyond credibility to assume that the organic worlds may have a like relationship to each other when other circumstances are favourable.

Hove, March 3. W. AINSLIE HOLLIS.

The α Particles from Radio-active Substances.

THE experiments of Rutherford and Hahn have shown that the ratio e/m has the same value, 5×10^3, for α rays, no matter from what source the rays are derived. They are, however, taken alone, incapable of deciding whether the particles are hydrogen molecules carrying the usual ionic charge, or helium atoms with twice that charge. In a recent paper in Roy. Soc. Proc., Prof. Townsend has shown that the positive ion produced by Röntgen rays has twice the ionic charge at the moment of formation. If his further experiments prove this true generally, then the question whether the α rays are hydrogen or helium must be definitely decided in favour of the latter, and the association of this gas with radio-active substances is accounted for. R. S. WILLOWS.

Cass Institute, E.C.

ANCIENT EGYPTIAN BURIAL CUSTOMS.[1]

WE have had to wait some little while for Prof. Garstang's publication of his discoveries in the necropolis of Beni Hasan during the years 1902–3–4. However, "better late than never." The publication is issued under the auspices of the University of Liverpool, in which Mr. Garstang now professes the methods and practice of archæology. We must congratulate Prof. Garstang on his appointment. As a professional excavator of untiring industry and "go," he has been known to the archæological world for some years; and he has been a lucky excavator also. Nobody knows better than the digger that luck, no less than a keen eye and "sense of the probable," knowledge of the appearance of disturbed and undisturbed land, &c., is an important ally to him; and the discoverer of the other half of the Menes tablet at Nagada should gratefully admit his obligations to Dame Fortuna.

No such stroke of luck marked the excavations at Beni Hasan. The results were all what might have been expected and predicted of a necropolis of the eleventh and twelfth dynasties. Except for a few more than usually elaborate models and some very fine cartonnage mummy-coverings of a type not previously noted, they are not new. As always in tombs of this date, we have little but the rectangular coffins and models of workmen, slaves, boats with their crews, granaries, and so forth, which are well known in our museums. A large number of tombs was discovered, and the number of objects found in them was enormous. How to publish this huge mass of material, mostly of types already well known, was a difficult question.

To publish everything scientifically, in the manner of the Egypt Exploration Fund, would have been a most expensive task, as well as (since the antiquities found are mostly of a kind well known already) an unnecessary one. A scientific publication of similar type, but containing only the most important finds, would have been the expedient which most archæologists would have adopted. Prof. Garstang has, however, chosen rather to adopt a novel plan; he has written simply a description of the burial customs of the Egyptians under the Middle Kingdom, illustrated by typical examples of the objects found at Beni Hasan. Whether this decision was wise or not it is difficult to say. As a matter of personal opinion, the other alternative of a modified publication on the lines of one of the annual volumes of the Egypt Exploration Fund would seem preferable. The result of Prof. Garstang's decision is that we have here a book which is at once a more or less popular work on the burial customs of ancient Egypt, but only deals with this subject in part, and a scientific report of the results of the excavations at Beni Hasan which is of unhandy form, and is written and illustrated in an inconvenient way. The book is too heavy as well as too expensive for a popular treatise, while for a scientific work the larger format of the Fund's publications is infinitely preferable. The treatment of the subject-matter is too general and scrappy for a scientific report, and the illustrations, being scattered throughout the text instead of concentrated in plates, may be appropriately arranged for a popular book, but are most ill designed for reference by the scientific student. On the whole, we think Prof. Garstang's decision unfortunate, and we hope that in future he will publish his discoveries in the admirable manner of his former publications, with their large, thin format and groups of plates at intervals throughout the volume. Let him keep his strictly scientific publications and his *œuvres de vulgarisation* entirely apart. A popular book from his pen on the burial customs of ancient Egypt which should really cover the whole subject would be most welcome.

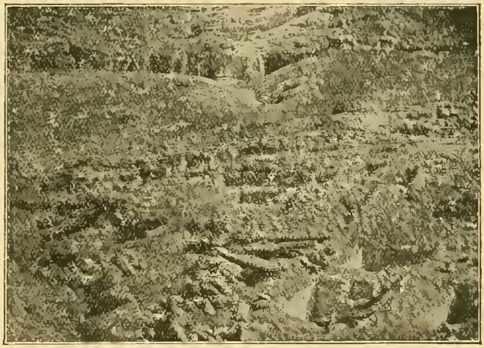


FIG. 1.—Position of the Pit Tombs below the Gallery.

In spite of its defects, however, the present volume is a most interesting contribution to archæological literature. As specimens of the admirable photographs with which it is illustrated, we here reproduce in Fig. 1 a view showing the position of the pit-tombs excavated by Prof. Garstang in relation to the gallery-tombs of the princes of Beni Hasan, which are so well known to every visitor to Egypt; in Fig. 2 a view of the interior of a tomb as discovered and after removing the *débris*, which shows how the coffins and models of boats, &c., are found, and incidentally shows how thorough Prof. Garstang's archæological methods are in respect of complete photographic recording; and Fig. 3, a model of a group of two officers playing draughts on board ship, showing the cabin against which are propped their great shields and arrow-cases. This is a very interesting specimen of the numberless models found, which give us so complete an idea of what the

[1] "Burial Customs of Ancient Egypt." By Prof. J. Garstang. Pp. xv+250. (London: A. Constable and Co., Ltd., 1907.) Price 1*l.* 11*s.* 6*d.* net.

Egyptians looked like in the third millennium B.C. Of no other people at so remote an age do we know so much, and we may well bless that pious care for the

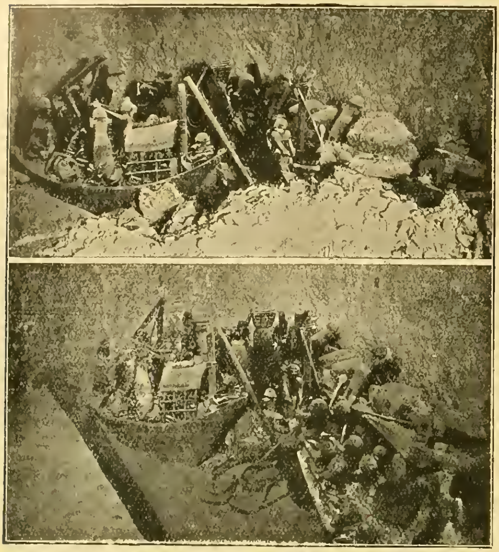

FIG. 2.—(a) Interior of Tomb as discovered. (b) The same after removing the Débris.

ancient dead which provided them with these little representations of their life on earth.

Very few slips of any kind have crept into the text, but we notice one on p. 169, in which it is said that the names of the vases and other offerings painted on the coffins illustrated in Fig. 171 "are given in difficult hieratic writing." The names shown are in linear hieroglyphics, and are quite easy to read. The

FIG. 3.—Officers playing Draughts on board ship. Model from a Tomb.

only unworthy photograph in the book is Fig. 4, in which the cliffs illustrated are by no means clear.

At the end of his preface, Prof. Garstang says that his assistant, Mr. Harold Jones, is now leaving him to pursue an independent path as a painter. This is to be regretted from the point of view of archæology, as Mr. Jones would, as his work with Prof. Garstang has shown, have been a valuable recruit to the ranks of the excavators.

H. R. HALL.

SLEEPING SICKNESS.[1]

WHEN the campaign against malaria was commenced, our knowledge of the parasitic agent of that disease was practically complete, and in no essential particular has our knowledge of the mode of transmission changed since the discovery of the anopheline-malarial cycle. But when we consider sleeping sickness the matter is very different. Our knowledge of trypanosomes is even yet in its infancy. It has, for instance, been asserted over and over again that sexual differences exist in trypanosomes, and on this basis have been constructed developmental cycles which indeed may exist, but in proof of which the evidence hitherto adduced has been practically nil; and indeed two of the latest observers, Moore and Breinl, not only find no evidence of this sexual difference, at least in the blood, but describe two new phases of trypanosomes, viz. a so-called minute latent form, which comes into existence mainly when the ordinary forms from one cause or another have disappeared from the peripheral circulation, and resistant cystic forms, which appear when an animal is treated with atoxyl.

We have, according to these authors, a cycle of the trypanosome going on in the body hitherto unsuspected, and we also have encystment of trypanosomes under injurious influences. If this be true, it shows that, unlike malaria, we know but little of the complete life-cycle of trypanosomes, for of these forms we know so far only of their bare existence. This discovery, then, opens the whole question of the life-cycle of trypanosomes, including the question also whether there are sexual forms or no. There are further questions which are equally obscure. While, in the case of malaria, shortly after the discovery of the all-essential importance of some of the anophelines in its transmission close attention was paid to the habits of these mosquitoes, in the case of tsetse-flies we know about their habits comparatively little. It is perhaps an exaggeration to say that we know now no more about tsetse-flies than we did when Bruce discovered that *Gl. morsitans* transmitted the trypanosome (*T. brucei*) of ngana, but at any rate we can sum up in a few words what we know of the habits of the fly:—(1) The only place so far discovered where the tsetses deposit their larvæ has been among the roots of banana-trees; (2) they haunt the scrub or bush along the margins of lakes and rivers, and are seldom found far from water. The reason for this distribution is unknown, though one might conjecture that it has something to do with their food supply. (3) The sources of their food supply are also very imperfectly known. Is blood a necessity for their existence in nature? That they pursue man voraciously is known, but what other animals do they feed on? Koch recently has confirmed the observation that they suck crocodiles' blood, and holds that this is their main if not sole food; and has even gone so far as to suggest that the destruction of crocodiles would cause the disappearance of the fly. The

[1] Proceedings of the First International Conference on the Sleeping Sickness held at London in June, 1907; and further paper respecting the Proceedings of the Conference.

destruction of crocodiles is a comparatively easy matter, as the eggs, sixty or seventy, can be collected from the nests, the sites of which are well known to the native. Possibly, however, aquatic birds would still furnish them with blood. The duration of their life, their breeding habits, the habits of different species, the conditions which give rise to "fly belts," are almost unknown. It is somewhat remarkable that so little is known, although many expeditions have now studied sleeping sickness; the fly, however, has surely been somewhat neglected. One fact of great practical importance has, however, become clear, viz. that clearing the jungle drives away the fly, and to this we shall return. When we consider next the mode by which the fly transmits the disease, we find ourselves in the midst of controversy.

One view is that the transmission is a mechanical one, *i.e.* the fly carries infection as an inoculating needle from one animal to another, and the known experimental facts entirely support this view; and, further, we have the fact that in Dourine this is the sole (? also by fleas) known method, the mechanical transmission being in this case by sexual intercourse, a method which, according to Koch, also takes place to some extent in sleeping sickness. Another view, that a developmental cycle goes on in the fly, is based mainly on analogy and on the alleged existence of sexual forms of trypanosomes in the blood, and more especially in the gut, of flies. We will not enter here into the wilderness of arguments, but point out the following facts. The tsetses used for experimental purposes have hitherto, almost without exception, been caught in nature, consequently, *ex hypothesi*, some of them must contain the trypanosome in the required hypothetical developmental stage. These flies have then been fed on infected animals, and it was found that when now fed on fresh animals the latter only became eventually infected if the period that elapsed since the last feeding on infected animals was not longer than forty-eight hours, a fact explained on the mechanical view by the statement that after this time no longer can trypanosomes be found in the proboscis. Now, if these flies, on the contrary, contained a developmental stage of trypanosome, this result is inexplicable except on one hypothesis, viz. that during the feeding on infected animals (an unnecessary procedure on this view) the flies completely get rid of all trypanosomes in the necessary developmental stages in their salivary glands (?) by the preliminary feeding on the infected animals. This objection could be met by keeping flies caught in nature for forty-eight hours more or less. If now they are capable of infecting fresh animals it would be in favour of the developmental view and against the mechanical one; if not capable of infecting it would negative the developmental view, provided, of course, sufficient experiments were made to allow for experimental error, &c.

We might point out in this connection a possible explanation of the difficulties encountered by some observers in obtaining positive results in transmission experiments. In the case of anophelines caught actually in native huts where the inmates were highly infected with malaria, we have ourselves in certain instances found only 3 per cent. of the anophelines infected with parasites, a remarkably low figure. Had these anophelines been caught in cow-houses, where they often abound, we consider that it would have been possible to dissect thousands and find none infected. Now, in the case of tsetse-flies, they are not found in houses, but live in the open, so that unless the flies have bitten man they will not become infected with the trypanosome (unless, indeed, they have bitten some other unknown host), and if the flies used in these experiments are collected from parts of the bush where they have not bitten man (or other host of the trypanosome), it would be quite conceivable that thousands of flies might be used in transmission experiments with negative result, and even if they had an opportunity of biting man it is still conceivable that the number of infected ones might be very small if we consider the fact of the low figure of 3 per cent. for infected anophelines found by us in certain highly malarious districts.

If we consider the matter from another standpoint we see that again our knowledge is wanting. What is the source of the *T. gambiense*? Is it purely a man-to-man infection, as we believe to be the case in malaria, or can the fly convey the trypanosome to man from various animals? This would seem to be likely, for experimentally the fly has been proved to transmit to monkeys, so that there seems to be no *a priori* reason against thinking that the flies can transmit not only from man to man, but from man to animals and from animals to man. If this is so (but arguments can be brought against this view), then it has an important bearing on the results of isolation of the sick, for the remaining healthy population may be still living amidst infected animals, domestic and wild.

In cattle in the Congo, in sleeping-sickness areas, it is believed that the trypanosome is a different one, viz. *T. dimorphon*. Even if other reservoirs of *T. gambiense* exist, it must be admitted that the removal of the sick would remove one important source of infection, whatever proportion these bear to other reservoirs (if existent) of *T. gambiense*.

We should consider, then, that this is perhaps the most important point which requires immediate solution, and it can be determined only by a long series of laboratory inoculations.

A further point for decision, as we have seen, is the mode of transmission, mechanical or developmental, or both. This, perhaps, is of scientific rather than of immediate practical importance. Thirdly, we require a careful extended study of the habits of the fly.

But although much investigation remains to be done, we may now briefly recount what is being carried out in the light of our present knowledge.

Sleeping sickness can be detected in its early stages, first, by the enlargement of glands, *e.g.* those in the neck, an almost constant phenomenon (and the glands on puncture show trypanosomes); and, secondly, by the method recently used by Koch of examining fairly thick stained blood films on several occasions. We have thus means at our disposal of detecting early cases even when the person is to all outward appearances healthy.

(1) *Isolation.*—The removal of infected persons so far as possible to localities free from the fly, where they may be suitably treated, is certainly imperative.

(2) *Inspection posts.*—The spread of the disease to non-infected areas where the fly exists by means of infected persons should be controlled so far as possible by medical examination at inspection posts along the main routes of traffic. Although no doubt some will escape detection, yet the method is one which enables us largely to control the spread of the disease.

(3) *Treatment of the sick.*—We have in atoxyl an arsenic compound first introduced by Thomas and Breinl, undoubtedly the best drug hitherto used in combating the disease. Undoubtedly cases of sleeping sickness in Europeans have been cured by it, and lately Koch, in an extended trial of the drug, has spoken in laudatory terms of its use. He recommends the giving of half-gram doses on two consecutive days at intervals of ten days, and continuing the treatment for long periods. The method is slightly different from that advocated by the Liverpool School of Tropical Medicine when it first distributed atoxyl throughout the Congo, but Koch has

only modified the dosage, and he adds his testimony to the great value of the drug.

This method, should nothing supersede it, will thus become almost as valuable as that of quinine in the treatment of malaria. In Koch's words, "Daraus geht doch aber mit aller Bestimmtheit hervor, dass durch eine geeignete Atoxyl behandlung sehr vielen Schlafkranken das leben gerettet werden kann."

(4) *Destruction of tsetse-flies.*—This, so far as we know at present, is not directly practicable, but the flies can be driven away by cutting the jungle. The making of clearings where the natives most frequent, such as at watering places, river fords, and around villages, will certainly be beneficial.

For the present, then, we have at our disposal methods the results of which we shall soon learn. In conclusion, it is, I think, certain that when some of the disputed points indicated above are settled the campaign against the disease will be carried out with greater efficiency because based on more certain knowledge. J. W. W. S.

WATER VAPOUR IN THE MARTIAN ATMOSPHERE.

ONE of the most telling arguments which has been used against the possibility of the planet Mars being habitable has been that spectroscopists have failed to detect with certainty the presence of water vapour in the planet's atmosphere. It now seems probable that this objection will have to be abandoned, for, in a telegram recently received by Sir Norman Lockyer, Prof. Lowell announces that Mr. Slipher has got on repeated plates—specially prepared for this research—the water vapour bands *a* and near D stronger in the spectrum of Mars than in that of the moon at the same altitude.

Should Prof. Lowell's further researches confirm it, this result is one of the most important links in the remarkable chain of evidence for a habitable Mars. The photography of the canals was a great step forward, but the presence of these features was unconvincing unless it could be proved that the water to fill them in their proper seasons was available. Similarly, the seasonal increase and decrease in the dimensions of the snow-caps were thought to be conclusive evidence for the presence of water until the frozen carbon dioxide theory was advanced, although this theory left unexplained the ill-defined edges of the disappearing snowfields. But, so far as our present knowledge goes, it is difficult to see how carbon dioxide is able to produce the intensification of the water-vapour bands in the spectrum of the planet's atmosphere.

For many years, in fact since the actual existence of permanent features on the planet's surface was established, this question of water vapour—of the existence of a substance capable of producing clouds and mists—has been one of the chief points of contention among areographers. So far back as 1863 Sir Norman Lockyer, in a communication to the Royal Astronomical Society (Memoirs, vol. xxxii., p. 179, 1863), describing his observations of Mars during the opposition of 1862, stated that "although the complete fixity of the main features of the planet has been thus placed beyond all doubt, daily—nay, *hourly*—changes in the detail and in the tones of the different parts of the planet, both light and dark, occur. These changes are, I doubt not, caused by the transit of clouds over the different features." The drawings accompanying the memoir illustrated the changes mentioned, and confirmed the suspicions of cloud effects noticed by Secchi in 1858. But the assumption that these effects were caused by clouds and mists entailed the assumption of the presence of water vapour in the planet's atmosphere, and the spectroscopic evidence for this has hitherto been too indefinite. Suspected by Huggins and Vogel in 1867 and 1873 respectively, its presence was negatived by the subsequent spectroscopic researches of Campbell and Keeler, but now it appears certain, from this latest result from the Lowell Observatory, that water vapour is one of the concomitants of the Martian atmosphere.

In his recent book, "Is Mars Habitable?" reviewed by Dr. Lockyer in NATURE for February 13 (p. 337), Dr. Russel Wallace insisted on the absence of spectroscopic evidence as a strong argument against the presence of water vapour. This objection is now removed, and once more it becomes reasonable to suppose that the Martian surface is, at least to some extent, supplied with that compound which, to terrestrial minds, is one of the essentials of habitability. At the same time, the theories advanced by Prof. Lowell to explain the remarkable variety of appearances and changes from season to season, disclosed by his wonderful observations, have received support worthy of their brilliant conceptions.

WILLIAM E. ROLSTON.

NOTES.

IN an announcement in last week's NATURE it was stated that Prof. Kamerlingh Onnes had succeeded in liquefying helium. It should have been stated that the gas was solidified, no intermediate liquid stage being observed. The demonstration was made in the presence of Prof. H. A. Lorentz and Prof. J. P. Kuenen, both of the University of Leyden. The method adopted is described by the Leyden correspondent of the *Daily Telegraph* (March 10) as follows, and is the same as that used with success by both Sir James Dewar and Prof. Olszewski. The only noteworthy point is the large amount of helium used for the instantaneous expansion. "To make this experiment," Prof. Onnes says, "I placed a tube with thick sides, containing a thinner one for extra protection against external warming influences, in a vessel filled with liquid hydrogen, at $-434°$ F., and in this tube about one and a half gallon of helium was compressed under 100 atmospheres. On allowing expansion to a lower temperature a cloud appeared, which increased as the expansion *in vacuo* continued. Out of the nebulous mass a white flocculent substance gathered in the inner tube, where—although the tube was well closed—it evaporated within twenty seconds. Some solid substance, however, was left, the pressure in the tube meanwhile rising to one atmosphere, and when the valve was opened and the pressure was reduced this substance exhaled almost immediately, no sign of liquefaction being observable. The substance which remained at a temperature of $-434°$ F. was solid helium." We are glad to be able to print the telegraphic message sent to Sir James Dewar by Prof. Onnes on March 5, and Sir James Dewar's reply to it:—Prof. Onnes to Sir James Dewar, Royal Institution, London: "Converted helium into solid. Last evaporating parts show considerable vapour pressures, as if liquid state is jumped over." Sir James Dewar to Prof. Onnes, University, Leyden: "Congratulations. Glad my anticipation of the possibility of the achievement by known methods confirmed. My helium work arrested by ill-health, but hope to continue later on."

THE council of the British Association has nominated Prof. J. J. Thomson, F.R.S., as president of the association for the meeting to be held next year in Winnipeg, and Prof. Thomson has accepted the invitation to occupy that office.

THE third congress of experimental psychology will be held at Frankfort on April 22–25.

WE deeply regret to announce that Dr. H. C. Sorby, F.R.S., died at Sheffield on Monday, March 9, at eighty-one years of age.

PROF. E. RUTHERFORD, F.R.S., has been awarded the Bressa prize of 9600 lire (384*l.*) by the Turin Academy of Sciences.

PROF. H. POINCARÉ, professor of mathematical astronomy in the University of Paris, has been elected a member of the French Academy.

PROF. W. S. HANDLEY will deliver the Hunterian lecture on "The Natural Cure of Cancer" at the Royal College of Surgeons to-morrow, Friday, March 13, at 5 p.m.

A REUTER message from Melbourne reports the death on March 8, at seventy-seven years of age, of Dr. A. W. Howitt, C.M.G., author of "The Native Tribes of South-East Australia" and other important anthropological works.

A CELEBRATION of the jubilee of the presentation of the Darwin-Wallace joint essay to the Linnean Society on July 1, 1858, will take place on July 1 next; the details are not complete, but it is intended that an afternoon meeting and an evening reception shall take place on the day named, with the award of copies of a special medal, and subsequent publication of the proceedings of the celebration.

THE steamer *Nimrod*, of Lieut. Shackleton's Antarctic expedition, has returned to Christchurch, New Zealand, from the Antarctic. The *Nimrod* is expected to return to the Antarctic next January to fetch the expedition, and she should be back in England some time in the later part of 1909. The *Daily Mail* of March 7 contains a narrative of the expedition, so far as it has gone, by the leader, Lieut. Shackleton.

THE President of the Local Government Board has authorised for the current year the following researches, in addition to those already announced, under the grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease:—(1) further studies by Drs. Andrewes and Horder as to methods of inhibiting in the animal body the activities of infection by certain cocci; (2) a study of the various forms of pneumonia, especially in children, by Mr. Foulerton; (3) a study of acid-fast bacilli in butter, by Dr. Nabarro; (4) an investigation of the injurious gases evolved during artificial illumination, by Dr. J. Wade.

REUTER'S Agency states that the second International Conference on Sleeping Sickness met on Monday at the Foreign Office. It is understood that the chief business of the conference will be the discussion of a draft general Act dealing with measures for combating the disease which has already been drawn up by the British Government and submitted to the various countries represented at the conference. There is further to be discussed a counter-draft Act prepared by the German Government which contains some slight modification of the British proposals. The complete list of delegates of the seven countries represented at the conference is as follows:—*Germany:* Dr. Robert Koch, Herr H. de Jacobs, Dr. Steudel; *Spain:* the Marquis de Villalobar, Dr. F. Murillo Palacios; *Congo Free State:* Colonel Lantonnois, Dr. van Campenhout; *France:* M. Le Myre de Vilers, M. Ronssin, Dr. Kermorgant, Dr. Cureau, Dr. Giard; *Great Britain:* Lord Fitzmaurice, Sir W. Foster, M.P., Mr. A. W. Clarke. Mr. H. J. Read, C.M.G., Sir Patrick Manson, Dr. Rose Bradford, F.R.S., Sir R. Boyce, F.R.S., Colonel D. Bruce, C.B., F.R.S.; *Italy:* Prof. Rocco Santoliquido, Prof. Adolfo Cotta; *Portugal:* Dr. Ayres Kopke. The Lord Mayor will entertain the president and delegates of the conference at luncheon at the Mansion House on Monday next, March 16.

WE regret to read in Tuesday's *Times* that Dr. W. E. Wilson, F.R.S., died on Friday last, March 6, at fifty-six years of age. For many years Dr. Wilson gave disinterested and devoted attachment to research in astronomy and physics, and his work secured for him a high place among scientific investigators. In December, 1870, he was engaged on the total solar eclipse expedition to Oran, and in 1872 he built an astronomical observatory at Daramona, Ireland, and equipped it with a 12-inch reflector by Grubb. Nine years later this was superseded by a more completely equipped observatory containing a fine reflecting telescope of 2 feet aperture, with mounting of the most modern design. In 1891 this was re-mounted and provided with electric control for astronomical photography. With this instrument Dr. Wilson obtained some remarkable photographs of celestial objects, including the moon and many nebulæ and stellar clusters. In later years a physical laboratory and mechanical workshop were added to the astronomical observatory, and in the laboratory many important researches on radiant heat and light were carried on by him. Among the subjects of his papers read before various scientific societies are "Experimental Investigations on the Effective Radiation from the Sun." Other important publications of his are entitled "The Absorption of Heat in the Solar Atmosphere," "The Temperature of the Carbons in the Electric Arc," "The Effect of Pressure of the Surrounding Gas on the Temperature of the Crater of the Electric Arc," "The Thermal Radiation from Sun-spots," and "Radiation from a Perfect Radiator." His papers published before the year 1900 were issued separately in a volume entitled "Astronomical and Physical Researches made at Mr. Wilson's Observatory, Daramona, Westmeath," in which appear reproductions of some of his celestial photographs. Dr. Wilson's scientific work was recognised by his election as a Fellow of the Royal Society in 1896, and by the degree of Doctor of Science conferred on him, *honoris causa*, by Dublin University a few years later.

BY the untimely death, at the age of sixty-one, of Sir Denzil Ibbetson, India has lost one of her most eminent anthropologists. He joined the Punjab Civil Service in 1870, and his remarkable report on the revision of settlement in the district of Karnal, situated in the south-east of the province, led to his appointment as superintendent of the census of the province in 1881. The report on Karnal was a remarkable achievement. It was based upon a profound knowledge of the peasant classes, their mode of life, social institutions, and religious beliefs. Students of the rural classes in northern India had long been aware that their religion was to be found, not, as the Max Müller school contended, in the sacred books recorded in Sanskrit, a language familiar only to a few Pundits, but in the cults and beliefs connected with the worship of the rural "godlings," as Ibbetson designated them. But the case for this novel view of Indian popular religion was now for the first time clearly advocated in attractive literary form, and from intimate, personal knowledge. These conclusions were repeated and extended in his census report of 1881, which, in addition to admirable chapters on peasant religion, contained a singularly elaborate account of Hindu and Mussulman castes, tribes, and sects. The weak point of the investigation was that it was purely ethnographical, and ignored the physical characteristics of the people, a subject of which the writer possessed no knowledge. This report, of which the chapters on religion and caste were reprinted in 1883 under the title of "Outlines of Panjab Ethnography," forms an excellent manual of the subject. Additions to the information contained in it have, it is true, been made in the later census reports of Messrs. E. D. Maclagan and H. A. Rose, but the substantial accuracy of Ibbetson's work remains unaffected. His reports suggested and inspired the investigations on similar lines conducted by Sir H. Risley in Bengal, by Mr. W. Crooke in the United Provinces of Agra and Oudh, and by Mr. E. Thurston in Madras. The Punjab Government would be well advised to re-publish, as the best memorial of the late Lieutenant-Governor, the reports on which his reputation as an anthropologist will mainly depend.

A further contribution to the mass of literature relating to the Mexican cotton-boll weevil is made in Bulletin No. 73 of the Entomological Bureau of the U.S. Department of Agriculture, in which Mr. W. D. Price discusses the numerous parasites preying upon that beetle.

We have received a copy of the forty-first report of the Peabody Museum of American Archæology and Ethnology at Harvard, in which special attention is directed to an expedition recently sent to South America to procure collections. The expedition, which has been well received by the officials of the various districts visited, has already secured valuable specimens and data.

In the eighth quarterly report on the scientific work of the Lancashire and Western Sea-Fisheries District, Prof. Herdman announces that, owing to his absence on a visit to the Ceylon pearl-oyster fisheries, the publication of the annual sea-fishes laboratory report will be delayed for a short period beyond the usual date. Plankton will form a considerable item in that report; while of more general interest will be an account, by Mr. J. Pearson, of all that can be ascertained with regard to the life-history and economic value of the edible crab.

Bulletin No. 50 of the Agricultural Experiment Station at Storrs, Connecticut, is devoted to the rearing of young pigeons—"squabs" as they are locally called—for the market. It is generally supposed that this industry is one which can be profitably undertaken by any person with no previous experience, but this the author—Mr. C. K. Graham—shows to be an altogether mistaken idea. In a properly managed establishment each pair of pigeons ought to produce on an average five pairs of squabs annually; only a few produce more than seven pairs, and in one case where eleven were brought forth none of these were reared to maturity.

The February issue (vol. ii., No. 4) of the *Journal of Economic Biology* is devoted to the parasitic insects of the Chermes and Coccus groups, Mr. E. R. Burdon discussing the European members of the former genus, while Mr. R. Newstead describes three species belonging to the same family as the latter found on cocoa, rubber, and other plants in western Africa. In the case of Chermes, it is stated that much investigation is still required with regard to the life-history of the European species, some of which present puzzling problems in connection with their migrations and the "intermediate hosts" they affect during their developmental cycles. The second paper deals mainly with structural details.

To the fiftieth volume, part iii., of the Smithsonian Miscellaneous Contributions, Mr. Bruno Müller contributes a long and elaborate paper on the air-sacs of pigeons, based on an investigation undertaken for the purpose of finally setting at rest the disputed question as to the function of these structures in birds generally. The author refuses to accept any one of the theories hitherto proposed, and comes to the conclusion that the air-sacs, together with the air-cavities in bones, are not to be regarded as organs with any special function, but rather as a system of empty interspaces. "Their value lies in their emptiness, that is, in their containing nothing that offers resistance or has an appreciable weight. Flying is the highest form of locomotion, and as such only possible to a body of high mechanical efficiency. Our most effective machines are by no means compact and solid, but composed of parts as strong as possible in themselves and arranged in the most appropriate manner. The interspaces between the parts are left empty and taken up by air. The Sauropsida, at the time they obtained the power of flight, became adapted to its mechanical requirements, and thereby similar to the efficient machines mentioned above; they divested themselves of all superfluous material, filling the body-space thus obtained with air sacs."

In No. 29 of the Scientific Memoirs of the Government of India, Captain Christophers, I.M.S., discusses the disease of dogs due to the protozoan parasite *Piroplasma canis*. The symptomatology of the disease, the morphology of the parasite, and its transmission by the tick *R. sanguineus*, are fully described, and the developmental cycle of *P. canis* in the tick detailed. In the tick the parasite becomes a club-shaped body, then a zygote which breaks up into sporoblasts, and these again into sporozoites. A full bibliography of piroplasmosis in general is appended, and the memoir is illustrated with diagrams and two plates. In Memoir No. 30 of the same series, Captain Harvey, I.M.S., and Captain McKendrick, I.M.S., discuss the theory and practice of antirabic immunisation, and conclude that the methods of Högyes and of Ferrans, in which fresh material is used, present certain advantages over those in which dried or heated material is employed for purposes of antirabic immunisation.

The geographical variation in birds, with especial reference to the effects of climatic humidity, forms the subject of a paper by Mr. C. W. Beebe in the first number of a new serial issued by the New York Zoological Society. Unfortunately, the cover and title-page are lettered *Zoologia*, whereas, as we learn from an erratum-slip, the designation should be *Zoologica*. The serial is published by the society at New York, the first number being dated September 25, 1907. Mr. Beebe attaches great importance to the effects of humidity in producing local phases in particular species, and refers to the well-known fact that while hot, damp situations tend to melanism, dry, sandy localities are equally favourable to the production of light tints. One of the most marked instances of this occurs in the pigeons of the genus Scardafella when kept in captivity in a warm, humid atmosphere. In the typical *S. inca* the whole breast is uniformly pale-coloured, but specimens kept in captivity under the above conditions assume after the first moult the characters of *S. i.*

dialeucos, and after the second those of the Brazilian *S. ridgwayi*, which exhibit a progressive degree of dark marking on the breast. Later on the captive birds develop dark markings unparalleled in any wild species. The author then discusses the bearing of these facts on the recognition of geographical races and species of birds, concluding, if we rightly understand his argument, that such recognition need not on this account be abandoned.

It is a matter of considerable interest to botanists that a new edition of the "Botanist's Directory" is being prepared by Mr. I. Dörfler, of Vienna. The last (second) edition was published in 1902, and owing to the changes that take place in six years is much in need of revision. The care bestowed on the work by the publishers, and the general support accorded by botanists in all parts of the world, render the book authentic and remarkably complete.

Dr. S. Schonland contributes to the Records of the Albany Museum, vol. ii., part ii., the diagnoses of new species of Aloe, Crassula, Cotyledon, and Kalanchoe collected in various South African States. The most singular is *Crassula Engleri*, of which all the flowers examined showed stamens only and no female organs, furnishing evidence of diœcism. The same author is responsible for the first part of a list of flowering plants found in the districts of Albany and Bathurst, Cape Colony, that is supplementary to an earlier enumeration in the Records. A new species of Gasteria is recorded.

The physiology and morphology of some Californian hepatics form the subject of a paper contributed by Mr. H. B. Humphreys to the Proceedings of the Washington Academy of Sciences, vol. x. (January). The author describes an endophytic fungus developing sclerotia that was commonly found in the vegetative parts of plants of *Fossombronia longiseta*. Fungi were also found associated with *Aneura multifida*, *Anthoceros Pearsoni*, and *Porella bolanderi*. In all these cases there was every indication that the fungus acted as a parasite. Another feature of interest examined was the development of tubers by the Fossombronia and two species of Anthoceros; these serve to tide the plants over the dry season. The author also investigated the power of plants and spores to resist desiccation. The use of Knop's solution for germinating spores is noteworthy.

A monograph on the stem of the flax plant, prepared by Miss T. Tammes, has been published in the *Natuurkundige Verhandelingen van de hollandsche Maatschappij der Wetenschappen*, vol. vi., part iv. Certain problems connected with flax culture, such as the usual practice of importing seed from Russia, the influence of soil, dimensions of the fibres, &c., are discussed. With regard to the origin of the cultivated plant, the author sees no reason to connect it with *Linum angustifolium*, *Linum humile*, or any other wild species. It was found that the length of the fibres, varying on the average between 25 mm. and 40 mm., is greatest in long and thick stems; a maximum length of 120 mm. is recorded. The fibres increase in length from the base of the stem upwards to within a short distance below the fruit.

The Carnegie Institution of Washington has issued an elaborate research memoir, covering 144 pages, on high steam-pressures in locomotive service, by Mr. W. F. M. Goss. The results apply to practice involving single-expansion locomotives using saturated steam. The results of the tests show that the higher the pressure the smaller the possible gain resulting from a given increment of pressure. A simple locomotive using saturated steam will render efficient service when the running pressure is as low as 160 lb. No argument is to be found in the economic performance of the engine which can justify the use of pressures greater than 200 lb.

Five palæontological contributions to the geology of Western Australia are contained in Bulletin No. 27 of the Geological Survey of that colony. They comprise notes on plant remains from the Collie coalfield by Mr. R. Etheridge, and on fossils from the same coalfield by Mr. F. Chapman, two reports on fossils from the Irwin River coalfield by Mr. R. Etheridge, and a report on the foraminifera from a calcareous marlstone at Gingin by Mr. W. Howchin. They add considerably to the knowledge of the organic remains of the rocks of Western Australia, and two of the contributions throw light upon the vexed question of the geological age of the Collie River Coal-measures, and are of scientific interest in their relation to the important question of the distribution of Glossopteris flora. A re-examination of two leaf fragments, previously thought possibly to belong to the Mesozoic genus Sagenopteris, proves them to belong to the Palæozoic genus Glossopteris.

The occurrence of "black rain" in Ireland on October 8–9, 1907, is reported by Dr. O. Boeddicker in *Symons's Meteorological Magazine* for February. On the afternoon of October 8 a dark cloud approached Birr from the S.E., and "black rain" was reported from several places. A letter addressed by Lord Rosse to the *Irish Times* brought a large number of replies, showing that the fall of soot was greater to the S.E. and E. of Birr than to the N.W.; the deposit was considerable in Westmeath, Meath, and Monaghan, and was also traced to the west of Mayo. The evidence seems to show that the cloud originated in South Wales, crossed the Irish Channel and the whole of Ireland, finally disgorging its soot into the Atlantic Ocean.

In *Ciel et Terre* of January 1, M. J. Vincent gives an account of the unmanned balloon ascent of July 25, 1907, in which the extraordinary altitude of 26,557 metres was reached. The tandem balloons left Uccle (near Brussels) a few minutes before 7h. a.m. (G.M.T.), wind E.N.E., temperature 12°·1 C. The usual inversion was well shown; at 12,112 metres the fall in the thermometer, which read −57°·0 C. (−70°·6 F.), was arrested, and was succeeded by a sudden rise of 6°·7 C. between that height and 13,591 metres. An isothermal zone was then met with, followed by another rise which slowly brought the reading to −42°·2 at about 8h. 6m. a.m., the time when the upper balloon burst. The ventilation of the thermometer was sufficient during the whole of the ascent. The humidity began to decrease rapidly at 1016 metres, where it was 72, at 1690 metres it was 22, and at 6109 metres it had fallen to 9; it decreased but little after that, the lowest reading being 6. At the time of the inversion the wind changed from S.S.W. to W.; then during the slight inversion which followed up to 26½ kilometres two currents were met with, the lower from S.S.E. and the upper from E.; on descending, the S.S.E. current was replaced by a southerly wind.

A thorough examination of the relative merits of the radiomicrometer, the linear thermopile, the radiometer, and the bolometer, for the measurement of radiation, has been made by Mr. W. W. Coblentz, of the United States Bureau of Standards, and is published in the January number of the Bulletin. The conclusion arrived at is that the bolometer is the quickest acting of the four, and should be used in all cases in which there is much variation of the radiation with time. On the other hand, if the source of radiation is constant, the radiometer is the most sensitive, particularly in the infra-red. The radiomicrometer, although capable of improvement, is not likely to reach one-fifth the sensitiveness of the bolometer. The Rubens thermopile, when its heat capacity is diminished by the use of thinner wire, is as sensitive as the bolometer, and is to be recommended for the measurement of very weak radiation on account of its greater steadiness.

ACCORDING to the *résumé* of communications made to the Societé française de Physique on February 7, Drs. Hemsalech and de Watteville find the flame spectra of metals extend far into the ultra-violet, and are much richer in lines than they have been thought to be. The method used by the authors is a modification of that originally used by M. Gouy. They obtain the finely divided material to be studied, and mix it with the gases proceeding to the burner, by forming an electric arc between two electrodes of the material placed in a bulb through which one of the gases passes. If two such arcs between different metals are used, the spectra of the two metals are superposed. If the gas is filtered between the arc and the flame the lines are scarcely affected, while the continuous spectrum is very much diminished in intensity.

WE have received from Messrs. John Wheldon and Co. a catalogue of books and papers offered for sale on microscopical science in all its branches, including an important collection of works on Diatomaceæ.

A CIRCULAR has reached us referring to the issue of publications in connection with the Indian Forest Department. It has been decided that in future the forest literature shall appear in two chief forms, described, respectively, as Indian Forest Records and as Memoirs. In addition to these publications, it is proposed to issue pamphlets and leaflets on professional subjects.

THE Royal Statistical Society has issued a new catalogue, which comprises, with certain exceptions, all works included in the society's library on December 31, 1906. The number of books and separate publications is approximately fifty thousand. The general rules adopted in the compilation of the catalogue are stated with clearness, and statisticians should find the new list a great convenience.

THE Society for Promoting Christian Knowledge proposes to issue the following books on scientific subjects in May next:—"Turbines," by Engineer-Commander A. E. Tompkins, R.N., second edition, enlarged and revised; "Spinning Tops," by Prof. J. Perry, F.R.S., revised edition, with an appendix on the gyrostat and the monorail; "The Fundamental Conceptions of Chemistry," by Prof. S. M. Jorgensen, translated from the latest German edition, with additions by Mr. M. P. Applebey.

OUR ASTRONOMICAL COLUMN.

THE PARALLAX OF THE ANDROMEDA NEBULA.—No. 4, vol. viii., of the *Astronomiska Iakttagelser och Undersökningar å Stockholms Observatorium* is devoted to the results of an investigation of the parallax of the Andromeda nebula. The observations on which the results are based were made in two groups, the first set of fifteen photographs being taken during the period 1902–4, the second, including forty-seven photographs, covering the season 1904–5. Dr. Karl Bohlin, by whom the investigation has been carried out, describes fully the methods employed, and finds for the parallax of the nebula the definitive value $+0''\cdot171$.

THE ORBIT OF γ VIRGINIS.—A re-investigation of the orbit of γ Virginis has convinced Dr. Doberck that the differences between the calculated and observed positions of that star, when near the periastron passage, are at least partly due to the perturbations to which he recently directed attention. It also seems probable that changes in the shapes of the components, and even explosive action, may exert some influence on the orbit. Dr. Doberck suggests that spectroscopic observations of double stars should prove especially useful in cases where the orbit is very eccentric if made while the companion is close to the principal star. The elements now given show the period of γ Virginis to be 182·30 years, and the eccentricity of the orbit to be 0·88736. The hypothetical parallax is $0''\cdot116$ (*Astronomische Nachrichten*, No. 4235, p. 161, February 29).

THE LARGE SOLAR PROMINENCE OF MAY 21, 1907.—In No. 1, vol. xxvii., of the *Astrophysical Journal* (p. 78, January), Father Fényi compares his visual observations of a large eruptive prominence which he observed at Kalocsa on May 21, 1907, with the photographic observations of the same prominence made by Mr. Fox at the Yerkes Observatory (NATURE, p. 90, No. 1987, November 28, 1907). The visual observations give lower altitudes than the photographic, and, on comparing the sketch made at the same time as Mr. Fox's second photograph, it is seen that the forms are so different that no part of them can be identified; on the whole, the sketch more strongly resembles the first photograph made some fifty minutes earlier. The visual observations also show a much quicker ascension of the prominence material than do the simultaneous photographs, the rate being 54 km. per second instead of 30 km.; no change of form was observed visually during the time occupied in observing eleven transits. Father Fényi records that he has never observed the subsidence of a prominence of great height. With prominences of low altitudes the descent of the material is the usual occurrence, but dissipation at great altitudes appears to be the rule for those which attain great heights.

SPANISH OBSERVATIONS OF THE TOTAL SOLAR ECLIPSE OF AUGUST, 1905.—The results of the eclipse observations made at Soria, Spain, in August, 1905, by the members of the eclipse expedition from the Marine Observatory of San Fernando, are embodied in a handsome volume recently published under the direction of Captain Don Tomás de Azcárate, director of the observatory. Numerous photographs of the chromospheric spectrum and of the corona were obtained, and some of them are reproduced in the volume. Nearly five hundred lines were measured in the spectra of the chromosphere, and their wave-lengths are given, together with the probable origins and their wave-lengths as determined by Lockyer, Dyson, Evershed, and other eclipse observers. The volume also contains the results of the meteorological observations made at Soria, and the results of the observations of the contacts, &c., made at San Fernando and many other stations in Spain.

A NEW VARIABLE OF THE U GEMINORUM TYPE.—A telegram from the Kiel Centralstelle announces that the variable star 31.1907 Aurigæ was observed by Prof. Hartwig on March 6 and found to be of the irregular class, similar to U Geminorum; the magnitude was 9·0.

THE CANADIAN ASTRONOMICAL HANDBOOK FOR 1908.—The second annual handbook published by the Royal Astronomical Society of Canada contains a great deal of information useful to amateur astronomers. Ephemerides and charts for the positions of the major planets, lists of interesting coloured, variable, and double stars, and a calendar of astronomical occurrences for the current year are among the many useful data given, whilst there is also a mass of information more especially useful to Canadian observers.

THE USE OF GYROSTATS.

At a recent meeting of the Physical Society a model was exhibited which purported to illustrate Mr. Brennan's mono-rail railway. Prof. Perry, president of the society, made the following remarks, which he was afterwards requested to edit and publish:—

In 1874 two famous men made a great mistake in endeavouring to prevent the saloon of a vessel from rolling by using a rapidly rotating wheel. Mr. MacFarlane Gray pointed out the mistake. It is only when the wheel is allowed to precess that it can exercise a steadying effect; the torque or moment which it exerts is equal to the angular speed of precession multiplied by the moment of momentum of the spinning wheel.

It is astonishing how many engineers who know the laws of motion of translation are ignorant of angular motion, and yet the analogies between the two sets of laws are perfectly simple. I have set out these analogies in my book on "Applied Mechanics."

The last of these, between centripetal force on a body moving in a curved path and torque or couple on a body rotating about an axis, is the simple key to all gyrostatic and spinning-top calculations. When the spin of a top is greatly reduced, it is necessary to remember that the total moment of momentum is not about the spinning axis (see my "Applied Mechanics," p. 594). Correction for this is, I suppose, what introduces the complexity which scares the students of the subject of the vagaries of tops; but in all cases that are likely to come before an engineer, it would be absurd to study such a correction, and consequently calculation is exceedingly simple.

Inventors using gyrostats have succeeded in doing the following things:—

(1) Keeping the platform of a quick-firing gun level on board ship, however the ship may roll or pitch. Keeping a submarine vessel or flying machine with any plane exactly horizontal or inclined in any specified way. These were probably first described by Mr. Brennan. It is easy to effect such objects as these without the use of a gyrostat. By means of spirit levels it is possible to command powerful electric or other motors to keep anything always level. The actual methods employed by Mr. Beauchamp Tower (an hydraulic method) and by myself (an electric method) depend upon the use of a gyrostat which is really a pendulum, the spinning axis being vertical.

(2) Greatly reducing the rolling or pitching of a ship, or the rolling of a saloon in the ship. This is the problem which Mr. Schlick has solved with great success, at all events in the case of torpedo-boats.

(3) In Mr. Brennan's mono-rail railway, keeping the resultant force due to weight, wind pressure, centrifugal force, &c., exactly in line with the rail, so that however the load on a waggon may alter in position, and although the waggon may be going round a curve, the waggon is quickly brought to a position such that there are no forces tending to alter its angular position. The car leans over *towards* a sudden gust of wind or towards the centre of curvature if going round a curved rail.

(4) I need not refer to such matters as the use of gyrostats in the correction of compasses on board ship.

Problems (2) and (3) are those to which I wish to refer. It is to be remembered that without gyrostatic apparatus a ship is necessarily stable, a mono-rail waggon is unstable.

Mr. Schlick uses a large wheel of ten or twenty tons revolving about an axis EF (Fig. 1), the mean position of which is vertical. Its bearings are in a frame EFCD, which can move about a thwartship axes CD. Its centre of gravity is below this axis. Let the ship have rolled through the small angle R from its upright position; the axis EF has precessed through the angle P from a vertical position. Let θ stand for d/dt. Let the moment of momentum of the wheel about its axis be m. Now if the ship were held fast so that she could not roll, we might study the vibratory motion P. The effect of the roll is merely to introduce a term $m\theta$R increasing P. Thus we have

$$I_1\theta^2P + f\theta P - m\theta R + bP = 0. \quad . \quad . \quad . \quad . \quad (1)$$

where $f\theta$P is a fluid friction introduced by dash pots acting at A and B, bP is the righting moment of the frame, and I_1 its moment of inertia about the thwartship axis. Now write out the usual equation of motion of the ship vibrating about a longitudinal axis through its centre of gravity, its moment of inertia being I, but introduce a moment $m\theta$P tending to diminish R.

Then we have

$$I\theta^2R + F\theta R + m\theta P + a(R - \alpha) = 0. \quad . \quad . \quad . \quad (2)$$

if $\alpha = \alpha_0 \sin qt$ is the thwartship inclination of the *sea* to the horizontal, and a is the righting moment of the ship per unit angle, being the weight of the ship multiplied by the metacentric height. $F\theta$R is the moment due to friction against the sea.

Solving these equations just as if θ were a constant, we have from (1)

$$P = \frac{m\theta R}{I_1\theta^2 + f\theta + b},$$

so that (2) becomes

$$\left(I\theta^2 + F\theta + a + \frac{m^2\theta^2}{I_1\theta^2 + f\theta + b}\right)R = a\alpha. \quad . \quad . \quad . \quad (3)$$

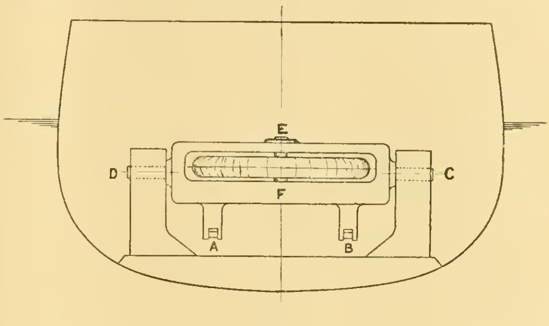

FIG. 1.

Clearing of fractions we find

$$\{II_1\theta^4 + (FI_1 + fI)\theta^3 + (aI_1 + bI + m^2 + Ff)\theta^2 + (bF + af)\theta + ab\}R = (I_1\theta^2 + f\theta + b)a\alpha. \quad . \quad . \quad . \quad (4)$$

Replacing θ^2 by $-q^2$, and θ^4 by q^4 (see my "Calculus for Engineers," p. 237), we can at once express $\frac{R_0}{\alpha_0}$ if R_0 is the amplitude of the roll, and, of course,

$$P_0 = \frac{mqR_0}{\sqrt{(b - I_1q^2)^2 + f^2q^2}}. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

I am here studying the forced vibrations, and not the natural vibrations. In any particular case it is quite easy to calculate R_0/α_0 for a number of values of q, and information is obtainable which is quite different from what comes from a study of the natural vibrations (that is, taking $\alpha = 0$). Besides, it is the very easiest kind of arithmetical calculation, replacing rather troublesome mathematics. To many, indeed I may say to all students, the calculation of the unreal roots of a biquadratic is troublesome, and this must be done if the natural vibration is to be studied. It is obvious that the real parts of the roots of the resulting equation in R (when α is 0) are negative, and therefore the motion is stable.[1]

If, however, we make a of (2) negative, as it is in the

[1] The well known conditions that the real parts of all the roots of $\theta^4 + a\theta^3 + b\theta^2 + c\theta + d = 0$ shall be negative, are that a, b, c, and d shall be positive, and also that $abc - c^2 - a^2d$ shall be positive.

Brennan case, it will be found that the motion is not stable. Even without friction the vibration would become greater and greater, and friction makes matters worse. Indeed, no form of the Schlick method can be applied to the Brennan waggon. But to return to the ship.

It will be found that the amplitude of P is much greater than that of R, and in practice it is necessary to have stops to prevent P becoming too great. Of course, when further increase of P is prevented by a stop, the roll proceeds as if the wheel were not spinning.

I have not seen it mentioned, but I should think that Mr. Schlick would let his wheel revolve like Mr. Brennan's, in a very perfect vacuum inside a case, because the power wasted in friction of a wheel against an atmosphere is proportional to the density of the atmosphere. I have found that the best shape of wheel is one like a fly-wheel with a thin disc inside the rim instead of arms; there is more moment of momentum per pound to be obtained in this way than by building up a wheel like a compound disc, as a gun is built up of tubes shrunk on; and also it is much better than the form of wheel adopted by Laval in his turbine. I need not say, also, that the moment of momentum per pound of steel is proportional to the radius of the wheel; the greater the radius, therefore, the better.

It is assumed that by the use of bilge keels and rolling chambers, and as low a metacentric height as is allowable, we have already lengthened the time of vibration and damped the roll R as much as possible. Using (2) or (5), we find P if R is known, and usually the quick vibration is much more magnified in P than the slow one.

Let us consider a numerical example. Using engineers' units, let $I=10^8$, $a=2\times10^7$, $I_1=7000$, $b=70{,}000$, $m=2{\cdot}5\times10^6$, and $F=4\times10^6$, and let us find answers to (4) for two values of f. These numbers are nearly right for a vessel of 6000 tons, metacentric height 18 inches, with a natural period of fourteen seconds. Its gyrostat wheel weighs about ten tons, with a 6-feet radius and an angular velocity of 100 radians per second. The frame and wheel have an oscillating period about the axis CD of about two seconds. These answers are compared with the case of the gyrostat not in action, that is, $m=0$, or precession prevented.

If the gyrostat is not in action, it is easy to see that

$$R_0=\alpha_0\div\sqrt{\left(1-\frac{I}{a}q^2\right)^2+\frac{F^2}{a^2}q^2}\quad . \quad . \quad . \quad (6)$$

The natural vibration has a damping term $\epsilon^{-Ft/2I}$ with a periodic time nearly $2\pi\sqrt{\frac{I}{a}}$.

I take F such that the amplitude diminishes by about 25 per cent. in one period (about fourteen seconds). It will be noticed that the F term of the formula (6) is important only near the critical q or $q=0{\cdot}4472$. It will be found that the F term in (4) is of insignificant effect.

Again, the values of $\frac{R_0}{\alpha_0}$ get large for large values of q, because there is a quick natural vibration as well as a slow one. I have not thought it worth while to tabulate these higher values.

T	q	Values of R_0/α_0		
		Gyrostat not acting	Gyrostat acting	
		$f=5\times10^4$	$f=5\times10^4$	$f=15\times10^4$
630	0·01	1·0	1·0	1·0

11·42	0·55	1·92		
10·5	0·6	1·25	0·55	0·351

It is interesting to calculate $P_0\div\alpha_0$ for all values of q, and especially for the larger values of q.

Free Vibration.—Using the above numbers and $\alpha=0$, so that the ship is gradually coming to rest, we are led to

$$R=A\epsilon^{-0{\cdot}02t}\sin 0{\cdot}447t\quad . \quad . \quad . \quad . \quad . \quad (7)$$

if the gyrostat is not acting. This is a periodic time of fourteen seconds, and the damping is such as to reduce the amplitude of roll by 25 per cent. in each complete period.

When the gyrostat is acting and $f=50{,}000$, we are led to

$$R=A\epsilon^{-0{\cdot}025t}\sin 0{\cdot}324t+B\epsilon^{-3{\cdot}573t}\sin(2{\cdot}519t+e)\quad . \quad (8)$$

We may neglect the quick vibrations of $2\frac{1}{2}$ seconds' period, which are damped out very rapidly. The slower have a period of nineteen seconds, the amplitude of roll being diminished by 30 per cent. in every complete period. Note that $P_0=50\,R_0$ if $q=2{\cdot}519$, and $P_0=11{\cdot}3\,R_0$ if $q=0{\cdot}324$.

When the gyrostat is acting and $f=3\times10^5$, or six times as great, we are led to

$$R=A\epsilon^{-0{\cdot}02t}+B\epsilon^{-42{\cdot}2t}+C\epsilon^{-0{\cdot}204t}\sin 1{\cdot}703t,\quad . \quad (9)$$

so that the slower periodic motion has disappeared, and the quick one, the period of which is nearly 3·7 seconds, is rapidly destroyed. For both (8) and (9) it is interesting and easy to calculate P.

In solving the biquadratics which lead to such answers, let it be noticed that we are led usually to roots $-\alpha\pm\beta i$ and $-m\pm ni$, where $i=\sqrt{-1}$, n and m being much smaller than α and β. If we leave out the last two terms of

$$\theta^4+a\theta^3+b\theta^2+c\theta+d=0\quad . \quad . \quad . \quad . \quad (10)$$

we get the larger roots, approximately; if we leave out the first two terms we may not get m, but we get a good approximation to n, and it is n which it is most important to know. The following is a quick method of finding the roots with any amount of accuracy that is required. We know that

$$a=2(\alpha+m),$$
$$b=\alpha^2+\beta^2+m^2+n^2+4\alpha m,$$
$$c=2m(\alpha^2+\beta^2)+2\alpha(m^2+n^2),$$
$$d=(\alpha^2+\beta^2)(m^2+n^2).$$

The numerical example given above, where $f=5\times10^4$, requires us to solve

$$\theta^4+7{\cdot}16\theta^3+19{\cdot}42\theta^2+1{\cdot}83\theta+2=0.$$

First assume that $m=0$, so that $\alpha=3{\cdot}58$. We see then that the sum of $\alpha^2+\beta^2$ and m^2+n^2 is 19·42, and their product is 2, so that we can find them.

$$x^2+19{\cdot}42x+2=0$$
gives $\alpha^2+\beta^2=19{\cdot}42$, $m^2+n^2=0{\cdot}103$.
Then $0{\cdot}915$ or $\frac{1}{2}c=19{\cdot}42m+3{\cdot}58\times0{\cdot}103$
or $m=0{\cdot}0282$.

Secondly assume that $m=0{\cdot}0282$, so that $\alpha=3{\cdot}5519$; taking $x^2+19{\cdot}02x+2=0$ we get $\alpha^2+\beta^2=19{\cdot}02$; $m^2+n^2=0{\cdot}10515$, $\frac{1}{2}c=0{\cdot}915=19{\cdot}02m+3{\cdot}553\times0{\cdot}105$ gives $m=0{\cdot}0285$.

Assuming m to have this value, we may proceed to a third calculation. In this way we get closer and closer to the true value of m, and therefore to the true values of α, β, and n. In practice I find that the two calculations such as I give here are sufficient.

It may be taken as roughly true from (4) that the effective moment of inertia of the ship is increased from I to $I+\frac{m^2}{b^2}$, so that the time of a slow vibration is multiplied by

$$(1+m^2/Ib)^{\frac{1}{2}}.$$

If all ships and their gear are similar, it will be found that m^2/Ib is inversely proportional to the dimensions. Thus if a 100-ton boat has its period increased by 50 per cent., then a perfectly similar ship of 2700 tons will have its period lengthened by only 19 per cent.

It may be, however, that the proportions should be different in vessels of different size, and it is not fair without further experience to make a comparison which seems so unfavourable to the method. Besides, experience alone can show how the dash-pot friction may depend upon the size of the ship. Probably, too, large ships may be regarded as being steady enough already.

If we apply the Schlick method to Mr. Brennan's car, as a of (4) (putting $\alpha = 0$) is negative, there is instability of motion whether there is or is not friction. We may, however, do as the exhibitor of the model (at the Physical Society meeting) has done—make b also negative. That is, make the gyrostat frame unstable by having the centre of gravity of the frame EAB above the axis DG. In this case, if there is absolutely no friction either of the f or F kind, there will be steady vibrations about a mean position, but any friction will cause the swings to get larger and larger. It is to be noticed that even without friction there will be instability if m, the moment of momentum of the fly-wheel, is less than a certain amount. Mr. Brennan's method of working is quite different. Fig. 2 shows his model car (about 6 feet long). It is driven by electric accumulators carried by the car. His gyrostat wheels are driven by electromotors, not shown in Fig. 3; as they are revolving in nearly vacuous spaces they consume but little power, and even if the current were stopped they would continue running at a sufficiently high speed to be effective for a length of time.

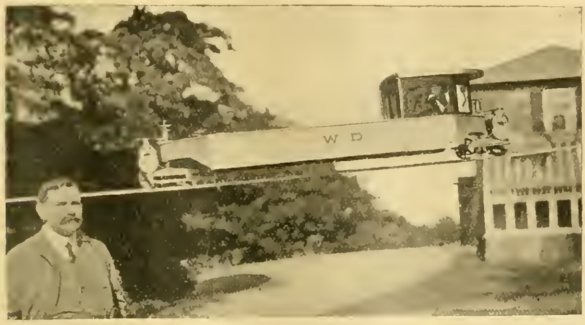

Fig. 2.

It will be found that energy is wasted by friction, and also work has to be done in bringing the car to a new position of equilibrium, and all this is supplied by the electromotors. Should the gyrostat really stop or reach a certain low speed, two supports are automatically dropped, one on either side of the car; each of them drops until it reaches the ground, one of them dropping perhaps much farther than the other.

The real full-size car which Mr. Brennan is now constructing may be pulled with other cars by any kind of locomotive, using electricity or steam or petrol, or each of its wheels may be a driving wheel. He would prefer to generate electric power on his train, and to drive every wheel with an electromotor. His wheels are so independent of one another that they can take very sharp curves and vertical inequalities of the rail. The rail is fastened to sleepers lying on ground that may have sidelong slope. The model car runs on an iron gas-pipe; the ground is nowhere levelled or cut, and at one place the rail is a steel wire rope spanning a gorge (Fig. 2). It is interesting to stop the car in the middle of this rope and to swing the rope sidewise, watching the perfect automatic balancing. The car may with confidence be left here for hours, balancing itself with nobody in charge. If the load on the car—great lead weights—be dumped about into new positions, the car effects balance with no apparent effort. But if, the car not running but merely balancing itself, a person standing on the ground pushes against it, the car will push in opposition, and by pushing judiciously a person can really disturb the car's vertical position considerably; it is as if an indignant animal were resisting the push. Left to itself now, the car quickly rights itself.

The car is supported by a mono-rail bogie at each end; each bogie has two wheels pivoted vertically and horizontally, so that curves may be very sharp and the ground may be uneven.

Fig. 3 is a diagrammatic representation of Mr. Brennan's pair of gyrostats in sectional elevation and plan. The cases G and G′, inside which the wheels F and F′ are rotating *in vacuo* at the same speed and in opposite directions (driven by electromotors not shown in the figure), are pivoted about vertical axes EJ and E′J′. They are connected by spur-toothed segments JJ and J′J′, so that their precessional motions are equal and opposite. The whole system is pivoted about C, a longitudinal axis. Thus when precessing so that H comes out of the paper, so will H′, and when H goes into the paper, so does H′.

When the car is in equilibrium the axes KH and K′H′ are in line NN′ across the car in the plane of the paper. They are also in a nearly horizontal line which is at right angles to the total resultant force on the car. I will call this the mid-position.

Let $\frac{1}{2}m$ be the moment of momentum of either wheel. Let us suppose the car to tilt so that the shelf D comes up against H, the spinning axis (or a roller driven by

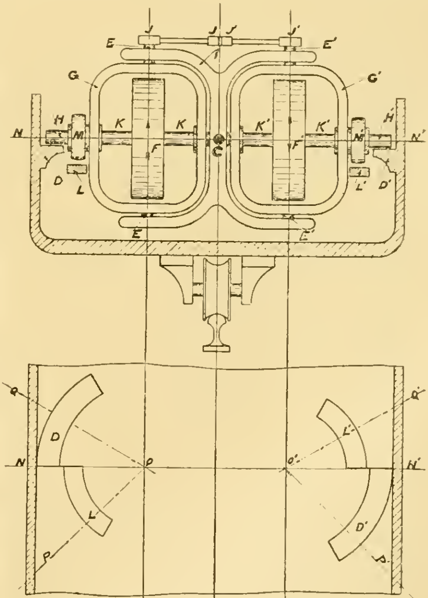

Fig. 3.

the spinning axis) of the gyrostat. H begins to roll away from me, and if no slipping occurred (but there is always slipping, and, indeed, slipping is a necessary condition) it would roll, that is, the gyrostats would precess with a constant angular velocity α, exerting the moment $m\alpha$ upon the shelf D, and therefore on the car.[1]

This precession continues until the roller and the shelf cease to touch. At first H lifts with the shelf, and afterwards the shelf moves downwards, followed for some distance by the roller. If the tilt had been in the opposite direction, the shelf D would have acted upon the roller H′, and caused just the opposite kind of precession, and a moment of the opposite kind.

We now have the spindles out of their mid-positions as OQ, O′Q′. How are they brought back to NOO′N′ with H permanently lowered?

It is the essence of Mr. Brennan's invention that, after a restoring moment has been applied to the car, the spindles shall go back to the position NOO′N′ with H permanently lowered, so as to be ready to act again.

He effects this object in various ways. Some ways described in his patents are quite different from what is used on the model, and the method to be used on the full-size waggon will again be quite different. I will describe one of these methods. Mr. Brennan tells me that he considers this old method to be crude, but he is naturally unwilling to allow me to publish his latest method.

D′ is a circular shelf extending from the mid-position in my direction; D is a similar shelf extending from the mid-position into the paper or away from me. It is on these shelves that H′ and H roll, causing precession, as I have just described. When H′ is inside the paper or when H is outside the paper they find no shelf to roll upon. There are, however, two other shelves, L and L′, for two other rollers, M and M′, which are attached to the frames concentric with the spindles. They are free to rotate, but are not rotated by the spindles. When they are pressed by their shelves L or L′ this causes negative precession, and they roll towards the NOO′N′ position. There is, of course, friction at their supports retarding their rotation, and therefore the precession. The important thing to remember is that H and H′ when they touch their shelves (when one is touching, the other is not touching) cause a precession away from the mid-position at a rate α which produces a restoring moment $m\alpha$ of constant amount (except for slipping), whereas when M or M′ touches its shelf L or L′ (when one is touching the other is not touching), the pressure on the shelf and friction determine the rate of precession towards the mid-position as well as the small vertical motion.

Suppose the tilt to be corrected is R, when D presses H upward. The moment $m\alpha$ and its time of action (the total momental impulse) are too great, and R is over-corrected; this causes the rollers M′ to act on L′, and the spindles return to the mid-position; they go beyond the mid-position, and now the roller H′ acts on D′, and there is a return to the mid-position and beyond it, and so it goes on—the swings of the gyrostats out of and into the mid-position, and the vibrations of the car about its position of equilibrium getting rapidly less and less, until again neither H or H′ nor M or M′ is touching a shelf. It is indeed marvellous to see how rapidly the swings decay.[2]

It will be seen that by using the two gyrostats instead of one, when there is a curve on the line, although the plane NOO′N′ rotates, and we may say that the gyrostats precess, the tilting couples which they exercise are equal and opposite.

It is evident that this method of Mr. Brennan is altogether different in character from that of Mr. Schlick.

[1] I am supposing the precessional angles to be small; when the angles are like NOQ, N′O′Q′, Fig. 3, the sum of the moments of the two gyrostats would be $m\alpha \cos$ NOQ, α being constant, if there were no slipping; but there is always slipping, and the good working of the apparatus requires that there shall be such slipping α is not constant, and it is always less than what it would be if there was true rolling.

[2] If in Fig. 3 R is the angle which the waggon makes with its position of equilibrium; if M is the moment with which the shelf D acts clockwise upon H, and P is the angle of precession QoN; and if μ is the coefficient of friction between D and H, then in the first part of the action above described $I\theta^2R + m\theta P - M = 0$, $m\theta R - i\theta^2 P + \mu M = 0$, $(I_1\theta^2 - hw)R + M = 0$, if I_1, I and $\frac{1}{2}i$ are moments of inertia of the waggon about the rail, of the frames about C, and of the frame G about EJ; $\frac{1}{2}m$ is the moment of momentum of either wheel. These equations are easily solved on the conditions that at $t=0$, $R=R_0$, $\theta R=0$, $P=0$, $\theta P=0$. Assuming no play, that is, that as soon as H leaves D, M′ touches L′, we can now find the return to the mid-position from a new set of equations. Friction retards the return, it must be remembered. The motions are exceedingly interesting when numerical values of I_1, I, i, &c., are taken, but the practical man will find it more interesting to make an experimental study of what happens.

Work is here actually done which must be supplied by the electromotors. The restoring moment applied to the car may be made as great as we please by increasing the diameter of H. It is true that we cannot in this way alter the total momental impulse, and this is the important thing.

One of the most important things to know is this: the Brennan model is wonderfully successful; the weight of the apparatus is not a large fraction of the weight of the waggon; will this also be the case with a real car which weighs 1000 times as much? If at any instant a condition of things is suddenly produced so that the waggon makes an angle R_0 with its position of equilibrium, if its weight is W, its centre of gravity at the height h above the rail, if I_1 is its moment of inertia about the rail as axis, if $\frac{1}{2}m$ is the moment of momentum of each gyrostat wheel, the momental impulse mP_1 ought, roughly, to be equal to $CR_0\sqrt{I_1Wh}$, where C is a constant. I use P_1 for the total angular precession at first. Now the tilt to be corrected, R_0, may be due to wind pressure, to a sudden shifting of the centre of gravity, or to centrifugal force, and it is not easy to compare these things in waggons of different sizes. If, however, we take it that the size of each dimension of the waggon is multiplied by n and the size of each dimension of the gyrostatic apparatus is multiplied by p, and the wheels have the same peripheral speeds, we find the following results:—For wind, R_0 is proportional to n^{-1}. For centrifugal force it seems reasonable to take the speed of a waggon as proportional to n, and mean radius of rail curves proportional to n^2. In this case the result is again that R_0 is proportional to n^{-1}. As for a possible accidental shifting of the centre of gravity because of the displacement of part of the cargo w through the distance d, if we take $w \propto n^3$ and $d \propto n$, we find with greater and greater accuracy as w is a smaller fraction of the whole weight, $R_0 \propto n^{-1}$.

Taking P_1, the maximum angle of precession, to be the same in all cases, the above relation leads to the result that $p=n^{\frac{7}{8}}$, or that the fractional weight of the apparatus as compared with that of the waggon is proportional to $W^{-0 \cdot 125}$, where W is the weight of the waggon. Thus, if we take $n=10$, that is, every dimension of the model multiplied by 10 or its weight by 1000, then $p=7 \cdot 5$, so that the weight of the gyrostat apparatus is only multiplied by 420. If in the model the apparatus was 10 per cent. of the whole weight, in the large waggon the apparatus is only 4 per cent. of the whole weight. In fact, the larger the waggon the less proportion of its weight and volume is occupied by the apparatus, a result which must be very satisfactory to Mr. Brennan.

In the cases both of Mr. Schlick and Mr. Brennan, it has to be remembered that if the diameter of the wheel be increased in greater proportion than the dimensions of the ship or waggon, or other dimensions of the wheel, the proportional weight of the apparatus may be diminished. A wheel of twice the diameter, but of the same weight, may have twice the moment of momentum and may be twice as effective. I assume the stresses in the material to be the same.

ON THE PHYSICAL ASPECT OF THE ATOMIC THEORY.[1]

THE lecture began by setting out a physical reason *a priori* why matter should be constituted of discrete particles instead of being continuous. The requirements of physics demand an æther to serve as the means of communication between portions of matter out of contact with each other, and space can hardly be conceived as *fully* occupied simultaneously by two media, matter and æther; hence the matter must be constituted of discrete centres, or nuclei, determining permanent collocations of energy in the æther, which are, in fact, primordial atoms and their fields of force. The feasible problem of atomic physics is to build up an adequate idea of the dynamic constitution of these æthereal fields of force; there is the problem

[1] Abstract of the Wilde Lecture of the Manchester Literary and Philosophical Society, delivered on March 3 by Prof. J. Larmor, Sec.R.S.

beyond, to determine the intrinsic constitution of the central nuclei to which they are attached, which may remain permanently beyond our ken. The expansion of our ideas about the atoms, and their structural connection with the æther, was traced from their origin in Descartes, through Huygens and Newton, down to the more definite modern types of representation, as regards various essential features, that are afforded by the vortex atom and the electron.

In the hands of the physicists, especially Newton and Young, the atom had already become a complex structure, capable of definite, inherent, periods of free vibration, but, so far as physics was concerned, the same substance might include various kinds of atoms. The fundamental advance of Dalton, which assured an adequate domain to chemistry as an exact science, was the proof that each compound substance is definite as regards its molecule, and that all atoms of the same elementary body are identical. Whether this absolute identity points to the atom of each chemical element being a dynamically balanced structure of primordial atoms, one of a limited number of possible definite types of structure—which would be a perfectly reasonable way of accounting for this remarkable identity—remains an open question. The periodic relations of the elements, connected most closely with the name of Mendeléeff, certainly indicate that, whatever may be the case as regards the kernel, the outer structure of the atom, so to speak, which is the link through the æther between the nucleus and the outside world, is constituted on the basis of a common ultimate element which may be the electron.

The remark of Maxwell seems still to retain its force, that the mechanism of biological evolution could hardly reside in atoms, primordial or other, which had not much vaster underlying complication than is needed for their purely physical relations. The facts of biology may possibly demand a hypothesis such as the above, that atoms not in intimate contact interact through the æther according to general physical laws, in the manner required to constitute the physical cosmos, but that there may also be a closer interpenetration of atomic nuclei in which far more complex agencies are involved.

The mechanical atom of the earlier physicists, considered in this physical aspect, as an unknown core determining the field of activity in the surrounding æther, has had, since Faraday's discoveries in electrolysis, to take on a more definite form as the electrical atom. The result had been fully reached by Faraday himself, though it needed to be enforced later by Helmholtz, that the energies which have play in chemical combination are of electrical origin, implying thereby, according to Maxwell's interpretation, energies of intrinsic stress and motion brought to bear from atomic stores located in the adjacent æther. This doctrine has led on to the modern theory of purely electric atoms, which was already demonstrable on theoretical grounds, of course in a way less definite than we now know it, before the very remarkable discovery of electrons actually free had been reached, through the phenomena of radio-activity either electrically induced or spontaneous. Here again there is the same choice of points of view open to tentative development. We may proceed on a limited hypothesis as if the electrons are the sole primordial atoms; or we may assume that there are various ultimate atoms which have existence and structure of their own, of type largely unknown and independent of the æther, and that the electrons which are associated with them, whether temporarily or intrinsically, form merely one feature of their constitution, viz. their means of communication with the æther, and through it with other atoms at a distance to form an ordered universe.

In any case we are right in following out the hypothesis, there being, in fact, none other open to us, that the purely physical manifestations of atoms—those, namely, that, owing to the simple interconnection involved in their common seat in the æther, aggregate into the definite physical qualities of matter in bulk—are in the main or in most circumstances practically a group by themselves, and that they are thus capable of being investigated on these broad, simple principles of dynamics, which Newton definitely formulated as a suitable foundation for the analysis of general physical activity, as it presents itself in the universe. This so-called mechanical hypothesis has been eminently the fruitful one; it pointed the way to the principle of the conservation of energy, and is now elucidating the wider principle of its definitely limited availability; it gave a rational explanation of the spectrum and of radiation in general, which has proved a trustworthy and precise guide to investigation of phenomena far below the surface, such as the selective dispersion of light and the magnetic action on radiation; it reduced electrical phenomena to order and control, and connected them with light. It must therefore be presumed to be available as the clue for the further elucidation of pressing problems, such as the nature of the transmission of gravitation and of the intimate operation of chemical affinities.

The tendency to reject dynamical analysis as artificial in such subjects as electrodynamics, which received some stimulus from the theoretical writings of Hertz, seems to overlook the fact that it was precisely as a compact working basis suitable for the formulation of experience in its more general aspects that the Newtonian scheme of dynamics was put forward by its author. In the course of time that scheme has become wider and more elastic through the generalisations of Lagrange and Hamilton, expounded forcibly on the physical side by Kelvin, Helmholtz, and various others. But to take over the final results, and dress them in new language devoid of the dynamical implication, seems to involve a misreading of scientific evolution.

This position may be enforced by a quotation from the final exposition of Newton's views on the scope of natural philosophy in general, inserted by himself at the end of the famous "Queries," in "Opticks," ed. 3, p. 377:—"To tell us that every Species of Things is endow'd with an occult specifick Quality by which it acts and produces manifest Effects, is to tell us nothing: But to derive two or three general Principles of Motion from Phaenomena, and afterwards to tell us how the Properties and Actions of all corporeal Things follow from those manifest Principles, would be a very great step in Philosophy, though the Causes of those Principles were not yet discovered: And therefore I scruple not to propose the Principles of Motion above mention'd, they being of very general Extent, and leave their Causes to be found out." Then he proceeds to associate his laws of motion with an atomic theory.

A review of the electrical side of the atomic theory requires a consideration of the phenomena of ionisation in solutions. The theoretical difficulties which have presented themselves in this subject were discussed, in particular the nature of the energy changes which must occur when a salt is dissolved and thus split into separate ions. Reasoning from the processes of the voltaic cell, as expounded after Faraday by Helmholtz, the view is advanced that an equivalent of purely local potential energy of affinity with the solvent must be exhausted in order to provide for the separation of the ions, but without much violent motional disturbance such as would diffuse partially away into the form of heat. This absence of such motional dissipation of the energies of affinity, as indicated, for example, by their almost complete mechanical availability in a Daniell's cell, is perhaps connected with the intimate contacts in confined spaces which are characteristic of the processes at the electrodes by which the chemical change is effected. It is suggested that a similar mode of explanation applies to the very high, sometimes nearly complete, mechanical availability (Berthelot) of the energy of chemical transformations in dense media such as liquids and solids, as contrasted with dilute systems such as gases, which the recent work of Nernst and his pupils has brought again to the front.

The lecture passes on to touch on those extensive branches of chemical physics to which the constitution of the atom is not essential, where only a statistical grasp of the molecular associations and dissociations that are taking place is required. The quantitative theory of chemical equilibrium and of progress of chemical change as regards dilute systems comes under this head, of which the prototype and the most highly developed example is the kinetic theory of gases. The modern theory of electrodynamics, as based on the displacements and motions of electrons, is in the main analogous, and the theory of gravitation, when it comes to light, will be of the same kind.

In particular, the molecular aspect of reaction in gases is passed under review. Reasons are brought forward for holding that in gases all ultimate reactions are of necessity mono- or bi-molecular. If this be so, the important work now proceeding with regard to the effect of impurities in promoting or inhibiting gaseous reactions must lead to fuller knowledge of the transient molecules or radicals which are formed in the destructive encounter of a pair of the reacting molecules, and are the carriers or intermediaries leading finally to poly-molecular change; while the same transient combinations may be approachable independently from another side as affording the interpretation of the complex banded spectra of emission or absorption in gaseous media.

The very remarkable and most fruitful and prophetic symbolic theories of molecular structure, especially for the complex molecules of organic chemistry, have not yet proved capable of dynamical interpretation; it seems necessary, however, to admit, on account of the wide range of physical properties that are nearly atomically additive, that stereochemical collocations do represent in some real way the actual aggregation of the atoms instead of mere symbolical representation of it. Recent investigation appears to bring out in certain cases a somewhat definite relation between the configuration of the molecule and the crystalline form of its physical aggregations, which, though reasonable, could not have been foreseen *a priori*; exact crystallographic measurements may thus in time afford another intimate clue to the molecular structures in related series of compounds.

A NEW METHOD OF STEREOSCOPIC PHOTOGRAPHY.

An entirely novel suggestion for the production of stereoscopic photographs is proposed by Prof. G. Lippmann in the current number of the *Comptes rendus* of the Paris Academy of Sciences (March 2). Let a lens be constructed of a material possessing a refractive index n, the segments forming the front and back of the lens having the same centre of curvature and the ratio of the radius of curvature of the front segment to that at the back being $n-1$. The front surface is the receiving lens, and corresponds to the lens of the eye; the back surface is covered with the sensitive emulsion, and corresponds to the retina. Owing to the chosen relation between the curvatures of the two faces an image of a point is formed by the front surface on the back one. The system is reversible; a ray of light proceeding from any point of the receiving surface will pass out at the front over exactly the same path as that taken by the incoming light in acting on the sensitive film, and this will be true in spite of any imperfection of the lens surfaces.

Prof. Lippmann now imagines a material such as celluloid moulded back and front, so that the whole surface is covered with microscopic cells, each of which is an elementary cell possessing the properties of the single lens described above. The whole film resembles the compound eye of insects. This plate, sensitised, is exposed in full daylight to the objects to be represented, no photographic lens being required. The result of the operation would be a series of microscopic images fixed each on the "retina" of one of the cells. Seen from the side of the sensitive layer, the whole plate would present a uniformly grey appearance. But seen from the front and illuminated from behind the plate (supposed converted into a positive), the photograph would appear, and would possess the following peculiarities. It would appear in true relief, exactly as in nature, and shifting the eye about would produce a change in the photograph seen, the effect being as if the observer stood in front of a window. By stepping from side to side, in the latter case, fresh portions of the landscape would come into view, the whole always being bounded by the four sides of the window. In the case of such a plate as that described, the effect would be precisely similar.

As the author remarks in the paper, the technical difficulties in the preparation of such a plate would be very great. The chief difficulty would be the fulfilment of the condition necessary for the clear definition of each image in each elementary cell; the ratio of the radii of curvature must be equal to $n-1$. Considering the thickness of the film, this difficulty would appear to be insuperable, but it is to be hoped that an attempt will be made to put this idea into practice, however imperfectly.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—During the last four years the average income of the botanic garden has been 1708*l.*, to which the University chest has contributed 1175*l.*, the rest being made up of money from trust funds and from rents. The botanic garden syndicate now points out that the income is no longer sufficient to cover the expenses. The syndicate estimates that in future, if the gardens are to maintain their high position amongst kindred institutions, some additional income must be found, and it is recommended that the present grant from the University chest to the botanic garden be increased by the sum of 220*l.* per annum.

The next combined examination for sixty-seven entrance scholarships and a large number of exhibitions at Pembroke, Gonville and Caius, King's, Jesus, Christ's, St. John's, and Emmanuel Colleges will be held on Tuesday, December 1, and following days. Mathematics, classics, and natural sciences will be the subjects of examination at all these colleges. Some of the colleges allow candidates who intend to study mechanical sciences to compete for scholarships and exhibitions by taking the papers set in mathematics or natural science. The colleges desire it to be known that any candidate for a scholarship may signify in writing his wish not to receive the emolument of the same if elected thereto, and that such candidate may be elected to a scholarship which may be honorary only and without emolument, but shall carry with it all other privileges attached to the position of a scholar. The amount thus set free will serve to increase the number of scholarships or exhibitions open to other candidates.

Glasgow.—Among the honorary degrees to be conferred by the University on April 22 are the following:—*LL.D.*: Mr. G. T. Beilby, F.R.S., chairman of the governors of Glasgow and West of Scotland Technical College; Colonel David Bruce, C.B., F.R.S.; Dr. J. J. Dobbie, F.R.S., director of the Royal Scottish Museum, Edinburgh; Mr. R. Kidston, F.R.S.; and Dr. J. C. McVail, county medical officer, Stirlingshire and Dumbartonshire.

Dr. R. Stewart MacDougall, on his appointment to the lectureship in botany in Edinburgh University, has resigned his position as biologist on the staff of the Edinburgh and East of Scotland College of Agriculture.

Mr. A. L. Bowley, reader in statistics in the University of London, will give a course of ten lectures on elementary applications of mathematics to statistical data at the School of Economics, at 7 p.m., on Thursdays, March 26 and April 2, resuming after the Easter vacation on May 7, and continuing thereafter for seven consecutive Thursdays.

The Earl of Rosebery will visit University College on the afternoon of Thursday, March 26, and will formally open the new libraries and the new south wing, which includes lecture-rooms for the faculty of arts, the departments of geology, hygiene, and experimental psychology, also large extensions of the departments of applied mathematics, of mechanical, electrical, and municipal engineering, and accommodation for the new hydraulic laboratory.

The first volume of the report of the U.S. Commissioner of Education for the year ending June 30, 1906, has been received from Washington. In addition to chapters summarising the progress made during the year under review in the various departments of American education, the report contains a series of excellent articles on educational administration in various European and other countries. A useful summary of the different sections of the report is provided in the commissioner's introduction, and from this digest we notice there were, during 1905–6, 622 institutions of higher education reporting to the Washington Bureau of Education. The total number of professors and instructors in these institutions reached 23,950, and the number of students 258,603—an increase of 9430 on the preceding year. The value of the property possessed by the 622 institutions amounted to 110,815,400*l.*, of which 49,686,100*l.* was the amount of productive funds. The aggregate income of these institutions for the year was 8,956,700*l.* The total value of all gifts reported amounted to 3,543,300*l.*; Harvard University received 443,600*l.*; Yale University, 229,100*l.*; Columbia University, New York, 210,000*l.*; the University of Pennsylvania, 109,000*l.*; and the North-Western University, Illinois, and Princetown University, New Jersey, each received about 105,000*l.* In this report, for the first time, the number of students in schools of technology is not given separately, because, as the commissioner points out, there has been an erroneous opinion in Europe and elsewhere that there is no higher technical training in America outside the schools of technology, whereas the ordinary universities grant nearly twice as many degrees in science as the technical colleges, and are doing excellent work in pure and applied science generally.

WE have received a couple of pamphlets (Leipzig: Verlag der Durr'schen Buchhandlung) which indicate the continued interest of the German public in both sides of the question of school reform. One of these pamphlets ("Die Stadt Berlin und das Reformgymnasium") is a reprint of a strenuous argument, which was originally delivered by Stadtschulrat Dr. Carl Michaelis in 1904, against tampering with the school system of the capital. Dr. Michaelis has brought the statistical portion of his address up to date, and finds in recent educational history nothing to weaken his former contention that the establishment of a Reformgymnasium in Berlin is demanded neither by the success of the reform movement generally nor by the specific educational conditions of the city. Further, while he makes it clear that he is far from opposed to well-considered changes in other directions, he defends the old gymnasium against the reformers as an indispensable part of the school system. In particular, he criticises the contention that the lower classes should be preparatory equally to all the recognised forms of secondary school, partly on the ground that the advantage which this arrangement is alleged to give the parent in selecting the school suitable to the abilities of his child is illusory, partly on the ground that no plan devised on these lines can accord with the necessary conception of a gymnasial education. Many of these arguments appear also in the second pamphlet ("Mathematik und Reformgymnasium"), in which Dr. H. Vogt endeavours to show that the teaching of mathematics suffers in respect both of the time given to the subject and of the value of the instruction where it is attempted to superimpose the gymnasial classes upon a foundation common to all the higher schools. The same firm of publishers has reprinted the address delivered in the University of Erlangen by Dr. Richard Falckenberg on the occasion of the centenary of the death of Kant (February 12, 1904).

THE second annual report, dealing with the year 1907, of the president and treasurer of the Carnegie Foundation for the Advancement of Teaching has reached us. It will be remembered that Mr. Carnegie's gift of two million pounds sterling was intended to serve primarily in the establishment of retiring allowances for teachers in the institutions of higher learning in the United States, Canada, and Newfoundland, but that he left it to be administered for this purpose in such a manner as the trustees might decide to be wise. The fears expressed in some quarters that such a gift in the hands of a limited number of men might prove a centralised power which would hinder rather than aid the progress of education do not seem to have been well founded. Since the inauguration of the foundation down to September 30 last, grants have been made to 166 persons (eighteen of whom died during the period), involving an annual budget of 46,032*l.* Of this amount, 20,230*l.* was devoted to retiring allowances in accepted institutions, and 17,702*l.* to retiring allowances made to individuals. In the group of retirements on the basis of age an interesting comparison is made; the number of allowances granted on this basis to professors not in accepted institutions before October, 1906, was eighteen; since then only eight similar allowances have been made. This indicates that the number of aged professors whom on account of their distinguished merit alone the trustees would be likely to add to the holders of allowances is rapidly diminishing. It is also interesting to note that retiring allowances to professors in State universities are made only when the services rendered to learning by the applicant have been of great distinction. As indicative of the number of applications made to the trustees, it may be stated that the files of the foundation show that 500 applications have been refused. It is satisfactory to learn that when once the principles of award have been decided upon finally, the trustees will see that the retiring allowance comes to the recipient "as a right, not as a charity; as a thing earned in the regular course of service, not a courtesy."

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, February 14.—Prof. J. Perry, F.R.S., president, in the chair.—Annual general meeting. Address by the newly elected president, Dr. C. **Chree**. Dr. Chree referred to the magnetic results obtained by the National Antarctic Expedition of 1901–4. The expedition was furnished with magnetographs, and the reduction and discussion of the curves has been done by the National Physical Laboratory. Before describing the results, the president spoke of the nature of the preparations that might be made in any future national scientific expedition. The observers should have a preliminary training lasting over some months, and should be practised in the use of instruments. These instruments ought to be ready for use and fully tested months before the date of the expedition. A programme should be got out in good time, so as to admit of rehearsals by the observers. An inquiry, after the return of the expedition, into the value of the results obtained might be useful in securing that meritorious work in science would not be overlooked. Lantern-slides relating to the diurnal inequalities of the magnetic elements in the Antarctic were exhibited and described. Slides of corresponding Kew results were shown for intercomparison. The president dwelt on the relatively highly disturbed nature of the Antarctic records. In the Antarctic, the declination and horizontal force magnets were practically never at rest. So large and incessant were the disturbances that no idea of the nature of the regular diurnal inequality was obtainable from inspection of individual curves. Diurnal inequalities, however, derived from the curves of single months, and still more of a whole season of the year, proved to be of a comparatively smooth character.

Royal Meteorological Society, February 19.—Dr. H. R. Mill, president, in the chair.—The formation of "snow rollers" observed at Ryton on Dunsmore, near Coventry, on January 29–30, 1907: C. **Browett**. It seems that the flakes of a light fluffy layer of surface snow are made adhesive by a rise in the temperature of the air above the freezing point, while the under snow remains cold and dry, and the particles of damp surface snow are enabled to adhere to each other, but not to the dry under snow. A strong wind may then push over little projections of the surface snow and start them rolling, when, of course, they will travel and grow until the resistances overcome the propelling power of the wind. These "snow rollers" vary in size, some being only a few inches in diameter, while at times others have been seen 2 feet or more in length.—Comparison of ships' barometer readings with those deduced from land observations: E. **Gold**. This paper contained the result of a preliminary investigation undertaken at the Meteorological Office into the relation between the barometer readings taken on ships during their passage across a line between Falmouth and Brest, and the readings deduced for the ships' positions from the observations at these places and the trend of the isobars, on the assumption of regular pressure changes. Taking into account the various causes which can appreciably influence the height of the barometer on board ship, it appears that until the two chief ones—the wind and the vertical acceleration effects—are eliminated, it will be impossible to draw any satisfactory conclusions regarding the relative values of atmospheric pressure over sea and land. It can be said in general that there appears to be a tendency for the barometric pressure to be lower between Falmouth and Brest than would be expected from the land observations.

Geological Society, February 19.—Sir Archibald Geikie, K.C.B., Sec.R.S., president, in the chair.—The two earth-movements of Colonsay: W. B. **Wright**. The supposed Torridonian rocks of Colonsay exhibit in their folding and cleavage the effects of two movements analogous in their results to those proved by Mr. Clough in the Cowal district of Argyll. Not only the planes of the first or slaty cleavage, but also the quartz veins formed along them, have been folded by the second movement, and may be observed to be crossed at considerable angles by the cleavage produced during this second movement. An extensive series of lamprophyre dykes, obviously later than the first cleavage, are found to be folded and cleaved by the second movement. Moreover, some of these dykes traverse and are chilled against a mass of syenite, which can also be proved to be later than the first cleavage. The distinctness of these two movements is, therefore, considered to be completely established. The second cleavage being of the nature of strain-slip, its development along the axial planes of the folds is of interest, and is briefly discussed.—Notes on the River Wey: H. **Bury**. The part of the River Wey within the Wealden area is divided into six sections:—(1) the consequent river cutting the Chalk at Guildford; (2) the subsequent stream coming in from the east at Shalford; (3) the western subsequent stream parallel to the Hog's Back; (4) the continuation of the last westward (the Tilford River), rising at Selborne and receiving many tributaries, including the Headley River, from between Blackdown and Hindhead; (5) the short obsequent section from Farnham to Tilford (the Waverley River); and (6) the portion above Farnham coming from Alton and beyond (the Farnham River). Part i. deals with the relation of sections (6), (5), and (4) to the Blackwater; part ii. with the Palæolithic Gravels of Farnham; and part iii. with the Farnham branch of the Wey and the Alton district, which is remarkable in that there is a complicated series of Chalk valleys, which spread over some fifty square miles of country and discharge their waters into the Wealden area.

Royal Microscopical Society, February 19.—Mr. A. N. Disney in the chair.—An improved type of mercury vapour lamp for use with the microscope: J. E. **Barnard**.—Eyepieces for the microscope: Mr. **Nelson**.—Results of observations, extending over a period of four years, on a rare protophyte: Rev. E. **Tozer**.—Dimorphism in the recent foraminifer *Alveolina boscii*: F. **Chapman**.—*Biddulphia mobiliensis*: Mr. **Nelson**. The author described some exceedingly minute secondary markings in the primary areolations of this diatom, discovered by him.

Faraday Society, February 25.—Dr. T. M. Lowry in the chair.—Hydrolysis as illustrated by heats of neutralisation: V. H. **Veley**. It is pointed out that a correlation of hydrolysis values and basic constants deduced therefrom with those of heats of neutralisation presents important issues. Determinations by an accurate method at different temperatures are required to test the validity of Nernst equation $Q = RT^2\epsilon\frac{d\log^{10}K}{dt}$. Relationships of a general character are discussed for the hydrochlorides of nitrogen bases, also of certain sodium salts of phenols and organic acids. The effect on thermoneutrality and basic constants by the introduction of a second amino-grouping is considered. Finally, it is pointed out that determinations are required of hydrolysis values at considerable dilution of certain metallic chlorides.—A study of the sulphur anion and of complex sulphur anions: Joseph **Knox**. The solubility of HgS, red and black, in Na_2S, K_2S, and BaS solutions has been determined, and has been found to depend on the formation of the complex anion HgS_2''. By its greater solubility in these solutions the black modification of HgS has been shown to be the less stable form. The constant for the formation of the complex anion from the ions Hg'' and S'' is

$$k = \frac{[HgS_2'']}{[Hg''][S'']^2} = 5\cdot 1 \times 10^{54}.$$

From saturated solutions of Na_2S and HgS a crystalline double sulphide of sodium and mercury, $2Na_2S,5HgS,3H_2O$, has been isolated. From the study of the complex formation between HgS and Na_2S it is concluded that Na_2S is almost completely hydrolysed into NaOH and NaSH.

Royal Anthropological Institute, February 25.—Mr. A. L. Lewis in the chair.—Montenegrin manners and customs: M. Edith **Durham**. An account was given of the people's beliefs in spirits and fabulous serpents, with their marriage arrangements and funeral ceremonies. All cousins, to whatever degree, are considered as blood relations, and marriage between them is prohibited, and it is interesting to note that godfatherhood is also a recognised relationship, a godson becoming of blood kin to all his godfather's relations.

CAMBRIDGE.

Philosophical Society, January 27.—Dr. Hobson, president, in the chair.—(1) Exhibition and description of a portion of a fossil jaw of one of the Equidæ (British East Africa); (2) exhibition of zebra skins (thirteen) and skulls (four) from British East Africa, with special reference to the problem of the centre of distribution of the three species of zebras: Prof. **Ridgeway**.—A new genus of Ixodoidea, together with a description of eleven new species of ticks: Prof. **Nuttall** and C. **Warburton**.—(1) Report on the brain of a microcephalous idiot; (2) description of a microcephalous new-born pig: Dr. **Duckworth**.

February 10.—Mr. S. Ruhemann, vice-president, in the chair.—The nature of γ rays: Prof. J. J. **Thomson**. The author supported the view that the γ rays have a structure similar to that ascribed to the Röntgen rays in his "Discharge of Electricity through Gases," consisting of small pulses of electric force, the pulses having a very small area as well as being very thin. These pulses form a system made up of separate units, which may be at considerable distances from each other. Each of the units possesses mass, momentum, and energy. It was shown that all the properties of the γ rays could be explained on this view without the introduction of the somewhat far-fetched hypotheses which are necessary if the view that the γ rays are combinations of positive and negative ions is adopted.—The velocity of kathodic secondary radiation: Prof. J. J. **Thomson**. A method of measuring the velocity of secondary kathode rays from gases was described, and by the use of this method it was shown that the maximum velocity of the secondary rays is independent of that of the primary rays. Cases were described in which the velocity of the secondary rays was greater than that of the primary rays from which they originated, showing that the secondary rays result from a kind of explosion of the atoms of the gas through which the primary rays pass.—The spectrum of the discharge from a glowing lime kathode in mercury vapour: F. **Horton**. The discharge tube used had a kathode consisting of a strip of platinum foil covered with lime or a mixture of lime and baryta. This could be heated by means of an electric current. The anode was either aluminium, platinum, or mercury. The spectrum showed the lines of the residual gas and those of mercury. On pumping out the residual gas its spectrum gradually disappeared and the mercury spectrum increased in brilliancy, and, at the same time, three new lines appeared in the orange and two new lines in the red. These lines were quite sharp and bright, and are not given in the ordinary tables of mercury lines. Experiments showed that these lines were not due to calcium or barium, but were connected with the presence of mercury vapour in the discharge tube. It seems probable, therefore, that the method of producing the ionisation used in these experiments gives rise to spectral lines which do not occur in the ordinary vacuum tube, arc, or spark spectra of mercury.—An example of complex double integration: Dr. A. C. **Dixon**.

DUBLIN.

Royal Dublin Society, February 18.—Prof. Sydney Young, F.R.S., in the chair.—*Spongospora Solani*, Brunch.: Prof. T. **Johnson**. The author gave an account of a scab which he found last summer doing much harm to the potato crop along the west coast of Ireland. The scab is caused by *Spongospora Solani*, Brunch., a slime-fungus allied to Plasmodiophora. The author describes the germination of the spores, as well as the resting plasmodium, and concludes that Spongospora agrees in its mode of reproduction with Ceratiomyxa, as described by Jahn, not with the other Myxomycetes. The author had the opportunity, through the kindness of Colonel Prain, F.R.S., the director of the Royal Gardens, Kew, of examining the spore-balls of *Sorosporium scabies* (Berk.), Fisch. d. Wald., which agree with those of *Spongospora Solani*. He expresses the opinion that *S. scabies* may prove to be, not a member of Ustilaginaceæ, but identical with *Spongospora Solani*, a slime-fungus.—The radium content of deep-sea sediments: Prof. J. **Joly**. The paper is a record of experiments on material kindly supplied by Sir John Murray, F.R.S. The quantity of radium is found to increase with distance from land, the central Pacific oozes (Radiolarian ooze and Red Clay) rising above 50×10^{-12} grams radium per gram. Manganese nodules, Globigerina ooze, and Blue Mud were also examined. The Blue Mud is poorer in radium than many terrestrial sediments.

PARIS.

Academy of Sciences, March 2.—M. H. Becquerel in the chair.—Some phosphorescence spectra: Henri **Becquerel**. A comparison of the phosphorescent and flame spectra of various specimens of fluor-spar, apatite, and scheelite from different localities. The bands cannot be wholly attributed to the traces of rare earths present in these minerals.—Reversible photographs: G. **Lippmann** (see p. 452).—Machines for driving away hail: J. **Violle**. So far as can be settled by direct experiments, a single detonation is practically without effect on a storm cloud. The effects of volleys from a large number of hail cannon seem to be capricious; a violent storm is practically unaffected by them, but a slowly moving cloud approaching the district by a known path may be diverted successfully.—Lithium in active minerals: Sir William **Ramsay** and Alex. **Cameron**. Referring to the results of Prof. McCoy and of Mlle. Gleditsch on the presence of lithium in certain radio-active minerals, it is pointed out that lithium is not regarded as the sole product of change when copper salts are treated with the radium emanation; other members of the alkali group may also be produced (see NATURE, March 5, p. 412).—The direct hydrogenation of the aromatic quinones: Paul **Sabatier** and A. **Mailhe**. With reduced nickel at 100° C., quinone is converted nearly quantitatively into hydroquinone. At higher temperatures products of decomposition, phenol and benzene, are found. The reaction also applies to toluquinone, paraxyloquinone, and thymoquinone.—Surfaces with coincident lines of curvature: L. **Raffy**.—The case of reduction of the differential equations of the trajectory of an electrified corpuscle in a magnetic field: Carl **Störmer**.—Electrical measurement of small lengths: A. **Guillet**.—The voltaic arc working in an enclosed space limited by a thick wall: Adolphe **Minet**.—The heat of vaporisation of propionic acid: A. **Faucon**. This constant, measured with the Berthelot apparatus, was found to be 90·4. This gives a Trouton constant of 16·2, lower than the normal figure of 20 to 21. Formic and acetic acids show the same abnormality.—The determination of the atomic weight of europium: G. **Jantsch**. The purity of the europium preparation and its freedom from samarium and gadolinium was proved by superimposing the arc spectra of all three on the same plate. The only lines common to the three were the parasitic lines from the arc, belonging to iron, silicon, and magnesium in the carbon electrodes. The ratio $Eu_2(SO_4)_3 8H_2O : Eu_2O_3$ was determined experimentally, and gave an atomic weight of 152 (O = 16). This is in close agreement with the number previously found by MM. Urbain and Lacombe.—The oxidation of platinum: C. **Marie**. Evidence has been obtained that a minute amount of an oxide of platinum can be produced by the action of various oxidising agents at the ordinary temperature.—A new type of combination of sulphur with certain iodides: V. **Auger**. The preparation of the following compounds is described:—$CHI_3.3S_8$, $C_2I_4.4S_8$, $AsI_3.3S_8$, $SbI_3.3S_8$. All these are well crystallised, and have been analysed.—Syntheses by means of the mixed organometallic derivatives of zinc. Ketone alcohols: E. E. **Blaise** and I. **Herman**. The ketone alcohol $C_2H_5.CO.C(CH_3)_2.OH$ has been obtained by the action of $C_2H_5.Zn.I$ upon $CH_3.CO.O.C(CH_3)_2.COCl$, and subsequent saponification with cold dilute caustic soda solution.—The preparation and characters of crystallised *d*-talite: Gabriel **Bertrand** and P. **Bruneau**. A detailed description is given of the improvements in E. Fischer's method of preparing *d*-talite, by means of which, starting with galactonic acid, 7·5 per cent. of the re-crystallised substance is obtained instead of 1 per cent. of the carbohydrate in the form of syrup. The physical and chemical properties of the crystallised product are given.—Physico-chemical researches on soaps considered as colloids: André **Mayer**, Georges **Schaeffer**, and E. F. **Terroine**.—The sorting of minerals by the electromagnet: A. **Chevallier** and L. **Vérain**.—The application to thoria of a general method of synthesis of fluorides and silicates: A. **Duboin**.—The existence of cephalic glands in *Machilis maritima*: L. **Bruntz**.—A Lepidoptera (*Zeuzera pyrina*) causing damage to the cork tree in Algeria: P. **Lesne**.—Spectroscopic examination of the bile: A. **Auché**. The method is based on the production of a characteristic absorption spectrum by bilirubin when oxidised under certain conditions which are defined.—Some new work on kala-azar cultures: inoculation of the dog: etiology: Charles **Nicolle**.—The rocks and Permian strata at Châtillon-sur-Saône (Vosges): A. **Doby**.—The existence of a Permian fauna and flora at Madagascar: Marcellin **Boule**.—The infra-Lias of Hodna (Algeria): J. **Savornin**.

CALCUTTA.

Asiatic Society of Bengal, February 5.—Hindustani-English glossary of birds, chiefly from Jerdon: Lieut.-Colonel D. C. **Phillott** and Pandit Gobin Lal **Bonnerjee**.—Notes on the pollination of flowers in India. Note No. 5. Some autumn observations in the Sikkim Himalaya: I. H. **Burkill**. The observations were made above 7000 feet in the autumns of 1904 and 1906, on two journeys from Darjeeling along the Singlela ridge. The climate of the ridge is a very moist one, and an unusual percentage of flowers are pendent, possibly profiting thereby because their honey escapes dilution and their pollen injury from the rain. Bombi visit many of the flowers, even working in the rain, and are found at all elevations; a long-tongued Bombyliid fly of the genus Lycastris is frequent about 8000 feet to 9000 feet. The trees of the ridge are almost all spring-flowering, and the flowering plants of the autumn flora are almost all herbs.—Notes on the pollination of flowers in India. Note No. 6. The spring flora in the Simla Hills: I. H. **Burkill**. Observations made in the end of April and beginning of May, 1906 and 1907, are recorded. The flora and fauna are very European in character, but the flora is of a much more specialised type than is the spring flora of, for instance, the Grampians of Scotland. The weather in May is generally dry, and pendulous flowers are not very numerous.—Fat of the Himalayan bear: D. **Hooper**. Analysis of the fat of *Ursus torquatus* as used medicinally in the Himalaya.—Monograph of sea-snakes: Captain F. **Wall**. A full and illustrated account of the sea-snakes of the world based on study in several museums.—A note on the calm region in the atmosphere, which in the neighbourhood of Calcutta, during the cold season, is at a height of 3000 feet to 4000 feet: C. **Little**. The object of the note is to make known the existence of the calm region at almost a uniform height throughout any one cold season, as well as from year to year. The information has been collected by observing paper balloons of different sizes, some filled with coal gas and some with hydrogen, and brief details are given of the method of observation. The altitude and azimuth of the balloon were noted at intervals of two minutes, and at the same time the diameter of the image of the balloon in a 3-inch telescope of 42 inches focal length was measured by a micrometer. Assuming this last measurement to be x thousandths of an inch, the distance would be 126,000/x feet, the balloon being 3 feet in diameter. From these measurements the position of the object in space is determined, and consequently the air movements at the different levels to which the object rises, assuming the air movement to be horizontal. With a 3-feet balloon filled with hydrogen gas, or with one of 6 feet diameter filled with coal gas, the greatest elevation attained varies from 7000 feet to 10,000 feet. It has been found in all cases that up to 4000 feet the air movement is quite different from what it is above that level, and that in passing from the lower to the upper layer of air the balloon passes through one that has very little motion.

DIARY OF SOCIETIES.

THURSDAY, MARCH 12.

ROYAL SOCIETY, at 4.30.—Description of the Brain of Mr. Charles Babbage, F.R.S.: Sir Victor Horsley, F.R.S.—The Origin and Destiny of Cholesterol in the Animal Organism. Part II, The Excretion of Cholesterol by the Dog: C. Dorée and J. A. Gardner.—On Reciprocal Innervation in Vaso-motor Reflexes and the Action of Strychnine and of Chloroform thereon: Dr. W. M. Bayliss, F.R.S.—Bacteria as Agents in the Oxidation of Amorphous Carbon: Prof. M. C. Potter.—The Life-history of *Trypanosoma equiperdum*: Prof. J. E. Salvin-Moore and Anton Breinl.

ROYAL INSTITUTION, at 3.—Early British History and Epigraphy: Sir John Rhys.

ROYAL SOCIETY OF ARTS, at 4.30.—Progress in the Native States of India during the past Forty Years: Sir David W. K. Barr, K.C.S.I.

MATHEMATICAL SOCIETY, at 5.30.—On the Projective Geometry of some Covariants of a Binary Quintic: Prof. E. B. Elliott.—On the Inequalities connecting the Double and Repeated Upper and Lower Integrals of a Function of Two Variables: Dr. W. H. Young.—On the Operational Expression of Taylor's Theorem: W. F. Sheppard.—On a Formula for the Sum of a Finite Number of Terms of the Hypergeometric Series when the Fourth Element is Unity (Second Paper): Prof. M. J. M. Hill.—Note on a Soluble Dynamical Problem: Prof. L. J. Rogers.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—America Re-visited, 1907: Sir W. H. Preece, K.C.B., F.R.S.

FRIDAY, MARCH 13.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Observations of the Transit of Mercury, 1907 November 14: T. F. Claxton.—Photometric Measurements of Saturn, 1907 August–December: J. M. Baldwin.—Reappearance of Saturn's Ring, 1908 January: R. T. A. Innes.—On the Orbits of Σ 483, Σ 2438, Σ 3123, 8 Sextantis = A. C. 5, and Δ 15: T. J. J. See.—On the Lunar Inequalities due to the Motion of the Ecliptic and the Figure of the Earth: E. W. Brown.—On the Variability of the Nucleus of the Planetary Nebula N.G.C. 7662: E. E. Barnard.—Measures of Southern Binary Stars in 1907: John Tebbutt.—Double Star Observations, 1902–1907: W. H. Maw.—Further Considerations on the Correlations of Stellar Characters: Winifred Gibson and Karl Pearson.—The Perturbations of Halley's Comet, 1759–1910: P. H. Cowell and A. C. D. Crommelin.—*Probable Papers*: A Suggested Explanation of the Ancient Jewish Calendar Dates in the Aramaic Papyri Translated by Prof. A. H. Sayce and Mr. A. E. Cowley: E. B. Knobel.—The Perturbations of Halley's Comet in the Past (Third Paper), the Period 1066–1301: P. H. Cowell and A. C. D. Crommelin.—On the Relative Numbers of Star Images Photographed in Different Parts of the Plates for the Oxford Portion of the Astrographic Catalogue (Second Paper): H. H. Turner.—Note on the Discovery of a Moving Object near Jupiter (1901 C. J.): Royal Observatory, Greenwich.

ROYAL INSTITUTION, at 9.—Transatlantic Wireless Telegraphy: Chevalier G. Marconi.

PHYSICAL SOCIETY, at 8.—On Certain Dynamical Analogues of Temperature Equilibrium: Prof. G. H. Bryan.—Experiments on Artificial Fulgurites: Miss D. D. Butcher.—The Distribution in Electric Fields of the Active Deposits of Thorium and Actinium: S. Russ.

MALACOLOGICAL SOCIETY, at 8.—Descriptions of Two New Species of Synapterpes, Pils., and a New Species of South American Strophocheilus: Hugh C. Fulton.—Description of a New Species of Plectopylis: G. K. Gude.—On the Mollusca of some Holocene Deposits of the Thames River System: A. S. Kennard and B. B. Woodward.—Note on the Radula of *Pomatias elegans*: Rev. E. W. Bowell.—The Application of Poli's Generic Names: A. J. Jukes-Browne and J. H. Ponsonby.

SATURDAY, MARCH 14.

ROYAL INSTITUTION, at 3.—Electric Discharges through Gases: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 16.

ROYAL SOCIETY OF ARTS, at 8.—Fuel and its Future: Prof. V. B. Lewes.

TUESDAY, MARCH 17.

ROYAL INSTITUTION, at 3.—Membranes: Their Structure, Uses and Products: Prof. W. Stirling.

ROYAL STATISTICAL SOCIETY, at 5.

ZOOLOGICAL SOCIETY, at 8.30.—Some Observations on the Effects of Pressure upon the Direction of Hair in Mammals: Dr. W. A. Kidd.—The Rudd Exploration of S. Africa, IX. List of Mammals obtained by Mr. Grant on the Gorongoza Mountains, Portuguese S. E. Africa: O. Thomas, F.R.S., and R. C. Wroughton.—Notes upon some Species and Geographical Races of Serows (Capricornis) and Gorals (Næmorhedus) based upon Specimens exhibited in the Society's Gardens: R. I. Pocock.

MINERALOGICAL SOCIETY, at 8.—On the Occurrence of Minerals developed by Pneumatolitic Action in the Bodmin and Camelford Areas: G. Barrow and H. H. COAL MINING.

Practical Coal Mining. By Leading Experts in Mining and Engineering. Edited by W. S. Boulton. Vol. ii., pp. vi + 161–348; vol. iii., pp. viii + 192; vol. iv., pp. viii + 193–404. (London: The Gresham Publishing Company, 1907.) Price 6*s.* net each.

IN NATURE of May 23, 1907, a notice was published of the first instalment of this work, which, when completed in six volumes, is intended to cover the whole ground of modern coal-mining practice. Three further volumes have been received, containing the conclusion of Prof. H. Louis' section on shaft sinking, which broke off in the middle of a paragraph, and sections on breaking ground by Mr. H. F. Bulman, on methods of working and timbering by Mr. E. H. Robertson, on haulage by Prof. G. R. Thompson, on winding by Prof. C. Latham, on pumping by Mr. W. E. Lishman, on ventilation by Mr. H. W. G. Halbaum, and on transmission of power by Mr. W. E. Lishman. This division of responsibility among many contributors renders a certain want of harmony in the treatment of the subject-matter inevitable. The work will, however, certainly prove as a whole a valuable addition to coal-mining literature.

The concluding instalment of the section on shaft sinking by Prof. H. Louis is excellent. Recent German experience of shaft sinking in difficult cases recorded by Riemer and other Continental authorities is set forth in concise form; details of cost hitherto unpublished are given, and the accompanying sixty-five illustrations, unlike most of the others in the work, have in every case an indication of the scale to which they are drawn.

The fifth section, on breaking ground, covering fifty-nine pages, contains much practical information on driving stone drifts and on coal-cutting machines. The details relating to explosives do not, however, exceed a few words, and no description is given of the rock drills employed in driving stone-drifts.

The sixth section, on methods of working and timbering, the most important branch of mining, covers only fifty-four pages, and the illustrations are not very happily chosen. Altogether this section does not compare favourably with the treatment the subjects have received in the existing treatises by Hughes, Pamely, and others.

The seventh section, on haulage, which forms the commencement of vol. iii., covers seventy-four pages, and has been carefully compiled, the information given regarding tubs, rails, haulage, roads and systems of haulage being concise, accurate, and up to date. Interesting details are furnished of the recent application of mechanical conveyors in the road leading from each working face to the level beneath in steep seams. In regular seams, not seriously disturbed by faults, much is to be hoped from the application of conveyor systems; but there will always remain a large number of mines in disturbed areas where the natural conditions preclude such systematic working, and thus give scope to the ingenuity of the manager in arranging his system of secondary haulage.

The eighth section, on winding, covers ninety pages, and is adequate as far as it goes. Less hackneyed illustrations might have been selected with advantage, and more attention might usefully have been given to the great changes in winding that have taken place in recent years. The operating of main winding gears by electricity, for example, is dealt with in fifty lines. Winding by electricity is, it is true, little practised in Great Britain, although there is a large plant of 1500 horse-power in South Wales. In Germany, however, winding by electricity is making rapid progress. One firm alone has in hand about forty winding engines, some dealing with 2000 tons of coal per day and lifting from depths of 900 yards.

The ninth section, on pumping, covers 83 pages, and contains a concise summary of the recent literature on mine drainage, with well-selected illustrations of the principal types of pumps.

The tenth section, on ventilation, covers 80 pages, gives the prinçples on which the practice of mine-ventilation is based and discusses the theory of the centrifugal fan. The properties of mine gases and the instruments of measurement are also briefly dealt with.

The eleventh section, on transmission of power, deals first with electricity as the leading power agent, and then in turn with steam, compressed air, and hydraulic power. In this section various topics, such as winding, hauling, pumping, ventilation, and coal-cutting, are incidentally dealt with, the result being that there is a certain amount of clashing with previous sections. The Kaselowsky pump, for example, described on p. 403, is also described on p. 244 of the same volume.

The work is profusely illustrated, the three volumes containing 293 illustrations and twenty plates; and the type is large and clear. The ornate binding and the garish frontispieces are, perhaps, a little wanting in dignity for a comprehensive treatise on mining.

MALARIA AND NATIONAL DECAY.

Malaria. A Neglected Factor in the History of Greece and Rome. By W. H. S. Jones. With an introduction by Major R. Ross, C.B., F.R.S., and a concluding chapter by G. G. Ellett. Pp. vii + 108. (Cambridge: Bowes and Bowes; London: Macmillan and Co., Ltd., 1907.) Price 2*s.* 6*d.* net.

THE subject of the rise and decline of nations and of the causes to which they are due is of perennial interest. One of the problems which historians have striven to solve is the great change in the Greek character which occurred during the fourth century B.C. To quote from Mr. Jones's essay: —

"Home life took precedence of city-life. Patriotism decayed, and lofty aspirations almost ceased to stir the hearts of men. In art there appeared a tendency to sentimentalism; philosophy in many quarters became distinctly pessimistic. Some schools of thought actually took 'absence of feeling' or 'absence of care' as the highest goal of human endeavour. Dissatisfaction and querulousness are marked characteristics of the age. By 300 B.C. the Greeks had lost much of their manly vigour and intellectual strength."

In seeking for a cause for so remarkable a change the pregnant suggestion was made by Major Ross that widespread disease—particularly those "endemic diseases, which when introduced oppress a country for ever"—may have had far-reaching effects in modifying and moulding a new national character. Thus, in many of the southern States of America, the ill-health produced by widespread infection with the hook-worm has been held by American parasitologists to be largely responsible for the sloth and want of enterprise exhibited by the inhabitants of those districts. Recent investigations into the prevalence of malaria in Greece by Major Ross and others suggest that this disease may have been introduced into the country during the period mentioned, and may have been the factor bringing about this remarkable alteration of national characteristics. For malaria has not necessarily always been endemic in the districts in which it is now found. For example, Mauritius was free from malaria up to 1866, in which year it was introduced, and has caused infinite injury to the island ever since.

Mr. Jones has sought in the ancient authors for evidence which may serve to show when malaria was introduced into Greece, and what its effects may have been on the race, and has embodied the results of his researches in this interesting book. With two exceptions there seem to be no references in the classic writers to any disease which could be malaria before the middle of the fifth century B.C. It is in the "Wasps of Aristophanes" (422 B.C.) that the word πυρετός (used, generally in the plural, for malaria) first occurs in Greek literature (with a single exception in the "Iliad"). It is a singular coincidence that three years previously the Athenians were engaged on the island of Sphacteria, which is now one of the most malarial centres in the Mediterranean. The Peloponnesian war followed, large tracts of land were allowed to go out of cultivation, and it seems not unreasonable to conclude that the malaria parasites, introduced from Italy by Greek slaves or perhaps by the Carthaginians, then spread gradually over the country.

The word μελαγχολία and its cognates occur in Greek literature soon after the word πυρετός became common. Now the primary meaning of "melancholy" (derived from μέλαινα χολή, "black bile") seems to have been "excitable" or nervous. In the medical writers, tertian and quartan fevers were said to be derived from yellow and black bile respectively. Galen says that "large spleens are caused by 'melancholy humour'" (humour being used in the sense of a morbid fluid), and Hippocrates remarks that cases of "melancholy" occur in the autumn, which is the malarial season. It would therefore seem that the "melancholy" of these early writers is malarial cachexia. Mr. Jones arrives at the conclusion that "malaria was certainly prevalent in many parts of Greece, including Attica, during the fourth century B.C., though Greece was not 'highly infected,'" and that "the change which gradually came over the Greek character from 400 B.C. onwards, was one which would certainly have been aided, and was in all probability at least partially caused by the same disease."

In a similar manner the introduction of malaria into Italy is discussed, and it is inferred that this disease did not exist there much before 200 B.C., but was prevalent from 50 B.C. onwards. It seems plausible that it was introduced by Hannibal's Carthaginian mercenaries. As in Greece, so in Rome, it left its mark on the national character:—"Malaria made the Greek weak and inefficient; it turned the sterner Roman into a blood-thirsty brute—*atra bilis* made its victims mad."

Mr. G. Ellett contributes a final chapter, and among other points directs attention to the immunity from malaria enjoyed by progressive Japan contrasted with her stagnant neighbour China, where malaria is prevalent. Major Ross's foreword describes the manner in which malaria is disseminated by the mosquito, and some of the results of malarial infection, and serves as a fitting introduction to this interesting essay, particularly for the non-medical reader. Besides being interesting, the book has been issued with an object—to show how important it is to stamp out malaria wherever possible. R. T. H.

ELECTRICITY OLD AND NEW.

Cours d'Électricité. By H. Pellat. 3 vols. Vol. i., pp. vi+329; price 10 francs. Vol. ii., pp. 554; price 18 francs. Vol. iii., pp. vi+290; price 10 francs. (Paris: Gauthier-Villars, 1901, 1903, 1908.)

Les Découvertes modernes en Physique. By O. Manville. Pp. iii+186. (Paris: A. Hermann, 1908.) Price 5 francs.

M. PELLAT has published the courses of lectures which he gave from 1898 to 1907, covering the whole science of electricity. The first volume deals with electrostatics, the second with currents and magnetism, the third with the later developments of electrolysis and gaseous conduction. The course is intended and suited for somewhat advanced students, and no limitations are placed upon the use of mathematics; for the most part, little attention is given to experimental arrangements.

In the case of a work by a physicist so distinguished as M. Pellat it is unnecessary to criticise details; accuracy and soundness in all essentials may be assumed. The only remarks which a reviewer can offer concern the method of treatment; and it is in this respect that M. Pellat's volumes call for comment, for the order in which the subject-matter is introduced is entirely unconventional. The author believes that the usual development is illogical, and has endeavoured to correct this fault.

Thus he refuses to develop electrostatics from the basis of Coulomb's law on the ground that, if that law is taken as the starting-point, some hypothesis must be introduced, when media of different dielectric constant are considered. Accordingly he starts from experiments with a Faraday cylinder and an electrometer, and only introduces Gauss's theorem and the law of the inverse square after he has established almost all the important propositions. But any given proposition can only be established validly by any process of argument from an irreducible number of primary propositions or assumptions. If the assumption of which M. Pellat speaks is necessary to the development of the subject, then, if his arguments are sound, that assumption or its equivalent must be introduced at some stage. The difference between M. Pellat's treatment and that adopted ordinarily is not that the former requires fewer primary propositions than the latter, but that in the former those propositions are introduced as the direct consequence of some experiment, while in the latter they are introduced as hypotheses verified subsequently by the agreement of deductions from them with experiment. Now we insist most strongly that it is the latter process which is the more logical, for it is the process by which experimental sciences are actually developed. It is perniciously misleading to attempt to apply to such sciences arguments of the kind used in pure mathematics, for it is impossible to deduce any mathematical conclusion whatever from any experiment without an hypothesis; there is always an error of experiment. In our opinion, there are only two methods by which a science may be developed logically, neither of which is adopted by M. Pellat. The first is to follow the historical development, pointing out the stages at which hypotheses are introduced; the second is to define at the outset the concepts used and the propositions relating them, and to show that these lead to conclusions in harmony with experiment.

M. Pellat also prefers to develop electrodynamics directly from the mutual action of currents, introducing the concept of magnetism as a subsidiary function, and then applying it to the phenomena of magnetic substances. His reason for this unconventional procedure is that magnetism is a fictitious quantity which does not exist, but only behaves as if it existed—a distinction too subtle for our comprehension. But here surely the author is abandoning his logical principles. Magnetism is only introduced into the study of current actions because the properties of permanent magnets happened to be examined before those of currents; if the historical order had been reversed, there would have been no need for the conception. If the author is ready to brave all the inconveniences that attend the ignoration of the history of the subject for the sake of logic, surely consistency to his scheme should make him abandon a notion so purely historical as magnetism.

Remark should also be made on M. Pellat's strange neglect of Maxwell's theory of the electromagnetic field. A complete description is given of Hertz's experiments on electric waves, but the theory on which alone they are intelligible is relegated to a few pages in an appended note. Rowland's fundamental research, proving the identity of the electrostatic and electromagnetic conceptions of a current, is referred to in a brief phrase and attributed to Röntgen and Hertz. In some other places the work shows a lack of proportion in the space that is given to different subjects; twenty pages on electrostatic generators seems excessive, but on the other hand the chapter on dynamos and motors is excellent, and contains much that is too often excluded from physical textbooks. The last volume is on a somewhat different plane from its predecessors; it is more advanced, and contains discussions of many controversial points. We welcome an excellent last chapter on the elements of gaseous conduction.

It must not be thought that our remarks imply any disparagement of the work as a treatise for students; criticism has only been directed where it is challenged. English students are not so well provided in this subject that they would not welcome a translation. There is only one really serious defect in the book in its present form—the absence of an index.

M. Manville's book may be regarded in some respects as an attempt to supplement that of M. Pellat. The author complains that his countrymen have not realised yet the importance of the latest physical research. He thinks that they may have been hindered by the absence of a suitable summary which renders unnecessary reference to original memoirs, and has set himself to supply the defect. In less than 200 pages he treats of kathode and Röntgen rays, ionisation of gases, radio-activity, and general electron theory. Two subjects are also introduced which can hardly be termed modern; we should have thought that his exposition of the simple facts of electrolysis might have made way for more valuable matter, but apparently he is right in assuming that Maxwell's work has not been assimilated by those for whom he writes.

M. Manville's project is admirable, but we fear that his powers are not equal to his intentions, for he himself has not mastered these subjects completely. There are several actual mistakes, but a still more serious fault is to be found in his failure to show the connection between many of the phenomena which he describes. Though the various methods by which a gas may be rendered a conductor are treated in some detail, the only reference to the modern theory of ionisation, by which these methods may be correlated, is contained in a brief and inadequate paragraph at the end of the chapter. The account of the kathode rays is satisfactory, but there is no reference to the mechanism of the electric discharge in which they have their origin, nor is any distinction made between the electron and the ion which it forms. The chapter on radio-activity is a list of unconnected facts, while the theory of Rutherford and Soddy is dismissed as insufficient for the strange reason that it gives no account of induced activity! If not more than six pages could be spared for the application of the electron theory to optics, conduction and chemistry, it would have been better to leave such matters unmentioned. In view of recent speculations on the density and rigidity of the æther, it is hardly judicious to describe that medium as "ultra-gaseux."

As an example of actual inaccuracy we may quote the statement that solid dielectrics are ionised by Röntgen rays in the same way as gases. Our confidence in the author's analysis is shaken severely by a calculation on p. 67, where the maximum current obtainable between two electrodes of constant potential difference, but variable distance, is deduced from the condition that the differential coefficient of the current with respect to the *time* should be zero.

French books are apt to err in matters of typography, but such an abundance of misprints and misspellings cannot be left unnoticed; Prof. Townsend comes in for specially hard treatment. On the other hand, we are accustomed to expect French authors to redeem these deficiencies by a graceful literary style; but M. Manville's aberrations would be hardly tolerated in England. It is with great regret that we have to express our opinion that a design contemplated so wisely should remain still in need of successful execution. N. R. C.

OUR BOOK SHELF.

The Oceanic Languages: their Grammatical Structure, Vocabulary, and Origin. By Dr. D. Macdonald. Pp. xv+352. (London: Henry Frowde, 1907.) Price 10s. 6d. net.

In this volume, Dr. Macdonald sets forth the proposition that the Oceanic languages originated in the Arabian peninsula, and are thus cognate with the Semitic tongues. The primitive Oceanic he regards as a sister language of Arabic, Himyaritic, Ethiopic, Assyrian, Phœnician, Hebrew, and Aramaic, and Efate, Samoan, Malagasy, Malay, &c., as cousins of the modern Semitic dialects. He regards the people speaking the Oceanic languages in Madagascar, the Malay Archipelago, Melanesia, and Polynesia as one great, though diversified, race or people, and the languages themselves as constituting one great family. This unity of race is, however, negatived by the known ethnological data.

Although entitled "The Oceanic Languages," the work is mainly a dictionary of the Efate language of the New Hebrides, preceded by a discussion on the phonology, triliteralism, word-building, pronouns, and particles of the same language. These grammatical elements are compared with those of the Semitic languages taken collectively, so as to show a correspondence of forms. There is no attempt to give a comparative grammar of the Oceanic languages, though some few languages of the region, mainly Malagasy, Malay, other New Hebrides dialects, and Polynesian, are dealt with partially. In the absence of a comparative treatment of the Oceanic languages, some statements, such as those relating to the loss of gender in Oceanic pronouns (p. 75), the modern use of plural pronouns for singular, the representation of the Semitic nunation by final *na* or *n* in Malagasy and Malay (p. 92), are open to doubt, and cannot be accepted without some adequate proof being given.

The work is well printed, but it would have been better to print all the Semitic words in Roman character instead of occasionally using the Ethiopic, Syriac, Arabic, or Hebrew characters without transcription. In the preliminary (grammatical) part of the book there is a large amount of cross-reference, by which the illustration of some statement has to be sought in hundreds of places in the body of the book. In the dictionary, comparison of the Efate words is more fully made with the Semitic than with the Oceanic tongues, and here there are also numerous cross-references.

In conclusion, it may be said that the similarity of form in words and particles which Dr. Macdonald has shown in Efate and Semitic is no proof that they were originally the same, and exactly the same method has been employed to affirm the relationship of the Oceanic languages to Aryan, Australian, and American. The history of the Oceanic languages, as a whole, must be traced out before the apparent affinities of one of them can be held to establish a relationship of the whole group to some other linguistic group. S. H. R.

Searchlights: their Theory, Construction, and Application. By F. Nerz. Translated by Charles Rogers. Pp. vii+137. (London: Archibald Constable and Co., Ltd., 1907.) Price 7s. 6d. net.

The use of searchlights has rapidly extended during recent years, with the result that the want of a good treatise, dealing with their principles of construction and the methods of using them, has made itself acutely felt. The volume at present under review is a translation of the treatise on searchlights in Prof. Voit's "Sammlung elektrotechnische Vorträge," but much new matter has been added, so that it now forms an epitome of the latest practice. After dealing with the optical principles utilised in the construction of searchlights, special attention being paid to parabolic mirrors, the performance of searchlights and the methods of testing their mirrors are discussed. The applications of searchlights in the field, in land fortresses, for coast defence, and on battleships then receive attention. For field purposes a light equipment is now obtainable, consisting of a waggon carrying a petrol motor and a dynamo, coupled to another waggon which carries the searchlight and a transportable tower for elevating it. Searchlight equipments for fortresses may be either fixed, partially movable, or wholly movable; each type receives adequate consideration.

For coast defence, special arrangements, such as dispersers, are sometimes required, and these, in their turn, necessitate special protecting devices. Searchlights are indispensable to a battleship; without their aid a night attack of torpedo boats could not be repelled, hence the application of searchlights to naval purposes receives very careful consideration. The details of construction are then described and illustrated, attention being paid to the different forms of arc lamp, their method of control, and the various optical accessories which form part of a complete equipment. The scientific principles utilised are so carefully and lucidly explained that they will be readily understood by one who has previously had little acquaintance with them. Various forms of transportable power supply are described and illustrated in the last chapter, and the book ends with an appendix which briefly describes the physical units used in photometry. No book could meet the want which led to its compilation better than this one does. E. E.

Beyond Good and Evil. Prelude to a Philosophy of the Future. By Friedrich Nietzsche. Authorised translation by Helen Zimmern. Pp. xv+268. (Edinburgh and London: T. N. Foulis, 1907.) Price 5s. net.

"All prudent, worldly wise men follow more or less approximately the practice which Nietzsche teaches, notwithstanding the opposite principles which they perhaps profess to hold," says Mr. Thomas Common in an introduction to this translation, and it will interest and instruct those who are unfamiliar with Nietzsche's philosophy to read what the philosopher has to say here on the natural history of morals and other subjects. No reader will complain that there are not questions enough for thought raised.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Habitability of Mars.

INASMUCH as Dr. Wallace has sent me his book through his publishers, as I gather from the wrapper—though it is not so expressed—I suppose it is incumbent on me to acknowledge it, since he clearly expects some sort of reply. The effect of its perusal is to show me again how cogent is the argument for the habitability of Mars, for only by many misstatements of fact, wholly unintentional, of course, can Dr. Wallace make out even a seeming case upon the other side. A physicist will not need to have these errors pointed out to him, but as most readers are unable to correct them for themselves it may be wise to instance a few to show how his house of cards tumbles down in consequence.

On p. 22 he quotes from Miss Clerke to prove that the cap could only supply 2 inches of water over the irrigated districts. Let us assume her own estimate of snow deposited, and merely correct her mathematical and topographic mistakes. She states the maximum area which the cap covers to be 2,400,000 square miles. Now the south cap comes down to 36°.5 latitude on the average, and an easy calculation shows this to occupy 11,330,000 square miles, or to be more than four times as great. Next, she supposes the natural dark areas of the planet to be irrigated, which they are not, mistaking them for the canal system, which, instead of 17,000,000 square miles, covers, oases and all, only about 4,750,000 according to our measures, remembering that the whole of it is not watered from one cap. By combining these two corrections we find, not 2 inches of water for each bit of ground, but 2½ feet, and this according to her own estimate, which there is no reason to suppose not to be two or three times too small. So that it is the argument of Dr. Wallace, and not the cap, that fails to hold water.

An equally fatal flaw affects Dr. Wallace's argument for temperature. Here he bases his deduction on a misstatement of Prof. Poynting. Prof. Poynting states that in my paper on the mean temperature of Mars I took no due account of the blanketing effect of air. Not only did I expressly take it into account, but I did so in the only way it can correctly be taken, not by hypothesis, but by direct appeal to what takes place on earth under a clear and under a cloudy sky by night; and I am glad to know that in a paper he has sent to the *Phil. Mag.* on the subject Prof. Very, the bolometric authority on matters of temperature to-day, agrees with both my method and my conclusion for Mars, and points out where Prof. Poynting's calculations are fallacious.

Another omission is no less telling. Dr. Wallace apparently is unaware that Prof. Very's bolometric determination of the moon's heat, which for delicacy surpasses any previous ones, makes the temperature on the moon during the lunar day reach 356° F. above Fahrenheit zero.

Many more such misunderstandings might be mentioned occurring throughout the book, such as where, from not giving its context, he makes me appear to say that water-vapour is one of the heavier gases, which, of course, I did not.

Again, his theory, taken from Chamberlin, that the interior of Mars can have completely lost its heat in the very process of contraction, and yet later have suffered a meteoric bombardment sufficient to give it a heated outer layer, is mechanically whimsical, not to say impossible. For it can be shown that Mars could not have captured any meteoric swarms not substantially travelling in its own orbit when it coalesced into a planetary mass, and any meteors subsequently encountered could only have fallen on it as it passed through a swarm, yielding a relatively insignificant amount of matter. Any such effect would be even more pronounced on the earth, of the occurrence of which there is no evidence.

Misstatements cannot be too carefully avoided in science, especially when a man, however eminent in one branch, is wandering into another not his own. Dr. Wallace, whose intentions are of the highest, will appreciate this. Indeed, if criticism were confined, as common-sense counsels, to those versed in the phenomena, we should hear very little about the inhabitability of Mars.

Boston, March 6. PERCIVAL LOWELL.

DR. J. W. EVANS'S letter in NATURE of February 27 seems to invite notice from me in respect to three of the subjects with which it deals.

(1) As regards temperature. In most physical problems temperature may be regarded as a single definite measurement, which I understand to be Dr. Evans's point of view; but this ceases to be legitimate in molecular physics whenever the behaviour of an individual molecule comes under consideration. Temperature has then to be recognised as not one, but many, measurements, chiefly of two groups of activities, one group associated with the events that go on *within* the molecule and are in touch with the activities of the æther, and the other group mainly concerned with the journeys of the molecule through space and with one section of the events that occur during each of the encounters to which it may have to submit. Dr. Evans will find this subject referred to, and partly dealt with, at p. 76 of the *Astrophysical Journal* for July, 1904, or in the *Phil. Mag.* of the preceding month. On the other hand, in molar physics (as also in the kinetic theory of gas as usually treated) we have no occasion to deal with individuals; we are only concerned with swarms of molecules acting on one another and changing their behaviour so frequently that the activities of or within the molecules come into operation in too rapid succession to be distinguishable. All that we can then detect is that these numberless activities furnish an average outcome of energy which fortunately is (except in certain critical instances) sufficiently steady to admit of measurement, and is then what we call the temperature. But this jumbling together of unlike activities is not admissible when the question is about individual molecules—as when our object is to learn the conditions under which the lightest gaseous molecules of an atmosphere, which are those most violently tossed about, can occasionally and *one by one* drift away from their atmosphere.

(2) The question whether we can know that Mars is unable to prevent the escape of water is in effect almost the same question as whether we may trust the evidence that helium is in process of escaping from the earth, inasmuch as the dynamical conditions in these two problems are nearly identical. The evidence in the case of helium, so far as it was known eight years ago, Dr. Evans will find on pp. 369, &c., of the *Astrophysical Journal* for June, 1900. It should be added that the discoveries since that date about helium have materially strengthened the evidence then available.

(3) Dr. Evans bases an argument on the early state of the earth, which he thinks could not have been followed by the presence of water in modern times if some molecules can now escape from a planet in the way I have supposed. This, I believe, is a mistake. In the remote past the potential of attraction of the dilated earth of those days may have been, as supposed by Dr. Evans, so much less than now that multitudes of molecules now on the earth were not then upon it. So much may be conceded. But then, as now, these molecules were under the influence of the sun's attraction, and did not range beyond a ring round the sun, in which the earth also travelled—like the rings of Saturn or the asteroids of the solar system. Afterwards, when the earth shrank and the potential of its attraction rose to near its present amount, such of these molecules as encountered the earth were unable to escape again, and we now find them upon the earth. There is therefore no such conflict as Dr. Evans supposed between this possible past and the argument I have based upon observed facts, viz. upon the absence of all the gases of its atmosphere from the moon, and on the escape from the earth of molecules of hydrogen and helium which is still going on.

The more deductive method of investigating the escape of gases from atmospheres, without the premisses from observation of which I have latterly made use—which deductive method I attempted in former times, and upon which others have relied since—will, I am persuaded, continue to be incompetent to deal with this real problem of nature unless man's knowledge of molecular physics receive such unhoped-for accessions as will enable him to trace the history of single molecules. Meanwhile, what I advocate is that we avail ourselves of the mixed method, which introduces data established by observation to supplement the deductive method at the point where the deductive method fails. G. JOHNSTONE STONEY.

30 Chepstow Crescent, W., March 6.

Postscript, added March 13.—NATURE of yesterday's date announces the last supposed spectroscopic detection of water vapour upon Mars by one of Prof. Lowell's assistants. Observations of a like kind had been recorded by Sir Wm. Huggins and Prof. Vogel, and the wave-lengths of three of the lines observed were measured by Vogel, two of which may possibly be water lines recorded by Rowland, but not the third.

On the other hand, Campbell and Keeler in a better climate did not see them. Now, however, they seem to have appeared again. This would be the behaviour of a very variable coloured vapour like NO_2; and what I should desire is that an adequate study be made of the absorption spectra of the several such vapours which are unable to maintain themselves in our atmosphere on account of the presence of water, but are presumably to be found on Mars if water does not exist on Mars, and which if present will account for the orange colour of large tracts upon that planet, and for the variations of its colour at different seasons which are conspicuous.

It is to be regretted that the observers to whom we owe so much—from Schiaparelli to Lowell—have kept in view only one of the competing views as to the state of things on Mars instead of at each step considering them both, especially as the one they have preferred is that which some physicists have felt to be the least probable.

G. JOHNSTONE STONEY.

The Isothermal Layer of the Atmosphere.

LIKE Dr. Chree (p. 437) I have had experience of the vagaries of self-recording instruments, but I have generally been able to trace them to some remediable defect in the instrument or to the ignorance or carelessness of those who use them. I fancy that the man who constantly uses a certain instrument, and uses it intelligently and not by mere rule-of-thumb, has a fairly correct notion of the magnitude of the errors to which it is liable. If not, what reliance are we to place on any instrumental observations?

It is quite natural, however, to doubt the observations, and when this investigation first commenced I confess that I did the same. Now that hundreds of ascents have been made with different instruments, in different countries and in widely different circumstances, and all the results obtained are in striking agreement, such a view seems to me to be quite untenable. It is true that different instruments sent up with the same balloon have given widely different temperatures, but the results have been published, not concealed, and the instruments improved. I ascribe these discrepancies, which are the exception, not the rule, to solar insolation, which we avoid in England by making our observations after sunset.

With regard to the general question, the difficulties of registering a true temperature are two:—(1) stagnant and unmixed air which may be at different temperatures in different parts of the same garden; (2) the proximity of bodies of large thermal capacity, which by radiation and convection mask the true air temperature. Kites and balloons when they have left the earth are free from these errors, excepting that No. 1 applies to a balloon which does not burst when swimming at its highest point. Since, however, stagnant air does not matter provided sufficient time is allowed, and in this case time is allowed, I do not see what source of error there can be save solar insolation.

My belief in the accuracy of the thermometric results obtained in England is based on inference from the following facts. If a good trace, together with the constants of the instrument, is given to two persons, they, working quite independently of each other, will get practically identical results. If the trace and instrument only be given to two persons, they, each calibrating the instrument for himself, will obtain similar results for temperature within the limits stated, but the agreement for height may differ by a kilometre or more in the higher parts. Hence I believe in the accuracy of the temperatures, but do not claim any great accuracy for the heights.

Now with reference to Dr. Chree's questions.

(1) Each station is held responsible for the accuracy of its own results, and I am not acquainted with the routine pursued at each individual station, but the general practice certainly is to test each instrument in spirit cooled by solid CO_2 both before and after each ascent.

(2) Answered above.

(3) No. The instruments used on the Continent are expensive, and being heavier require a more expensive balloon, and we have no funds with which to meet the expense, especially when it is remembered that balloons and instruments in England are lost about three times out of ten. We hope that this will be done on the Continent before long. W. H. DINES.

Classification of Secondary X-Radiators.

IN NATURE of February 13 there is a letter by Dr. C. G. Barkla and Mr. C. A. Sadler in which the authors divide the elements—according to the qualities of the secondary X-rays emitted by them—into four groups founded upon the atomic weights, without consideration of any other quality of the element. It may be of interest to mention that practically the same classification was given by me as early as 1896 in the *Naturwissenschaftliche Rundschau* (vol. xi., p. 485), and that this classification was also dealt with in a treatise published by Prof. Voller and myself in the *Annalen der Physik und Chemie* (vol. lxi., p. 88, 1897). To this treatise there is added a table printed directly by the secondary rays of a great number of elements, and this shows not only the great difference between the elements of the different groups, but also the agreement in the behaviour of the various elements of the same group. B. WALTER.

Hamburg, Physikalisches Staatslaboratorium, March 2.

Gods and Godlings.

LEST some readers should infer from your obituary note on Sir Denzil Ibbetson (March 12, p. 443) that this distinguished anthropologist invented the word "godlings" for the rural deities of India, it is worth noting that "godling" was good English in the sixteenth century, and has never been allowed to drop. The Philological Society's "New English Dictionary" quotes Lambarde's "Perambulation of Kent" (1570-6) on raising altars "to this our newe found Godlyng"; and examples from Drummond of Hawthornden, Dryden, and Peter Pindar show the convenience of the word. Coleridge preferred "godkin" for a minor deity with masculine attributes, but sanctioned "goddessling." Charles Colton in 1675 permitted a certain cult of "little Goddikins"; Coventry Patmore regarded "godlet" as the more dignified appellative. Anthropologists have therefore had a fairly ample choice; but it should be added that in some of the above examples, at least, Dr. Murray and his coadjutors suspected a "jocular" intention.

DAVID PATRICK.

Tabulated Values of Certain Integrals.

IN NATURE, October 24, 1907 (p. 630), the integrals $x=\frac{k}{2}\int \cos u^2du$ and $y=\frac{k}{2}\int \sin u^2du$ are given. I shall be grateful if any of your readers can inform me where I can obtain tables of the numerical values of these integrals, or any other tables that will reduce the labour of the numerical calculation of them. C. E. ADAMS.

CANADIAN GLACIERS.[1]

IN Dr. Sherzer's elaborate memoir on five glaciers in the Canadian Cordillera, we have a contribution to the study of ice-streams not less important than that recently undertaken by the Indian Geological Survey, which was recently noticed in these columns (p. 201). Easy of access, and thus well adapted for study, these Canadian glaciers lie between the 51st and 52nd parallel, that is to say, very nearly on the latitude of London; two of them, the Victoria and the Wenkchemna, being east of the continental divide, the third, the Yoho, west of it, while the Illecillewaet and the Asulkan glaciers are in the Selkirks. The peaks of each range often vary from ten to eleven thousand feet in elevation, rarely exceeding the latter, and though they form rather more continuous walls and exhibit less contorted strata, remind us of the Swiss Oberland, west of the Kanderthal. The ranges, in fact, are carved out of stratified rocks, the deposition of which began quite early in the Cambrian period (the crystalline Archæan floor being invisible in this region) and continued through Palæozoic and Mesozoic ages until the end of the Laramie. Then this enormous mass of sediment, supposed to measure from ten to twelve miles in thickness, was slowly bent up into a very broad and flattened arch—designated, inappropriately as we think, by the modern mongrel term, a peneplain—which was duly carved into peak and valley by the ordinary forces of subaërial erosion. Through Cenozoic (*sic*) ages until the beginning of the Pleistocene (why the diphthong should be abolished in one name and retained in the other we fail to understand) rain and rivers were the chief sculpturing agents, but with the latter, ice began to make its mark on the rocks. There was, in fact, a Glacial epoch here as well as in the European Alps, and Dr. Sherzer tells us that signs are found of two, and one case of three, advances of the ice, followed by retreats. We should have welcomed a rather more precise description of the materials deposited on these occasions than is conveyed by the terms "till" and "ground moraine," because the identification of the latter is often, as we know from experience, a function of the writer's imagination, but we infer that in this case the deposits alter in character as the distance from the present ends of the glaciers increases, much as they do in the Alps of Europe.

Photo. *Notman and Son, Montreal.*

FIG. 1.—Illecillewaet Glacier in 1888.

In the case of each glacier, very careful observations have been made on the present position of its end, the signs of advance or retreat, the nature and quantity of moraine, and the structure and other physical properties of the ice. No one of them is really large, the Victoria, of which the fullest description is given, not exceeding more than about three miles in length. Starting at Abbot's Pass (about 9500 feet) on the divide, its ice emerges from beneath the snow about 2000 feet lower down, and melts away after descending about 1500 feet more. According to the description, it exhibits all the features usual in an Alpine glacier—crevasses, moulins, stratification, blue bands, shear planes, a granular structure, and sometimes even the disputed capillary tubes. Observations were made to determine the rate of movement, which, if

FIG. 2.—Illecillewaet Glacier in 1905, from approximately the same view-point as Fig. 1.

[1] "Glaciers of the Canadian Rockies and Selkirks (Smithsonian Expedition of 1904)." By Dr. William Hittell Sherzer. Pp. xii+135. (Washington: Smithsonian Institution, 1907.)

these be confirmed, is unusually slow, a maximum of 60 feet a year.

The Wenkchemna receives the name of a Piedmont glacier, rather on the Bottom's dream principle, for, though formed by the lateral union of several short ice-streams (called "commensal" because they are fed from different sources), they come to an end high up in a mountain valley. The Yoho glacier, on the west side of the divide, is split into two by a rocky rib at its lower end, and is unusually free from surface débris. The Illecillewaet glacier, best known of those in the Selkirks, with its steep cascade of shattered *séracs*, forms an imposing feature in the landscape, but, as a comparison of the accompanying figures plainly shows, retreated considerably between 1888 and 1905. The Asulkan glacier is the smallest and most southern of the five, but is nevertheless a fine object.

Lakets, moraines, and other "leavings" of the ice show that all these glaciers have retreated in comparatively recent times, but more facts must be gathered before the periodicity of their movements can be ascertained. It is, however, as Dr. Sherzer points out, not unlikely to agree with the approximate thirty-five and a half years already inferred for other districts, and we may notice in passing that in these mountains the "Chinook" wind is a substitute for the Alpine "Föhn." He claims for glaciers a certain amount of erosive action—the scooping out of small lake-basins in favourable circumstances, and the conversion of valleys in their lower parts from V-shaped into U-shaped. The latter may be; but we cannot help remarking that in the Alps, where the ice at equal distances can hardly have been less in quantity, it seems to have been singularly incapable of effacing any pre-existent feature of importance. Dr. Sherzer also claims that ice can exercise a plucking action, but apparently only when passing over a much-jointed quartzite. Obviously, this would be the worst possible material for making *roches moutonnées*, but even here we should like a little more proof that the glacier has mastered the "art of pluck."

The so-called "bear den" moraines—piles of coarse broken rock without the usual infilling of fine material—seem to be one of the more exceptional features of this region. Dr. Sherzer regards them as records of "landslides" upon the ice from the higher peaks. That would explain their structure, but we doubt whether an earthquake is needed to start a "berg fall." Not to mention earlier instances, those near Elm in the Sernfthal and from Turtle mountain in Alberta occurred without any seismic disturbance. The prismatic structure in "ice dykes" is also remarkable, and recalls that exhibited in *glacières* and pond-ice—a subject once much discussed, among other places, in the first and second volumes of NATURE. On the whole, though sometimes, perhaps, a little too diffuse in describing the well-known, Dr. Sherzer has made a valuable and remarkably well-illustrated contribution to the literature of glaciers.

T. G. BONNEY.

THE FORTHCOMING MATHEMATICAL CONGRESS AT ROME.

AS was announced in NATURE for February 6, the fourth International Congress of Mathematicians will be held at Rome in the week before Easter. The congress meets once every four years, the previous places of meeting being Zürich, Paris, and Heidelberg. On this occasion the order of proceedings will be as follows:—

Sunday, April 5; Reception at the Aula Magna by the principal of the University, at 9.30 p.m. Monday, April 6: Inaugural meeting at 10 a.m. at the Capitol, at which Prof. Volterra will read a discourse on Italian mathematics in the last half of the nineteenth century. At 3 p.m. a general meeting will be held at the Reale Accademia dei Lincei for the election of a president and for the award of the Guccia medal, followed by two lectures. From Tuesday, April 7, to Saturday, April 11, the congress will meet in four sections every morning at 9 a.m., the subjects of the sections being (1) arithmetic, algebra, and analysis; (2) geometry; (3) applied mathematics; (4) philosophy, history, and teaching of mathematics. In the section of applied mathematics the subject of actuarial mathematics will be introduced by Prof. Toja for the first time at these congresses. On each of the afternoons of April 7, 8, and 10, two lectures will be given, commencing at 3.30 p.m. Thursday, April 9: Visit to the Palatine by invitation of the Minister of Public Instruction, at 3 p.m. Saturday, April 11: Concluding general meeting; arrangements for date and place of next congress. Ninth and tenth lectures. Sunday, April 12: Visit to Hadrian's villa and lunch at Tivoli.

In addition, a reception will be given by the municipality in the museum of the Capitol on some evening during the week.

The lectures arranged are as follows:—Darboux (infinitesimal geometry), Forsyth (partial differential equations of the second order), Hilbert (method of infinite number of independent variables), Klein (the "Mathematical Encyclopædia"), Lorentz (partition of energy between matter and ether), Mittag-Leffler (representation of functions of a complex variable), Newcomb (lunar theory), Picard (analysis and mathematical physics), Poincaré (subject to be announced), Veronese (non-archimedean geometry).

From March 25 to May 5 the Italian State railways will issue tickets at reduced fares to those attending the congress from the frontier stations, as well as for ten separate journeys in any part of Italy. In addition, all members are granted free admission to the principal museums and galleries in Rome between April 1 and April 12. The subscription is fixed at 25 lire (1*l.*) for members, or 15 lire for those belonging to the family of a member who desire to enjoy the same privileges; but to obtain railway vouchers for the outward journey subscriptions have to be received before March 25 by the treasurer, Prof. Vincenzo Reina, 5 Piazza S. Pietro in Vincoli, Rome.

From the point of view of the English mathematician, the time fixed for the congress this year is somewhat inconvenient, as those who attend will doubtless wish to see something of Rome at the same time, and not only are our Easter vacations, as a rule, very short, but in many cases they do not even cover the period fixed for the congress. These difficulties could have been obviated by holding the congress at its more usual time in the summer vacation, and had this been done no inconvenience would probably have been experienced from the heat, though some people might have been deterred from attending owing to fears in this respect. In view of the fact that only seven Englishmen attended the last congress, it is important that everyone who can attend should do so this time, even if this involves an extension of their holiday beyond the ordinary limits of the school or college vacation. It would be a great pity if anyone were debarred from attending these gatherings merely for the sake of a week's teaching to a class of elementary pupils, and it is to be hoped that the governing bodies of our schools and colleges will not allow such small obstacles to stand in the way of their mathematical representatives being present on such occasions. Otherwise there is a danger of their mathematical teaching running into a narrow groove. In regard to future meeting-places of the congress, this matter is, of course, decided at the final meeting in April, but it may not be out of place to express the hope that the congress of 1912 will be held somewhere within the British Isles.

G. H. BRYAN.

PREHISTORIC CHEMISTRY.

ANCIENT Egypt always exercises an intense fascination for the student of the past, particularly as its written records are amplified by its "human documents" in the shape of mummies. This interest has, during the past few years, been intensified by the valuable series of anatomical studies on mummified remains which have issued from the Government School of Medicine at Cairo under the auspices of Prof. Elliot Smith. Not the least important of these is from the pen of Mr. W. A. Schmidt,[1] who has investigated mummified material of different epochs from the chemical and biological point of view. Some of the mummies he worked with carry us back to prehistoric periods, 6000 years ago, before the art of embalming as practised in later times was known to the inhabitants of the Nile valley.

It is remarkable that, in spite of this lapse of time, organic materials, which of all others are liable to decay, should still manifest in the test-tube their characteristic reactions. The presence of solid and volatile fatty acids, proteins, and cholesterin, with traces of intact fat, was demonstrable. The high percentage of fatty acids leads the author to the conclusion that they originate, not wholly from fat, but mainly from the body proteins. The formation of adipocere in the muscles of corpses left in water or buried in damp soil was adduced by the French observers in their work at the Morgue in Paris as evidence of the possible conversion of protein into fatty material. At the present time, however, the doctrine of the metabolic change of protein into fat is regarded with scepticism by most physiologists, in spite of the large amount of fatty acid radicals in the protein molecule.

The mummy protein, although it retains the general characters of albuminous material, has lost those specific properties which enable us to distinguish that of human origin from that which is found in other parts of the animal kingdom. In other words, it no longer gives what is termed the "biological reaction." This is disappointing, although it was doubtless expected. Mr. Schmidt also found that he could no longer detect hæmoglobin, and the substance regarded as blood by previous observers was doubtless composed of coloured gum and resin employed in embalming. In reference to the process of embalming itself, he was unable to find any soda; the so-called natrium bath really consisted of a solution of common salt. The old Egyptians simply pickled their corpses in brine, and the various balsams used were mere accessories which could have exerted no real influence on the process of mummification. The real agent at work here was undoubtedly the extraordinarily dry climate of Egypt, and it is this also which has acted as a preservative of the organic material which can still be identified.

The research reminds me of a small piece of work which was carried out by Dr. Otto Rosenheim[2] in my laboratory a few years ago. Small pieces of the carapace of a fossil Eurypterid were placed at his disposal by Sir E. Ray Lankester and Mr. Bather, of the Natural History Museum, and he was able to demonstrate in them the presence of chitin, their organic substratum. In this case one was dealing with prehistoric material compared with which an Egyptian mummy is quite recent. This kind of work appeals to the imagination, and one can only hope that if it is continued, still further light and interest will be thrown on the records of past ages.

DR. H. C. SORBY, F.R.S.

ON March 9, Dr. Henry Clifton Sorby, F.R.S., died, aged eighty-two, at his residence in Sheffield. The news of his death, although not unexpected, was received in the city of steel with profound regret, and those who had had the privilege of knowing Dr. Sorby felt that science had lost one of her greatest sons and that Sheffield must now look back upon "another yesterday." It is a little difficult for many of the inhabitants of "steelopolis" to realise that never again can they see the familiar figure hurrying along with bowed head, or the grave face, with, in its eyes, that far-off look which sees things beyond the ken of most men.

It is more than a little sad for those who could venture to intercept him with a "Good morning, Doctor," to know that never more can they receive his semi-startled, ultra-courteous recognition and hearty handshake, or again hear the cheery, almost laughing "*Good* morning. How are you?"

Combined with a complete absence of self-consciousness, two great personal characteristics of Dr. Sorby (which much handicapped him from the worldly point of view of non-scientific honours) were modesty and an immovable love of truth. The characteristic last named somewhat dimmed the brilliancy and lucidity of his papers, since in an enunciation he could never bring himself to omit any possible or even improbable qualification concerning the accuracy of the particular theory he happened to be formulating from his observed facts.

As a speaker Dr. Sorby could not claim to be an orator, but he had, nevertheless, a peculiar style all his own, by means of which he fully conveyed his meaning to his sympathetic audiences. Dr. Sorby belonged to a past generation of men of science the like of whom the world will do well to breed again. He loved science for her own sake, but so far from holding the view that science applied was science degraded, his almost child-like pleasure on hearing that some of his discoveries had been of practical use in the great workaday world was good to see. Dr. Sorby was not a family man, and though in easy circumstances he laboriously devoted his life to scientific research. The fact that those services to science were never adequately rewarded remains a permanent disgrace to the powers that be.

Turning from personal matters to the works of this great man of science, the writer is confronted by the fact that he must attempt the impossible task of compressing into a few hundred words an account of the labours of a versatile genius spread over a period of nearly sixty years, and embodied in about 240 papers, a number which, taking into consideration the length of Sorby's scientific life, corresponds to an average of four papers *per annum*.

His first research on sulphur and phosphorus in agricultural crops was published in 1847; his last paper on geology was written a few months before his death.

In 1849 Sorby founded the science of petrography, preparing in that year the first rock section ever examined by transmitted light. His alleged "wild ideas" as to the capabilities of this method were laughed at by the authorities of the period. Indeed, for a young man, not long past his teens, to attempt to upset the generally accepted dictum of de Saussure that mountains could not be examined by microscopes was regarded as bordering on presumption. In the early 'fifties, Sorby was much engaged on the subjects of the crystalline tetramorphism of carbon and the vexed question of slaty cleavage. In connection with the latter, in spite of rebukes, he persisted in his work, and in 1857 the young man of science buried both the electric and the 45° theories, by proving that slaty cleavage was due to the fact that lateral pressure on argillaceous rocks compressed them in one direction, elongated them in another, thus setting the small particles with their longest dimensions parallel, and so developing the characteristic structure in a plane perpendicular to the pressure.

In 1856 Sorby enunciated his now generally accepted theory that the Cleveland ironstone hills had been originally calcium carbonate, which had been gradually replaced by carbonate of iron derived from associated strata.

In the organic world Sorby did much work on colouring matters, and in this connection, for practical value, his microspectroscopic examinations of blood perhaps stand first. In 1865 he described his "new form of spectrum microscope" and the results registered thereby before the British Association. Proceeding upon information published by Hoppe, and two years later (1864) in greater detail by Prof. Stokes, Sorby exhaustively examined the microspectroscopic properties of red and brown cruorine and hæmatin, and from these figured no less than seven characteristic absorption spectra, showing incidentally that well-marked bands could be obtained from a minute blood-stain when only one-thousandth part of a grain of colouring matter was present. The importance of such marvellously delicate analysis was at once obvious to medical men and public analysts liable to be called upon to give evidence in criminal cases.

Sorby, the "Father of Petrography," was also destined to become the Father of Metallography.[1] His pioneer discoveries in petrography led him to the sagacious conception that steel itself might be a crystallised igneous rock; and in February, 1864, he placed in the hands of metallurgists for all time a new and most valuable method of scientific investigation.

On that date he read before the Sheffield Literary and Philosophical Society a paper "On a New Method of Illustrating the Structure of Various Kinds of Blister Steel by Nature Printing." In this paper he revealed the cellular structure of hard blister steel. He then attempted to produce artificial meteorites, but his efforts were not attended with success, because, as is known now, his experimental conditions were unsuitable, and it was not until 1904 that an "artificial meteorite" was described in NATURE on November 10, p. 32.

Sorby (as evidenced by the numerous carefully dated and initialled iron and steel sections now in the writer's possession[2]) worked on iron and steel metallography during the years 1863, 1864 and 1865, and, taking into consideration the meagre chemical data then extant, his final theory as to the nature of steel seems almost of the order of inspiration. He described crystals of nearly pure iron as consisting probably of interfering cubes and octahedra, and after a lapse of nearly forty-three years the accuracy of his conclusions (with only sectional planes to guide him) remains unshaken. In his "pearly constituent" (now called pearlite) he discovered a mineral the importance of which to mankind is still in this, the steel age, imperfectly realised. His "intensely hard constituent" is the cementite of the modern metallographer. The pearly constituent Sorby described thus:—"The optical characters of this substance led me to conclude that it had a very fine laminar structure before I was able to prove it by the use of high powers. It seems difficult, if not impossible, to explain its structure by supposing that it is an accidental mixture, whereas the facts are easily explained, if we suppose that it exists as a *compound*[1] at a high temperature, and breaks up into a *mixture* on further cooling, as more fully described in my paper on the use of high powers. For this reason it will be convenient to retain the name *pearly constituent* with the understanding that, *as seen when cold*, it is a mixture."

Persistent attempts to disprove the accuracy of Sorby's views of the nature of pearlite have, up to the present, consistently failed. Sorby's efforts to analyse pearlite quantitatively by micrographic means were, from the very nature of the problem, unsuccessful. He provisionally suggested that the hard plates constituted about 33 per cent. of the mass. Subsequent researches have shown that analyses on planes of section are misleading. The quantitative determination of the percentage and composition of these plates in pearlite occupied (in the metallurgical laboratories which were founded at Sheffield, largely owing to the energy and interest of Dr. Sorby) a period of three years, 1891–4, and was only accomplished by a triple attack conducted (*a*) by the microscope; (*b*) by quasi-quantitative pyrometric measurements of the heat of transformation of pearlite; and (*c*) by differential chemical analysis of the carbides as distinguished from carbon. The result obtained and now generally accepted indicated that in pure pearlite the percentage of hard plates always approximates 13.

It would occupy an inordinate amount of space even to summarise the results of Sorby's work conducted on his yacht *Glimpse* in connection with marine zoology. Dr. Sorby was a member of the Established Church, and made considerable researches in ecclesiastical architecture.

In concluding, it may be remarked that the final answer to the more or less good-natured derision with which his first rock section was regarded in 1849 was given, not by Dr. Sorby himself, but fifty-seven years afterwards by a cloud of witnesses at the centenary meeting of the Geological Society in February, 1906. Then many of the most distinguished foreign and British petrographers sent to the invalid man of science the following special message, expressing their "profound conviction of the important service rendered to the branch of geological science which they cultivate by the pioneer labours of Dr. Henry Clifton Sorby. They deplore the circumstances which prevent him from joining them on this interesting occasion, but beg to be allowed to assure him of their great admiration of his life's work, of their filial regard and deep affection."

Of Dr. Sorby it cannot be said that a prophet has no honour in his own country. Amongst the

[1] The attempt made by an American writer to transfer this title to a Russian metallurgist is best answered by silence.

[2] Some years ago the writer was exhibiting Sorby's pioneer sections of iron and steel at the Royal Institution, and was asked by an interested spectator, "How much each are you asking for them?"

[1] This is now known as hardenite (writer's note).

most treasured possessions of the University of Sheffield will always remain the marble bust of Sorby at the entrance to the Firth Hall, and his portrait, which hangs in the council room. So—his "task accomplished and the long day done."

"Beyond the loom of the last lone star, through open darkness hurled
Further than rebel comet dared or hiving star-swarm swirled
Sits he with those that praise our God for that they served His world."

J. O. A.

NOTES.

We regret to learn at the moment of going to press of the death of Sir John Eliot, K.C.I.E., F.R.S., who until recently was the distinguished head of the Indian Meteorological Service.

At the anniversary meeting of the Royal Irish Academy on Monday, March 16, the following were elected as honorary members of the academy in the section of science:—Sir Archibald Geikie, K.C.B., F.R.S.; Prof. J. C. Kapteyn, Groningen; Prof. A. A. Michelson, Chicago; Prof. J. D. van der Waals, Amsterdam; and Dr. A. R. Wallace, F.R.S.

It is understood that provision will be made by the Canadian Government in the estimates for the coming financial year for a grant of 25,000 dollars (5000*l.*) by the Dominion Parliament towards the expenses of the British Association's visit to Winnipeg next year. The city of Winnipeg itself proposes to make a grant of 5000 dollars (1000*l.*). The week of the meeting will probably be from August 25 to September 1, 1909.

A memorial to the late Sir Leopold McClintock is to be placed in Westminster Abbey, with the consent of the Dean and Chapter. The memorial will consist of an alabaster slab, underneath the monument to Sir John Franklin, whose fate was definitely ascertained by Sir Leopold during his celebrated expedition on board the *Fox*. The inscription will be as follows:—"Here also is commemorated Admiral Sir Leopold McClintock, 1819–1907. Discoverer of the Fate of Franklin in 1859." The expense of the memorial has been undertaken by the Royal Society, the Royal Geographical Society, and Trinity House.

The Canadian Mining Institute is arranging, in connection with its summer meeting, a general excursion to the mineral districts of Nova Scotia, Quebec, Ontario, and British Columbia, starting towards the end of August next. Members of the Institution of Mining and Metallurgy have been invited to take part in the general excursion (or any part of it) on the same specially favourable conditions as will be accorded to its own members. The Dominion Government, and the various provincial governments concerned, will cooperate in making the excursion a success, and the occasion will afford an excellent opportunity for engineers to inspect the important mineral areas of the Dominion.

The second International Conference on Sleeping Sickness, to the proceedings of which attention was directed in our issue of last week, has terminated without being able to agree on the draft convention before it. Reuter's Agency states that the French and Italian plenipotentiaries declared themselves unable to accept a proposal, made at the last conference in June and then unanimously recommended, for the establishment of a central bureau in London. It was proposed that the work connected with sleeping sickness should be taken over by a hygiene bureau to be established in Paris, but this proposal the German plenipotentiaries declined to accept, and they strongly supported the British plan for the establishment of a bureau in London. The president (Lord Strathcona), the vice-presidents, and council of the Royal Institute of Public Health gave a dinner on March 11 at the Hôtel Métropole "to meet the delegates of the International Sleeping Sickness Conference." Lord Strathcona presided, and in proposing the health of the delegates to the international conference hoped that the result of that and successive conferences will be, if not to eliminate, at all events to mitigate the great scourge of sleeping sickness. Dr. Koch, in reply, said it is but the duty of medical men to investigate diseases. Especially is this the case with countries which, on account of their colonies, are particularly interested in certain dangerous diseases. Dr. Cureau expressed the thanks of the French delegates. The Marquis de Villalobar, Prof. S. Liquido, Colonel Lantonnois, Dr. Kopke, and Sir Walter Foster also replied.

The Bakerian lecture of the Royal Society will be delivered on Thursday next, March 26, by Prof. C. H. Lees, F.R.S., upon the subject of the thermal conductivities of solids.

We have received a copy of the introductory number of *Neue Weltanschauung*, a scientific journal to be published at Stuttgart in monthly parts at fourpence each. It appears that a Neue Weltanschauung Society has been established at Stuttgart which is to issue, not only the monthly journal bearing the same name, but likewise another publication at irregular intervals. We shall be better able to judge of the merits of the former when we receive one of the regular numbers.

In the March issue of *British Birds* Mr. N. F. Ticehurst records a number of bird-bones obtained by excavating an ancient mound known as the Broch of Ayre, near the Bay of Ayr, in Orkney. The most interesting of these is an imperfect leg-bone of the great auk, a species hitherto unknown from the Orkney mainland. It would, however, remarks the author, be rash to take the evidence of such a specimen as proof that the bird was once an inhabitant of the mainland.

No. 1579 of the Proceedings of the U.S. National Museum contains an interesting account of the mode of collecting the sap of the Mexican agave and manufacturing therefrom the national beverage known as *pulque*. When the agave is in the proper condition some of the leaves are stripped away so as to expose the central core of unfurled leaves; a year later the core is cut out bodily, and a hollow made in the base to serve as a reservoir for the limpid sap, which soon flows from the wound, and is stated to have a taste very like cocoanut-milk. The sap, or *aquamiel*, is drawn off by means of a siphon, and transported in skins to undergo fermentation, and thus be converted into pulque.

We have been favoured with a reprint of a note published in the *American Naturalist* for December last, in which Mr. F. T. Lewis disputes the commonly accepted view that the mimicry among South American butterflies is connected with birds. The original mimicry theory, it is explained, has been so extended as to embrace and account for not only resemblances between an edible and an inedible form, but also between two inedible species. The author now raises the question whether the resemblances have anything to do with edibility, or the reverse, and quotes Werner and Weismann to the effect that they have not. One of the arguments used is that, as a general rule, birds do not molest butterflies to any great extent. The real explanation of the resemblances in question will, in the author's opinion, be supplied by a chemical theory of animal coloration.

The third part of the Bergen's Museum *Aarbog* for 1907 contains a long article by Mr. C. F. Kolderup on Scandinavian glaciation. At the period of greatest extension, it appears that the whole country was covered with an ice-sheet moving in a westerly direction altogether independent of local contours. When, however, the ice began to diminish, the direction of movement gradually became more and more dependent upon that of the valleys, until finally the ice-sheet became resolved into a number of large isolated glaciers filling the latter. Some geologists admit only one great Ice age, and deny the intercalation of a warm period between two such maxima, during which the snow well-nigh disappeared from the Scandinavian highlands. The evidence of the moraines and their embedded shells is, however, in the author's opinion, amply sufficient to justify belief in such an intercalation. Indeed, the occurrence of several oscillations of level, with concomitant climatic changes, appears to be demonstrated.

The Cotteswold Naturalists' Field Club has recently issued in part i. of its sixteenth volume a paper by Dr. C. G. Cullis and Mr. L. Richardson on the Old Red Sandstone conglomerate of the Forest of Dean, in which gold has undoubtedly been detected. A comparison with the "banket" beds of the Rand is made, favourable to the Forest of Dean so far as convenience in working goes; but the authors do not commit themselves as to the average gold-contents of the British deposit. The same part contains several papers on local geology, and a finely illustrated account of species of the terebratuloid genus Cincta, by Mr. S. S. Buckman. *Terebratula numismalis* here finds itself split up into a number of species of Quenstedt's genus Cincta, which has priority over several other names.

The fourth part of vol. xx. of the Proceedings of the Geologists' Association (January, 1908, price 3*s.*) consists of a complete memoir by Dr. A. W. Rowe on the zones of the White Chalk of the Isle of Wight, with an index that includes all places and fossil species mentioned in this and in the four memoirs that have preceded it. Mr. C. D. Sherborn, who has often collaborated in this great zonal work, supplies coloured maps on a large scale, and the photographic illustrations are of extraordinary delicacy and beauty. Dr. Rowe's twelve years' labour is here brought worthily to a conclusion, and the necessity of accurate zonal collection, if one would study any sequence of fossil forms, is again set clearly before the reader. The true course of invertebrate evolution can, after all, be traced only by the painstaking methods of field observation inaugurated by William Smith at the close of the eighteenth century.

In the *Bolletino* of the Italian Seismological Society Prof. Mario Baratta gives a detailed account of the methods of construction adopted in re-building the Calabrian villages destroyed in the earthquake of September 8, 1905. Frame buildings in wood, filled in with masonry or concrete, were largely adopted, and armoured concrete for the more important buildings. The report would have been of greater interest had it contained an account of the behaviour of these erections in the earthquake of October 23, 1907, which was said, in the daily newspapers, to have destroyed some of the newly built villages.

We have received an advance copy of a paper by Dr. E. Oddone, to be published in the *Bolletino della Società Sismologica Italiana*, in which he makes the suggestion, already put forward by Prof. Milne in the last report of the British Association committee on seismological investigations, regarding the possibility of a causal connection between the two earthquakes on August 16, 1906, which occurred within about thirty-two minutes of each other, one in the northern Pacific, the other in Chile. This interval being approximately that which the wave motion of the second phase might be expected to take in travelling from the origin of the one earthquake to that of the other, it is suggested that the arrival of these waves was the determining cause of the time of occurrence of the Valparaiso earthquake. An objection to the acceptance of this suggestion is the uncertainty as to whether the second-phase waves are not extinguished before reaching a distance of 120° from the origin, that is to say, somewhat less than the distance separating the origins of the two earthquakes in question.

The Queensland Geological Survey has issued a Bulletin (No. 216), by Mr. B. Dunstan, on the Great Fitzroy copper and gold mine, Mount Chalmers, Rockhampton district. The ore deposits, which have been known since 1860, occur in quartzite, which appears to be the result of the alteration of limestone. It is estimated that there is about 145,000 tons of ore still available, containing $4\frac{1}{2}$ per cent. of copper, $3\frac{1}{2}$ dwt. of gold per ton, and 1 ounce of silver per ton.

The weathering of coal forms the subject of an investigation by Prof. S. W. Parr and Mr. N. D. Hamilton (University of Illinois, Bulletin No. 17). They find that an exudation of combustible gases from coal occurs from the time of breaking out of the sample from the seam, and that an absorption of oxygen accompanies the exudation. The process of deterioration is probably due to oxidation of hydrogen or of hydrocarbons. It may also be due to a simple loss of combustible gases and their replacement by oxygen. The extent of the deterioration varies with different coals, but the deterioration is probably most active during the first two or three weeks from the taking of the sample.

An interesting monograph on the rural highways of Wisconsin, by Mr. W. O. Hotchkiss, has been issued (Bulletin No. 18) by the Wisconsin Geological and Natural History Survey. It covers 136 pages, and is illustrated by sixteen plates. The improvement of the rural highways of the State is a matter to which much attention has been devoted, and the author supplies useful information regarding methods of road construction. He gives a summary of the general principles of making roads, and discusses the conditions obtaining in the State of Wisconsin. In conclusion, he adds a digest of the laws of those States where legislation in the matter of roads has received most careful attention.

In comparison with the thorough treatment of bridge trusses by eminent writers, very little attention has been devoted to roof trusses, and consequently the exhaustive study described by Dr. N. Clifford Ricker in the University of Illinois Bulletin, No. 16, forms a valuable addition to technical literature. The investigation had for its original object the determination of a formula for the weight of roof trusses more accurate than those in existence. Other interesting results were incidentally obtained, and the Bulletin gives in detail the results obtained in reference to the formulæ for normal wind pressure, the system of calculation and design, the form of stress sheet, the formula for weight of truss, the comparative weights of trusses of various materials, the economical distance between trusses, length of panels and number of purlins per panel, the effect of raising the lower chord at the centre of span (from which no advantage results), and the most economical ratio of rise to span of roof trusses.

We have received parts i. and ii. of the meteorological report of the Survey Department of Egypt for the year 1905. Part i. contains very complete hourly readings and means for each month at Helwan Observatory. Attention is directed to the well-marked daily and annual variations of wind direction and to its prevalence to the east of north, whereas in the Delta it is usually west of north. Part ii. deals with climatological stations, rainfall, and river-gauge observations in Egypt and the Sudan. The annual rainfall was in excess in the Delta and in the Sudan, but deficient in the Cairo district and over middle Egypt. The Nile flood did not reach its mean level at any time during the year.

A discussion by Prof. J. Schneider of the moon's influence on the wind components at Hamburg is published in vol. xxx. (1907) of *Aus dem Archiv der deutschen Seewarte*. As the work was undertaken principally with the view of ascertaining whether any daily or half-daily influence was exhibited, only the observations for the six winter months, 1887–1896, were used, so that the influence of the sun might be eliminated as much as possible. Among the various results, we note that from the records of the best anemometers the moon's influence is shown to be practically imperceptible in the daily range; the results for anomalistic months show that both components (W.-E. and S.-N.) apparently increase with the approach of the moon to the earth, and decrease as it recedes. The values are tabulated in various ways; for details we must refer to the paper in question.

In the Bulletin of the Manila Weather Bureau for March, 1907, Father Algué gives an account of a typhoon of extraordinary intensity which visited the Caroline Islands in that month. The storm apparently formed to the south of Ponape (Eastern Carolines) between March 24 and 26, and moved in a W.N.W. direction to Wlea (Western Carolines), where it arrived on the morning of March 29; by the afternoon of March 30 it reached Mackenzie Island (lat. 10° N., long. 140° E.), when it began to re-curve to the N. and E., passing to the N. of the Ladrones Islands (lat. 20° N., long. 145° E.) on the evening of April 3. In the Wlea group the destruction was almost complete; immense waves carried away houses and everything in their path, and some 200 persons perished on two of the islands. At 7h. 30m. a.m. on March 29 the barometer there read 28·58 inches, and fell rapidly to 27·24 inches at 10h. a.m.; at 4h. p.m. it had risen to 29·10 inches. The wind blew with typhoon force from N.N.E. and N.E. from 3h. a.m. to 10h. a.m., and then shifted to S.E. and S.W., and was still blowing a hurricane from S.S.E. at 8h. p.m. The influence of the storm was not felt in the Philippines, but owing to the vigilance of Father Lopinot, observer at Yap (Western Carolines), who took hourly observations during its passage in that locality, the Manila Observatory was enabled to give timely warning of danger in the Pacific to China and Japan when the cyclone centre was some 1100 miles distant.

From Messrs. C. F. Casella and Co., of 11, Rochester Row, Victoria Street, S.W., we have received a set of the "Stonyhurst Sun Discs" which they have recently issued. These discs have been made at the suggestion, and with the assistance, of Father Cortie, and are similar to those used at Stonyhurst College Observatory for a number of years for the determination of the heliographic positions of sun-spots and faculæ. Each set includes eight discs, and on each of these is a true orthographic projection of the parallels of latitude and longitude corresponding to the value of the declination of the sun's centre, from 0° to ±7°, for each period of the year. The discs are 6 inches in diameter, and are nicely printed on cardboard, for use with a projected image of the sun, or on transparent glazed linen for use with a drawing of the solar disc. Each set is enclosed in a strong cloth wallet, and may be obtained from the above firm at the price of 10s. 6*d*. per set.

The January number of the *Astrophysical Journal* contains a very suggestive article, by Mr. E. Goldstein, of Berlin, on the two-fold line spectra of chemical elements. Mr. Goldstein has found, during a long series of experiments, in which he produced his spectra by employing heavier condenser discharges than have hitherto been employed, that he could replace the well-known spectra of the alkali metals rubidium, cæsium, and potassium by an entirely new line spectrum. Previous workers have found some of the new lines appearing with the arc spectra, but have not succeeded in eliminating the latter; in Mr. Goldstein's spectra, however, the new sets of lines appeared alone. As the lines of the ordinary arc spectra fit themselves into series, whilst the new lines fit into no series, it appears that powerful discharges extinguish all the series lines and replace them by non-series lines in the case of the three metals named. In the case of sodium, Mr. Goldstein has not yet succeeded in eliminating the series lines, only in weakening them, whilst in the case of lithium the effect is still less marked. As the density of the discharge necessary to affect the transformation from the series to the non-series, or "fundamental spectra" ("Grundspectra"), lines appears to increase as the atomic weights decrease, it may be that increased experimental facilities will bring sodium and lithium into line with the other three alkalies. Amongst a number of other important suggestions, reference is made to the possibility of the ordinary, or "series," line spectra being emitted by regular groupings of particles which, when subjected to a heavy condenser discharge such as was employed in the present experiments, are broken up, leaving single particles which emit the single uncorrelated lines of the "fundamental spectra."

The firm of Gustav Fischer (Jena) has published an address on the modern analysis of psychical phenomena delivered by Prof. A. Hoche at the congress of German Naturalists and Physicians held at Dresden last September. Dr. Hoche, who spoke from a point of view that would exclude all quasi-metaphysical discussion from psychology, characterised the present phase of the science as one of "spade-work" carried out by many hands over a wide area, such as commonly recurs after a period of rapid deepening and widening of our conceptions. Progress has presented itself in the form of new demands upon psychology, followed by the appearance of new methods of investigation and the conception of new aims for its efforts. Under the first of these headings fall the applications of psychology to the scientific study of history and religion, as well as to matters of legal and medical interest. Among the new modes of investigation are the comparative methods, which have to a great extent taken the place of the older introspection; the experimental method, which commands most attention in the present day; and the pathological method, which, taking advantage of nature's own experiments, has thrown much light on the real character of the contents of some parts of our normal experience. Finally, the newer aims of psychology include the attempts to classify actual personalities with reference to standard equilibrated types, and to find a field for practical applications in pedagogy and in the treatment of criminals.

At the suggestion of Prof. A. A. Michelson, Mr. L. E. Gurney, of the University of Chicago, has investigated the viscosity of water at very low rates of shear in order to determine whether any change in its value occurs when the motion of the liquid is slight. The water was enclosed between concentric cylinders, the outer one of which was rotated at a measured rate about its axis, while the inner one was prevented from rotating by means of a couple of measured moment. For rates of shear varying from 5 radians down to 0·66 radian per second the author finds no evidence of an increase of viscosity as large as 1 per cent. (*Physical Review*, January).

In the *Physikalische Zeitschrift* for March 1 Dr. W. Lohmann describes his measurements of the Zeeman effect for the principal lines of helium. The helium tubes were placed in cylindrical holes bored through the pole pieces of the electromagnet in such a way that the electric current through them flowed parallel to the magnetic field. The separation of the outer from the middle lines of the triplets produced was observed by means of an echelon spectroscope. Dr. Lohmann finds that the separation measured on the scale of reciprocal wave-lengths, *i.e.* the quantity $d\lambda/\lambda^2$, where $d\lambda$ is the observed change of the wave-length λ, is the same for the whole of the nine lines of helium observed, and is proportional to the strength of the magnetic field used. He considers this result points to an extremely simple form of helium atom.

Prof. Augusto Righi announces the discovery of a new type of rays in the *Rendiconti dei Lincei* for February 2. It was Plücker who first observed that kathode rays, immersed in a strong magnetic field, trace out the magnetic lines of force. This is now held to mean that the projected electrons really describe high-pitched spirals about the lines of force, which nearly coincide with those lines when the field is very strong. Now Prof. Righi has found that these rays do not, as a rule, convey an electric charge. They are therefore not simple kathode rays. They are more probably sets of molecular magnets, constituted by electrons revolving about positive atoms in the planetary fashion. Such systems would possess considerable stability in a magnetic field of the same sign. They would not, of course, carry an electric charge, being themselves neutral combinations, but less close than ordinary chemical combinations. As the field gets weaker, the orbits would open out, and the system would be retarded, and might even return to the kathode. Prof. Righi has found evidences of such return. He proposes the term "magnetic rays" for the new radiation.

A work on "Stone: Quarrying and Preparation for the Market," by Mr. A. Greenwell and Mr. J. V. Elsden, will shortly be published by the Chichester Press, Furnival Street, London, E.C.

The thirty-eighth annual report of the Wellington College Natural Science Society has been received. It deals with the society's work during 1907, and serves to show that the activity of the members is well maintained. A complete meteorological report for the year is included in addition to the proceedings of the society.

The Royal Swedish Academy of Sciences is publishing a new edition of Swedenborg's scientific works in Swedish and the original Latin. The first volume has appeared, and two others are in the press. These three volumes include Swedenborg's contributions to geology, chemistry, physics, mechanics, and cosmology. Introductions are provided to the various volumes, that to the first by Prof. Alfred G. Nathorst, and those to the second and third by Prof. Svante Arrhenius, while those for forthcoming volumes on anatomy and physiology will be by Profs. Gustaf Retzius and S. E. Henschen respectively. The volumes are being edited by Mr. A. H. Stroh, of Philadelphia, and the price of each volume is 8*s*., payable in advance.

The general report on the operations of the Survey of India administered under the Government of India during 1905–6 is now available. It has been prepared under the direction of Colonel F. B. Longe, R.E., Surveyor-General of India, and deals with the operations of the department for the survey year ending September 30, 1906. It appears that the total out-turn of detail topographical and forest surveys on all scales was 23,312 square miles, against 26,340 square miles of similar surveys during the previous year, and that no surveys on a smaller scale than 1 inch equal to the mile were carried out during the year. The total area triangulated or traversed for topographical or forest surveys was 27,134, against 19,265 square miles for the previous year. The total area of cadastral and special surveys was 2982 square miles, and the area traversed was 6464 square miles, as compared with 7305 square miles of survey and 6398 square miles of traversing in 1904–5. Among special observations during the year may be mentioned systematic vertical observations of the Himalayan peaks of Kedarnath, Srikanta, Jaunli, Bander Punch, and Nanda Devi from stations near Dehra Dun; if this series of observations can be continued over five or six years the varying effects of refraction and snowfall will be deducible. Pendulum observations were carried across the plains of the Punjab from Simla to Quetta, and the results have proved that a zone of excessive density crosses the Punjab plains from north to south, underlying Montgomery, Ferozepore, and Mian Mir. The field work of the magnetic survey over different portions of the country has been continued and extended.

OUR ASTRONOMICAL COLUMN.

A Possibly New Satellite to Jupiter.—A note in No. 4237 of the *Astronomische Nachrichten* (p. 207, March 6) announces the discovery of a new minor planet, or, possibly, a satellite, near Jupiter. The object was discovered by Mr. P. Melotte on a plate taken by him with the 30-inch equatorial reflector on January 27, and is of the sixteenth magnitude; it has been observed at Greenwich on seven nights since that date, and Prof. Wolf photographed it at Heidelberg on March 3. Should this faint object prove to be a minor planet, its temporary designation will be 1908 CJ, and it will probably prove to be a unique object, as regards its orbit, of its class. But it seems likely—so far as can be judged from the few observations yet made—that it is, really, an eighth member of Jupiter's satellite system, and if this is so it is probably the faintest and most distant yet discovered.

OBSERVATIONS OF JUPITER DURING THE PRESENT OPPOSITION.—M. P. Vincart, of Antwerp, to whom we referred in our issue of January 16 (No. 1994, p. 259) as having made his own reflector, describes his more recent observations of Jupiter in No. 3 of the *Gazette Astronomique* (p. 27). On February 5 the shadow of the fourth satellite, projected on to the bay of the Red Spot, appeared elongated, and was encircled by a brilliant halo where it came in contact with the Red Spot. On February 13, despite prolonged attention, M. Vincart was unable to find the least trace of the regular markings recently described by Mr. Bolton.

M. Vincart states that with his instrument he is able to separate, clearly, the components of γ^2 Andromedæ, whilst with the naked eye he is able to count thirteen stars in the Pleiades and to see Jupiter's third satellite when at its elongations.

RECENT OBSERVATIONS OF VENUS.—The third number of the *Gazette Astronomique* (February 29, p. 21) contains an interesting description, by Mr. J. M. Harg, of Lisburn, Ireland, of his recent observations of Venus, made with refractors of 104 mm. and 123 mm. aperture, and using a magnifying power of 200. Four sets of markings were recognised from time to time during the period December 29 to January 20, and are illustrated by the drawings accompanying the note. The first, in longitude 180°, is a long oblique shadow; the second is in longitude 270°, and is an irregularly shaped marking showing numerous details in its outline; the third is a doubtfully permanent, double marking in longitude 0°; and the fourth is of a curiously bent form in longitude 90°. Mr. Harg's observations indicate that the rotation period does not exceed 23h. 28m.

THE SYSTEM OF ζ URSÆ MAJORIS (MIZAR).—Prof. Frost, in a brief note communicated to No. 4235 of the *Astronomische Nachrichten* (p. 171, February 29), confirms Dr. Ludendorff's observation of the variable radial velocity of the fainter component of ζ Ursæ Majoris, but states that the Yerkes spectrograms show a greater range of velocity, varying from -17 km. to $+10$ km. per second; the period of the variation cannot yet be stated.

The plates of Alcor, the naked-eye companion to Mizar, show that the radial velocity of this star also is variable, the changes in the spectrum being so rapid that it has been found necessary to take spectrograms in continuous succession for several hours; it seems probable that the period will be found to be exceedingly short. A qualitative examination of the spectra obtained shows that the 4481 Mg line and the hydrogen lines are sometimes double, sometimes single. The displacement of the 4481 line with respect to the Ti line of nearly the same wave-length also varies considerably.

MARS AS THE ABODE OF LIFE.—The title of Prof. Lowell's article in the March number of the *Century Magazine* is "The Sun Dominant," and in it the author discusses the analogies between areographical and terrestrial conditions. The evolution of the conditions of habitability on the earth is described, and it is shown that the same kind of evolution is probably taking place on Mars. From the fact that the same species of animals, often the same individuals, are able to sustain life under the vastly different conditions of temperature and atmospheric pressure exhibited at various altitudes in the Andes and similar mountain ranges, it is argued that the variations of temperature and the constant lowness of the pressure on Mars should prove no bar to the possibility of living creatures existing there. The presence of water—demonstrated, since the article was written, by Mr. Slipher's spectrograms—and of vegetation are also discussed, and the article concludes with a discussion of the mode in which the presence of organic life is manifested.

THE VARIABLE STAR 31, 1907, AURIGÆ.—A telegram from Prof. Hartwig, published in No. 4238 of the *Astronomische Nachrichten* (p. 223, March 9), states that the variable star 31, 1907, Aurigæ, which he has found to be of the U-Geminorum type, was of the ninth magnitude on March 6, having increased four magnitudes in one day, whilst within eight days it was less than the fourteenth magnitude.

THE CARNEGIE INSTITUTION.

THE "Year-book" for 1907 of the Carnegie Institution of Washington is now available. It contains the minutes of the last meeting of the board of trustees, the reports of the president, Prof. R. S. Woodward, and the executive committee of the institution, and the reports on investigations and projects. The volume, of 230 pages, serves excellently to indicate the admirable work in science which is being done by means of the grants made by the institution. The subjoined summary of the reports shows the position of the institution and some of the directions in which progress was made during the past year.

At the meeting of the board of trustees in December last a letter from Mr. Andrew Carnegie was read announcing his intention to add 400,000*l.* to the endowment of the institution. The financial statement for the year ending October 31, 1907, shows that the assets of the institution, including real estate and equipments, amounted to nearly two and a quarter millions sterling, the endowment being 2,000,000*l.* At this meeting of trustees the following general appropriations were made for the present year:—publication fund, 10,000*l.*; administration, 10,000*l.*; grants for departments and large projects, 75,988*l.*; and for previously implied grants, new minor grants, and research assistants, 10,000*l.*

The report of the president for the financial year 1906–7 shows that the amounts available during that year were:—for large grants, 109,538*l.*; for minor grants, 15,226*l.*; for research assistants, 5080*l.*; and for publication, 16,400*l.* The aggregate receipts from interest on endowment, interest on deposits in banks, sales of publications, and miscellaneous items, amounted to 578,274*l.*

From the income of the institution during the last six years there has been spent, for large projects, 240,462*l.*; for minor and special projects, 138,530*l.*; and for publication, 28,117*l.* The gross sums allotted to large projects since the organisation of the institution amounted to 271,237*l.*, and for minor projects and research assistants to 156,936*l.*

The report of the president also summarises the work of the various departments of the institution. The department of botanical research is engaged on a series of problems the elucidation of which cannot fail to be of the greatest interest and value, whether applied to the restricted field of botany or to the broader domain of biology. By means of observation, experiment, and measurement it is proposed to determine, as nearly as may be, the conditions of development, growth, distribution, migration, and variation of desert plants. Thus, in addition to systematic studies of the forms and distribution of these plants, there must be carried on studies of the factors of temperature, rainfall, evaporation, soil moisture, and anatomical and physiological adaptability. The location of the desert laboratory in a country affording a wide range of plant-forms, as well as a wide range of conditions in altitude, temperature, soil-moisture and soil-composition, presents unequalled opportunities for such studies. Along with these lines of work, the anatomical, physical, and physiological researches of the department staff have already resulted in noteworthy contributions to biological science.

The work of the department of experimental evolution is progressing favourably along lines explained in preceding reports, the principal problems under investigation being those of heredity in plants and animals.

The completion and occupancy of the geophysical laboratory mark a noteworthy advance in the progress of the novel and difficult experimental work carried on in this department of research.

The experiments and investigations of Mr. Luther Burbank in horticulture, and the work of preparing a scientific account of his methods and achievements, are progressing as favourably as the available division of time and labour will permit.

During the season under review, as hitherto, the department of marine biology has extended its laboratory and collecting facilities to specialists in zoological research, eleven such guests having availed themselves of the opportunities afforded at Dry Tortugas and in the adjacent regions accessible by means of the vessels of the department.

The work of the department of meridian astrometry during the year was mainly devoted to preparations for its larger enterprise of a comprehensive catalogue giving accurate positions of all stars from the brightest to the seventh magnitude, inclusive. Amongst these preparations is a preliminary catalogue, embracing the precise positions for upwards of 6000 stars, which has been brought to substantial completion during the year. This will not only be of great service to the department, but it will be of signal aid also to astronomical science in general. Preparations for the establishment of a temporary observatory in the southern hemisphere are likewise approaching completion. An exhaustive study of the meridian instrument to be used at this observatory has been made, so that its constants and peculiarities may be well known before observations with it are begun.

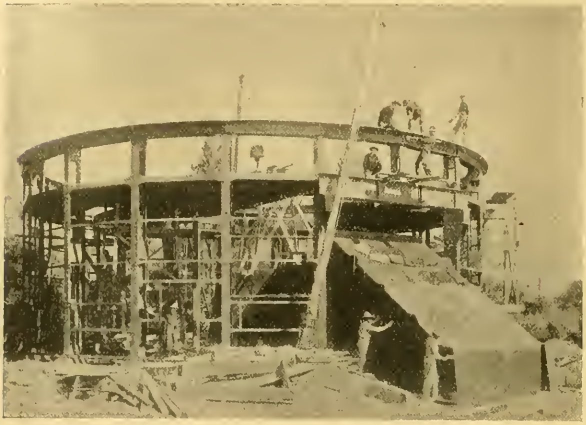

FIG. 1.—Steel Building for 60-inch Reflector, Mount Wilson Solar Observatory.

In conformity with the provision made by the board of trustees at its last meeting for the establishment of a laboratory to be devoted especially to an extension of the physical and chemical investigations in nutrition carried on hitherto under the direction of Profs. Atwater and Benedict, steps were taken early in the year to select a suitable site and to prepare tentative plans for the building. Since experiments on men in an abnormal as well as in a normal condition of nutriment are contemplated, one of the first requirements of a site was proximity to hospitals whence pathological cases may be furnished. It was decided to establish the proposed laboratory in the city of Boston, near the powerhouse of the Harvard Medical School.

The work of the solar observatory is still largely in the preparatory stage, and is thus as much a work of engineering as of astronomy. The novelties of construction, equipment, and programme of research for the observatory, along with the initial difficulties presented by a mountain site, conspire to make the undertaking a formidable one.

The optical parts of the 60-inch reflecting telescope have been made ready for mounting, but owing to the labour strikes at San Francisco the completion of the dome for the telescope may delay its erection until the spring of 1908. The novel tower telescopic apparatus, part of which is above and part below the ground-level, has been substantially completed. This consists essentially of a vertical telescope with a 12-inch objective and 60 feet focal length in combination with a Littrow grating spectrograph of 30 feet focal length, thus furnishing a powerful component in the battery of instruments for direct observations of the sun.

Preparations for grinding, figuring, and testing the 100-inch reflector, the construction of which was rendered possible by the gift of Mr. J. D. Hooker, have likewise gone forward. A fire-proof building for this work has been constructed, and the necessary grinding machine is nearing completion. In the meantime it is expected that the Plate Glass Company of St. Gobain, France, will soon have the large disc for this reflector ready for shipment, since it was successfully cast on August 28 last. In the rough, this disc will weigh about 4·5 tons.

Simultaneously with these varied works of construction, daily photoheliographic and spectroheliographic observations have been made by aid of the Snow telescope. Daily studies of the sun and sun-spot spectra have supplemented these observations, and to them have been added pyrheliometric and solar magnetic measurements, along with numerous laboratory investigations bearing directly on the physical properties of the sun.

The year for the department of terrestrial magnetism has been one of varied activities, and one specially fruitful in the quantity and quality of the results attained. The operations have embraced magnetic surveys of the North Pacific Ocean; surveys on land in Alaska, Bermuda Islands, Canada, Central America, China, Mexico, and South Pacific Islands.

The list of publications issued during the year shows that thirty-eight volumes were published, with an aggregate of 3428 quarto pages and 6284 octavo pages respectively. Moreover, there are now in the press twenty-three volumes. The total cost of completed publications issued during the five years ending with that under review reaches 33,897*l*. As regards the general aspects of this subject, there are indications of over-production in the line

FIG. 2.—Vertical Cœlostat or Tower Telescope, Mount Wilson Solar Observatory.

of scientific publications. The world appears to be accumulating knowledge faster than it can be assimilated. Even by aid of the comprehensive bibliographies now issued, it is difficult, if not impossible, for the specialist to become conversant with the current literature of his own field. On the other hand, the standard of excellence in publications is undoubtedly higher now than at any previous epoch, although it may not have kept pace adequately with the increasing productivity of our times.

SOME LONDON PROBLEMS.

London's Traffic.

The deputation a short time ago from Browning Hall to the London County Council, and the numerous references which have been made in Parliament and elsewhere to the question, make it appear likely that before very long steps will be taken by the Government to establish a Traffic Board for London. In fact, the President of the Board of Trade has given us to understand that his department is in favour of it, and that he will endeavour to get the matter settled without delay; for the new Traffic Department of the Board of Trade cannot be anything but a temporary step.

Among the mass of valuable information collected by the last Royal Commission not the least interesting was that dealing with the history of this problem, for the London traffic problem is almost as old as the city itself. From the earliest days London has suffered from the congestion of its narrow streets, arising from the accumulation of traffic and the encroachments of buildings, and just as at the present day so in previous centuries every attempt made to widen individual streets or to provide increased facilities led to such an increase of traffic in that particular avenue as to render the final state of congestion worse than before. Nothing is more characteristic of the traffic problem than this phenomenon, that every increase of facilities produces an increase of traffic, and so on.

Spasmodic attempts had been made by the corporation of London and other bodies to widen streets here and there, and during the earlier part of the seventeenth century several proposals were brought forward, but were shelved owing to the state of politics at the time.

After the Restoration, however, and just before the Great Fire, an Act was passed for repairing and enlarging the streets with the express object of improving traffic, stating that many streets were too narrow for vehicles. It is interesting to note, however, that increased traffic was anticipated, and the Act also provided for the regulation and licensing of hackney carriages; but immediately after came the plague and the fire, after which a new Act was passed. This was London's great opportunity, and both Sir Christopher Wren and John Evelyn brought forward comprehensive schemes for rebuilding. Had either of these been followed, untold millions would have been subsequently saved to London. It would to-day have been one of the most orderly and carefully laid out cities, with great avenues radiating from the centre. Had this taken place the subsequent growth of the suburbs would have naturally followed on the same plan, and the present heterogeneous arrangements of suburban streets would have never grown up.

In the eighteenth century the conditions were very analogous to those of the nineteenth. If we suppose mail coaches for railways, riding horses for bicycles, hackney carriages for cabs and motors, we see that London was even then provided with a considerable variety of means of transport.

The first Parliamentary Committee upon metropolitan traffic met in 1830, the matter being brought into prominence by the imminence of railways being built in the London district. Other committees succeeded, and in 1842 a Royal Commission was appointed under the Earl of Lincoln, the Commissioner of Woods and Forests, as chairman; various improvements were therein suggested, but it was not until 1853 that Parliament gave a definite start to the modern idea of London local government.

In 1845 the need of improved means of locomotion were realised, and no fewer than nineteen Bills were promoted in that year dealing with railways in the metropolitan district, at least one of them containing the suggestions for a metropolitan central station.

Not until 1854, however, did the first underground line from Paddington to Farringdon Street receive Parliamentary sanction. It was opened in 1863, and was followed by the construction of a similar line from Victoria to Kensington in 1868, but the inner circle was not completed until 1884.

London's Port.

The chief difficulty under which London suffers in connection with its port, as in connection with so many other matters, arises from its age. It is so much older than its rival ports that steps which are taken by them so as to keep them up to date are rendered far more difficult in the case of London. Nothing is easier than to point to Rotterdam or Liverpool as examples of what might be done, but those who do so too often forget the fact that the Port of London has a history of 500 years, compared with less than a century of serious trading in those other ports. The Port of London question is a good, nay, one of the best, examples of the truth that "circumstances alter cases."

The result is that there are an inordinate number of authorities concerned in dealing with the question, and an inordinate number of vested interests to be considered. Moreover, the conditions of transport have changed very materially. In the Middle Ages London was the *entrepôt* for the whole of western Europe. The East Indiamen unloaded there, and their cargoes were distributed by smaller vessels over the whole of western Europe. At the beginning of the nineteenth century, however, trade began to go to other ports. The rise of Liverpool, Glasgow, Hamburg, Antwerp, &c., means that the population surrounding those ports are now no longer supplied from London. Nevertheless, the great increase of population in London itself and all England as a whole, maintains the actual amount of traffic coming into London at its former figure, and London acts as a distributing centre for 10,000,000 to 12,000,000 persons.

The control of the Thames is in the hands of the Thames Conservancy, the dock companies, the Trinity House, the Corporation of the City of London, and the County Council, while the wharfingers and lightermen also have most important interests.

In Liverpool, on the other hand, or in Glasgow, the Harbour Trust has practically a monopoly of authority, and this enables a policy to be adopted which is far less trammelled by outside interference.

Certain of the docks in London are so old that it is impossible to think of modernising them in any way, but the India Docks could undoubtedly be very much improved, while the Tilbury Docks are said to be capable of docking nearly any ship at present afloat. The problem of docking, however, is one that has to be constantly altering on account of the growth of steamships. Hence docks, if they be large enough to-day, would, in a few years' time, be too small, and any docks which are now constructed, in order to have something in hand, need to be of the order of 1000 feet in length. It is not, however, in length that the docks are so much lacking in London, but in the depth of the sills, which render it impossible for vessels of more than 30 feet to enter, for the Royal Albert Dock can take ships up to 536 feet long.

New York and Boston are arranging for 40-feet channels into their ports and steamers are to-day leaving Baltimore loaded down to 32 feet, whereas, at the present time, a ship drawing only 28 feet may be delayed for five hours in the Thames on any day.

What is really wanted is a channel at least 30 feet deep at low tide and 1000 feet wide, as far as the Albert Dock gates, and 1000 feet is not at all too wide to allow a 750-feet vessel to be turned.

Numbers of schemes are constantly being brought out dealing with the port, such as the Thames Barrage Scheme of last year, in which the whole river was to be docked from Gravesend upward, providing for deep-water quays. Less ambitious proposals are the docking of the River Lea and the provision of jetties at Canvey Island, and minor alterations of the docks. All these are, however, matters which should be dealt with by the Trust if one be appointed.

LONDON'S ATMOSPHERE.

Several causes have recently combined to direct attention to the question of London's atmosphere. The memorandum issued last year by the First Commissioner of Works relating to the damage done to vegetation in the parks, the recent report by the L.C.C. upon the regulation of the smoke nuisance, and the invention of several smokeless fuels, have alike brought home to the public the fact that we have as yet only touched the outskirts of the problem of smoke nuisance. Useful as the various palliatives suggested may prove, consideration of them must always ultimately lead to the fundamental question, Why should any fuel be burned in London at all?

From its position in the Thames Valley, London will probably always be subject to white fogs, and the presence of six million human beings and numerous animals must always be the cause of great pollution of the atmosphere. There is all the more reason, therefore, for seeking some way of reducing or removing the present consumption, within the metropolitan area, of nearly fifteen million tons of fuel annually. Regulations and the use of smokeless fuels would undoubtedly be a move in the right direction, and might to some extent reduce the amount of the visible products of combustion. They would, however, hardly affect that equally important side of the problem, the production of carbonic and sulphurous acids. To do this to any considerable extent means the ultimate abolition of the consumption of fuel in the metropolitan area. Utopian as such a step may appear at the present time, the evidence tendered before Parliament during the past few years in connection with the proposed supply of electric power shows that the establishment of a large central system would have undoubtedly tended in this direction.

This result involves two steps:—

First, the reduction, by the adoption of improved methods, of the total quantity of coal burned to produce the power required in the metropolitan area; and, secondly, the removal of the place of combustion to the metropolitan limits.[1]

These two results can only be secured by the general substitution of electric power for other forms.

Let us now consider to what extent it is to-day practicable for electricity to replace the direct combustion of coal in various industries.

Owing to the high price of electricity, the use of gas for street lighting is in many cases still quite as cheap as the electric light, while there are still many parts of London where power derived from gas engines is even cheaper than the supply of electric power at present available; but the abolition of gas for lighting the streets and for driving gas engines will certainly follow its abandonment for lighting purposes in good private houses, if only the price of electricity be reduced sufficiently low. The flame arc lamp, containing as it does the necessary rays for piercing a fog, removes the objections which apply both to ordinary arc lamps and to incandescent mantles, and is the most suitable system of lighting for important streets which one could have. If electricity were available in London at a maximum price of $\frac{3}{4}d.$ a unit for street lighting, there would be a great saving effected over every other system of lighting now in use. At the present time, however, interior electric lighting is chiefly used in the West End and in large shops and offices where the price is a secondary consideration, while public lighting is only done widely where the municipality itself provides the current. It cannot be said to have penetrated the poorer quarters in the way that gas has done by means of penny-in-the-slot meters, which it was recently stated bring in to the Gas Light and Coke Company 1,000,000*l.* per annum; but at $1\frac{1}{2}d.$ to $2d.$ per unit, electric light would certainly be cheaper than any gas which is being sold in the metropolitan area to-day.

The adoption of electricity for suburban traffic is long past the experimental stage, and provided power can be obtained sufficiently cheaply, there is nothing to prevent all the railways in London being driven electrically. The experience already obtained on the North-Eastern Railway, where the heavy suburban traffic is handled electrically, or at Liverpool or on the Underground Railway, has shown this. That the haulage of main-line trains by electricity in suburban areas is also feasible is proved by the fact that the two most important railway companies in New York—the Pennsylvania and the New York Central Companies—have arranged to haul the whole of their main-line trains by electric locomotives while in the suburban districts.

Nearly half the cost of operating suburban services by electricity is due to the cost of the power, while in many cases the capital outlay on the generating station forms half the total cost of the electrification. Thus the price of electricity and the difference in capital outlay between the erection of independent stations or its avoidance may make all the difference between it being commercially feasible to electrify or not; but at the present time there is no means by which the railway companies of London can get a suitable supply except by putting up stations for themselves. The supplies which are at present in existence are on too small a scale, and were primarily intended for lighting purposes. Moreover, as the law stands, the majority of the electric lighting authorities can only supply for use in their own areas, so that the railway companies would be obliged to purchase their supplies piecemeal along their routes. As there are twenty-one different systems in London, the impracticability of this, for this reason alone, is obvious. The cost of electrification under these conditions would, of course, be out of the question. In order to be really satisfactory the price of power should be of the order of $\frac{1}{2}d.$ per unit. On the Tyne, the North-Eastern Railway Company pays rather more than this, but in London the higher cost of coal would be far more counterbalanced by the enormous output. The average consumption of locomotives at the present time is 4 lb. to 5 lb per horse-power, as against 2 lb. per horse-power in a central generating station. It has been estimated that the total horse-power required for operating the *present suburban line traffic* in the London district would be 120,000, while the suburban traffic on main lines would take another 30,000, and that an annual production in all of some 600,000,000 Board of Trade units would be needed. As a matter of fact, a larger output would probably be required, because one of the chief objects of electrification is to enable a more frequent service to be run; but as the total output of the London electric lighting stations last year was of the order of 150,000,000 units, it is obvious that one cannot look to them for a supply for this purpose even if they were all united into one station and supplying on one system, instead of supplying from more than fifty stations with more than twenty systems. It is a question of price, and the price is one the existing systems cannot supply at.

Coming now to the factories, it will be noted that these account for nearly one-half of the coal consumption of London, and probably for three-quarters of the smoke and deleterious fumes; yet these offer the best field for electric power of any, for the possibility of driving factories electrically has been conclusively demonstrated on the Tyne, where, practically speaking, every factory and shipyard on the north bank of the river obtains its supply from the power company which is there in operation. Power is applied to all kinds of purposes. The three-phase electric motors, which contain no exposed electrical parts, work without trouble in the most exposed conditions.

Cranes, both stationary and travelling, are more conveniently operated by electric motors than by the old vertical boilers and engines. In fact, there are practically

[1] So far as gas consumption goes this question of removal has partly taken place already. In place of the seventeen or eighteen gas companies with works scattered throughout London which are shown on the old Ordnance maps, there are now practically three authorities, and by far the larger part of the coal consumption to make gas for London is used on the Greenwich Marsh or at Beckton.

no uses to which the electric motor does not lend itself in factories.

The objection which is often raised, however, to the replacing of steam-driven machinery by electricity, especially in chemical works, breweries, soap works, &c., is that the steam is required for heating and boiling; but here, again, it is a question of price only; the chief chemist of one of the most important soap makers in the east of London recently stated that it was purely a question of price for him to use electricity for boiling purposes instead of steam, and he estimated that it would pay him to do this if he could obtain it at not more than ½*d.* per unit.

Now a certain number of London factories are already supplied from the existing lighting stations. So great are the benefits of electricity that it has paid people to adopt it even although electric energy is so expensive, for so long as electricity is provided from electric lighting stations as an adjunct, so long must it necessarily be expensive; but the wholesale adoption of electricity in factories on the scale that it has taken place on Tyneside can only take place when electricity is produced on an enormous scale, and is used for all purposes in the district. Hitherto, power has been supplied as a bye-product of electric lighting, and this accounts for the fact that out of 555,000 horse-power required to drive the factories in the industrial districts of London, only some 26,000 or 27,000 horse-power of electric power is obtained from the present stations.

This great field that remains can only be tapped by putting down a system for the express purpose of supplying the power needs of East London; while such a scheme must, in order to produce cheaply, have as great a variety of consumers as possible, it cannot hope to be completely successful if it is made an adjunct of electric lighting or electric traction. Power supply must be the first aim of the undertaking, even although in the process of getting a power supply an even greater load may be obtained from the supply to railways.

The consumption of coal in domestic fires accounts for 4,570,000 tons a year, or 25 per cent. of the total consumption. Electric heating has hitherto been very little used, and even in America is confined to the heating of tramcars and workshops in places where it is only a question of the cost of electric energy is undoubted, and that electricity forms a most convenient agent in heating and cooking, and can replace all other forms, is now generally admitted. The reason is this, that whereas the ordinary gas fire only, as a rule, gives out from one-half to one-third of its heat usefully, while the best stove probably does not give out more than about 75 per cent. of its heat, the efficiency of the electric radiator is practically 100 per cent. It can be shown that if the cost of electricity be 1*s.* 3*d.*, it is as cheap for cooking as gas at 3*s.* per 1000 feet; but to compete with coal at 25*s.* a ton for heating, electricity must be supplied about ⅓*d.* per unit. In a number of houses already electric radiators are being adopted on account of their convenience, even though they cost somewhat more than gas fires; with cheap electricity they would be adopted universally.

Thus, although electricity for heating and cooking has been looked upon as a purely Utopian proposal, as a matter of fact the time is not far distant when it will be found quite as cheap as any other form of heating. It is true that an electric radiator in its present form, although efficient in itself, converts but a very small portion of the energy of the *coal* into heat; but this is, of course, due to the inefficiency of the present methods of producing electricity, and there can be little doubt that we shall before very long witness a very considerable improvement in this respect. Whereas the best modern turbines and boilers convert only 15 per cent. of the energy of the coal into electricity, the internal combustion engine converts 35 per cent.; but even at the present time such are the advantages of electricity for heating and cooking, such is its applicability, such is the cost of re-decorating and cleansing in London, that at prices considerably higher than those above stated electricity would be as cheap to adopt as coal or gas. The question again resolves itself into one of price.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The Goldsmiths' Company has resolved to make a grant of 10,000*l.* for the purpose of founding and endowing a readership in metallurgy, such readership to be associated with the name of the company. It is hoped that research and other work in the precious metals, and the theory and practice of assaying, will be kept somewhat prominently in view in connection with the proposed readership.

Mr. R. H. Biffen has been elected to the recently established chair of agricultural botany. Mr. Biffen is the author of numerous papers, the earlier of which dealt with the preparation of india-rubber and the coagulation of latex, and he has devoted a great deal of attention to fungi. His researches on the hybridisation of wheat and barley have attracted the attention of civilised Governments throughout the world, and attempts have been made to induce him to leave England and place his services at the disposal of at least one foreign Government. It is satisfactory that largely owing to the generosity of the Drapers' Company Mr. Biffen will be able to continue to carry on his researches in Cambridge.

Mr. C. L. Boulenger has been appointed assistant to the superintendent of the museum of zoology from March 25 to September 30, 1908.

On Friday evening, March 13, Lord Alverstone distributed the certificates and prizes at the South-Western Polytechnic Institute, Chelsea. The report of the principal to the governing body showed that the session 1906–7 had been a very successful one, the highest honour obtained being the D.Sc. degree of Mr. Crocker, who had done all the necessary chemical research in the institute. In the course of a short address, Lord Alverstone laid great stress on the necessity for concentration in study. The development of any one subject is so great at the present time that the utmost concentration of thought is required to advance knowledge. He took as illustration the discoveries of Lord Kelvin in regard to the mariner's compass.

The reports for the year ending June 30, 1907, of the librarian of the U.S. Congress and of the superintendent of the library building and grounds have been received from Washington. As indicative of the generous scale on which this great American library is subsidised, it may be stated that the appropriations made for the present year reach 123,000*l.*, and that the salaries to be paid during the year for the various officers reach 69,570*l.* In 1907 the number of books in the library reached 1,433,848, representing a gain of 54,604 over the previous year. In addition there were nearly 100,000 maps and charts and a quarter of a million prints. The most important accessions to the library were the Yudin library, consisting of 80,000 works relating to Siberia and Russia, and a notable collection of the literature of Japan, consisting of some 9000 works.

A Bill to promote agricultural education and nature-study in public elementary schools, introduced in the House of Commons by Mr. Jesse Collings, was read a second time on March 11. The object of the Bill is to provide for the teaching in all public elementary schools of agricultural and horticultural subjects; to give facilities for nature-study, and generally by means of object-lessons to cultivate habits of observation and inquiry on the part of the pupils. To this end the Bill provides for school gardens and such collection of objects as may be necessary for the practical illustration of the instruction given. The education specified in the Bill, while optional in urban schools, is to be compulsory in all schools situate in rural and semi-rural districts. A special grant, not exceeding 75 per cent. of the cost, is provided for in the Bill towards the expenses of local education authorities in carrying out the provisions of the Bill.

In his capacity of Chancellor of the Bombay University, Sir George Clarke presided at the recent annual Convocation of the University and delivered an address. From a report of his speech in the *Pioneer Mail* we learn that the Chancellor directed attention to the fact that at present there is in the University no provision for post-graduate training, which, in Japan, can be carried on for five years. The University at present receives immature students, and has been unable to utilise the best of its teaching powers and to train up to the high standard now required to produce leaders of original research and professors in the great departments of knowledge. The institute which the munificence of the late Mr. Tata is providing will afford facilities for post-graduate courses in science, and Sir George Clarke expressed the hope that the University will be able to move in this direction in the future. India, he continued, is crying aloud for science, but in the last years only twenty-five degrees of Bachelor of Science were conferred as compared with 1321 Bachelorships of Arts. The Bombay system is defective in regard to scientific training. The inculcation of scientific ideas does not begin early enough, and cannot be carried far enough, for want of adequately equipped laboratories. In Japan science is taught in the upper primary courses, but does not appear until a much later stage in Bombay, and may almost be said to be confined to the colleges, which cannot all be equipped with the expensive appliances necessary for the training they ought to be able to impart. The attempt to make each college into a complete teaching university must, the Chancellor said, necessarily fail, and concentration, in the case of science training especially, appears to be essential. A beneficent patron of learning could render no better aid to the advancement of science than by providing the University with first-class physical and chemical laboratories. Principal Sharp has pointed out that expenditure on education in India would have to be increased from about four millions sterling to twenty-seven millions to provide an amount per head equal to that available in Japan.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 20.—"Notes on the Application of Low Temperatures to some Chemical Problems: (1) Use of Charcoal in Vapour Density Determinations; (2) Rotatory Power of Organic Substances." By Sir James **Dewar** and Dr. H. O. **Jones**.

(1) In a recent paper (*Phil. Mag.*, 1907, vi., 14, 408) Barkla and Sadler describe the investigation of the penetrating power of secondary Röntgen radiations emitted by different elements, which they find to be dependent on the atomic weight of the elements. The behaviour of nickel could only be reconciled with that of other elements by assigning to it an atomic weight of 61·4, a value considerably higher than the accepted value, 58·7.

Determinations of the vapour density of nickel carbonyl made by the authors (Proc. Roy. Soc., 1903, lxxi., 427) had given no indication that the accepted value for the atomic weight of nickel was too low, but it was considered of interest to make further determinations at low pressures, when the vapour would approximately obey the gas laws.

A new method of manipulation was devised for this purpose depending on the use of charcoal at low temperatures for absorbing gases.

A large flask, the volume of which with the connecting tubes was 2163·2 c.c., was connected to a mercury manometer and exhausted by means of a Fleuss pump followed by charcoal in liquid air. The flask was surrounded by melting ice, and the vapour admitted to any desired pressure. The mass of gas was finally collected in a weighed charcoal reservoir by immersing this in liquid air. Thus the weight of vapour filling the flask at 0° C. under a known pressure was easily determined. The accuracy of the method is dependent on the determination of pressure, since the errors in the other operations are comparatively negligible.

In order to test the method the vapour densities of carbon dioxide, sulphur dioxide, and ether were determined, and the following results (referred to 1 c.c. of hydrogen as 0·00009 gram) show that the method readily gives results sufficiently accurate for the purpose in hand:—

CO_2		SO_2		Ether	
Press mm.	V.D.	Press mm.	V.D.	Press mm.	V.D.
115·4	21·91	76·1	31·81	31·4	36·90
206·5	21·98	198·5	31·94	63·9	36·91

The theoretical values of these vapour densities are 21·83, 31·79, and 36·76 respectively.

Determinations of the vapour density of nickel carbonyl were then made, with the following results:—

Press mm.	V.D.	Press mm.	V.D.	Press mm.	V.D.
16·6	84·67	41·7	84·69	46·8	84·79

Taking the atomic weight of nickel as 58·3 (H = 1), the theoretical density is 84·73, whereas on the assumption of the atomic weight suggested by Barkla and Sadler, 60·95 (H = 1), the vapour density would be 86·05. These experiments therefore show that it is impossible that the atomic weight of nickel should be as high as 60·95.

The accuracy of the method used could be greatly improved by the use of a larger vessel and more delicate manometric measurement, and if the charcoal condenser was made of metal instead of glass the method might be applied to the more volatile gases.

(2) A preliminary account is given of the results obtained in determining the rotatory power of optically active carbon compounds at low temperatures. Two substances, *l*-nicotine and "bitter orange oil," were selected as suitable for examination, because their solutions in ethyl alcohol could be solidified without losing their transparency, and on account of their high rotatory powers. Up to the present it has only been found possible to make observations down to about −100° C., since below this double refraction interferes with the reading of the polarimeter.

A solution of nicotine (21·2 grams in 100 c.c.) which gave a rotation of −30° at +20° C. gave a rotation of −22° at −120° C.

The relation between temperature and rotatory power is approximately linear, and shows that nicotine behaves below 0° C. just as it does above that temperature. The specific rotatory power at −115° C. is calculated to be −99°, and, assuming the linear relation to hold, would be about −54° at −273° C.

The rotatory power of bitter orange oil increases with diminishing temperature below 0° C. as it does above that temperature.

A 20 per cent. solution in alcohol, which gave a rotation of +18°·5 at +8° C., gave a rotation of +25°·5 at −95° C. The relation between temperature and rotatory power is linear, and the calculated specific rotatory power at −273° C. would be about +156°.

Similar results have been obtained with other substances, and these show that the molecules of optically active carbon compounds would exhibit in all probability considerable rotatory power at the lowest temperatures we can command.

Linnean Society, February 20.—Lieut.-Col. Prain, F.R.S., vice-president, in the chair.—Wild types and species of the tuber-bearing Solanums: A. W. **Sutton.** Many hundreds of attempts were made to fertilise *Solanum Maglia* with the cultivated potato, but only one hybrid seedling resulted, from a cross made in July, 1887, and though cultivated for twenty years it has shown no superiority to ordinary potatoes. The so-called "*Solanum Commersonii*, Violet," was stated to be a mutation obtained through bud variation from the wild *Solanum Commersonii*, Dunal. In opposition to this claim, many growers assert that it is identical with a German potato, the "Blue Giant," raised by Herr Paulsen. Many wild types of tuber-bearing Solanums have been experimented with during the last few years. All these wild types flower freely, but in every case where a wild type produces fruit it has, with the exception of *Solanum etuberosum*, reproduced itself absolutely pure from seed, whereas all varieties of the cultivated potato which produce seed give rise to the greatest possible variation in the seedlings, none corresponding exactly to the parent. There is also a striking difference in the form of the pollen-grains of the wild types of tuber-bearing Solanums compared with pollen-grains of cultivated potatoes, the former being elliptical and the latter very irregular in form. *Solanum etuberosum* is the only wild type of which the seedlings have not reproduced the typical form, but have, on the other hand, given precisely the same variation in habit of foliage, form, size, and colour of tuber, &c., as is found in the seedlings from the cultivated potato. During the twenty years of cultivation, no plant of *Solanum etuberosum* has ever been noticed as affected by the fungus *Phytophthora infestans*, although during the whole period it has been grown in close association with potatoes which have suffered more or less from it year after year. It is a fact that the potatoes originally introduced into England or into Europe were certainly introduced as cultivated potatoes, and not as wild types, and also that it is at least doubtful whether in Chili, Peru, or elsewhere, any specific type of tuber-bearing Solanum (apart from *Solanum etuberosum*) can be found which will, under cultivation, give plants at all like the potato of commerce.—Life-histories and larval habits of the tiger-beetles (Cicindelidæ): Dr. V. E. **Shelford.** The paper is intended to be followed by a series in which the distribution, variation, effects of environment, and evolution of colour will be considered. Eleven races were studied, and the results detailed from three or four thousand individuals which had been reared to maturity; the detailed account of *Cicindela purpurea* is followed by a comparison of the other races, and the paper concludes with a bibliography.

March 5.—Lieut.-Col. Prain, F.R.S., vice-president, in the chair.—A possible case of mimicry in the common sole: Dr. A. T. **Masterman.** There are two species of weever-fish, *Trachinus draco* and *T. vipera*, both venomous, with the poison concentrated at the spines of the first dorsal fin and the opercular spine. These fishes bury themselves in the sand until only the top of its head, with eyes, mouth, and dorsal fins are above the sand. The dorsal fin is of intense black, and conspicuous amongst the sand when protruded; it has been suggested that this may be regarded as a warning signal to the enemies of these fishes. The right or upper pectoral fin of the common sole (*Solea vulgaris*) is well developed, and the upper half of that fin has a large, deep, black patch. It also has the habit of concealing itself under the sand, and the distribution of the weever-fishes and the common sole is almost the same. In the other species of sole the pectoral fin is smaller, or almost wholly wanting. The suggestion is that the common sole has adopted the habit and coloration of the weever-fishes as a protective measure.—The morphology of Stigmaria and of its appendages in comparison with recent Lycopodiales: Prof. F. E. **Weiss.** The discovery by Binney of an organic connection between Stigmaria and the base of Sigillaria did not settle definitely the morphological value of the stigmarian axis. It might still be regarded either as a large bifurcating root bearing lateral roots or as an underground stem (rhizome), in which case its appendages might be adventitious roots (Scott) or leaves modified to serve absorptive purposes (Solms-Laubach), or possibly both kinds of lateral organs might be present (Renault). Some recent observations have tended to re-open the discussion of the morphology of the appendages, particularly the recognition of peripheral "transfusion" tracheids in the stigmarian appendages and the presence of a parichnos-strand in these organs. But though both have their counterpart in the leaves of the Lepidodendraceæ, the author only sees analogy and not homology in these structures, and believes their presence is due to the physiological requirements of the organs in question. On the whole, it seems likely that these problematical organs are lateral extensions of the protocorm of a primitive member of the Lycopodiales.

Physical Society, February 28.—Dr. C. Chree, F.R.S., president, in the chair.—The contact potential differences determined by means of null solutions: S. W. J. **Smith** and H. **Moss.** When a mercury jet breaks in the surface of an electrolyte there is an E.M.F. between the jet and a still immersed mercury electrode. If the contact p.d. between the still mercury and the solution is π_s, that between the jet and the solution being π_d, the observed E.M.F. is $E_p = \pi_s - \pi_d$. This E.M.F. is found to be equal to the polarising E.M.F., E_m, required to produce the maximum surface-tension between mercury and the electrolyte. Since $E_m = \pi_s - \pi_m$, where π_m is the p.d. between the Hg and the electrolyte when the surface-tension is a maximum, it follows that $\pi_m = \pi_d$. A solution for which $E_p = 0$ is called by Palmaer a "null solution." He found by trial two solutions for which $E_p = 0$. Although he concluded that $\pi_s = \pi_d = 0$, without special assumptions, the only necessary conclusion is $\pi_s = \pi_d = \pi_m$. The object of this paper is to show that Palmaer's deduction is wrong. If an experimental method can be found of obtaining from any electrolyte MX a solution for which $E_m = 0$, then an indefinite number of null solutions can be obtained. Such a method consists in the addition to the electrolyte of a small quantity of M_2S. A number of null solutions were found, including one which gave results identical with those obtained by Palmaer.—An experimental examination of Gibbs's theory of surface concentration regarded as the basis of adsorption, and its application to the theory of dyeing: W. C. M. **Lewis.** An experimental investigation of Gibbs's theory of surface concentration. A particular form of the more general equation is

$$\Gamma = \frac{-c}{RT}\frac{d\sigma}{dc},$$

where Γ = the excess mass of solute per sq. cm. surface, c = the bulk concentration of the solution, T = the absolute temperature, R = the gas constant, and σ = the surface-tension. Assuming surface-tension effects to be the basis of adsorption, measurements were made of the quantities above. The material at the surface of which adsorption took place consisted of a pure hydrocarbon oil. The material adsorbed was bile-salt in aqueous solution. The interfacial tension σ was measured by the drop-pipette method. Γ was measured in two ways:—(1) at the surface of oil-drops of radius about 1 mm., and (2) at the surface of drops of radius about 10^{-4} mm., *i.e.* emulsion particles. The general result was that the actual values found for Γ exceeded the calculated by about fifty times the latter, the conclusion being that there is a discrepancy of considerable magnitude.

Zoological Society, March 3.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—A young female Kordofan giraffe: P. C. **Mitchell.** The author compared the coloration of this specimen, born at the gardens, with that of its parents and with that of a young female giraffe from Nigeria, now living in the society's collection, and stated that the evidence to be derived from the study of this specimen strengthened the case for the distinctness of the giraffes from Kordofan and Nigeria.—A comparison of the neotropical species of Corallus, *C. cookii* with *C. madagascariensis*, and on some points in the anatomy of *Corallus caninus*: F. E. **Beddard.**—A new species of monkey of the genus Cercopithecus: R. I. **Pocock.** The species differs from *C. neglectus* principally in the absence of the black band across the head, in the reddish tinge of the hairs beneath the callosities, and in the similarity in colouring between the tail and the body. It is proposed to name this new monkey *Cercopithecus ezrae*.

Entomological Society, March 4.—Mr. C. O. Waterhouse, president, in the chair.—*Exhibits.*—F. B. **Jennings**: (*a*) A specimen of the weevil *Phyllobius maculicornis*, Germ., retaining both the "false" mandibles, and another in which one of them is intact, both from Enfield, also a single example of *P. urticae*, De G., from Cheshunt, retaining one of these mandibles, the particular point of interest in connection with the false mandibles in these species being that they are toothed in the centre; (*b*) a remarkable specimen of the common Chrysomelid beetle, *Sermyla halensis*, L., from Deal, showing unusual coloration of the elytra, which are blue and coppery-red instead of bright green; and (*c*), on behalf of Mr. C. J. Pool, a specimen of *Otiorrhynchus tenebricosus*, Herbst, from Newport, I.W., and of *Barynotus obscurus*, F., from Galway, Ireland, in the first of which both the pupal mandibles were toothed, and in the second not.—H. St. J. **Donisthorpe**: *Otiorrhynchus sulcatus*, *Polydrusus sericeus*, and *Osmius bohemanni* with pupal mandibles. The Otiorrhynchus was dug up in its pupal cell at Oakham in 1895.—The Rev. G. **Wheeler**: A case containing specimens of Melitæid butterflies taken by him at Reazzino in Tessin, near Bellinzona, which he had identified with

Assmann's *Melitaea aurelia*, var. *britomartis*, they being absolutely identical with the specimens so labelled in the Swiss national collections at Berne. The close affinity on the underside with *M. dictynna* made separation superficially very difficult, and until all forms were reared from the ovum it would be impossible to determine whether *britomartis* constituted a separate species or not.—*Papers*.—Descriptions of new species of Lepidoptera-Heterocera from the south-east of Brazil: H. D. **Jones.**—*Erebia lefebvrei* and *Lycaena pyrenaica*: Dr. T. A. **Chapman.**—A contribution to the classification of the coleopterous family Dynastidæ: G. J. **Arrow.**—Hymenoptera-Aculeata collected in Algeria by the Rev. A. E. Eaton and the Rev. F. D. Morice, part iii., Anthophila: E. **Saunders.**

Royal Meteorological Society, March 11.—Dr. H. R. Mill, president, in the chair.—The dawn of meteorology: Dr. G. **Hellmann.** Some of the modern weather proverbs can be traced back to Indo-Germanic and Babylonian sources. Some of the tablets excavated from old Babylon contain references to the weather. Speaking of the names of the winds and their combinations, Dr. Hellmann said that the cardinal points, north, east, south, west, were found in old Babylonian times. The Greeks were the first to make meteorological observations, and had parapegmata or weather almanacks fixed on public columns. The measurement of rain was first recorded in Palestine. After referring to the first idea of the thermoscope, the lecturer alluded to the meteorology of Aristotle, and said that it had very little influence on English meteorologists. It was the fathers of the Church who kept meteorology alive, for in their works on the Creation they devoted much attention to the atmosphere. The writings of the Venerable Bede were also referred to. The resuscitation of experimental science in the thirteenth century led to the development of regular meteorological observations in the fourteenth century. The earliest known record in this country was kept by the Rev. William Merle at Oxford from January, 1337, to January, 1344, the manuscript of which is still in the Bodleian library.

Mathematical Society, March 12.—Prof. W. Burnside, president, in the chair.—The projective geometry of some covariants of a binary quintic: Prof. E. B. **Elliott.** The roots of the quintic being represented by points on a conic, ruler constructions, depending only on symmetric functions of the roots, and not on the roots individually, are given for those linear covariants which are of degrees 5 and 7 in the coefficients, and for the quadratic covariant which is of degree 2 in the coefficients. Constructions are also obtained for the linear covariants of degrees 11 and 13 in cases where the roots of the quintic are known individually. It appears that sets of four linear covariants and three quadratic covariants can be arranged as a quadrangle on a conic and the pairs of points in which the conic is met by the sides of the harmonic triangle of the quadrangle, but that two members of such sets of seven covariants are reducible to simpler members of a complete system.—The inequalities connecting the double and repeated upper and lower integrals of a function of two variables: Dr. W. H. **Young.** Difficulties arise in the theory of integration of a function which may become infinite, especially as to the possibility of replacing a double integral of such a function by a repeated integral. The paper contains a systematic investigation of such cases, and conditions are obtained which are sufficient to secure that the double integral can be evaluated as a repeated integral.—The operational expression of Taylor's theorem: Dr. W. F. **Sheppard.** Cases arise in which it is desired to express $f(x+y)$ in a form depending on $f(x)$, some differential coefficients of $f(x)$, and some differential coefficients of $f(x+y)$. Operational formulæ are obtained for such cases, and the remainders discussed.—Note on a soluble dynamical problem: Prof. L. J. **Rogers.** The problem is of a general type which includes Jacobi's problem of the attraction of a body to two fixed centres and various problems appropriately expressed in terms of elliptic coordinates.—A formula for the sum of a finite number of terms of the hypergeometric series when the fourth element is unity (second paper): Prof. M. J. M. **Hill.** The formula previously obtained by the author was proved to hold for the sum of s terms of the series $F(\alpha, \beta, \gamma, 1)$, provided $\gamma-\alpha-\beta$ is not zero or a negative integer. It is now proved to hold in the case of the negative integer, and the appropriate modification is obtained in the case of the zero value.

Royal Astronomical Society, March 13.—Mr. H. F. Newall, F.R.S., president, in the chair.—A suggested explanation of the ancient Jewish calendar dates in the Aramaic papyri, translated by Prof. A. H. Sayce and Mr. A. E. Cowley: E. B. **Knobel.** The papyri are business documents relating to a Hebrew colony in Syene, and date from B.C. 471 to 410; they have duplicate dates, according to the Egyptian and Jewish reckoning, and are thus of unique importance for the elucidation of the ancient Jewish calendar, about which very little has hitherto been known. The Egyptian year and chronology are perfectly well understood. The period of the documents is extended by a Babylonian record of the eclipse of B.C. 523, translated by Father Strassmaier, in which the Jewish date is also given, and from these data a calendar has been constructed.—Double-star observations, 1902–7: W. H. **Maw.** The author described his method of measuring the position angle of a bright star and faint companion. The wire was set near the bright star, at right angles to the line joining the two stars; it was then found easy to estimate a perpendicular to the wire.—Investigations on the distribution and motions of stars: F. W. **Dyson.** The conclusions of Prof. Kapteyn and Mr. Eddington as to two drifts of stars were confirmed, and the same result found from stars in the southern hemisphere.—The variability of the nucleus of the planetary nebula N.G.C. 7662: E. E. **Barnard.** A drawing made with the Yerkes telescope showed the nebula as a broad ring with a dark space in the centre, in which was a star-like nucleus. From Prof. Barnard's observations of the variability of this nucleus Prof. Turner deduced a period of $27\frac{1}{2}$ days.—Note on the discovery of a moving faint object near Jupiter: **Royal Observatory, Greenwich.** The object had been detected by Mr. Melotte on several plates taken for Jupiter's sixth and seventh satellites. It was not yet certain whether it is a new satellite or a minor planet moving very near Jupiter, but in either case it appeared of much interest.—The relative number of star images photographed in different parts of the plates for the Oxford portion of the Astrographic Catalogue: H. H. **Turner.**—The perturbations of Halley's comet, 1759–1900: P. H. **Cowell** and A. C. D. **Crommelin.** Further investigations indicated that Pontécoulant's date for the perihelion passage in 1910 was somewhat too late; the most probable date is April 8.—The perturbations of Halley's comet in the past. Third paper, the period 1066–1301: P. H. **Cowell** and A. C. D. **Crommelin.** Four returns of the comet from 1066–1301 now appeared to be well identified from Chinese and European observations. It had been found that a satisfactory identification of the return of 1222 was obtained by accepting the Chinese observations as they stood, and making a change in the interpretation of the Western records.

CAMBRIDGE.

Philosophical Society, February 24.—Mr. D. Sharp, vice-president, in the chair.—Relation between the geographical distribution and the classification of the Onychophora: Prof. **Sedgwick.** The Onychophora comprise the single genus Peripatus, which was discovered in St. Vincent in the Antilles in 1826. Later, specimens of it were obtained from South Africa and Australasia, and its arthropodan nature was established by Moseley in 1874. In 1888 it was shown by the author of the present communication that the species of it fell into discontinuous groups, all capable of precise definition. At present seven such groups are known, each occurring in a definite geographical area. The geographical groups, together with the names which have been applied to them by the author, are as follows:—(1) Neo-Peripatus from the neotropical region as far south as Rio de Janeiro; (2) Congo-Peripatus from the Congo district in Africa; (3) Eo-Peripatus from Malaya (Malacca and Sumatra); (4) Capo-Peripatus from South Africa (Natal to Cape Town); (5) Melano-Peripatus from New Britain; (6) Austro-Peripatus from Australia, Tasmania, and New Zealand; (7) Chilio-Peripatus from Chili. The author showed (1) that these geographical groups of species are natural zoological groups, the members of which are more closely allied to each other than to those of the other groups; (2) that the distinguishing specific characters are distributed in an entirely haphazard manner among the different specific groups, so that it is quite impossible to show their phylogenetic affinities by any tree-like arrangement.—The method of impregnation in Peripatus: Prof. **Sedgwick.**—Exhibition and description of Welwitschia collected by Prof. Pearson: Prof. **Seward.**—Note on a method of demonstrating the syncytial appendages of the placental villi: Dr. **Duckworth.** The placenta provides material for a ready and quick method of demonstrating the appearance of multicellular or syncytial masses of protoplasm. Small portions of the placenta are stained in bulk, and the syncytial appendages can be easily shown by teazing out the villous processes from whence they spring. Six new species of the Ixodoidea: W. F. **Cooper** and L. E. **Robinson.**—Note on the protozoan intestinal parasites of frogs and toads: C. C. **Dobell.**

Edinburgh.

Royal Society, March 2.—Dr. John Horne, F.R.S., vice-president, in the chair.—A preliminary notice of new iron-bacteria: Dr. D. **Ellis.** Five new forms were described, four being new species and one—*Notofolium ferrugineum*—a new genus. They had all been discovered in the iron waters of Scotland. The methods of reproduction were the same in all, namely, a process of conidia formation, and also by transverse splitting of individuals.—The effect of load and vibrations upon magnetism in nickel; supplementary communication: James **Russell.** In determining the effect of off-and-on load the two important factors were the position on the loop and the intensity of the vibrations. In particular, the conditions under which the Villari reversal shows in nickel were studied and described. —A simplified calendar: Alex. **Philip.** The aim of the author was to establish a perpetual calendar by arranging so that any particular day of the month would be the same day of the week. This was accomplished by making New Year's Day a day apart, not to be reckoned in the months or weeks. January would begin on what is now the second. There would be exactly fifty-two weeks of seven days, and by a slight re-arrangement four quarters of three months of ninety-one days in all. The proposed system did not interfere in any way with astronomical principles, the odd day in Leap Year to be treated like New Year's Day, as a midsummer holiday between June and July. So far as the author knew, it violated no scientific principle.

Paris.

Academy of Sciences, March 9.—M. H. Becquerel in the chair.—The neutral alkaline and alkaline earth carbonates: M. **de Forcrand.** A re-calculation, with some new experimental data, of the whole of the thermochemical data relating to the carbonates of sodium, potassium, rubidium, cæsium, lithium, calcium, strontium, and barium. The bearing of these results upon the temperatures of dissociation of these carbonates is also discussed.—The Ordovician iron minerals of Lower Normandy and Maine: M. **Œhlert.**—New researches on variable stars: Charles **Nordmann.** The amplitude and form of the luminous variation of the two variable stars studied differ markedly according to the part of the visible spectrum compared.—A hyperelliptic surface of the fourth degree upon which are traced thirty right lines: E. **Traynard.**—Problems of elasticity in two dimensions: G. **Kolossoff.**—A case of reduction of the differential equations of the trajectory of an electrified corpuscle in a magnetic field: Carl **Störmer.**—The increase in the sensitiveness of electrolytic detectors under various influences: Édouard **Branly.** The effects produced by a rise of temperature, mechanical agitation, and gaseous disengagement in the electrolyte are separately discussed. —The theory of Brownian motion: P. **Langevin.** A simplified proof of Einstein's formula is given, and this is shown to be identical with the formula of Smoluchowski. —Singing flames reinforcing several notes: G. **Athanasiadis.**—A spectrophotometric arrangement: J. **Thovert.** —The action of alkaline salts with fixed base on the combustion of gases and fixed combustibles: M. **Dautriche.** The effect produced on the heat evolved by several nitro explosives by the addition of alkaline salts was studied, with especial reference to the safe use of these explosives in fiery mines. The salts of the alkaline earths, according to these experiments, appear to prevent the combustion of the carbon monoxide formed by the detonation, and thus add to the safety of the explosive.— Combustion without flame and the inflammation of gases at the extremity of a metallic tube: Jean **Meunier.**—The composition of the starch grain: Mme. Z. **Gatin-Gruzewska.** A method is given for separating the amylopectin and amylose by means of dilute alkali and subsequent neutralisation with acetic acid.—Observations on the preceding note: L. **Maquenne.**—The duration of the peroxydiastases in seeds: MM. **Brocq-Rousseu** and Edmond **Gain.** Seeds varying in age from two to upwards of 2000 years were examined for the presence of peroxydiastases. These ferments may disappear in seeds only twenty years old; two exceptional cases were found in which seeds more than 200 years old still gave the reaction for peroxydiastase.—The metamorphism and tectonic of the Palæozoic strata of Morvan and the Loire: Albert **Michel-Lévy.**—The eruptions of the Limagne. Seven periods of volcanic activity from the Lower Miocene to the Pleistocene: Ph. **Glangeaud.**—Observation of a case of ball lightning: Isidore **Bay.** This was observed on May 26, 1907, at Saint Georges-de-Reneins. An incandescent ball was seen, lasting five minutes. On its disappearance the disruptive effects of ordinary lightning were observed.

Göttingen.

Royal Society of Sciences.—The *Nachrichten* (mathematico-physical section), part v. for 1907, contains the following memoirs contributed to the society:—

July 20.—Difference-formulæ for the calculation of optical systems: K. **Schwarzschild.**

October 26.—Contributions to the theory of atmospheric electricity: E. **Riecke.**

November 23.—The potential gradient in the positive glow, from observations by H. Schwienhorst: E. **Riecke.** —Comparison of the magnitudes of horizontal magnetic intensity at Potsdam and Cheltenham in the year 1904: F. **Linke.**—A calculation of the wave-length of the Röntgen rays from Planck's "energy-element": W. **Wien.**— Langbeinite ($K_2SO_4.2MgSO_4$) and vanthoffite

$$(3Na_2SO_4.MgSO_4):$$

R. **Nacken.**—The uniformisation of given analytical curves (ii.): P. **Koebe.**

December 7.—The nature and age of the geological displacements in the neighbourhood of the Sackberg and in the valley of the Leine at Alfeld and Elze: A. **von Koenen.**—The proper motions of the fixed stars: K. **Schwarzschild.**

December 21.—An application of the theory of invariants to the development in series of integrals, particularly rational, elliptic, and hyperelliptic: W. F. **Meyer.**

The business communications (part ii., 1907) of the same society include a report by K. **Schwarzschild** on Lambert's letters on cosmology.

New South Wales.

Royal Society, December 4, 1907.—Mr. H. Deane, president, in the chair.—The effect of Polar ice on the weather: E. **Du Faur.** The author urged the necessity for frequent accurate observations on the varying position of Antarctic ice, at points within easy access of Hobart, on account of its influence upon southern climate. Provision should be made for frequent, even annual, observations to be taken for the future in the Victoria quadrant.—A comparison of the rainfall of Sydney and Melbourne, 1876 to 1905: A. **Duckworth.** The average rainfall of Sydney is given as 47·36 inches, and that of Melbourne as 24·92 inches. In Sydney, the year 1888 was the driest and 1890 the wettest, whilst in Melbourne 1898 was the driest and 1887 the wettest. If we were to judge solely from the *amount* of the annual rainfall of Sydney, without regard to its periodical distribution and the intensity of its precipitation, it might be said there was no actual period of serious drought, the rainfall of Sydney being below the average of Melbourne only in the exceptional year 1888. The divergencies in the rainfall of these two great cities were so striking as to tend to make one careful in formulating any conclusions based on the rainfall experience of either city taken alone.—The Australian Melaleucas and their essential oils, part ii.: R. T. **Baker** and H. G. **Smith.** This section (part ii.) of the subject covers an investigation of the two species, *Melaleuca uncinata*, R. Br., and *Melaleuca nodosa*, Sm. The former is restricted more particularly to the interior of the continent, not having been recorded east of the dividing range. It does, however, occur on Kangaroo Island. It is mostly a slender shrub having acicular leaves terminating with slender hooks. *M. nodosa* is a coastal plant, and is a more compact shrub.—Aboriginal navigation and other notes: R. H. **Mathews.**—A short volumetric method for the estimation of sulphuric acid: Dr. T. **Cooksey.** The method depends upon the volumetric estimation of the excess of barium salt left in solution after the precipitation of the sulphuric acid as sulphate of baryta. The barium is estimated by standard carbonate of soda—phenolphthalein being used as indicator. Spirit of wine is added to promote the rapid precipitation of the barium carbonate.

DIARY OF SOCIETIES.

THURSDAY, MARCH 19.

ROYAL SOCIETY, at 4.30.—On Vapour-pressure and Osmotic Pressure of Strong Solutions: Prof. H. L. Callendar, F.R.S.—On Secondary β-Rays: Prof. J. A. McClelland.—On the Measurement of the Atmospheric Electric Potential Gradient and the Earth-air Current: C. T. R. Wilson, F.R.S. —Note on the Trajectories of Rifled Projectiles with Various Shapes of Head: A. Mallock, F.R.S.

ROYAL INSTITUTION, at 3.—Standardisation in Various Aspects: (1) Mechanical Engineering: Dr. R. T. Glazebrook, F.R.S.

ROYAL SOCIETY OF ARTS, at 8.—The Navigation of the Air: Dr. H. S. Hele-Shaw, F.R.S.

CHEMICAL SOCIETY, at 8.30.—The Constitution of Electronegative "Thiocyanates": A. E. Dixon and J. Taylor.—An Improved Form of Pyknometer: W. R. Bousfield.—The Quantitative Conversion of Aromatic Hydrazines into Diazonium Salts: F. D. Chattaway.—The Action of Heat on α-Hydroxycarboxylic Acids, Part iv., Racemic αα-Dihydroxyadipic Acid and Meso αα-Dihydroxyadipic Acid: H. R. Le Sueur.—The Spontaneous Crystallisation of Sodium Sulphate Solutions: H. Hartley, B. M. Jones, and G. A. Hutchinson.—Quantitative Relations of Salts of Thallium and its Separation from Silver: J. F. Spencer and Miss M. Le Pla.—Constitution of Hydroxyazo Compounds, Action of Diazomethane and of Mercuric Acetate: C. Smith and A. D. Mitchell.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—New Alternate Current Instruments: Dr. W. E. Sumpner and J. W. Record.

LINNEAN SOCIETY, at 8.—The Podosomata of the Atlantic and the Arctic Oceans: Rev. Canon Norman, F.R.S.—A Revision of the Genus Codonopsis: T. F. Chipp.—On the Holothurians from the Red Sea: E. Hindle.

INSTITUTION OF MINING AND METALLURGY, at 8.—Annual General Meeting.

FRIDAY, MARCH 20.

ROYAL INSTITUTION, at 9.—Recent Earthquakes: Prof. J. Milne, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Stresses in Brick Arches: J. D. W. Ball.

SATURDAY, MARCH 21.

ROYAL INSTITUTION, at 3.—Electric Discharges through Gases: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 23.

ROYAL SOCIETY OF ARTS, at 8.—Fuel and its Future: Prof. V. B. Lewes.

SOCIOLOGICAL SOCIETY, at 8.—The Definition of Magic: Principal Jevons.

TUESDAY, MARCH 24.

ROYAL INSTITUTION, at 3.—The Egyptian Sudan: its History, Monuments, and Peoples, Past and Present: Dr. E. A. Wallis Budge.

ROYAL SOCIETY OF ARTS, at 4.30.—The Mineral Resources of Western Australia: Hon. C. H. Rason.

FARADAY SOCIETY, at 8.—Presidential Address: Some Aspects of the Work of Lord Kelvin: Sir Oliver Lodge, F.R.S.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—(1) Sinhalese Magic, with Especial Reference to Charming Ceremonies and Amulets; (2) Exhibition of Amulets, Objects employed by Devil Dancers and Buddhist Votive Offerings: Dr. W. L. Hildburgh.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Curzon Bridge, at Allahabad: R. R. Gales.—The Netravati Bridge, at Mangalore: A. S. Napier.

WEDNESDAY, MARCH 25.

ROYAL SOCIETY OF ARTS, at 8.—Recent Improvements in Decorators' Materials: A. S. Jennings.

BRITISH ASTRONOMICAL ASSOCIATION, at 5.

THURSDAY, MARCH 26.

ROYAL SOCIETY, at 4.30.—*Probable Papers*:—Bakerian Lecture: The Thermal Conductivities of Solids: Prof. C. H. Lees, F.R.S.—Comparison of the Board of Trade Ampere-Standard Balance and the British Association (Ayrton-Jones) Current Weigher: T. Mather, F.R.S., and F. E. Smith.—Note on the Rise of Meteorological Balloons and the Temperature of the Upper Air: A. Mallock, F.R.S.

ROYAL SOCIETY OF ARTS, at 8.—The Navigation of the Air: Dr. H. S. Hele-Shaw, F.R.S.

ROYAL INSTITUTION, at 3.—Standardisation in Various Aspects: (2) Electrical Engineering: Dr. R. T. Glazebrook, F.R.S.

CHEMICAL SOCIETY, at 5.—Annual General Meeting.—Presidential Address: The Electron as an Element: Sir William Ramsay, K.C.B., F.R.S.

FRIDAY, MARCH 27.

ROYAL INSTITUTION, at 9.—Radio-active Change in the Earth: the Hon. R. J. Strutt, F.R.S.

PHYSICAL SOCIETY, at 5.—(1) Notes on the Plug Permeameter; (2) On the Use of Shunts and Transformers with Alternate Current Measuring-Instruments; (3) On Wattmeters; Dr. C. V. Drysdale.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Combustion Processes in English Locomotive Fire-Boxes: Dr. F. J. Brislee.—Combustion Processes in American Locomotive Fire-Boxes: L. H. Fry.

SATURDAY, MARCH 28.

ROYAL INSTITUTION, at 3.—Electric Discharges through Gases: Prof. J. J. Thomson, F.R.S.

CONTENTS.

THURSDAY, MARCH 26, 1908.

MISLEADING SEISMOLOGY.

Earthquakes, an Introduction to Seismic Geology. By William Herbert Hobbs. Pp. xxxi+336. (New York: D. Appleton and Co., 1907.) Price 2 dollars net.

EARTHQUAKES have come home to us of late, and we presume that the more general interest, which is now taken in them, is the cause of the publication of this book, on a subject with which the author seems very imperfectly acquainted. The key-note of the work is struck very early in the book, in a summary of the history of modern seismology, which would lead one to suppose that little of any importance had been done outside Germany and Austria; no mention is made of the Seismological Society of Japan, and it is erroneously stated that the International Seismological Association has "published at regular intervals the 'Beiträge zur Geophysik.'" The reports of the sessions of the association have certainly been published as supplementary volumes of this periodical, which is an independent publication, and one of the reasons for the abstention of those seismologists who have held aloof is that the association has been made to appear as the appanage of a private venture.

A large part of the book is devoted to the geological aspect of seismology, and in this we find what the author regards as his contribution to the science. He plots on a map the places at which earthquakes have been felt, or have exhibited a greater degree of violence, draws a series of straight lines through them, which he calls seismotectonic lines, and regards it as a remarkable fact that these lines should intersect at the points through which they are drawn. To a small extent the "seismotectonic" lines represent a truth which has long been known to students of seismology, but by far the greater number of them are mere figments of the pencil and the ruler, and it is remarkable that the author should make no reference, in this connection, to Col. Harboe's theory of extended earthquake origins, a theory which has some resemblance to that of Prof. Hobbs, but is based on more extensive data, and makes no attempt to force the origins into straight lines.

The author's unfamiliarity with the subject is most conspicuous in his treatment of seismometry, whether by observation of the effects of earthquakes or by the use of instruments. We find no mention of West's formula, or even of acceleration as the cause of earthquake damage, but we do find a most remarkable suggestion that the "simplest and one of the best" of seismoscopes may be made by setting up an ordinary lead pencil upon its end, in part immersed in a bath of sand; it is gravely added that an inch scale may be marked on the pencil by simple notches, to enable the depth of the immersion to be recorded. We can imagine the enthusiastic seismologist frantically digging out the ruins of his dwelling and anxiously determining the direction in which the pencil, embedded, say, only three inches in the sand, had been overturned! Seriously, we wonder if Prof. Hobbs has any idea of the shock necessary to overturn a lead pencil standing on a smooth, hard surface, let alone embedded in sand; it seems a very unstable object, and easily upset, but the shock which will throw it down is severe enough to alarm many people, and even to cause damage to buildings; moreover, the direction of overthrow is now known to indicate little or nothing regarding the wave motion of the earthquake. After this it is not surprising that the description of the horizontal pendulum seismograph should be wrong both as to theory and practice.

This brief review of some of the more striking faults in the book must not be supposed to mean that it is altogether bad. As an introduction to seismology, or even to seismic geology, it is the most misleading that we know, but for the reader who comes to it with sufficient previous knowledge it contains suggestive passages, and as we perused the book we were haunted by the consciousness that its author was capable of better work; we searched for the word which would describe its character until a marginal heading, in block type, supplied the want in "crudeness."

GERMAN SCHOOL BOTANY.

(1) *Mikroskopisches und physiologisches Praktikum der Botanik für Lehrer.* By G. Müller. Pp. xvi+224. (Leipzig and Berlin: B. G. Teubner, 1907.) Price 4.80 marks.

(2) *Handboek der botanische Micrographie.* By Dr. J. W. Moll. Pp. xxii+350. (Gröningen: J. B. Wolters, 1907.) Price 4.25 francs.

(3) *Grundzüge der Pflanzenkunde.* By Prof. K. Smalian. Zweite Auflage. Pp. 288; with 36 coloured plates. (Leipzig: G. Freytag; Vienna: F. Tempsky, 1908.) Price 4 marks.

(4) *Anatomische Physiologie der Pflanzen und der Menschen.* By Prof. K. Smalian. Pp. 86. (Leipzig: G. Freytag; Vienna: F. Tempsky, 1908.) Price 1.40 marks.

(1) ALTHOUGH it is the general practice among teaching botanists to combine in lectures the explanation of physiological principles with descriptions of the organs involved, the combination of microscopical anatomy with physiology in a practical book is unusual. In the present instance there is complete separation into a course of microscopical exercises that occupies about three-quarters of the volume, and a set of physiological experiments and deductions. The anatomical course begins with a description of the necessary apparatus for microscopical technique, after which there follows a series of studies of the cell, stem, leaf, and root, nearly identical with the types in Strasburger's "Botanisches Praktikum," in so far as these relate to flowering plants. This part of the book is excellent, especially for teachers who wish to become thoroughly conversant with all details and skilled in manipulation. The directions are explicit, the hints on reagents and methods are practical, and the accom-

paniment of typical illustrations will be found useful. The physiological course does not produce such a favourable impression. The conduction of water and salts bulks largely in the foreground, and, seeing that it is an unsolved problem, it would seem more rational to give it less prominence. Generally speaking, the experiments appear to have been chosen rather to demonstrate dogmatic ideas than to serve as exercises practicable for general students.

(2) It is an advantage to teachers to obtain an insight into the methods adopted in other classes than their own, and botanists will welcome this introduction to the botanical courses planned by Prof. Moll for students in the University of Gröningen. In the first place the author discusses the comparative uses of demonstrations and practical classes. In practical work, although duly insisting on the necessity for good drawings, he places a high estimate on carefully written descriptions, and in this connection details his schemes for ensuring completeness by taking each character in order. A general course of histology and anatomy is outlined in a series of two hundred and fifty exercises. Some of the specimens selected for examination are innovations, and the examples of bacteria, with hints for obtaining and cultivating them, are particularly useful. On the other hand, the studies of tissues are not well defined or complete; one observes also notable omissions in the systematic types, and a somewhat too rigid uniformity in the use of tests. A special syllabus of products included in the Dutch pharmacopœia is inserted for the benefit of pharmaceutical students in the university, but the most valuable feature is the list of special investigations suitable for advanced students, that are based on, and intended to repeat, original researches. The book can be recommended to teachers having a knowledge of the Dutch language, especially during the preparation of a course of practical botany, as likely to furnish them with new ideas.

(3) This volume consists of a collation of botanical descriptions and information arranged according to the natural orders. The author's object has been to present his information in an attractive form, and to depict the *tout ensemble* of the plant. In this respect he has been quite successful, but he might with advantage have brought into greater prominence the scientific principles of classification, and would thereby have rendered the book more suitable for the purpose intended, as a text-book for use in a "Realschule." The information relates to pollination devices, seed dispersal, and general ecology, also to common insect pests, plants of economic importance, and morphological peculiarities. The sequence is similar to that prescribed by Engler, but differs mainly in the treatment of the dicotyledons, where a beginning is made with the Ranunculaceæ while the Caryophyllaceæ and orders with imperfect flowers are deferred to the end of the Archichlamydeæ. The space devoted to the cryptogams is necessarily so limited that it would have been wiser to omit them and to have extended the account of some of the phanerogams. The book is well illustrated throughout, and is provided with thirty-six coloured plates that are beautifully reproduced. It is a book that would be appreciated by boys and many of their elders who take a keen interest in botany.

(4) It is rightly impressed upon students that the physiology of plants and animals shows certain features in common, whence it might be expected that there would be an advantage in treating the two subjects in one volume. In the present case there is no special attempt to compare the physiological activities in the two kingdoms. The first part provides a concise account of the elements of plant physiology, but is not written with the view of stimulating practical experiment; in fact, the few pieces of apparatus represented in the illustrations are open to serious criticism. The second part, dealing with human physiology, is almost more concerned with form than function.

ELEMENTARY PHYSICS.

(1) *The New Matriculation Heat.* Pp. viii+276; *The New Matriculation Light.* Pp. viii+282; *The New Matriculation Sound.* Pp. viii+211. (Cambridge: University Tutorial Press, Ltd., 1908.) Price 2*s.* 6*d.*, 2*s.* 6*d.*, and 2*s.* respectively.

(2) *A First Year's Course in Geometry and Physics.* By Ernest Young. Pp. xi+169. (London: G. Bell and Sons, 1907.) Price 2*s.* 6*d.*

(3) *A Second Year's Course in Practical Physics.* Pp. vii+148; *A Third Year's Course in Practical Physics.* By James Sinclair. Pp. viii+125. (London: B. Bell and Sons, 1907.) Price 1*s.* 6*d.* each volume.

(1) THESE manuals cover the ground of the London University matriculation syllabus in heat, light, and sound. The treatment is lucid and concise, and thoroughly in accordance with the most recent methods of teaching elementary physics. An outstanding feature of these books is the inclusion of a number of experiments which may be performed with the most simple and inexpensive apparatus, and from which satisfactory results may be obtained.

In the volume on "Heat" a chapter is devoted to methods of approximation, and this should prove extremely useful to the student in reducing observations of actual experiments or performing the numerical exercises with which the book is plentifully supplied. One notes with pleasure, in the chapter on hygrometry, the omission of the classic "Daniell." A simple method for determining the "thermal conductivity" of india-rubber is described in the chapter on heat conduction, and serves well enough to illustrate the definition to elementary students, a point which, as a rule, has been neglected in text-books of this standard. In Expt. 47, p. 135, paraffin wax is a somewhat unsatisfactory substance for the determination of melting point by the cooling-curve method, at least for beginners. On p. 140 it would have been better to use the term "latent heat of water" as synonymous with "latent heat of fusion of ice," and not "latent heat of ice."

The volume on "Light" calls for little comment. The optical formulæ are obtained by the usual geometrical methods, the sign convention being made clear. The "power" of a lens is defined, and attention is directed to the optician's mode of calling a convex lens positive. "Dispersion," "the eye," and "defects of vision" are very clearly treated.

The first six chapters in the volume on "Sound" are devoted to vibratory and wave motion, and the author has succeeded in giving a very clear, and at the same time elementary, exposition of these somewhat difficult subjects for the beginner.

The three volumes form a suitable introduction to the study of physics.

(2) This book is intended for use in schools where a four years' course is given as outlined by the present regulations of the Board of Education. The book is divided into three parts. Part i. represents a first term's work in geometry and physics; part ii. a second and third term's work in geometry; part iii. a second and third term's work in physics. The book is a copious collection of examples and practical exercises in illustration of the chief elementary geometrical properties of the straight line, parallels, triangles, quadrilaterals, polygons, and circles. The construction and use of scales, graphs, measurements of length, area, volume, and density are also dealt with. No instructions are given as to the method of using the instruments employed in performing the various exercises. These are left for the teacher to supply. The book should prove extremely useful as a class-book, the multiplicity and variety of the exercises being a boon to any teacher for purposes either of work in class, in the laboratory, or at home.

(3) These are two elementary laboratory text-books forming, as their titles imply, a second and third years' course in practical physics for schools. The second year's manual deals chiefly with heat, and contains descriptions of methods of performing upwards of seventy experiments, the subjects treated including thermometry, measurement of coefficients of expansion, calorimetry, conduction, convection, radiation, solution, distillation, and crystallisation. In addition, questions and supplementary exercises are given after many of the experiments. The book strikes one as being hurriedly compiled, the diagrams in very few instances being referred to in the text. Again, on p. 81 a wire 12in. long 3/32in. diameter is to be bent 2 cm. from the end. Is such confusion intended? The experiments described on conduction and radiation are novel, use being made of an indicating paint prepared by Mr. Walter Jamieson. This paint, which is colourless at ordinary temperatures, turns green when heated, the green colour disappearing on cooling. The range of sensitiveness may be from 80° C. to 21° C. Objection must be raised to the designation of the curve in the diagram on p. 82 as "heat-curve." Temperature-gradient would be better. We must disagree with the remark on p. 42, footnote; it is certain a boy will be more readily convinced of the anomalous expansion of water by use of the apparatus described in the text (previously described by Mr. H. E. Hadley in the *School World* for June, 1901) than by the performance of Hope's experiment. The diagram of the constant volume air thermometer on p. 53 is unnecessarily complicated, and does not appear any more exact than that on p. 50.

The third year's course is devoted entirely to optics, and is similar in plan to the manual on heat. There are upwards of fifty experiments which may be performed with simple apparatus, and the book contains many supplementary exercises and questions. Experiments 6, 7, 8, pp. 11–19, on photometry are misleading, viz., "To find the relation between the illuminating power and the distance of sources of light." The "intensity of illumination" at a point due to a given source will vary with the distance, but the "illuminating power" of the source remains the same.

OUR BOOK SHELF.

The Mechanism of Speech. Lectures delivered before the American Association to promote the Teaching of Speech to the Deaf by Alexander Graham Bell. Second edition. Pp. xv+133. (New York and London: Funk and Wagnall's Company, 1907.) Price 1.20 dollars net.

THIS is the second edition of a work already reviewed in NATURE, December 27, 1906 (vol. lxxv., p. 196). The first edition was printed during the author's absence in Europe, and he had no opportunity of revising the proofs. As the printers could scarcely be expected to be familiar with the somewhat complicated symbols used by the author's father, Melville Bell, a number of typographical mistakes had crept in. These have now been corrected. A full account is given of Mr. Melville Bell's ingenious system of symbols, which are intended to express the position of various parts of the vocal apparatus in the production of articulate sounds, and illustrations are afforded of the methods by which deaf children can be led to understand the meaning of these symbols, and are thus guided in the operation of placing their vocal organs in the position required for a given word. By patient training and by following the judicious maxims of Mr. Graham Bell a wonderful degree of success has been attained in the education of the deaf.

Mr. Melville Bell's symbols express words, not in letters, nor in the wave vibrations revealed by the phonograph or gramophone, but in forms that indicate precisely the physiological position of the articulating mechanism necessary for the production of a given sound. A first glance at these strange symbols gives one the impression of the system being too complex for practical purposes, but with the aid of Mr. Graham Bell's instructions it soon becomes easy. The writer in a short time found that he could both write and interpret the symbols. One can readily see how the system might be of use to travellers, as, by means of the symbols, they could write down the sounds of an unknown tongue and reproduce them. A knowledge of this system and the use of a phonograph would be invaluable to those who desire to register the articulate expressions of savage tribes. JOHN G. MCKENDRICK.

The Moths of the British Isles. By Richard South. First Series, containing the Families Sphingidæ to Noctuidæ. Pp. vi+343, plates 159, text-figures 24. (London: F. Warne and Co., 1907.) Price 7s. 6d. net.

BOOKS on British butterflies and moths are now plentiful enough, but we have never seen any which have pleased us so well as the series of which this book is the second volume. It is true that technicalities, even the characters of families and genera, are almost entirely omitted, but the amount of practical information is nearly as great as that to be found in the more bulky work of Mr. Barrett, who dealt with about 100 species in each volume. No popular book, of course, can compete with the huge encyclopædic work of Mr. Tutt; but then he often devotes 40 or 50 pages of very closely printed but large 8vo. pages to a single species, and his work is only slightly illustrated. Mr. South, however, gives us a profusion of admirable illustrations, and much bulk is saved by an arrangement by which the plates (except the frontispiece) are on opposite sides of the same leaf, in most cases coloured figures of moths occupying one side and plain figures of transformations the other. The introduction is good, and includes useful figures of antennæ and wing-markings, &c., and also remarks on collecting.

The general arrangement followed is that of Staudinger's catalogue of 1901. One point of interest in successive works on British Lepidoptera is the shifting of localities for species, combined with the actual extinction of some, and the discovery or naturalisation of others. The comparison of a series of successive works like those of Petiver, Haworth, Stephens, Westwood and Humphreys, Stainton, and Barrett would bring this out very strongly. Most of the best localities of the older London entomologists has been built over or otherwise destroyed; the best locality for "blues," &c., near Brighton, is now turned into allotments; and several species of butterflies and moths common in many parts of England only fifty years ago are now on the verge of extinction as British species.

We must not omit to mention that Mr. South does not share Stainton's prejudice against English names. In Stainton's time it might have been necessary to discourage their use as against that of Latin names; but at present the latter are so familiar that it is no longer necessary. One suggestion we should like to make. The index is good, but we think a table of contents would also be useful; and if restricted to headings and families, it need not occupy more than a single page W. F. K.

Physiologie und Anatomie des Menschen mit ausblicken auf den ganzen Kreis der Wirbeltiere. By Dr. Felix Kienitz-Gerloff. Pp. vi+130. (Leipzig: B. G. Teubner, 1907.) Price 3 marks.

THIS is a small elementary text-book with a scope similar to that of Huxley's "Elementary Lessons in Physiology." It presents clearly and accurately the main facts of physiology and anatomy from a general educational point of view. While the skeleton, muscles and joints are dismissed with appropriate brevity, the central nervous system, sense organs, excretory organs, and the alimentary, respiratory, and circulatory systems are treated in some detail. As opportunity offers, matters pertaining to general health find suitable mention. The text is lightened by frequent and interesting references to comparative anatomy. The illustrations are taken from standard text-books of anatomy, and are both numerous and well chosen. Although the book is primarily intended for students in a school of agriculture, it ought to have a wide and general circulation. W. W.

The Elements of Geography. By J. H. N. Stephenson. Part i., General Geography. Pp. xiii+160; with illustrations and maps. (London: Edward Stanford, 1908.) Price 3*s.* 6*d.*

WHAT Mr. Stephenson describes as "general" is more commonly known among teachers as "physical" geography; but since an understanding of the broad principles with which he deals in this attractive book must precede a study of the geography of special areas, his title sufficiently describes the character of his chapters. The section styled "organic" geography will prove especially useful to teachers as indicating the way in which man's development has been modified by his surroundings, and the manner in which man in his turn has influenced the character and distribution of life on the globe. The book is exceptionally rich in well-executed maps which will increase greatly its usefulness as a class-manual. The volume may be recommended to the careful attention of teachers of geography.

Lehrbuch der Chemie und Mineralogie für die vierte Klasse der Realschulen. By Franz von Hemmelmayr and Dr. Karl Brunner (the Mineralogical Portion by Heinrich Leitenberger). Third edition. Pp. 180; with two coloured plates. (Vienna: F. Tempsky, 1906.) Price 2kr. 10hel.

THIS is an elementary class-book for use in the fourth class in the Austrian State schools, that is, for boys of about twelve or thirteen years of age. It covers much the same ground as the usual elementary class-books on chemistry. In the longest portion of the book, that on inorganic chemistry, however, there are added brief descriptions of the more important minerals which yield the elements under discussion; the pupil is thus at the same time told how chemical compounds and elements occur in nature. Figures are given of crystals of these minerals, but several of them have been placed upside down in the text. There is a short section on organic chemistry, in which prominence is given to compounds of everyday use. The book is very well and clearly printed on good paper.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Cotton Plant.

THE full acknowledgment Sir George Watt has given to the slight assistance which I was able to afford him—in those portions of his book which deal with Egyptian cotton—renders criticism difficult, but there are a few points arising from Lieut.-Colonel Prain's recent letter (February 6, p. 318) which seem to call for comment.

While not possessing any general knowledge of the genus Gossypium, I have had occasion during the last three years to grow, and to examine in some detail, a number of pedigree cultures of Egyptian cotton—as well as of Uplands and others—in researches on Mendel's law. One result of this work is that I can fully endorse your reviewer's argument that the cotton plant can be studied successfully for systematic purposes in living material only. The herbarium method has many limitations, the most conspicuous of which is perhaps the tendency to take the extreme form of some character which has a large range of fluctuation as the differentiating mark of a variety or species.

Colonel Prain affirms that the ideas of your reviewer as to the meaning of the terms "species" and "variety" do not accord with accepted usage. My general position is the reverse of Colonel Prain's, in that I am unable to obtain any idea as to the nature of species in the genus Gossypium by studying the names accorded by Watt to certain plants with which I am acquainted. A particular case is that of the Sudanese tree cottons from Senaar, referred to in the "Wild and Cultivated Cottons of the World" by my numbers 213–1 and 213–2 (pp. 113 and 138). These were supplied to me by Mr. A. G. Braun, of the Woods and Forests Department, Khartoum, in a sample of seed which had been sent from Senaar Province. This sample was sown at Ghizeh, and the material sent to Kew was taken from two adjacent plants in the same row, these being plants developed from embryos which had ripened on a tree in Senaar. The reason for sending material from two different plants was because this row showed two distinct leaf-forms, some of the plants having much wider leaf-lobes than the others, and these two types were represented by 213-1 and 213-2. In no other respect could any distinction be drawn between the two types, at least on any character within my grasp; moreover, they all flowered within the same week, ripened within the same week, grew to a remarkably uniform height, and had similar habits of growth; with the one exception of the leaf-shape they were far more alike than a similar group of plants taken from a field of any variety of Egyptian cotton. These two forms were separated by Watt into *G. arboreum* and *G. Nanking*, because "a yellow-flowered *G. arboreum* with deeply laciniate bracteoles and three glands on the under surface of the leaf would destroy the specific isolations" (p. 138). I incline to think that the laciniation of the bracteoles and the glandulation of the leaves should have been made the subject of comparative study—in order to ascertain their capacity for fluctuation—before such erratic characters were entrusted with the responsibility for this violent separation of the two forms into two separate species. Such comparative study would at least have been commenced had these plants been seen growing side by side in my plot.

On the other hand, we find on p. 181 that Moqui Indian cotton from Arizona (209-3) and "Hindi" weed cotton of Egypt (55 A) are placed together under *G. punctatum*. Waiving the query as to why Hindi, a naked-seeded cotton, should be placed in the fuzzy-seeded section, I should like on other grounds—but in all diffidence—to advance the opinion that if the two strains could be grown together at Kew, or examined side by side on my plot in Egypt, they would be systematically removed from one another by a wide interval.

The employment of common names has also been mentioned by Colonel Prain; the following instance, therefore, does not seem altogether pointless:—the plant referred to as 56.C.2 (p. 224) came from a sample of Afifi cotton, and bears lint of the brown Afifi colour; this colour is the characteristic and sole morphological distinction of Afifi from Abbassi, the latter bearing white lint, so that 56.C.2 could by no possibility be described legitimately as "close to Abbassi or Afifi."

The cultivated varieties of Egyptian cottons—and probably of Uplands—consist of many different strains mingled together and cross-fertilised, resembling one another in a few obvious characters of economic importance. Thus, on p. 224, Watt describes the strain 142, plant A, as being distinct from the Abbassi plant described in par. 2 of the same page. In point of fact, No. 142 was taken from a prize sample of Abbassi.

Though I wish to see an exact method adopted for the investigation of this labyrinthine genus, such method to be based on pedigree culture and statistical inquiry, I am nevertheless grateful to Sir George Watt for having gathered together the mass of detailed information which is to be found in his book, and I hope—with Colonel Prain—that we shall not have to wait long for the publication of further researches on the subject.

W. LAWRENCE BALLS.

Cairo, February 27.

IN the courteous letter in which Mr. Balls exercises his right to criticise details in Sir G. Watt's work on cotton, as to which he considers himself a competent judge, he gives expression to some misapprehension that it may be well to remove.

It has not been affirmed that the ideas of the writer of the review which appeared in NATURE for January 16 as to "species" and "varieties" do not accord with accepted usage. What it was necessary to point out was that the reviewer had not made it clear that his interpretation of these words accords with accepted usage. There are two passages in the review in which the words are dealt with together; in one passage they are so used as to imply that the status of a variety is the same as that of a species; in the other they are so used as to indicate that a species is subordinate in status to a variety. The ideas of the reviewer may be as precise as those of Mr. Balls; they may, on the other hand, be as loose as his own phraseology; he has given us no means of deciding.

The position assumed by me has already been explicitly stated. I have reserved perfect freedom of judgment as regards the acceptance of Watt's conclusions, not as to the limits of species in the genus Gossypium alone, but as to all the issues involved. When he explains that his general position is the reverse of this, it will be felt that Mr. Balls does himself an injustice.

The name of the distinguished public servant referred to by Mr. Balls is Mr. A. F. Broun, and is not as given in Mr. Balls' letter.

D. PRAIN.

The Isothermal Layer of the Atmosphere.

IN his letter in NATURE of February 27 Mr. Dines asks why the adiabatic conditions which prevail in the lower part of our atmosphere should suddenly cease at a height of about 40,000 feet. The answer comes more readily if the question is altered to, Why does the isothermal condition of the outer layers of our atmosphere suddenly cease at about 40,000 feet? The isothermal condition or even increased temperature with height is the condition which would naturally prevail in an atmosphere surrounding a smooth sphere. For if the sphere is a very hot one its entire gaseous envelope should acquire its temperature, whereas if the solid sphere, like our earth, is cold, and if heat from the sun is warming the atmosphere by radiation, one may expect the outer layers to be warm and the lower layers to be the coldest ones. If, however, there are irregularities, as, for instance, mountain chains on the earth's surface, then the air, whenever it is forced over them, parts with its moisture as it rises on the one side and then descends on the other side as a dry and hot *Foehn*, in which wind the conditions are perfectly adiabatic, the temperature gradient rising steadily with decreasing height. It seems, therefore, that it is our mountain ranges which prevent the isothermal condition from descending below the height at which effective mixing or moisture removing occurs.

This leads to the conclusion that if at one time our mountain ranges were lower than at present, the isothermal condition and its low temperature will also have been lower than at present. This may have been the case during Glacial periods. On the other hand, during tropical periods our mountain ranges may have been higher than they are at present; the isothermal condition will have ended at a higher level, and the steady rise of temperature below this boundary will have resulted in a very high temperature on the earth's surface.

I remember discussing this subject about twenty years ago at Aix-la-Chapelle with Dr. A. Ritter, who had only recently in Wiedemann's *Annalen* (vols. v.–viii., "Heights of Atmospheres and Conditions of Nebulæ") dealt with it very exhaustively. If I am not mistaken, it was the *Foehn* wind which had first led to these inquiries, but, strange to say, Dr. Ritter relied on molecular motions for the necessary mixing of the layers. This may have been due to his feeling that if isothermal conditions were conceded, an interstellar atmosphere would have to be postulated. We therefore almost naturally disagreed as to the possibility of condensing the so-called permanent gases, which fact had not then been accomplished. My view was that if nitrogen and oxygen should be condensable, and if the adiabatic condition existed up to the outer limits of our atmosphere, then, at the zero temperature to be found there, both gases would condense and sink to the lower levels, to be followed by further and further layers until the whole atmosphere would be deposited on the earth's surface. Dr. Ritter merely pushed this difficulty further away by saying that, even if oxygen and nitrogen could be condensed, our atmosphere might nevertheless be surrounded by hydrogen. Now that hydrogen has been condensed, helium would have to take its place, or, and this is a view not easily accepted, our earth may be surrounded by a very attenuated and possibly warm interstellar atmosphere. I think that the recent experiments to which Mr. Dines refers by showing that the conditions of the outer atmosphere are isothermal, and Sir James Dewar's experiences with non-conducting power of high vacua are leading to the conclusion that there is a comparatively warm interstellar atmosphere.

C. E. STROMEYER.

"Lancefield," West Didsbury, March 3.

ONE would naturally expect the upper part of any large mass of fluid to be the warmer, because that condition is a possible one, whereas the converse is not possible as a permanent condition, since it involves a warmer, and therefore in general a lighter, portion of the fluid remaining under a heavier. But when dealing with a gas it is necessary to use the term "warmer" in a special sense, for which the convenient expression "potentially warmer" has been used. This means that the temperature is referred to some standard pressure, and taken as what it would be after adiabatic reduction to that pressure. In this sense the air gets rapidly warmer as we ascend, at the rate of about 0°·4 C. to each 100 metres, but if there were sufficient mixing we should expect to find the same potential temperature throughout, just as in a pond the heavier water is found at the bottom, but in a fast-running stream the specific gravity and the temperature are the same throughout.

We have no evidence at the present time to show how the isothermal layer is influenced by a mountain range, but there are immense stretches of sea and land so far removed from any high mountains that we can hardly suppose any such influence to exist over them.

It must be remembered that the chief heating and cooling effects on our atmosphere are applied at the bottom by contact with the ground. Pure air is almost pervious to radiation. There may be sources of heat to the upper layers; the electric currents which produce the aurora have been suggested, but I do not see that this affords any explanation of the sudden cessation of the temperature gradient.

The well-known phenomena of shooting stars apparently quite negative the suggestion of a stellar atmosphere; beside which, unless it were moving with the earth, in which case it would cease to be stellar, such an atmosphere would produce an enormously increased pressure on the forward side of the earth as it pursued its course round the sun.

W. H. DINES.

The Penetrating Radiation.

IN a letter to NATURE of February 13, the question is raised by Mr. W. W. Strong whether the larger proportion of the penetrating radiation may not arise from active matter in the air rather than in the ground. Unless the earth's supply of active matter is augmented from without, or unless it arises in a manner at present unknown, the question may be negatived, and a numerical answer given with some approach to accuracy.

Strutt has found about 3×10^{-12} grams of radium as the average amount present in 1 c.c. of soil. I have found about 10^{-16} grams of radium to be a measure of the amount of radium emanation present per c.c. of the atmosphere (*Phil. Mag.*, December, 1907). These two quantities are nearly proportional to the amounts of radium C produced per c.c. in earth and in air. The ratio is 30,000 to 1.

But McClelland and Wigger have found that the coefficients of absorption of the γ rays are proportional to the densities of the absorbers, so that the absorptions of the γ rays from radium C by soil and by air are as their densities, about 2000 to 1.

Now it has been proved (*Phil. Mag.*, September, 1906) that, for a given electroscope near the earth's surface, the penetrating radiations from earth and from air will be in the ratio Q/λ to Q'/λ', where Q, Q' are the quantities of radium per c.c. in soil and air, and λ, λ' are the coefficients of absorption of the γ rays by soil and air.

Hence the penetrating radiations from the radium C in the ground and from that in the air are in the ratio of the two ratios above stated, namely, 15 to 1.

Moreover, the radium C in the air is carried earthwards, not only by falling rain, snow, dust, or smoke, but by the potential difference in the atmosphere. The active matter on the earth's surface is thus augmented and that in the air decreased.

Observers in both hemispheres have found evidence of thorium C in the air, the activity being about half that of the radium C present. The emanation of thorium decays about 6000 times as fast as the emanation of radium, and has a poor chance of escaping from the soil, so that (1) the amount of thorium C in the ground probably exceeds the amount of radium C, and (2) the thorium C in the ground will be more than fifteen times that in the air.

We may conclude, then, that at most localities the penetrating radiation due to active matter in the air is less than one-fifteenth of that due to active matter in the earth.

Mosaic Origin of the Atomic Theory.

THE recent correspondence on the subject of the identity of the inventor of the atomic theory has led me to think that the following quotation from one of the foremost English scholars of the seventeenth century is worthy of some passing notice in this connection. Ralph Cudworth, D.D. (1617–1688), was the author of a colossal monument to Greek philosophy, the "Intellectual System of the Universe." A smaller work of that author, which was published posthumously (1731), contains the following paragraphs, which throw a glimmering light (new, probably, to most eyes) on the historic continuity of *ancient* philosophy and "modern" science:—

"1. Wherefore we have made it evident, that that very *Mechanical* or *Atomical* Philosophy, that hath been lately restored by *Cartesius* and *Gassendus*, as to the main Substance of it, was not only elder than *Epicurus*, but also than *Plato* and *Aristotle*, nay, than *Democritus* and *Leucippus* also, the commonly reputed Fathers of it. And therefore we have no Reason to discredit the report of *Posidonius* the *Stoick*, who, as *Strabo* tells us, affirmed this *Atomical* Philosophy to have been antienter than the Times of the *Trojan* War, and first to have been brought into *Greece* out of *Phenicia*. *If we may believe* Posidonius *the Stoick, the Doctrine of Atoms is antienter than the Times of the Trojan War, and was first invented and deliver'd by one* Moschus *a* Sidonian, or rather *a Phenician*, as *Sextus Empiricus* cites the Testimony of *Posidonius*. Democritus *and* Epicurus *invented the Doctrine of Atoms, unless we make that Physiology to be antienter, and derive it, as* Posidonius *the Stoick doth, from one* Moschus, *a* Phenician. And since it is certain from what we have shewed, that neither *Epicurus* nor yet *Democritus* were the first Inventors of this Physiology, this Testimony of *Posidonius* the Stoick ought in Reason to be admitted by us.

"2. Now what can be more probable than that this *Moschus* the Phenician, that *Posidonius* speaks of, is the very same Person with that *Moschus* the Physiologer, that *Jamblichus* mentions in the Life of *Pythagoras*, where he affirms, that *Pythagaras* living some time at *Sidon* in *Phenicia*, conversed with the Prophets that were the Successors of *Mochus* the Physiologer, and was instructed by them. *He conversed with the Prophets that were the Successors of* Mochus *and other* Phenician *Priests*. And what can be more certain than that both *Mochus* and *Moschus*, the *Phenician* and Philosopher, was no other than *Moses* the *Jewish* Lawgiver, as *Arcerius* rightly guesses. *It seems that it ought to be read* Moschus, *unless any had rather read it* Mochus or Moses. Wherefore according to the Antient Tradition, *Moschus* or *Moses* the *Phenician* being the First Author of the *Atomical* Philosophy, it ought to be called neither *Epicurean* nor *Democritical*, but *Moschical*, or *Mosaical*."

Dublin, February 26. JOHN KNOTT.

Tabulated Values of Certain Integrals.

IN reply to the letter of Mr. C. E. Adams in NATURE of March 19, a table of the values of the integrals required will be found in Airy's "Undulatory Theory of Optics" (Macmillan and Co., Ltd., 1877) on p. 158.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

VII.—THE ABERDEEN CIRCLES (*Continued*).[2]

IN December, 1906, I gave an account of my measures of four examples of a very special type of circle which is only to be found, so far as I know, in Aberdeenshire. They were described in relation to other circles by Mr. Lewis in his paper on the stone circles of Scotland. My wife and I again went to Aberdeen last autumn and measured another twenty-five, leaving, I believe, still more than a hundred to be examined.

The survey last year has greatly increased the interest in them, and I hope to show that a complete inquiry into them may advance science in many directions, especially if other allied questions are included in the research.

The instrument employed in the reconnaissance, for time did not allow of a complete survey, was a compass clinometer of Barker's pattern, giving azimuths and angular heights of the horizon, say, to half a degree, a reading quite as fine as can be hoped for, considering the rough condition of the monuments, and the presence of trees on the horizon in many cases. As I said in my 1906 notes, observations of the height of the horizon in winter, when the trees are leafless, are very desirable.

In the observations last year, the orientation was determined by attempting to find the direction of the line across the circle at right angles to the face of the recumbent stone. Last year I worked differently.

The method of observation adopted was to measure the azimuth of the line lying along the common N. and S. surfaces of the supporters and recumbent stone, and in the eastern direction where possible. When there was no common line, supporters and recumbent stone were dealt with separately. In some of the complete and undisturbed triliths the correspondence of the azimuths of both surfaces showed that immense care had been taken in selecting and "planting" the stones.

The mean of the azimuths thus obtained, deducting 90°, gave the direction of the observing line across the circle.

In some cases it seemed as if the circle builders had got this line in the first instance by erecting two stones on the opposite side of the circle about the same distance apart as the two supporters—a kind of avenue, the surfaces of the recumbent stone being placed at right angles to this line.

This premised, I next give a comparison between the Cornwall and Aberdeen monuments:—

(1) Assuming that the recumbent stone in Aberdeenshire was used as a directrix, like the outstanding stones of the Cornish and Gorsedd circles, all the conclusions I arrived at in Cornwall and on Dartmoor are abundantly confirmed.

(2) I have examined no circle in Aberdeenshire the astronomical use of which, with one or two exceptions to be referred to later, is not perfectly obvious in the light of former work.

(3) The directions indicated by the Aberdeen recumbent or directing stones are generally the same as those indicated by the outstanding stones in Cornwall. The exceptions are that the cardinal points N. true and W. true are indicated in the former.

(4) The N. and the W. true alignments may indicate an advance in astronomical knowledge. The N. alignments suggest that time at night was determined by circumpolar stars. The W. alignment shows that the equinoxes were fixed as well as the solstices.

(5) Of the twenty-nine circles I have examined, fifteen are clock-star circles, two are May-year, and three solstitial. Of special circles we have four facing N. and one facing W.

(6) Arcturus and Capella were used as clock-stars in Cornwall; in the higher latitude of Aberdeen Castor might have been used.

(7) So far, and quite provisionally until a larger number of circles is examined, I think Castor was not used.

(8) In the clock-star circles the azimuths range from N. 4° E. to N. 29° E. These azimuths, taking the heights of horizon into account, give us N. declinations from $34^\circ\ 45'$ to 31°. If Capella is in question, the dates lie between B.C. 1200 and B.C. 2000; if Arcturus, B.C. 950 and B.C. 250. Mean dates are:—Capella, B.C. 1600; Arcturus, B.C. 600.

I append a diagram which shows the connections existing between the azimuths, the elevation of the horizon—both measured quantities—and the declinations, and dates of the use of the clock-stars. The numbers on the curves refer to the fifteen clock-star circles enumerated below:—

FIG. 20.—The recumbent or directing stone and supporters of the Cothie Muir Circle, a normal example.

1, Braehead Leslie; 2, Leylodge; 3, Loudon Wood; 4, Tomnagorn; 5, Wanton Wells; 6, Old Keig; 7, South Fornet; 13, Nether Boddam; 8, Aikey Brae; 9, Castle Fraser; 10, New Craig; 11, Loanhead of Daviot; 12, Kirkton of Bourtie; 14, Cothie Muir; 15, Eslie the Greater.

Note that on the diagram the circle (13) is misplaced. The azimuth should be $21^\circ\ 15'$, not $11^\circ\ 15'$; consequently the (13) circle should be moved along the "2° hill" curve until it touches the circle (5).

As an illustration of the use of the curve, take the case of the Cothie Muir circle, number 14. The true azimuth across the circle, *i.e.* at right angles to the recumbent stone, was found to be N. $18^\circ\ 55'$ E., and the elevation of the horizon in that direction 4°. Projecting the point where the $18^\circ\ 55'$ azimuth ordinate intersects the "4° hill" curve, on to the declination scale, we get $34^\circ\ 42'$ N. as the declination. Referring to the time scales for Arcturus and Capella, it is seen

[1] Continued from p. 416.
[2] NATURE, vol. lxxv., p. 150.

that the former had this declination in 920 B.C., the latter in 1300 B.C.

(9) There is so far no absolute demonstration as to which of the stars in question was used, or whether they were used at different times. Some light may be thrown on this point if the approximate dates of the solstitial circles at Midmar, Sunhoney and Stonehead can be determined, using the change of obliquity.

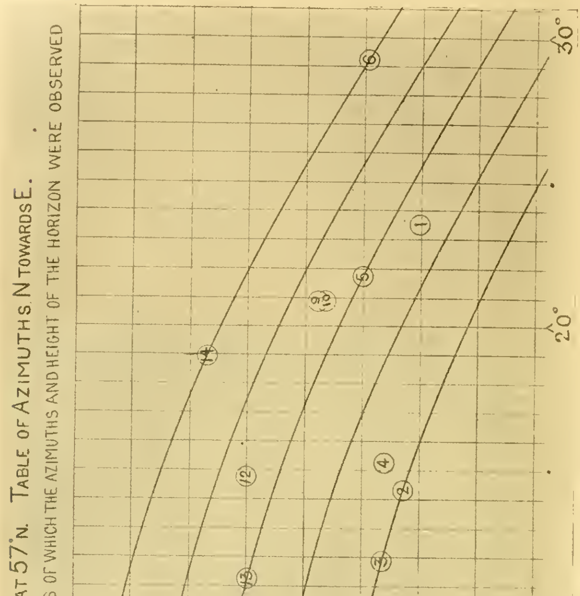

Fig. 21.—Showing azimuths and heights of hills.

This question of date is, of course, one of surpassing interest, and it is not a little curious that the conditions at Aberdeen are such that no direct solution of the problem is so far possible.

But there are some sidelights.

Against the older date is the fact that the Aberdeen circles, even May-year circles, differ in the method of alignment used in other parts of Britain, including the west coast of Scotland, at the earlier date. But the presence of the recumbent stone is not the only difference; the central stone of the Gorsedd is generally replaced by a cairn, or rings or mounds of stones. The true N. alignments at Dyce, Whitehill Wood, Raes of Clune and Candle Hill (Insch) have no counterpart in the South, and they may be held to indicate possibly an advance in the manner of determining time at night, and therefore an erection at a more recent date.

Again, the work at the various circles showed that the Aberdeen system of alignment is far inferior to that of the employment of an outstanding stone some distance away from the circle as in the Cornish monuments. But it must not be taken for granted that this inferior method of alignment meant an inferior knowledge of astronomy, which we should be justified in associating with an earlier date. I am rather inclined to attribute it to the fact that an exact knowledge of the length of the year and of the number of days in each quarter having been gained, exact alignments became less necessary. As time went on, the circle became of less importance as an astronomical instrument, though its other uses remained, and this latter view seems strengthened by the fact that in Aberdeenshire the circles are very frequently located on the tops of low hills, convenient places of assembly, whereas in Cornwall this, so far as I now remember, did not often happen. The Aberdeenshire circles, indeed, are generally at a much lower level, among the cultivation. It was chiefly the astronomical requirement of a clear horizon which was fulfilled in Cornwall and Dartmoor, at heights from 1000 to 1500 feet.

Another strong argument against the older date is the absence of cromlechs in the Aberdeen district.

May we not take the absence of the cromlech and the presence of the cist as another proof of modernity? By cist I mean an obvious grave as opposed to the "chambered cairns" of some authors, which were as obviously not built as graves merely. These "chambered cairns," I take it, are really the interiors of barrows, and are large examples of cromlechs. It is immaterial whether the barrows were built of stones or earth to make the chambers rain-tight. This would depend upon which was most handy—stones in Scotland, chalk at Stonehenge, earth in Cornwall.

Now while "cists" are common to Scotland, Dartmoor and Cornwall, the "chambered cairn" or cromlech is in Scotland special to the west coast. I do not know at present whether there is any representative of it nearer to Aberdeen than Callernish or Stenness. The difference between the east and west coast of Scotland is thus strongly emphasised, and the view of a difference of time in the building operations is strengthened.

I now return for a moment from the side-lights to the clock-star conditions, in order to give a table of the measurements, from which the declinations of the stars were determined by means of a curve connecting azimuth and declination, for different elevations of the horizon, for the general latitude of 57° N.; consequently the measurements are not final, but are sufficiently accurate for a preliminary discussion.

Between 2000 B.C. and 1 B.C Arcturus and Capella were the only first-magnitude stars to come within the declination range shown in the table, and, as my results show that they were used as clock-stars in Cornwall and Devon, I consider that the evidence in their favour warrants the assumption that one of them was used as a clock-star by the circle-builders of Aberdeenshire. I give the dates for both.

Circles at—	Azimuths: Magnetic, mean of observations	Azimuths: True, at right-angles across circle	Elevation of the horizon	Declination N.	Dates B.C.: Arcturus	Dates B.C.: Capella
	° ′	° ′	°	° ′		
Braehead Leslie... ...	132 20	N. 23 35 E.	$1\frac{1}{2}$	30 58	250	2000
Leylodge	123 0	N. 14 15 E.	0	31 18	330	1940

Kirkton of Bourtie ...	123 30	N. 14 45 E.	$2\frac{1}{2}$	33 57	770	1460
Cothie Muir	127 40	N. 18 55 E.	4	34 42	920	1300
Eslie the Greater ...	113 30	N. 4 45 E.	$2\frac{1}{2}$	35 5	980	1230

In future notes, after referring to some more "side-lights," I shall give the measurements of the May-year and solstitial circles.

Norman Lockyer.

PROPOSED ALTERATION IN THE CALENDAR.

THE last great alteration in the calendar was that which was known as the Gregorian Reformation. It was promulgated in 1582, and at once accepted in all countries which were under the Roman obedience in ecclesiastical matters, but only gradually adopted by those belonging to the Reformed Western Church (which are all usually called Protestant, though that term strictly pertains to the Lutherans only), whilst the Eastern Church adheres still to the old Julian style.

Now it is often forgotten that the change then made was two-fold, the two parts having really no reference to each other, and the assertion frequently made that the Gregorian calendar was constructed, or nearly so, to agree with the astronomical length of the year, applies to only one of these changes, the other, which made a violent hiatus in the succession of days, being effected with a totally different object. For if the year were to be assigned its true length and not the $365\frac{1}{4}$ days decreed by Julius Cæsar, it would at first sight have seemed most natural to choose a convenient epoch, such as the end of a century, and simply arrange the omission of a leap-year at certain stated times from that. (Here we may parenthetically remark that a regulation to drop a leap-year at the end of each 132nd year would have been more accurate, and quite as simple as that actually adopted.) But it was also thought necessary to bring back the vernal equinox to the date it occupied, not at the Christian era, but at the time of the Council of Nicæa in the fourth century. Hence ten days were omitted from the current sequence, and when England came into line with other western countries, eleven days were omitted in 1752. This, of course, makes great care necessary in comparing events as given in English and Continental narratives between 1582 and 1752.

The change now proposed, and recently brought before the House of Commons by Mr. Pearce, is of a much more drastic kind It is not a reformation of the Gregorian calendar as regards the length of the year (and a small change of the rule, as already mentioned, would improve its accuracy at long intervals), but a proposal to alter the succession of the days of the week and of the month to secure a degree of symmetry in their correspondence, and an equality in the four quarters of the year. Thus the first of January and the leap-year day, which, however, is to be, not in February, but in June, have each to be considered in every respect a *dies non*; if either falls on a Sunday, not that day, but the next is to be reckoned as Sunday, which, of course, would occasionally throw Sunday one day, or even two days, ahead of its place in the sequence of seven days.

Now it may safely be affirmed that, not only for its practical inconvenience and disturbance of the uniformity and continuity which are so desirable in a calendar, but for other reasons also, even more weighty, this alteration can never be accepted in Christian countries, nor could it commend itself if we began *de novo*.

As regards the days of the month, the case is different. The existing arrangement was a perversion ot that decreed by Julius Cæsar. He ordained that the year should begin with January, the 1st being the day of new moon nearest the winter solstice when the change was made, and that that month should have thirty-one days and each alternate month afterwards, the rest to have thirty, excepting February, which should have twenty-nine days in common years and thirty days in leap-years, to fall *every* fourth year. In the reign of Augustus, who looked upon August as his special month, though it was not that of his birth, the convenient and easily to be remembered arrangement of Julius was altered in order that August might have as many days as July. By the earlier arrangement the days of the successive months were 31, 29 (or 30), 31, 30, 31, 30, 31, 30, 31, 30, 31, 30; by the later (now followed), 31, 28 (or 29), 31, 30, 31, 30, 31, 31, 30, 31, 30, 31.

No doubt Cæsar placed the leap-day in February because that had been the last month of the year in the old Roman calendar. There would be no harm, if we were starting afresh, in placing it in June as proposed by Mr. Pearce; but it would injure continuity (always a desirable thing in itself) and not attain his object unless the day, as well as New Year's Day, were made a *dies non*, both in the week and in the month. Neither of these would be convenient; the first is, for other reasons also, inadmissible.

On one point we agree with Mr. Pearce, and that is as regards the incidence of Easter. There is a common, but false, impression that the existing cumbrous arrangement has the authority of the Council of Nicæa. All that that council decreed was, in opposition to the so-called Quartodecimans, that Easter should always be kept on a Sunday; the particular Sunday was regulated by various cycles, the Metonic being usually followed, and the present rule was initiated by the advisers of Pope Gregory XIII., the English Prayer-Book rule arriving at the same end, when our calendar was reformed, by a slightly different process. It has not secured uniformity in Christendom because the Eastern church still follows the Julian calendar, and therefore its Easter is usually different from ours. A rule to keep Easter on the second Sunday in April (when the first Easter in all probability fell) would be very convenient, but it is an ecclesiastical question, and the alteration should be the act of the whole church. To make it always on the same day of the month, as well as week, as Mr. Pearce proposes, could not be done without accepting his other drastic and inadmissible proposals.

W. T. L.

PECULIARITIES IN THE STRUCTURE OF SOME HEAVENLY BODIES.

PROF. SUESS has recently contributed a suggestive paper on peculiarities in the structure of some of the heavenly bodies [1] to the Academy of Sciences of Vienna. He remarks at the outset that the present phase of geology is similar to that of anatomy at the time when the structure of the human body was first compared with that of other living organisms. For the purpose of comparative study it is essential that the earth should be regarded as a whole, and when this is done it becomes fairly obvious that acid rocks and their derivatives, which form so large a portion of the visible surface, are far less important as constituents of the globe than might at first sight be supposed. We see but little of those heavy substances to which the earth owes its high density, and which appear to be more closely associated with the basic than with the acid rocks. Our author considers that for the general purpose which he has in view three main types of rock should be recognised—SiAl rocks (sal or salic rocks), SiMg rocks (sima or simic rocks), and NiFe rocks (nife or nific rocks). For the simic rocks containing chromium and iron he uses the term crofesima. The most important occurrences of platinum are in the crofesimic rocks, which also contain almost always traces of nickel. These rocks are of deep-seated origin, and it is a significant fact that they frequently occur as intrusions along planes of movement in the younger mountain chains, such as the Alps, *e.g.* zone of Ivrea.

In 1901 the author, in a letter to Sir Norman Lockyer (NATURE, October 24, 1901, p. 629), directed attention to the fact that the metals associated with the basic rocks are not only distinct from those which often accompany the acid rocks, but that they agree closely with those which stand out prominently in the Fraunhofer spectrum and in α Cygni. This led Sir Norman to institute a special research, with the result [2] that "the views of Prof. Suess were confirmed . . . and that the metals conspicuously represented in the spectra of the sun, the chromosphere, and α Cygni are, in the main, those which are associated with basic rocks; also that, with the possible exception of yttrium and lithium, the metals typical of acid rocks are not represented in α Cygni. There is, of course, evidence that several of the acid-rock-metals such as potassium, beryllium, cerium, tin and zirconium are represented in the Fraunhoferic spectrum, but the solar lines are in each case inconspicuous."

[1] "Über Einzelheiten in der Beschaffenheit einiger Himmelskörper" (*Sitz. d. k. Akad. d. Wiss. Mathem-naturw. Klasse*, Bd. cxvi., October, 1907.)

[2] "Spectroscopic Comparison of Metals present in Certain Terrestrial and Celestial Light-sources." (Solar Physics Committee, 1907.)

Commenting on the above quotation, Prof. Suess points out that if the composition of the earth be considered quantitatively there is every reason to believe that it would, if subjected to the necessary physical conditions, yield a sun in which the basic group of metals would spectroscopically dominate over the acid group.

In considering the distribution of metals of the basic, or, as he now expresses himself, of the simic group, the author directs attention to the local predominence in terrestrial occurrences of certain metals, *e.g.* titanium over nickel and *vice versâ*. Similarly, if γ Cygni be compared with α Cygni, titanium, strontium, and scandium will be seen to be more important, and iron, chromium, and magnesium less important in the former than in the latter.

The special importance of titanium in sun-spots is compared with the predominance of this metal (ilmenite) over nickel in the contents of the diamond-pipes of South Africa, which are regarded as the most striking terrestrial examples of gaseous eruptions.

In the concluding part of the paper the author briefly reviews the theories as to the origin of meteorites, and favours the view that they, together with the planetoids, represent the fragments of an anonymous planet which formerly occupied a position between Mars and Jupiter. "The centre of this planet," he says, "consisted of nife like that of Agram or Elbogen. Towards the exterior the proportion of magnesium increased, and a transition from nife to sima took place, as is probably the case with the earth, although the supposition cannot be verified by observation. A salic outer crust was absent unless it be represented by the perfectly molten tektites." [1]

SIR JOHN ELIOT, K.C.I.E., F.R.S.

THE news of the death of Sir John Eliot, K.C.I.E., F.R.S., in his sixty-ninth year, at his residence, Bon Porto, Cavalaire, Var, France, will be received with great regret by a very large circle of friends. His death was extremely sudden, and took place in the early morning of Wednesday, March 18. He was walking on a steep hill in his own grounds, superintending the work of his men, when he suddenly sat down and passed away. The cause of death is said to have been apoplexy.

Sir John Eliot was throughout his life a most indefatigable worker, and since his retirement from the Indian Service about five years ago he had continued to work with unabated vigour. Indeed, the strenuous work which he undertook may perhaps have undermined his health, and have caused his premature death. He was one of the most genial companions possible, having a most charming personality, together with a keen sense of humour. He was most widely read and well informed in almost every subject, and at the same time he was one of the most modest of men. He was a most accomplished musician, and played the organ and piano with very great execution and feeling. He was also

[1] This term has been proposed by Dr. F. E. Suess ("Die Herkunft der Moldavite und verwandter Gläser," *Jahr. geol. Reichsanst.*. 1900, p. 193) for certain peculiar vitreous bodies which he refers to an extra-terrestrial origin.

greatly loved and esteemed by his subordinates and fellow-workers, and by his many friends.

Sir John Eliot had a most distinguished career, and the major part of his life was devoted to India, at first to educational work, and later on to Indian meteorological problems. He was born at Lamesby, in Durham, on May 25, 1839. The details of his earlier education have not been recorded, but he went up to Cambridge University about 1866 and took his degree from St. John's College in 1869, and was second (bracketed) wrangler and first Smith's prizeman of his year. He was then elected to a fellowship at St. John's College, which he held from 1869 up to his marriage in 1876. As a young man his health was not very robust, and he was advised to avoid the climate of England, so that after taking his degree he accepted an appointment in the Indian Government Service as professor of mathematics at the Roorkee Engineering College. This he held from 1869 to 1872. He was then transferred to the regular Indian Educational Service as professor of mathematics at the Muir Central College at Allahabad, an appointment which he held from 1872 to 1874.

About this time he turned his special attention to physics rather than to pure mathematics, and also undertook certain meteorological work at Allahabad. In 1874 he was appointed professor of physical science at the Presidency College, Calcutta, and combined this with the post of meteorological reporter to the Government of Bengal, both of which he held from 1874 to 1886. He was then appointed meteorological reporter to the Government of India and director general of Indian observatories, an appointment which he held until he retired in January, 1903. On his retirement the Government of India published in the *Gazette of India* a most complimentary resolution thanking him for "his long and meritorious services."

As an educationist he has left his mark in the various colleges in India in which he worked, and also in the Calcutta University, of which he was for many years a most distinguished Fellow. Many of the present generation of educated Indian gentlemen who are holding very prominent positions are largely indebted to Sir John Eliot, not only for his actual teaching, which was of a particularly high order, but also for his kindliness and sympathy towards his students. The example shown by his work and character had a great effect on all brought in contact with him, and he was very greatly respected and loved by his students and by all classes of Indian gentlemen, for it may be truly said of him that his great abilities were more than equalled by his extreme modesty and invariable kindness.

In his capacity as Fellow of the Calcutta University he also did very notable work, and by his great influence and marked powers of persuasion he was able to introduce many considerable reforms into the courses of instruction in mathematics and physical science, and in the latter case he was specially successful in making the courses more practical and more thorough than they had hitherto been.

As a meteorologist, India also owes him a large debt of gratitude. As meteorological reporter to the Government of Bengal, he largely extended the meteorological system, and introduced daily weather reports with charts based on telegraphic information, and he also instituted a very comprehensive and effective system of storm warnings for coast stations round the Bay of Bengal, and of flood warnings for inland stations. One of his earliest meteorological papers was a "History of the Backergunge Cyclone of 1876," in which storm about two hundred thousand people were drowned in about half an hour by a huge storm wave, which swept over the Island of Sandip.

In this monograph Sir John Eliot largely developed and extended the theory of the formation of cyclones. This publication indeed excited a good deal of attention both in India and in England, and in both instances this was unusual. So much attention was directed to this memoir and to the cyclone which it described that a request was made in the House of Commons for the report to be produced and laid on the table, and it was then made available to those interested in England.

The reputation as a meteorologist which Sir John Eliot gained while occupying the post of meteorological reporter to the Government of Bengal rendered it a foregone conclusion that when the higher post of meteorological reporter to the Government of India fell vacant it would be offered to him. This post had been created about the year 1875 or 1876, and its first incumbent was the late Mr. H. F. Blanford, F.R.S. Up to about 1875 there had only been local officers in charge of the meteorology of the different provinces (such as Bengal, Madras, and Bombay) into which India is divided, but it was felt that if Indian meteorology was to make any real progress it must be studied as a whole, and not piecemeal. Hence the appointment of meteorological reporter under the Imperial or Indian Government was created, and all the observations taken in the various provinces were, after local use, sent on to the Indian Meteorological Department. Much and most valuable work was done by Mr. Blanford in the development of the department on an Imperial basis, and also in the foundation of systematic and organised investigation and in the prompt diffusion of meteorological information thus obtained, but, as in all great schemes, the progress of consolidation of the work in its imperial aspects was rather difficult.

With Mr. Blanford's work as a basis, Sir John (then, of course, Mr.) Eliot was able to make more rapid progress. He largely increased the area from which observations were received, and also the number of reporting stations in the area already covered. Indeed, during his tenure of office he almost doubled the number of stations which sent in reports, and extended them so as to get observations from very high altitudes (11,000 feet elevation), and also from outlying places like Kashmir and the routes leading towards Central Asia, and from such places as Leh, Ladakh, Dras, &c. He made the work of the observatories more accurate and more systematic, and arranged that by telegraphic communication the latest meteorological information from all parts of the Indian Empire in the form of daily weather reports with charts should be at once available at headquarters.

Indeed, it is not too much to say that from the time he took over charge of the Indian Meteorological Department, its efficiency and usefulness were very largely increased, and that he brought it quite into line with the most modern meteorological organisations. Under him the department published many series of most valuable results and memoirs. He also developed a complete system of storm warnings for the whole of the coast-line of India and Burma, extending over some thousands of miles, and also established flood warnings for the whole of India by which telegraphic warnings are sent of expected floods to all engineers in charge of irrigation and other large works, and in other cases where similar damage may occur. Daily reports with charts dealing with the sea areas of the Bay of Bengal and Indian Ocean were also established, and, further, he established a most valuable system of seasonal forecasts, which gradually became of very great value, though naturally to begin with they were rather tentative and experimental.

Those who navigate Indian seas are also especially indebted to Sir John Eliot for his work, "Handbook of Cyclonic Storms in the Bay of Bengal," which has in all human probability been the means of saving many vessels and valuable property—possibly from destruction and certainly from damage—by enabling such vessels, by the rules laid down in that work, to avoid the more dangerous parts of these cyclones, and also generally to escape from them altogether by the knowledge thus given of the indications of the approach of such storms and of the tracks usually followed by them in the different months of the year.

Indeed, it would be an easy matter to prove that in many instances the information and warnings conveyed from the Indian Meteorological Department have been the means of helping that Government and individuals in a most remarkable manner, and that even to put the matter on the lowest ground, it has saved the State vast sums of money by giving accurate information of the precise meteorological conditions of the country, and timely warnings of possible famines, and in some cases, when famine seemed looming in the immediate future, of timely information of approaching rainfall, which at once would do away with the necessity of starting famine relief operations on a large scale. The Indian Meteorological Department has far more than justified its existence, for it has really proved itself of far greater value than its relatively small cost.

Sir John Eliot was also very greatly interested in the subject of solar physics, and he was largely instrumental in starting the solar physics observatory at Kodaikanal, in southern India, and immediately on his retirement he was appointed as a member of the Solar Physics Committee, and also on other scientific bodies, and he worked quite as hard as he had always done in India. Indeed, he was at work up to the last, for on the Monday before his death he was engaged on his new book, "A Handbook of Indian Meteorology," and said he was making great progress with it.

One who knows well the work of Sir John Eliot after his return to Europe writes as follows:—

"Sir John Eliot left India full of enthusiasm for the future of his department. As a public servant he had the rare satisfaction of knowing that a scientific enterprise begun with some doubt and misgiving, had, under his direction, established its claim to a recognised position, and had justified the anticipations of its promoters. His last official step was to secure for his successor the increase of the scientific staff of which he had himself felt the need.

"On his return to England he gave expression to his experience and his aspirations in an address to the British Association at Cambridge in 1904 as president of the subsection for astronomy and cosmical physics. Reviewing his own work and stimulated by his success, he looked beyond the forecasts of to-morrow's weather to anticipating, on strictly scientific grounds, the character of the seasons by the correlation of meteorological phenomena over extended regions of the earth and their possible relation with solar changes. He became secretary of the Solar Commission, originated upon the proposition of Sir Norman Lockyer by the International Meteorological Committee, which met at Southport in 1903. The purpose of the committee was to collect comparable meteorological data from all parts of the world and solar data for comparison with them. He spent a considerable part of his last stay in England in planning new arrangements for carrying out the objects of the Commission. In the latter part of his address at Cambridge he advocated the organisation of the British contribution to this side of meteorological work upon an imperial basis. He realised that an imperial combination would treat such questions with a breadth of view that is not possible or permissible in any single colony or dependency, guided, as it must be, by the narrower consideration of its immediate needs.

"His plan was to provide for organised observations from areas too wide to be within the control of any single Government; to place the material thus obtained at the service of workers in all parts of the world by publishing it while it was still of direct practical utility and to ensure its application to the service of the Empire by a special staff of trained workers.

"Anyone who reads the address cannot fail to catch something of his enthusiasm. There is a ring of the 'land of hope and glory' about his appeal for the extension of our knowledge of the facts. 'Wider still and wider be thy boundaries set' bespeaks the ideal of his meteorological method, and it was to the various parts of the King's dominions that he looked for its realisation. The task was no light one. The British Association made a beginning, but imperial wheels grind very slowly. It says much for Eliot and for India that he carried with him the active support of the Indian Government for the proposal. He welcomed the idea of a meeting of British meteorologists in Canada, because it gave him the opportunity of getting a step forward, and although conscious of the personal sacrifice which it involved, he undertook to make the journey to Ottawa this year for the purpose. The intention cannot be fulfilled."

"It is a bitter disappointment to all his fellow-workers that death has brought his efforts to an untimely end. His enthusiasm was entirely free from any suggestion of selfishness or personal ambition; he could speak from an unique position with unrivalled experience. There is no one now to take his place. But the idea remains, and this country seldom wants for men when there is real work to be done. Remembering Eliot's achievements we are emboldened to fall back upon the refrain, and to add the second couplet without misgiving."

Among the more prominent of Sir John Eliot's publications are numerous accounts of cyclones and severe cyclonic storms occurring within Indian seas; also numerous meteorological discussions contributed to the Indian Meteorological Memoirs, to the Indian Cyclone Memoirs, to the Journal of the Asiatic Society of Bengal, and to the Quarterly Journal of the Royal Meteorological Society; his "Handbook of Cyclonic Storms in the Bay of Bengal" (already mentioned), and his last publication, which took the form of that most valuable work, "The Climatological Atlas of India," published by the authority of the Government of India only a few months ago; while at the time of his death he was engaged in writing a "Handbook of Indian Meteorology" to accompany this, also to be published under the direction of the Government of India.

Sir John Eliot was elected a Fellow of the Royal Society in 1895; he was created a C.I.E. in 1897, and was given his K.C.I.E. in 1903 on his retirement. In 1877 he married Mary, daughter of Mr. Wm. Nevill, of Godalming; his widow survives him, and he has left three sons. A. P.

NOTES.

SIR OLIVER LODGE was unable to deliver his presidential address to the Faraday Society on Tuesday on account of an attack of influenza, from which, however, he is now recovering.

WE regret to state that the Duke of Devonshire died at Cannes on Tuesday morning, at seventy-four years of age. The Duke was a Fellow of the Royal Society and Chancellor of the University of Cambridge.

THE Right Hon. A. J. Balfour, F.R.S., has been elected a corresponding member of the French Academy of Moral and Political Sciences in succession to Lord Reay, who has been elected an associate.

THE Paris Academy of Sciences has accepted a legacy of 400*l*. from M. Sabatier to found a biennial prize to be known as the Sabatier prize.

ON the drill ground at Issy-les-Moulineaux on Friday, March 20, Mr. H. Farman traversed the complete circle two and a half times with his aëroplane, the length of the flight being 2750 yards, and the time 2m. 15s.

WITH regard to the inquiry of a correspondent (NATURE, March 5, p. 417) for particulars concerning the mist and Sicilian earthquake of 1783, Mr. E. A. Martin, The Museum, Croydon, writes to point out that Gilbert White has a reference thereto in his Letter 65 to Barrington ("Natural History of Selborne").

DR. HALL-EDWARDS, who recently had his left hand amputated in consequence of X-ray dermatitis, has been granted a Civil List pension of 120*l*. a year. When Dr. Hall-Edwards has recovered from the effects of the amputation, another operation will be necessary, and at least four fingers of his right hand will have to be amputated.

ON Thursday next, April 2, Mr. R. Lydekker will begin a course of two lectures at the Royal Institution on (1) "The Animals of Africa," (2) "The Animals of South America." The Friday evening discourse on April 3 will be delivered by the Right Hon. Lord Montagu of Beaulieu on "The Modern Motor-car," and on April 10 by Prof. J. J. Thomson on "The Carriers of Positive Electricity."

THE death is announced, in his seventieth year, of Dr. D. B. St. John Roosa, president of the New York Medical Post-graduate School, and professor of diseases of the eye in that institution. He formerly held chairs in the University of the City of New York and the University of Vermont. He was the author of a pocket medical lexicon and of various treatises on the eye and the ear.

PROF. W. A. KELLERMAN, who has held the professorship of botany at the Ohio State University since 1891, has died of malaria in Guatemala, which country he was visiting in order to study its flora. He was born in 1850, graduated at Cornell in 1874, and had taught botany at the Wisconsin State Normal School and the Kansas State Agricultural College. He was perhaps most widely known as founder and editor of the *Journal of Mycology*. Among his books were "Flora of Kansas," "Spring Flora of Ohio," and "Phyto-Theca."

REFERRING to the article on "Some London Problems" published in our issue of March 19, a correspondent directs attention to the arrangement for the construction of deep-water wharves near Gravesend, in Long Reach, about five miles above Tilbury. These wharves have been licensed by the Thames Conservancy and approved by the Board of Trade, though their construction has been delayed because of the Port Bill. This wharf will be capable, our correspondent states, of dealing with three million tons of traffic a year.

THE Royal Commission on Coast Erosion has been directed to inquire whether, in connection with reclaimed lands or otherwise, it is desirable to make an experiment in afforestation as a means of increasing employment during periods of depression in the labour market, and, if so, by what authority and under what conditions such experiment should be conducted. The following new members have been added to the commission:—Mr. J. Galvin, Mr. E. S. Howard, C.B., Mr. H. C. Monro, C.B., Dr. W. Somerville, Mr. F. Story, and Mr. J. Ward, M.P.

THE sixty-first annual meeting of the Palæontographical Society was held on March 20 in the rooms of the Geological Society, Burlington House, Dr. Henry Woodward, F.R.S., president, in the chair. The annual report alluded to the unusually varied contents of the volume for 1907, due to an attempt to provide indexes and title-pages for several monographs which were either complete or discontinued. The council is beginning to favour the plan of publishing smaller works, and has included in the current volume a complete monograph of British Conulariæ, by Miss Ida L. Slater, with five plates drawn by the author. The council welcomed a contribution from the Carnegie Trust for the Universities of Scotland, which provided five plates of Scottish Carboniferous fishes described by Dr. Traquair. Mrs. G. B. Longstaff, Mr. H. A. Allen, Dr. F. A. Bather, and Mr. William Hill were elected new members of council. Dr. Henry Woodward, F.R.S., Dr. G. J. Hinde, F.R.S., and Dr. A. Smith Woodward, F.R.S., were re-elected president, treasurer, and secretary respectively.

NO. 3 of the 1908 issue of the Bulletin of the Imperial Academy of St. Petersburg contains an elaborate and well-illustrated account of the developmental history of the echinoderm Echiurus, by Dr. N. Salensky.

THE third part of vol. vii. of the *Emu*—issued as a special supplement—is devoted to a list of Australian birds on the model of the one now in course of issue by the British Museum. The compiler, Mr. G. M. Mathews, who has recently come to reside in this country, announces his intention of issuing an illustrated work on the birds of Australia, to which the present "hand-list" is a preliminary.

RECENT issues of the Proceedings of the U.S. National Museum include papers by Mr. A. H. Clark on the crinoid genus Comatula (No. 1585), and on the occurrence of infrabasals in certain modern pentacrinids (No. 1582), as well as one (No. 1580) by Mr. C. B. Wilson on North American parasitic copepod crustaceans, and another (No. 1586) by Miss Richardson on isopods from the northern Pacific.

IN an article published in the *National Geographic Magazine* for February under the title of "The Policemen of the Air," Mr. H. W. Henshaw raises the question as to what would happen if birds were completely exterminated. "No one," he observes, "can foretell with absolute certainty, but it is more than likely—nay, it is almost certain—that within a limited time not only would successful agriculture become impossible, but the destruction of the greater part of vegetation would follow. It is believed that a permanent reduction in the numbers of our birds, even if no species are actually exterminated, will inevitably be followed by disastrous consequences." It is added that bird-protection in the United States requires specially stringent laws on account of the large influx of immigrants from southern Europe, to whom every bird, no matter how small, is regarded as food which ought not to be wasted.

A FURTHER contribution to the controversy with regard to the alleged existence of a British willow-titmouse (*Parus atricapillus kleinschmidti*) is made by Mr. H. B. Booth in the March number of the *Naturalist*. It has been stated that the principal differences between willow-titmice and marsh-titmice are that the feathers on the crown and forehead are longer and more loosely constructed in the former than in the latter. The edges of these feathers are also glossy black in the marsh-titmouse, thus causing the crown to be glossy and of a deeper blackness than that of the willow-titmouse, which is brownish or sooty black. In the latter, again, the tail is distinctly graduated, instead of being almost squared. To these differences Mr. Booth adds the darker rufous colour of the flanks and underparts of the willow-titmouse.

THE evolution of the elephant forms the subject of an interesting article by Mr. R. S. Lull, in the March number of the *American Naturalist*. Starting with the fact that they made their first appearance in the Fayum district of Egypt during the Eocene, the author considers it probable that the proboscideans remained in Africa during the Oligocene, although we have no direct evidence to that effect. Be this as it may, the four-tusked mastodon (*Tetrabelodon angustidens*) made its appearance in the early Miocene of Mogara and Tunisia, whence it migrated by means of a land-bridge connecting Tunisia and Sicily with Italy, and thence by way of Greece, into Asia. Having reached that continent, it apparently gave rise to the Indian *Mastodon cautleyi* and *M. latidens*, from which in turn sprang the primitive, or stegodont, elephants, and from these again elephants of the modern type. Later on the typical elephants themselves migrated westwards to Europe, and thence to Africa, while in the other direction they travelled by way of Bering Strait to America. Hence we are led to conclude, as has been previously pointed out by Mr. Lydekker, that while the Proboscidea originated in Africa, the modern African elephant is of Asiatic parentage, and was an immigrant into the land of its forefathers in company with the ancestors of the giraffes, okapis, and antelopes which now dominate Ethiopia. It is added that, next to man, elephants have been the greatest travellers of all mammals, having reached practically all parts of the world.

UNDER the heading of "Investigations on the Development of Trypanosomes in Tsetse-flies and other Diptera," Prof. E. A. Minchin gives in the March number of the *Quarterly Journal of Microscopical Science* the results of his investigations during a sojourn in Uganda as a member of the commission on sleeping sickness. In the author's opinion, it may now be admitted that trypanosomes undergo development (as distinct from multiplication) in invertebrate hosts, more especially tsetse-flies. It is, however, remarkable that, whereas *Trypanosoma brucei* undergoes a complete cycle of development in at least one kind of tsetse, this is not the case with *T. gambiense*. The explanation suggested is that *Glossina palpalis*, the only kind of tsetse found at Entebbe, is not the proper host of *T. gambiense*, a suggestion supported by the fact that sleeping sickness is a disease of comparatively recent introduction into Uganda. That the Gambian trypanosome has a proper host of its own cannot be doubted, and it is probable this may be a native of the Congo, where it is suggested further investigations on sleeping sickness might advantageously be conducted. In Uganda *T. gambiense* merely commences its developmental cycle in *G. palpalis*, by which, in that district, it is transmitted to the human subject in a purely mechanical and direct manner.

WE have received from Messrs. Zeiss a pamphlet descriptive of Siedentopf's paraboloid condenser, with which an exceedingly well corrected dark ground illumination may be obtained for microscopical work. For observation, medium and high-power dry objectives should be employed. The apparatus is particularly adapted for the observation of such minute objects as bacteria and their flagella, spirochætes, &c., in the fresh and living state, and for photographing the same under these conditions. We have also received Messrs. Zeiss's general catalogue of apparatus for ultramicroscopy, which contains much matter of interest.

IN the *Journal of Hygiene* for January (vol. viii., No. 1) Miss Harriette Chick contributes an interesting article on the theory of disinfection. She shows that a very complete analogy exists between a chemical reaction and the process of disinfection, one reagent being represented by the disinfectant, and the second by the protoplasm of the bacterium. In the case of anthrax spores, the course of disinfection apparently proceeds in accordance with the well-known equation for a unimolecular reaction, if numbers expressing "concentration of reacting substance" are replaced by "numbers of surviving bacteria." A non-sporing organism, *B. paratyphosus*, shows a departure from the simple law owing to permanent differences in resistance to disinfectants among the individual organisms, the younger bacteria proving to be the more resistant. The process of disinfection is influenced by temperature in an orderly manner, and the well-known equation of Arrhenius can be applied. Some evidence was obtained that, in disinfection with mercuric chloride, a toxic compound is formed between the metal and the substance of the bacterial cell.

THE principal article in the *Bulletin du Jardin Impérial Botanique* of St. Petersburg (vol. vii., parts v.–vi.) is an account of the soil and vegetation of the district of Jaila, in the Crimea, communicated by Mr. A. Krischtofowitsch.

TAMARIND seeds are to be reckoned among the fairly nutritious plant products that have been reported to provide food during periods of famine in India. The pulp of the fruit is an esteemed ingredient of certain condiments. The kernels of the seeds when freed from the skin and roasted furnish a not unwholesome flour suitable for mixing with cereals to make small cakes. Further details and analyses are given in the *Agricultural Ledger* (No. 2, 1907) prepared by Mr. D. Hooper and published by the Government of India.

THE annual publication "One and All Gardening" has reached its thirteenth issue. Among the numerous articles, Mr. H. J. Wright furnishes an account of garden, teaching in schools, in which he provides a working plan for laying out a school garden, and summarises the progress made in different counties. Mr. S. L. Bastin contributes a note on the method of retarding flowers. The editor takes for his subject the formation of garden associations to stimulate horticulture in country and town; in this connection Mr. F. H. Stead records a remarkable development of gardens in the borough of Walworth, where last year more than one hundred gardens were entered for competition at the local flower show.

THE fauna and flora of the Snares and Auckland Islands form the subject of an ecological descriptive sketch contributed by Dr. L. Cockayne to the *New Zealand Times* (December 11, 1907). The author refers to the evidence furnished by the animal and plant life on the Snares in favour of the view that when a land area is curtailed the exceptional species most frequently survive in the struggle for existence, and so reduced areas generally contain numerous endemic species. The meadows of the

Auckland Isles furnish numerous choice plants, notably the species of the composite genus Pleurophyllum, *Myosotis capitata*, a Celmisia, and gentians. Characteristic plant associations on the islands are the tussock-grasses, *Poa scoparia*, *Poa foliosa*, and *Danthonia bromoides*, confined to special localities determined chiefly by wind conditions.

THE preservation of plants so as to maintain their green colour has been attempted in several ways. Prof. Trail some years ago recommended the use of a solution of acetate of copper in acetic acid, whereby compounds of chlorophyll with copper are formed. He contributes a note to the *Kew Bulletin* (No. 2) to point out the advantage of using a boiling solution. In the same number an article on Jequié manicoba refers to the occurrence in north-east Brazil of rubber trees allied to *Manihot Glaziovii*, the source of Ceara rubber. According to German botanists, three other species, *dichotoma*, *heptaphylla*, and *piauhyensis*, should be distinguished; they are named after the regions in which they grow as Jequié, S. Francisco, and Piauhy manicobas; all are considered to be more valuable than *Manihot Glaziovii*. Determinations of new plants are published as "Diagnoses Africanæ, XXI.," and "New Orchids, XXXI." The identification and occurrence of different patchouli plants form the subject of another article, and Mr. A. D. Cotton discusses the appearance in Great Britain of the alga *Colpomenia sinuosa*, indigenous in the Mediterranean.

THE report of the Chief Inspector of Mines of Mysore for the year 1905–6 (Madras, 1908) is devoted chiefly to official data on the progress of the Kolar gold mines. A decline in production is noticeable, due mainly to the decline in grade of the ore milled. There was also noticeable an increased death-rate from accidents in 1905, due mainly to a serious underground fire at the Nundydroog mine. The total value of gold bullion produced from the commencement of mining operations in Mysore up to the end of 1905 was 23,384,532*l*.

THE Geological Survey of Great Britain issued two additional west-country memoirs at the close of 1907. Mr. Clement Reid's "Geology of the Country around Mevagissey" (price 2*s*.) illustrates Sheet 353, which includes also the gneissic islet of the Eddystone from Sheet 354. This relic is probably part of an Archæan mass running east-north-east, which has governed the trend of the earth-folds in the Mevagissey district. The memoir points out how the Silurian rocks, coloured as "Grauwacke" in the old map of 1839, have now been delineated in some detail; but volunteers are asked for who will elucidate the difficulties still remaining. Beautiful examples of shear-structure in banded slates are given in the photographic plates. The second memoir is by Mr. Ussher, in explanation of Sheet 348, on "The Geology of the Country around Plymouth and Liskeard" (price 3*s*.), and forms a very notable contribution to our knowledge of British Devonian strata. Dr. Flett describes the numerous volcanic and intrusive rocks occurring here on various horizons. An unconformity is suggested between the Lower and Middle Culm-measures, to account for the occurrence of both series directly on Upper Devonian beds in the northern portion of the map. Mr. Ussher believes that the submerged valleys cut in the rock on the south coast owe most of their depth to river-erosion during the epoch of elevation that gave us the raised beach of the district. When this beach, therefore, was being formed at sea-level, these valleys ended in merely shallow tidal inlets. This conclusion is, as Mr. Ussher points out, in opposition to views put forward for similar phenomena in the south of Ireland. Mr. D. A. Macalister contributes a report on the mines and minerals of the district. The colour-printed maps accompanying the memoirs above mentioned are published at 1*s*. 6*d*. each, and include, as usual, clear longitudinal sections of the country in the margins.

ACCORDING to a report in the Proceedings of the Philadelphia Academy for December, 1907, the glaciers of Alberta and British Columbia are passing through a period of shrinkage, which attained special development during the year under review. The Asulkan glacier, for example, which for several years was stationary or slightly advancing, showed a marked decrease during the past season. "Preceded by a cold and stormy winter and a summer with low average of sunshine and low temperature, these conditions point to an interesting series of changes which may ultimately throw some light on the relation between weather conditions and glacier change."

THE Scottish Oceanographic Laboratory at Edinburgh has recently issued, in the shape of a small pamphlet, an account by Dr. J. Hjort, of Bergen, of some of the results of modern international oceanic research. The account, which is translated from the Norwegian, deals firstly with the new methods of current-measurement, and then with the life-history and development of several of the commoner food-fishes, such as haddock, herring, saith, cod, and plaice. Diagrammatic illustrations are given of the form and size of the scales of these fishes at different periods of existence, and the means of thereby ascertaining the approximate age of any individual fish. The ages of the plaice are illustrated, on the other hand, by diagrammatic sketches to scale of four specimens at as many stages of existence. The pamphlet should be of considerable value to all who are connected with our fisheries.

A DETAILED account by Mr. A. Schmauss of twenty-one unmanned balloon ascents made in 1907 at Munich is published in an excerpt paper from the regular meteorological year-book of Bavaria. The experiments, which were made with great care, show that in the lower air strata the temperature gradient is subject to great oscillations, and that the greatest decrease of temperature with height is found between 5 and 8 kilometres. Between 8 and 11 kilometres there is a transitional zone leading to the upper isothermal layer or inversion. After this stratum of increasing temperature follows another slowly augmenting decrease of temperature from about 14 kilometres upwards. Between 1 and 5 kilometres the same rate of decrease of temperature that exists at mountain stations was found to hold good.

IN the *U.S. Monthly Weather Review* for October, 1907, Mr. H. H. Clayton (by permission of Prof. A. L. Rotch) discusses the lagging of temperature changes at great heights behind those at the earth's surface, and types of pressure changes at different levels, as shown by the records of sounding balloons liberated at St. Louis in April and May, 1906. The observations show that at all heights above about 1 kilometre the temperature changes occur later with increasing elevation; at 10 kilometres the maxima and minima are generally about twenty-four hours later than on the ground. Only a few observations at 15 kilometres were available, but they appear to show that the irregular ranges of temperature at that height are much less than at sea-level. Referring to the maxima and minima of pressure, it is found that at 10 kilometres the curve is almost the reverse of that at sea-level; at 15 kilometres it is somewhat similar to that at 10 kilometres, but the ranges are much reduced.

Among other useful articles we may mention Mr. W. A. Bentley's interesting studies of frost and ice crystals, and a mathematical investigation by Prof. F. H. Bigelow on vortices in the atmosphere.

Tidal bores in China and Japan form the subject of two recent papers differing widely in character. In the *Popular Science Monthly* for March Dr. Charles Keyser Edmunds gives an illustrated account of his visit to the Hangchow bore, while a bore in Odawara which sometimes does much destruction is treated from the hydrodynamical point of view by Prof. H. Nagaoka in a short note in the Proceedings of the Tokyo Mathematico-Physical Society for November last.

The Bulletin of the American Mathematical Society for March contains an account of a joint meeting held at Chicago in December last between mathematicians and engineers for the discussion of the teaching of mathematics to engineering students. The discussion in question refers mainly to the mathematical requirements of the average engineer who is occupied exclusively in practical applications of known methods. Little or nothing is said by the speakers about the growing need of original workers, who, by bringing the highest mathematical knowledge to bear on engineering problems, are able to devise new methods, and to guide the ordinary practical experimenter.

A suggestion for a new economic arithmetic is the subject of a short paper in the *Economic Journal* for March by Prof. T. N. Carver. The author's ideas are simple and practical, and at the same time scientific. He considers that the teaching of arithmetic can be illustrated with advantage by simple problems based on tables, of which he gives as an example one showing the quantity of corn grown with varying quantities of labour on a given quantity of land. The problems that can be worked out as exercises with such a table include the following:—Given the cost of labour and the value of the corn, how many days' labour can be most profitably devoted to the cultivation of the fields? Or, again, given the number of available days' labour, how many acres can be most profitably cultivated? It is pointed out that complicated mathematical methods or the plotting of curves are unnecessary for the solution of such simple problems, and the author quotes the existing methods of dealing with tariff reform controversy as an instance of the want of such simple training. In support of the author's view, it must be admitted that there is a great deal commonly taught under "arithmetic" which might well be superseded by such studies as he suggests. But where are the statistics necessary for such a course to be obtained?

The *National Geographic Magazine* (xix., 1) contains an illustrated account of Dr. Alexander Graham Bell's experiments with his *Cygnet* man-lifting kite. This kite was sent up in December, 1907, both with and without a man, Lieut. Selfridge having ascended 168 feet with it, and having remained in the air for more than seven minutes. The kite is described as "tetrahedral" in shape —perhaps it would be better to describe it as a triangular prism with oblique ends. It measures 13 metres laterally at the top and 10 metres at the bottom, 3 metres longitudinally at the bottom, and 3 metres in oblique height. It consists of 3393 winged cells having a surface of 183·6 square metres. It weighs 85 kilograms, and is provided with floats, weighing 9·4 kilograms, which enable it to rest on the surface of a sheet of water. In the experiments performed at Baldeck, Nova Scotia, the kite flew with remarkable steadiness, and Dr. Bell considers this fact a justification for extending the experiments to motor-driven machines constructed on a similar principle.

An interesting lecture was given by Sir William Preece at the Institution of Electrical Engineers on March 12 on his recent visit to America, and the various improvements in constructional and engineering work since his previous visits were dealt with. The sky-scraper buildings appear to afford a considerable day load in that they employ numerous lifts which are constantly in use, but the public supply does not benefit from these very much, as in the larger buildings the tendency is to erect private plants. On the telephone question, America seems to have gone ahead of us on this side. In most of the hotels telephones are installed in every bedroom, so that business may be transacted with any part of the country. This applies also to the restaurants, where telephones may be plugged on to your table if desired. The Telephone Tariff question has also been thoroughly considered in America, and the message rate has been adopted in preference to the simple annual rental.

In the Proceedings of the American Academy of Arts and Sciences (vol. xliii., No. 12) Messrs. Gregory P. Baxter and John H. Wilson describe a number of re-determinations of the atomic weight of lead, the true value of which is at present uncertain owing to the wide discrepancies in the results of previous workers. The method of analysis adopted consisted in determining the proportion of chlorine in lead chloride by precipitation with silver nitrate; this method seemed the best to use in view of the fact that the halogen can be determined with great accuracy, and the elimination of moisture from lead chloride is easily effected by fusion of the salt in a current of hydrogen chloride. Silver chloride, moreover, when precipitated from a dilute solution of lead chloride, does not contain an amount of occluded lead salt large enough to be detected. Special care was taken, of course, in the purification of the materials employed. The results obtained were very concordant, varying in one series, in which the ratio $PbCl_2 : 2Ag$ was determined, from 207·173 to 207·202, with an average of 207·188; in another series, based on the ratio $PbCl_2 : 2AgCl$, the average 207·191 was obtained, with a range of variation from 207·181 to 207·204. The mean result, $Pb = 207{\cdot}19$ ($O = 16$, $Ag = 107{\cdot}93$), is nearly three-tenths of a unit higher than the value for the atomic weight of lead now in use.

A second edition of Mr. J. W. Hayward's "First Stage Steam" has been published by Mr. W. B. Clive.

The spring list of the Oxford University Press includes "Floral Mechanism" (part i., types 1 to 12), by Dr. A. H. Church, and "Lectures on Evolution," by Prof. E. B. Poulton, F.R.S.

Messrs. A. Gallenkamp and Co., Ltd., have issued a catalogue of the Meker hot-flame burners, Dennstedt's combustion furnaces, accessories for use with the furnaces, and cylinders of compressed air, which they are now prepared to supply.

A sixth edition of Mr. W. T. Lynn's "Remarkable Eclipses" has been issued by Messrs. S. Bagster and Sons, Ltd. The booklet has been brought up to date, and provides a sketch of interesting facts connected with solar and lunar eclipses.

Messrs. A. and C. Black will publish shortly a book on "Kafir Socialism," by Mr. Dudley Kidd; a book on botany for young children, by Mr. O. V. Darbishire, of Manchester University; and a re-issue, at a popular price, of the fourth edition of the late Miss Agnes M. Clerke's "History of Astronomy in the Nineteenth Century."

THE Bibliographischen Institut of Leipzig and Vienna has sent us the first part of a second revised and enlarged edition of Dr. M. W. Meyer's popular work on general astronomy entitled "Das Weltgebäude." The edition will be completed in fourteen parts, to be published at the price of one mark each.

IT is announced that papers on parasitology, which have hitherto appeared in the *Journal of Hygiene*, will in the future be published in a separate volume to be entitled *Parasitology, a Supplement to the Journal of Hygiene.* The publication will be edited by Prof. Nuttall and Mr. Shipley.

A THIRD edition of Mr. Douglas English's "Wee Tim'rous Beasties" has been published by Messrs. Cassell and Co., Ltd. These studies of animal life and character were reviewed in the issue of NATURE for December 24, 1903 (vol. lxix., p. 176), on which occasion we reproduced one of the excellent illustrations with which the volume is plentifully supplied.

WE have rece'ved a copy of an interesting and fairly complete international catalogue of the more important periodical publications of the world, which has been compiled by Prof. Émile Guarini, and published in Paris by MM. H. Dunod and E. Pinat. The price is 3 francs, and the catalogue gives the address, publisher, and price of 4063 reviews and journals classified according to countries.

MESSRS. PAWSON AND BRAILSFORD, of Sheffield, have published a third edition of Mr. J. Simpson's "The Wild Rabbit in a New Aspect, or Rabbit Warrens combined with Poultry Farming and Fruit Culture." The book has been revised and enlarged, contains several illustrations, and will probably assist the encouragement of rabbit warrens and rabbit farming, whether conducted for sport or profit.

ANOTHER volume has been added to the series dealing with the fauna of British India, including Ceylon and Burma, edited by Lieut.-Colonel C. T. Bingham, and published under the authority of the Secretary of State for India by Messrs. Taylor and Francis. The new volume continues the consideration of the Coleoptera, and is concerned with a portion of the family Chrysomelidæ. It is the work of the late Mr. Martin Jacoby. In a short preface the editor expresses the hope that the book will direct the attention of collectors in India to this somewhat neglected but important group of phytophagous beetles, and prove of assistance to them in their study.

OUR ASTRONOMICAL COLUMN.

WATER VAPOUR IN THE MARTIAN ATMOSPHERE.—A glance at a print from a series of spectrograms taken by Mr. Slipher on January 15, which Prof. Lowell has kindly sent to Sir Norman Lockyer, leaves but little doubt that water vapour is present in the atmosphere of Mars. This print includes two spectra of the moon and one of Mars, and whilst the *a* band is absent from the former, it is quite a marked feature of the latter spectrum. The exposure for the spectrum of Mars was from 5h. 35m. to 8h. 30m., the mean altitude of the planet being 43°, whilst those for the moon were made at 15h. 26m., the altitude being 30°; the aqueous vapour per cubic foot of air, during the exposures, was found to be 1·25 grains.

THE DISPERSION OF LIGHT IN INTERSTELLAR SPACE.—In No. 6 (February 10, p. 266) of the *Comptes rendus* Dr. C. Nordmann described a method whereby the dispersion of light in interstellar space might possibly be determined. Briefly, the method consists in making photometric observations of quickly changing variable stars, the light of the star being first passed through different coloured screens for each observation. If all radiations traverse space with equal velocities, such observations should give light-curves agreeing in phase among themselves and with those determined in the ordinary method; but if some radiations are relatively retarded, then the light-curves so determined should exhibit marked deviations of phase. Three liquid screens transmitting only radiations of $\lambda\lambda = 5900$ to the extreme red, 5900 to 4900 and 4900 to the ultra-violet, respectively, were prepared, and Dr. Nordmann's preliminary results are published in No. 8 (February 24, p. 383) of the *Comptes rendus*.

Algol and λ Tauri were the stars examined, and in both cases it was found that, whilst the light-curves obtained when the several screens were successively employed agree in amplitude and form with the ordinary light-curves, there is a measurable difference in the epoch of any specific phase. With Algol the difference in time for the red and blue screens amounted to sixteen minutes, whilst for the red and green screens the difference was nine minutes; these preliminary values are probably correct to within about three minutes. The difference between red and blue for λ Tauri was about forty to sixty minutes, *i.e.* approximately three times the analogous difference in the case of Algol; that is to say, the parallax of λ Tauri is, presumably, about one-third that of Algol. Combining these results with Pritchard's value for the parallax of Algol, 0″·0556, it follows, assuming space to be homogeneous, that the difference between the velocities of the extreme ends of the visible spectrum amounts to something of the order of 150m. per second.

Dr. Nordmann points out that this method of investigation offers great possibilities in several lines of research, among which the determination of the parallaxes of variable stars and the gauging of space for dark absorbing material would not be the least interesting from a cosmological point of view.

THE MOVING OBJECT NEAR JUPITER.—Some revised Greenwich positions for the suspected new Jovian satellite are given in No. 4239 of the *Astronomische Nachrichten* (p. 235). This object was observed by Prof. Albrecht at the Lick Observatory on March 8, and its visual magnitude was recorded by Prof. Aitken as 15·0.

DISTRIBUTION OF STANDARD TIME IN EGYPT.—The February number of the Cairo Scientific Journal (vol. ii., No. 17, p. 50) contains a very interesting account, by Captain H. G. Lyons, of the methods of determining and distributing standard civil time in Egypt. The standard now used is the East Europe Time of the thirtieth meridian E. of Greenwich, and Captain Lyons's history of the long sequence of events which led to its adoption is of great interest. The organisation for the distribution appears now to be efficient, and is described and illustrated in the article under notice.

OBSERVATIONS OF ALGOL VARIABLES.—The results of a systematic investigation of the light-changes of ten Algol variables are published by Dr. K. Graff in No. 11 of the *Mitteilungen der Hamburger Sternwarte*. The observations were made during the years 1905, 1906, and 1907, and Dr. Graff, in addition to giving the observational and derived values and the method of reduction, gives charts of the regions surrounding the variables, and a light-curve for each. The stars observed were W Delphini, SW, SY, UW, VW, and WW Cygni, U Sagittæ, Z Persei, Z Draconis, and RW Tauri.

NEBULÆ AND NEBULOSITIES OBSERVED BY PROF. BARNARD. —The purity of the atmosphere at the Mount Wilson Observatory is once more emphasised by some results described by Prof. Barnard in No. 4239 of the *Astronomische Nachrichten* (p. 231, March 17). Nebulosities suspected on earlier photographs are shown unmistakably on those taken during Prof. Barnard's sojourn at Mount Wilson; considerable extensions are shown on others. Messier 8, 16, 17, and 20 are amongst those now described, and in the case of the last-named, the Trifid nebula, extensions appear which have not been seen before by Prof. Barnard; the greatest diameter is 36′ long, in a S.E. and N.W. direction, and the numerous black lanes, which have made this nebula celebrated, are beautifully shown.

RUSSIAN SCIENTIFIC PUBLICATIONS.

In the Journal of the Imperial Russian Geographical Society, vol. xlii., parts ii. and iii., Mr. V. U. Grigorieff writes on the agricultural position of the natives of the Minusin country, Yenisei government. The author carefully examines the economic and legal relations of Russian colonists and aborigines, and considers that agricultural prospects are good, but would be improved by the introduction of scientific methods. The Tartar natives of Minusin have changed but little during centuries of intercourse with Russians, and this persistence of racial characteristics and habits contradicts the opinion of some investigators that the natives will disappear unless Russified. It is interesting to note that cattle-rearing is carried on best on the borders of steppe and forest land, and is not so satisfactory if conducted exclusively in the steppe or the forest.

Mr. A. V. Koltshak describes the last expedition in search of Baron Toll to Bennett Island, which was fitted out by the Academy of Sciences. The Baron left the vessel *Dawn* in May, 1902, with the intention of exploring the island. The search expedition came across some notes by the Baron, indicating the date of his departure for the south. Thorough search failed to reveal fresh traces, and there appears to be no doubt that the names of Baron Toll and his party have to be added to the long roll of explorers who, since Sir John Franklin, have perished in Arctic regions in the cause of science. Mr. K. N. Tultshinsky writes on a commercial journey to Bering Straits, during which he witnessed mining operations in Alaska. Statistics of means of communication in Russia are contributed by Mr. I. F. Borkovsky.

The various Tartar tribes along the Volga and the conditions of their education have been studied by Mme. S. V. Tshitsherin, who worked among them during the famine of 1899. She describes the "Ilminsky" system of education, the work of an enlightened, patriotic Russian and Slavophil, N. I. Ilminsky, who spent many years among the heathen tribes, winning their love and esteem by sympathy and knowledge of their languages and conditions, and will be remembered for his philanthropic efforts to introduce Russian civilisation. Statistics of population and interesting illustrations accompany this article.

An important contribution, by Mr. A. I. Voieikoff, bears the comprehensive title of "Distribution of Populations of the Earth in Dependence upon Natural Conditions and the Activity of Man," with numerous statistics and charts. It is tempting to dwell on Mr. Voieikoff's facts and figures at great length. In Siberia, Turkestan, and the Caucasus there are opportunities and land enough to sustain millions if the necessary knowledge and capital were applied. Of countries of which details of population are published, New Zealand possesses the smallest mortality, and this may be accounted for by its agricultural people living in plenty, the small number of children, and the fact that the mothers do not labour in the field; but New Zealand is still in its immigration stage, and there are few old men as compared with Ontario and Australia, where the process of colonisation began earlier. Paucity of births in Australia is a serious question. Such hindrances to population as plagues, artificial feeding of infants, and alcoholism are discussed, and two conclusions arrived at are worth noting:—(1) degeneration undoubtedly exists among the more cultured classes of the Russian nation and in the manufacturing population; (2) alcoholism is less prevalent among the Russian people than among other nations of Europe and their colonies. Alcoholism, *i.e.* chronic poisoning by alcohol through daily—though moderate—use of *vodka* or beer, must be distinguished from drunkenness. Scarcely a question is left untouched, and the author's studies range over ancient and modern history, medical and registrars' reports, and the trade statistics of many countries.

Vol. xxxvi., part ii., of the Proceedings of the Imperial Society of Naturalists of St. Petersburg contains a vast amount of important and interesting material. Prof. N. E. Wedensky contributes an obituary notice, with a portrait and account of the work, of Prof. I. M. Setchenoff, an eminent physiologist, pupil of Du Bois Reymond, Funke, Ludwig, and Helmholtz, founder and teacher in the Russian physiological school, and a leading authority on the brain and nerves. With the death of this man of science Russia lost a distinguished son. A list of his writings on medical and chemical subjects follows. An exhaustive study of fresh-water Rhizopoda is given by Mr. S. Averintseff, who begins with the physical properties of protoplasm and passes to the structure of shells. A bibliography, lists of species, and handsome plates are given. The first section is taken up with the general morphology and physiology of Rhizopoda, the second is devoted to *R. testacea*, and a further part on *R. nuda* is promised.

The rest of the volume is occupied with papers on the study of nerves. Mr. W. K. Denemark examines and describes the excitability and conductibility of nerves exposed to the action of distilled water. This influence, due to the extraction of salts, produces in nerves the successive functional alterations observed under the influence of positive agents—narcotics, salt solutions, high temperature, &c. Restitution is only effected by the application of sodium salts. The author considers that the presence of sodium salts in the chemical structure of a nerve is absolutely essential for its functions. The effects of a constant current on a nerve which has been subjected to the action of narcotics are described by Mr. N. N. Malisheff. Mr. G. Levitsheff details the action of halogen acids on nerves, and Mme. H. N. Gulinoff the influence of freezing. Prof. N. E. Wedensky contributes a lengthy paper on the effects of strychnine intoxication on the reflex system.

In No. 17 of the Proceedings of the Zoological and Zootomical Cabinets of St. Petersburg University, Mr. V. Zhuk writes on the lamprey, describing external marks, the organs, skin, skeleton, and muscles, with illustrations. An extensive bibliography of Cyclostomi follows. Studies in the anatomy of Piscicola are furnished by Mr. V. D. Zelensky, with a German *résumé*. *P. geometra* is the only species found in European fresh waters. Mr. Zelensky treats (1) metamerism with reference to the nervous system, and (2) the vessel system. A short bibliography follows. Mr. V. M. Shimkevitsh, one of the editors, writes on the correlations of Bilateria and Radiata. In conclusion, he remarks that, speaking generally, the principle of gradual displacement of one source of origin by a neighbouring one, sometimes even developed from another embryonic layer, has had far greater application in embryology than is usually considered. This principle enables a comparison between organs not at all homologous in origin to be established.

In the Proceedings of the Imperial Society of Naturalists, vol. xxxiv., part v., Mr. K. D. Glinka records extensive observations with regard to weathering. Observations of this nature, he points out, should not be confined to the surface of soils, but should embrace lower strata. An alumino-silicate dissolved in water may, in favourable circumstances, give rise to a series of new combinations, *e.g.* zeolites. Analysis of a fresh piece of rock shows that out of 1 per cent. of alumina, 0·72 per cent. is lost in solution. This high solution indicates that a considerable portion of alumina in sandstone does not exist in the form of primary silicates, but in a free form. The author discusses the genesis of the mineral serizite, first discovered in the Taunus range, and taken for talc, to which it bears external resemblance. Numerous tables of analyses are furnished. Taking widely separate districts in Russia, Mr. Glinka describes weathering of biotites, augites, zeolites, &c., at considerable length. There is a short report by Prof. P. A. Zemiatchensky on the rate of weathering of sand and limestone formations, with hints as to calculation of their antiquity. Mr. V. Lehmann sends a contribution, with a plate, on Terebratulacea in layers with *Virgatites virgatus* and *Oxynoticeras catenulatus*. The attention of palæontologists has been directed chiefly to the study of ammonites, and it is important to examine other forms. The author corrects the hitherto accepted list.

The Bulletin of the Imperial Academy of Sciences is worthy of comparison with the highest publications of this nature. We have received three handsome volumes, containing the proceedings of the physico-mathematical section. In vol. xxii., Mr. T. Wyragevitch writes on the Actinia of the Black Sea in the neighbourhood of Balaclava, and Mr. A. Borissiak contributes notes on

Black Sea plankton. Astronomers will be interested in the calculations of Mr. G. A. Tikhoff with regard to the position of stars. Of wide general interest is the article by Mr. K. N. Davidoff on the islands of the Indo-Australian archipelago. The fusion of Europeans and Malays in Amboina has produced a curious type, and the Malay tongue is mingled with Dutch and Portuguese words. According to a horrid custom, a would-be bridegroom cannot be accepted until he makes the maiden an offering of the head of an enemy. Mr. A. Birula writes on the Solifugæ of Persia, with frequent references to Mr. R. Pocock's notes on this order. In vol. xxiii., the eminent naturalist Mr. V. Bianchi describes Passeriformes and Palæarctic larks (Alaudidæ), basing his observations on collections in the museums of London, Tring, and Paris. He expresses indebtedness to Dr. Bowdler Sharpe, the Hon. W. Rothschild, and other naturalists for help.

Mr. N. Donitch contributes reports of observations of the annular solar eclipse of March, 1904, made at Cambodia, and of the total solar eclipse of August, 1905. In the latter case, observations were made at Alcala and Assouan, and Mr. Donitch acknowledges indebtedness for assistance from members of the British Survey Department in Egypt. Notes of inundations at St. Petersburg are furnished by Mr. S. Griboyedoff, and lengthy studies of rainfall in the capital, with diagrams and tables, are given by Mr. E. Rosenthal. Mr. A. Belopolsky's investigations of the radial velocity of the variable star Algol appear in vol. xxiv., and there is another astronomical paper, by Mme. Zhilov, on the proximate absolute orbit of the minor planet Doris. Mr. V. Bianchi describes a new species of pheasant from the mountain regions of western China. Balloon experiments at Kutshino are described by Mr. V. Kuznetsoff. From fossils collected by the polar expedition of Baron Toll, 1900–3, Mme. M. Pavloff is able to draw deductions as to the changes of climate of east Siberia from the Tertiary period. Several papers on aërial mechanics are by Mr. D. P. Riabushinsky, and Mr. M. Golenkin writes on a botanical visit to Java. The report of the geological museum of Peter the Great (Academy of Sciences) concludes the volume.

THE CORALS OF HAWAII.[1]

THE madreporarian corals present some of the most difficult problems in the matter of the determination of species that are to be found in the whole range of the animal kingdom. So difficult are these problems that Mr. Bernard in his indefatigable labour on the catalogue of the Madreporaria of the British Museum frankly gave them up, and, abandoning the time-honoured binomial system, adopted a new numerico-geographical system of nomenclature.

The difficulty arises from our want of knowledge of the influence played by environmental conditions in the formation of the characters that are presented by a colony of coral polyps and the skeletal structures to which they give rise. In the absence of any direct experimental evidence, upon which alone the problems can be solved, it has been the custom to give specific names to groups of specimens which seem to be separated from other and similar groups of specimens by appreciable differences in the sum total of their characters. The species that are thus constituted inevitably break down if new specimens are found that are intermediate in character between the specific groups already determined, but when they are based on the examination of a very large number of specimens collected from a restricted area, they have at least the advantage of serving a useful purpose for the systematist for a considerable period of time.

It is this system which Mr. Vaughan has adopted in the very handsome memoir of 415 pages, and illustrated by ninety-six plates, which appears under the modest title of "Bulletin 59 of the Publications of the United States National Museum." The author has given himself the task of examining a very large number of specimens from the Hawaiian Islands and the island of Laysan, of forming a conclusion as to the most convenient limits for the specific groups, and of giving an opinion on the species problem based on his extensive knowledge and experience of these corals. The result is a work which cannot fail to be of essential importance to all those who are interested in the Madreporaria, and a most noteworthy addition to human knowledge.

But in spite of its undoubted value, and in spite of the great skill and labour that have been spent in its compilation, there are some points in this memoir on which it is necessary to offer a few words of criticism, not in any unfriendly spirit, but in the hope that they may influence in some way those who follow in the author's footsteps and attempt to write a memoir of a similar kind.

Our knowledge of the anatomy of the coral polyps themselves, as distinct from the skeletal structures they form, is admittedly imperfect, but the researches of Moseley, Bourne, Fowler, Duerden and others have at least thrown some light on the relations of the genera and on those characters of the species that are comparatively free from environmental variation. Such evidence as these researches afford must be taken into consideration in any satisfactory scheme of classification, and must be used, so far as it is possible to use it, in conjunction with the evidence derived from the structure of the skeletal characters.

In the light of this evidence, for example, the division of the order into the old suborders Imperforata and Perforata breaks down. The perforate Eupsammiidæ are not related to the Madreporidæ and Poritidæ so closely as to justify their inclusion in the same suborder, whereas the imperforate Pocilloporidæ are not related to the Oculinidæ and Stylophoridæ with which they were formerly associated, but exhibit much closer affinities with some of the Imperforata. It may be true, as Mr. Vaughan remarks, that there is at present no satisfactory classification of the Madreporaria. It may be that for many years to come no classification will be suggested that will be satisfactory to all students of the group. But there is no reason whatever for ignoring the valuable researches of Duerden, and for retaining a classification that is altogether antiquated and misleading, such as the one that is used in this memoir.

It is clear that until we have obtained far more information than we have at present concerning the structure of the soft parts of the coral anatomy, the skeletal characters must play the most important part in the determination of species, but in such a determination every character that the hard parts exhibit must receive its due recognition. For example, it is well known that some genera, and perhaps some species, are more liable than others to be influenced by the presence of epizoic crustacea, worms, and other animals, and no description of a series of specimens is satisfactory if this influence is altogether ignored. The genus Pocillopora is one of those that is particularly liable to the attacks of the crab Hapalocarcinus, and in a note by Prof. Verrill that is quoted by the author (p. 88), the statement is made that the species of this genus in the Hawaiian Islands are usually subject to the malformations caused by this epizoite. But in the descriptions of the species of this genus the author makes no reference to the crab galls, nor are they clearly shown in any of the photographs that are given to illustrate the text. This is a serious oversight, for when the memoir is used for the purpose of the identification of the species of Pocillopora, the galls will at once present a difficulty which the museum curator will not be able to solve by its help. He will ask how far he is able to neglect the presence of these galls, or in what respect they are the determining cause of the general form of growth upon which the species and varieties are founded.

An interesting form described in the volume is *Leptoseris tubulifera*, which differs from the other species of the genus in showing a number of hollow, tubular cavities around which the corallum is folded. Similar tubes are found in the alcyonarian genus Solenocaulon, in the stylasterine genus Errina, and in the madreporarian genera Neohelia, Amphihelia, &c., and in all these cases there seems to be little doubt that they are due to the influence on growth of epizoic crustacea or worms. It is difficult to believe that this is not also the case in *Leptoseris tubulifera*, and if it is the specific distinction from *L. hawaiiensis* is not very clear.

[1] "Recent Madreporaria of the Hawaiian Islands and Laysan." By T. Wayland Vaughan. Pp. ix+427; illustrated. (Washington: Government Printing Office, 1907.)

Finally, objection must be taken to the proposal to substitute the generic name Acropora for the well-known and widely distributed coral that is usually called Madrepora, a proposal originally due to Verrill, but one which cannot be accepted. The name Madrepora has been used for this genus since the time of Lamarck (1801), and has become definitely established by use in all the principal memoirs on the subject and in the museums of the world. To change it now can lead to no useful purpose, and can but produce a perfectly unnecessary confusion; and the confusion will be all the worse confounded if, as is proposed, the generic name be transferred to the equally well-known imperforate coral Oculina.

It may be true that if we are entirely to conform to the so-called rules of nomenclature the change is justified, but these rules were drawn up, not for the confusion of science, but for its convenience and for the sake of simplicity; and when it is found, as in this case, that they are likely to produce just the opposite effect from that for which they were intended they must either be amended or broken. This is by no means an isolated case, for it has been proposed on the same plea that we should use the name Polypus for the common octopus, Astacus for the lobster, Potamobius for the fresh-water crayfish, and that many other changes of a similar kind should be introduced. It has been found in practice, not only inconvenient, but practically impossible, to make these changes, and the customary names are still used. So it will be with the name Madrepora. We may argue and plead as we like for the change, but custom is too strong for us, and the proposal will not be accepted. The time has come when the committee of the International Congress of Zoology should reconsider seriously the question of the maintenance of the names of well-known or widely distributed genera, and endeavour thereby to prevent the confusion with which the strict adherence to Linnean nomenclature threatens us.

S. J. Hickson.

COMMEMORATIVE DINNER TO SIR WILLIAM RAMSAY, K.C.B., F.R.S.

In commemoration of the twenty-first anniversary of Sir William Ramsay's election to the chair of chemistry in University College, London, the professors of the college entertained him to dinner on March 18. The Provost, Dr. T. Gregory Foster, was in the chair, and covers were laid for eighty persons. The guests included Lord Rayleigh, Lord Reay, Sir Norman Lockyer, Sir Alexander Kennedy, the Master of the Temple, the Masters of the Worshipful Companies of Drapers, Mercers, and Carpenters, the president of the Society of Chemical Industry, the Clerk of the Fishmongers' Company, Prof. H. B. Dixon, Prof. A. Smithells, Prof. J. M. Thomson, Prof. Meldola, Mr T. Harrison Townsend, Mr. Henry Higgs, Mr. M. Carteighe, Dr. E. M. Borrago, Dr. F. Clowes, and Colonel Wolseley Cox.

After the toast to the King had been drunk with due honour, the chairman explained that the dinner was, in the first place, the means of expressing the personal affection and admiration of his colleagues for Sir William Ramsay. Leaving it to others to tell what Sir William's contributions to science had been, the chairman referred to the services he had rendered to the college and to London by establishing a great school of chemistry, and also to his perseverance and tact in questions relating to the re-organisation of the University of London. He had never been weary of expressing the great principles of the true relation of examinations to teaching in the University, and of emphasising the view so strongly held by him that in all university examinations the candidates' teachers should of necessity have a share.

Lord Rayleigh then proposed the health of Sir William Ramsay. He told how, twenty-one years ago, when he was secretary of the Royal Society, papers from Ramsay passed in rapid succession through his hands. Many of the older members, perhaps because they were old, hardly approved of his new methods; but, fortunately, these papers were accepted. Proceeding, he reminded the company of the work which Sir William had done in investigating the gases of the atmosphere, of the never failing energy which led him to new discoveries.

Prof. Dixon seconded the toast, and in doing so attempted to take the view of a later generation in looking back on Sir William Ramsay's work. Having briefly summarised that work as a contribution to the developments of chemistry, he concluded by comparing his activity to that of radium itself.

The toast having been enthusiastically drunk, Sir William Ramsay replied. After thanking his colleagues for their invariable kindness and helpfulness, and his assistants and students for their loyalty and devotion to their work, he emphasised the debt that he owed to them in whatever he had accomplished, and went on to explain how he had received the first suggestion which led to the discovery of argon, and how generously Lord Rayleigh had allowed him to follow out that suggestion. He dwelt, further, on the questions raised by the chairman in connection with university organisation, and expressed the hope that the University of London would even more fully than it had at present develop the principles to which reference had been made.

At a later stage in the evening, in reply to an inquiry from one of the guests as to when a new laboratory would be built for Sir William, the chairman stated that, though they have the ground and the plans, they have not yet obtained the money for buildings.

Prof. Ker then proposed the health of the other guests, and Lord Reay replied. In view of his close connection with the college as president and chairman, his lordship said that he could hardly consider himself a guest within the college walls, but he thanked the professors for having done him the honour to invite him to commemorate with them Sir William Ramsay's twenty-first anniversary. He proceeded to tell of the great work which Sir William had done in advising Mr. Tata about the organisation of the new institute that he had founded in India, and how Sir William's influence was likely to be extended through the fact that one of his pupils, Dr. Morris Travers, was holding the position of head of that institution. Referring to the need of new laboratories for the chemical department, and the inconvenient accommodation now provided for Sir William Ramsay, Lord Reay hoped that just as at Essen the little cottage had been preserved from which the great Krupp gun factory was developed, so that when the new laboratories were built, which his lordship hoped would be soon, the room in which Sir William Ramsay's discoveries had been made should be also preserved.

Expressions of regret for absence were received from the Chancellor of the University (Lord Rosebery), from the Principal (Sir Arthur Rücker), from Profs. Tilden, Crum Brown, and many others.

NEW SLIDE-RULES.

Messrs. J. J. Griffin and Sons, Ltd., of Kingsway, London, have sent examples of two slide-rules which they are introducing at a very low price—the longer one, which is 25 cm. in length, at 2*s.*, and the shorter, which is 12·5 cm. in length, at 1*s.* These rules with their slides are made of card, and the divisions are printed. In point of clearness and accuracy they are nearly equal to the best rules divided on celluloid, and they are vastly superior to the old-fashioned box-wood rules of thirty or forty years ago. In each case the upper lines of the slide and of the rule go from 1 to 10 twice over or from 1 to 100, being what are called "A" and "B" lines, while the lower lines of the slide and of the rule are on twice the scale, being "D" lines. Each is provided with a cursor with chisel pointers both to right and left. The back of the slide and all the remaining spaces on the rule are left plain. The accuracy of the surfaces of juxtaposition is specially noteworthy, and is greatly in excess of what is generally associated with card structures. Each is provided with a paper imitation-leather case. With rules such as these, the real utility of the slide-rule may, it is hoped, be brought home to thousands to whom the expense of the now nearly universal celluloid rule is prohibitive; it may even be hoped that some daring mathematical master in a public school may see fit to inculcate the wholesome practice of making calculations not vastly more accurate than any possible knowledge of the data can be, and use rules such as these both to exemplify the idea and to let schoolboys know how the daily arithmetic of the laboratory and of the workshop is carried out. Masters should also find them useful for curve tracing on squared paper, as the coordinates of any parabola or rectangular hyperbola, or of any curve representing the law of inverse squares, can be read off from the rule with a single setting of the slide.

With such inexpensive slide-rules it is to be hoped that the makers will in time provide two spare slides at a slight additional cost. For instance, one should be divided so as to give sines and tangents; the second should have a scale of equal parts to give logarithms and a log log or P line for exponential calculations. They might also with advantage print on the back of the rule constants that are frequently required, but at no extra cost.

With such extra slides the master would be able to illustrate further curve tracing, and the line of sines would be specially useful in the optical class for reading off angles of incidence and of refraction with any refractive index, or for showing the necessity of total internal reflection when the scale of sines stops short of the number representing the refractive index. He would also find it useful in solving triangles.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Dr. G. H. F. Nuttall, F.R.S., Quick professor of biology and fellow of Christ's College, Cambridge, has been elected to a professorial fellowship at Magdalene College.

MANCHESTER.—By the will of Mr. G. Harrison, who died on January 21, 10,000*l.* is bequeathed to Owens College for scholarships or fellowships, or such similar purposes as the council of the college may direct, subject to the words "George Harrison" being always associated with the objects provided for by this bequest.

SIR FREDERICK WILLS has contributed another 5000*l.* to the fund for establishing a university at Bristol. This brings his contribution up to 10,000*l.* At the beginning of this year Mr. H. O. Wills promised 100,000*l.* toward the endowment of the university provided a charter be granted within two years.

THE University of London Union Society appears to have made good progress since its formation in July, 1906. The annual report for 1906–7 shows that at the end of the session there were 377 members, 180 of whom were graduates. Monthly meetings for discussion were held during the Lent and Easter terms of 1907, and, in addition, friendly relations have been established with the Students' Representative Council, the University Athletic Union, and the University Musical Society. The new union is modelled on the lines of those existing at Oxford and Cambridge, and deserves the support especially of the students of London colleges affiliated to the University. Intending members should apply to the secretary, Mr. D. W. H. Bell, 20 Maxey Road, Plumstead.

A BILL to establish compulsory continuation schools in England and Wales, and to amend the Education Acts of 1870 and 1902 in respect of the age of compulsory school attendance, was introduced in the House of Commons on Tuesday by Mr. Chiozza-Money, and read a first time. In introducing the Bill, Mr. Chiozza-Money said that according to the last census there were in England and Wales 5,000,000 youths of both sexes between the ages of fifteen and twenty-one, and of these not more than 400,000 were receiving any measure of systematic training. This does not include the children of the upper and middle classes, but if 400,000 be added the extraordinary conclusion is arrived at that out of 5,000,000 young people between fifteen and twenty-one years of age only 800,000 continue training after leaving the elementary schools. The practical result is that untrained boys and girls drift into the ranks of the incompetent, the unskilled, and the unemployed. The Bill abolishes all partial or total exemptions of boys and girls under fourteen years of age. It abolishes half-timers, making fourteen years the lowest age at which a boy or girl might leave an elementary school. A continuation scholar is defined as a boy between the ages of fourteen and seventeen, and a girl between the ages of fourteen and sixteen. The Bill makes it the duty of the education authority to establish continuation schools, with technical classes, and the attendance of continuation scholars is made compulsory on the parent and the employer. The hours of attendance would be six per week, spread over one, two, or three days. The cost of carrying out the provisions of the Bill would be defrayed out of money voted by Parliament.

ABOUT a year ago the Board of Education requested its Consultative Committee to consider and advise the Board what methods are desirable and possible, under existing legislation, for securing greater local interest in the administration of elementary education in administrative counties by some form of devolution or delegation of certain powers and duties of the local authority to district or other strictly local committees. The committee has reported to the Board, and the report has been published (Cd. 3952). A prefatory memorandum states that the findings of the committee are under the consideration of the Board, and that the report has been published to provide information in view of the discussion arising out of the Bill recently introduced in the House of Commons to secure compulsory devolution. The Consultative Committee has arrived at certain general conclusions which should prove of value in assisting intelligent action. Every education committee, it is suggested, should, so far as existing powers go, secure as managers of schools the services of persons familiar with the educational needs of the locality and likely to be regarded with confidence and sympathy by parents, teachers, and the education authority. At the same time, there are certain duties requiring a wide outlook and broad educational experience which, the committee thinks, should be reserved by the authority itself. A certain number of counties exist which might with advantage create some form of local subcommittees and delegate to them duties appropriate to their needs and circumstances. It is very important to notice that the Consultative Committee states that it would be difficult, if not impossible, to devise any uniform system which would give general satisfaction throughout the country. It would be fatal to efficiency if a parochial spirit became predominant in the administration of education. It is desirable by all means to encourage an interest in educational matters in all districts by every legitimate means, but every step must be taken to ensure that the supply of efficient education in every locality is a national matter which must not be left at the mercies of local prejudices.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 5, 1907.—"Localisation of Function in the Lemur's Brain." By Dr. F. W. **Mott**, F.R.S., and Prof. W. D. **Halliburton**, F.R.S.

The brain of the lemur, the lowest of the ape-like animals, does not appear to have been subjected previously to a thorough examination. Page May and Elliott Smith brought a brief communication on the subject before the Cambridge meeting of the British Association in 1904. Their experiments were apparently limited to stimulation of the cerebral cortex, and they have never published a full account of their work. Brodmann has worked out some of the histological details of the structure of the cortex cerebri, and Max Volsch has performed a stimulation experiment upon one lemur. The work of these investigators will be referred to again in the course of this paper.

(1) The brain of the lemur has a simple convolutional pattern, and the fissures are few and for the most part shallow.

(2) The motor areas are limited to the central region of the cortex.

(3) Extirpation of the excitable areas is followed by transitory paralysis of the corresponding regions on the opposite side of the body, and by degeneration of the tracts which pass to the bulbar or spinal grey matter which controls these movements. Degeneration also occurs in commisural (callosal) and association tracts in the cerebrum.

(4) The motor areas are characterised histologically by the presence of Betz cells. Localisation by histological study is therefore possible, and there is a close correspondence of the results so obtained with those obtained experimentally.

(5) There are, however, two types of motor cortex in the lemur's brain. The large type of Betz cell is found in the greater part of the motor cortex, particularly where limb and body movements are represented. The smaller type of Betz cell is found in the area governing face, tongue, ear, and eye movements, and in this excitable region there is a layer of granules; it is therefore probably sensorimotor.

(6) Although the investigation relates in the main to motor representation, histological examination of the occipital (and especially calcarine) region shows it to possess the structural characters of the visual cortex in other animals. That no eye movements could be elicited by faradic stimulation of this region is probably due to the difficulty of the experiment, as explained in the text.

February 13.—"On the Determination of Viscosity at High Temperatures." By Dr. C. E. **Fawsitt.** Communicated by Prof. Andrew Gray, F.R.S.

Measurements of viscosity at temperatures higher than 300° C. to 400° C. present considerable difficulties, and until the present year this subject has not been touched by experimenters.

The present communication contains a description of the method used. The method is suitable for the measurement of the viscosity of liquids which are not very viscous —not more than, say, fifty times as viscous as water—and is especially designed for the determination of the viscosity of molten metals and salts. The determination of the viscosity of salts up to 1200° C., or even higher, can be quite satisfactorily carried out by this method. Determinations of the viscosity of metals are much more difficult, owing to the impossibility of preventing a certain amount of surface oxidation. The smallest trace of surface oxidation will completely spoil a series of observations, and the prevention of oxidation is really the chief difficulty in such determinations.

The method used is based on the method originally given by Coulomb, the modifications introduced being due to the special nature of the determinations. In Coulomb's method a horizontal disc is allowed to execute horizontal vibrations about a vertical suspending wire attached to its centre. The viscosity of the liquid can be calculated from the rate of decay of amplitude.

In making a series of observations with this apparatus, the disc is allowed to sink about half an inch below the surface of the liquid. The amplitude of the oscillations is indicated by a pointer (wire) at right angles to the top of the iron rod which carries the disc, and the pointer moves above a circular scale divided into degrees.

With this apparatus, the determination of the viscosity of a liquid is accurate to within 5 per cent. of the absolute value, unless there are special circumstances, as in the case of molten metals, when the results are apt to come out considerably too high.

The results obtained show the availability of this method for the determination of viscosity up to the highest temperature at which a platinum capillary has been used.

Chemical Society, March 5.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—The solubility of iodine in water: H. **Hartley** and N. P. **Campbell.** The solubility of iodine in water has been determined at 18°, 25°, 35°, 45°, and 55°, and the heat of solution has been calculated from the temperature coefficient of the solubility.—Nitro-derivatives of *o*-xylene (preliminary note): A. W. **Crossley** and Miss N. **Renouf.** *o*-Xylene yields two trinitro-derivatives, the one melting at 71° and the other at 115° (compare Noelting and Thesmar, *Ber.*, 1902, xxxv., 634). A new dinitro-*o*-xylene melting at 82° has also been isolated, and a substance melting at 115° which is a dinitro-derivative of some condensed benzene ring derivative.—Substituted dihydrobenzenes, part ii., 1 : 1-dimethyl-$\Delta^{2:4}$-dihydrobenzene and 1 : 1-dimethyl-$\Delta^{2:5}$-dihydrobenzene: A. W. **Crossley** and Miss N. **Renouf.** Dimethyldihydrobenzene prepared by the elimination of 2HBr from 3 : 5-dibromo-1 : 1-dimethylhexahydrobenzene has been proved to consist of a mixture in approximately equal parts of these two hydrocarbons, thus refuting the adverse criticisms of Harries and Antoni (*Annalen*, 1903, cccxxviii., 66) on the work published by Crossley and Le Sueur (Trans., 1902, lxxxi., 821).—The viscosity of aqueous pyridine solutions: A. E. **Dunstan** and F. B. T. **Thole.** The authors have repeated their experiments on the viscosity of aqueous pyridine solutions, and find that the same discontinuities occur in the curve as were previously observed (compare Hartley and others, Proc., 1908, xxiv., 22).—The action of thionyl chloride on the methylene ethers of catechol derivatives, ii., piperonyloin, piperil, and hydropiperin: G. **Barger** and A. J. **Ewins.**—Traces of a new tin-group element in thorianite: Miss C. de Brereton **Evans.** The dark brown sulphide of the new element separates with arsenious sulphide, from which it differs in being soluble in water, to form a deep brown solution. It yields a hygroscopic brown oxide, which on reduction in hydrogen furnishes a grey metal. Incidentally, proof was obtained of the presence in thorianite of arsenic, mercury, bismuth, molybdenum, and selenium.—The sulphination of phenolic ethers and the influence of substituents: S. **Smiles** and R. **Le Rossignol.** The authors have confirmed the conclusion that the sulphonium base derived from phenetole is produced in three stages, at which the sulphinic acid, sulphoxide, and base are consecutively formed, by isolating the sulphinic acid.—The relation between unsaturation and optical activity, part ii., alkaloid salts of corresponding saturated or unsaturated acids: T. P. **Hilditch.**—The wandering of bromine in the transformation of nitroaminobromobenzenes: K. J. P. **Orton** and Miss C. **Pearson.**—A new isomeride of vanillin occurring in the root of a species of Chlorocodon, preliminary note: E. **Goulding** and R. G. **Pelly.** The results obtained show that the odorous constituent of Chlorocodon root is a monomethyl ether of a dihydroxybenzaldehyde having an odour intermediate between that of vanillin and piperonal, but which is not identical with vanillin or any of its known isomerides.—The volatile oil of the leaves of *Ocimum viride*, preliminary note: E. **Goulding** and R. G. **Pelly.** The composition of the oil is approximately as follows:—thymol, 32 per cent.; alcohols (calculated as $C_{10}H_{18}O$), 40 per cent.; esters (calculated as $C_{10}H_{17}.OAc$), 2 per cent.; the remainder consists chiefly of a terpene (or possibly a mixture of terpenes), which is a liquid of pleasant lemon-like odour, boiling at 160°–166°.—Experiments on the synthesis of the terpenes, part xii., synthesis of terpins, terpineols, and terpenes derived from the methyl*iso*propyl*cyclo*pentanes, $Me.C_5H_8.CHMe_2$: W. N. **Haworth** and W. H. **Perkin,** jun.—The initial change of the radium emanation: N. V. **Sidgwick** and H. T. **Tizard.**

Geological Society, March 4.—Prof. W. J. Sollas, F.R.S., president, in the chair.—*Metriorhynchus brachyrhynchus*, Deslong., from the Oxford Clay near Peterborough: E. T. **Leeds.** Two skulls have recently been obtained from the Saurian zone of the Lower Oxford Clay, in the neighbourhood of Dogsthorpe, Peterborough. The mandibles were missing. The two specimens have been referred to *Metriorhynchus brachyrhynchus*. This is believed to be the first recorded occurrence of the species in England.—The high-level platforms of Bodmin Moor, and their relation to the deposits of stream-tin and wolfram: G. **Barrow.** In this area there are three platforms:—one, which is marine and of Pliocene age, terminating in a steep slope at 430 feet; a second, at a height of 750 feet, seen about Camelford and at the foot of Delabole Hill; and a third, a little under 1000 feet, first recognised on Davidstow Moor. The superficial deposits which bear tin above the 750-feet platform differ markedly at times from those below it. These deposits are not so concentrated as the stream-sorted material below, but they have been frequently worked in past times. The veins from which the wolfram is derived have been found close to the points where the "wash" is enriched by their denudation. The success of working depends to some extent on the slope of the granite-floor on which the detritus rests. On Bodmin Moor the larger marshes have a floor of kaolinised granite, but there is a difficulty in working it at many points in consequence of the water-logging by peaty water.

Royal Anthropological Institute, March 10.—Prof. W. Ridgeway, president, in the chair.—The origin of the crescent as a Mohammedan badge: Prof. **Ridgeway.** It was demonstrated that the crescent badge had its origin, not in the new moon, as generally supposed, but in the well-known amulet formed of a claw or tusk. These in course of time were placed base to base, with the result that the crescent form arose. The two tushes are joined together by string or by a silver plate, but in later examples the amulet is carved out of one piece of material and all traces of the joint are lost, except that in some cases a panel of ornament survives to mark where the join was originally. Examples were exhibited from Turkey, Greece, Africa, and New Guinea, and Prof. Ridgeway traced the amulet back so far as the date of the sanctuary of Artemis Orthia at Sparta, where an example was discovered in the recent excavations. The crescent seen on modern English horse-trappings was also shown to have originated in this amulet.—Some Megalithic remains in central France: A. L. **Lewis.** The paper dealt principally with monuments in the neighbourhood of Autun, including the dolmen at La Rochefort and the standing stones at St. Pantaléon. With these last the author compared other lines of stones at Carnac, Gezer, Dartmoor, and in the Khasi Hills. He also dealt with the two types of circle in Scotland, and showed that they had each a definite locality, those with recumbent stones being found only around Aberdeen, while those with great chambered cairns in the middle are found round Inverness. He was of the opinion that the two types of circle were contemporary, and that the differences were solely due to local influences.

Physical Society, March 13.—Dr Charles Chree, F.R.S., president, in the chair.—The distribution in electric fields of the active deposits of radium, thorium, and actinium: S. **Russ.** The first experiments were made with the active deposit produced from radium emanation. The amount of active deposit directed to a kathode decreases as the pressure in the vessel is reduced, but after a certain pressure is reached the amount going to an anode shows a corresponding increase under the same conditions. The main feature brought out is that at the lowest pressure reached almost as much activity is obtained on the anode as on the kathode, while at atmospheric pressure the activity of the latter is about twenty times that of the former. Similar experiments conducted in hydrogen, air, and sulphur dioxide indicate that the collisions between the active deposit particles and the gaseous molecules play an important part in the distribution of the active deposit in electric fields. Experiments on similar lines with thorium and actinium show that while at atmospheric pressure nearly the whole of the active deposit particles of thorium are directed to the kathode, this is not necessarily the case with actinium. Other observations indicate that the sign of the electrical charge exhibited by the active deposit particles of actinium is a function of the distance that these particles have travelled through the containing gas before reaching the electrodes.—Note on certain dynamical analogues of temperature equilibrium: Prof. G. H. **Bryan.** Attention is directed to the following results of a method described in 1900 (Archives Néerlandaises) under the title of "Energy Accelerations":—(1) In a system of uniformly distributed particles, a stationary state of statistical equilibrium cannot exist under the Newtonian law of force, whether the forces between the particles be attractive or repulsive, except when the particles are at rest in a state of unstable equilibrium. (2) For energy-equilibrium to exist the force between the particles, if repulsive, must vary according to a higher power of the inverse distance than the square; if attractive, it must vary according to a lower inverse power than the square of the distance. (3) In a system in which the kinetic energy cannot be expressed as a quadratic function of the velocities with constant coefficients, the equations of energy-equilibrium no longer take the form of linear relations between the various components of kinetic energy, so that the commonly assumed analogue between temperature and kinetic energy becomes inapplicable.

CAMBRIDGE.

Philosophical Society, March 9.—Dr. Hobson, president, in the chair.—(1) The formation of lactic acid and carbonic acid during muscular contraction and rigor mortis; (2) the complete hydrolytic decomposition of egg-albumin at 180° C., and on the constitution and synthesis of dead and living albumin: Dr. **Latham.**—(1) The formation of γ-pyrone compounds from acetylenic acids; (2) the action of mustard oils on the ethyl esters of malonic and cyanoacetic acids: S. **Ruhemann.**—The absorption spectra of some compounds obtained from pyridine and collidine: J. E. **Purvis.**—The limitations of the copper-zinc couple method in estimating nitrates: J. E. **Purvis** and R. M. **Courtauld.**—A double sulphate of guanidine and aluminium: F. **Ferraboschi.**—The property of a double-six of lines, and its meaning in hypergeometry: H. W. **Richmond.**—Energy accelerations and partition of energy: C. W. **Follett.**

PARIS.

Academy of Sciences, March 16.—M. H. Becquerel in the chair.—The extension of the theorem of Clausius: E. H. **Amagat.**—The characters of tuberculous infection in their relations with the diagnosis of tuberculosis: S. **Arloing** and L. **Thévenot.** In a *post mortem* examination the absence of macroscopic lesions is no proof of the absence of tuberculous infection, and this is the explanation of the occasional want of agreement between the experimental diagnosis (sero-agglutination or application of tuberculin to the skin or conjunctiva) and the *post mortem* examination.—Report by the committee on the application of the metric system to French coinage. The views of various commissions dealing with this question from the date of the foundation of the metric system are reviewed, and the question of the advisability of introducing a 25-centime piece considered, and reported on unfavourably. To preserve the unity of the metric system the committee conclude that the only coins should be 1, 2, and 5 centimes, 1, 2, and 5 decimes, 1, 2 and 5, 10, 20, 50, and 100 francs, and this view is confirmed by the academy.—The dispersion of light in celestial space. The history of the question and the first results: G. A. **Tikhoff.**—The presence of water vapour in the atmosphere of the planet Mars: P. **Lowell.** Photographic observations made at the Flagstaff Observatory, Arizona, U.S., during January of this year, establish the presence of water vapour in the atmosphere of Mars. The plates used were rendered sensitive to the extreme red rays, and with an exposure of two to three hours were capable of photographing the spectrum in the neighbourhood of the band a, the most intense band due to water vapour. Photographs of the spectrum of Mars clearly show this band a, whilst the spectrum of the moon taken on the same plate shows no trace of this band, thus eliminating the effects of the earth's atmosphere (see NATURE, March 12, and p. 497 of the present number).—The series of Taylorian polynomials: A. **Buhl.**—The general solution of the problem of equilibrium in the theory of elasticity, in the case where the forces are applied at the surface: A. **Korn.**—The electrolysis of solutions of hydrochloric acid: Th. **Guilloz.** In a recent note on this subject M. Doumer, on the basis of his experiments, raises objections to Hittorf's theory of electrolysis. In the present note the author directs attention to recent work by Noyes and Sammet on the mobility of H and Cl ions in dilute solutions of hydrochloric acid, and points out that these researches afford an experimental proof that the disturbances due to the evolution of oxygen during electrolysis are without effect on the transport numbers.—The velocity of evaporation and a method of determining the hygrometric state: P. **Vaillant.** The liquid the evaporation of which is being studied is placed on a balance, and the rate of evaporation deduced from ten oscillations of the beam. The formula $Q=B(F-f)$, where Q is the quantity evaporated in a given time, F the pressure of the saturated vapour, and f the pressure of the water vapour in the atmosphere surrounding the balance, was shown to be valid experimentally. By using pure water and pure sulphuric acid successively the method can be applied to give f, the determination being reduced to two weighings.—The hydrates of arsenic acid: M. **Auger.**—The pseudomorphoses of the microclines in micrograntes from the valley of the Meuse (Ardennes): Jacques **de Lapparent.**—The magmatic parameters of the volcanic series of Anglona and Logudoro (Sardinia): M. **Deprat.**—Asymmetry of the figure and its origin: Richard **Liebreich.** From the examination of several thousand human skulls, dating from prehistoric times to the present day, the author considers that asymmetry is the normal form of the human figure, and is not, as supposed by Lombroso, a sign of degeneration. A simple physiological reason is put forward as the cause of this asymmetry, which is regarded as the necessary result of the erect position of the human species.—The quantity of X-rays absorbed and transmitted by the successive layers of tissues: H. **Guilleminot.**—An attempt at grafting articular tissues: Henri **Judet.**

CALCUTTA.

Asiatic Society of Bengal, March 4.—Certain unpublised drawings of antiquities in Orissa and northern Circars: Manmohan **Chakravarti.** This paper invites attention to the eleven folios of drawings received by the society in December, 1822, and forming a part of the remarkable collection of Lieut.-Colonel Colin Mackenzie. It takes up two of the folios dealing with the antiquities of Orissa and northern Circars; the one of the smaller size (B) has eighty-five originals, while the other of the larger size has two originals and thirty-two duplicates, and gives a brief description of each in the Appendices A and B. They contain interesting drawings of Hindu sculptures, pillars, and other architectural designs, drawn in 1815.—The exact determination of the fastness of the more common indigenous dyes of Bengal, and comparison with typical synthetic dye-stuffs, part ii., dyeing on silk: E. R. **Watson.**—Oil of *Lawsonia alba*: D. **Hooper.**—A general theory of osculating conics: Prof. **Syamadas Mukhopadhyaya.**

DIARY OF SOCIETIES.

THURSDAY, MARCH 26.

ROYAL SOCIETY, at 4.30.—Bakerian Lecture: The Thermal and Electrical Conductivities of Metals and Alloys at Low Temperatures: Prof. C. H. Lees, F.R.S.—Note on the Values of the Board of Trade Standards of Current and Electromotive Force: T. Mather, F.R.S., and F. E. Smith.—Note on the Rise of Meteorological Balloons and the Temperature of the Upper Air: A. Mallock, F.R.S.

ROYAL SOCIETY OF ARTS, at 8.—The Navigation of the Air: Dr. H. S. Hele-Shaw, F.R.S.

ROYAL INSTITUTION, at 3.—Standardisation in Various Aspects: (2) Electrical Engineering: Dr. R. T. Glazebrook, F.R.S.

ELECTRICITY AND MATTER.

The Corpuscular Theory of Matter. By Prof. J. J. Thomson, F.R.S. Pp. vii + 172. (London: Archibald Constable and Co., Ltd., 1907.) Price 7s. 6d. net.

THE present volume is an expansion of six lectures delivered by Prof. J. J. Thomson in his capacity of professor at the Royal Institution. It is a simple and clear account of the development of the corpuscular, or, as some prefer to call it, the electronic, theory of matter to explain the passage of electricity through metals and gases. The last two chapters are devoted to consideration of the properties of model atoms built up of corpuscles, and the evidence in favour of the view that the number of the corpuscles in an atom is about the same as its atomic weight in terms of hydrogen.

The proof of the independent existence in matter of electrons of mass small compared with the atoms has supplied a great stimulus to the attack of that most important problem of physics, the connection between electricity and matter. This attack has been conducted both on experimental and theoretical lines, and while only a beginning has been made, yet the results already obtained have been instrumental in giving a much clearer and deeper insight into the conditions of the problem, and afford considerable justification for the hope of still greater advances in the immediate future. There has been a tendency in some quarters to view with alarm, if not with distrust, the philosophic speculations of the physicist, more particularly when dealing with the question of the constitution of the chemist's atom. It is apparently considered indelicate to pry too deeply into the mysteries of atomic structure, especially if mathematical analysis is the instrument of investigation. This attitude appears somewhat unreasonable to the average physicist, and arises largely from a misunderstanding of the relative place of theory and experiment in physical science. A student of the history of physical science cannot fail to be impressed by the notable part played by mathematical physics in the development of the subject, and there is no obvious reason why the cooperation between the two branches of the subject should not be as fruitful in the future. The physicist from his training is seldom content merely to describe phenomena, but seeks for some form of theory that will serve to give a general explanation of the facts and to show their relation with other branches of the subject. In dealing with such a complicated and intangible problem as the constitution of the atom, it is essential that theory should go hand in hand with experiment, for without some kind of theory the experimenter is in most cases as helpless as a ship without a rudder.

This attitude of the physicist is very well expressed by Prof. J. J. Thomson in the opening chapter. After mentioning the postulates on which the corpuscula theory of matter is based, he proceeds:—

"From the point of view of the physicist, a theory of matter is a policy rather than a creed; its object is to connect or coordinate apparently diverse phenomena, and above all to suggest, stimulate and direct experiment. It ought to furnish a compass which, if followed, will lead the observer further and further into previously unexplored regions. Whether these regions will be barren or fertile experience alone will decide; but at any rate, one who is guided in this way will travel onward in a definite direction, and will not wander aimlessly to and fro."

The working out of the logical consequences of a simple theory and the comparison of the deductions with experiment is eminently scientific, and of great importance to the specialist who is able to form a critical estimate of the adequacy of the theory. The danger of too free a use of hypothesis is not so much for the specialist as for the general reader who, from lack of expert knowledge or of time, is unable to form a critical judgment on the matter. In such a case there is a tendency to assume that a theory which may be admittedly tentative in character represents the final, accepted views on the subject.

Two of the most interesting chapters of the book are devoted to the application of the corpuscular theory to explain the passage of electricity through metals. In one chapter the theory developed is similar in general outlines to that originally advanced by the author and the late Prof. Drude. The corpuscles which are responsible for the passage of electricity through a conductor are supposed to be free from the molecules for a time sufficiently long for them to be in temperature equilibrium with the molecules of the metal. This implies that the corpuscles behave like a gas, and that temperature equilibrium is reached when the mean kinetic energy of the corpuscle has become equal to that of a molecule of a gas at the same temperature. The passage of the current is then supposed to result from the drift of these free charged corpuscles, brought about by the action of the external electric field applied to the conductor. This theory is shown to account in a satisfactory way for the connection between thermal and electric conductivities of metal, and with minor assumptions for the Peltier and Thomson effects. Prof. Thomson points out that this form of theory suffers from one very serious defect. In order to account for the conductivities observed in metals, it is necessary to assume the presence of such a large number of free corpuscles in the metal that the specific heat of these alone, quite independently of the atoms of the metal itself, is about ten times greater than that experimentally observed. The author in the next chapter develops another form of the theory which is free from this objection, and at the same time fits in with the facts to be explained equally well as the first theory. The second method supposes that the corpuscles are not free in the metal except for the time required to pass from one atom to another. They are pulled out of the atoms of the metals by the action of the surrounding matter, and immediately pass into adjacent atoms. This view materially reduces the number of corpuscles required for the transfer of electricity. In both these forms of theory the atoms of the metal itself are supposed immobile, and to play no direct appreciable part in the transfer of the current.

The important question of the type of radiation to be expected from a metal on the above theories is fully considered. Since the corpuscles are suddenly started and stopped, they must radiate energy in the form of thin pulses analogous to the pulses which are supposed to constitute the Röntgen rays. Lorentz has shown that if this radiation be analysed by means of Fourier's series, the amplitude of the long waves agrees closely with that deduced independently of such assumptions by means of the thermodynamical theory. Prof. Thomson, however, points out that the main radiation must consist of short waves analogous to very easily absorbed Röntgen rays. It would be of great interest and importance if the presence of such a type of radiation from metals could be experimentally detected. In another chapter the author explains the construction and properties of his well-known "model" atoms built up of rings of rotating corpuscles. No one can fail to admire the ingenuity displayed in the construction of such atoms, and in showing the remarkable way in which they imitate many of the known properties of the atom. On this hypothesis the properties of the atom are dependent on the number and arrangement of the negative corpuscles. The corresponding positive electricity, which is distributed throughout the volume of a sphere, merely serves as a cement to hold the atom together. This form of atom, while it has many advantages from the point of view of calculation, is somewhat artificial, for it implicitly assumes very peculiar properties for the positive electricity. To say that a positively charged body is one that has lost a negative corpuscle is not an explanation, but begs the question of the nature of positive electricity. The trend of modern views is to diminish in some directions the importance of the negative charge and to emphasise that of the positive. This is borne out by the author's estimates that the number of free corpuscles in an atom is about the same as its atomic weight in terms of hydrogen. Until we have a clearer idea of the nature of positive electricity we cannot hope to form a clear view of the constitution of the atom. The proof of the existence of a positive electron —the counterpart of the negative—if such exists, would be of enormous importance to theory and experiment. The problem of the nature of positive electricity is now very much to the fore, and it is to be hoped that we shall not have to wait too long for a solution.

Like all Prof. Thomson's books, the present volume is lucidly and simply written, while the mathematical analysis required for the development of the consequences of the theory is made as simple as possible. To all those interested in the latest views of the connection between electricity and matter this book will be very welcome. E. R.

CHARTING THE WORLD'S COMMERCE.

Atlas of the World's Commerce. Compiled from the Latest Official Returns at the Edinburgh Geographical Institute, and edited by J. G. Bartholomew. (London: G. Newnes, Ltd.) Twenty-two parts, each *6d.* net.

MR. BARTHOLOMEW is a skilled hand at map-making, and in setting himself to chart the commerce of the world he has undertaken a gigantic task. With the aid of 176 large pages of coloured plates, containing more than 1000 maps and diagrams, he attempts to describe the products, imports, exports, commercial conditions and economic statistics of all the leading countries of the world, and he says quite justly that the successful accomplishment of such a work must throw much needed light on the solution of the great problem of international trade which we in British politics call "the fiscal question." His first object is to show whence we derive our food, drink, clothing, and all that we use in our daily lives. No better text could be chosen for the enlightenment of our politicians, whatever be their fiscal views, and indeed of all who would understand where England really stands in the world of commerce, and what are the essentials of her future as the central force of a great Empire.

The very immensity of Mr. Bartholomew's undertaking tends to lessen its topical value. For instance, the last three years have been momentous in their effect upon the sources of British food supply, and Mr. Bartholomew can be of little help to the man who would understand how far we are dependent upon foreign and how far upon colonial supplies, when he only carries us down to the year 1903. Canada, for instance, figures in Mr. Bartholomew's diagrams as yielding less than 86 million bushels of wheat. The produce of her western section alone was in 1906 considerably in excess of that figure. The fiscal controversy is especially associated with the food production of the newer countries, and the usefulness of Mr. Bartholomew's diagrams, so far as the fiscal controversy is concerned, goes little beyond the course of our dependence upon the older countries, such as the United States, Russia, &c. For his distribution of the chief sources of the British supply of wheat, Mr. Bartholomew brings us no further down than the 1901–3 average, from which we see that the Canadian percentage was 8·4 and the United States percentage 45·5. The limited usefulness of such figures is evident when it is noted that in 1906 the Canadian proportion was at least $12\frac{1}{2}$ per cent. and the United States proportion 37 per cent. There may have been insuperable difficulties in carrying the averages down to a more recent period, but it is obvious that, in the absence of more recent figures, it is necessary to endorse with qualification Mr. Bartholomew's claim that in his new atlas "the whole fiscal question is clearly illustrated."

We may note one other respect in which the topical usefulness of Mr. Bartholomew's investigations is limited, and it is a vital one. In dealing with the import and export trade of the United Kingdom

(p. 33), the imports are lumped together with no allowance for the fact that in some cases large proportions are re-exported, and therefore, except from the point of view of the shipper, the gross totals throw no light on the industry of the country, in fact they can only mislead. The importance of this allowance for re-exports is shown in the textile group. Thus, of the 52,400,000*l.* worth of imports of cotton, no less than 7,000,000*l.* worth was re-exported, and of the wool imports of 26,600,000*l.* no less than 11,200,000*l.* If Mr. Bartholomew had these calculations in mind, he would hardly have ventured upon the conclusion he draws in a note to this diagram in the following words:—

"It is at once evident that articles of food greatly preponderate, the value amounting indeed to 40 per cent. of the total. Raw material accounts for more than 28 per cent., of which $16\frac{1}{2}$ represent textile fibres."

But we would not leave Mr. Bartholomew's atlas without a recognition of the enormous labour it must have involved, and of its successes in several directions. The maps are excellent, and the table of the commodities of commerce and the gazetteer of countries and ports of the world have obvious uses.

MASONRY AND CONCRETE ARCHES.

Symmetrical Masonry Arches. By M. A. Howe. Pp. x+170. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1906.) Price 10*s.* 6*d.* net.

The author's object in this text-book has been to present in a simple and direct form a method which can be employed in the design of masonry arches according to the elastic theory. He points out that since such arches are built of materials and under conditions which are more or less uncertain in character, the use of rigidly accurate formulæ is not necessary.

The first portion of the book consists of two chapters, in which the various formulæ which are required in the design of such arches are deduced, and then several examples are worked out in detail to illustrate the application of the formulæ. Independent formulæ are obtained for the effects of bending, axial thrust, and temperature; these formulæ are then combined, but the author points out that as the effect of axial stress is small, except in very flat arches, it may in general be neglected in obtaining a combined formula. For symmetrical arches fixed at the ends, the following conditions must be satisfied, viz., the central angle and the relative elevations at the supports must each remain unchanged, and the length of span must remain constant; Mr. Howe is therefore able to obtain three equations involving the three unknown quantities—moment, vertical reaction, and horizontal thrust at the supports of the arch. He then proceeds to deal with a number of special cases of loading, and discusses fully the temperature effects; graphical representations are frequently used to show the results obtained by analysis.

The last part of this portion of the book is devoted first to a discussion of the trustworthiness of the elastic theory when applied to ribs composed of natural stone voussoirs, and to plain and reinforced concrete ribs (the author comes to the conclusion that the theory may be used with confidence so long as no tensile stresses occur); and secondly to a collection of empirical formulæ for the thickness of the ring at the crown and at the supports in stone arches, and for the thickness of the abutments. The examples of the applications of the formulæ, which are fully worked out, cover the following cases: (1) An arch for a single-track railway bridge of 60-feet span and a rise of 8 feet, the arch ring to be constructed of granite; (2) an arch with a clear span of 50 feet and a rise of 10 feet, constructed of reinforced concrete (in both cases the maximum stresses produced by dead load, live load, and changes of temperature are computed); (3) the author takes again the data employed in the second example, and gives an ingenious and much shorter method for working out the values of the horizontal reactions and bending moments at different sections of the arch. In the fourth chapter, dimensioned illustrations are given of a few typical arches, and, in the form of an appendix, data have been brought together for 500 arch bridges of masonry, plain concrete, and reinforced concrete. The data in this appendix will be of considerable service to engineers who may be called upon to design arch bridges of one or other of these materials.

OUR BOOK SHELF.

Das Kausalitätsprinzip der Biologie. By Dr. Friedrich Strecker. Pp. viii+153. (Leipzig: W. Engelmann, 1907.) Price 3 marks.

Von Baer said that the chief end of biology was to refer the formative forces of organisms to the general forces and vital directions (Lebensrichtungen) of the Kosmos. According to the mechanists this is rapidly being done; according to the neo-vitalists this is not being done at all, for the characteristic activities of living creatures cannot be described in the formulæ of physicochemical happenings, and there is in the organism an autonomous regulative force or entelechy. Biologists oscillate between these two positions, or dogmatically entrench themselves in either of them, very much as philosophers did in regard to empiricism and rationalism before Kant's critique showed a better way. Dr. Strecker seeks to be a daysman between the two biological schools, laying his hands upon them both, pointing out that there is truth on both sides, but that there is a third outlook which dominates both. For the practical methods and analytic results of the "Entwicklungsmechaniker," such as Roux, the author has an appreciative respect; his criticism is epistemological rather than biological; he does not think that there is any hope of rationally interpreting organisms in mechanistic formulæ. For the neo-vitalists he has also much that is good to say, for they at least do not give a false simplicity to the facts of life; on the other hand, he does not hold with an "entelechy," which seems to be an ingenuous way of bundling all the difficulties into one term, and saying "there's an end of it." The fact is that the mechanists and the vitalists are tarred with the same stick, they are *ekgenetic*, they seek to interpret results which have come to be, instead of concentrating attention on the process of becoming, which is the *engenetic* method. In the inorganic world we have to do with passive *things*, with an externally conditioned series of sequences; in the world of organisms we have to do with *creative agents*, with an internal activity, like that of our own psychical life, with engenetic doings, not with ekgenetic occurrences. The only way to get at the gist of the organism, its internal creativeness, is as we get at our own internal life—engenetically. Man crowns the evolution series, his most distinctive feature is his psychical experience, and it is in the light of this that we must try to read the secret of the dominating, correlating, regulating principle in the life of organisms. This, at least, is what we understand this exceedingly abstract treatise to mean. J. A. T.

Pharmakognostisches Praktikum. By Dr. Ludwig Koch and Dr. Ernst Gilg. Pp. viii+272; illustrated. (Berlin: Gebrüder Borntraeger, 1907.) Price 6.80 marks.

It appears that the recent edition of the German Pharmacopœia has placed additional responsibility upon the German pharmacist, and he is now required to be practically cognisant with the microscopical characteristics of the medicinal plants in their entire as well as in their powdered form. The book before us deals with the above subject, and is intended to be used as a laboratory handbook for pharmaceutical students.

The initial chapter is devoted to the methods of preparing microscopical specimens of the respective plants and their powders, and staining them appropriately. In addition, the adequate magnification for drawing and photographing the respective objects is fully dealt with. The microscopical characteristics of all the official medicinal plants, or rather the parts of them which are official, are fully described, and following upon such description is an account of the microscopical appearance presented by the powdered drug. The order followed in the book corresponds to the part of the plant which is official; for instance, the cortices are all considered together, the rhizomes together, the roots together, and so forth. The whole subject is treated in great detail, and abundant illustrations are scattered through the text of the microscopic appearance of the respective preparations. The volume commences with a table of contents and concludes with a register, from which latter it appears that no fewer than eighty drugs are described.

Die Pendulations-theorie. By Dr. Heinrich Simroth. Pp. xii+564; maps. (Leipzig: K. Grethleius, 1907.) Price 12 marks.

Taking as his basis Dr. Paul Reibisch's "Ein Gestaltungsprinzip der Erde" (1901), supplemented by Mr. D. Kreichgauer's "Die Äquatorfrage in der Geologie" (1902), the author of the curious volume before us discusses the effects which would, in his opinion, be produced on the animal life of the globe by secular changes in the direction of the polar axis. Mr. Kreichgauer, it seems, is of opinion that in the course of geological time the two poles have actually changed places, and also that during such oscillations huge "wobbles" or waves have been produced in the earth's crust in the intervening latitudes. These "wobbles," if we understand him rightly, the author believes have produced marked effects on the distribution of animal life, having, so to speak, "shaken" the various groups into particular positions. The distribution of all the chief groups is discussed according to the new theory, and in many cases illustrated by maps.

Without in any way committing ourselves to an opinion on the author's views, it may be pointed out that several of these maps are inaccurate. The one illustrating the distribution of ichthyosaurs (p. 249) ignores, for instance, the fact that remains of these reptiles have been obtained from more than one locality in Africa, which is left a blank in the map in question. This being so, it is difficult to see what value attaches to Dr. Simroth's conclusions in this and several other cases. R. L.

The Minimising of Maurice, being the Adventures of a very small Boy among very small Things. By Rev. S. N. Sedgwick. Pp. ix+150. (London: Elliot Stock, 1907.) Price 5s. net.

A word to "grown-ups" which prefaces this volume asserts "there are quite a lot of things in it *which only children are able to understand*"—the italics are not ours. There are "baby" language, indifferent verse, and talking animals in great profusion, but, despite all these, we are very doubtful as to whether the book will really appeal to children. The illustrations are good, and these at least will set young readers questioning and observing. We should have preferred a simple account in good literary English of the forms of animal life introduced, and so would most of the children we know.

Les Progrès de la Photographie astronomique. By Prof. P. Stroobant. Pp. 34; illustrated. (Brussels: M. Hayez, 112 rue de Louvain, 1907.)

This thirty-four page extract from *l'Annuaire astronomique de l'Observatoire royal de Belgique pour* 1908 is typical of those services which Prof. Stroobant is continually rendering to contemporary astronomy. It contains in a concise and lucid form descriptions of the methods by which photography renders such valuable services to astronomical research. The photography of regions, such as nebulæ, the discovery of minor planets and satellites by the photographical method, the investigation of the physical peculiarities of comets and of the solar photosphere, the observations of variable stars and of proper motions are all dealt with in turn, and in each case the text is illustrated by excellent reproductions of actual photographs. Duplicate, detachable plates, for use in a stereoscope, are included in order to illustrate the value of Prof. Wolf's stereocomparator method for the detection of small proper motions and of variations in magnitude. W. E. R.

(1) *I laterizi.* By Ing. G Revere. Pp. x+298; 134 figures. Price 3.50 lire.
(2) *La Tecnologia delle Saldature autogene dei Metalli.* By Prof. S. Ragno. Pp. iii+129. (Milan: Ulrico Hoepli, 1907.) Price 2 lire.

These are recent additions to the "Manueli Hoepli," a collection which numbered 900 of these small pocket-books on April 1, 1907. Mr. Revere's book deals with brickwork. It opens with general and historical information, and then deals in succession with the selection and extraction of the clay, its subsequent preparation, brick-making machinery, the drying process, and finally the brick kiln. The need of such a book has arisen through the great development that has taken place in the brick industry in recent years, notably in Italy, where improved machinery has been largely introduced.

Prof. Ragno's manual deals with the soldering and welding of metals. Five methods are distinguished, namely, the electric, oxy-hydrogen, oxy-acetylene, oxy-gas, and aluminium methods. The advantages of these methods are discussed. Two appendices deal respectively with the cutting of metals by means of an oxygen jet and the methods of producing oxygen commercial'·

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Mendelian Characters among Shorthorns.

I have just come upon a phenomenon which, although it may be interesting to naturalists, may be alarming to breeders of Shorthorn cattle. It is that the roan Shorthorn is a hybrid, and must remain so for ever.

The data on which this statement is based are to be found in a paper on the inheritance of coat-colour in cattle, by Miss A. Barrington and Prof. Karl Pearson, published in *Biometrika* for March, 1906.

For the purposes o their paper these authors, having examined in the Shorthorn Herd-book the pedigrees of more than 2000 calves, noted the colours of these and their parents, and analysed and tabulated the figures found. They divided the sires and dams according to the colours under which they are registered, and then made an analysis of the colours of the calves produced. There are five different colours registered, viz. red, red and little white, red and white, roan, and white. A sire of any one of these colours may be bred with a dam of any one of them. Miss Barrington and Prof. Pearson made an analysis of the colours of the calves produced by bulls of all the five colours when bred with cows of every one of the same five colours. For instance, they found that by mating 514 roan bulls with 514 roan cows there had been produced eighty-six red calves, thirty-one red with little white calves, thirty-five red and white calves, 278 roan calves, and eighty-four white calves.

These cases at a first glance give rise to no Mendelian suggestion. No more does the full collection of cases. Miss Barrington and Prof. Pearson failed to find in them any Mendelian indications.

But if we consider the nature and history of the Shorthorn breed the Mendelian characters come out. The Shorthorn is a composite breed. A hundred and fifty years ago it consisted of at least three, and possibly four, different strains. The chief ancestry came from the Low Countries. They were red-and-white flecked cattle—*fleckvieh*. In Durham and Yorkshire they wedged themselves in between the original British black cattle in the north and the Anglo-Saxon red cattle in the south. They also possibly reached westwards to the Longhorns. The Anglo-Saxon red cattle were probably the purest. The northern black cattle and the western Longhorns were not pure. They were intermixed with white cattle—cattle which had been introduced originally by the Romans. It was impossible for the recently introduced flecked cattle not to become mixed with black blood in the north, with white blood in the north and west, and with red blood in the south. Breeders, however, did not like the black blood, and it was soon bred out. The white was retained, but, so far as I know, it is difficult to say how much Anglo-Saxon red blood was retained. It is on that ground any uncertainty arises. But, if red blood was retained, it was nearly related to the red and white blood introduced from the Continent.

If we look upon the Anglo-Saxon red cattle and the Low Country red-and-white cattle as being of one race, then, since the black blood was bred out, the Shorthorn is a combination of two races. If we look upon these red and red-and-white cattle as different races, then the Shorthorn is a combination of three.

I tried to find Mendelian characters among the cases collected by Miss Barrington and Prof. Pearson by assuming the Shorthorn to be a three-fold combination, but unsuccessfully. Then Prof. Arthur Thomson's account of the blue Andalusian fowl in his newly published "Heredity" suggested the idea that the red, red and little white, and red-and-white Shorthorns might be taken as one race. Are not these Shorthorns splashed reds just as one of the blue Andalusian parents is "splashed white"? The Shorthorn, then, becomes a composite breed with one parent white and the other splashed red. Assuming this to be so, then the Mendelian characters of the Shorthorn come out. There are one or two small discrepancies, but they can be explained. It is sometimes difficult to say whether a calf is red-and-white or roan. Thus all that are labelled red and white may not be really red and white, and all that are labelled roan may not be really roan. Among Shorthorn breeders white calves are not desirable. Cases of false registration and the substitution of another calf for a white—that is, giving a red or a roan calf a white calf's pedigree—have not been unknown. Thus some red or roan calves may not be the progeny of the parents attributed to them. For the same reason that white calves are undesirable, a good many white calves are not registered at all. Thus the real numbers of white calves born are greater than the numbers registered, and the number of matings recorded is less than it ought to be through matings that produced white calves being unrecorded. For the reason that white calves are not wanted, a white bull and a white cow are very seldom mated. Thus very few such matings are registered.

Assuming the Shorthorn to be a combination of two races, a red and white, then, according to the Mendelian formulæ as exemplified by the blue Andalusian fowl, we ought to get the following results:—

(1) Red crossed by red should give red calves.

(2) White crossed by white should give white calves.

(3) Red crossed by white should give roans.

(4) Roans inbred should give reds, whites, and roans in the proportion of 1, 1, 2.

(5) Roans crossed by reds should give roans and reds in equal proportions.

(6) Roans crossed by whites should give roans and whites in equal proportions.

This, giving heed to the expected exceptions as indicated above, is what we find, viz.:—

	Red	Roan	White
438 Reds crossed by reds give ...	413 ...	25 ...	0
3 Whites crossed by whites give	0 ...	0 ...	3
71 Reds crossed by white give...	3 ...	68 ...	0
514 Roans crossed by roans give ...	152 ...	278 ...	84
456 Roans crossed by reds give ...	226 ...	230 ...	0
23 Roans crossed by whites give...	0 ...	14 ...	9

For the breeder of Shorthorns this means that, if he wishes to avoid white calves, he is limited to three crosses, viz. red with red, red with roan, and red with white. He gets whites when whites are bred together, when whites are bred with roans, or when roans are bred together.

James Wilson.

Royal College of Science, Dublin, March 19.

The Nature of γ and X-Rays.

In a letter to Nature of January 23 (p. 270) Prof. Bragg mentions the results of some experiments on γ rays from which he concludes that the ether pulse theory of γ rays is not tenable, but which support his theory that the γ rays consist of neutral pairs revolving in a plane containing their direction of translation. From the close resemblance of X-rays to γ rays he assumes that they also consist of neutral pairs. His reasoning seems to be that if the γ rays are ether pulses only, they should produce in any substance which they strike secondary kathode rays which come off equally in all directions, and if they do not the ether pulse theory cannot be correct.

Prof. Bragg's experiments show that the secondary kathode rays coming from the side of a substance on which the γ rays fall differ in the amount of ionisation they produce from those coming from the side from which the γ rays emerge. Also that the "emergence" kathode rays from a substance of low atomic weight are greater than those from a substance of higher atomic weight, while with the "incidence" kathode rays the substance of high atomic weight gives off more than the substance of lower.

I have been working for some time upon the secondary kathode rays produced by X-rays with a form of apparatus which can be easily adapted for a repetition, with X-rays, of Prof. Bragg's experiments with γ rays (see *Amer. Jour. Sci.*, October, 1907, p. 285). I have therefore tried to find out whether his results with γ rays hold also for X-rays.

Following closely Prof. Bragg's method of procedure with pairs of metals consisting of lead and aluminium, copper and aluminium, and copper and lead, I found that in every case the ionisation due to the "emergence" secondary kathode rays was greater than that due to the "incidence" rays. The "incidence" secondary rays were, in different experiments, from 50 per cent. to 90 per cent. of the "emergence." It appeared, however, that the difference was not as large in the case of lead as in the case of copper. This is in agreement with Prof. Bragg's result for γ rays.

A separate experiment showed that the thickness of the layer of copper from which the secondary rays can emerge is not great enough to absorb the primary rays to an extent sufficient to account for the marked difference between the "emergence" and "incidence" secondary rays.

On the other hand, however, both the "emergence" and "incidence" secondary radiation produced greater ionisation when it came from a metal of high atomic weight than when it came from a metal of lower atomic weight. This difference was very marked with the above-mentioned pairs, and also with lead and carbon. This is directly opposite to the effect observed by Prof. Bragg with γ rays.

It should be noticed that the ionisation chambers used in these experiments were so short that a very small fraction of the secondary X-rays coming from the metals was absorbed in them, while they were long enough to absorb all the secondary kathode rays. Thus practically all the ionisation was due to the secondary kathode rays.

Although these experiments, together with those of Prof. Bragg, show that for both X-rays and γ rays the secondary kathode rays are not produced equally in all directions, I cannot agree with Prof. Bragg that the evidence is conclusive that X-rays and γ rays must consist of some type of radiation other than electromagnetic pulses. The reason he gives on the neutral pair theory for lack of symmetry in the secondary rays is that these secondary rays are the negative parts of the primary pairs. As these primary neutral pairs possess momentum in the direction of propagation, it is natural to suppose that their negative parts, when liberated from the positive, would be more likely to continue in their original direction than to turn back.

On the other hand, an electromagnetic pulse possesses momentum also in the direction of propagation. Though little is known of the mechanism of the production of secondary kathode rays by ether pulses, it is not unreasonable to suppose that an ether pulse could contribute some of its momentum to the secondary kathode particles, causing them to go more in the direction of propagation of the primary than in any other.

Since we know that X-rays, which come from a region where electrons are being violently accelerated, must consist in part, at least, of ether pulses, and since all the experimental evidence previously gathered in regard to their nature has been favourable to the ether pulse theory, it seems to me more reasonable to look to the ether pulse theory for an explanation of both X-rays and γ rays than to a theory of neutral pairs. It must, however, be recognised that this lack of symmetry in the secondary kathode rays is a difficulty in the way of the ether pulse theory which needs explanation. I hope soon to determine by means of absorption experiments whether this lack of symmetry is due to a difference in penetrating power or quantity of secondary kathode rays.

Martinmas in May.

Sir Norman Lockyer in his book on "Stonehenge" connects the festival of St. Martin, which falls on November 11, with the beginning of winter in the May-November year, which falls astronomically on November 9. He does not, however, seem to be aware that there was another festival of St. Martin which fell on May 12. This was the *Subventio St. Martini*, a festival which was appointed to be observed by a council held at Tours in 841 to commemorate the restoration of the relics of the saint to Tours after they had been hidden on account of the incursions of the Northmen. Sir Harris Nicolas in his "Chronology of History," published in 1838, stated that the festival was still observed in the province of Tours. The date of the appointment of the festival is late, but reverence for sacred stones survived until long after that time, and it might be worth while to try to discover whether any connection can be traced between the appointment of the festival and an attempt to discourage the old stone-worship.

It seems clear that it was this festival of the *Subventio* which is alluded to in the entry in the Parker Manuscript of the Old English Chronicle for the year 913:—"In this year about Martinmas King Edward bade build the northern fortress at Hertford, between the rivers Maran, Beane, and Lea: and then after that in the summer between Gang-days and Midsummer King Edward went with part of his forces to Maldon in Essex." The King opened his campaign at Martinmas, May 12, by commencing a fortress at Hertford, and then between Rogationtide (May 23–25) and Midsummer he marched to Maldon. The fact that the chronicler regards the period between May 25 and June 24 as summer has a bearing on the question of the observance of a May-November year. It is likely that the Martinmas of 919 is also the May festival, but it is clear that the Martinmas of 918 and of 921 must be the festival in November.

An Annotated Copy of Newton's "Principia."

About three months ago I was asked to look through a list of old books, which had recently come to Australia as portion of the personal property in an estate which had been in Chancery some years. The books had become the property of a resident of this city, who employed an agent to dispose of them.

Among a number of books which I bought was a copy of Newton's "Principia," and when I came to examine it more closely I found that it was one of the original edition of 1687, with the imprimatur of S. Pepys "Reg. Soc. Præses Julii 5 1686." I found also that it contained nearly five pages of MS. additions and corrections for a second edition, written in Latin, as well as numerous corrigenda throughout the book, with occasional detailed alterations in the diagrams.

Inside the cover, in another handwriting, there was the following note:—"The Amendments in this book were written by Sir Isaac's own hand. See his original MSS. of his Optics in Trin. Coll. Library, Cambridge."

I have since compared the handwriting of these "additions and corrections" with a facsimile of Sir Isaac Newton's handwriting in the Commonwealth Parliamentary library, and consider there is a distinct similarity.

I have now had the first two pages of the notes photographed, and have forwarded them to the librarian of the college referred to in the note, with the view of a further comparison.

The notes are punctiliously detailed, with a reference to each page, and the alterations in the body of the text of the book are made with almost microscopic care. As the notes are headed as intended for a second edition, I cannot see what other source but the mind and hand of the author they could have come from.

I am informed by the former owner of the book (Mr. H. C. Elderton) that it belonged to the family of James, of Ightham Court, Kent, probably to Sir Demetrius James, who is supposed to have been knighted about the year 1685. It and a number of other old books formed a small collection which were set apart, packed in oak chests, and stowed away in an old clock-tower, where they remained ever since until brought to Australia.

I shall let you know the result of my inquiries, and, in the meantime, perhaps some of your numerous scientific readers may be able to throw some light on the book's history, for if it should be Sir Isaac Newton's personal copy, and contain his personal notes, it must become an object of great interest to the scientific world.

Bruce Smith.

149 Phillip Street, Sydney, Australia, February 25.

TWO COUNTY BIRD-BOOKS.[1]

To write a history of the birds of Yorkshire, so far the largest of our English counties as to include almost every kind of natural feature to be found in this country, was no light undertaking, and Mr. Nelson is to be congratulated on the conclusion of his labours, extending over many years, and upon the able way in which he has arranged and digested the unrivalled and exceptionally complete mass of material placed at his disposal, which has been accumulated by the numerous ornithologists who, from the time of Thomas Allis (who wrote the first complete list of Yorkshire birds in 1844) down to the present day, have been engaged in working out the local ornithology of this great section of England. This information Mr. Nelson has been able to supplement with his own observations for many years past. The scope of the work is comprehensive. The account of each species includes particulars of faunistic position, distribution, migration, nidification, folklore, varieties, and vernacular names; whilst the report on the birds of Yorkshire prepared for the York meeting of the British Association in 1844 by Thomas Allis is here published for the first time. A voluminous introduction deals with the physical aspect of the county and the several districts into which the great diversity of its natural features has made it convenient to divide it. Following this, migration, so remarkable on the Yorkshire coast from its geographical position, is duly considered, and the chapter concludes with a review of the avifauna of the county.

Situate about midway on the eastern seaboard of the British Isles, and directly opposite the European continent, Yorkshire is sufficiently far south to include species the distribution of which is of the southern type—such as the nuthatch and nightingale, which find in it the northern limit of their range—while it is sufficiently far north to admit of the inclusion of such species as the curlew, dunlin, &c., "which here meet with their southern breeding limits." These remarks, though true on the whole, must not be taken in too literal a sense, for both the last-named birds breed in Great Britain further south than Yorkshire. The author states that the avifauna of Yorkshire, compared with that of other counties, stands unrivalled, not only in its numerical extent, but also—a circumstance of much greater significance—in the inherent richness which is shown by the number of species breeding annually within its limits. That this should be so would be anticipated by anyone who has read the topographical description of the county, in which are found wild mountainous country, heathery moorlands, and romantic dales; pasture and arable land, woodlands, marshlands, chalk wolds, and a coast line 117 miles long, and one of the most diversified possessed by any English county. We find, indeed, in Yorkshire almost every kind of natural feature that England affords.

The configuration of the coast line materially increases the advantage of the position, which is still more enhanced by the possession of two such projections as Spurn Point and Flamborough Head (the latter on the same parallel of latitude as Heligoland, the island which is so famous for the vast hordes of migratory birds which pass and repass it in spring and autumn), which as a locality productive of rare birds has few equals.

R. Fortune.

Fig. 1.—Unusual Site for a Dipper's Nest, on the River Nidd. From "The Birds of Yorkshire."

We accordingly find Yorkshire accredited with a list of 325 species after excluding 21 recorded on insufficient evidence. Of these no fewer than 123 are considered to be annual breeders. It is in this list of breeding species (which it owes to its size, diversity of natural features, surface, soil and climate, and to its peculiar geographical position) that the strength of the Yorkshire list mainly consists.

Among the resident species are the nuthatch, woodlark, and lesser spotted woodpecker, which here find the northern limit of their general distribution in Britain during the breeding season; the raven, buzzard, and peregrine falcon—now reduced to a few pairs—as well as the goldfinch and the sheldrake, both of which are local. The nightingale, reed-warbler, wryneck, turtle dove, and stone curlew

[1] (1) "The Birds of Yorkshire. Being a Historical Account of the Avifauna of the County." By T. H. Nelson, with the cooperation of W. Eagle Clarke and F. Boyes. 2 Vols. Pp. xlv+xii+843; illustrated. (London: A. Brown and Sons, Ltd., 1907.) Price 25s. net.
(2) "Notes on the Birds of Kent." By R. J. Balston, Rev. C. W. Shepherd, and E. Bartlett. Pp. xix+465; with 9 plates and a map. (London: R. H. Porter, 1908. Price 20s. net.

(among the summer migrants) reach in Yorkshire the northern limit of their annual distribution during the breeding season. If we add to these and other well-known midland and southern species the very local pied flycatcher, which is common in many localities, and such moorland and fell birds as the merlin, twite, dipper, grey wagtail, grouse, golden plover, dunlin, and curlew, various wild ducks, and the numerous rock birds which resort to the sea cliffs in the nesting season, we get a breeding avifauna which is probably unequalled by that of any block of adjacent English counties equal to Yorkshire in size, although it is surpassed by that of North Wales, with a much smaller area. Yorkshire is, however, singularly deficient in terns.

Among the many rare and accidental visitors may be mentioned the Siberian meadow bunting (the only known European example), the cuneate-tailed gull—better known as the wedge-tailed or Ross's gull—and Bulwer's petrel, which were both until recently unique as British specimens, the desert wheatear, rufous turtle dove, McQueen's bustard, &c. Like other districts, Yorkshire has lost several breeding species, *e.g.* the kite, the harriers, bittern, bustard, grey geese, avocet, ruff, godwit, and black tern. Probably the article which will claim the most general attention and to which many ornithologists will turn first, is that on the guillemot and the famous "loomery" on the Flamborough cliffs. A most interesting and valuable account of this bird and its breeding habits, and the extraordinary variation in the colour and markings of its eggs, will be found here; as also of the practice of climbing for eggs carried out on the Yorkshire cliffs, accompanied by some excellent illustrations, which make the account given quite clear to those who have never been present at this harvest of the cliffs. Notwithstanding the fact that about 80,000 eggs is the average yearly "take," it is stated that there is no diminution in the numbers of the birds. But the egg collecting is carried out with some care, some portions of the cliffs being "fallowed" occasionally; and, moreover, there are dangerous parts of the cliffs which are never climbed, and in these places the birds hatch out their first eggs without interference.

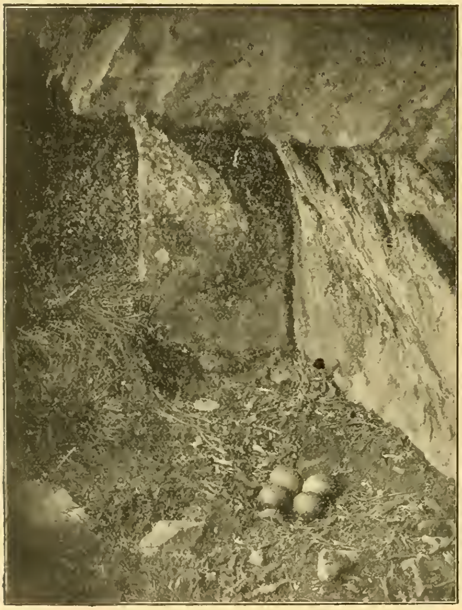

FIG. 2.—Peregrine Falcon's Eyrie, North-west Yorkshire. From "The Birds of Yorkshire."

In the carefully prepared articles on each species, the history in the county of the declining or recently extinct birds is fully given, every bit of available evidence and information having been most praiseworthily preserved. Especial attention may be directed to the excellent articles on the raven, the rarer birds of prey, and the great bustard. A point is made of the earliest allusion to each species as a Yorkshire bird. In this connection we notice that the author has included as an early reference to the black grouse a letter from Fr. Jessop to John Ray, written in 1668, saying he had stuffed the skins of a moor cock and moor hen. We may point out that at that time these names were used to designate the cock and hen of the red grouse. For although the word grouse is now applied almost exclusively to the red grouse, it probably originally belonged to the black grouse or black game, our "grouse" being commonly spoken of until comparatively recent times as moorgame. That the latter was the bird referred to by Jessop is quite clear from another letter addressed by him to Willoughby (*vide* Derham's "Philosophical Letters," p. 367). The work is lavishly illustrated, and many of the illustrations are most interesting, or give pleasing scenes of bird-life. But the greater part are photographs of nests and eggs, and as satisfactory or unsatisfactory as such illustrations must be. Many, indeed most, photographic representations of the nests and eggs of small birds are "faked"—the nests tilted forward or unnaturally exposed in order that the contents may be seen, and the eggs must be arranged in order that all of them may come into view. You cannot see the eggs in a reed-warbler's nest by looking at it sideways, nor can you see the whole five eggs in any small nest without looking directly down upon it. Tits' nests are not naturally exposed to the gaze. Pictures of nesting scenes and sites are far more valuable.

The photographing of birds' nests has been rather overdone. A large proportion of such pictures are worth little, and many of them do not really represent what would be seen by the observer; and it is to be regretted that in their desire to get prints of the nests of different species the disciples of this new sport have made many a pair of birds desert their eggs, and by keeping away their parents have caused young birds to suffer from prolonged exposure to cold, from which they so often do not recover. No nest of a really rare bird, at all events, should be subjected to risks of this kind. The same species can always, if it is really desirable, be photographed where it is comparatively common.

But there are many good and useful pictures in these volumes. The dipper's nest on a branch, the sparrow-hawk's, showing the tufts of down; the falcon's eyrie, and the crow's nest showing the tree, may be mentioned; while sites such as Cautley Crag, the island in Swinsty Reservoir, the Humber mudflats at Spurn, Hornsea Mere, and the many views of cliff scenery, as well as the snow scene with red grouse sitting on the roof of a moorland cottage in Teesdale, illustrate most excellently the ornithological characters of Yorkshire. The errata, in which there is a curious misprint, is not quite complete, and omits to state that *lesser* spotted woodpecker should be *greater* (p. 276), and *blue* tit should be *great* tit (p. 114). There are two indices, but unfortunately no map.

The latest work on the birds of Kent (which from its title, indeed, does not claim to be a complete history of the subject) is founded on the material brought together in connection with a certain area of that county; but in that limited portion of the county it was noticed that the avifauna would scarcely be of sufficient importance to fill even a small work. It was therefore found advisable to take in the whole of the county. It was also thought desirable to collect all the material hitherto written, and give to those who have done so much towards our knowledge of the birds of Kent full credit for their observations. This has in the main been carried out, and the result has been a compilation giving us a great deal of information about the birds of Kent. Indeed, so anxious have the authors been to give all possible credit to those who have written anything about the local ornithology that they have been misleo into including in their book a number of notes and observations which were not worth reproduction, and the discursiveness of which has made it extremely difficult to arrange the facts in the present work in an orderly and systematic manner. In fact, the book is very well described by its title, and although the reader has never been led to expect a systematic history (from a local point of view) of the birds of Kent, the book is a storehouse of facts relating thereto.

We should have been glad to have a complete book on the subject to fill up a blank in the county bird-book shelf; a volume with more personal observations from the authors, and a compilation more complete. The present volume has not been brought up to date. For instance, a valuable paper published in the *Zoologist* so long ago as February, 1907, has been quite overlooked. Had this been consulted the sheldrake might have been added to the list of ducks breeding in Kent, while the status in the county of the shoveller and some other ducks, as given in the volume under notice, would have been somewhat modified. Nor has the information relating to the various birds always been brought down even to recent years.

Concerning the guillemot breeding on the Kentish coast, we have a description of the breeding colony in St. Margaret's Bay, written so long ago as 1852, and a note on the same made in 1887, but nothing more recent in the way of exact information about the bird breeding on the coast at the present day, although we are told that the bird is, during the summer and breeding season, very numerous. It would surely have been worth the while of one of the authors to ascertain the exact conditions of the breeding place or places after the lapse of twenty years. This is only one instance out of several. Again, on turning to the articles on the birds more particularly associated with Kent, we find that the greater part of that on the Sandwich tern consists of matter written in the eighteenth century, and we are left in doubt as to whether this bird still breeds annually on the coast or not.

The article on the Kentish plover is more satisfying, although it consists almost entirely of quotations (excellent in themselves), with no qualifications, remarks, or annotations by the authors. An exact statement of the status in Kent of each bird would have been welcome. Kent is credited with a list of 320 species, but of these the black grouse is stated to have long been extinct. We cannot quite follow the authors in their application of this word when they go on to say that many of the birds, which might also come under the same word, such as the crane, bustards, cream-coloured courser, &c., are likely to become occasional visitors, *although comparatively extinct in the county* (italics ours). There are certainly no grounds for calling the last-named bird "extinct" in the county, as it has never been anything more than a purely accidental straggler to these islands; while the other two species are absolutely, and not only comparatively, extinct as native birds in Great Britain, although they may occur from time to time as visitors. Speaking of the rarer visitors to Kent, the authors remark on one very extraordinary circumstance, viz. that a very large number of the rare seed-eating and other birds should have been found on the Sussex coast, whereas none of them have been observed in the adjoining county of Kent; and the suspicion here expressed that most of these birds have been introduced by human agency has certainly been entertained by many people.

The introduction contains an excellent topographical account of this maritime county (with its 140 miles of coast lapped by tidal water) and its natural features. There is an index, and a map of a handy size and sufficient for its purpose. The frontispiece to this well-got-up volume is a picture from a photograph of a bit of woodland with a woodcock on her nest, and is one of the most beautifully executed and successful pictures of this kind we have ever met with. The difficulty in at first seeing the sitting bird, and the failure of the eye to pick it up at once on again glancing at the picture, as well as the way the figure and details of the bird seem to grow on the sight when once it is located, or located once more, is an admirable representation of the real facts of such cases. The other eight full-page plates depict birds—like the masked shrike, which has only occurred once in Great Britain—especially associated with Kent, and (especially the one named) are very welcome. But they would have been more useful had they been more correctly coloured. The wing coverts of the lesser kestrel should not have been grey, and the legs of the avocet should have been bluish-grey and not olive-green, a colour which has been also used for the legs of the Kentish plover instead of the correct black or brownish-black. Ornithologists will be glad to have the voluminous literature relating to the birds of Kent collected in this nice-looking volume, the paper, binding, and general get-up of which do the publisher great credit.

MODERN NITRE BEDS.

EVER since the invention of "villainous saltpetre," the provision of a sufficiency of nitrates has been one of the preoccupations of a ministry of war, and the necessity has become greater rather than less under the conditions of modern warfare. The potassium nitrate that was required for the fabrication of gunpowder is now replaced by the nitric acid used in making the various types of nitro-explosives, but it is always the nitric ion that has to supply the oxygen, and the consumption in a modern battle attains a magnitude of which our immediate predecessors using black powder had no conception. Indeed, one truly scientific argument against war may be drawn from the enormous losses it occasions in the world's limited stock of combined nitrogen.

Up to the middle of the nineteenth century, India was the only source of nitrates on a large scale, and though a certain amount of nitre was recovered from the efflorescence of the walls of cellars and from artificially made beds of earth mixed with decaying animal matter, it was not until the closing of the seas to France during the wars of the Directory that the necessity of an internal supply of nitrates directed the attention of the French savants to the process of nitrification. Their labours reduced to a system the making of nitric beds, but the maximum production was never more than about 5 kilos. of nitre per metre cube after the bed had been established for two years.

It was nearly eighty years later that the researches of Schloesing and Müntz, Warington and Winogradsky showed that nitrification was brought about by bacteria, and at the same time afforded a justification and an explanation of the procedure which had been worked out empirically for the nitre bed. The discovery of the nitrate of soda deposits in Chile left no place for the old nitre beds, but as MM. Müntz and Lainé point out in a very interesting memoir lately presented to the Société d'Encouragement pour l'Industrie nationale (T. cix., pp. 951–1042. Paris, 1907), the conditions that prevailed at the close of the eighteenth century might recur, and France be again driven to manufacture her war stores of nitrates at home. The authors have therefore been studying in detail the process of nitrification on a large scale to ascertain if the process could be so quickened and intensified as to have any practical value. Starting with sulphate of ammonia as a home product obtainable on a large scale, they worked out the conditions of temperature, concentration, nature of medium, &c., which would result in the maximum formation of nitrates. The most important step they have made is to show that humus, so far from being inhibitive of nitrification, as most organic substances are, is actually favourable, so that peat or turf, which is almost wholly humus, by reason of its great water-absorbing powers and the large surface it offers, becomes the best of all substrata for nitrification, if it is also supplied with a sufficiency of carbonate of lime, and a vigorous growth of the necessary organisms is first established in it.

As a final result of their investigations, MM. Müntz and Lainé show that the optimum production of nitrates is attained when the ammoniacal liquids percolate through successive beds prepared of finely divided peat mixed with carbonate of lime. It is impossible to begin with a concentrated solution of the sulphate of ammonia, 7·5 grams per litre being about the optimum when the "nitrière" is in full activity; but after this liquid has been nitrified, successive additions of fresh sulphate of ammonia can be made, and the liquid put through another bed until a concentration of 47 grams of calcium nitrate per litre is reached, a figure which is still well below the limit of 20 per cent. at which nitrification ceases. With such an installation the authors expect a daily formation of 7·5 kilos. of nitrate of calcium per metre cube of turf, which represents an extraordinary advance upon the old nitre beds producing 5 kilos. of potassium nitrate per metre cube in two years.

Of course, the process at present is not within the domain of practical politics; ammoniacal nitrogen has practically the same market value as the nitric nitrogen produced, so that the labour expended and the cost of evaporating the final solution would all be wasted; but, as the authors began by pointing out, the occasion may yet arise when a country without command of the sea may require to manufacture its own nitrates. Then "nitrières" could be established by a peat bog to convert into nitrates the ammonia which could be distilled out of the peat. The only doubt that occurs to us is what opening the recent electrical methods of making nitrates from atmospheric nitrogen will even then leave for such a process.

A. D. H.

PROMINENCE AND CORONAL STRUCTURE.[1]

ANYONE who has studied the forms of the corona observed at different eclipses knows that these forms change from time to time, going through phases which are more or less repeated every eleven or twelve years according to the solar activity. I have previously indicated (*Monthly Notices*, R.A.S., vol. lxiii., No. 8, p. 481) that there is reason to believe that these changes of shape depend, not on sun-spot action, but on the position and percentage frequency of solar prominences, so that when prominences are most frequent, either near the solar poles or equator, the coronal streamers follow suit.

Prominences can now be observed and photographed every day, but coronal streamers and the lower corona can only as yet be seen during eclipses. From photographs taken during eclipses, it is difficult always to associate certain streamers with prominences, and indeed this should be the case. The reason for this is that prominences are only seen on the limb of the sun that is in profile in such photographs, while streamers may be observed in perspective in addition. The base of a large streamer need not necessarily, therefore, be situated on the solar limb.

It is, I think, now generally acknowledged that a study of eclipse photographs has shown that there is an intimate association (*a*) between streamers and the lower corona, and (*b*) between the lower corona and prominences. The more, therefore, the form of the lower corona can be attributed to prominence action the more the streamers will depend on prominence activity.

In the eclipses of 1898, 1901, and 1905 "arched" or "envelope" structures were photographed. Thus Prof. Dyson, in describing the series of three arches he photographed in 1901, said, "A very remarkable arch in the corona. Round the prominence three separate arches are shown, one inside the other. . . . They have the appearance of cloud over an eruption."

Again, the Astronomer Royal, referring to his photographs of the 1905 eclipse, writes, "very bright prominence associated with oval rings and arched structure in the corona."

The question arises, are these "arched" forms composed of prominence or coronal material? Photographs taken with prismatic cameras during these eclipses might answer this question, since they are capable of recording, in monochromatic light, images of the sun's surroundings.

An examination of such photographs taken by the Solar Physics Observatory's expedition had, however, shown no indication of any such "arch" systems, but it is quite possible that the comparative faintness of the objects in question and the insufficient lengths of exposure given may account for their absence in the records.

So far as I am aware, no such series of "arches" has been photographed except during the eclipses above mentioned, so that whether the material composing the arches is "coronal" or "prominence" is still undecided.

Although the routine work with the spectroheliograph of the Solar Physics Observatory since the year 1904 has been to secure, daily if possible, photographs of the sun's disc and limb in the wavelength of the "K" line of calcium, it was not until July 17 of last year that a photograph was obtained which presented a magnificent series of "arches."

[1] Abstract of a paper read before the Royal Society on January 16 (Roy. Soc. Proc., Series A, vol. lxxx., No. A 537, pp. 178–183).

The disturbed area on the sun was situated near the south pole in the eastern quadrant. Two photographs of this region were secured, one at 3h. 14m. p.m., G.M.T., and the other at 3h. 50m. p.m., G.M.T. In the first (*see* Fig. 1) the arches are clearly visible and complete, but in the second they are less discernible and partially broken up, in spite of the fact that the second photograph had the better exposure.

The most conspicuous feature of the whole disturbed area, shown in Fig. 1, is the series of three concentric arches, which nearly reach down to the chromosphere. Their heights, as measured from the chromosphere, are 1′·5, 2′·9, and 3′·6. The radii of the arches photographed and measured by Prof. Dyson for the 1901 eclipse were 1′·2, 2′·4, and 3′·7. It will thus be seen that both are of about the same order of magnitude.

It will be noticed further that the intensity of the arches is not uniform; thus the outside one has five points of increased intensity, while the next in order has three such maximum points. On the eastern side of these arches there is another distinct semi-oval which intersects two of the three main arches. On the southern side are some minor projections from the chromosphere which by their curvature seem to indicate that they form part of the whole disturbance.

The magnitude of this very active region will be more readily grasped when it is stated that the extreme portions were separated by 12′·7 and the highest point from the chromosphere measured 3′·6. Thus the breadth extended 353,000 miles, or more than three-quarters of a solar radius, and the height was about 101,600 miles.

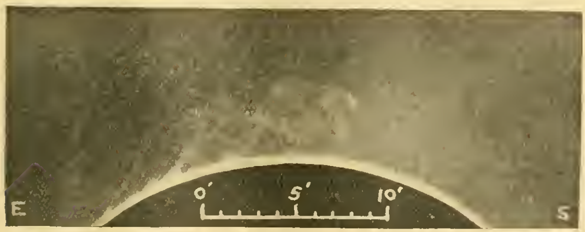

Fig. 1.—A prominence in the form of "arches" photographed in "K" light on July 17, 1907, at the Solar Physics Observatory, South Kensington.

It is interesting to note that there is apparently no large prominence underlying these envelopes, but whether there is one just on the near or far side of the limb cannot be stated.

The above photograph demonstrates that "arches" similar in form and magnitude to those secured during eclipses have now been photographed in the light of calcium vapour. This indicates that at any rate one of the components of the material of which they are built up is calcium. As the spectrum of the corona has no line at this wave-length, the deduction may be made that the arches photographed during eclipses are most probably of "prominence" and not of "coronal" material.

We have, therefore, another link in the chain to show the dependence of the form of the corona on prominence activity.

Since the above paper was communicated to the Royal Society, M. A. Hansky has published the results of his discussion of the corona pictures he secured at the total solar eclipse of August, 1905, and one of the conclusions which he has arrived at is as follows:—

"Il est très probable que la forme et la direction des rayons coronaux dépendent de la form et la direction des protubérances au-dessus desquelles ils se trouvent" (*Mitt. d. Nikolai-Hauptsternwarte zu Pulkowa*, Band ii., 1907, No. 19, p. 118).

William J. S. Lockyer.

DR. A. W. HOWITT, C.M.G.

By the death of Dr. A. W. Howitt, recorded in Nature of March 12 (p. 443), a link has snapped between the old days of the perilous exploration of Australia and the detailed scientific investigations of the present day. As early as 1858, Mr. Howitt's knowledge of bush-craft was such that a syndicate in Melbourne appointed him head of an expedition to acquire a tract of the "Promised Land" in Central Australia, of the existence of which Warburton had recently confirmed the report of Stuart. In 1860 he conducted a prospecting expedition in Gippsland. The following year he was selected to lead a party in search of the ill-fated Burke and Wills Expedition, of which John King, the last survivor, was rescued; later Mr. Howitt penetrated into the Great Stony Desert. Thus for many years Mr. Howitt had a wide personal acquaintance with the physical characters of southern and south-eastern Australia. On his numerous expeditions and journeys he came into close and friendly contact with the natives, some of whom were in a condition of complete savagery, and, later on, circumstances enabled him to acquire considerable influence over tribes in south-east Australia, so much so that he was even permitted to be present at their sacred ceremonies.

In 1873, Mr. Howitt joined the late Dr. Lorimer Fison in investigating the classificatory system of relationship which obtains among certain tribes, as well as the tribal class system and the rules of marriage and descent connected therewith. These investigations were published in 1880 in their memorable book, "Kamilaroi and Kurnai," which laid the foundations of a truer conception of Australian sociology than was previously possible. Of similar joint authorship were papers "From Mother-right to Father-right" and "On the Deme and the Horde," in the Journal of the Anthropological Institute (1882, 1884). In the same journal, from 1883 to 1908, Mr. Howitt published a series of papers of great value dealing with Australian sociology, initiation ceremonies, religion, and other phases of native customs and beliefs. In the production of these Mr. Howitt was assisted by some sixty correspondents from various parts of the continent; these informants were subjected to continued questioning, which elicited more detailed knowledge. Mr. Howitt also published in the annual report of the Australasian Association for the Advancement of Science (1890, 1891, 1901), papers "On the Use of Gesture Language in Australian Tribes," "Anthropology in Australia," and "On Trade Centres in Australian Tribes." On the occasion of the meeting of the British Association in Cambridge in 1904, the University of Cambridge presented Mr. Howitt with the honorary degree of Doctor in Science, in recognition of his ethnological investigations. Later in the same year Dr. Howitt published, with Messrs. Macmillan and Co., Ltd., his great work on "The Native Tribes of South-east Australia," in which is embodied his life's work in ethnology. By far the greater part of the materials was collected and recorded before 1889. Since then the native tribes have more or less died out, and in the older settlements of south-eastern Australia the tribal remnants have now almost lost the knowledge of the beliefs and customs of their fathers. Fortunately, Dr. Howitt began to observe and collect information before it was too late, but even then much had disappeared.

Dr. Howitt's book contains a great mass of information concerning numerous tribes, and thus it serves as an invaluable storehouse for students, but it is more than this, as it embodies the mature opinions of the father of Australian ethnology, who, by his kindly and sympathetic nature, was able to gain and retain the confidence of his native friends. The opinion of a man of such prolonged and varied experience in the field, combined with the knowledge of what others had collected, must always carry weight. The collecting and recording of complete ethnological data are naturally matters of first importance, but of even greater interest is the true appreciation of the ideas which underlie the actions of men. He who has lived among the people he describes should be the best interpreter of their ideas and ideals, and in these matters we are not likely to find a surer guide than the genial explorer and student whose death will be deplored by ethnologists all the world over.

A. C. Haddon.

NOTES.

The astronomical section of the Paris Academy of Sciences has elected M. Maurice Hamy, of the Paris Observatory, to succeed the late Dr. Janssen as a member of that section of the academy. M. Hamy entered the observatory in 1884, and was awarded the Lalande prize in 1895.

The Paris correspondent of the *Times* states that the Academy of Sciences has appointed a committee, composed of MM. Becquerel, Bouquet de la Grye, and Poincaré, to consider a suggestion by M. Bouquet de la Grye concerning the application of wireless telegraphy to the problem of the determination of longitude at sea. The idea is to utilise the wireless telegraphy station of the Eiffel Tower in order to send, for instance, every night at midnight a Hertzian signal giving the time of the meridian of Paris. M. Bouquet de la Grye thinks, indeed, that if a wireless telegraphy station were established at the Peak of Teneriffe signals could be detected completely around the earth.

The next International Congress of Archæology will be held at Cairo in 1909.

For the purpose of discussing subjects of interest to those concerned in the work of museums, art galleries, and kindred institutions, a conference of members of the Museums Association and others interested will be held in the Harris Free Public Library and Museum, Preston, on the afternoon of Saturday, April 11.

The twenty-fourth annual meeting of the Society of Dyers and Colourists will be held on April 3, at 4.30 p.m., at the Technical College, Bradford. The president, Prof. R. Meldola, F.R.S., will deliver his presidential address on "The Founding of the Coal-tar Colour Industry." The first awards of the Perkin medal will be made to Profs. C. Graebe and C. Liebermann for their synthesis of alizarin. On the evening of the same day the members of the society will dine together at the Great Northern Victoria Hotel, Bradford.

Earthquake shocks occurred at Mexico City during the evening of March 26, and were felt also at Guanajuata and Rincon. The town of Chilapa, in the State of Guerrero, was destroyed. The disturbances were recorded by Prof. Milne, F.R.S., at Shide, in the Isle of Wight; by Prof. Belar at Laibach, Austria; and by Prof. Michie Smith in southern India, all of whom communicated their observations to the *Daily Mail*. The earthquake is reported to have begun soon after 11 p.m. on March 26, to have reached its maximum at 11.53 p.m., and continued for more than three hours. The shock was felt at St. Thomas, in the West Indies.

We learn from the April number of *Nature Notes*, the magazine of the Selborne Society, that at last a Bill is to be introduced into Parliament to restrict the importation of birds' skins, and so prevent in some measure the rapid extermination of beautiful birds, of which the egret ("osprey") and birds-of-paradise are typical examples. A short time ago, Lord Avebury, president of the Selborne Society, called together a meeting of representatives of the various learned societies at his house to consider whether legislation ought to be attempted, and this being the general opinion of those present, the main features of a Bill drafted by Mr. James Buckland were adopted for presentation to the societies interested.

Efforts are being made to form an Institute of Metals, which it is hoped by the promoters will follow similar lines to the Iron and Steel Institute. The proposed institute is intended to advance the knowledge of non-ferrous metals and their alloys, more especially copper, zinc, tin, aluminium, lead, nickel, silver, and platinum; to form a means of communication between members of the same trade; and to arrange periodical meetings for the purpose of discussing practical and scientific subjects relating to the metallurgy and use of the metals enumerated. A preliminary meeting was held in Manchester on March 11, and was well attended. A representative committee comprising practical men engaged in the industries concerned and men of science was elected, and it was decided to arrange a further meeting in London. This special meeting will, we are informed, be held on June 10 next, at 2.30 p.m., at the Institution of Mechanical Engineers, Westminster. On this occasion the committee will report progress, and it is hoped the proposed institute will be constituted formally. All inquiries should be addressed to Mr. William H. Johnson, c/o Messrs. R. Johnson, Clapham and Morris, Ltd., 24 and 26 Lever Street, Manchester, who is acting for the honorary secretary, Prof. Carpenter, during his indisposition.

In the March issue of the Bulletin of the St. Petersburg Academy, Dr. E. Jäderholm gives a preliminary account of the hydroid polyps collected in the Arctic Ocean north of Siberia by the Russian Polar Expedition of 1900–3, while Dr. Salensky continues his description of the development of the gephyrean worm (mis-called echinoderm on p. 493 of our last issue) Echiurus.

The American white ant (*Termes flavipes*) and the bag-worm (*Thyridopteryx ephemeraeformis*) constitute, respectively, the subjects of two illustrated "Circulars," Nos. 50 and 97, of the U.S. Bureau of Entomology. An excellent account is given in the first of these of the social economy of the white ant, and the damage inflicted by the species in the Southern United States.

The existence of an intimate relationship between the fauna of the eastern coast of Arctic North America and that of northern Europe has for some years been admitted by naturalists. Supplementary evidence to the same effect is afforded by a recent study on the part of Mr. J. A. Cushman of minute fresh-water crustaceans from Labrador and Newfoundland, the results of which are published in No. 1589 of the Proceedings of the U.S. National Museum. Cladocera were represented in the collection by seven and the Copepoda by one species, all of which are common to Europe.

The second part of the new Leipzig journal *Vorträge und Aufsatze über Entwickelungsmechanik der Organismen* is devoted to a paper read by Mr. Jacques Loeb before the International Zoological Congress held at Boston (Mass.) in August last, on the chemical character of the secretions of the reproductive organs. Starting with the axiom that the special prerogative of living organisms is the power of automatic reproduction, the author proceeds to describe the chemical composition of the reproductive elements, and the bearing of this on certain biological theories.

Zeitung fur Literatur, Kunst und Wissenschaft for March 15 contains a summary of the results of the Hamburg Expedition to the Magellan Strait in 1892–3, as detailed in a work of three volumes just issued by the Hamburg Museum of Natural History. A feature on which the Hamburgers specially pride themselves is that the expedition was practically "run" by the municipality and inhabitants of their own city, while even the scientific workers are to a great extent their own fellow-citizens. According to the notice in the *Zeitung*, special attention appears to have been directed to the subject of "bipolarity," that is to say, the occurrence of similar types of animal life at the two poles and their absence from almost the whole of the intervening area. The geological and faunistic resemblances of South Africa, South America, and Australia are also referred to, with the remark that most of the common types indicate extremely ancient forms of life.

The importance—or rather the absolute necessity—of cooperation among workers in different branches of biological research formed the subject of discussion at a meeting of the American Society of Naturalists in December last, in which Profs. Lillie, Trelease, Donaldson, Howell, and Angell took part. The discussion is reported *in extenso* in *Science* of March 5. The first speaker, Prof. Lillie, took for his text the American Marine Biological Laboratory as an example of cooperation, not only among the members of its governing body, but with various other institutions. As it is, several branches of sciences are represented in the laboratory, but it is suggested that it will be necessary to add a chemical section. Prof. Trelease, on the other hand, took his illustrations from the fact that at the present day interest in biology centres on the mechanism of animals and plants, and their relations to environment—factors demanding the cooperation of morphological and physiological research. A further advantage claimed for cooperation is that by its means alone is it possible to discover the most productive and original research-workers.

A part (vol. iii., No. 4) of the Records of the Botanical Survey of India is assigned to a revision of the Indo-Malayan species of Cedrela undertaken by Prof. C. de Candolle. The author restores to the genus the species separated by some systematists under a genus Toona. The columnar receptacle of the flower is noted as a character of systematic value. As it was found difficult to assign specific limits to the specimens ranging round the species Toona, the forms are split up into numerous varieties. Of three new species created, *Cedrela Hainesii* is the most notable on account of the staminodes that are present in the flower.

Writing on the Florida strangling figs, an article intended for the nineteenth annual report of the Missouri Garden, Prof. E. A. Bessey describes the characters of the two indigenous species *Ficus aurea* and *Ficus populnea*. The former commonly, the latter rarely, begins life as an epiphyte; in this connection it was experimentally determined that the seeds of *Ficus aurea* require light for germination. The seeds of *Ficus populnea* show a less marked light requirement. Neither species develops the two distinct types of pistillate flowers known as seed and gall flowers, but larvæ are produced if the flowers are visited by ovipositing Blastophagæ; otherwise seeds are formed.

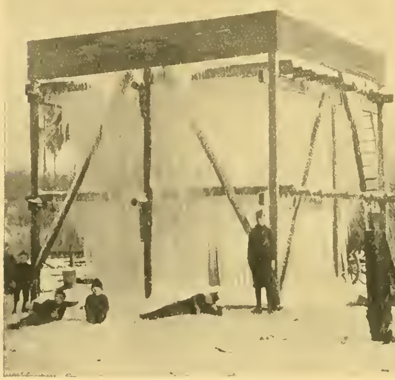
The early stages of development of the sporangia and the sporocarps of Azolla have been carefully studied by Miss W. F. Pfeiffer; the account published in the *Botanical Gazette* (December, 1907) corrects and amplifies previous information on the subject. In all cases a megasporangium is formed at an apex, and the wall rising below as an annulus quickly outgrows and encloses the sporangium. The development of the megasporangium is normal up to the formation of eight tetrads. Meanwhile, the microsporangia begin to appear as initial cells on the broad stalk of the megasporangium. At this stage, for reasons undetermined, either the megasporangium develops and the microsporangia cease to grow, or the megasporangium aborts and the microsporangia then develop normally.

Mr. L. Wray contributes to the Journal of the Federated Malay States Museum (vol. ii., No. 2) an account of a Malay varnish that is prepared from the resin obtained by making incisions in the bark of the tree *Garcinia merguensis*. The same writer publishes a short account of a native method of embroidering with gold thread, and a note on an opium substitute favoured by the Malays in some districts. The latter, known as "biak," is made from the leaves of *Mitragyne speciosa*. The dried leaves are powdered and mixed with water to form a decoction, or an extract is made that is smoked like "chandul," the extract of opium. In the same number will be found a hand-list of birds of the Malay Peninsula compiled by Mr. H. C. Robinson.

Mr. N. W. Thomas, in his "Bibliography of Anthropology and Folk-lore," published under the auspices of the Royal Anthropological Institute and the Folk-lore Society, has issued the first number of an annual series which will be indispensable to all students of the subjects with which it deals. His bibliography includes papers and articles in no fewer than 165 publications—proceedings of learned societies, magazines, and other ephemeral literature. In subsequent issues we may hope for a more full analysis of the papers with which the compiler deals. But, as it stands, this pamphlet, which is provided with excellent indexes, serves a distinctly useful purpose.

Lawyers in India have long been aware that, besides what may be called the official or sacerdotal view of law contained in the Institutes of Manu and other codes of the same kind, there is a vast mass of local and tribal usage which is independent of, and in many cases directly opposed to, the legislation of the Brahmans. The powerful tribal organisation in the Punjab has made the conflict between these two bodies of law more obvious than in other parts of the Empire. The materials for a study of the subject are voluminous and complex, and Mr. H. A. Rose, the superintendent of the Ethnographical Survey, has done useful service in codifying the district reports in his recently issued "Compendium of the Punjab Customary Law." He divides his subject into three chapters—marriage, inheritance, alienation—and in connection with such subjects as endogamy, exogamy, polyandry, and polygamy he has collected a mass of curious facts which will be interesting to anthropologists, particularly as they represent the usages of a very primitive type of tribal society.

Mr. H. Warth sends us a photograph, here reproduced, representing a method in use in south Germany for producing ice from pure water in winter. The photograph was taken last January in Balingen (Württemberg). The illustration shows a large wooden framework in two storeys, 6 metres square and 6 metres high. Each storey is covered with a floor of eighteen parallel beams, in the



Production of large Icicles.

centre of which a tube, encased in wood, rises beyond the upper floor. This tube is connected with the water-main, and the water issues through a rotating disc, which sends a moving spray on the beams. As the water drops from the beams icicles are formed, which reach the middle floor and finally the ground. The volume of water is regulated according to the temperature of the air, which may vary between $-3°$ C. and $-18°$ C. During low temperature 20 cubic metres of ice may be formed in one night. As the ice retains the shape of isolated columns, it is easily broken up and removed. The ice is then stored for use in summer.

In the Transactions of the South African Philosophical Society of December, 1907, Mr. J. R. Sutton, of Kenilworth (Kimberley), discusses the question of the supposed cloud-dispersing power of the full moon. From observations of the state of the night sky at Potsdam from January, 1894, to June, 1900 (*Met. Zeits.*, May, 1907), Herr Meissner found no such dispersing power, but a minimum amount of cloud about the time of new moon and a maximum shortly after full. Mr. Sutton thinks that if there be no lunar influence whatever upon the clouds something like Meissner's result might be expected, as the moonlight makes clouds visible (see Schmid's "Lehrbuch d. Met.," 1860, p. 681). At Kenilworth Mr. Sutton finds that cirrus and cirro-stratus appear to dissolve at sunset, but the rising moon makes them plainly visible again. The 8h. p.m. observations taken between January, 1900, and January, 1907, show considerably more cloud between the third and eighteenth lunar day than between the eighteenth and third. Dr. Shaw's interesting paper, "La Lune mange les Nuages" (Quart. Journ. Roy. Met. Soc., April, 1902), shows that any diminution of a floating cloud is due to evaporation by loss of heat, and that "any effect of direct radiation from the moon may be quite properly disregarded."

The Survey Department of the Egyptian Ministry of Finance has issued, as a pamphlet of thirty-eight pages with thirteen index maps, a list of maps, plans, and publications published up to December 31, 1907. The list includes town maps, cadastral maps, topographical maps of Egypt, special maps, and maps of the different provinces.

Prof. E. Guarini has published a pamphlet (Paris, 1908) on the resources of Peru. The mineral resources include many rich deposits of gold, silver, copper, and iron ores, which are at present unworked owing to lack of economical methods of transport. The author believes that by the introduction of electric-power transmission and electric smelting, Peru might rank amongst the leading industrial States of the world.

The question of handling materials in industrial plants is one continually presenting itself to owners and engineers for proper solution, and some striking illustrations showing the remarkable progress recently made in America in economical material-handling equipments are given by Mr. Werner Boecklin in the *Engineering Magazine* (vol. xxxiv., No. 6). The depreciation of such equipments is necessarily high, but in the majority of cases an increase in the first cost, which will materially decrease this charge, is warranted. In the same issue Mr. T. Kennard Thomson describes the construction of hoisting machinery for the handling of materials. He shows that here, as elsewhere in the domain of modern enterprise, economy in unit costs and maximum of output can be secured only where intelligent use is made of the mechanical facilities afforded for the handling of material.

The application of the camera as an adjunct to topographical mapping began practically with its invention, and it has been employed with varying success since that time. An interesting development is described in the bi-monthly Bulletin of the American Institute of Mining Engineers (1908, No. 19) by Mr. C. W. Wright, who has successfully employed in the field a panoramic camera taking a 5-inch by 12-inch view, including an angle of 140°. The plotting of a map from the views taken by the phototheodolite is a tedious process, and the office work is many times greater than that required for the same amount of mapping by the panoramic camera.

With the view of ascertaining whether the results of recent chemical investigations would be of value in lessening the amount of evaporator scale formed in the sugar mills of Hawaii, an elaborate series of experiments was carried out by Mr. S. S. Peck, and the results are published in Bulletin No. 21 of the Hawaiian Sugar Planters

Association (Honolulu, 1908). While the results offer no precise solution to this problem, they explain some of the phenomena of scale formation, and contain much of interest to other investigators, practical and theoretical, of this question, perhaps giving them a clue which will lead to the discovery of a successful method of treating the juice of the cane which will inhibit to some extent the formation of scale during evaporation.

Mr. W. Gallatly has published (Cambridge: Elijah Johnson, 30 Trinity Street) a pamphlet on the nine-point circle, consisting of a collection of short notes reprinted from the *Mathematical Gazette* and other sources. Most of the notes deal with analytical rather than geometrical properties associated with a triangle and the circle in question.

In the Proceedings of the American Academy of Arts and Sciences, xliii., 8, Messrs. C. R. Sanger and O. F. Black discuss the quantitative determination of arsenic by the Gutzeit method. They find that consistent results can be obtained, and the main difficulties avoided, by allowing the arsenic deposit to travel along a strip of paper, and by sensitising this with mercuric chloride in preference to silver nitrate.

In the Proceedings of the Tokyo Mathematico-Physical Society (January), K. Aichi discusses the capacity of nearly spherical electrical conductors. The property, obvious from the general principles of the theory of maxima and minima, that the capacity of a nearly spherical conductor is, to the first order of small quantities, equal to that of a spherical conductor of equal area, is deduced from analytical formulæ.

In *Engineering* of March 27 illustrations are given of the new plant of the Stavely Ironworks, Chesterfield, an undertaking with a record of two centuries. The new works are of great interest, not because of any distinctive departure, but because great discrimination has been exercised in weighing the relative merits of different systems in order that the many mechanical features in the complete equipment should harmonise with the aim to ensure efficiency.

The application of electricity is fast revolutionising many industries, and an interesting application in the chemical industry is described in the Journal of the Franklin Institute by Mr. E. R. Taylor, who gives an account of the process and apparatus for the production in the electric furnace of carbon bisulphide, the manufacture of which in retorts is one of the most disagreeable of manufactures. The furnace used is 10 feet in diameter and 20 feet high, and will produce 5000 lb. per twenty-four hours with economy and satisfaction. Two electrodes only are provided. The market for carbon bisulphide is a limited one, and no larger furnace than those now in use would be justified under present conditions. But were the market for carbon bisulphide as large and as regular as that for pig iron, the size of the furnace need only be limited by market requirements and the amount of electricity available.

Under the title "Two Oxford Physiologists" (Clarendon Press, Oxford, price 1*s*.), Prof. Francis Gotch has published an address, delivered before the Oxford University extension summer meeting of last year, which deals with the life and work of Richard Lower (1631–1691) and John Mayow (1643–1679). The address contains an admirable account of the work of Lower, who is best known as being the first to carry out the transfusion of blood from one animal to another, and of Mayow, who first recognised the true nature of respiration, and whose "medico-physical works" have just been translated from Latin into English (Nature, vol. lxxvii., p. 339). Prof. Gotch's eloquent address has an especial interest for the general reader in so far as it throws a clear light on the conditions under which scientific work was performed in the seventeenth century.

We have received a reprint of a lecture by Prof. Stéphane Leduc on "Diffusion and Osmosis" delivered before the meeting held at Rheims in 1907 of the French Association for the Advancement of Science. Certain remarkable experiments are described dealing with the formation and properties of the so-called "waves of diffusion"; the phenomena dealt with, although evidently due to the transmission of material particles, are accompanied by effects entirely similar to those produced by wave motion, especially in so far as they show interference and diffraction. It is stated also that by means of diffusion under certain chosen conditions, using merely solutions of different concentration coloured with a little Indian ink, the phenomena of karyokinesis can be reproduced in their proper order and form. Peculiar growths, presenting an appearance similar to that of true vegetable growths, can also be obtained by leaving "seeds," consisting, for example, of copper sulphate mixed with sugar, in an aqueous solution of potassium ferrocyanide saturated with common salt, and containing more or less gelatin and other salts (see accompanying figure). In different experiments growths analogous to roots, rhizomes, stems, leaves, and terminal organs of true plants were obtained, each with a characteristic internal structure depending on the nature of the salts in solution. By these experiments the interesting question is raised, how far the morphology of ordinary plants is determined by purely osmotic phenomena.

Osmotic growths.

In 1869 Bunsen wrote to Sir Henry Roscoe an account of a mysterious explosion caused by touching with the finger some reduced rhodium and iridium. The question of the explosive platinum metals has been taken up several times since then by various investigators, but the exact cause of the explosive properties of these metals has not been made clear. The explosive material is obtained by treating the zinc alloy of the platinum metal with an acid, and has been regarded as an allotropic modification of the metal. In the *Zeitschrift fur physikalische Chemie* for February 25 is an interesting account, by E. Cohen and Th. Strengers, of a long series of experiments on this subject. It was found that the residues from the action of hydrochloric acid upon zinc alloys of rhodium, iridium, ruthenium, and platinum are explosive; palladium and osmium do not furnish explosive residues. Explosive rhodium is now shown to contain both oxygen and hydrogen, and if air is carefully excluded during the removal of the zinc by the acid, the residue is not explosive. The heat evolved during the explosion was measured, and found to be of the same order of magnitude as the heat of combination of the quantities of hydrogen and oxygen actually occluded by the metal. The most probable explanation of the explosive properties of these reduced platinum metals is that the explosion is due to the sudden combination of the occluded hydrogen and oxygen. It was found, however, that in the case of ruthenium an explosive material was obtained even if oxygen was rigorously excluded during the separation from zinc, and this point still remains to be cleared up. In one of the calorimetric measurements, 4 grams of the rhodium destroyed a platinum calorimeter. A photograph of the remains of the calorimeter after the operation is given, and the authors remark that the effect of the explosion of *a pound* of this material (the quantity Bunsen had in the experiment above mentioned) can be easily imagined. Bunsen, fortunately, escaped with superficial burns on the face and severe burns on the hands.

THE name of Dr. R. W. Stewart should have been given as the author of the books on heat, light, and sound for matriculation candidates reviewed in NATURE of March 26 (p. 482).

MR. H. J. GLAISHER has published the April issue of his catalogue of publishers' remainders; it contains particulars of many scientific and other books which, though in a new condition, are offered at greatly reduced prices.

MESSRS. OLIVER AND BOYD have published a second edition of "Structural and Field Geology for Students of Pure and Applied Science," by Prof. James Geikie, F.R.S. The first edition of this work was reviewed at length in NATURE of July 6, 1905 (vol. lxxii., p. 223), and the present issue differs but little from its predecessor, though some omissions have been supplied and a number of emendations and corrections made.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN APRIL:—

April 4. 1h. 24m. Venus in conjunction with Moon. Venus 5° 52′ N.
,, 1h. 28m. Mars in conjunction with Moon. Mars 4° 15′ N.
,, 3h. 27m. Venus in conjunction with Mars. Venus 1° 37′ N.
9. 10h. 55m. Jupiter in conjunction with Moon. Jupiter 1° 21′ S.
14. 11h. 56m. Minimum of Algol (β Persei).
17. 8h. 45m. Minimum of Algol (β Persei).
19-22. Epoch of April Meteors (Radiant 271° + 33°).
20. Venus. Illuminated portion of disc = 0·540.
22. 3h. 12m. Uranus in conjunction with Moon. Uranus 0° 27′ N.
24. 4h. 45m. to 8h. 27m. Transit of Jupiter's Sat. III. (Ganymede).
26. 7h. Venus at maximum elongation (45° 37′ E.).

COMET 1907 II.—We have received an abstract of a paper read by Prof. E. Weiss before the Vienna Academy of Sciences on February 6, in which the author directs attention to the striking similarity of the orbit of comet 1907 II. to that of the comet of 1742. It appears probable that they refer to the same body, having a period of 165 years. From the fact that the earth passes very near to the ascending node of the cometary orbit towards the end of March, Prof. Weiss expects that a fairly rich meteor shower, from a radiant at $\alpha = 307°·6$, $\delta = -60°·7$, should be observed in the southern hemisphere.

THE PRESIDENT OF THE ASTROGRAPHIC CONGRESS.—At the request of several members of the permanent committee of the Astrographic Congress, Sir David Gill has, we understand, proposed to the permanent committee that M. Baillaud, the new director of the Paris Observatory, should be elected president of the international congress in succession to the late M. Loewy. Remembering the important part played by France in the labours expended on the Carte du Ciel, the generous support of the Institute of France in the publication of the committee's reports, and the great and successful efforts of Admiral Mouchez, M. Tisserand, and M. Loewy in the furtherance of the work, it is almost as a matter of course that the director of the Paris Observatory should be elected to fill the important position of president of the international committee.

THE HELIUM, D_3, LINE IN THE SOLAR SPECTRUM.—In No. 394 (March, p. 133) of the *Observatory*, Captain Daunt continues the discussion as to the presence of D_3 as a dark line in the solar spectrum, raised by the photographs taken at Kodaikanal by Mr. Nagaraja last year, and comes to the conclusion that the fine dark line shown on the photographs is not an absorption effect of D_3 at all. The main objection raised by Captain Daunt is that the fine dark line on the photographs runs right across the spectrum, and is sligtly widened over the spot, whereas, according to his own and to Mr. Buss's observations, the helium absorption line is generally very broken and patchy, and has never been seen over the spot itself; it always appears in the faculic areas surrounding the spot.

TWO REMARKABLE SPECTROSCOPIC BINARIES.—In a note published in the *Observatory* (No. 394, p. 139, March) Mr. Gore shows that two spectroscopic binaries, α Carinæ and α Pavonis, recently discovered at the Lick Observatory, must have remarkably small masses. In the case of the former, if the inclination of the orbit be 90°, the mass is but 0·007 of the sun's mass, and if the inclination is 30° this value is only increased to 0·056. The corresponding mass values for α Pavonis are 0·00047 and 0·0038 respectively, and in this case the result is more remarkable still, for α Pavonis is a brighter star, mag. 2·12; its spectrum is of the Orion type. Mr. Gore suggests that both these stars are probably near our system, and an effort should be made to determine their parallaxes.

VARIATION IN THE RADIAL VELOCITY OF β URSÆ MAJORIS.—In No. 4239 of the *Astronomische Nachrichten* Dr. H. Ludendorff announces that plates taken at Potsdam show the radial velocity of β Ursæ Majoris to be variable. The values given range from −6 km. (March 27, 1904) to −26 km. (April 28, 1905), and in a footnote it is stated that later observations show the period to be twenty-seven days.

DR. NORDMANN'S VARIABLE STAR OBSERVATIONS.—Following up the researches mentioned in these columns last week (p. 497), Dr. Charles Nordmann has obtained equally striking results from observations of β Lyræ and δ Cephei. In these cases the epochs of maxima and minima, as observed through the coloured screens, agree with the ephemerides, but the amplitude and form of the light-curves vary with the region of the spectrum observed. Thus for β Lyræ the difference between the principal maximum and minimum amounts to 0·66 magnitude with the red, 0·94 magnitude with the green, and 1·34 magnitude with the blue screen. The differences between the two principal maxima vary from 0·3 magnitude with the blue to zero with the red screen, and it is shown that this star emits a greater proportion of the less refrangible rays at the principal than at the secondary minimum. Similar results accrue from the observations of δ Cephei (*Comptes rendus*, No. 10, p. 518, March 9).

THE NATIONAL PHYSICAL LABORATORY DURING 1907.

THE report for 1907 of the National Physical Laboratory, presented to the general board on the occasion of the annual meeting and inspection of the laboratory on March 20, contains abundant evidence of the rapid growth and extension of its activities during the past few years, as well as of the usefulness and importance of the research work which such an institution is able to undertake. Following closely upon the report of the Treasury Committee, which has done valuable service, both to the laboratory and to the public, in defining more precisely the limits to be set and the conditions to be observed in regard to the acceptance of certain classes of test work, this account of the past year's work affords conclusive evidence that the organisation of special departments for the verification of instruments and examination of materials need be no hindrance to the concurrent prosecution of those researches which constitute the most important part of the laboratory's work.

It is interesting to note the changes effected since the opening of the laboratory in 1901. Apart from the observatory department at Richmond, the laboratory originally comprised a physics department at Bushy House and an engineering department housed in an adjoining building of two bays. At the present time the accommodation afforded in Bushy House is supplemented by that of three other buildings, together covering an area at least double that of Bushy House itself, in addition to a smaller building mainly devoted to the test work for the Indian Government, transferred to the laboratory from Coopers Hill, and a special building erected for the War Office standard leading screw lathe. Of the three larger buildings, the engineering building is now nearly doubled in size; the building for electrotechnics and photometry was completed in 1905, and considerable progress has been made with its equipment, which is described in a special appendix to the report, referred to below; while the building for metrology has been more recently erected, and the transference to it of the comparators and apparatus for measurements of length is only now being begun. One special feature of the metrology building is a long passage arranged for the verification of 50-metre surveying tapes and wires, whether on the flat or in catenary.

Of general public as well as of special scientific interest is the completion of the new magnetic observatory at Eskdalemuir, in Dumfriesshire. Primarily intended for the resumption of the magnetic work interrupted at Kew by the coming of the electric tram, it will be equipped generally with the recording and other apparatus necessary to a first-class meteorological station, and will maintain a close connection with its parent institution at Richmond. Dr. Chree's admirable work in the analysis and interpretation of the Kew records will thus be continued and extended. Eskdalemuir is situated towards the head of the Esk valley, some eighteen miles from Lockerbie on the Caledonian, and from Langholm on the North British Railway, sufficiently far from the nearest point of either line to be secure from magnetic disturbance. The locality promises to be no less free from social perturbations, and the relief measures to be adopted in the event of a severe winter will no doubt engage the attention of the committee at an early date. Mr. G. W. Walker, of Trinity College, Cambridge, and Glasgow University, is the first superintendent.

Among other matters of general interest, one or two branches of work recently undertaken by the laboratory may be referred to shortly. The transference to the laboratory of the Indian Government test work has led to the formation of a new department, of which Mr. Rosenhain is superintendent. The equipment of the new building in which the work is carried out has been systematically planned with the view of securing ease and rapidity of working; a description of the arrangements and of the methods of analysis employed is given in the report of the department.

Fig. 1.—General view of large bay of Electrotechnical Building, looking east.

The testing of taximeters, undertaken for the Commissioner of Police, has aroused a good deal of public attention. The tests applied consist of an exhaustive examination both in the laboratory and on the road of one instrument of a type, and of its mechanism, and of a simpler verification of the accuracy of each individual instrument. The tests are carried out at the laboratory, but a building has been erected in the Lambeth Road for the reception of taximeters for re-examination after use.

The testing of glow-lamps under the specification issued by the Engineering Standards Committee may also be mentioned here. The Lamp-testing Bureau of New York is responsible for reporting annually on some 13,000,000 lamps, to the benefit alike of the manufacturer and the consumer. Indications are not wanting of a demand for such tests in this country; increased facilities for the work are being provided in the photometry department.

Turning now to research, the papers published during the year include some of the most important work carried out by the laboratory. Foremost among these must be mentioned the three papers on the fundamental electrical units, for which—in conjunction, as regards some parts of the work, with Prof. Ayrton, Mr. Mather, and Dr. Lowry—Mr. F. E. Smith is responsible, and which, with an earlier paper on mercury resistance standards, embody the results of the work of the electrical standards department from the foundation of the laboratory. We shall, no doubt, have occasion to refer more particularly to these three papers in dealing with the "Collected Researches" of the laboratory, vols. iii. and iv. of which are now ready for issue. The ampere balance, planned originally by Viriamu Jones and Ayrton, the electrical part of which was constructed at the laboratory, with such modifications of the original design as experience showed to be necessary, under Mr. Smith's supervision, has given results "far exceeding that secured in any absolute determination of any electrical unit. . . . The balance was intended to give the ampere to 1 part in 10,000, but about 1 part in 50,000 appears to have been attained. A little uncertainty exists as to the value of g and the axial length of the coils; the latter uncertainty may shortly be removed" (by the construction of new coils).

The work on the comparison of various forms of silver voltameter has led to results of the same order of accuracy. Mr. Smith has shown that under specified conditions all the different types of voltameter experimented with give identical results for the electrochemical equivalent to within 2 parts in 100,000. In a suggested specification for the international ampere the Rayleigh form is recommended as the easiest to erect.

The paper on the Weston cadmium cell summarises the results of all the observations made at the National Physical Laboratory, and establishes the reproducibility and constancy of the cell. The results of comparisons between American, French, German, and English cells are given in the report, and show that standard cadmium cells can be set up by different experimenters with different materials to agree within a few parts in 100,000.

The results obtained in these researches and in those simultaneously carried on in the standardising institutions of Washington, Paris, and Berlin should make the way clear for the International Conference on Electrical Units to be held in London probably this year. Mr. Smith is to be congratulated on having placed the laboratory in the forefront of the institutions engaged in this work. The construction of the Lorentz apparatus, to be presented to the laboratory by the Drapers' Company, has been already commenced, and may perhaps be completed within the current year.

The research work of other departments must be dealt with more shortly. Mr. Campbell has published a valuable series of papers on mutual inductances: construction of standards, and methods of measurement. These latter include the use of a novel form of vibration galvanometer. Dr. Harker's high-temperature work has been delayed by his illness, but a new type of high-temperature furnace has been devised which promises well for the uniform heating of fairly large objects to about 2500° C. In the metrology department much time has been devoted to the development of methods of measurement of screws, and a 4-metre standard bar has been divided and calibrated. Mr. Hunter, in the optical department, has devised a method of considerable interest for the measurement of definition, more especially of photographic lenses. In the electrotechnics department a research on the dielectric resistance of insulating materials, undertaken for the Engineering Standards Committee, has been delayed by the failure of the 100,000-volt transformer under construction.

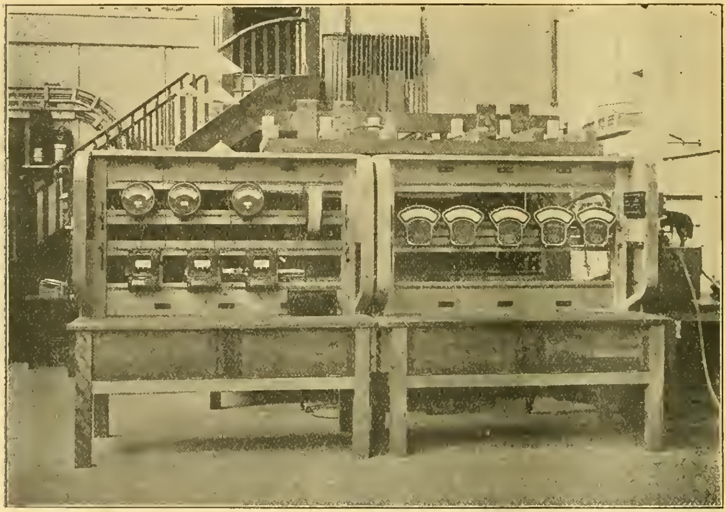


FIG. 2.—General view of one of the instrument-testing stations.

In the engineering department, Dr. Stanton has completed some important researches. The wind-pressure work has established interesting results as regards the relative pressures on large and small plates, which receive remarkable confirmation from the experiments of M. Eiffel. The comparison of open-air results on large models with those obtained earlier for small models shows that the values for large surfaces in the open can be inferred with accuracy from observations in the laboratory. Other researches carried out deal with the resistance of materials under repeated stresses and blows in four forms of impact testing machine, and the elastic limits of material under alternating stress.

In the new department for metallurgy Mr. Rosenhain has been very active, and at least three researches of first-rate importance were in progress during the year under his direction. The most interesting is perhaps the investigation of the alloys of aluminium, copper, and manganese, in continuation of the work carried out by Dr. Carpenter on the aluminium-copper alloys, which appears in vol. iii. of the "Collected Researches." For the purpose of the metallurgical research an ultra-violet microscopic outfit has been installed for obtaining photomicrographs at magnifications up to 3600 diameters.

The report is followed by an appendix, which gives some details as to the equipment of the electrotechnical laboratory (including the department for photometry). Much yet remains to be done to complete the equipment of this building, but the arrangements have been planned with the view of meeting the demands which are likely to arise, and the account given is of no little interest and utility. The chief feature is probably the careful provision made for the distribution of voltage and current about the building, the utmost flexibility in this respect being essential for the varied purposes of test and research.

The building—mainly on one floor—comprises one large bay (Fig. 1) for machines and alternating current test work, two parallel rooms of half the area for heavier test work and resistance and direct-current work respectively, with offices and workshops beyond. The photometry section, on two floors, runs at right angles to these on the east. Above are the rooms for the photometric measurements, with a 90-feet track for arc-lamp work; the ground floor provides accommodation for life tests, and is already largely occupied with the specially designed life-test racks necessary to cope with the probable demand to which reference has been already made. The results of the work on light standards at the laboratory since 1903 were laid before the Institution of Electrical Engineers by Mr. Paterson in December, 1906, in a paper which gained an institution premium, and much time has been devoted during 1907 to work on the pentane standard, while the photometry of differently coloured lights is also receiving attention.

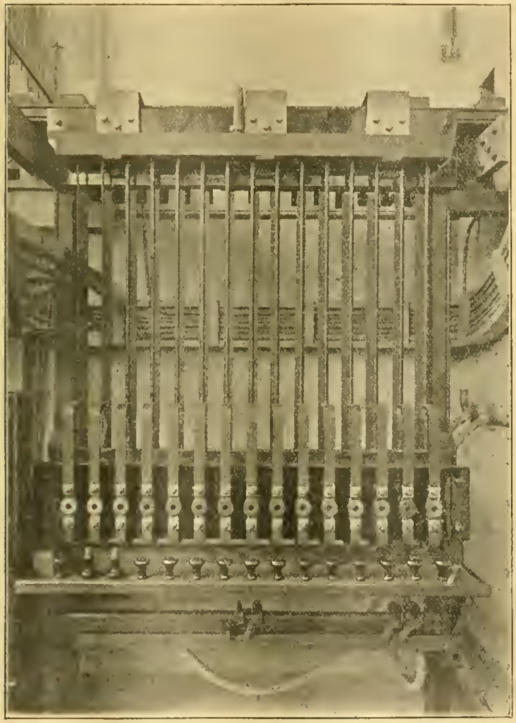

FIG. 3.—Water cooled regulating resistances—capacity 6000 amperes.

The instruments for alternating current standard work occupy the centre of the main bay (Fig. 1); on the right, under a platform to screen off light, are the two standard electrostatic voltmeters, reading up to 400 volts, on two approximately circular scales 26 feet in length, with an accuracy of 1 part in 10,000. Outside the building, on the opposite side of the main bay, is a small, entirely detached, fire-proof high-tension transformer house, to be occupied by the 100,000-volt transformer, with the aid of which it is proposed that Mr. Rayner should continue the valuable researches on insulating materials already published. Twelve-inch ducts carry the high-tension current into the large bay.

Fig. 2 gives a general view of an instrument testing station—or testing bench—at the east end of the large bay (see Fig. 1). The bench part of the stand in front is arranged as a cupboard with glass top, in which instruments of horizontal type can be tested at any temperature; for other purposes the glass can be covered with teak lids. The back compartment contains heating lamps and a fan for carrying the heated air to any part of the station, the upper part being arranged so that it can be covered with a thin celluloid cover. Above the station may be seen the main heavy current leads. In Fig. 3 are shown the water-cooled regulating resistances employed for heavy current work, of 6000 amperes capacity.

The resistance room, in charge of Mr. Melsom, contains arrangements for all high and low resistance work, except that on ultimate standards; for tests on cables, insulation testing sets, &c., and for dry-cell testing. For accommodating accumulators under test a small building has been erected outside the north wall.

Mr. Paterson and his collaborators have given the utmost attention to all detail throughout the building, the benefit of which will doubtless be felt as the work increases.

Although the development of the laboratory since 1901 has been rapid, it is clear that even now it has but barely reached its most active period of growth. The need and the value of the services it can render become progressively more apparent, and Dr. Glazebrook's able administration and untiring energy may be expected to produce even greater, if perhaps not so obvious, advances in the next seven years.

THE NORTH SEA FISHERIES INVESTIGATIONS.

WHEN the British Government in 1902 undertook to cooperate with other countries bordering on the North Sea in an investigation into the fisheries of that region, it delegated its share of the work in the north to the Scottish Fishery Board and in the south to the Marine Biological Association of the United Kingdom. The latter has now issued its second report upon the work done by its naturalists and hydrographer covering the period 1904–5.

Four papers are included, and the first is by Dr. Wallace on the age and growth-rate of plaice in the southern North Sea, and is the result of the application of a method of determining the age of the fish by the otolith or "ear-stone." Various attempts have been made to determine the age of fishes. The scales furnish some evidence, but in most cases, at any rate, they are hard to read. The otolith method, on the other hand, is easy, and much more rapid than the scale method.

The otolith shows on its surface a series of concentric rings alternately light and dark, and Reibisch in 1899 found that each light ring represented the growth of the otolith during the summer, while the dark rings represented winter growth. There seems to be no difference in structure in the alternate rings, the different appearance being produced entirely by a difference in the density of the substance. In the light opaque rings the particles are more closely packed, while in the dark more or less transparent rings the particles are farther apart. Since

Reibisch's discovery of the importance of these rings as an indication of the age of the individual fish, Redecke, Johansen, and Wallace have all independently proved the correctness of his discovery.

In the present paper Dr. Wallace applies the method to determine the rate of growth of the plaice, its distribution in relation to age, and other points of interest with regard to the habits and life of the species.

Previous to the application of this method the only means of getting approximately at the age of the fish was by measuring the length of large numbers of individuals and obtaining a frequency curve, but, as Dr. Wallace points out, this method had many disadvantages which are avoided by the otolith method.

By examination of the otoliths, not only is the average length for any age determined, but also the maximum and minimum lengths are obtained. The only assumption made is that all plaice emerge from the egg on April 1! Since the plaice only spawns once a year, and the spawning season at the most lasts three months, the error, owing to this assumption, is negligible.

Having determined the "age-groups," Dr. Wallace discusses their distribution in the area investigated, and in connection with this is brought out the existence of a "selective migration," that is, the distribution or sorting out of individuals according to size. The larger fish of the year tend to move into deeper water than the smaller. It is not a new observation that large fish are found in deeper water, but age is a factor which has not previously been taken into consideration. At any depth are to be found fish representing the larger ones of a recent year, the average sized ones of an earlier year, and the smaller ones of a still earlier year, and so on, but the bulk of the fish of any one size will belong to one particular year, so that at any given depth we shall find the fish of one particular year dominant.

Although this is the rule up to three or perhaps four years old, these older fish seem to be affected by other factors not yet sufficiently understood, as on apparently similar grounds the average size of the fish may differ considerably.

In discussing the average growth-rate of the plaice in the southern North Sea, Dr. Wallace points out that there is a different average growth-rate in the two sexes, and also that the longevity of the female is greater than that of the male. Up to five years of age the average number of males and females is apparently the same, but after that the males rapidly fall off in numbers, and in plaice of eight years old and upwards 91 per cent. are females. The males arrive at maturity one or even two years earlier than the females, and after seven years practically cease to grow.

Views of the concave (outer) surfaces of right otoliths of twenty-five plaice, mostly with four rings. Magnified about three times.

We reproduce one of the excellent series of photographs of otoliths taken by Mr. R. A. Todd, representing the right otoliths of twenty plaice. The fish were 27 cm. long, and the majority were four years old, as can be seen from the otoliths, which nearly all show four white rings.

Dr. Wallace's paper is somewhat difficult reading owing to the short paragraphs and frequent interpolation of tables, diagrams, and references. A short summary covering all the ground would, we think, in the circumstances have been specially useful.

Mr. R. A. Todd has continued his researches on the food of fishes, and some most valuable results are brought out by his laborious work. First he notes the fact that the younger fish of every species examined (thirty-four in all) chiefly depend upon crustacea for their sustenance, amphipods, cumacea, and decapod larvæ forming the chief food supplies.

Secondly, he shows that although in the young fish competition between all species may be great, in the adults competition is not nearly so keen, except in certain cases which he mentions. The chief food of all fishes appears to be fish, molluscs, and crustaceans, but a few species seem to favour echinoderms and cœlenterates as supplementary supplies. Competition is avoided by each species preferring some few particular species, which often seem to form its staple diet.

Mr. Todd's researches have led to some interesting observations as to a fasting period peculiar to one or two Pleuronectidæ. It seems that this is connected with the spawning period, as in the salmon, but in the case of the plaice it is chiefly the male which abstains from food, since on the spawning grounds "the greater the excess of ♂ over ♀ the greater the proportion of empty stomachs."

The report upon the plankton of the English Channel, by Dr. L. H. Gough, contains some interesting observations as to the causes of distribution. In spite of the fact that the minute organisms constituting the plankton are primarily dependent for their distribution on the water movements, there are two characteristic classes, the oceanic, found only away from land, and the neritic, found in shallow waters. Salinity was at first supposed to be the determining factor, it being thought that the oceanic forms could not survive in the fresher waters near the coast, but Dr. Gough points out that these forms are capable of withstanding a greater range of salinity than is to be met with in the region explored. The most recent theory to account for this distribution is that the decomposing organic matters in the shallower waters where bottom fauna and flora flourish are poisons to the oceanic species, whereas they are either innocuous to or possibly necessary for the neritic species.

The fourth paper in the report deals with the surface waters of the North Atlantic Ocean south of 60° N. lat. from September, 1904, to December, 1905. Mr. D. J. Matthews explains that the paper is almost entirely descriptive, giving an account of the distribution of surface salinity and temperature over a period of sixteen months. Samples of water have been obtained over a large area through the assistance of the captains of a number of steamers.

Even during the short period covered certain striking facts have been observed as to the movements of the waters. For instance, a distinct waxing and waning of the Labrador current has been detected.

Monthly charts showing temperature and salinity for the whole sixteen months add greatly to the interest of the paper.

The volume forms a valuable contribution to science.

Frank Balfour Browne.

EXTENSIONS AT UNIVERSITY COLLEGE, LONDON.

On Thursday last, March 26, the Chancellor of the University of London, the Earl of Rosebery, visited University College, the occasion being the opening of the new libraries and the south wing after the changes made consequent upon the removal of the boys' school to Hampstead.

The Chancellor on his arrival was met by the Vice-Chancellor (Sir William Collins), Sir Philip Magnus, Lord Reay, Sir Edward Busk, Sir Felix Schuster, Sir Arthur Rücker, Dr. T. Gregory Foster, Dr. Bourne Benson, the deans of the college faculties, and other members of the college committee. After an inspection of the alterations, the Chancellor proceeded to the botanical theatre and gave an address, formally declaring the new libraries and south wing open.

In his address Lord Rosebery said they met on a very interesting occasion, because they met to celebrate the fact that, owing to the removal of University College School, the accommodation of University College itself had been increased by fully one-third, and that therefore it had taken one more gigantic stride onward in its progress as a great centre of university life. To achieve this result great exertions had been made. No less than 270,000*l.* had been raised by the magnificent bounty of various donors. As a result of these donations there had been found room for scientific departments hitherto inadequately housed. There had been found room for an adequate museum and class-rooms for geology; a biometrical laboratory for research, which enabled Prof. Karl Pearson to continue his experiments in much more advantageous circumstances; a laboratory had been added of national eugenics (owing to the bounty of Mr. Francis Galton) which could not but be of great advantage to that portion of the curriculum. In the school of engineering a museum had been added, and a hydraulic laboratory. In the school of electrical engineering the accommodation had been doubled. The research laboratory of experimental psychology had been lodged in entirely new quarters. The department of hygiene had been greatly enlarged and largely equipped mainly by the generosity of the Chadwick trustees. In the faculty of arts eleven new lecture-rooms had been added. But perhaps the library was the most remarkable feature of the new enlargement. The method of arrangement required notice by everyone who was interested in that subject—a large general library and a series of specialised libraries in enclosed subdivisions which served as conference rooms for teachers and pupils.

Last, but not least, Lord Rosebery alluded to the extra accommodation for the students of the union. He honestly thought that no wiser thing could have been done by the authorities than to make their students feel it not merely a class-room, but a home, and to give them accommodation where they could spend their leisure hours as their elders did in clubs. He had reason to believe that the University College Debating Society was one of the most formidable of those academic parliaments which sometimes invited their seniors to address them on the principle, he thought, on which the Spartans were wont to place a drunken helot in their midst to serve as a melancholy example of what might happen to them if they did not stop in time. He also directed attention to the new recreation grounds and the residential hall at Ealing, which will be ready next October.

This was a record of manifold activities and of splendid beneficence. It inspired certain expectations in those who were interested in the work of University College and of the University of London. There they had a college which yielded to few colleges in the world in its appliances, situated in the midst of the greatest metropolis in the world, educating and rearing hundreds and hundreds of students, the centre of one form of university life in the metropolis. What a long way they were from the old Stinkumalee, as it was derisively called by Theodore Hook. Stinkumalee, he told his young hearers, was the atrocious name that was applied to University College in the days of its youth. Did it not show what an enormous march had been made by that college since the time when it was known by such a nickname as that?

The whole of London at this moment was teeming with university life. All this life irresistibly was drawn to the University of London. He was sometimes tempted to ask himself if the machinery of their university was adequate to the great strain that was being put upon it by the multiplications of the institutions that were under its fostering care. He sometimes doubted, if they were to undertake new tasks and burdens, whether their constitution was sufficiently elastic to undertake them. They had not all the power that tradition gave of the splendour of antiquity, but they had the advantage of the vigour, the adaptability of extreme youth. They were a new bottle into which new wine could be abundantly poured without risk. He pleaded that University College might not forget its youth, because its youth was its strength, and he thought it well that he should put this consideration before them, because the occasion was not a light one, either in the history of the University or of the College, because the visit of the symbolic head of the University to University College on that occasion emphasised and embodied the alliance between the University and a college which had so lately taken place, and from which he and they all augured such immense advantage in the future.

The thanks of the meeting to the Chancellor were accorded on the motion of the Vice-Chancellor, seconded by Lord Reay (the chairman of the college committee), and supported by the Provost, Dr. T. Gregory Foster. On leaving, Lord Rosebery shortly addressed the students in the cloisters, declaring that they had had good advice poured over them like pots of ointment, like spikenards of eloquence. He would only detain them then to point out that the University in the last resort depended upon the men it turned out. He asked them, and it was his only message for the day, to turn out ladies and gentlemen worthy of the University of London.

In addition to the outline given by Lord Rosebery, we may signalise more in detail the changes in the engineering departments. In general engineering the drawing office has been enlarged and arranged so as to provide separate junior and senior offices controllable from the same demonstrators' boxes. There is accommodation now for 100 students working at the same time. Space has been provided for an engineering museum, the equipment of which has already begun. A small engineering demonstration room has been added. In the electrical department the lecture theatre has been removed to a quieter position, and is now a more commodious room. An excellent research laboratory has been provided, where the professor and his students are continuing their researches on wireless telegraphy. These include the design and insertion of instruments for measuring electrical waves used in wireless telegraphy, dielectrics, and the photometry of electric lamps. A private room, a small demonstration room, and an adequate apparatus room have been added.

In the department of applied mathematics the extensions include a general research laboratory. At the present time an elaborate research in craniology is being carried out. There are 2500 crania in store, of which 1600 are Egyptian of about 1500 B.C. and 900 Egyptian of about 7000 B.C., sent at various times by Prof. Petrie from Egypt.

The department of experimental psychology has two new rooms with adjoining dark-room accommodation allotted to it. The experimental methods now deal with all the higher intellectual processes, including attention, memory, association of ideas, judgment, apperception, the emotions, and will.

In general, we may say that the alterations enable large portions of the work of the college to be carried out in greatly more favourable circumstances than hitherto. The rooms are provided and the workers also. Much, however, is still required in the way of equipment and of endowment of research, so as to enable this to be carried out in a thoroughly efficient manner.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Manchester.—By the death of the Duke of Devonshire the University has lost its Chancellor, and although it is only a few months ago that the late Duke was elected to this office, he had as president, first of the Owens College and latterly of the University, on many occasions taken an active part in forwarding the interests of the institution.

Under the will of the late Mrs. John Rylands, the University directly benefits by a legacy amounting to 75,000*l.*, and, in addition, the munificent endowment of the John Rylands library will be of great service to many engaged in literary study and research.

Two further recent bequests must be recorded. Mr. George Harrison, of Manchester, a retired cotton spinner, has left 10,000*l.* for the foundation of scholarships or fellowships, and Mrs. Margaret Stern, of East Barnet, 500*l.*

Prof. Ernest Rutherford, F.R.S., has been awarded the Bressa prize by the Academy of Science of Turin in recognition of the importance of his researches during the past three years.

Prof. W. Boyd Dawkins, F.R.S., has announced his intention of resigning the chair of geology, which he has held since 1874, at the end of the present session; he will, however, accept an honorary professorship and give special courses of lectures. Prof. Dawkins will continue to take an active part in the affairs of the Manchester Museum, in which he has taken so great an interest since he first came to Manchester in 1869 as its curator.

Lord Rayleigh will probably be elected to the vacant Chancellorship of the University of Cambridge in succession to the late Duke of Devonshire.

There will be an annual exhibition of students' work at the Borough Polytechnic Institute, Borough Road, S.E., on Saturday, April 4.

It is announced that Prof. A. Crum Brown, F.R.S., professor of chemistry in the University of Edinburgh, contemplates retiring at an early date from the chair which he has occupied since 1869.

Prof. P. J. White having been granted leave of absence for six months on account of ill-health, the Senate of the University College of North Wales has appointed Dr. W. A. Cunnington acting head of the department of zoology for the summer term.

The Department of Agriculture and Technical Instruction for Ireland issued recently in pamphlet form the lectures delivered during 1906 in connection with the department's scheme of short summer courses for teachers, and an account of technical instruction in Ballymena by Mr. P. F. Gillies, which appeared first in the department's Journal.

In connection with the forthcoming Franco-British Exhibition, a "children's week" is to be held. A number of French school children and their teachers, half of whom will represent secondary schools and half elementary schools, will be present. The scheme is receiving the support and sympathy of the French and British Governments, and careful preparations are being made to secure the comfort and health of the visitors. A daily educational course is to be given in the British section of education, in which both French and English children will participate. Physical exercises and games typical of both countries will take a prominent part. *Tableaux vivants*, in which the children of both nations will join, illustrating historical events and symbolical of the advantages of peace and the *entente cordiale*, will be another important item of the week's proceedings. The idea is excellent, and we are sure that no pains will be spared to make it a complete success.

In introducing in the House of Commons on Tuesday a Bill to make further provision with respect to university education in Ireland, the Chief Secretary for Ireland adopted Sir Norman Lockyer's plea for a two-power standard in education as well as in naval defence. He pointed out that the provision of adequate facilities for higher education is as necessary as the aim to be at least twice as strong at sea as any two foreign nations. A short visit to Strassburg would be sufficient to show what the people of Germany are doing for the people of Alsace, and would also show that foreign universities may do this country, during every hour of every day of the academic year, a considerable amount of injury by way of competition. Something has been done in England, Scotland, and Wales to supply this undoubted want. A number of teaching universities have of recent years sprung up among our great and murky towns—Manchester, Liverpool, Leeds, Sheffield, and Birmingham are now being associated in the minds of their younger citizens, not merely with docks and warehouses, not merely with shops and factories, least of all with gaols, lunatic asylums, and workhouses, but nobler structures from which are streaming forth the inspiring traditions, the ever-strengthening traditions, of university life and training. The Bill introduced proposes to establish two new universities in Ireland; these two universities to have their seats respectively in Dublin and in Belfast. In Belfast there will be but one college, the present Queen's College, and it will not be able to have any other, except, of course, by a subsequent Act of Parliament. Dublin will have three constituent colleges, and three only—Cork, Galway, and the new college, with a charter and an incorporated body in Dublin. The existing Royal University will be dissolved as from some appointed day, and its buildings, property, and endowments will be dealt with in a manner mentioned in the Bill. It is suggested, as a matter of finance, that the 20,000*l.* from the Irish Church Fund shall be divided into two equal parts, and that the university in Belfast shall take 10,000*l.* for maintenance and the new university in Dublin the other 10,000*l.* for maintenance. In addition to the present charge on the Irish Church Fund of 20,000*l.* there is a present charge upon the Exchequer of 36,500*l.*, which the Bill proposes to increase to 80,000*l.* This is the provision by way of new endowment, 43,500*l.* Belfast will thus get 10,000*l.* for its university, part of the Irish Church Fund; it will also have 18,000*l.* by way of annual endowment, making in all 28,000*l.* a year. The new college in Dublin has first of all to be built, and then endowed and maintained, and the proposal is that out of the moneys suggested 32,000*l.* a year shall endow and maintain the new university in Dublin when it has once been started. Then the income of the Queen's College, Cork, will be increased to 18,000*l.* a year, and the income of Queen's College, Galway, will be increased to 12,000*l.* a year. It is proposed also that a grant of 60,000*l.* should be made to the new University of Belfast to enable it to provide itself with a university worthy of the province to which it belongs. It is believed that a *maximum* sum for the purpose of the University and college in Dublin should be 150,000*l.*, which, it is hoped, will be sufficient first of all to complete the present university buildings.

SOCIETIES AND ACADEMIES.

London.

Zoological Society, March 17.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Some observations on the effects of pressure upon the direction of hair in mammals: Dr. W. **Kidd.** This paper was a sequel to other communications on the subject of the direction of hair, and consisted chiefly of the observed effects of the pressure of harness on certain regions of the coats of domestic horses. This pressure was shown to produce reversed areas of hair, and it was held that these results supported the view put forward in other papers that changes in the arrangement of hair are due to mechanical causes. Fifty-three cases were brought together, and eight different regions of the coats of the horse were shown in which the effects of pressure were found.—Mammals obtained by Mr. C. H. B. Grant in the Gorongoza Mountains, Portuguese S.E. Africa: O. **Thomas** and R. C. **Wroughton.** This was the ninth of the series of papers on the mammals of the Rudd Exploration of South Africa. One hundred and fifty specimens were dealt with, belonging to thirty-one species and subspecies, of which three were described as new.—Notes upon some species and geographical races of serows (Capricornis) and gorals (Næmorhedus), based upon specimens exhibited in the society's gardens: R. I. **Pocock.** It was pointed out that the "grey" goral of the Himalayas was originally described by Hardwicke as *Antilope goral*, and that the "brown" goral, to which the specific title *goral* has been applied in recent literature, required a new name. The author proposed to call it *Naemorhedus hodgsoni*. Concerning the genus Capricornis, he stated that although only one form had been hitherto distinguished from the Himalayas, the available material pointed to the existence of at least four subspecies in that mountain range.

Geological Society, March 18.—Prof. W. J. Sollas, F.R.S., president, in the chair.—The Carboniferous rocks at Loughshinny (county Dublin), with an account of the faunal succession and correlation: Dr. C. A. **Matley** and Dr. A. **Vaughan.** After an introduction recalling the succession at Rush, already described by the authors, a detailed account is furnished of the various sections in the Loughshinny area. About 1100 feet of Carboniferous rocks are exposed. They consist mainly of limestone, but also include a thick mass of conglomerate and many intercalated beds of shale and chert. The rocks have been much folded, and to some extent faulted. The lowest rocks belong to some part of the Dibunophyllum zone, the higher range through Cyathaxonia beds into Posidonomya Limestones and shales of Pendleside age. The Lane Conglomerate may be on or near the horizon of the Rush Conglomerate. Local decalcification has caused the more or less complete disappearance of some of the Cyathaxonia and Posidonomya Limestones. The region was close to an old shore-line of the Carboniferous Limestone Sea, the actual position of which appears to have been almost parallel to, and a short distance seaward of, the present coast-line between Rush and Skerries.—A note on the petrology and physiography of Western Liberia (West Coast of Africa): J. **Parkinson.** The country is low-lying, with a gradual rise northward from shore-level, and rivers mature in character with alluvial flats raised above flood-level. Where the River Tuma falls into the River St. Paul the remnant of a hanging valley can be seen. Flat-topped ridges and isolated hills trending parallel to the foliation of the gneiss are characteristic of the country around Sanoyei and Boporo. There is a striking absence of late deposits of old gravels and sands. In the southern part of the district there are indications of a series of garnetiferous gneisses, tremolite schists, kyanite schists or gneisses, garnet-graphite gneisses, &c., associated with others of granitic type, the latter being apparently free from microcline and containing a pleochroic pyroxene. These rocks are replaced in the north by biotite gneisses and hornblende schists, which have an approximate and singularly constant east-and-west (magnetic) strike in their foliation. Microcline is common. These old crystalline rocks are cut by an extensive series of basalts and ophitic dolerites, resembling so closely the post-Cretaceous dykes of Southern Nigeria that it is difficult to avoid the conclusion that they are of the same age.

Linnean Society, March 19.—Mr. H. W. Monckton, treasurer and vice-president, in the chair.—*Exhibits* (by permission of the director, Royal Botanic Gardens, Kew).—W. B. **Hemsley**: A second specimen of *Platanthera chlorantha* with three spurs. The plant exhibited a spike, each flower of which had the three petals spurred, a case of true peloria, whereas the specimen shown on January 17, 1907, had the three sepals spurred, a case of false peloria.—T. A. **Sprague**: Female flowers and fruits of *Sterculia Alexandri*, Harv., an extremely rare tree from Uitenhage, the only locality known for it.—C. H. **Wright**: Specimens of (*a*) *Sphaerothylax algiformis*, Bisch., a rare South African podostemaceous plant; (*b*) *Archangiopteris Henryi*, Christ and Gilsenh., a Chinese genus of Marattiaceæ, of which a better supply of material had been recently obtained.—*Papers*.—The Podostomata (=Pycnogonida) of the temperate Atlantic and Arctic Oceans: Canon A. M. **Norman.** The classification of Sars had been adopted, and the paper itself contained a complete enumeration of the group within the regions specified.—Amphipoda Gammaridea from the Indian Ocean, British East Africa, and the Red Sea: A. O. **Walker.** The total number of species from the three collections was fifty, in thirty-six genera, seven being new to science, and one being the type of a new genus.—A revision of the genus Codonopsis: T. F. **Chipp.** The author included the genus Glosocomia of D. Don, and other species which could not well be assigned to either. The genus was divided into four sections, dependent upon the attachment and insertion of the corolla and calyx. Finally, the distribution of this genus along the mountain ranges of Asia was described and illustrated by a map on the screen.—The Holothurians of the Sudanese Red Sea: E. **Hindle.**

PARIS.

Academy of Sciences, March 25. M. H. Becquerel in the chair.—The theory of flow over a vertical thin edge and without lateral contraction: J. **Boussinesq.** The results of the theoretical investigation of the author are compared with the empirical formula of Bazin, the latter representing numerous experiments. The agreement is moderately satisfactory.—The theory of electrocapillarity: M. **Gouy.**—The determination, at the Observatory of Paris, of the systematic errors in the reproductions of the *réseaux* of the chart of the heavens: Jules **Baillaud.**—The applicability and various modes of representation of surfaces with coinciding lines of curvature: L. **Raffy.**—The application of an alternative method to the biharmonic problem: S. **Zaremba.**—Remark concerning a note on the differential equations of an electrified corpuscle in a magnetic field: Carl **Störmer.**—The gases arising from electric sparks: M. **de Broglie.** It has been shown by de Watteville and Hemsalech that if the air supply of a Bunsen burner passes over two metallic terminals between which electric sparks are passed, the flame of the burner gives the spectrum of the metal of the electrodes. The author has examined air thus treated, and finds it to contain ions of feeble mobility (about 10 μ per second in a field of 1 volt per cm.), neutral centres capable of being transformed into ions of feeble mobility by exposure to radium or Röntgen rays, and fine particles visible in a strong beam of light. The last are in part electrified, and probably constitute the chief source of the spectrum obtained.—The absorption spectra of crystals of the rare earths in a magnetic field at the temperatures of the liquefaction and solidification of hydrogen: Jean **Becquerel** and H. Kamerlingh **Onnes.** Previous work at temperatures down to $-190°$ C. has shown that the size of the bands varies proportionally to the square root of the temperature. At $-259°$ C. the majority of the bands no longer follow this simple law. Two of the bands from xenotime appear to pass through a minimum, and are wider at $-259°$ C. than at $-253°$ C. A few of the bands, however, appear to follow the same law as down to $-190°$ C. Down to the temperature of liquid air, all the bands show an increase of intensity corresponding to an increase of absorption. This does not hold for lower temperatures, and for each band there is a temperature at which the absorption passes through a maximum.—The detection of minute quantities of helium in minerals: F. **Bordas.** The exhaustion is carried out by means of charcoal cooled to the temperature of liquid air, and a Plücker tube is interposed between the vessel in which the mineral is heated and the charcoal vessels. The helium being much less readily absorbed by the cooled charcoal, very minute quantities can be detected. Helium has been recognised in this apparatus in 0·02 gram of Japanese naegeite. The photography of the vibrations of the voice: M. **Marage.** The vibrations fall on a thin membrane of india-rubber, and are transmitted from this to a small plane mirror. Two reproductions of the photographs obtained accompany the paper. The apparatus, once set, can unroll, expose, develop, and fix 25 metres of paper without any manipulation. Various suggestions are made for practical applications.—Some examples of lines presenting a Zeeman phenomenon abnormal in the sense of the magnetic lines of force: A. **Dufour.** The second spectrum of hydrogen is formed of three types of line, the first being unacted on in the field, the second giving the ordinary Zeeman effect, and the third the abnormal Zeeman effect.—The action of chlorine upon dithymol: H. **Cousin.** The products of the action are a dichlorothymol, a dichlorothymoquinone, and a dichloride of the latter compound.—Some derivatives of phenylisoxazolone: A. **Wahl** and André **Meyer.** Condensation is readily effected between phenylisoxazolone and aromatic aldehydes, the product being precipitated in nearly quantitative yield.—The products of the action of aluminium chloride and hydrochloric acid gas on benzene: G. **Gustavson.** Methyl-phenyl*cyclo*pentane has been isolated from the numerous products of this reaction.—Some derivatives of thiophene: V. **Thomas.** Magnesium acts on α-iodothiophene in presence of ether, giving an organomagnesium compound which behaves similarly to phenyl magnesium iodide in many of its reactions. Details of the products resulting from the action of various ketones are given.—The formation of acetic aldehyde in alcoholic fermentations: A. **Trillat.** The experiments described prove that acetic aldehyde is not a true product of fermentation, since if the fermentation is carried out in the presence of hydrogen or carbon dioxide, air being carefully excluded, no aldehyde can be detected. If air is freely admitted during the fermentation, more aldehyde is produced than if a little air is present.—The production of gum in the Moringa: F. **Jadin** and Volcy **Boucher.**—The phytology of the eastern region of Kabylie and Djurdjura: G. **Lapie.**—The levers in the organism: A. **Guillemin.** A discussion of the efficiency of the leg muscles and bones considered as levers.—The discovery of Palæolithic paintings of man and animals in the Portel cave: René **Jeannel.** More than forty paintings of animals and human beings have been found on the walls of this cave. None of the designs have been cut into the rock, and they are coloured either black or red, both in line and flat wash. Some of the objects are partially masked by stalagmitic deposit. Two designs represent man on foot in profile; others represent bison, reindeer, and horses, the last being the most numerous. Photographs have been taken of some of the objects, and the remainder will be photographed shortly.—Anemometric studies of helices copied from animals: Paul **Amans.**—The Pliocene and Pleistocene eruptions of Limagne: Ph. **Glangeaud.**—Contribution to the study of the solar calorific radiation: C. **Féry** and G. **Millochau.**

DIARY OF SOCIETIES.

THURSDAY, April 2.

Royal Society, at 4.30.—Complete Survey of the Cell Lamination of the Cerebral Cortex of the Lemur: Dr. F. W. Mott, F.R.S., and Miss A. M. Kelley.—The Alcoholic Ferment of Yeast Juice. Part III The Function of Phosphates in the Fermentation of Glucose by Yeast Juice: A. Harden and W. J. Young.—The Antagonistic Action of Calcium upon the Inhibitory Effect of Magnesium: S. J. Meltzer and J. Auer.—Studies on Enzyme Action, XI., The Hydrolysis of Raffinose. XII., Emulsin: Prof. H. E. Armstrong, F.R.S., and others.
Royal Institution, at 3.—The Animals of Africa: R. Lydekker, F.R.S.

CONTENTS.

THURSDAY, APRIL 9, 1908.

EXPERIMENTAL EMBRYOLOGY.

Experimental-Zoologie. Part i. Embryogenese. Eine Zusammenfassung der durch Versuche ermittelten Gesetzmässigkeiten tierischer Ei-Entwicklung (Befruchtung, Furchung, Organbildung). By Dr. Hans Przibram. Pp. 125; 16 plates. (Leipzig und Wien: Franz Deuticke, 1907.) Price 7 marks.

SOME three years ago Dr. Przibram, who is well known as a brilliant representative of the school of experimental zoologists, published "An Introduction to Experimental Morphology," which met with wide acceptance. The present volume is an expansion of part of the "Introduction," and forms an independent treatise on experimental embryology. It is to be followed by four other parts, dealing with regeneration, evolution, vitality, and function, and the whole will form a text-book of experimental zoology. If the subsequent parts are like the one before us in lucidity and thoroughness, Dr. Przibram will earn the gratitude of all interested in this dynamic aspect of the science; and who, nowadays, can afford to stand aloof? The present volume discusses, in the light of experimental results, the processes of fertilisation, cleavage, gastrulation, and differentiation, and sums up in an analysis of the influence of chemical stimuli, moisture, density of the medium, pressure, gravity, electricity and magnetism, light and heat. There is a copious and carefully executed bibliography, and the figures in the plates, which are partly compiled and partly original, are very clear and interesting.

The author discusses large and difficult problems, in regard to which there is room for considerable difference of opinion, but his treatment of these is thoroughly objective and undogmatic. We cannot do better than give some samples of his general conclusions. Fertilisation, whether artificial or spermatic, brings about a withdrawal of water from the egg; this accelerates the vital processes which are going on of themselves, and the egg passes from a relatively resting state to progressive development. The unfertilised egg has an organisation of different kinds of substances which guarantees the forthcoming manifoldness. The direction of the first cleavage is in a plane at right angles to the axis of the first karyokinetic spindle, and the position of the latter is determined by the geometrical architecture of the egg and the fertilisation-meridian (on which the spermatozoon enters).

In regard to the familiar sequence of centrosome division, astrosphere formation, nuclear division, cytoplasmic division, and perhaps also the progressive differentiation of the blastomeres, we must not suppose that any particular link in the chain is the necessary cause of the next link; we must rather suppose that a common cause evokes them in succession, and that their cooperation secures the typical development. Provisionally we may say that the common cause of the mitotic phenomena lies in a localised change in the fluidity of the enchylemma and the associated rearrangement of a monocentric into a dicentric surface-tension-system. The second and subsequent cleavages depend on a rhythmic recurrence of the metabolic relations involved in the first cleavage (the entrance of oxygen conditioning the continuance of the metabolism, the intensity of which changes with the changes in the proportion of absorbent surface to assimilatory volume), and on the presence of antagonistic substances, which partly prevent the complete separation of the blastomeres (calcium), and partly secure a certain cohesion (sodium).

The arrangement of the blastomeres depends on Plateau's law of the smallest surface, modified by differences in the consistence of different parts of the ovum, which are also responsible for the different sizes of the blastomeres (Balfour's law). Blastulation and gastrulation depend on chemotactic influences, which are set at work by metabolic processes, and admit not only of passive-mechanical displacements, but of active migrations as well. In different zones of the egg there are chemically different substances which normally condition the differentiation of the various organs. Thus the blastomeres acquire a prospective value. If there is no rearrangement of material, an artificial fractioning of the egg is followed by a self-differentiation of the fragments, so that semi-embryos, quarto-embryos, and so on, result; but if a re-arrangement is effected, restoring the *status quo* of the intact ovum, then dwarf complete embryos result. The prospective potency of such blastomeres is greater than their prospective value. The influence of external factors is subsidiary when compared with the internal formative factors, and animal embryogenesis may be described as an almost quite perfect self-differentiation in Roux's sense.

We have stated these general conclusions because of their great interest, but it must be noted that the bulk of the book is a terse statement of concrete facts from which the expert student may draw his own conclusions, and at this stage that is well.

J. A. T.

GEOLOGICAL REVIVALISM.

Geologische Prinzipienfragen. By E. Reyer. Pp. x+202. (Leipzig: W. Engelmann, 1907.) Price 4.40 marks.

THIS work recalls, with renewed interest, a remarkable paper by Mr. Reyer on the Schlossberg of Teplitz, to which the attention of the present writer was directed by Prof. Judd nearly thirty years ago. Are not some of Reyer's models still preserved in London, and have not these models, and respectful visits to the Schlossberg itself, influenced many of us in our attempts at teaching ever since? Mr. Reyer, however, when he went further into the theory of the formation of mountains by the protrusion of masses from below and the gliding of the superincumbent layers, found the geological world opposed to him, and he turned, as he now informs us (p. v.), to fields of sociological activity. Yet he should surely be satisfied with the numerous references to his work, especially on volcanic questions, in Zittel's "History of Geology" or Geikie's monumental "Text-book." Ampferer's recent exposition of "Unterströmung," moreover, as a cause of mountain-crumpling comes very near in many of its details, though not in its foundations, to Reyer's theory of superficial "Strömung" (see Nature, vol. lxxvi., 1907, p. 423). Though Ampferer quotes very few authorities, it seems likely that Reyer's views are still fructifying, even if they bear forbidden fruit. At any rate, we may welcome his return to the arena at a time when no champion can assert that his own views on mountain-building have satisfied all known conditions.

Mr. Reyer himself, in this clearly-written treatise, proposes to leave his statements and arguments unburdened by a bibliography. The numerous illustrative diagrams suggest in most cases drawings made from models, and some of them represent the results of experiments performed in plastic materials. There is a freshness of exposition that brings home to us many facts that are familiar, but which are often liable to be passed over without adequate consideration. The exposition itself is, if we may say so, diagrammatic. The author points out very early how delta-deposits slide upon the rocks beneath them, and how a loose valley-side moves out towards the river, which carries away the material, and thus renders the land-flow less apparent. From p. 52 onward we read of massive extrusions of material from the molten interior of the earth, and we remember the sliding of the deltas when we are asked to picture successive extrusions as lifting the crust above them and allowing of a lateral slip of the ruptured sedimentary layers. The great difference between these postulated extrusions and our common notions of intrusive bodies appears to lie in their long-continued and successive character, whereby a later igneous mass causes a previous one to bulge up and swell out as a coat, through which the later mass may break. It is urged that if this occurs below a deep ocean, the extruded matter may become as crystalline as granite, and subsequent sediments may be laid down on it with a false appearance of having been invaded.

All this should probably be kept in mind, but we doubt if the average field-observer has been so often misled as Mr. Reyer would wish us to believe. He opposes the idea of the differentiation of a common igneous magma (p. 61), since acid and basic magmas must have separated early in the history of a cooling globe, and massive protrusions are likely to mix them up again, so as to produce the phenomena observed. Such protrusions or extrusions are held to be sufficient to explain the existence of infolds of sediments between adjacent igneous masses (pp. 69 and 155); and an admitted revival of the "crater of elevation" theory appears on p. 73. There is much in the book that is in pleasant accord with the views consistently maintained in Britain in regard to the relations of various types of igneous rock; and the principle of successive extrusions (or may we say intrusions?) has been adopted, to mention only two examples, by Prof. Sollas for the Leinster Chain and by Dr. Harker for the gabbros of the Cuillin Hills.

Mr. Reyer's views cannot fail to make us think more carefully, and we trust that his book will be widely read by those who have to interpret the history of great regions of the crust. We may hereafter be grateful to him for maintaining the theory of gravitational gliding (pp. 142, 147, &c.) as opposed to the crumpling of strata by lateral thrust against the influence of gravitation. In this respect he has relighted a very ancient candle, which burnt brightly in Scrope's hands in 1825 ("Considerations on Volcanos," pp. 201–2). It will now, in all probability, never be entirely put out. Grenville A. J. Cole.

HYDRAULICS.

Hydraulics. By F. C. Lea. Pp. xii + 536. (London: Edward Arnold, 1908.) Price 18*s*. net.

WHATEVER may be the extent to which the science of hydraulics was neglected during the century which elapsed between the theoretical researches of Bernouilli and the practical applications of Armstrong, it cannot be urged that there is any lack of attention to the subject at the present time, if one be permitted to judge from the number of text-books which have appeared within recent years, and even within the last few months. So striking an output must surely be fraught with great potentialities.

The science of hydraulics has a field which is somewhat vague and ill-defined, and is of greater or less extent according to the views of different writers. Originally, the definition of the term only covered a reference to the laws which governed the motion of fluids in pipes and water-courses. Then it was extended to include the use of water for motive purposes, and the means and appliances by which that end was achieved. Other developments have followed, and now it is rare to find two text-books covering even approximately the same ground, or agreeing in respect of either limits or order of treatment. We are acquainted with one treatise which includes within its purview the principles of lubrication; with another which regards what is commonly differentiated as the science of pneumatics as a constituent section; with a third which ignores the motion of bodies in fluids; and so on.

The range of the treatise under consideration, though not so extreme as in some cases, is nevertheless exceedingly comprehensive, and it may be added that the treatment is very complete. In view of the license to which allusion has just been made, we do not presume to offer any criticism on the propriety of presenting the elementary principles of hydrostatics as an introduction to the subject; we ourselves should hardly have thought of referring to a text-book on hydraulics for them. No doubt it is useful for the student to have his memory refreshed on fundamentals, though he may not unreasonably be supposed to have acquired a competent knowledge of them elsewhere. Still, there they are for consultation, if required, and they form a not inapt introduction.

The laws governing floating bodies are touched upon, and investigation is carried so far as to cover the eminently practical and up-to-date case of the floating dock. From these considerations, the author proceeds to deal with the subject of fluids in motion, which constitutes the essential feature of the book. He makes Bernouilli's theorem his starting-point, following on to Torricelli's law and the theory of flow through mouthpieces with the coefficients due to various forms of orifice. Then, having dealt with weirs, he directs his attention to fluid flow through pipes and channels, explaining the well-known basic formula,

$$v=c\sqrt{mi},$$

and quoting the values assigned to the coefficient by Chezy, Bazin, Darcy, Ganguillet and Kutter, and others. This brings us to chapter vii., in which we find a description of the methods adopted for gauging the flow of water through an orifice, in streams and in pipes, including a brief reference to Stromeyer's suggestion for the use of a chemical agent. Chapter viii. treats of the impact of water on vanes, and thence it is a natural transition to water-wheels and turbines in chapter ix. Both this chapter and the following, on pumps, are very full and explicit, and are effectively illustrated by a number of typical examples. Chapter xi. is devoted to an exemplification of the application of hydraulic power to industrial purposes by means of various machines. In two short concluding chapters the author deals with the modern investigation of stream-line flow and the resistance to motion of bodies in water.

An admirable feature of the work is the large number of worked numerical examples. The type is clear and the illustrations are good. Altogether the work forms an excellent text-book, and is cordially to be recommended to students of this most interesting and useful science.

TECHNICAL CHEMICAL ANALYSIS.

Traité complet d'Analyse chimique appliquée aux Essais industriels. By J. Post and B. Neumann. Second French edition, by Dr. L. Gautier. Vol. i., part i. (pp. 217, price 6.50 francs). Vol. ii., part i. (pp. 202, price 6 francs). (Paris: Librairie scientifique, A Hermann, 1907–8.)

THE present review is concerned with the first two instalments of the second French edition of a German treatise on technical chemical analysis, which has already passed through three editions in the original. The complete work will consist of two volumes divided into eight sections, each section dealing with some special branch of analytical practice, and the editors have secured the cooperation of some twenty-seven eminent contributors in order that the various chapters may embody the results of the latest experience. Judging by the style of the first two sections, now before us, it would appear that the editors are aiming rather at a clear and succinct outline of contemporary analytical method, and of the general nature of the materials to which they are applied, than at an elaborate and detailed treatise. Subject to this proviso, they may be congratulated on having so far achieved a considerable measure of success, and their efforts may be commended to British chemists who feel the need of a manual of this description.

Vol. i., part i., deals with such subjects as water, solid fuels, pyrometry, and gas analysis in a fairly complete and satisfactory manner. The opening chapter on water analysis (pp. 1–38), by Dr. H. Vogel, of Berlin, is somewhat too compressed and desultory to be of real use, and might be advantageously enlarged in future editions. Then follows an excellent *résumé* by Dr. H. Langbein of the methods in vogue for the chemical analysis and calorific valuation of solid fuels (pp. 39–73); the value of this chapter would have been enhanced by a fuller treatment of the ash analysis of coals and its importance in relation to the various uses of the raw fuel. The third chapter, by Prof. B. Neumann, of Darmstadt, on pyrometry (pp. 74–126), deals very completely with the various thermoelectrical and optical methods used in technical practice, and so far as these methods are concerned the treatment of the subject is all that could be desired. The scanty references to the air thermometer and to electrical resistance methods are, however, to be regretted.

The concluding chapter, on gas analysis (pp. 127–217), also by Prof. Neumann, is disappointing in that it deals with little else than the crude and untrustworthy methods of Hempel and Orsat (or various modifications of them), which have long been the despair of workers, who instinctively demand something both accurate and convenient, and which, we had hoped, were being rapidly discarded in technical laboratories. In these days, when the applications of gaseous fuels are increasing daily, the introduction of really accurate methods of gas analysis in technical practice is fast becoming an urgent necessity, and it is quite a mistaken notion that methods of precision are necessarily inconvenient or tedious, and therefore unsuited to the exigencies of a works laboratory. The opinion of Dreschmidt, quoted on p. 136, as to the incompleteness of the absorption of carbonic oxide by an ammoniacal solution of cuprous chloride may be disputed, since it can easily be demonstrated that a properly prepared and *fresh* solution will absorb the gas almost as rapidly, and, for all practical purposes, as completely, as a caustic alkali absorbs carbon dioxide. It may also be remarked that there is no reference to gas calorimetry in this chapter.

Vol. ii., part i., dealing with the physical, mechanical, and chemical testing of limestones, mortars, cements, ceramic products, glass, and the like, has been entrusted to Drs. H. Seger and E. Cramer, of Berlin. Their treatment of the subject is admirably clear and succinct, and will certainly be appreciated by all general readers. Whilst there is nothing very new, good judgment has been exercised in selecting the best methods and appliances, and the whole is a singularly well-balanced production, and eminently readable. The one fault to be found with their work is the paucity of the references to analytical literature.

The two sections are clearly printed and admirably illustrated, but, as is unfortunately the case with the majority of chemical treatises published on the Continent, references to British work and authorities are conspicuous by their absence. W. A. B.

BRITISH ARCHÆOLOGISTS IN ITALY.

Papers of the British School at Rome. Vol. iv. Pp. x+296; illustrated. (London: Macmillan and Co., Ltd., 1907.) Price 31*s.* 6*d.* net.

THE "Papers of the British School at Rome," while similar in format, are not similar in form to the "Annals of the British School at Rome," nor can they be precisely similar in content, since the pleasure of chronicling the results of actual excavations is denied to the director of the British School at Rome. Let us always gratefully recognise the greater liberality of the Hellenic authorities and the greater tolerance of the Greek archæologists, who, while naturally and rightly desirous of keeping Greek antiquities in Greece, at the same time recognise the fact that the antiquities of classic Greece and Rome are the heritage of the whole civilised world, not of one country alone, and admit that the privilege of searching for them should be freely extended to all who have the money and the will to carry out the work. Some day, perhaps, the Italians will do likewise. Until then, British archæologists in Italy are confined to the contemplative life, and can do little more than write papers of the type presented in the volume under review.

The director, Mr. Thomas Ashby, most approaches the standard of the practical work of the Athens school in his very interesting paper on the "Classical Topography of the Roman Campagna," which is illustrated by good photographs, perhaps somewhat unnecessarily reproduced abroad, either in France or Italy, as the lettering beneath them shows. Probably we hardly realise how intensely hideous was the Roman style of country-house architecture, until we see such a place as Sette Bassi, which Mr. Ashby illustrates. It must have looked exactly like a warehouse, or, more probably, a piano factory. All the beauty and grace of "classical" architecture is Greek; the Romans were by nature as inclined to unredeemed utilitarian ugliness in their architecture as are the Germans or ourselves. Of the other papers, Mr. A. J. B. Wace's "Studies in Roman Historical Reliefs" is an interesting piece of critical work. Mr. Yeames, late of the British Museum, assistant director of the school, has some interesting remarks on Roman art of the post-Antonine period (first half of the third century A.D.) as exemplified in a small ivory statuette of a *gobbo* or hunchback in the British Museum.

The last paper, and in some ways the most important, is on "The Early Iron Age in South Italy," by Mr. T. E. Peet, who reaches interesting conclusions. In his preface the director says that the papers

"of Mr. Yeames and Mr. Peet, the latter especially, though still belonging to the archæological sphere, deal with departments of it which have not previously found a place in the Papers of the School."

Since to the minds of many the department of archæology represented by Mr. Peet's paper seems the most important of all, it is to be hoped that no future Papers of the School at Rome will fail to contain some contribution on the prehistoric antiquities of Italy, about which we want to know far more than we do at present. H. H.

OUR BOOK SHELF.

Armature Construction. By H. M. Hobart and A. G. Ellis. Pp. ix+348. (London: Whittaker and Co., 1907.) Price 15*s.* net.

THE widespread use of dynamo electric machinery for all sorts of purposes is sufficient justification, if such be required, of treatises dealing with the design and construction of such machinery. Many books have been written on this subject, but we believe this is the first time that a complete volume has been devoted to the consideration of the construction of what is, perhaps, the most important part of any dynamo, viz. the armature.

To those who know anything of this class of machinery, it will be obvious that there is ample scope for a writer with first-hand knowledge to compile an interesting and valuable book; to mention only one point, the practical construction of a good commutator is a process full of interest. The book before us will certainly repay careful study in spite of a certain lack of proportion which is very noticeable.

A very brief summary of the contents is as follows: The first seven chapters describe the various workshop processes whereby the mechanical parts of the armature are built up, that is to say, the armature stampings, the spider, and the commutator; the next two chapters are devoted to armature windings for direct-current machines and for alternators, treated diagrammatically; and the last four chapters to the methods of winding and to finishing and testing. When it is stated that 172 pages (including full-page illustrations) out of a total of about 390 are devoted to winding diagrams alone, it will be apparent that the authors have allowed their enthusiasm for such diagrams to get the better of their judgment. There is no doubt that the subject is of great interest, but in the opinion of the present writer the two lengthy chapters devoted to it are quite out of place in such a work; in so far as explanations are necessary for the proper understanding of subsequent chapters, three or four pages would be ample to furnish all that are required.

The chapters that deal with construction pure and simple are well written and illustrated, and contain a large quantity of valuable information. Chapter ii., on armature laminations, is perhaps the best in the book, and contains specifications for the composition of suitable steel; the various methods of testing the quality of the steel are described, and constants are given which may be taken as satisfactory. The process of stamping the core plates is given in detail, and is illustrated with a number of photographs of slotting presses and other tools. The other chapters are also full of interest, and, but for the error of judgment mentioned above, the whole book might be unreservedly recommended to those who from one cause or another are concerned with the practical details of armature construction.

The Dancing Mouse; a Study in Animal Behaviour. By Robert M. Yerkes. Pp. xxi+290. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1907.) Price 5*s.* net.

The most characteristic feature of the best psychology of the present day is the tendency to look for much of the explanation of mental life in its antecedents and surroundings. The older individualistic position is being rapidly left behind. The continuity of mind is now as clearly recognised as the continuity of life. Lower forms of mental activity, in the race no less than in the individual, are found to throw much light upon the nature of developed human consciousness. Such forms are, however, matters of inference, not of direct observation; it is therefore not surprising that the science of comparative psychology is so far from keeping pace with its elder brother, comparative anatomy. The work thus far done has been of a somewhat sporadic nature, in one prominent case, at least, vitiated by faulty psychological theory. More decided progress may be looked for in the application of the experimental method.

Dr. Yerkes's book on the Japanese dancing mouse, the first of a series to be devoted to the study of animal behaviour, is an excellent example of this plan of procedure. A very full description is given of the two principal forms of test employed, viz., the light-discrimination test and the labyrinth test. The former was employed to investigate not only the visual discrimination of the animal, but also its powers of learning by experience and of retaining the lessons thus learnt. As "motive" to the use of the discriminative faculty, Dr. Yerkes employed punishment, in the form of mild electric shocks for mistakes made, considering this not only more humane than the motive of hunger usually employed in such experiments, but also better adapted to the peculiarities of behaviour of the animal, viz., its superabundant activity. Here the criticism at once suggests itself that such a mode of procedure would probably encourage a mechanical production of habit in the animal, and fail to stimulate any germs of higher mental faculty that might be present. The results obtained certainly fail to show the presence of any reasoning power above sense discrimination. Even the inference to power of discrimination may not be completely justified. Sense-differentiation and the mechanical working of hedonic selection would seem able to account for all the facts. Yet the mice might have been capable of higher mental processes, *e.g.* in terms of kinæsthetic imagery, which the experiments failed to call into operation owing to the insufficiency of the stimulus or motive employed.

Apart from its value as a contribution to science, the book is an extremely readable one, and is, moreover, admirably bound and printed. W. B.

Studies in the Medicine of Ancient India. Part i., Osteology, or the Bones of the Human Body. By Dr. A. F. Rudolf Hoernle, C.I.E. Pp. xii+252. (Oxford: Clarendon Press, 1907.) Price 10*s.* 6*d.*

Some time ago, when Dr. Hoernle was preparing an edition of two old Indian medical tracts, preserved in the Bower manuscript of the fifth century A.D., he was surprised to find how little we knew of medicine as taught and practised in Ancient India. The volume under review is the first fruit of a resolve to make good that deficiency in the history of medicine so far as it can now be made good by a study of existing manuscripts and documents. Of the three systems of medicine which have come down to us the most ancient is that ascribed to Ātreya, a physician who is assigned by Dr. Hoernle to the sixth century B.C.; the system ascribed to Susruta, the surgeon, is nearly as ancient; the third system, that of Vāgbhaṭa, the Galen of the mediæval East, as Dr. Hoernle describes him, dates from the seventh century A.D., and is a compound of the two older systems.

Evidently amongst the ancient Indians, as among medical men of to-day, a knowledge of the bones was regarded as fundamental in the study of medicine. In the system of Ātreya the number of bones in the human body is given as 360 (the nails, teeth, and *tooth sockets* are counted as separate bones); in that of Suśruta 300, while in Vāgbhata's system they number 360. In modern text-books of anatomy the number of bones is variously estimated from 200 to 214, the number varying according to the inclusion or exclusion of certain small bones and some which are only occasionally present. The ancient Indian anatomist shows an intimate knowledge of animal tissues in classifying the cartilages with bones; he regarded cartilage as an immature form of bone. In the course of transcription the text naturally became corrupt; for instance, in Ātreya's system the two *humeri*, four wrist bones and two eyes (their outer coat was believed to be cartilaginous, hence they were classified as bones) came to be omitted, but the total number of 360 was made good by increasing the number of face and neck bones. In all three systems the thumb is stated to have three joints or phalanges; Dr. Hoernle points out that a similar mistake is made in the summary of bones given in the Talmud. The Talmudic summary, probably derived from the Greek school at Alexandria, follows very closely the systems of Ancient India. How far the systems of medicine amongst the early Greeks and the Ancient Indians were related cannot yet be estimated; thanks to the labours of Dr. Hoernle we know much more of the systems practised amongst the Indians than amongst the Greeks.

Altogether Dr. Hoernle, although not a medical man himself, has laid medical men under a deep obligation to him by rendering so easily accessible the knowledge and practice of physicians who tended the sick in northern India some centuries before Christ was born.

The Sea-shore, Shown to the Children. By Janet Harvey Kelman. Described by Rev. Theodore Wood. Pp. xi+146; with 48 coloured plates. (London and Edinburgh: T. C. and E. C. Jack, n.d.) Price 2*s.* 6*d.* net.

This book belongs to the "Shown to the Children" series, and consists of forty-eight coloured plates with a short description written in the simplest possible language of each of the subjects depicted.

From such an immense choice of material it was no doubt difficult to decide what should be described and what left out, but, on the whole, we think that the choice has been a very good one. The chief objection to the book is the use of English names for most of the objects described. Some of these names are unfamiliar to us, while others are surely local. In some cases the generic name has been used, *e.g.* Chiton, Purpura, Pinna, Terebella, &c., and we think it would have been an advantage if this system had been more freely adopted, the English names only being used where there could be no doubt whatever as to their being well-known ones. Alcyonium is called "the sea-finger"; in some localities, at least, it is known as "dead men's fingers." Pleurobrachia is called "the sea-acorn," but in another well-known book of the sea-shore its English name is given as "the sea-gooseberry." The name "sea-acorn" is usually applied to a barnacle.

This attempt to give English names to objects not well known has led to an unfortunate use of the terms caterpillar and chrysalis, which are here applied to the zoæa and megalopa stages of the crab.

We can understand the desire on the part of the author to bring home to the children the fact that the zoæa and caterpillar represent the larval stage in the life-histories of crab and butterfly, and that the chrysalis of the butterfly and the megalopa of the crab are also corresponding stages, but to call a zoæa a caterpillar and a megalopa a chrysalis is carrying comparison too far.

Frank Balfour Browne.

Déviations des Compas. By Pierre Engel. Pp. vi + 64; with 3 plates. (Paris: Gauthier-Villars, 1907.) Price 2.75 francs.

The brief introduction well describes the subject-matter of the book. It is divided into four parts. The first consists of a theoretical study of the magnetic field of a ship. It is quite simple, and involves no knowledge of mathematics beyond the rudiments of trigonometry. The second part is equally elementary in its treatment, and deals with the action of the field in question on a magnetic needle, together with an outline of the principle of compensation. The third part deals with the compensation of the Thomson or Kelvin compass, while the fourth part consists of various information and remarks, both general and particular, relating to the Thomson compass. Of the plates, the third and fourth are charts of the world showing curves of equal horizontal intensity and equal magnetic inclination respectively. Ensign Engel has produced a book which should be of great use to naval officers, to whom a knowledge of the principles of the modern mariner's compass is indispensable, but to whom a highly mathematical treatment would be prohibitive.

Bulletin of Miscellaneous Information. Royal Botanic Gardens, Kew. Pp. 421 + 152. (London: Darling and Son, 1907.) Price 5*s.*

This volume of the *Kew Bulletin* is the second of the regenerated series. For the most part the contents are connected with systematic or economic botany. Herbarium workers have contributed lists of new flowering plants from Africa and elsewhere, reductions of the Wallichian herbarium, identifications of algæ and fungi, and special articles. The rubber boom is reflected in several articles, notably in the accounts of Guayule rubber, obtained from *Parthenium argentatum*, and of Mgoa rubber, the product of the East African tree *Mascarenhasia elastica.* Various additions have been made to the wild fauna and flora of the gardens, the most important being the list of lepidoptera compiled by Mr. A. L. Simmons. Notes on the cricket-bat willow and on gardens and parks in South Wales represent the work of members of the gardens' staff, and articles have been contributed from India and Africa by former members of the staff.

The Will to Doubt: an Essay in Philosophy for the General Thinker. By Alfred H. Lloyd. Pp. xi + 285. (London: Swan Sonnenschein and Co., Ltd., 1907.) Price 4*s.* 6*d.*

The thesis defended in this, the latest, volume of Prof. Muirhead's ethical library is that doubt is no mere negative of belief, but a positive element absolutely necessary to real life. It is true that the common-sense view of the world is full of contradictions that furnish abundant food for doubt, and that no less must be said of the more special and abstract views which constitute the sciences. But though Prof. Lloyd thus agrees with Mr. F. H. Bradley in holding that our experience at all its levels is "riddled with contradictions," he does not follow the Oxford philosopher to his famous conclusion that all experience is therefore only of "appearance" and not of "reality." In his view, on the contrary, contradiction actually serves experience by holding it down to the real world which it would otherwise miss. It follows that the "doubter's world" must always present certain positive features which will accord with the principles of Descartes, the typical modern doubter. Among these will be found psychophysical parallelism and "the immortality of whatever is indeed real."

Prof. Lloyd's argument is interesting, and is ably, if not always convincingly, developed, but suffers from his somewhat perverse and strained efforts after brilliance of style. He has, moreover, shown more courage than prudence in choosing a title which inevitably suggests comparison of his work with that of his compatriot, Prof. William James.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

An Annotated Copy of Newton's "Principia."

It may interest your correspondent (p. 510) to know that Le Neve, in his "Pedigrees of Knights" (Harleian Soc., 1873, viii., p. 192), states that Sir Demetrius James, of Itham, was knighted on May 10, 1665. An account of the family may be found in Hasted's "History of Kent," vol. ii., p. 247.

Much information about the preparation of the second edition of the "Principia" may be found in Brewster's "Memoirs of Sir Isaac Newton," vol. ii., p. 273 *et seq.*, but it is needless to burden your columns with quotations from so accessible a book. Two specially bearing on the point at issue will suffice:—"Even in November 1702, when he [Newton] was visited by Bd. Greves, who saw in his hands an interleaved and corrected copy of the Principia, he would not acknowledge that he had any intention to reprint it." "In a letter dated October 11 [1709], Newton intimated to Cotes that he had sent him by Mr. Whiston 'the greatest part of the copy of his Principia, in order to a new edition,' thanked him for his letter of the 18th of August, and requested him not to be at the trouble of examining all the Demonstrations, but 'to print by the copy sent him, correcting only such faults as occur in reading over the sheets,' which would entail upon him 'more labour than it was fit to give him.'"

The results of Mr. Smith's further inquiries will be awaited with interest.

Proposed Alteration in the Calendar.

With reference to the proposed alteration of the calendar so ably discussed by "W. T. L." in Nature of March 26, it seems to me that the drastic scheme advocated by Mr. Pearce is not only inadmissible because interfering with the continuity of the weeks, but it is not the simplest scheme that could be adopted, even allowing the interference proposed.

The Positivist Calendar agrees with Mr. Pearce's proposal in that it divides the year into fifty-two weeks with a supernumerary day which is not included in any week, and with two such supernumerary days in leap years. The two calendars are also alike in that these supernumerary days are not included in any month. But the Positivist Calendar is the simpler of the two in that it makes all the months of the same length, namely, four weeks; and Blackstone informs us that in law a month means "28 days, unless otherwise expressed."

This makes the number of months in the year thirteen; but it has this advantage over Mr. Pearce's scheme, that not only are the months all of the same length, but that they all begin on the same day of the week, and thus any given day of the month is on the same day of the week in every month.

The seven-day week, which is no doubt descended from the Jewish week, is one of the most widely spread institutions in the world. All Christian and all Mohammedan nations, although they may agree in little else, agree in respecting the week; and it would be impossible to induce many of them to interrupt the continuity of their weeks by excluding one day annually from any week and two days every fourth year, and unless the change were international and all but universal it would only introduce confusion and destroy that identity of the week which now obtains throughout Christendom and Mohammedom.

Helium in the Atmosphere.

Recent investigations have demonstrated the widespread presence of the inert gases in the crystalline rocks, and the Hon. R. J. Strutt has shown that while the bulk of the gases in granite consists of nitrogen, there is a small but appreciable quantity of argon and helium, the former amounting to from three to four times the latter. On the disintegration of the rocks a portion of these must find their way into the atmosphere. The question arises whether our present atmosphere contains the accumulations of past accessions from the earth's crust, in the same way as the sodium chloride in the sea represents, subject to certain qualifications, the sum of the contributions of the rivers in the past.

It is found, however, that while the air examined in our laboratories contains about 1 per cent. of argon, there are only one or two parts in a million of helium. The small proportion of the latter has given rise to the suggestion that it is escaping from the atmosphere as fast as it enters it. This receives no support from the kinetic theory of gases. Dr. G. H. Bryan calculates (Phil. Trans., A, cxcvi., p. 19) that at a temperature of 127° C. it would take eighty-four thousand million years to remove a layer 1 centimetre thick of helium from the surface of the earth. In other words, the pressure of the gas which at the beginning of that period was found at the height of a centimetre would at its end, other conditions remaining the same, be found at the surface of the earth.

Dr. Johnstone Stoney, however, supposes that there may be extraordinary molecular velocities, due to collisions and other causes, which result in the loss of helium. Such an hypothesis, however, is quite unnecessary, for, according to the ordinary views as to the constitution of gases, they will not distribute themselves uniformly in the atmosphere, but to a certain extent take up positions according to their relative densities. Mr. J. H. Jeans ("Dynamical Theory of Gases," 1904, p. 316) calculates that if helium forms a millionth part by volume of the air at sea-level, it must amount to more than 2 per cent. at an altitude, which is dependent on temperature. With our increasing knowledge of atmospheric temperature and the distribution of helium in the earth's crust, we ought soon to be in a position to calculate the present amount of free helium, and employ it to obtain an approximate higher limit for the total disintegration of crystalline rocks since the consolidation of the earth's crust.

J. W. Evans.

April Meteors.

Moonlight will prove a serious impediment to observations of the Lyrids in the present year, the more especially as, according to calculations made by the writer, the general maximum of these meteors will take place immediately after full moon. The following are particulars as to when meteor showers at this period may be expected to make their appearance, and the computed intensity of the display in each instance, the results being expressed in Greenwich Mean Time:—

Epoch, April 18. Shower of second order of magnitude; the maxima precede the epoch, the principal of which occur on April 16, 6h. 25m.; April 16, 14h.; and April 17, 6h. 50m.

Epoch, April 18, 15h. This shower is of the twenty-second order of magnitude, and has its principal maxima on April 16, 7h. 45m.; April 16, 9h. 40m.; and April 17, 13h. This minor shower has also two secondary maxima, occurring on April 17, 23h., and April 18, 3h., respectively.

Epoch, April 21. This shower is of the twenty-first order of magnitude, its principal maxima, which precede the epoch, occurring on April 19, 16h. 35m.; April 19, 19h. 20m.; and April 20, 17h.

Towards the end of April there is another meteor shower of the ninth order of magnitude, the epoch of which occurs on April 29, 6h., and the principal maxima of which fall on April 27, 16h.; April 27, 19h. 30m.; and April 27, 21h.

As a general rule, the intensity of a meteoric display is inversely as its estimated order of magnitude; hence meteors may be expected to be most abundant on the night of April 16, as the two strongest maxima of a shower of the second order of magnitude occur on this date, besides two maxima of another shower which is partly superimposed on the former. Lyrids will probably be most in evidence on the morning of April 17.

Dublin. John R. Henry.

Coloration of Glass and Quartz by Radium.

On many occasions attention has been directed to the coloration of glass and quartz by the rays from radium. The coloration of glass is generally connected with the presence of manganese or lead, and I venture to suggest that in quartz too the darkening arises from the association of some foreign substance with the silica.

A small plate of quartz crystal was exposed to radium for three weeks, and became, not only irregularly violet at one place, but also showed two sharply defined parallel lines strongly coloured, with the space between them scarcely affected. On the other hand, a quantity of powdered chemically pure silica acquired no colour after the same exposure. It may also be pointed out that pure boric acid, fused to a transparent plate and protected from moisture, was unaffected by radium even after two months' continuous exposure to the rays.

Borax, however, will show a slight action after three weeks, and both these substances afford, when incorporated with a small quantity of pure sodium silicate, a good basis for the production of experimental glasses to test the action of radium when other constituents, such as lead, iron, &c., are added either singly or together.

It may be found that the coloration by radium will serve as a test for the purity of the silica used in making vessels for certain classes of chemical research, so that, apart from its physical interest, the matter seems worth following up.

An Early Notice of Neolithic Implements.

The subjoined quotation must, I think, be among the earliest specific descriptions of a Neolithic implement found in this country.

Newbery's "A Compendious History of the World" (vol. i., London, 1768, pp. 11–12):—"That the earth has been amazingly altered since its first formation is evident from the spoils of the sea being daily discovered even in the midst of rocks and the tops of mountains: to which let me add that the skeletons, horns, &c., of the animals of one country, have been dug out of the bogs and mines of another, even at an immense distance, and where such animals are not now to be found: even stones have been discovered at a great distance in the earth, which bore evident marks of art about them; and some time since I had two taken out of a peat pit near Newbury in Berks, which were large, ground to an edge in the form of an ax, and so perfect that wood might be cut with them."

John L. Myres.

NOTES ON ANCIENT BRITISH MONUMENTS.[1]

VIII.—THE ABERDEEN CIRCLES (*Continued*).

IN my last notes I dealt, amongst other matters, with those circles devoted, as I believe, to the observation of clock-stars. It is from these that dates can be derived when we are sure of the star. I pointed out that we were not sure of the star, which might have been either Arcturus or Capella.

I must confess that although, as I have already said, there is no definite proof that the period of B.C. 600 is to be preferred to B.C. 1600 as the mean time of the setting out of the Aberdeen circles, such considerations as I then gave point to the more recent date. I may add that the N. circles, if used to determine the time at night, tell the same tale. With little knowledge of the heavens we can understand the importance of an exact alignment to Arcturus or Capella when, in my view, the astronomer-priest took his departure and told the curate left in charge to "keep her at that"; but when the stars were more familiar there would be less need to indicate the rising places of either Arcturus or Capella, and the four circles with due N. alignment indicate probably that there was no longer need for a rising star to be considered; the position of the brighter stars in relation to the Pole star in the circumpolar region itself could be used, and there can be little doubt that it then became a question of the nightly voyage of the Great Bear round Polaris. In such observations we have the beginning of the employment of the "night dial" used throughout Britain until a century ago, and of the system of observation by which the Arabs in the Soudan still tell the time at night to within ten minutes.

The question of the number of stones in the circles may also help us. The once existing condition of things at Crichie, fully illustrated in Anderson's admirable book on Scotland in pagan times ("Stone Age," p. 105), is worthy of consideration. The circle consisted of six stones only; the meridian is clearly marked, and my observations made from the outstanding stone show that it was quite accurately laid off. This fact and the other that the cist was found in the middle *of a north alignment* are, in my mind, proofs of relative modernity. One question, then, is, May we accept all small circles, such as Crichie and Tuack, as being more modern than those in Cornwall and even in Aberdeenshire, where the number of stones in the circle is greater? The many interments in these circles also favour this view.

And now a word about the May-year circles; from these astronomically we can get no date, but we know that in the south they preceded the solstitial circles, and perhaps it is permissible to make the same assumption for Aberdeenshire, but in this case we deal with recumbent stones, so again they are dissimilar, and therefore their date is probably not the same as that of those in the south.

[1] Continued from p. 489.

So far as my work has gone, we have alignments to the May year at Berry Brae and Hatton of Ardoyne; the remains of a May-year avenue at Ardlair and another marked on the Ordnance map near Kirkton of Clatt. The true azimuths of the May sunrise near Aberdeen are approximately:—

Sea horizon	N. 57 50 E.
Hills 1°	60
,, 2°	61 30

In my reductions I have taken the magnetic variation at W. 18° 45′ provisionally until the recent results obtained by the Admiralty and Ordnance Survey are known.

It is remarkable that either the recumbent stones or supporters, or both, have been disturbed in these May-year circles, suggesting a practice acted on by the Egyptian priests in regard to the worship of any other sun- or star-god than the one to which they were specially attached.

This is an argument in favour of the erection of the May-year circles before the solstitial ones at Midmar, Sunhoney and Stonehead, which have been left intact.

FIG. 22.—Contrasting the directing stone and supporters at Ardlair.

The most remarkable case of disturbance is at Ardlair, on the N.W. of the circle area.

This is one of the exceptional cases to which I referred in (2), where the only May-year avenue I have measured occurs, hence the circle may once have been a May-year one. With the single exception of Old Bourtree Bush, where the recumbent stone is due E. of the centre of the circle to define the place of the equinoctial sunsets, all the circles I have measured have the recumbent stone in the S.W. quadrant. This general condition has been previously noted by Mr. Coles, and also by Mr. Ritchie, who informs me that in the case of the only variation from this law he has noted, it is known that the recumbent stone, having been moved by the farmer, was *wrongly replaced* when he was compelled to restore it.

At Ardlair the recumbent stone is in the S.E. quadrant, but there are indications that this was not its original position. It is unlike any other recumbent stone I have seen; I believe its many sharp angles and cracks are due to the action of fire, and the angles and cracks are all the more striking since both supporters are rounded and crackless.

The removal of the stone from its position *facing* the May sunrise, subjecting it to the action of fire, and placing it between two stones in the circle, so that its *length* would lie *in the direction of that sunrise*, are all suggested as acts of the solstitial priests.

The mean of all my measures gives an azimuth *along* the stone and its supporters of N. 61° 15′ E.; the azimuth of the May sunrise with hills 2° high is N. 61° 30′ E.

The other exceptional case is at Garrol, where there has been great disturbance, and where, as at Ardlair, the length of the recumbent stone lies in the direction which points to the rise of the May sun, the mean of many measures giving N. 61° 45′ E.

My measurements of the May-year circles were as follows:—

May-year. Sun's Declination 16° 20′ N. (*May* 6, *August* 8).

Circle at—	Azimuths. Magnetic, mean of observations.	Azimuths. True, at right-angles across circle.	Elevation of the horizon	Declination N.	Dates. May.	Dates. August.
	°		°	° ′		
Berry Brae	170	N. 61 15 E.	1	15 30	May 3	Aug. 11
Hatton of Ardoyne	166	N. 57 15 E.	½ (assumed)	17 8	May 9	Aug. 5
Mean of above...	..	...	...	16 19	May 6	Aug. 8

Some of the previous measures in Cornwall may be given for comparison:—

Monument at—	Azimuth (true).	Elevation of horizon.	Declination N.	Dates. May.	Dates. August.
Boscawen-un—Circle to two large menhirs	N. 66 50 E.	1 0	14 55	May 1	Aug. 13
Merry Maidens—Circle to Fuugou	N. 64 0 E.	0 30	16 21	May 6	Aug. 8
Tregeseal—Circle to Longstone...	N. 67 20 E.	1 18	15 3	May 2	Aug. 13
Longstone (Tregeseal) To W. Lanyon Quoit .	N. 67 0 E.	0 0	14 3	Apr. 29	Aug. 16
Down Tor—Direction of avenue......	N. 67 0 E.	0 30 (assumed)	14 23	Apr. 30	Aug. 15

Lesquoit cromlech—Orientation of cromlech.	N. 64 0 E.	1 30	16 55	May 8	Aug. 6
Druids Altar (Pawton)—Orientation of cromlech.	N. 64 0 E.	1 30	16 55	May 8	Aug 6
Mean of above .. .	..	...	15 38	May 4	Aug. 10

In addition to these, I have found[1] that Lukis[2] and Borlase[3] give plans of a number of cromlechs in Cornwall which appear to be oriented to the May sun. They are as follows:—

Cromlech.	Authority.	Azimuth.
Lanyon Quoit	Borlase; plate xxi	N. 66 E.
Mulfra Quoit	Lukis; plate xix.....	N. 63 E.
Chywoone Quoit..................	Lukis; plate xx ...	N. 64 E.
Zennor Quoit	Lukis; plate xxi...	N. 64 E.
Three Brothers Grugith .. .	Lukis; plate xxiii	N. 64 E.
Mean of above .	.. ..	N. 64 12′ E.

Assuming an elevation of the horizon between ½° and 1°, this mean value is the exact azimuth of the May sunrise in Cornwall.

I next give details touching the solstitial circles. With these, accurate measurement is a difficult matter, and, as the determination of the date of erection from the variation of the obliquity of the ecliptic entails very precise measures, I content myself with pointing out that the declinations are probably solstitial and that they agree, in the mean, with the values previously obtained for the English solstitial circles.

Circle at—	Azimuths. Magnetic, mean of observations.	Azimuths. True, at right-angles across circle.	Elevation of the horizon.	Declination N.

Mean of above	...	..	23 34

General Conclusions.

Should subsequent inquiries confirm the balance of argument against the use of Capella, we shall be led to the following conclusions:—

(*a*) Dealing with the circles already measured by me in the two localities, the Aberdeen circles are more than a thousand years younger than those of Cornwall and the west coast; and here we have one reason why the east-coast circles are dissimilar, and those at Callernish and Stenness to the west are similar, to the Cornish circles.

(*b*) With this great difference of time to deal with, we have also probably a difference of origin between the West coast and East coast swarms.

(*c*) As the May year is still supreme in Scotland generally, it is clear that the solstitial Aberdonians were at some point of time overpowered in influence by a return wave from the west of Scotland.

Since my return from Aberdeen Mr. Horton Bolitho, one of the hon. secretaries of the Cornwall branch of the Society for the Astronomical Study of Ancient Monuments, and whose knowledge of the Cornish alignments is second to none, has sent me the following information concerning the circles in Perthshire:—

"I examined six circles in Perthshire last year and this, but I found no trace of recumbent stones such as are associated with the Aberdeen circles. The Perthshire circles closely resemble the circles of Cornwall, showing traces of May-year and solstitial alignments with at least one clear use of a clock-star in azimuth N. 18° E. Trees prevented any fine measurements being taken, and local assistance in searching for outstanding stones was lacking. In two of the best pre-

[1] See NATURE, No. 1987, vol. lxxvii., p. 84, November 28, 1907.
[2] "The Prehistoric Stone Monuments of Britain—Cornwall."
[3] "Antiquities of Cornwall."

[1] At Sunhoney, as the recumbent stone was curved and irregular, it was simpler to measure directly across the circle at right-angles to the length of the recumbent stone; the magnetic azimuth thus obtained was 71° 20.

served circles I found a central or 'Gorsedd' stone, and in one case two central stones."

Mr. Bolitho's observations then intensify the purely local fashion of the Aberdeen circles.

One of the associated inquiries to which I have referred will be to trace the existence of recumbent stones in some part of Europe; another will be to see if the area of the recumbent stone has also special ethnological or craniological characteristics.

With regard to the first point, Anderson ("Stone Age," p. 124) tells us that in Norway and Sweden there is no example of a circle with a recumbent stone and supporters.

With regard to the second, the paper on British ethnology by Mr. J. Gray (*Man*, April, 1902) is full of promise.

A point worthy of notice is the great preponderance in the number of circles used to take the time at night over those enabling the seasonal changes and the sun's place throughout the year to be fixed. In Cornwall both were equally provided for.

We may, I think, include the circles with a north alignment with the clock-star circles as used to determine the time at night. They are respectively situated at Dyce, Whitehill Wood, Raes of Clune and Candle Hill (Insch). As before stated, they probably represent a later development when the observer's knowledge was so far advanced that he needed only the cardinal point in order to recognise the clock-stars which it was necessary for him to observe.

Judging by the trouble taken to determine time at night by the use of special circles in Aberdeen, religious services at fixed hours of the night are suggested to be as early as the time of the circle builders.

As these night observations were common to the two localities, we may conclude that in both, the circle associated with the *via sacra*, the chambered cairn, the holy well and the holy thorn, and the sacred festivals, represent the earlier form of the monastery buildings of later times.

I am anxious to conclude by expressing our deep obligations to many helpers. First of all to Dr. Fraser for his invitation to come and do some more work, his generous hospitality, and the use of his motor-car for the examination of the circles within a radius of twenty miles of the Granite City, some of which we saw under his own guidance. That is the first point; next comes the local help in four distinct regions—Inverurie, Durris, Buchan and Insch. For the Inverurie district Mr. Ritchie, of Port Elphinstone, gave up two of his precious Saturday holidays, during which he piloted us to many circles which he had most carefully selected from a much larger number as being best worth examining.

At Durris Mr. Braid and his son took us to the circles at Eslie and the Raes of Clune, and, further, had prepared a careful plan of the latter circle, thus fulfilling a promise made last year.

On our arrival at Mintlaw for the study of the Buchan circles, we found the Rev. Dr. Forrest, Mr. Ainslie, and his assistant, Mr. Gall, at the station, and with their help several circles near Mintlaw and Lonmay were measured.

Later on we proceeded to Insch, and passed two nights in the comfortable Railway Hotel there. The obliging landlord, Mr. Haddon, had taken immense pains to secure local information. Colonel Smith, and Mr. J. Graham Callander who had only returned two days from studying Greek inscriptions in Asia Minor, accompanied us on each of the days, and with their help we were enabled to measure seven circles, some of them many miles from our headquarters.

NORMAN LOCKYER.

TREES.

AMONG the many excellent books which have been written about trees there are none, in our opinion, better than the present work.[1] It is full of interest from cover to cover. The many beautiful photographs of the different parts of trees are strikingly true to nature, and, having been taken from fresh material, they show the salient features of the different species much more clearly than could be observed from dried herbarium specimens. We have also beautiful portraits of the various trees themselves in summer and winter condition, as well as special plates illustrating the appearance of the bark. The accompanying illustration will speak for itself.

In his introduction Prof. Groom has given a very interesting and clear account of the various members, both vegetative and reproductive, which make up the body of the tree. The special function of each part

Bark of Cork Oak. Part of an illustration in "Trees and their Life histories."

and the influence of the environment on its activity is described in a way which the non-botanical reader should have no difficulty in following and thus laying a clear foundation for the better understanding of trees and their life-histories. It is difficult to say which part of the book is best, but in the introduction the author has broken new ground. A great fault in many similar works is that they contain a mere accumulation of facts, and dry, formal descriptions of different trees and their various parts, which the non-botanical reader may learn and thus get to know the various species by head mark. This is all very well so far as it goes, but surely it will make

[1] "Trees and their Life-histories." By Prof. P. Groom. Pp. xvi+407; illustrated from photos. by H. Irving. (London: Cassell and Co., Ltd., 1907.) Price 25s. net.

the study of trees much more intelligible and interesting when the meaning of structure and form is clearly and simply described to the student, as in the present work.

After this excellently written and beautifully illustrated introduction, the author takes up the gymnosperms. He does not attempt to deal with every known species, but certainly there are few which are likely to be met with in various pinetums, parks, and forests in this country which have not been dealt with. The life-history of each is clearly and well described and illustrated by photographs. As Prof. Groom states in his preface, "Particular trees have been selected for more detailed discussion, so as to serve as types by which to demonstrate certain structural features or general phenomena observable in tree-life." The study of the conifers appeals to a vast number of people, and a distinct gap in the existing literature has been filled by this work. No doubt other books give descriptions of the different species, but these are too condensed and technical to be of any use to the general reader. The broad-leaved trees are similarly dealt with in an interesting and masterly manner. Analytical tables and diagnosis of families have been added. These, together with the numerous illustrations and the special mention of distinctive features which is prefixed to the account of every tree described, will certainly ensure facility and accuracy in identifying the different knds of trees with which the reader is likely to come in contact.

The author is to be congratulated upon the production of a work which should certainly be in the possession of all those interested directly or indirectly in trees and their growth. A. W. B.

DR. JAMES BELL, C.B., F.R.S.

We regret to have to announce the death, on March 31, in his eighty-fourth year, of Dr. James Bell, formerly principal of the Somerset House laboratory. Dr. Bell was a native of County Armagh, and entering the Inland Revenue Service became, when a comparatively young man, an assistant in the chemical department of Somerset House, then under the charge of Mr. George Phillips. This department, the forerunner of the present Government Laboratory, was the outcome of the Tobacco Act of 1842, and was created with the object of supplementing the provisions of that Act in suppressing the adulteration of tobacco. For his chemical education Dr. Bell was mainly indebted to the late Prof. Williamson. Indeed, in the early days of the Somerset House laboratory a close association existed between it and University College, and a number of the first assistants were trained in theoretical and practical chemistry in the Gower Street laboratories, and some of them, like Duffy, Kay and Railton, were encouraged by Dr. Williamson, then in the full vigour of his scientific activity, to try their prentice hands at original investigation. In the first years of its existence the laboratory, the staff of which consisted solely of Mr. Phillips himself, was almost exclusively engaged on the objects for which it was founded, but as its utility became more and more apparent its operations were gradually extended, and eventually embraced the examination of practically every excisable article. The laboratory at this period was also largely concerned with inquiries as to the brewing values of various materials, and on the methods of determining original gravities, and on the denaturing of spirits of wine so as to permit its use for manufacturing purposes without danger to the revenue—all of which work found its application in subsequent Acts of Parliament.

On the death of Mr. Kay, Mr. Bell became deputy principal, and he continued in that office until the retirement of Mr. Phillips in 1874, when he succeeded to the principalship, holding that position until his resignation in 1894. During the fifty years of its existence the operations of the laboratory had greatly extended, and it had contracted associations with practically every Government department which had need of chemical advice and assistance, in addition to the large extension of its work connected with Revenue matters. Much of this development took place during Dr. Bell's principalship. But to the public at large Dr. Bell's tenure of the office was mainly signalised by the association of the Somerset House laboratory with what is in reality one of the least important of its many duties, viz. the Food and Drugs Acts. This popular misapprehension of the proper functions of the laboratory is no doubt due to occasional newspaper references to the fact that a disputed case of analysis of some food-stuff, drink or drug has been referred by magistrates to the Commissioners of Inland Revenue for the opinion of their chemical advisers. As a matter of history, this connection of the Somerset House laboratory with the Food and Drugs Acts occurred at the very time that Dr. Bell succeeded to the principalship, as a result of a report of a Select Committee of the House of Commons on the working of the Act of 1872, and this circumstance caused the laboratory to be known to the public at large to a much greater extent than formerly.

The new responsibility thus thrown on Dr. Bell involved a very considerable increase of work on the department, not so much in actual analysis of referred samples as in investigations into the methods of food analysis in general and in the establishment of standards of quality. Thirty years ago the methods of food analysis were, for the most part, in a very unsatisfactory condition. The great teachers of chemical analysis, Berzelius, Rose, Wöhler, Thomson, Bunsen, Fresenius, and the men trained in their schools, were mainly concerned in the discovery and elaboration of the methods of mineral analysis, and very little attention had been paid to processes for the systematic examination of food with a view to the determination of its quality or to the detection of adulteration. The first Food and Drugs Act was largely ineffective owing to this circumstance. When the office of a public analyst was first created, practically each analyst had to devise his own methods, and at the outset no uniformity or agreement was possible. The condition of things to which this gave rise, with the consequent frequent instances of injustice, was indeed the cause of the appointment of the Select Committee above referred to.

As regards methods of analysis, Dr. Bell, as the referee eventually appointed under the Act of 1875, was in no better position than other analysts who held office under the Act, and he at once turned all the force and ability of his laboratory to the elaboration of the methods for the examination of such articles of food and drink as experience showed most frequently came within the purview of the Act. In this work he was assisted by some of the most competent analysts the laboratory ever possessed, notably Mr. George Lewin, the late Mr. Harkness, the late Mr. John Holmes, and Mr. Cameron, each of whom did yeoman service in getting together the material embodied in the work by which Dr. Bell is best known, viz. his "Chemistry of Foods." It was mainly in recognition of the service thus rendered to the community that Dr. Bell was elected into the Royal Society in 1884, and was made, two years later, a graduate of the Royal University of Dublin. His official position further led to his selection as president of the Institute of Chemistry in 1888. He was one of the original members of the Institute, and took much interest in its operations. He was made a Companion of the Bath in 1889.

Dr. Bell enjoyed the respect and esteem of many successive Boards of Inland Revenue, who found in him a shrewd and astute adviser of ripened judgment and large experience, eminently cautious and sound. His *bonhomie* and geniality, his strong common sense and tactful sympathy, his fair-mindedness and obvious impartiality rendered him an admirable agent in the conduct of the occasionally complicated and difficult adjustments of the apparently conflicting interests of the "Trade" and the Revenue, which the head of the laboratory is now and again called upon to determine. He was loyally served by his staff, who entertained warm feelings of regard and affection for him. Many of them testified to their appreciation of his many good qualities by their presence at his funeral on Saturday last at Ewell.

T. E. T.

NOTES.

The sixteenth James Forrest lecture of the Institution of Civil Engineers will be delivered at the institution on Monday, April 27, by Prof. Henry Louis, who has selected for his subject "Unsolved Problems in Metal Mining."

The Geological Society of London is taking a poll of all the fellows resident in the United Kingdom to ascertain whether a majority is in favour of admitting women to the society, and, if so, whether as fellows or as associates.

Dr. W. N. Shaw, F.R.S., and Dr. T. H. Warren, Vice-Chancellor of the University of Oxford, have been elected members of the Athenæum Club under the provisions of the rule of the club which empowers the annual election by the committee of three persons "of distinguished eminence in science, literature, the arts, or for public services."

Dr. Henri Deslandres, who since 1897 has been assistant director of the observatory at Meudon, has been appointed director to succeed the late Dr. Janssen.

Dr. J. N. Langley, F.R.S., professor of physiology in the University of Cambridge, has been elected a foreign member of the Royal Danish Scientific Society.

The third International Congress of Philosophy will be held at Heidelberg from August 31 to September 5. Prof. Windelberg is to be president, and Dr. Elsenhaus Plock, of Heidelberg, is acting as secretary.

The annual dinner of the Institution of Mining and Metallurgy will be held at the Hotel Cecil on Friday, May 8. The president, Mr. A. James, will preside, and many distinguished guests have already accepted invitations to be present.

We learn from the *British Medical Journal* that the Town Council of West Ham has passed a resolution authorising the placing of a bronze tablet on the house in Upton Lane, Forest Gate, now St. Peter's Vicarage, where Lord Lister was born.

The sixth International Congress of Psychology will be held at Geneva from August 31 to September 4, 1909. Prof. E. Claparède, professor of physiological psychology in the University of Geneva, is the general secretary of the congress, and may be addressed at Champel, 11, Geneva.

A new Polar expedition is being equipped, under the auspices of the Russian Ministry of Marine, with the object of discovering a north-east passage between the Atlantic and Pacific Oceans, and thereby accelerating naval communication between Western and Far Eastern Russia.

A correspondent sends us a page from "Wind und Wetter," by Prof. E. Lommel (Munich: R. Oldenbourg, 1873), containing a description of the dark cloud which covered Europe and a part of Asia in 1873 (see Nature, March 5, p. 417, and March 26, p. 493).

The body of Emanuel Swedenborg, who died in 1772 and was buried in the Swedish Church, Prince's Square, Ratcliff Highway, was removed on Tuesday from its place of sepulture and conveyed to Dartmouth, where it was placed on board the Swedish cruiser *Fylgia* for conveyance to Sweden.

A general meeting of the American Philosophical Society will be held at Philadelphia on April 23–25. The preliminary programme, a copy of which has reached us, shows that thirty-six papers on important scientific subjects will be brought before the meeting by leading men of science in the United States.

The Back bequest for 1908 has been awarded by the Royal Geographical Society to Lieutenant George Mulock, R.N., on account of the survey work which he did on the National Antarctic Expedition, and the map in six sheets which he prepared after the expedition returned.

A message from Stockholm states that it is the intention of the Swedish Government to ask the Riksdag to make a grant for a scientific expedition to Spitsbergen in the coming summer for geological and geographical research. Prof. Gerard de Geer, the Rector of the University of Stockholm, will be the leader of the expedition.

It is proposed to hold a conference of meteorologists representative of the United Kingdom and of the British colonies and dependencies in the course of the summer in Canada on the invitation of the Royal Society of Canada. The meeting was originally fixed for the last week in May. We are now informed by Mr. R. F. Stupart, director of the Canadian Meteorological Service, that it has been postponed, and is to be held in Quebec in the last week of July, immediately after the celebration of the tercentenary of Champlain's landing.

An adult living specimen of *Lepidosiren paradoxa*—the South American lung-fish—reached the natural history department of Glasgow University some months ago, and has remained in a healthy condition. To this—the first living specimen which has ever reached the Old World—there have just been added eight others obtained by Mr. W. E. Agar on his recent expedition. It is hoped that in time it may be found possible to induce them to breed in captivity.

The summer meeting of the American Association for the Advancement of Science will be held at Dartmouth College, Hanover, N.H., during the week beginning June 29. A committee, under the chairmanship of Prof. R. Fletcher, has been appointed to make the necessary arrangements. An invitation has been received from the president of the Blue Mountain Forest Association for members of the association to visit the Blue Mountain Forest, otherwise known as the Corbin Blue Mountain Park or Preserve, covering about 40,000 acres, where the celebrated herds of buffalo, deer, mountain goats, boars, &c., may be seen.

Agricultural science in America has lost a promising writer and teacher by the death, in his forty-second year, of Prof. Willis G. Johnson. He was formerly an instructor in the University of Illinois, and was engaged in special investigations for the natural history laboratory of that State. Later he became State entomologist of Maryland, and organised the Maryland State Horticulture Department. Of late years he had written largely on fruit-tree pests and kindred subjects, and had edited the *American Agriculturist*.

With reference to his article in Nature of March 26 on the proposed alterations in the calendar, the author writes:—"In p. 489, col. 2, line 13, for 'each 132nd year' read 'each 128th year.' Dropping a leap year at the end of each latter period would be equivalent to having in that time 97 common years and 31 leap years, or 46,751 days in all, differing from 128 tropical years by only 0·00160 of a day. This is much more accurate than the Gregorian rule; and, if the latter is a little more easy to remember, that is of little advantage for what can come at most once in a lifetime."

In a letter to the Paris Academy of Sciences, Prince Roland Bonaparte announces his resolution to place the sum of 100,000 francs (3960*l.*) at the disposal of the academy for the encouragement of scientific research. This sum is not to be treated as capital, but is to be used freely in the form of annuities, not as rewards for work done, but to enable competent workers, who have already proved their capability, to carry out new researches which otherwise they would be unable to prosecute. In his letter to the academy—which appears in No. 9 of the *Comptes rendus* (March 2)—the Prince expresses the hope that his example may be followed to such an extent that a permanent fund, devoted to this end, may be established.

The following are among the lecture arrangements at the Royal Institution after Easter:—Mr. Gerald Stoney, two lectures on the development of the modern turbine and its application; Prof. F. T. Trouton, two lectures on (1) why light is believed to be a vibration, (2) what it is which vibrates; Prof. W. Stirling, two lectures on animal heat and allied phenomena; Mr. W. Bateson, three lectures on Mendelian heredity; Dr. A. Scott, three lectures on the chemistry of photography; and Mr. G. F. Scott Elliot, two lectures on Chile and the Chilians. The Friday evening meetings will be resumed on May 1, when Prof. J. Larmor will deliver a discourse on the scientific work of Lord Kelvin. Succeeding discourses will probably be given by Dr. J. Y. Buchanan, Dr. H. T. Bulstrode, Prof. J. C. Kapteyn, of the University of Gröningen, and Sir James Dewar.

A Reuter telegram states that Captain Ejnar Mikkelsen, who jointly commanded the Anglo-American Polar Expedition, returned from Alaska on April 2. Captain Mikkelsen started from Flaxman Island on October 16 and journeyed along the northern shore of Alaska, proceeding thence along the Yukon River towards Fort Gibson. The expedition traced the continental shelf in Beaufort Sea. Information was obtained concerning ocean currents which will be useful when Captain Mikkelsen makes another attempt to reach the unknown continent. Beyond the continental shelf there is water of great depth, demonstrating that Beaufort Sea is not a shallow basin, as has been supposed. The journey north was made along the 149th meridian, and soundings were taken occasionally. At a distance of sixty-four miles from the land it was impossible to touch bottom with a 320-fathom line. Mr. Ernest de Koven Leffingwell, the expedition's geologist, has remained at Flaxman Island to carry on scientific work.

In Nature of February 13 (p. 345) Dr. T. J. J. See gave a quotation from Strabo suggesting that Mochus of Sidon was the originator of the theory of atoms. Dr. Dreyer pointed out, however, in the following issue (p. 368) that the so-called book of Mochus is a literary forgery. Dr. See now writes to state that, though this is the case, it does not justify the inference that Mochus himself was not a real authority of weight. In reply, Dr. Dreyer asks why should it be necessary to accept the existence of Mochus as a historical fact, simply because Posidonius was taken in by the forgery? It is known from other evidence that his mind was not very critically inclined. The book of Mochus is only one of a number of apocryphal writings about Demokritus, most of which pretend to have been written by himself, and describe his skill as a sorcerer and magician. See Zeller, "Philosophie der Griechen," i., p. 842 (5th ed.), and Susemihl, "Geschichte der griechischen Litteratur in der Alexandrinerzeit," i., p. 483. Zeller points out that the roots of the philosophical doctrines of Leukippus and Demokritus are so clearly distinguishable in the earlier Greek philosophy that it is out of the question to deduce them from Eastern sources.

The report of the Royal Scottish Museum for 1907 records a marked increase in the number of visitors, the total exceeding that for the previous year by 92,000. Although this increase may be partially accounted for by an extension of the hours during which the museum is open, it apparently indicates an increased interest in the institution on the part of the public. An unsatisfactory feature is the presence of a bonded whiskey store within less than a dozen feet from part of the west wing of the museum.

According to the recently issued report, the Royal Zoological Society of Ireland enjoyed an unusually good season during 1907 in the matter of receipts, the gate-money showing an increase of nearly 1500*l.* over that of the preceding year. This satisfactory state of affairs is attributed in great part to the recent Dublin exhibition, aided, no doubt, by the improved attractions of the gardens themselves. On the other hand, the list of paying members shows a serious diminution. The report is illustrated by photographs of the new seal-pond and of several interesting animals. Lion-breeding continues to be carried on successfully and profitably. As the collection includes lions from both West and East Africa, as well as one from Persia, it would be interesting if the authorities would afford information as to the characteristics of these local forms.

A short editorial note in the January number of the *Indian Forester* refers to the very important subject of forests and water supply, but no data from Indian territories are quoted. The extent to which camphor has been planted in eastern Asia, India, Africa, and the United States is summarised in an article on the subject, and the methods of producing camphor synthetically are indicated. A reprinted article by Mr. A. M. Smith discussing the correlation between the moon's phase and the period of felling bamboos bears out the view that the phenomena which have led to the belief are connected with the amount of water in the culms; the amount varies greatly with transpiration and with the conditions of light.

Miss E. M. Farr has compiled a catalogue of the flora of the Canadian Rocky Mountains and the Selkirk Range that is published as vol. iii., No. 1, of the Contributions from the Botanical Laboratory of the University of Pennsylvania. Of conifers, *Pinus Murrayana* and *Picea Engelmanni* are dominant in the Rockies; *Larix Lyallii* is a conspicuous tree at high elevations, and *Tsuga Mertensiana* is another characteristic Alpine tree occurring in the west of the region. Among flowering plants, the grasses, sedges, Cruciferæ, Rosaceæ, and Compositæ are the largest orders. Numerous interesting Alpine plants are found, as *Erythronium grandiflorum*, known as the glacier lily, *Aquilegia formosa*, *Anemone Drummondii*, various saxifrages, *Parnassia Kotzebuei*, *Lutkea pectinata*, and *Vaccinium myrtilloides*. The plants growing on Sulphur Mountain, so-called because of the hot sulphur springs, include *Primula Maccalliana*, *Saxifraga caespitosa*, *Draba nivalis*, and *Hutchinsia calycina*.

A SEMI-POPULAR account of light-emitting plants, by Dr. C. Müller, is published in the February number of *Himmel und Erde*. In 1815 Heinrich recorded the observation that light is evolved by the wood of certain trees, and later John Heller rightly ascribed the phenomenon to fungi. Hartig identified one mycelium as that of *Agaricus melleus*, and more recently Molisch showed that the mycelium of other fungi produce the same effect. The fruiting bodies of *Agaricus Gardneri*, *A. igneus*, and *A. olearius* emit light, also the Australian fungi *Panus incandescens* and *Pleurotus canescens*. The light observed in connection with dead animal matter, attributable to bacteria, is due in certain cases to the presence of *Bacterium phosphoreum*, and it is peculiar that this organism only exists at temperatures below 30° C.; other bacteria produce the luminous effect in connection with marine fishes and animals. The emission of light at sea has been variously attributed to bacteria, Peridineæ, and Pyrocisteæ. A distinctly novel idea of utilising light-emitting bacteria to provide a lamp was devised by Dubois and Molisch.

WE have received from the president of the International Aëronautical Committee a summary of the places at which scientific kite and balloon ascents were made in the months September–December, 1907, in Europe, the United States, and at Helwan (Egypt). Heights of 20,000 metres and upwards were reached by registering balloons at Uccle, Brussels (25,990 metres on September 5), Strassburg, and Pyrton Hill (Oxon). The meteorological results are not stated in the summary.

THE Deutsche Seewarte has published the results of meteorological observations for 1906 at the stations under its control, consisting of ten stations of the second order, fifty-six storm-warning stations on the coasts of Germany and hourly readings at four normal observatories. These results have been published in practically the same form for twenty-nine years, and owing to the great care bestowed upon all details connected with the service, the volume is one of the most valuable annual contributions to the meteorology of Europe.

PART iii. of the year-book of the Meteorological Observatory of Agram contains the rainfall observations made in Croatia and Slavonia in the years 1903–6. In the last year there were 121 observing stations; the data form an important contribution to the climatology of those parts, the tables are worked out in great detail, and the precipitation is particularised by the usual international symbols. We note, however, that, contrary to the method obtaining in this country, the values are entered to the day of measurement instead of to the previous day.

THE usual annual summary of the climatology of the past year, based on observations made at Juvisy, appears in the February number of the *Bulletin de la Société astronomique de France*. It is pointed out, in discussing the monthly temperatures, that only on five occasions since the commencement of the nineteenth century has the mean temperature for the month of July been lower than it was in 1907. The relation between sun-spot activity and terrestrial temperature is discussed, and it is shown that from 1879 until 1897 the annual temperature curve followed the sun-spot curve, with a maximum in 1893. The parallelism was not continued, however, during the period 1897 to 1900, but in 1901–2 there was a temperature minimum corresponding to that of sun-spots. The sun-spot maximum of 1905 was not accompanied, in these latitudes, by a thermic maximum, but it is suggested the excessive rain of that year, with its resulting lowering of temperature, was occasioned by the excessive evaporation in tropical regions.

WE have received from the Danish Meteorological Institute its report on the state of the ice in the Arctic seas for 1907. The report is in its usual form.

THE Bulletin of the American Geographical Society for January contains an article by Prof. R. De C. Ward on some problems of the tropics. Prof. Ward emphasises the bounty of nature in providing all the necessaries of life in tropical latitudes, and the tendency for natives of such climates to make no attempts to attain higher civilisation. None of the energetic and enterprising nations of the world has developed under the easy conditions of life in the tropics. In considering the labour problem, the marked social gulf which is certain to ensue if white men attempt to develop tropical countries by aid of indolent natives is discussed. The white residents constitute a caste, and tend to become despotic, while the country is governed on the standards of the temperate zone. Reference is made to the tendency of Europeans to become enervated in a tropical climate, and the problem of tropical government is illustrated by the example of British India. After briefly discussing the seats of primitive civilisation, Prof. Ward directs attention to the migratory movements in history from colder to warmer climates, mentioning the descent of the barbarous tribes of the Himalayas into India, and the invasions of Greece and Rome from the north.

AN account of the earthquake of January 2, 1908, by Mr. Maxwell Hall, is published in the Jamaica weather report. The principal origin of this shock lay in the western part of the island, near Ipswich and Appleton. Rocks were thrown down in a railway cutting between these towns; many houses suffered damage in the district between Falmouth and Montego Bay; at Black River it is said that goods on shelves and in windows of shops on the south side of the High Street were thrown into the street, but those on the north side were thrown inwards. At Chapelton, Mr. Maxwell Hall reports that undulations of the ground could be seen as well as felt; this observation is interesting, as the shock was not severe, no damage was caused, and the violence, as defined by Mr. Hall, corresponds to about the fifth degree of the Mercalli scale.

IN an article in a Stuttgart newspaper, the *Deutsches Volksblatt*, Mr. Schips endeavours to apply recent chemical theories towards elucidating the origin and formation of the diamond from quartz-bearing rocks. The diamond, he points out, is always associated with silicates, and one of the minerals with radium emanation is always present. He concludes, therefore, that the diamond has been formed by the influence of the emanation on silicon.

In *Concrete and Constructional Engineering* for March Colonel J. Winn summarises recent progress in the development of reinforced concrete in Great Britain. During the past year steady advance has been made, and the decision to build the new General Post Office extensions and various small post offices of reinforced concrete will have a far-reaching effect. Another interesting article in the same issue, by Mr. W. R. Crane, deals with the use of concrete and reinforced concrete in mines. Details are given of concrete linings at several shafts in the United States. Other articles dealing with reinforced concrete in reservoir, aqueduct, and conduit construction, with a ten-storey reinforced concrete building in Pittsburg, with reinforced concrete bridges in Italy, sea defences in Holland, and leading jetty on the Manchester Ship Canal, illustrate in a striking manner the variety and number of the structures which are being executed in this material.

Two interesting papers were read before the Institution of Engineers and Shipbuilders in Scotland on March 17. Mr. H. A. Mavor discussed the electric propulsion of ships, giving a comparison of the results to be obtained on a ship of large size driven direct by steam turbines with what can be done by the application of electric gear. The ship, details of which are worked out, had a total of 17,000 horse-power delivered to the three propellers, and a speed of $20\frac{3}{4}$ knots. The propellers were 8 feet $1\frac{1}{2}$ inches in diameter, and the speed of revolution was 377 per minute. The maximum probable efficiency of these propellers is calculated to be 62 per cent. An electric equipment would, it is shown, permit of the use of propellers of about 14 feet diameter at 140 revolutions per minute, and an efficiency not less than 70 per cent.—an improvement more than sufficient to cover the loss in the electric motors. In the second paper Mr. W. H. Hatfield traced the evolution of malleable cast iron, and discussed its present position in the metallurgical world. He takes exception to the statement made in the report on the nomenclature of iron and steel that malleable cast iron should not be regarded as a variety of cast iron, inasmuch as it does not exhibit the extreme brittleness that characterises cast iron. He considers that it should properly be classed as cast iron. The nomenclature is, however, a matter of slight moment. The tests given by the author show that malleable cast iron can be produced giving a tensile strength of twenty-three tons per square inch with an elongation of 19 per cent., a reduction of area of 20·6 per cent., and a bending angle of 180°, results which are as good as those given by many samples of wrought iron. In structure, these castings are very similar to wrought iron.

In a note reprinted from the *Atti* of the Venetian Institution (Venice: C. Ferrari, 1908), Dr. U. Cisotti applies elliptic functions to the problem of efflux of a liquid from an opening containing an internal mouthpiece, a particular case of two-dimensional discontinuous motion. The paper forms the sequel to one in the *Rendiconti del Circolo matematico di Palermo*, xxv. (1908), on discontinuous motion in general.

The recently established Italian bi-monthly *Scienza pratica* contains a paper by Mr. Lorenzo d'Adda on the substitution of cement for steel in the armour of battleships. The idea was suggested to the writer by the way the Russian shells bounded off the batteries of the Japanese in the siege of Port Arthur without producing any great damage. Among the advantages suggested are a considerable saving of weight and cost; moreover, the author points out that efficient adhesion can be secured between the cement and iron owing to the similarity of their coefficients of expansion. Other papers are an illustrated obituary notice of the late Emilio Rossetti, late professor of physics at Buenos Ayres, who was also a pioneer of engineering in the Argentine Republic, and papers on the steam turbine and the trans-Apennine canal. A considerable collection of science abstracts, mainly dealing with engineering, is another important feature of the new journal.

Prof. Gruner, of Bern, has written a small pamphlet dealing with "The World of the Infinitely Small" at the instance of the Keplerbund of Godesberg, a society which aims at the spreading of a knowledge of science amongst the people. The author has succeeded in presenting his subject in a most fascinating manner. He approaches the infinitely small by a series of steps, one of which deals with ultra-microscopic vision, and may be mentioned as illustrating the author's method. The colour of ruby glass is due, he shows, to the presence in it of minute particles of gold too small to be seen with a microscope, under which the glass looks a uniform material. When, however, the glass is examined by the ultra-microscope the gold particles appear as points of light on a dark background like stars in the sky. What, he asks, would be the appearance of these particles if we could bring to bear on them a power which exceeded that of the ultra-microscope as much as the latter does that of the ordinary microscope?

The December (1907) number of *Terrestrial Magnetism and Atmospheric Electricity* contains an article by van Everdingen on the life and work of the late Dr. M. Snellen, director of the Royal Meteorological Institute of Holland. It deals mainly with the scientific and organising work of Dr. Snellen. Apart, however, from the character and importance of the scientific work in which Dr. Snellen was engaged, and which secured him many friends throughout the scientific world, his perfect mastery of the English tongue, his genial character, and his fund of anecdote made him a most welcome visitor to these shores, and increased the number of his admirers. We are glad to add our tribute of respect to that of the Dutch Meteorological Institute.

In the Bulletin of the U.S. Bureau of Standards for January, Messrs. W. A. Noyes and H. C. P. Weber give an account of their re-determination of the atomic weight of chlorine. The method consists in weighing the hydrogen absorbed in palladium and the chlorine in the form of potassium chloroplatinate. The hydrogen, on being passed over the heated chloroplatinate, combines with the chlorine to form hydrochloric acid, which is condensed and weighed. The mean result is 35·457, silver being 107·88. These values differ slightly from the 35·467 and 107·91 found recently by Prof. H. B. Dixon and Mr. E. C. Edgar by the same method.

According to the February number of the Journal of the Röntgen Society, the committee of the society, which has under consideration the establishment of a standard unit of radio-activity, has made an interim report in which it recommends that 1 milligram of pure radium bromide be regarded as the standard, and that the ionisation produced by the γ rays from it, after passing through 1 centimetre of lead, be taken as a measure of the unit of radio-activity. There are, however, certain difficulties in the adoption of these suggestions which the committee has still under consideration, and will deal with in a future report.

The Cambridge University Press has issued a fourth edition of "Petrology for Students: an Introduction to the

St... of Rocks under the Microscope," by Mr. Alfred Ha...er, F.R.S. The book has been revised, new figures hav... been added, and a few old ones have been withdrawn.

The U.S. Department of Agriculture has issued, at the request of librarians and others interested in entomology, a complete list of the publications of the Bureau of Entomology and those of the Department of Agriculture in general bearing on the same subject, and published by members of the Bureau or under its auspices. The list has been compiled by the librarian, Miss Mabel Colcord.

A second edition of "An Elementary Course of Practical Zoology," by the late Prof. T. Jeffery Parker and Prof. W. N. Parker, has been published by Messrs. Macmillan and Co., Ltd. The first edition was reviewed at length in the issue of Nature for April 12, 1900 (vol. lxi., p. 559). In the present edition some parts have been slightly extended, and various modifications made throughout; in addition, short accounts have been introduced of Monocystis, Nereis, and Obelia, and several new figures added.

The Carnegie Institution of Washington has published an "Index of Economic Material in Documents of the States of the United States: New York, 1789–1904." The index has been compiled by Mr. A. R. Hasse, of the New York Public Library, for the department of economics and sociology of the institution. The index runs to 553 large pages, and deals only with the printed reports of administrative officers, legislative committees, and special commissions of the States, and with governors' messages for the period since 1789.

OUR ASTRONOMICAL COLUMN.

Comet 1907*d*.—No. 4234 of the *Astronomische Nachrichten* (p. 159, February 22) contains Herr Kritzinger's continuation of his ephemeris for Daniel's comet. At present the calculated magnitude of this object is about 10·8, and the comet is situated about 2° north of μ Virginis.

Observatory Map of the Moon.—From Mr. Porthouse, of 6 Bates Street, Birch Lane, Longsight, Manchester, we have received a copy of his recently published map of the moon. This map is printed on a circle of 12 inches diameter, the different formations being shown very clearly in outline. At the side of the sheet is a printed list of the formations, with reference numbers and the diameters according to Neison. The map can be read easily in the dim light of the observatory, and can be obtained from the publisher for eightpence, post free.

The Recent Maximum of Mira Ceti.—From forty-one observations of Mira, made with an 8-inch telescope, a pair of field-glasses, and the naked eye, and extending from September 8, 1907, to January 29, M. Félix de Roy found that the maximum brightness occurred on November 1, 1907, with a magnitude of 3·41. From October 29·5 to November 4·5 the brightness of the star apparently remained constant. A comparison with M. Roy's observations of the 1906–7 maximum shows the period of fluctuation to be 318·5 days, some thirteen days shorter than it is given by Guthnick from the discussion of the observations made during the last three centuries; other observers of the recent changes place the maximum at dates varying from October 30 to November 9.

According to Chandler's computations, a maximum of Mira Cygni was due to take place on April 4·5. On March 9 and 26, respectively, M. de Roy estimated the magnitudes of this object to be 6·60 and 5·88 (*Gazette astronomique*, No. 4, March 31).

Sun-spot Observations.—In No. 4237 of the *Astronomische Nachrichten* (p. 205, March 6), Herr T. Epstein compares the results of his sun-spot observations made during the years 1905, 1906, and 1907. The figures for the half-years show that the maximum daily frequency took place in the second semester of 1905, and the yearly values indicate a steady decrease during 1906 and 1907. The ratio of the number of groups in the northern to the number in the southern hemisphere was almost reversed during 1907, for whereas in 1906 it was 1·55 : 1, in 1907 it was 1 : 1·28.

Meridian Circle Observations of Parallax Stars.—Lick Observatory Bulletin, No. 129, contains a list of forty-five stars which have been observed at the request of Dr. L. de Ball for use in his heliometer measures of parallax. The positions given are the results of 400 observations, made on twenty-five nights, by Prof. R. H. Tucker.

The Recent Total Solar Eclipse.—From a note in No. 1, vol. ii., of the Journal of the Royal Astronomical Society (Canada), we learn that the Lick Observatory eclipse party arrived back at Mount Hamilton on January 25. Rain fell during a part of the total phase, but some good photographs were obtained, for although the instruments were wet, they worked perfectly.

A New Expedition to the Southern Hemisphere.—With the object of extending Prof. Boss's fundamental catalogue work to the southern hemisphere, an expedition, under the direction of Prof. R. H. Tucker, of the Lick Observatory, is to be dispatched to either New Zealand, South America, or South Africa. The Carnegie Institution has offered to bear the expense of the proposed observatory, and it is expected that the work will take about three years to carry out. The large Pistor and Martins meridian circle of the Dudley Observatory (Albany, U.S.A.) will be employed for this work (Journal R.A.S., Canada, vol. ii., No. 1, p. 43).

The Hamburg Observatory.—Prof. Schorr's report of the Hamburg Observatory, for 1906, contains an account of the new buildings and instruments. The new observatory lies about 20 kilometres to the south-east of the present one, and is at an altitude of 40 metres above the Elbe. The buildings are in the shape of a **T**, and cover an area of 33,652 square metres. Among the new instruments is a Steinheil refractor of 60 cm. aperture and 9 m. focal length, to which is adapted a correcting lens for the purpose of photography, and a meridian circle of 19 cm. aperture and 2·3 m. focal length; the circles are of 74 cm. diameter, and are divided in 4′ intervals. Reports, in brief, of the 1905 and 1907 eclipse expeditions and of the variable-star observations and time-service are also given in the volume.

THE ZIEGLER POLAR EXPEDITION.[1]

In the introduction Mr. Fiala gives a somewhat scanty historical account of the expedition, a footnote referring the reader for details to his popular narrative "Fighting the Polar Ice." One gathers that the expedition was equipped by Mr. W. Ziegler, of New York—who died before its return—and that the vessel which conveyed the expedition to its objective, Franz Josef Land, in 1903 was lost, the party being eventually rescued in 1905.

Mr. Ziegler had the sagacity to leave the choice of a scientific leader to the National Geographic Society, and its selection of Mr. Peters seems justified by the results. Mr. Peters was himself to have prepared the scientific results for press, but shortly after his return to America he was appointed to the magnetic survey ship of the Carnegie Institution, and his duties as editor devolved on Mr. J. A. Fleming. The magnetic instruments, a unifilar magnetometer and a dip circle, were loaned by the U.S. Coast and Geodetic Survey, and a programme was prepared by Dr. L. A. Bauer. Meteorological instruments were lent by the U.S. Weather Bureau and the U.S. Signal Corps, and the completeness of the records obtained probably owes a good deal to the fact that one of the members of the expedition, Mr. Francis Long, was a trained observer of the U.S. Weather Bureau.

[1] "The Ziegler Polar Expedition 1903–5," Anthony Fiala, Commander. Scientific Results obtained under the direction of William J. Peters. Edited by John A. Fleming. Pp vii+630; with maps. (Washington, D.C. Published under the auspices of the National Geographic Society, 1907.)

The results appear under six sections:—magnetic, pp. 1–360; auroral, pp. 361–8; meteorological, pp. 369–488; tidal, pp. 489–596; astronomical, pp. 597–622; and map construction and survey work, pp. 623–630. The pocket at the end contains a map of the Polar regions down to latitude 65°, indicating the routes of the chief Polar expeditions, and two charts of Franz Josef Land, one of the whole archipelago and the other of the part surveyed by the Ziegler expedition.

The magnetic work consisted mainly of observations at Camp Abruzzi, Teplitz Bay (81° 47′·5 N. lat., 57° 59′ E. long.), from September 28, 1903, to July 1, 1904, and at Camp Ziegler, Alger Island (81° 21′·5 N. lat., 56° 5′ E. long.), from June 26 to July 30, 1905. Miscellaneous observations were also taken at Tromso, Archangel, Barents Sea, and *en route* from Teplitz Bay to Cape Flora. Teplitz Bay, in Rudolph Island, is in the extreme north of the group of islands forming Franz Josef Land; it was the station occupied by the Duke of the Abruzzi's Italian expedition in 1899–1900. Alger Island is towards the south of the group, while Cape Flora, in Northbrook Island (the site of the Jackson-Harmsworth expedition), is in the extreme south. Fig. 1 (from p. 604) shows the nature of the observatory at Teplitz Bay. Prefaced to the magnetic observations is a condensed narrative relating mainly to auroral appearances and observational details, but occasionally of more general interest, as the following extract from the February, 1904, record will show:—

"12:20:00 sky clear, no aurora; 12:22:56 bear trying to break into observatory; 12:23:20 aurora in south-east; 12:23:40 to 48 observer investigating outside to see if bear is gone." For some time after this incident the observer, following the example of the Nansen expedition, provided himself with a revolver, the presence of which is conscientiously recorded. Considering the absence of self-recording instruments, the magnetic results obtained are, thanks to Dr. Bauer's programme, remarkably extensive. Eye readings of the declination magnet were carried out, so far as the exigencies of the situation permitted, on the following plan. On one day each week readings were taken at two-minute intervals throughout the whole twenty-four hours; on a second day similar observations were made for eight hours, and on each of four other days for four hours. The observations on these last five days were so arranged as to cover all hours of the day; thus results were obtained in each week answering to observations at two-minute intervals for two complete days. Diurnal inequalities of declination were formed for each four-week period at Teplitz Bay, each hourly value being a mean from 4×2×30, or 240, readings. These inequalities are analysed in Fourier series and illustrated by curves. During the nine months at Teplitz Bay, the range of the regular diurnal inequality varied from 107′·1 in June to 26′·3 in February–March. The mean of the ranges from the two four-week periods November 29 to December 26 and December 27 to January 23 was 36′·7. The existence of so large a range in the Arctic mid-winter is noteworthy. Throughout the whole time the general character of the diurnal variation was an easterly movement (of the north end of the magnet) from about 8 p.m. to 5 a.m. The return movement to the west was fairly continuous and rapid in summer, but in winter there was usually a secondary east and west movement in the afternoon. The greater rapidity of the movement during the day, so characteristic in temperate latitudes, seems not to exist at Teplitz Bay except at midsummer. The corresponding analytical feature is the relatively small amplitude of the twelve-hour Fourier wave. The diurnal inequality of declination observed at Alger Island in June–July, 1905, had a somewhat smaller range, but was generally similar to that observed at Teplitz Bay at the previous midsummer. A satisfactory feature in connection with the declination observations is the frequency and consistency of the determinations of the true bearing of the distant marks employed.

More than fifty absolute observations of horizontal force and more than sixty observations of inclination (with two needles) were made at Teplitz Bay; at Alger Island there were sixteen observations of horizontal force and eight of inclination.

In accordance with the experience of previous Arctic observers, it was found that whilst magnetic storms and aurora were generally associated together, this was not always the case. Declination observations happened, fortunately, to be taken on November 1, 1903, during part of the great magnetic storm then in progress. In the course of 1h. 48m. the declination changed by 17° 18′, or some thirty-two times the corresponding change at the Cheltenham Observatory (where the horizontal force is about three times that at Teplitz Bay). If the same proportion existed throughout the rest of the storm, the declination range at Teplitz Bay must have exceeded 50°.

The auroral data are mainly descriptive, and there is no attempt at trigonometrical observations or tabular details. There are, however, nineteen handsome plates,

Fig. 1.—Exterior of Observatory at Teplitz Bay.

based on chalk sketches made by Mr. Fiala, illustrating a number of auroral types, especially the corona. Plates VII. and VIII. show banded structures having in some respects a somewhat striking resemblance to those produced artificially by Villard.[1]

Of the meteorological observations, the longest series consists of hourly records of wind velocities from a Robinson cup anemometer at Teplitz Bay from September, 1903, to May, 1905. Allowing for possible differences between American and English estimates of wind velocity, we may safely characterise Teplitz Bay as a windy place. The average velocity for the whole period was 14·6 miles per hour. Monthly means varied from 8·2 in August, 1904, to 24·2 in February, 1905, and 24·6 in December, 1903. On four days the mean hourly velocity exceeded sixty; on December 28, 1903, the mean velocity was no less than 73·4 miles per hour. In winter, high gales were associated with a low barometer and a high temperature. Changes of temperature were notably large and rapid. Eye readings were taken thrice a day, at 8 a.m., noon, and 8 p.m., of barometric pressure, temperature (from ordinary and from maximum and minimum thermometers), precipitation, wind (velocity and direction), and cloud (amount, species, direction of motion). These observa-

[1] Nature, vol. lxxvi., p. 481.

tions lasted at Teplitz Bay from September 1, 1903, to April 30, 1904, and at Cape Flora from May 21, 1904, to July 30, 1905. Taking the mean of the three daily readings, the monthly mean temperature varied at Cape Flora from $-19°·9$ F. in January to $+35°·6$ in July; at Teplitz Bay, March had the lowest mean temperature, $-19°·7$ F. At Cape Flora, the precipitation during the year ending with May, 1905, was equivalent to 21·37 inches of rain. A recording thermograph and barograph were in action at Teplitz Bay from October, 1903, to April, 1904, and a barograph was run at Cape Flora from June, 1904, to May, 1905. From the records of these instruments diurnal inequalities are deduced for individual months, and Fourier coefficients calculated. Taking arithmetic means from individual months, the amplitudes (in thousandths of an inch) of the three first terms in the case of the barometric pressure were :—

	24-hour	12-hour	8-hour
Teplitz Bay (winter)...	14	6	3
Cape Flora (year)	13	5	3

Tidal observations were made at Teplitz Bay from April 1 to June 3, 1904, and at Cape Flora from May 21 to August 31, 1904. Readings, to 0·01 foot, were taken on a tide staff once an hour, usually throughout the whole twenty-four hours. Fig. 2, reproduced from p. 493, shows the arrangements at Teplitz Bay. The wooden frame

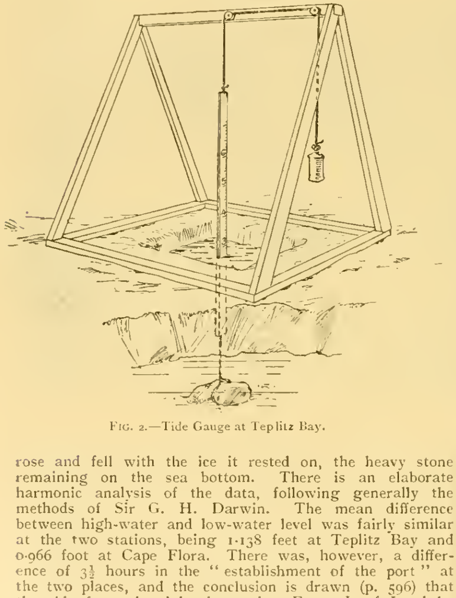

FIG. 2.—Tide Gauge at Teplitz Bay.

rose and fell with the ice it rested on, the heavy stone remaining on the sea bottom. There is an elaborate harmonic analysis of the data, following generally the methods of Sir G. H. Darwin. The mean difference between high-water and low-water level was fairly similar at the two stations, being 1·138 feet at Teplitz Bay and 0·966 foot at Cape Flora. There was, however, a difference of $3\frac{1}{2}$ hours in the "establishment of the port" at the two places, and the conclusion is drawn (p. 596) that the tide from the Atlantic reaches Franz Josef Land by two channels, the deeper, between Spitsbergen and Greenland, chiefly influencing Teplitz Bay, the other, between Spitsbergen and Norway, chiefly influencing Cape Flora.

The astronomical observations served to fix the latitude and longitude of the stations and the azimuths of the declination marks. Considerable care was evidently given to them, but they call for no special remark.

As will have already been inferred, one can have nothing but praise for the zeal displayed. Magnetic observers who took observations at two-minute intervals for eight hours on end, at temperatures below 0° F., cannot be accused of treating Arctic exploration as a pretence for a picnic. It may also be added that no trouble has been spared in making the most of the material collected. Valuable, however, as the results are, they must be accepted with several reservations. As the dates will have shown, the series of observations, especially the tidal ones, were short, and the representative nature of the results is thus exposed to more or less doubt. This consideration cannot but suggest itself to anyone who examines some of the data critically. Taking, for instance, the mean monthly data from the thermograph record at Teplitz Bay, we find that in March the 10 p.m., midnight, and 2 a.m. readings are the only ones of the two-hour readings to *exceed* the mean for the day, the *maximum* coming at 2 a.m.; but in April these are the precise hours to which the lowest temperatures are attached. Again, the diurnal inequality range is $3°·3$ in January, in the depth of the Arctic night, but only $0°·8$ in October. In the case of the magnetic data, there are other sources of uncertainty. There was appreciable local disturbance both at Teplitz Bay and Alger Island, and its precise effect, though probably not large, cannot be assigned. After the return of the magnetometer to America it was found that a cloth hood, believed to have been fastened to the end of the magnet box in 1899, had been attached with steel tacks. Observations at Cheltenham showed no effect on the declination, but a decrease of 250 γ (1 $\gamma \equiv 0·00001$ C.G.S.) in the horizontal force. A correction of $+255$ γ (or nearly 4 per cent.) was thence *calculated* and applied to observations made in the Arctic. In the case of the dip circle comparisons at Cheltenham before the expedition gave for the two needles corrections of only $+0'·2$ and $-0'·3$, but the corresponding corrections obtained after the expedition were $-4'·1$ and $-5'·6$.

In view of these uncertainties, and the lack of direct information as to diurnal change, the deductions made as to secular changes of horizontal force and inclination at Teplitz Bay by comparison with the results of the Italian observers for 1900 should be regarded with reserve.

Again, at Teplitz Bay there were only nine months' magnetic observations, and the deductions of diurnal inequalities for the three missing months, and thence for the year as a whole, are of somewhat doubtful value.

The deficiencies referred to are such as attach more or less to most expeditions, and there are probably few Polar observations which are not affected by at least as serious uncertainties. There are many points in connection with the observational programme and its execution which merit the attention of those contemplating magnetic or meteorological work in high latitudes. C. CHREE.

SANATORIA FOR CONSUMPTION.

AS a supplement to the thirty-fifth annual report of the Local Government Board, Dr. Bulstrode has published an imposing volume on "Sanatoria for Consumption and certain other Aspects of the Tuberculosis Question." This report, copiously illustrated by photographs, plans, and charts, extends to 700 pages, and is an admirable exposition of the present position of the problem of prevention of tuberculosis.

In part i. is set forth a general review of the changes which have taken place in medical opinion as to the etiology of tuberculosis and as to the mode of its invasion of the human body.

The theory of infection by inhalation of dust infected by dried sputum, and the evidence on which it is based, is reviewed; also the theory of von Behring that infection can be usually traced to the ingestion of tuberculous milk in infancy, remaining latent until some debilitating influence causes the focus of infection to light up to the undoing of the organism. Calmette's theory that direct infection occurs mainly by the ingestion of food tainted by droplets of infective expectoration is also discussed, and finally we have the conclusions of the Royal Commission on Tuberculosis, that a material amount of human tuberculosis is attributable to infection of the intestinal tract by "tubercle of bovine origin."

The proportion of tuberculosis due to this source, unfortunately, has never been definitely ascertained, but the pronouncement of the Royal Commission is important in the light of Koch's dogmatic statements as to the essential difference between human and bovine tubercle, and all this difference entails.

Dr. Bulstrode gives us many tables of statistics which prove the gradual but steady diminution of tuberculosis, and emphasise the curious phenomenon that this declension is much more marked among females.

In this satisfactory state of affairs sanitary reform, improved conditions of living, and higher wages have all played their part, but the report does not help us much to estimate the relative value of the various methods of attacking the disease which have been tried.

The difficulty of estimating the value of sanatorium treatment is brought out, and we are told that until this method has had a longer trial figures of results will only lead to confusion and misconception.

Stress is, however, laid on the fact that to obtain the best results from sanatorium treatment cases of tuberculosis must be treated in their earliest stages, and further, that after treatment an easy path of suitable work must be provided until a life of full activity can be tolerated by the patient.

The problems which arise in the selection of a sanatorium site, and the conditions necessary in sanatorium buildings, are thoroughly discussed. Dr. Bulstrode concludes that, with foresight and care, the erection of sanatoria with all actual essentials might be provided at a smaller cost than has hitherto been the case. This is an important conclusion, for if we are to provide adequately for the tuberculous population, many more sanatoria must be erected, and the question of money has ever been the chief difficulty in the way.

One of the most interesting chapters, which is amplified in part iv., relates to the German system of compulsory insurance as a factor in the control of phthisis. The figures given are striking, and we see here admirably exemplified the value of coordinated effort as opposed to the haphazard methods of control employed in the British Isles.

The conclusion is thrust upon us that in the control of phthisis Germany is far ahead of us. We are set an excellent example, which we would do well to follow. Our comparative failure is largely due to this want of coordination, and the waste of money and energy thereby entailed.

This part of the report concludes with a chapter on the teaching of hygiene in the public elementary schools. Tuberculosis is associated with ignorance no less than with poverty, so that there can be no question as to the importance of teaching elementary hygiene, especially so far as food values are concerned, as a means to the reduction of tuberculosis both in childhood and adult life.

In part ii. we are given a well-illustrated directory of all the public sanatoria in England and Wales, which should prove of much value for reference. This part of the report has been provided with an index, which might mercifully have been extended to the whole volume.

Part iii. is devoted to a discussion of notification of tuberculosis (voluntary and compulsory). There are as yet no data available by which the substantial utility of notification can be tested, and we must await a more extended experience before a decided opinion can be formed.

The whole volume is an admirable and comprehensive piece of work, which should be read by all interested directly or indirectly in the problems of tuberculosis.

R. Fielding-Ould.

THE SOCIETY OF DYERS AND COLOURISTS.

The twenty-fourth annual general meeting of the Society of Dyers and Colourists was held at Bradford on Friday, April 3, in the large hall of the Technical College. The president, Prof. Meldola, having taken the chair, the Lord Mayor of Bradford, on behalf of the town, welcomed the meeting, and especially the distinguished foreign visitors, Prof. Liebermann and Dr. Schreiner, who were present. The president then, on behalf of the society, awarded the Perkin medal, which for this occasion had been duplicated, to Profs. Graebe and Liebermann for their synthesis of alizarin in 1868. The medal was founded by the society in 1906 in honour of the late Sir William Perkin, and in celebration of the jubilee of the discovery of mauve, the first of the coal-tar colouring matters, the terms of its award being "for investigations, discoveries or inventions of high scientific or industrial importance applicable to or connected with the tinctorial industries."

In presenting the medals, which Prof. Liebermann received on behalf of himself and colleague, the president pointed out that this first presentation was in recognition of a discovery which, although made forty years ago, was still practically effective in enabling the tinctorial industry to be supplied with some of the most important of the artificial colouring matters. The synthesis of alizarin was of extreme scientific interest as having been the first case of the artificial production of a natural colouring matter, and it was also of particular importance as having exerted a marked influence on Perkin's career as a manufacturer and scientific investigator. Prof. Liebermann, on behalf of Prof. Graebe and himself, acknowledged the honour which had been conferred upon them, and in eloquent terms paid tribute to the memory of the late Sir William Perkin.

The president then delivered an address on the founding of the coal-tar colour industry, in which he reviewed Perkin's life-work from the technical side, and gave a history of the foundation and development of the Greenford Green factory, where all Perkin's industrial operations were conducted. On the motion of Mr. Hindley, seconded by Dr. Hertz and supported by Sir Robert Pullar, the president was thanked for his address, which was ordered to be published in the journal of the society.

In the evening the members and their guests dined at the Great Northern Victoria Hotel, the president occupying the chair, and being supported by Prof. Liebermann, the Lord Mayor, the ex-Lord Mayor, Sir Robert Pullar, Dr. C. Dreyfus, and representatives of most of the great dyeing and printing firms of the district, as well as by well-known authorities connected with the educational and scientific side of the tinctorial industry, such as Profs. A. G. Green (Leeds), W. M. Gardner (Bradford), Dr. J. C. Cain (London), Dr. Knecht (Manchester), and Mr. C. Rawson (Leicester), &c. All the officers of the society, which has its headquarters in Bradford, with sections in Manchester, the West Riding, and London, were also present. The toast of the society was proposed by the Lord Mayor, and responded to by Sir Robert Pullar. The president gave the toast of the medallists, which was enthusiastically received in both German and English forms, and to which Prof. Liebermann responded. The toast of the president was proposed by Mr. Ald. Godwin, the ex-Lord Mayor, in a humorous speech, and replied to from the chair. Dr. Schreiner, the inventor of the well-known process for "Schreinerising" fabrics, also addressed the meeting in acknowledgment of the honour done to his distinguished countrymen and to himself as a guest. As Prof. Graebe was unable through indisposition to be present at the gathering, a telegram was dispatched in the name of the society expressing regret at his absence and wishes for his speedy recovery.

ENCKE'S COMET.

The observations of Encke's comet made at the Heidelberg Observatory deviate so strongly from the predicted places that Dr. Backlund, the director of the Pulkowa Observatory, has thought it necessary to investigate the cause. He finds that the perturbations by Jupiter, which were calculated in duplicate by H. Kamensky and Fraulein Karolikowa, have been correctly applied, so far as they depend on the first power of the disturbing force, but that in the period 1901–4 the comet approached Jupiter almost as closely as is possible, and that in consequence perturbations of the second order are very sensible. The corrections to the several elements, depending on the action of Jupiter, were as follows:—

	1st Order	2nd Order
	′ ″	′ ″
Mean anomaly	+11 55·2 ...	−3 34·1
Long. perihelion	−0 8·5 ...	−0 15·7
Long. node	+0 4·8 ...	−1 0·2
Inclination	+1 2·0 ...	—
Excentricity	+2 39·8 ...	−1 7·6
Mean motion	+0″·9255 ...	−0″·3210

The corrections to the ephemeris, after applying the improved value of the perturbations, and taking into account the influence of the acceleration, are, for the three days:—

	1908, Jan. 3	Jan. 11	Jan. 19
Δα	+0 49·25	+0 40·31	+0 27·50
Δδ	−2 24·75	−2 21·69	−2 21·65

whereas the corrections to the published ephemeris, found by Dr. Kobold from Dr. Max Wolf's observations, are of quite a different character:—

	Δα	Δδ
1907 Dec. 25	+34·5	−24
1908 Jan. 2	+35·2	−24
,, ,, 13	+47·0	− 4·9
,, ,, 14	+47·2	− 3·6
,, ,, 15	+47·0	− 2·4
,, ,, 18	+45·3	+ 0·5
,, ,, 19	+44·3	+ 1·4

It will be seen that the neglected perturbations in no way explain the deviations between the computed and observed places. In declination these differences are particularly striking, and no permissible alterations to the elements will reduce them to the order of errors of observation.

Prof. Backlund makes two suggestions by way of explanation:—(1) that the object observed from December 25 to January 19 was not Encke's comet; (2) that this comet has divided itself into two parts, and that the part that has been observed has, by the process of dislocation, been deflected from the original orbit. Observations in the southern hemisphere, which will be possible in June, will decide this point. Dr. Backlund further points out that, previous to this year, the comet has never been observed before perihelion passage when the date of perihelion falls between April and July.

Dr. Ebell has computed a parabolic orbit from the observations made at Heidelberg, and the result is sufficiently surprising. The dates selected were January 2, 13, and 19, and the middle place is fairly well represented, but the outstanding errors on December 25 were $\Delta\lambda + 32'{\cdot}40$ and $\Delta\beta + 12'{\cdot}19$. The elements are as follows:—

T ... 1907 Dec. 6·0569 Berlin M.T.

$$\left.\begin{array}{lll}\omega & \ldots & 39^\circ\ 25'{\cdot}59 \\ \Omega & \ldots & 317\ \ 7{\cdot}25 \\ i & \ldots & 10\ 26{\cdot}99\end{array}\right\}\ 1908{\cdot}0$$

$\log q$ ... 0·58448

The node and inclination are not very different from those of Encke, but the perihelion distance is rivalled only by the comet of 1729. The material is not sufficient to derive an ellipse. It will probably be found that the Heidelberg object is not the comet of Encke.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

London.—The report of the committee of University College for the year 1907–8 has just been issued. During last session there were 1191 students, of whom 171 were registered as post-graduate and research students. The report deals, among other matters, with the work of the faculties for the past year, and gives a list of the researches and original papers published during that year. That list occupies thirteen octavo pages. Among the departments that seem to have been specially productive may be noted the department of applied mathematics under Prof. Karl Pearson, from which no fewer than twenty-eight papers were issued during the year. Seven of these were from the Francis Galton Laboratory of National Eugenics. The departments of chemistry under Sir William Ramsay and Prof. J. Norman Collie produced twenty-four original papers, while the subdepartment of spectroscopy issued seven. The list of post-graduate courses is valuable as an indication of the extensive provision for higher work that is now to be found in London. The report concludes with a summary of the urgent needs of the college if it is to meet the demands made upon it; they include the following:—

	Estimated Cost	Money Available
New buildings for anatomy, physiology, and pharmacology ...	£ 50,000	£ 15,250
New buildings for the department of chemistry. (The scheme could be carried out in two sections, costing 40,000*l.* and 30,000*l.* respectively) ...	70,000	nil
Building alterations and new equipment for botany and pathological chemistry ...	5,000	nil
Re-fitting of general library and completion of science library ...	5,000	nil

Dr. J. M. Fortescue Brickdale has been appointed director of the public health laboratory of University College, Bristol.

The Fishmongers' Company has given 1000*l.* towards the fund for carrying out the scheme of incorporation of King's College with the University of London.

Mr. Carnegie has given a further donation of a million pounds sterling to the Carnegie Foundation for the Advancement of Teaching. Attention was directed in our issue of March 12 (p. 452) to the admirable work done already by the foundation, which was two years ago inaugurated by Mr. Carnegie and endowed by him with two millions sterling. The fund, which now amounts to 3,000,000*l.*, is intended primarily to serve for providing retiring allowances for professors and others in universities and colleges in the United States, Canada, and Newfoundland. Originally the benefits of the foundation were confined to privately endowed educational institutions, and Mr. Carnegie has increased the fund so that professors in State institutions may also be eligible to participate in the benefits of the scheme.

The seventy-fourth annual report of Bootham School (York) Natural History, Literary, and Polytechnic Society, that for 1907, provides excellent evidence that in some English secondary schools at least the out-of-school hours are opportunities in which the boys may follow their natural bent and cultivate their individuality. The boys band themselves together in societies for the outdoor study of numerous branches of natural history; they record meteorological data, study the archæology of the neighbourhood, practise photography, work in metal and wood, and besides these and other practical pursuits they take part in a flourishing literary society. Boys and masters are to be congratulated upon the report, and the boys also on the fact that they are allowed to manage the societies largely by themselves.

It is well known, says the Journal of the Royal Society of Arts, that American employers give much more attention than has been the practice in this country to affording facilities to their managers and workpeople for obtaining technical knowledge. For example, a large organisation of spinners and manufacturers at Atalanta (Georgia) has adopted the following scheme for keeping their employees up to date in commercial and technical knowledge of the textile trade. A librarian is employed to secure all the latest books dealing with spinning, weaving, and textile engineering; all periodicals from all parts of the world bearing on the subjects are purchased or otherwise secured. The librarian prepares brief descriptions of the books, to which anyone may refer to get a quick idea of the contents. In some instances the whole periodical is filed; in others special articles are cut out, and sometimes foreign articles are translated and pasted in scrap-books. Everything is carefully indexed, and the library is open to any employee.

A nature-study course for women is to be given again this year at the Horticultural College, Swanley, Kent, during the summer holidays. The course will extend from August 1 to 12. Weather permitting, most of the instruction will be given out of doors, rambles in the country under the guidance of experienced teachers being the chief feature. It is hoped to combine the natural history excursions with points of antiquarian and other interest in outlying districts, and an endeavour will be made to render the course useful, both for home life and school work. The report for 1907 on the work of the college as a whole shows that good progress continues to be made. The chief feature of the year was the establishment of a course in natural history, which has for its object the training of third-year students who have passed the ordinary gardening course at the college and wish to increase their knowledge of natural history subjects in order to qualify as teachers of gardening and nature-study.

THE third International Congress for the Development of Drawing and Art Teaching is to be held in London from August 3 to 8 next. Previous meetings in Paris in 1900 and in Berne in 1904 proved very successful in stimulating the application of art to industry. The promoters of the London meeting direct attention to the fact that as a nation Great Britain compares unfavourably with her commercial competitors in the attention paid to applied art in technical schools. On these grounds, with others, an appeal is made to educational authorities and employers of labour to assist in making the forthcoming congress a success, both by contributions to the necessary funds and by interesting administrators and teachers in the scheme. Drawing should be allied with all subjects of study, but it is especially useful to the student of science, and it is to be hoped that the congress will lead to an improvement in the methods of teaching drawing in our schools, as well as to a recognition of its importance in a complete scheme of education. Full particulars of the London meeting can be obtained from the secretary of the congress, 151 Cannon Street, London, E.C.

THE second International Congress of Popular Education is to be held in Paris from October 1 to 4 next. It is being arranged by la Ligue française de l'Enseignement. Invitations have been sent to various educational associations in different parts of the world to send delegates to the congress. All expenses in connection with the congress are to be borne, we understand, by the league. Among the subjects to be introduced and discussed at the meetings in Paris may be mentioned:—Societies for the encouragement of the education of the masses, popular lectures and libraries, the education of women in household and maternal duties, professional education, the international exchange of children for educational purposes, and the system of visits by teachers for the study of foreign methods. It is hoped to publish the addresses and discussions at the congress, and in this way to bring together much valuable experience gained in different countries in the direction of solving difficult educational problems. There is every reason to hope that the meetings will prove even more successful than those of the first congress, held at Milan in 1906. All inquiries should be addressed to M. Léon Robelin, general secretary of la Ligue française de l'Enseignement, 16, rue de Miromesnil, Paris.

THE accounts for the year ending July 31, 1907, of the various London polytechnics show that the total ordinary receipts of all the institutions amounted for the year to 203,952*l*. The grants of the London County Council amounted to 77,358*l*., or 37·93 per cent. of the total receipts. Grants from the Board of Education reached 32,844*l*., or 16·11 per cent.; the amounts received from City Parochial Foundation were 28,330*l*., or 13·89 per cent., and from City companies, &c., 5917*l*., or 2·90 per cent. The total ordinary expenditure on revenue account of all the institutions amounted to 207,519*l*. Large increases occurred under two heads, viz. "teachers' salaries," 10,317*l*., and "apparatus and other educational appliances and furniture," 3116*l*. Taking the results as shown by the accounts, it is seen that, so far as ordinary income and expenditure are concerned, there was a deficit of 3567*l*. on the institutions as a whole. With regard to items of an exceptional nature—principally new building works and special equipment—the total income was 15,089*l*., of which the London County Council's grants amounted to 9401*l*., and the expenditure was 9113*l*. Of the total amount of revenue, it is interesting to note that the fees of students and members of the various polytechnics amounted in all to 47,255*l*., or 21·57 per cent., and what are called in the accounts voluntary subscriptions reached 9161*l*., or 4·18 per cent., nearly twice as much as in the previous year, though other percentages were practically the same in both years.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 5, 1907.—"On the Structure of *Sigillaria scutellata*, Brongn., and other Eusigillarian Stems, in Comparison with those of other Palæozoic Lycopods." By E. A. Newell **Arber** and Hugh H. **Thomas.** Communicated by Dr. D. H. Scott, F.R.S.

This paper contains the first full account of the structure of the Eusigillariæ or ribbed Sigillarias of the Rhytidolepis section. The stele has a well-marked pith, bounded by a continuous ring of scalariform tracheides—the primary wood—the outer margin of which is crenulated. The ribs are really formed of cortical tissues, and not by fused leaf-bases. They consist largely of phelloderm, and externally what is probably a small zone of primary cortex, which lay without the region of secondary meristermatic activity, still persists. The leaf-bases, consisting of thin-walled parenchymatous elements, merely form bracket-like projections from the ribs.

The presence of a ligule and a ligular pit has been detected for the first time. The course of the leaf-traces in the leaf-bases and cortical tissues has been followed with important results. The bundle is collateral, and without secondary wood. In the leaf-bases the trace consists of a *double xylem strand*, the two xylem groups being widely separated. These two strands unite as they pass through the phelloderm. The structure of the trace is almost identical with the foliar bundle of the leaf *Sigillariopsis sulcata*, which is obviously simply the leaf of a eusigillarian stem.

The parichnos increases greatly in size as we pass from the exterior of the stem to the inner margin of the periderm. The two strands further unite, first below and then above the trace, so that, at a deep level in the periderm, the trace is completely surrounded by a broad zone of this tissue.

January 16.—"The Conversion of Diamond into Coke in High Vacuum by Kathode Rays." By the Hon. C. A. **Parsons,** C.B., F.R.S., and Alan A. Campbell **Swi ton.**

The apparatus employed consisted of a Crookes tube furnished with two concave cup electrodes of aluminium which, when supplied with high-tension alternating current, acted alternately as kathode and anode, and accurately focussed the kathode rays on to the diamond, which was supported on a plate of iridium.

As the proper degree of vacuum was reached by means of mercury pumps, and as the volts were raised, the diamond in each of the two experiments made became red, and then intensely white hot, until with about 9600 volts and 45 milliamperes passing through the tube it commenced to become black.

Finally, with 11,200 volts and 48 milliamperes (537 watts), a rapid disintegration of the diamond took place with considerable increase in volume, the residue having much the appearance and consistency of coke. As measured by a Féry optical pyrometer, the disintegration took place at the temperature of 1890° C.

Observations of the spectra of the residual gases in the tube before and after the conversion of the diamond into coke showed differences, but these were not thought sufficiently marked to determine with exactitude any variation in the nature of the gases present.

January 23.—"Report on the Eruptions of the Soufrière in St. Vincent in 1902, and on a Visit to Montagne Pelée in Martinique. Part ii.—The Changes in the Districts and the Subsequent History of the Volcanoes." By Dr. Tempest **Anderson.** Communicated by Prof. T. G. Bonney, F.R.S.

The principal points of interest in the observations made during the author's second visit lie in (1) the changes wrought by denudation on the deposits left by that eruption; (2) the light thrown by those changes on the operation of the forces which had moulded the features of this island in its earlier history; (3) the information he was able to collect with regard to the volcanic disturbances subsequent to the great eruption of May, 1902; and (4) the return of vegetation to the devastated areas.

In the 1902 eruption a certain amount of the ejecta overtopped the Somma ring, *i.e.* the remains of the original great crater, and descended some of the valleys to the north of it; but by far the greater portion was discharged into the transverse depression which extends right across the island and separates the Soufrière from the mountain known as Morne Garu, about three miles to the south. The water from the crater lake was discharged at the beginning of the eruption down the Rabaka and Wallibu rivers, while the solid and gaseous ejecta, in the form of the incandescent avalanches and black clouds, descended to both sides of the island.

The most important geological phenomena were observed in the Wallibu district. These phenomena have been fully described in the published report, as also the subsidence of part of the coast. To this district, therefore, attention was especially directed in 1907 with the view of observing the further progress of the changes and the return of vegetation.

A description of the Wallibu valley is given in the full paper. In that district the beds of newer date have been dissected into flat-topped plateaux by small rivers running in deep gorges, which have again been filled in places by ejecta of eruptions and re-excavated in different degrees, and sometimes on different lines, leaving plateaux and terraces of different ages and heights. This action is well exemplified in the lower valley of the Wallibu. In the 1902 eruption this part of the valley was filled by the incandescent avalanche to a depth of at least 100 feet in the upper part, and less towards the sea, and it was in this deposit of hot ash that the explosions of steam and hot ash, flows of boiling mud, and other secondary phenomena took place. In 1907 almost the whole of this ash had been washed away, but a fragment remained in the shape of a terrace 60 feet to 80 feet high, situated on the north side of the valley. The ash of which it is formed is unstratified, and contains very few ejected blocks or fragments of any kind. The floor of the valley is all composed of water-sorted material, chiefly gravel and coarse sand, but with a good many blocks as big as a man's head. They represent ejected blocks and fragments of lava derived partly from the ash of 1902 and partly from older beds, the fine ash in each case having been washed away. The surface of the gravel bed showed marks of quite recent running water, and during the last winter, 1906–7, the river ran along the foot of the north bank of the valley. When examined in March, 1907, it ran along the south side of the valley, and had already in those few months excavated a new channel about 30 feet in depth. The stratification, as exposed in the side of this new valley, is very distinct, and the sorting by water, mentioned above, is very evident. Further up the mountain the remains of the avalanche became more abundant in the valley bottoms, and here they were also often better preserved, so that traces of the feather pattern erosion, so noticeable in 1902, were still visible on the surface. This was mainly due to the surface of these ash deposits, like those to be presently mentioned on the plateaux and on the ridges, having consolidated into a crust almost like a cement pavement which resists the action of the rain.

Another interesting point was observed with regard to these massive ash deposits. Instead of one stream re-establishing itself along the centre of the deposit, the tendency is for a new stream to form on each side at or near the junction of the new ash with the old valley slopes; and, as these streams deepen themselves, two new valleys are formed where only one previously existed, and the walls of each are composed on the one side of the new ash and on the other of older tuff, with occasional terraces of new ash. It appears to be due to the fact that the water from the old slopes, in running down into the original valley, meets the soft new ash, and at once turns down along the valley and so starts the new stream, and it seems likely that the chief cause of its so turning is that the surface of the deposit tends to be higher along the middle of the valley than at the sides, as is usual with mud-streams or glaciers. A good example of the action above described is to be found in a wide valley to the north of and parallel with the lower Wallibu valley, and bounded on the south by the Wallibu plateau. Before the 1812 eruption the Wallibu river flowed down this valley, but its course was changed after that eruption. The floor of the valley is now occupied by the gorges of two small rivers, divided by a very narrow ridge, formed of ash different from and less consolidated than that composing the walls of the main valley, and considerably lower than the Wallibu plateau. In 1902 both these gorges were filled with new ash to the level of the main valley floor. One of these, the Trespé gorge, now emptied of the 1902 ash, shows its north wall to be much higher than the south, and also formed of older and more consolidated tuff. The same conditions, with sides reversed, are seen in the other gorge, the higher bank in that case being the Wallibu plateau to the south.

The Wallibu plateau is composed of ash older than that dividing the above two small rivers, but still comparatively new, and its flat top and precipitous sides, both north and south, proclaim it to be in an early stage of denudation, while the south bank of the Wallibu river on the south of the plateau is composed of older tuff and lava, and shows a much more mature type of denudation, viz. sloping hills with rounded or ridged tops, and a good deal weathered into valleys or gullies. The north face of the plateau, like the south, is precipitous, and obviously much less advanced in weathering than the slopes of the Soufrière on the opposite side of the broad valley of the Wallibu Dry, and Trespé rivers to its north. The mass appears to be the remains of an avalanche, or succession of avalanches, of hot ash poured into the depression between the Soufrière and Morne Garu, on an enormously larger scale than anything formed by recent eruptions. It may be that the present bed of the Wallibu to the south and the broad valley to the north are enlarged and deeply excavated developments of the valleys that were formed at the sides of this prehistoric avalanche.

Descriptions of the changes in the fans and low plateaux subsequent to 1902, of the shore subsidence, and of the upper slopes of the mountain, are given in the full report, as well as a detailed description of the crater as seen in 1907.

The topography of the old crater is still correctly represented on the Admiralty Chart (published with the report, part i.). The whole of the interior of the crater is still quite bare, without any trace of returning vegetation; small patches of moss appear about the rim and on the slopes outside, then grasses, herbaceaus plants, and large sheets of ferns, and lastly, below a height of about 1500 feet, luxuriant tropical vegetation. It is interesting that this sequence presents many points of resemblance with that observed on Krakatoa.

The present condition of the devastated areas is described fully in the report, which contains also a history of subsidiary eruptions which followed the great one of May, 1902. The difference in character between the eruptions of the Soufrière and Montagne Pelée, referred to in the report of 1902, appears to have continued since that year, the outbursts from the former volcano being generally less frequent but more violent than from the latter.

The report also contains an account of a subsequent visit to the volcano of Montagne Pelée, in Martinique, with a description of the crater as the author then found it; a discussion of the phenomena of the remarkable extrusion and subsequent destruction of the dome and spine, which have been described by Lacroix and others, and a comparison of the sequelæ of the great eruptions in the two islands of Martinique and St. Vincent.

Entomological Society, March 18.—Mr. C. O. Waterhouse, president, in the chair.—*Exhibits*.—Dr. T. A. **Chapman**: Photographs of the empty egg-shells and young larvæ of *Papilio homerus*.—G. C. **Gahan**: (1) A remarkable larva of the Trictenomidæ, which, though heteromerous, was wholly different in character to the larvæ of that group;

(2) a larva of *Dascillus cervinus* from Ireland.—**President**: Photograph drawing of the larvæ of Coniopteryx, a small neuropteron common enough in its perfect state, but rarely found as a larva, when it may be beaten out of fir trees.—W. J. **Kaye**: Three Pereute species from the Chanchamayo district of Peru, viz. *P. leucodrosime*, *P. callinice*, and *P. callianira*, together with specimens of the Nymphaline *Adelpha lara*. These Pierines and Nymphaline occurred together at an elevation of from 2500 feet to 3000 feet. It was wrong to suppose that any *Heliconius melpomene*-like species entered the association, as Heliconius species of this pattern did not ascend to such an elevation, or if they ever did it was only as a rare exception. On the under-side, if when both Pereute and Adelpha are at rest they conceal the coloured portion of the fore-wing, the hind-wing would then give a very strong similarity of one to the other.—L. W. **Newman**: A long and varied series of *Smerinthus populi* bred from wild Bexley parents in June, 1907, the series ranging from extreme dark specimens (about 6 per cent.) to very light (about 10 per cent.), and pink shaded or tinged (about 20 per cent.), the remainder being intermediate forms.—*Paper*.—The larvæ of *Trictenotoma childreni*, Gray, and *Melittomma insulare*, Fairmaire: C. J. **Gahan**.

Chemical Society, March 19.—Sir William Ramsay, K.C.B., F.R.S., president, in the chair.—A new form of pyknometer: W. R. **Bousfield**.—The action of heat on α-hydroxycarboxylic acids, part iv., racemic-$\alpha\alpha'$-dihydroxyadipic acid and meso-$\alpha\alpha'$-dihydroxyadipic acid: H. R. **Le Sueur**. $\alpha\alpha'$-Dihydroxyadipic acid, melting at 146°, has been resolved into its optical antipodes by fractional crystallisation of its cinchonidine salt. The acid melting at 174°, when heated, forms a lactone-lactide, and must be regarded as the *meso-* or internally compensated variety.—The spontaneous crystallisation of sodium sulphate solutions: H. **Hartley**, B. M. **Jones**, and G. A. **Hutchinson**. The authors have examined the spontaneous crystallisation of sodium sulphate solutions, and have found that if the solutions are subjected to mechanical friction three of the four possible solid phases, viz. ice, $Na_2SO_4,7H_2O$, and Na_2SO_4 are produced spontaneously at different temperatures. The spontaneous crystallisation of the fourth solid phase, $Na_2SO_4,10H_2O$, is of rare occurrence.—Constitution of hydroxyazo-compounds. Action of diazomethane and of mercuric acetate: C. **Smith** (and in part A. D. **Mitchell**).—*Ortho*bromophenols and some bromonitrophenols: P. W. **Robertson**.—The constitution of thiocyanates containing an electronegative group: A. E. **Dixon** and J. **Taylor**.—The quantitative conversion of aromatic hydrazines into diazonium salts: F. D. **Chattaway**. All primary aromatic hydrazines can be quantitatively converted into the corresponding diazonium salts either by chlorine or by bromine. The operation can be most easily carried out by dissolving the hydrazine in glacial acetic acid, cooling the solution to about −15° by the addition of crushed ice, and either passing in a rapid stream of chlorine or adding the calculated quantity of bromine dissolved in acetic acid and similarly cooled by ice.—Quantitative separation of thallium from silver: J. F. **Spencer** and Miss M. **Le Pla**. A quantitative separation of the salts of silver and thallium is effected by a stream of chlorine, whereby the thallium is oxidised to the very soluble thallic chloride and the silver is precipitated as silver chloride. The thallium is eventually precipitated and weighed as thallous iodide.—Molecular volumes of the nitrites of silver, mercury, and the alkali metals: P. C. **Rây**.—Lithium nitrite and its decomposition by heat: P. C. **Rây**.—The existence in aqueous solutions of a univalent cadmium ion, a subvalent thallium ion, and a bivalent bismuth ion: H. G. **Denham**.—Note on the oxidation of phenylhydrazine by Caro's acid: J. C. **Cain**.—Some reactions of keten: F. **Chick** and N. T. M. **Wilsmore**.—*Para-* and *meta*-nitrosoacetanilide: J. C. **Cain**.—Labile isomerism among acyl-salicylamides and acyl-hydroxyamines: A. W. **Titherley**.

Royal Microscopical Society, March 18.—Lord Avebury, F.R.S., president, in the chair.—A series of fourteen mounted specimens of the rarer species of fresh-water polyzoa, mostly foreign species from Lake Tanganyika, Rhodesia, northern India, America, and Japan: C. F. **Rousselet**.—Annual address: seeds, with special reference to British plants: the **President**. Attention was confined to the dicotyledons, the consideration of seeds of the conifers and monocotyledons being deferred until next year. The subject was treated from the point of view of the dispersal of the seeds and fruits by various agencies.

Royal Anthropological Institute, March 24.—Prof. W. Ridgeway, president, in the chair.—Sinhalese magic: Dr. W. L. **Hildburgh**. The paper dealt with a variety of subjects, including charming ceremonies, astrology, and devil dancing. The charms were of various kinds, protective, for instance, to keep off evil spirits, or to guard the house, in which category amulets were included; love charms, charms to secure the favour of anyone, for example, a judge, and the like. A number of horoscopes were exhibited, which almost invariably take the form of a roll, as it is considered necessary to write each on a single leaf, which is best preserved in the roll form. The language in which horoscopes are written can only be read by the initiated, and consequently they are often translated, and the translations may be written in ordinary books without prejudicing the results. On the subject of devil dancing, Dr. Hildburgh exhibited a number of slides showing the different devils represented, and also a collection of the masks and costumes worn. Some of the devils represented are those who actually afflict the patient; others are powerful devils by whom the afflicting devils are controlled, while others again are devils who are afflicted as the patient is afflicted.

Edinburgh.

Royal Society, March 16.—Dr. R. H. Traquair, F.R.S., vice-president, in the chair.—The lamellibranch fauna found in the Millstone Grit of Scotland, and the lamellibranchs from the Silurian rocks of Girvan: Dr. Wheelton **Hind**. The first of these important papers contained an account of the lamellibranchs found by the staff of the Geological Survey of Scotland in beds of the Millstone Grit series, between the Castlecary Limestone and the Coal-measures. The fauna is quite unique, containing, for example, the remarkable genus Prothyris, not hitherto recorded from British Carboniferous rocks. The specific form seems to be identical with that found in the Upper Coal-measures of Nebraska. Although a few members in the newly discovered fauna of the Scottish series have been found in the Millstone Grit of Hazel Hill, Yorkshire, and in beds immediately below the Coal-measures of Bristol and South Wales, yet the fauna as a whole bears a striking resemblance to the fauna of the American Coal-measures. The second paper dealt with the fine series of lamellibranchs collected by Mrs. Robert Gray from the district of Girvan. Many of the shells were in remarkable preservation, enabling the details of the hinge plate and interior to be examined. It was interesting to note such a fine development of lamellibranchs in these early rocks. A great proportion of the species are probably new, and many of the genera are described for the first time from British specimens. Here again the resemblance to certain American faunæ, especially those from the Trenton and Hudson groups of Minnesota and New York, is very striking.—A test for continuity: Dr. W. H. **Young**.—The theory of hessians in the historical order of development: Dr. Thomas **Muir**.

Paris.

Academy of Sciences, March 30.—M. H. Becquerel in the chair.—Various properties of the curves expressing either by their envelope, or directly, the coefficients of yield m of a thin-walled vertical weir, without lateral contraction, as a function of the relative pressure N′ exercised under the sheets at the level of the sill: J. **Boussinesq**.—The determination of the time, both on land and at sea, with the aid of wireless telegraphy: Bouquet **de la Grye**. With the present installation at the Eiffel Tower, wireless signals can be sent a distance of 2000 kilometres, and it has been estimated that by increasing the electric energy this distance could be doubled. It is suggested that a special signal should be sent exactly at midnight, and it would have to be the subject of an international arrangement to avoid possible confusion by multiplication of such signals. Such a time signal would be of the greatest service to navigators within its radius.—On the proposal of the president, the examination of the proposition in the preceding note was referred to a committee composed of the members of the sections of astronomy, geography, navigation, and physics, together with MM. Darboux, Poincaré, and Cailletet.—The earthquake of March 26, 1908 (Chilapa, Mexico), registered at Paris: G. **Bigourdan.**—The manuscripts of Evariste Galois, catalogued by M. J. Jannery, and kept under this heading at the library of the Institute of France.—The relations between lecithin and tubercle bacilli and tuberculin: A. **Calmette,** L. **Massol,** and M. **Breton.** Using the hæmolytic action of snake poison in presence of lecithin as a test, the authors prove that the tubercle bacillus has an affinity for lecithin, and tuberculin behaves in a similar manner. The bearing of this on the reaction of tuberculin on the body is discussed.—The present state of the problem of the dispersion of light rays in interstellar spaces. A first attempt at the application to provisional determinations of stellar distances: Charles **Nordmann.** Discussing the recently published results of M. Tikhoff, the author points out that both their methods, although quite independent, lead to the same qualitative results, namely, that there is really produced a dispersion of light in interstellar space, and that it has the same sense as ordinary refractive media.—A phenomenon attributable to positive electrons in the spark spectrum of yttrium: Jean **Becquerel.** The experimental study of the Zeeman effect in the spark spectrum of yttrium gives results which may be most simply explained by assuming the presence of positive electrons.—The number of electrons in the atom: J. **Bosler.**—The determination of the factor of ionisation in solutions of hydrochloric acid: E. **Doumer.** A study of the ratio of the volumes of hydrogen and oxygen evolved during the electrolysis of solutions of hydrochloric acid of different concentrations with anodes of silver or mercury.—The density of the vapour of propionic acid: A. **Faucon.** By the method of Dumas the vapour density of propionic acid was found to vary from 3·27 at 123° C. to 2·57 at 210° C., the theoretical vapour density being 2·55. Two thermodynamical formulæ are applied to the results to calculate the heat of vaporisation of propionic acid.—The OH(1)Cl(2 : 4 : 6) trichlorophenol and its transformation into chloroquinones: E. **Léger.** The trichlorophenol is prepared by the action of a strong solution of sodium hypochlorite upon phenol; nitric acid (1·41) converts this into a mixture of trichloroquinone and tetrachloroquinone.—Styrolene oxide: MM. **Tiffeneau** and **Fourneau.**—The β-$\alpha\alpha$-dialkyl-ketone alcohols: E. E. **Blaise** and I. **Herman.**—The magmatic parameters of the series from the volcano Monte Ferru, Sardinia: M. **Deprat.**—Researches on the development of *Glocosporium nervisequum*: A. **Guilliermond.**—The Lagoa Santa race in the precolombian populations of the equator: M. **Rivet.**—The American Synalpheæ: M. **Coutière.**—The tectonic of the littoral of the Algero-Moroccan frontier: Louis **Gentil.**

THE CHEMISTRY OF THE HIGHER FUNGI.

Chemie der höheren Pilze, eine Monographie. By Dr. Julius Zellner. Pp. vi+257. (Leipzig: W. Engelmann, 1907.) Price 9 marks.

THE detection, isolation, and characterisation of the definite compounds resulting from the vital processes of living organisms is a branch of organic chemistry which is slowly developing and of which the progress is necessarily dependent upon the development of pure chemistry. In fact, it may be said that in some respects this department of biochemistry is in advance of the pure science, because the living organism has already furnished chemists with immense numbers of compounds which are quite definite, but of which the chemical constitution is at present unknown. Indeed, it may be stated in much wider terms that there is probably no such thing as an "indefinite" chemical compound in the whole animal or vegetable world. There is no doubt that many, perhaps the majority, of the organic compounds present in animals or plants are of very high molecular weights and of great atomic complexity, and there is also no doubt that many of the products which have been isolated and studied are complex mixtures or combinations of such complexes. But to speak of such products as "indefinite" is simply tantamount to the admission that our modern methods of research are inadequate, and that our knowledge of biochemistry must develop concurrently with the development of new methods for dealing with these highly complex molecules.

The ultimate aim and object of scientific chemical work in this field is presumably to follow the development of the various compounds in the living organism -- to detect the genetic relationships between the molecules for the purpose of learning how nature works in the vital laboratory. As a prelude to this knowledge it is necessary to get, in the first place, an inventory, as complete as possible, of the compounds actually known to exist in, or to be produced by, the animal or plant. With respect to plant chemistry it may be said that practically all the works dealing with this subject have hitherto been of the nature of such catalogues or inventories. Here and there, as the result of these studies, genetic relationships have been detected, but this field of research is urgently in need of systematic cultivation. As a subject it bristles with practical difficulties, and for the achievement of successful results the investigator should combine the qualifications of an expert chemist with those of the expert botanist. It is not surprising that, in the circumstances, the biostatical aspect of plant chemistry should have progressed so much more rapidly than the biodynamical aspect.

Dr. Zellner's monograph may be regarded as another contribution to plant chemistry from the biostatical side. It deals with a particularly interesting group, and will be found invaluable to students and workers in this field. By the "higher fungi" the author means all those orders generally classed as fungi with the exclusion of bacteria, moulds, and yeasts. The line of demarcation, as Dr. Zellner points out, is perhaps not, strictly speaking, a scientific one, but for practical purposes it is both justifiable and convenient, as bacteriology and fermentation have been developed into large and important branches of science, and their literature is amply provided for.

In treatment the present work follows the chemical rather than the botanical classification, the chapters, of which there are twenty-two, bearing the titles of the chemical families, beginning with the mineral constituents, and passing on to the hydrocarbons, fats, lecithins, alcohols, acids, amino-acids, purine group, bases, carbohydrates, tanning and colouring matters, resins and terpenes, proteins, &c. The chapters on the ferments and toxins of fungi will be of particular interest to many readers. One chapter is devoted to the consideration of the nutritive value of fungi, which the author does not consider to be very high. In this chapter there are many valuable tables giving the quantitative results of the analysis of the proximate constituents of large numbers of species. In the case of certain chemical families of very wide occurrence, such as the carbohydrates, the author has been obliged to interpolate tables based on the botanical classification. Thus in chapter xii. there is a tabulated list of no fewer than 233 species, giving the distribution of mannitol, mycose (trehalose) and glucose, or other reducing sugar, together with the name of the observer and the year of the discovery of the carbohydrates. In giving the details of the various compounds, the author has wisely thought it unnecessary to enlarge upon the chemistry of well-known and widely distributed substances which are of general occurrence in the vegetable kingdom. On the other hand, compounds of special interest in mycological chemistry, such, for example, as muscarin, ergotin, choline, &c., which are essentially, if not exclusively, products of fungi, are dealt with exhaustively. As is so generally the case with German writers of monographs on scientific subjects, the references to authorities are fully given.

As a contribution to scientific literature there is nothing in this work calling for criticism. The author, unlike many specialists, takes a remarkably fair view of the "perspective" of his subject, and the result is a work which may be described as concisely complete. It may savour of impertinence for a "foreigner" to complain of the spelling of his own language by a German writer, but those who are in the habit of following German work in our own subjects—*i.e.* the working men of science of this country generally—have become accustomed to certain established modes of spelling in such scientific publications as the *Berichte* of the German Chemical and Botanical Societies, and so forth. We in this country have become "hardened" (literally) into seeing K for C (hard); we have got over the first shock of seeing such words as Glukose, Fruktose, Mykose, &c., and we have even been obliged to admit that Muskarin is obtained from *Amanita muscaria*.[1] But now Dr. Zellner has a further shock for us, and we find such words as *Kalzium, Zitronensäure, Glyzerin, Azetyl*, &c., scattered throughout his pages. Thus (p. 97) Mykose forms an "*Oktoazetylverbindung*," which is no doubt chemically true, but, stated in this form, it seems to jar upon the orthographic nerve of the average English reader. All this is, of course, purely personal, perhaps old-fashioned or narrowly insular, and has nothing to do with the scientific merits of the work, which, as has already been said, are of a very high order, and every worker in the domain of plant chemistry will be grateful to the author for having produced it.

R. Meldola.

BOTANICAL INSTRUCTION.

Plant Biology. A Text-book of Elementary Botany arranged for Modern Methods of Teaching. By Dr. F. Cavers. Pp. xvi+460. (Cambridge: University Tutorial Press, 1907.) Price 3*s*. 6*d*.

Laboratory and Field Manual of Botany. By J. Y. Bergen and B. M. Davis. Pp. viii+257. (Boston and London: Ginn and Co., n.d.) Price 4*s*. 6*d*.

Studies in Plant Life. By J. Adams. Pp. v+179. (Dublin and Belfast: Fallon and Co., Ltd., n.d.)

Elementary Botany. By M. A. Liversidge. Pp. 128. (London: Blackie and Son, Ltd., 1907.) Price 1*s*. 6*d*. net.

Introduction to Elementary Botany. By Charlotte L. Laurie. Pp. viii+84. (London: Allman and Son, Ltd., n.d.) Price 1*s*. net.

Our Woodlands, Heaths and Hedges. By W. S. Coleman. Pp. viii+141; with 8 plates. New edition, entirely reset. (London: George Routledge and Sons, Ltd., 1907.) Price 1*s*.

THE advocates of an exclusively experimental course of study in the natural sciences are confronted with the difficulty of time limitations, so that in practice it becomes necessary to strike a balance between lecture and practical work. Dr. Cavers has indicated in "Plant Biology" the lines of work that he has found successful with training-college students, in which the training is almost entirely derived from observation and experiment. The foundation of the course consists of experiments—of which about three hundred and fifty are outlined—in connection with the nature and function of parts of the flowering plant; so far as possible the bean plant is used as the type. Flower and soil, biology and ecology provide a subsidiary section. The course differs mainly from ordinary practice in excluding the examination of selected types from the main groups and in the general omission of flowerless plants. With regard to the composition of the subject-matter, the author deserves great commendation; the arrangement is well planned, the experiments are generally simple and practicable, and the information is contrived to make the student think. A series of questions at the end of each chapter can be used either by the student or his instructor to gauge the progress that is being made. The appendices also contain much useful matter; hints on practical work refer to special opportunities afforded month by month; a summary of Engler's system of classification is provided, and a glossary of botanical terms.

The manual prepared by Mr. Bergen and Dr. Davis is a practical handbook primarily arranged in accordance with their text-book "Principles of Botany." The first part relates to the structure and physiology of seed plants. The plan adopted of outlining the instructions without detailed information that is left for the student himself to discover is good, but the authors have not been very happy in distinguishing between more and less important facts or in systematising the subject-matter. As an instance, it may be cited that the description of a typical young dicotyledonous stem is not particularly noted, while the structure of the climbing dicotyledonous stem receives undue prominence. The second part, indicating type studies of flowering and flowerless plants, is more felicitous. Spirogyra forms a suitable introduction for studying the cell in detail. Pleurococcus, Vaucheria, Ulothrix, and Œdogonium are chosen as the types of green algæ, while reference is also made to Ulva, Cladophora, and Coleochæte. Microsphæra, the lilac-mildew, is selected as the type of an Ascomycete, and the introduction of Marsilia is quite a desirable innovation. Ecology is dealt with in the third section under the headings of flower pollination, seed dissemination, types of vegetation, &c. The remainder of the book is devoted to accessory but valuable hints on reagents, methods of fixing and staining, cultures of the lower plants, and apparatus. Considered as a whole, the authors have provided a useful manual that presents a large amount of practical information in a limited amount of space.

The small book written by Mr. Adams is of an extremely superficial nature. Owing to generous spacing and a large number of illustrations, the text is less than would be expected. In the circumstances, it would have been advisable to give more space to the essentials of plant structure as exemplified in the flowering plant and to have omitted the cursory descriptions of flowerless plants and plant habitats. The author has taken pains to introduce facts of practical importance to the agriculturist, such as fertilisers, dwarf shoots, &c., but there is a lack of clearness and accuracy in some of the elementary definitions.

The limits of Miss Liversidge's book are set by the intention of covering the syllabus of work for the Oxford and Cambridge junior local examinations. It is evident that it has also been written rather with the view of giving facts for examination purposes than of training the young mind. There are four parts, assigned to external morphology, anatomy, physiology, and systematic botany. The design of the physiological part is good, but the experimental

[1] The familiar *Chemisches Central-Blatt* has now become a *Zentral-Blatt*.

instructions could be materially improved. The anatomical facts are clearly stated considering that this part of the subject is much more advanced than the rest of the book. But speaking generally, the author has aimed at brevity, and in so doing has sacrificed exactness; this is specially noticeable in the course of external morphology, where several mistakes and incomplete definitions occur.

The short introduction to elementary botany planned by Miss Laurie is a direct antithesis to the last, as the facts recorded are few, but they are deduced or suggested so as to arouse interest and stimulate experiment and thought. Written primarily for quite small children, it shows how facts in the life-history of plants may be taught from simple experiments, such as the growth of mustard seeds in a bottle In addition to morphology and the accompanying physiology, there are chapters on interrelation between plants and animals, climbing plants and colours of plants. Although the information is couched in a form understandable by young children, the book could be advantageously adopted as a first course for older children, and might be profitably consulted by many teachers as a guide to imparting instruction.

The observation of trees and shrubs is preeminently suited for a nature-study class, and possesses the advantage that there is much to be noted even during the winter months. A short, concise manual or primer at a modest price is an existing desideratum. The volume written by Mr. Coleman compasses the subject and certainly sells at a modest price, but it fails to satisfy the want alluded to. The author has culled much interesting information of a general and historic nature, but there is an almost entire absence of the numerous botanical features of interest, such as winter buds, arrangement of leaves, &c., and for identification the reader is mainly dependent upon the illustrations. The notes on animals and insects haunting the various trees and shrubs are so useful that one wishes the author had given more space to these facts of natural history. A list of British lepidopterous insects the caterpillars of which feed on certain plants is provided in an appendix.

APPLIED MATHEMATICS.

(1) *Computation and Mensuration.* By P. A. Lambert. Pp. ix+92. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1907.) Price 3*s.* 6*d.* net.

(2) *A First Statics.* By C. S. Jackson and R. M. Milne. Pp. viii+380. (London: J. M. Dent and Co., 1907.) Price 4*s.* net.

(3) *Practical Calculations for Engineers.* By C. E. Larard and H. A. Golding. Pp. xiii+455. (London: C. Griffin and Co., Ltd., 1907.) Price 6*s.* net.

(1) THE author says that the boys in the secondary schools of America are not taught to apply their mathematics independently, and consequently find, on entering college, that they have difficulty in making effective use of their theoretical knowledge, and this book is intended as a link between the school and college courses, to be studied either at the end of one or the beginning of the other.

The same deficiency is manifest in boys leaving our schools, and in this country is being met by improved teaching combined with practical work in the laboratory, as a regular part of the school course.

The book is admirably planned and written, is concise, neat in method and interesting, and meets a real want in a worthy manner. It begins with examples of direct measurement, approximate numbers, and contracted arithmetic, estimating the degree of accuracy by the number of decimal places; perhaps the number of significant figures would have been better. This is succeeded by examples of practical geometry, including the construction and measurement of triangles, and some squared-paper work. Then follows the volume of a prismatoid, and in later chapters on mensuration it is shown that the prismoidal formula, or Simpson's rule, is widely applicable. There is a useful chapter on trigonometrical computation, introducing very appropriately the notion of a vector with examples of vector summation. Logarithms and the slide rules are next considered, followed by an interesting chapter on limits, illustrated by several important convergent series. The author always seizes on the salient points, is never prolix, and the interest never flags; in each chapter the student is well started on his way, then provided with good and suggestive examples, and wisely left to his own resources. Thus, although the pages of the book are comparatively few, the usual ground is covered, and a thorough and efficient training in practical computation is provided. English teachers would do well to consult this work.

(2) This text-book proceeds on easy lines, and the student is provided with a wealth of examples at every stage from which to choose, the answers being collected at the end of the volume. In their scheme the authors have considered "the historical order of development of the subject, as indicating almost infallibly the line of least resistance." Thus in the first chapter the principle of the lever is introduced, and the law of moments for parallel forces is established by simple experiments, then illustrated by examples of ancient and modern steelyards and balances, and finally applied to find the conditions of equilibrium of three parallel forces in a plane. The next two chapters deal with the parallelogram law for forces at a point, the treatment being here again, as always, experimental, graphical, and analytical, with examples of useful applications in the arts. It is not quite clear why the authors should substitute the term "geometric" addition for *vector* addition, or why arrow-heads should "sometimes" instead of *always* be inserted in vector diagrams. In chapter iv. the principle of moments is again considered, being now deduced from that of the parallelogram and applied to couples. Then follow sections dealing with machines, friction, and centres of

gravity, the latter being somewhat extensively applied, including Guldinus's rules and mensuration problems. The concluding chapters relate to forces and jointed frames in two and three dimensions, with examples of roof and bridge trusses and cranes.

The general plan of the book is good, the endeavour being to "lay stress on the practical utility of the science" rather than on "rigour of deduction." In carrying out this very laudable idea, the authors, through lack of practical experience, sometimes err by giving drawings like that of the safety-valve on p. 242, in which the constructional details are almost offensively crude, or by giving examples like No. 16, p. 140, where the efficiency of a Weston differential pulley-block is stated to be 80 *per cent.*, or like No. 38, p. 77, in which a rail, supported at the ends and loaded as a beam at the middle, is said to be bent into a *circular arc*. In spite of these minor defects, however, the book can be recommended as affording an excellent introduction to statics.

(3) The general character of this work places it somewhere between the engineering pocket-book and the college text-book. The methods, formulæ, and appliances which a student encounters during a good college course in mechanical engineering are here, not demonstrated, but collected and described, systematically, and applied to such practical examples as are likely to occur in an engineering workshop. In section i. the subject-matter comprises arithmetical, graphical, and mechanical computations, by modern abbreviated methods, and includes technical mensuration, the use of the slide-rule and the planimeter, and mathematical tables. In section ii. we have laboratory experiments and calculations relating to machines, acceleration, momentum, force, work, energy, and power. Section iii. relates to boilers and heat engines, considered both from the thermodynamical and constructional point of view, with a chapter on the cost of motive power. These three sections are well adapted for students who have passed from college to practical work, in helping them to recall their theoretical knowledge as occasion may require. A good collection of examples will be found for practice. The style is perhaps somewhat diffuse, and there are a few minor defects, but this portion of the book will be appreciated in many quarters.

The fourth and concluding section, however, is of most interest and value. It deals with the business side of engineering, a branch that is beyond the usual college course, yet of paramount importance to the young aspiring engineer. The subjects discussed are the commercial aspects of engineering; the qualifications and duties of the works manager; the calculation of weights and the preparation of estimates and bills of costs; and the bonus and premium systems of wages. The authors give some most striking examples of the great value of squared-paper work in the systematic plotting of variable quantities in all branches of a manufacturing establishment, and the lessons to be learnt therefrom. This section is extremely suggestive, and will well repay the careful study of all practical engineers.

MULTUM IN PARVO.

(1) *Die Tierwelt des Mikroskops (die Urtiere).* By Dr. Richard Goldschmidt. Pp. iv+100; 39 figures. (Leipzig: B. G. Teubner, 1907.) Price 1.25 marks.

(2) *Das Süsswasser-Plankton.* By Dr. Otto Zacharias. Pp. iv+130; 49 figures. (Leipzig: B. G. Teubner, 1907.) Price 1.25 marks.

(3) *Befruchtung und Vererbung im Pflanzenreiche.* By Prof. K. Giesenhagen. Pp. iv+132; 31 figures. (Leipzig: Quelle and Meyer, 1907.) Price 1.25 marks.

(5) *Das Schmarotzertum im Tierreich und seine Bedeutung für die Artbildung.* By Prof. Ludwig von Graff. Pp. iv+132; 24 figures. (Leipzig: Quelle and Meyer, 1907.) Price 1.25 marks.

(6) *Die Mechanik des Geisteslebens.* By Prof. Max Verworn. Pp. iv+104; 11 figures. (Leipzig: B. G. Teubner, 1907.) Price 1.25 marks.

It was Leibniz who said that the more science advances the more it will be expressed in little books. If that is so, the recent abundant crop of primers may be regarded as a healthy sign—especially when we find that many of them are very good. It need hardly be said that an introduction to the study of parasitism by von Graff, or to the study of fresh-water plankton by Zacharias, cannot fail to be useful and stimulating. There is also an economic side to the phenomenon presented by the bundle of primers before us. It seems as if the great encyclopædias, which were relatively costly, were being replaced by these cheap booklets. Instead of saving up to purchase the huge volume P, containing much that he does not want, the student can buy at a shilling each three little treatises on parasitism, plankton, and protozoa. This expresses a democratisation of scientific literature, with its familiar analogue in the popular "sixpennies."

(1) In a clear and precise way, Dr. Richard Goldschmidt tells the story of the Protozoa—how they came to be known, where they are found, how they live, what part many of them play in the economy of the sea, what they have done in building up chalk cliffs and the like, and how they come into close quarters with man in malaria and sleeping sickness, and other diseases. With the aid of excellent figures, most of which are familiar, and some of which, like Max Schulze's Polystomella, could hardly be improved upon, the author introduces the student to the rhizopods, the infusorians and Sporozoa, and although the book will not, of course, enable the observer to identify many of the Protozoa which he may discover, it will help him to understand them and to realise how many problems even the common amœba still raises in a reflective mind.

(2) The indefatigable director of the biological station at Plön deals with a subject to the study of which a great part of his life has been honourably devoted—the fresh-water plankton. His treatment of

it seems to us to be peculiarly successful, as we would expect from one writing out of full knowledge and with strong enthusiasm, and what he has to say may be profitably read by many besides the laity. Besides descriptions of the various constituents of the plankton—crustaceans, rotifers, infusorians, algæ, and so on—Dr. Zacharias gives an account of methods of study, of the relations of the plankton to environmental conditions, of the origin of new species and varieties by isolation, of the inter-relations of plants and animals, of the application of hydrobiology to fisheries, and of the pioneer station at Plön.

(3) Prof. K. Giesenhagen deals with a subject more difficult than those of the two preceding volumes—namely, fertilisation and heredity in the vegetable kingdom. He begins with the phenomena in their simplest terms in the green algæ, and works gradually upwards through moss and fern to phanerogams, not forgetting the by-paths of parthenogenesis and vegetative multiplication. The point about his treatment is that he uses the facts as a basis for a discussion of the deep problems of heredity, such as those raised and in part solved by the discoveries of Mendel and his successors.

(4) Prof. Paul Gisevius has compressed into a small volume what every educated person should know about plants, and there is a flavour of intellectual "pemmican" in the result. He deals first with the structure of plants, both inside and outside; he then discusses nutrition and respiration, constructive metabolism, and the migration of material; he leads us from seed and seedling to the flowering, fruiting and withering; he takes a survey of the vegetable kingdom, and throws the light of the past on the present; and he ends up with the phenomena of reproduction and with breeding experiments. It seems to us that he attempts too much, carrying terseness to an extreme, but his work is well done.

(5) Prof. Ludwig von Graff supplies a masterly introduction to the study of parasitism among animals. Without overwhelming us with details, he takes us into the heart of the subject, and the style of the book is a model. Von Graff has much that is extremely interesting to relate—for parasitology has made great advances of recent years—and his discussion of such themes as the origin of the parasitic habit and the influence of parasitism on the parasite is very instructive. Admirable too are the tabular summaries of life-histories. The appalling list of human parasites, based on Braun's well-known treatise, reaches a total of 129, and this number must be greatly increased, since in not a few cases several species are counted as one.

(6) In some ways the most striking volume in this bundle of primers is that in which Prof. Max Verworn deals with "the mechanism of psychical life." It consists of five lectures on the physiological aspects of mental processes, and the author has been well advised to leave them with the vividness of oral discourse. He deals with the relations of mind and body (the dualism of which he regards as a superannuated fiction), with the processes, *e.g.* fatigue-changes, in the nervous elements, with the dissimilatory stimuli that pass incessantly through the intricate maze of nerve-fibres and ganglion-cells, with the fascinating phenomena of sleep and dreaming, and with the puzzles of suggestion and hypnosis. More, perhaps, than in regard to the other little books which we have noticed is there room here for difference of opinion, but all will agree that the author presents his view of psychical life with masterly clearness. It must be clearly noted that he refrains from giving his facts any philosophical setting, he argues neither for materialistic nor for spiritualistic interpretation, he aims at a physiological analysis of the sequences with which we are all familiar, and he does not conceal that his title expresses a scientific ideal rather than an actual achievement.

J. A. T.

OUR BOOK SHELF.

Index of Archaeological Papers (1665–1890). Edited by G. L. Gomme. Pp. xi+910. (London: A. Constable and Co., Ltd., 1907.) Price 25*s*. net.

This volume is in effect an author-index to the papers of archæological and kindred character published in the journals of learned societies and elsewhere during the twenty-five years prior to 1891. It includes the contents of some ninety-four periodicals, amounting in all to nearly 20,000 monographs under the authors' names. An appendix supplies a list of the titles which were found to have been omitted from the main classification during its compilation.

The papers of like characters which have appeared from 1891 until the last year or so have already been similarly treated in the annual index, published under the auspices of the Congress of Archæological Societies in union with the Society of Antiquaries. There is thus placed before the student of to-day, as the editor justly claims, a continuous index from the first publications in the Philosophical Transactions of the Royal Society down to the present time. This work is henceforth as indispensable to the student of British archæology, in particular, as are the tables of logarithms, sines, and cosines to the mathematician. The latter may be calculated, indeed, just as the archæological papers may be hunted out by individual workers; but those who in the past have wasted hours and days in turning over the pages of twenty-five times ninety-four volumes in search of their own quest will be grateful to Mr. Gomme and his helpers for their patient work, and for the completeness of the result.

This index includes within its scope, not only the archæology of the British Isles, but archæological fragments from many countries. Thus we find Evans (A. J.) on Albania, Birch, Budge, Petrie, Poole (R. S.), and Renouf on the problems of Egypt, Hogarth on inscriptions from Salonica, Ramsay on the results of his explorations in Phrygia and western Asia Minor, and so forth. The difficulty of editing such a mass of different material must have been very great, and the work laborious. Here and there we notice the inclusion, whether accidental or intentional, of papers which seem to us to be irrelevant; as, for example, "The Writings and Influence of Coleridge" (Redish), "The Height and Weight of Boys aged Fourteen in Town and Country Schools," and other more or less statistical writings, by Francis Galton. In other cases where folklore is the subject, discrimination is less easy; and we certainly think that the editor has been wise to incorporate writings of philological character in cases where the author's material was archæological. Thus M. Maspero on various features of Egyptian archæology and philology, and Sir J. Rhys covering similar ground in Wales, are not inappropriate.

There is one thing, however, which we commend earnestly to the Congress, namely, the preparation and publication of a supplementary place-index, which might be brought as nearly to date as possible, and would render this volume and the annual indexes doubly or trebly valuable. The fact that some fifty-four of the journals indexed are the publications of local archæological societies speaks for itself. With Mr. Gomme's work completed the rest would be easy; but it is none the less an urgent need.

Notions générales de Biologie et de Plasmogénie comparées. By Prof. A. L. Herrera. Translated by G. Renaudet. Pp xxviii + 260. (Berlin: W. Junk, 1906.) Price 10 marks.

THIS is a remarkable book, full of suggestive speculation, much of which is unlikely to command general acceptance, but at the same time the analogies which the author draws between emulsions of various sorts and organic form are full of interest.

The whole book seems to have arisen out of a series of notes for students, and its rather disconnected form retains the impress of this original design. The result is rather original, and arrests the attention even where one does not agree with the author.

Prof. Herrera suggests that organic structure arises as the result of precipitation, coagulation, or solidification modified by the presence of diffusion currents and similar influences. A large number of experiments are given in which commonly occurring organic structure is closely imitated by precipitations of silica, &c., under conditions which are carefully described.

There is a refreshing freedom from dogmatism, but the author has the full courage of his own convictions, as is shown by the crisp and clear definitions which he gives of phases of organic life that most investigators find difficult of satisfactory expression.

The work is introduced by a preface from the pen of Moritz Benedikt, professor of medicine at Vienna, who is, of course, in sympathy with the general trend of the book, whilst he is, like its author, alive to the many difficulties in establishing all the conclusions. A sentence from the final essay of the volume, also contributed by Prof. Benedikt, puts the main thesis of Herrera so clearly that we may be pardoned for quoting it:—" . . . le monde organique, et la vie, sont nées du monde minérale dans les masses de vésicules mousseuses hautment organisées."

Einführung in die Paläontologie. By Gustav Steinmann. Second edition. Pp. xii + 542; illustrated. (Leipzig: W. Engelmann, 1907.) Price 14 marks.

IN the matter of bulk this edition shows a marked increase over the first edition (1903); while, in most cases, at any rate, it appears to have been brought fairly well up to date. The ancestral proboscideans from the Egyptian Eocene are, for instance, duly noticed, and recent work on Patagonian Tertiary vertebrates likewise receives due attention. On the other hand, we notice an absence of any reference to Dr. Broom's opinion that the South African Triassic Tritylodon is, after all, a mammal; while in certain cases the author departs from the generally accepted classification without any apparent or sufficient reason. In the ungulate mammals, for example, the hippopotamus is removed from the Artiodactyla to find a place with Dinoceras and Coryphodon among the Amblypoda; in fact, Hippopotamus and the American Tertiary genus Merycochœrus are actually included in the family Coryphodontidæ. This is bad enough, but when we find Oreodon—the immediate ally of Merycochœrus—occupying its proper position in the neighbourhood of the camels, we are at a loss whether to attribute such eccentricities to mere carelessness or to lack of knowledge on the part of the author.

Carelessness cannot, however, be pleaded in the case of the phylogeny of the vertebrata given at the close of the volume. For there we have carefully compiled tables in which the dolphins are brigaded with ichthyosaurs as Ichthyotheria, while sperm-whales and plesiosaurs are grouped together as Plesiotheria, and whalebone whales and the mosasaurs as Thalattotheria. The giving of definite names to these incongruous groups is of itself a sufficient proof that the author regards them as definite phylogenetic assemblies, and not mere instances of adaptive analogy; but the matter is clinched by the following statement on p. 512, viz.:—" Wir sind also vor die Entscheidung gestellt, entweder ein unverständliches und geradezu übernatürliches Eingreifen vorauszusetzen, oder uns im Rahmen des gesetzmässigen Naturgeschehens die zahlreichen einzelnen Säugerstämme voneinander gesondert aus ebensovielen Stämmen der Reptilien herworgegangen zu denken."

With such eccentricities, alike in classification and phylogeny, we are unable to recommend Dr. Steinmann's volume as a trustworthy guide to the student of palæontology. Neither can we congratulate the publishers on the illustrations, unless, indeed, a " palæographic " style of art be deemed specially suitable to a palæontological treatise. R. L.

The Chemistry of the Diazo-compounds. By Dr. J. C. Cain. Pp. xi + 172. (London: Edward Arnold, 1908.) Price 10*s.* 6*d.* net.

WHEN we compare the steady output of monographs on chemical subjects on the Continent with the few publications of this class in English, we naturally ask whether English publishers are less enterprising than their neighbours, or English chemists less given to specialisation.

We are inclined to the former view, and regard it as a welcome sign that the new departure in English chemical literature, introduced in the form of physical chemistry manuals, and published under the editorship of Sir W. Ramsay, has found favour with another enterprising firm, and extended to organic chemistry. It is to be hoped that the present volume represents the first of a series of similar publications.

Although the chemistry of the diazo-compounds appears at first sight to be a subject of rather restricted range, it must not be forgotten that it is of direct technical importance, connected as it is with one of the largest branches of the colour industry. Moreover, a special interest attaches to the appearance of Dr. Cain's book at the present time, for it stands as a memorial of the fiftieth anniversary of Griess's famous discovery. Although Johann Peter Griess was a German, born and bred, the bulk of his researches on the diazo-compounds were carried on in this country, first whilst he was acting as assistant to Hofmann in London, and later during intervals of leisure extending over many years after his appointment as chemist to Messrs. Allsopp, brewers, of Burton-on-Trent.

The protean character of the chemical changes which the diazo-compounds exhibit, their close connection with colour chemistry, as well as their structural relations, which still furnish a perennial subject of discussion, appeal in turn to the scientific and industrial chemist (if this distinction between the two forms of chemical energy is permissible). The author has been able to write with the authority of long experience in the works and in the laboratory, and his exhaustive method of treatment has not rendered the subject either tedious or involved. It is, on the contrary, an eminently readable and attractive volume. It is divided into chapters describing the preparation and reactions of the diazo-compounds, their derivatives, and their constitution. In an appendix a short account is given of the author's new theory of their structure. This is not the place to enter upon a discussion of the subject, but a strong case is made out for the new view, which should stimulate fresh experimental work of an interesting character.

J. B. C.

Handbuch der Physik. By Dr. A. Winkelmann. Second edition. Fifth volume, second part: Elektrizitat und Magnetismus, II. Pp. xiv+971; illustrated. (Leipzig: J. A. Barth, 1908.) Price 16 marks.

THE present portion of this encyclopædic treatise consists of electrodynamics and induction, by K. Waitz; absolute measurements of magnetic and electric quantities, by A. Oberbeck; technical applications of induction, by Th. des Coudres; telephony, by L. Rellstab; and the theory of electric phenomena, by L. Graetz. Important though every one of these sections is, it is doubtless to the last that the reader will turn first on account of the great developments of theory during the last decade; and especially will he turn to the chapters on electrons and on the electromagnetic equations for bodies in motion. We have stated in reviewing the previous parts that the treatise is not intended for continuous reading. It is essentially an encyclopædia, a book of reference. But it is the treatise *per excellence* to which reference should be made by all those who wish to know what has been done and what theories have been enunciated in the domain of physics.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Condensation of Helium.

IN NATURE of March 12 I have found a note referring to my experiments on the expansion of helium, made in consequence of my determinations on the isothermals of helium, at $-252°$ C. and $-259°$ C., which yielded nearly $-5°$ K. for the critical temperature of helium.

The prosecution of the experiments has shown that what I observed in expanding the gas was not the evaporation of solid helium, but solution phenomena of solid hydrogen in gaseous helium. I have communicated to the Amsterdam Academy a note on my experiments, which at the moment leave the condensation of helium a yet undecided question.

Of course, I have written the details to Sir James Dewar, and I hoped to do so to you to-day, but by pressing duties I cannot do it before to-night, and you will probably go to press before that letter reaches you. So I beg to be allowed to send you first this short notice.

Leyden, April 14. H. KAMERLINGH ONNES.

Mendelian Characters among Shorthorns.

PROF. WILSON is welcome to any satisfaction he can obtain out of the Mendelian interpretation he gives to our statistics of coat-colour in Shorthorns. As a matter of fact, some readers may consider that the same interpretation is given with greater numerical accuracy on pp. 440–4 of our original memoir (*Biometrika*, vol. iv.). For example, we give 656 crosses of roan and *whole* red alone, resulting in 243 whole reds, eighty-five red and whites, and *four whites*. The remainder consists of 324 roans. Of this we say "the close approximation to the Mendelian number of the roans is noteworthy, but the appearance of 4(WW) is again impossible unless some of the reds are to be treated as heterozygous." Why does Prof. Wilson reduce our *total* red roan crosses to 456, and leave out the inconvenient four whites? Why does he give only three whites crossed by white as giving three whites, while we dealt with ninety-one such crosses giving eighty-six whites, *four roans, and one red*? Why, further, does he leave out the whole of our Table I. on p. 441? We followed up the white cattle pedigrees, writing to the breeders about special cases, and finding in the great bulk of instances the crosses and colours stated in the Herd-book confirmed. If it be asserted that the colours given in the Herd-book are incorrect, or, still more vitally, that the confirmation of those facts given to us by reputable breeders are misstatements, then the only conclusion is that Mendelism cannot be discussed on the basis of the Shorthorn data. That is a logical position; it is not, however, logical to use the data, and escape inconvenient facts by the statement that they are due to errors or to deception, or to omission to enter calves (which we found on inquiry among English large breeders to be not so frequent as has been asserted).

The facts stated by us on p. 442 of our paper, which cannot at present be made fully public, show that there are probably latent colour determinants in white cattle which can be made patent if two individuals of pure white coat, but one of mixed race, be crossed. Recent experiments seem to show that the actual amount of pigmentation in the coat is an inherited character in mammals; no explanation, Mendelian or other, which overlooks the difference between whole and parti-coloured animals can in the present state of our knowledge be considered satisfactory. As it is, the parti-coloured cattle are being bred out, and the possibility of this shows that red and parti-colour are *not* interchangeable. This point is illustrated again by the fact that in whole red crossings about 3 per cent. of roans appear, but in parti-colour crossings about 8 per cent. of roans occur. There is at the bottom of this, I believe, a physiological fact, and I am not prepared to overlook it by saying, with Prof. Wilson, that 438 red by red matings gave twenty-five roans, which are to be put down as due to errors and misstatements because they do not fit his view of the case.

Within broad lines Shorthorns do show segregation in the results of the crossings; this is really the great idea embodied in the Mendelian view. It may be possible on a determinantal theory to offer a reasonable account of the Shorthorn data; such a theory would certainly follow recent Mendelian work in discriminating between whole and parti-colour coats. On the other hand, it is a possible attitude to discard the data as untrustworthy; it is not logical, I hold, to discard just as much as you please of the data and no more in order to make it fit the simpler Mendelian ratios. KARL PEARSON.

Biometric Laboratory, University College.

THE validity of Prof. Pearson's criticism of the view that Shorthorn cattle are Mendelians turns upon the accuracy of my statements (*a*) that in the Herd-book roans are sometimes registered as reds and reds as roans; (*b*) that many white calves are not registered at all; and (*c*) that coloured calves are sometimes substituted for white ones. Unfortunately, these statements are all true, although the last one only need cause very serious regret. The following may make the position clearer.

A short time ago a very distinguished breeder was regretting the substitution of coloured calves and the difficulty of proving cases of substitution to be such. This breeder persistently uses white bulls in order to get roan calves from his red cows, and, in proof that red calves entered in the Herd-book as the progeny of reds and whites are probably substitutions, he mentioned that in all his experience he had got only one red calf from his white bulls and his red cows.

That red calf—a bull—came to Ireland, and is still alive. To the great disappointment of his owner, he has bred several white calves from roan cows.

First, by being the son of a white bull and a red cow, and, next, by breeding white calves from roan cows, this red bull disproves the theory that Shorthorns are Mendelians; but I had the privilege of seeing him this afternoon and he is not red, *he is roan*. He is, however, such a roan as might be mistaken for a red unless closely examined.

Here, then, is one of our most distinguished breeders referring to substitution, and making an error of description as regards the colour of a calf.

The last time I visited the farm where the above "red" bull is standing I saw some white calves, and this afternoon one of them, now six or eight weeks old, was missing. I asked the owner what had become of him, and got the reply, "I have sold him." This particular white calf may be referred to in the Herd-book by his breeder, but many another similar one is never referred to at all.

Prof. Pearson suggests that, if there are inaccuracies and misstatements in the Herd-book, "Mendelism cannot be discussed on the basis of the Shorthorn data." I do not agree. But, if not Mendelism, can biometric theories be discussed upon the same data?

The latter half of Prof. Pearson's letter does not bear much upon the present issue, but I should not be astonished, if his theories as to colour determinants and parti-colours are followed up, that each of the two races from which the Shorthorn is descended should split up into more than one variety.

Prof. Pearson thinks that, because I neglected the figures in the first part of his original paper, I was evading some of the data. This is not so. I did not notice that they comprised other data, for which I am sorry, because the ninety-one white crossings which gave eighty-six white calves, four roans, and one red, would have been helpful. I had not seen the original paper since the time it was published two years ago, and, when I conceived the idea that Shorthorns are Mendelians, I went straight to the two tables from which I quoted, in the belief that they contained all the relevant data collected by Miss Barrington and Prof. Pearson.

James Wilson.

Royal College of Science, Dublin, April 8.

The Nature of γ and X-Rays.

If I am putting the correct interpretation on Mr. Barkla's letter in Nature of February 6 (p. 319), I have to thank him for the admission that his experiments are not so contrary to the neutral pair theory as he had at first supposed.

Mr. Barkla still concludes, however, in favour of the ether pulse theory. He has compared the intensities of two secondary beams emitted by carbon under the influence of an unpolarised primary beam, the one returning on the track of the incident rays, the other moving in a perpendicular direction. His calculated ratio is 2 : 1; experiment gives 1·85 to 1 (*Phil. Mag.*, February, p. 293). Such an agreement has its value. But, at the same time, he finds that for harder rays the ratio drops to 1·45 to 1, with no sign of a limit. His theory is unable to predict this decline, far less to measure its amount. It is no compliment to the ether pulse theory to describe such incomplete successes as "absolutely conclusive evidence."

He invites me to suggest a theory of scattering which shall have as much success as his own. But, on the neutral pair theory, the laws of scattering must depend directly on the constitution of the atom, as to which it is scarcely possible to do more than speculate. It is not incumbent on me at this stage to frame an independent hypothesis by the success of which my older one is to be judged.

He wishes to avoid arguments founded on an experimental study of the γ rays. But it is quite legitimate to begin with the γ rays, and to carry the argument over to the X-rays, on the ground that there is an extremely close parallelism between the two types. Evidence of this sort cannot be avoided by resolutely facing the other way.

It will perhaps conduce to greater clearness if I state my position briefly.

(1) Nearly a year ago I pointed out that almost all the phenomena of γ and X-rays could be explained on a neutral pair theory at least as well as on an ether pulse theory. This applied particularly to all effects connected with the production of secondary kathode rays of high velocity, effects which are at the root of most of what has been observed.

(2) I have recently described some experiments carried out by Dr. Madsen and myself which seem to me to support my contention in the strongest way as regards the γ rays.

(3) Since X-rays and γ rays resemble each other so faithfully in most respects, particularly those connected with the high-speed kathode rays, I have therefore suggested that the experiments also support my contention regarding the nature of the bulk of the X-rays.

(4) There are a few outstanding phenomena of the X-rays which do not fit in so readily with a neutral pair hypothesis, particularly Marx's velocity experiment, and the diffraction experiments of Haga and Windt. These seem to prove the existence and activity of ether pulses. As regards Mr. Barkla's polarisation effects, I have indicated a possible way of explaining them on the neutral pair theory; but I am quite content to wait for the guidance of future experiments, amongst which Mr. Barkla's recent work will take its proper place.

(5) If I admit the existence of ether pulses, I do not thereby weaken my contention that the most important and effective part of γ and X-ray radiation is material. We know that ether pulses exist; it does not follow that they do everything. On the contrary, the evidence for the ether pulse theory is extremely weak in just this direction; there is a danger that the *post hoc* has been confused with the *propter hoc*. When I see a boy jerk his arm, and hear immediately afterwards a rattling on my roof, I know quite well that the motion of the boy's arm has set an air pulse going, but I do not conclude that one of my chimneys was in a dangerously explosive condition, and that the air pulse has precipitated the violent discharge of half a brick.

W. H. Bragg.

The Corrosion of Iron and Steel.

A paper describing the investigation of the causes of rusting of iron was read in May, 1907, before the New York Section of the American Chemical Society by Mr. William H. Walker and others, and has been recently printed in this country. After criticising the various explanations which have been put forward of the rusting of iron in contact with water, the authors approve the suggestion of Whitney that the first step in the process is the escape into the liquid of iron in the form of positively charged ions. In confirmation of this, the authors state that they succeeded in detecting iron by chemical tests in water which contained only a trace of electrolyte, and was free from oxygen and carbon dioxide, after the water had been in contact with iron.

Such an explanation would apply to a fact which confronted me some years since when investigating the cause of the action of water on lead. Every precaution was adopted to bring a surface of metallic lead absolutely free from oxide into contact with water free from dissolved gases, with the expectation that if these conditions were fully complied with no lead would pass into solution. In the course of the investigation the precautions which were taken to secure the conditions specified gradually became more stringent, and the amount of lead passing into solution was correspondingly reduced; but when the utmost possible care had been taken, lead in very minute proportion was still detectable in the water by chemical tests. It is of interest to note that the proportion of lead was constant when the contact of water with lead had been brought about in repeated experiments with some variations in detail. The impression produced by these results on my own mind was that undoubtedly lead in the metallic state must have passed into the water, and upon reconsideration of the experimental work and its results I feel satisfied that this was the case, and that the lead probably passed into the water as iron did in the experiments made by Whitney and repeated by the American investigators, when they brought iron into contact with water under conditions similar to those which I had secured.

The Grange, Dulwich.

THE GEOLOGY OF SOUTH VICTORIA LAND.[1]

THE National Antarctic Expedition is to be congratulated upon the care and promptitude with which its scientific collections are being worked out by the staff of the Natural History Museum. The results are being issued with the fulness of illustration and the excellent form characteristic of the publications of that institution. The work has been thoroughly supervised and edited. The first volume has a general preface by Sir Ray Lankester, and a special preface by Mr. Fletcher, in whose department the work of this volume was executed; the biological work is being edited by Mr. Jeffrey Bell. The first volume deals with the geological work of the expedition, and contains two reports. The first, by Mr. H. T. Ferrar, records his observations upon the stratigraphical and glacial geology. It is accompanied by a valuable geological map of the district around MacMurdo Sound, based on the topographical survey by Lieut. Mulock, and by an admirable series of photographs, that are a valuable supplement to the text, but by whom they were taken is not stated. The geological specimens obtained were mainly collected near the *Discovery's* winter quarters, and on the opposite part of the mainland. The extended field observations and the large amount of material collected are clearly the result of most indefatigable and courageous work, under difficult and dangerous conditions, and are a most important addition to Antarctic geology. The geological formations at MacMurdo Bay are divided by Mr. Ferrar into four series: the recent volcanic rocks of the islands; the gneiss and granite that form the foot hills and the basement of the mainland plateau; a wide series of horizontal sandstones, the Beacon Sandstones, that form the plateau of southern Victoria Land; and some dolerite sills intrusive into the Beacon Sandstones. Unfortunately there is no definite evidence as to the age of these sandstones. Some plant remains were found in them, and are described by Mr. Arber, according to whom they are "unfortunately of little value botanically"; he calls them "carbonaceous impressions," "which in all probability are of vegetable origin." Mr. Arber concludes that the specimens "neither permit of any opinion as to the botanical nature or affinities of the fossils themselves, nor of the geological age of the beds in which they occur." Considering the extent and abundant exposure of these sandstones, the apparent rarity of organic remains in them is significant. Mr. Ferrar devotes three chapters to glacial observations, and describes Ross's ice barrier as a Piedmont glacier, formed of confluent flows of land ice. The evidence offered in support of this conclusion is not very convincing, but until the issue of the meteorological data collected by the expedition, it is better to suspend judgment upon this question; and it may be hoped that Lieutenant Shackleton's expedition will collect further information as to the intimate structure of this ice.

The second part of the volume is occupied by Dr. Prior's report on the rocks of South Victoria Land. This report is masterly from its combination of refined petrographic research with insight into the tectonic bearings of the microscopic evidence. Dr. Prior shows that the volcanic rocks include basalts, kenytes, phonolites and trachytic phonolites; the dykes are of camptonite, kersantite, and banakite; and the basement rocks of South Victoria Land include granite, diorite, gneiss and a crystalline limestone, of which a specimen was found by Dr. Wilson. Dr. Prior's report contains an interesting discussion of the chemical relations of the rocks and their interpretation by the American quantitative system of classification. He shows that the district is a distinct petrographic province characterised by the association of limburgites with intermediate rocks, which are rich in alkali and contain anorthoclase as the predominant felspar. He has calculated the percentage mineral composition of the rocks and assigned to them the names they would receive in the American quantitative classification, and he concludes (p. 120) that "the result shows that the classification supplies a variety of names to rocks not differing very widely in chemical composition."

The sequence of the volcanic rocks is a question of much interest, especially as some field observations were regarded as showing that the trachytes were younger than the basalts; but Dr. Prior concludes from his study of the rocks that this view is improbable, and that the trachytes and kenytes preceded the basalts, as they did in the typical kenyte area in East Africa. The most widely interesting part of Dr. Prior's report is probably that discussing the geographical relations of South Victoria Land. He points out that the rocks are chemically allied to those of the Atlantic coast type, and not to those of the Pacific coast type. He, of course, recognises that, according to this use of the terms Atlantic and Pacific, the southern end of New Zealand must be regarded as of the Atlantic type, for the rocks of South Victoria Land are petrographically allied to those of Dunedin described by Dr. Marshall. An article in NATURE (in 1901, vol. lxiii., p. 610) on the probable geological relations of Victoria Land pointed out that the sudden change in the geographical grain of southern New Zealand might very likely be continued into Ant-

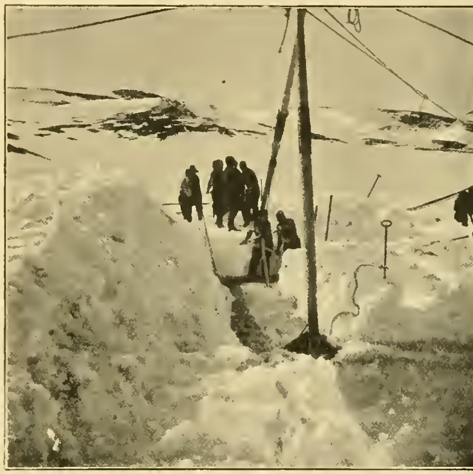

FIG. 1.—The two lower men are standing upon the upper surface of sea-ice depressed by snow below water-level. National Antarctic Expedition.

[1] National Antarctic Expedition, 1901–1904. Natural History, vol. i. Geology (Field-Geology: Petrography). Pp. xii+160; 10 plates and 2 maps. (By order of the Trustees of the British Museum, 1907.) Price 30s.

arctica, and that accordingly the view suggested by Reiter that the mountains of South Victoria Land were the continuation of the mountain chain of New Zealand might require modification. The geological results issued in this volume show that, as expected, South Victoria Land is a high plateau broken off to the east by the subsidences which have formed the Ross Sea. Moreover, the suspected affinities between Victoria Land and New Zealand have been greatly strengthened by the discovery of the kenyte series of Ross Island; and the predictions in NATURE (vol. lxiii., p 610) that "the palæontological results may be meagre" has proved only too true. Reiter's theory, however, requires one modification. The earlier descriptions of Victoria Land asserted the volcanic nature of the mountains on the plateau of South Victoria Land (as, *e.g.*, is the case in Mexico and parts of the Andes), whereas the volcanoes, at least in the area reached by the expedition, were limited to the foundered area in front of the plateau, as is the case in eastern Asia. Accordingly the structure of South Victoria Land may be of the inner or secondary Pacific type, and any remains of an outer or primary Pacific coast connecting New Zealand and Graham Land may be expected further to the east. The evidence is not yet sufficient for a final opinion, and an alternative interpretation, in deference to the petrographic evidence, is to regard the coast of South Victoria Land as of the Atlantic type; but there does not seem any clear reason why the distribution of volcanic rocks of different chemical types should be controlled by the nature of the crustal movements. The suggestion that fold movements produce volcanic rocks of the Pacific type, and subsidences those of the Atlantic type, is no real explanation; and though the coincidence is certainly widespread, it does not appear to be universal. The chemical character of the volcanic rocks can only be used as a test of the tectonic structure of coasts with important limitations; and the coastal types may still be regarded as based essentially on geographical structure, and not on the chemical composition of their lavas.

NAVIGATION OF THE AIR.[1]

THE author of this work at the outset states that he has no intention of writing a technical text-book, and his treatment of the subject, which embraces aërial navigation generally, is distinctly of a popular kind. Portions of the work, for example, those relating to ballooning and balloon photography, are dealt with in great detail, and show an intimate practical acquaintance with the subject; the section also relating to carrier pigeons, both in connection with ballooning and otherwise, is a welcome addition to the literature of the homing pigeon. On the other hand, some portions of the work are scarcely satisfactory, even from the popular standpoint, the chapter devoted to flying machines, for example, being a collection of scraps of information strung together without any definite scheme; on the face of it, this chapter is intended to be arranged in historical order, but

[1] "Airships Past and Present, together with Chapters on the Use of Balloons in Connection with Meteorology, Photography, and the Carrier Pigeon." By A. Hildebrandt. Translated by W. H. Story. Pp. xvi+364. (London: A. Constable and Co., Ltd., 1908.) Price 10s. 6d. net.

dates are not given where they are of importance, and even so well-known a worker in the field as Hargraves is practically ignored.

The illustrations are numerous, and, on the whole, are very good; of special interest is the photographic reproduction of a "double deck" Lilienthal machine in flight, which appears to be of the type used by the late Herr Lilienthal on the occasion of his last flight, when he unfortunately met with his fatal accident. Of the great variety of "birds' eye" photographs given, perhaps the most interesting are the cloud studies given in Figs. 125, 143, and 185; also a fine view of the pyramids of Egypt, Fig. 200.

The chapters on ballooning entitled "Ballooning as a Sport," "Scientific Ballooning," and "Balloon Photography," in addition to those on "Military Ballooning," make interesting reading, and constitute the most useful and trustworthy portion of the book; there is much information collected in pages devoted to these chapters that might be sought for elsewhere in vain. The account, however, is essentially of a popular kind; it is difficult to read these chapters without raising an "aëronautical appetite"; the description of over-sea ballooning and the illustrations of the de la Vaulx *deviator* are particularly interesting.

Lilienthal on his flying machine. From "Airships Past and Present."

It is when departing from the declared intention of the work that its author most lays himself open to criticism. Thus, on p. 17, in discussing the theory of the ascension of the *Montgolfiere,* there is a simple little pitfall into which the author has gratuitously precipitated himself. On the assumed barometric pressure of 30″ of mercury, it is stated (we may presume correctly) that the weight of a cubic foot of air heated to 212° F. is 0·059 lb. Herr Hildebrandt then goes on to say:—

"At a height of 8330 feet, a cubic foot of air at a temperature of 32 deg. Fahr. weighs only 0·059 lb., and therefore a 'Montgolfiere' cannot reach a greater height than this, seeing that the lift then disappears, unless the temperatures, given in the above table, can be exceeded."

The assumption made here seems to be that the air within the balloon does not expand as the pressure is relieved by altitude, just as if the air inside the balloon were contained by a hermetically sealed pressure-proof envelope.

On p. 30 a description is given of an aneroid barometer which certainly is a mistake; either the word *tube* has been used in translation instead of *diaphragm,* or else the author describes a particular aneroid (probably made by Bourdon, of Paris) instead of the aneroid as generally constructed; the almost universal practice of instrument makers is to employ a flexible diaphragm, not a tube as stated.

On p. 89 it is somewhat puzzling to find that most of the "dirigibles" have a greater content than that of their containing cylinder—according to the figures given. For example, a balloon 30 feet in diameter and 148 feet long is given as holding 137,500 cubic feet of gas; in view of the fact that a cylinder of these dimensions has a volume of only 105,000 cubic feet, this requires some explanation. Several other cases are equally incomprehensible.

On p. 96 the year 1862 is assigned to Phillips's "venetian blind" captive machine; this appears to be an error of about thirty years (antedate).

The fatal accident to Herr Lilienthal is stated to have been due to a want of adjustment, the machine turning over at a height of 50 feet from the ground. The authority for this version of the accident should be stated; the account, as published in NATURE (September 3, 1896), contributed by Prof. Carl Runge, from the evidence of an eye-witness (the assistant of Herr Lilienthal), made no mention of any error of adjustment, but attributed the capsize to a sudden gust, which carried the machine to a height of 30 metres (100 feet), from which the fatal plunge took place.

In the chapter on carrier pigeons an account of certain experiments, stated to have been made with trained swallows, is given, but again no trustworthy authority is mentioned. A passage may be quoted as follows:—"An Antwerp trainer sent up some swallows and pigeons at the same time at Compiègne, in France. The pigeons covered the distance of 145 miles in $3\frac{3}{4}$ hours, while the swallows arrived in 1 hour 7 minutes; the speed of the latter was therefore three times that of the former." Now the time taken by the pigeons appears to denote that there was no wind of consequence, and therefore the velocity of flight of a swallow may be calculated as 130 miles per hour, a conclusion full of improbability. Statements of this kind should only be inserted in a serious work after careful verification, and with the authority stated, place and time also being given, if possible.

NOTES.

THE fourth International Congress of Mathematicians was opened at Rome on Monday, April 6, in the presence of King Victor Emmanuel II., and the proceedings concluded on Saturday last, when an invitation was accepted to hold the congress of 1912 at Cambridge. The number of members shows a considerable increase on that of previous congresses, and a great deal of valuable work has been done in the sections. The Guccia medal has been awarded to Prof. Francesco Severi, for his papers on the geometry of algebraic surfaces. We hope to give an account of the proceedings of the congress next week.

IT was announced at the meeting of the Institution of Naval Architects on April 8 that the council had gratefully accepted an offer from Mr. A. F. Yarrow, vice-president of the institution, to defray the cost, up to 20,000*l.*, of an experimental tank for research purposes to be erected at the National Physical Laboratory, provided that cost of maintenance for the first ten years was assured. A committee is to be appointed to carry out the scheme. Papers on the employment of the steam-turbine for various classes of ships took a prominent place in the proceedings of the meeting. Lord Cawdor was elected president of the institution upon the retirement of Lord Glasgow.

The annual conversazione of the Selborne Society will be held at Burlington Gardens, New Bond Street, W., on Friday, May 1, from 7.30 to 11 p.m.

The death is announced, in his eighty-seventh year, of Prof. Franz von Leydig, of the University of Bonn, distinguished by his studies in comparative histology and various works upon anatomical subjects.

Mr. J. P. Johnson, of Johannesburg, has been commissioned by the Government of Orange River Colony to investigate and report on the Bushmen sculptures and paintings in that territory.

At Issy les Moulineaux on March 11, M. Delagrange, mounted upon an aëroplane, traversed the marked circuit seven times, the total distance being about 10 kilometres, in 9m. 15s. The motor with which M. Delagrange's machine is provided is a forty horse-power light cylinder Antoinette.

The Town Council of West Ham has resolved to confer the freedom of the borough on Lord Lister, "who was born in the county borough, and has rendered such illustrious service to the human race by his famous discovery of the antiseptic system of treatment in surgery and in a variety of other ways connected with science and the alleviation of pain and suffering."

Reuter's Agency learns that the British Government has decided to take independent action regarding sleeping sickness by establishing a National Sleeping Sickness Bureau with headquarters in London. It will be remembered that the recent international conference in London collapsed mainly owing to the opposition offered to the proposal to establish any international bureau in London. Alternative recommendations in favour of Paris and Brussels were put forward at the time, but no agreement was come to on the question. The British National Bureau will be managed by a strong committee. Annual grants will be made by the Imperial and Sudanese Governments. To combat sleeping sickness, Great Britain and Germany are concluding a convention on the subject of joint measures for the prevention of the malady in Uganda and German East Africa. This is expected to be signed at an early date.

The Naples Table Association for Promoting Laboratory Research by Women announces the offer of a fourth prize of one thousand dollars for the best thesis written by a woman, on a scientific subject, embodying new observations and new conclusions based on an independent laboratory research in biological, chemical, or physical science. The theses offered in competition are to be presented to the executive committee of the association, and must be in the hands of the chairman of the committee on the prize, Mrs. Ellen H. Richards, Massachusetts Institute of Technology, Boston, Mass., before February 25, 1909. The prize will be awarded at the annual meeting in April, 1909. The papers presented will be judged by a board of examiners, or by such specialists as they may choose. The board of examiners is constituted as follows:—*Biological sciences*, Dr. W. H. Howell, Johns Hopkins Medical School; *chemical sciences*, Dr. T. W. Richards, Harvard University; *physical sciences*, Dr. A. A. Michelson, University of Chicago.

We have received a somewhat belated copy (published in 1906) of No. 26 of the *North American Fauna*—U.S. Department of Agriculture—in which Mr. A. H. Howell classifies the little skunks of the genus Spilogale.

To Nos. 3 and 4 of vol. xxix. of Notes from the Leyden Museum, Dr. E. D. van Oort contributes two papers on Papuan birds, in the second of which he describes, under the name of *Casuarius casuarius bistriatus*, an apparently new race of cassowary from the north coast of New Guinea. It is remarkable that this bird appears to be related to an Aru Island species, and thus quite different from those inhabiting the interior of New Guinea. A coloured plate of the head and neck is given.

To *British Birds* for April Messrs. Witherby and Ticehurst contribute an article on the spread of the little owl in England. This owl cannot now be regarded otherwise than as an introduced species in England, owing to the fact that so many have been turned loose in various parts of the country. The process began in 1843 at Walton Park, Yorkshire, but the chief centres of spread have in recent years been Hampshire, Tring, Edenbridge in Kent, and Oundle. From Oundle the birds appear to have reached Woburn, where they breed freely. They also breed near Watford and other parts of Hertfordshire, while from the Kent centre these owls have colonised a considerable portion of the south-east of England.

In an article on the seasonal colour-change in birds, published in the January number of the *American Naturalist*, Mr. C. W. Beebe states that certain tanagers and bobolinks, which had been prevented from breeding, were kept during autumn in a darkened chamber with a somewhat increased supply of food. The consequence was that the brilliant breeding-plumage was retained throughout the winter. Early in the following spring the birds were returned to normal conditions, and speedily moulted. The new plumage was, however, the nuptial dress, and not the dull winter livery, which was skipped. The sequence of plumage-change is not, therefore, invariable, but evidently in some degree dependent on external factors in the environment.

The faculty of orientating their position, or the sense of direction, is considered by Mr. Benjamin Kidd, in the April number of the *Century Illustrated Magazine*, to be the most remarkable phenomenon in animal instinct. "This faculty of judging direction seems to bear no relation to the place of the animal in the general scale of intelligence. It is possessed to a considerable degree by dogs and cats, but in a very high degree by seals, which find their way back year after year to their rookeries from enormous distances in the open sea. It reaches a high degree of perfection in migratory birds not otherwise noted for intelligence. . . . The turtles which annually visit Ascension Island to deposit their eggs afford another example of the perfection of this instinct. How these reptiles can find this comparatively small speck of land in the midst of a vast ocean is, with our present knowledge, unaccountable."

Two pamphlets dealing with the food of American birds have just come to hand. In the first of these (from the Year-book of the U.S. Agricultural Department for 1906), Mr. W. L. McAtee gives a list of species feeding upon scale-insects, among which those included in the States under the name of grosbeaks occupy a prominent position. According to the second paper, which is by the same author, and forms Bulletin No. 32 of the Bureau of the Biological Survey, the birds last-named are valuable in other respects to the agriculturist and horticulturist. It should be mentioned that in America the scarlet cardinal and other members of the genus Cardinalis are commonly termed grosbeaks, and it is to this group that the remarks of the author apply. These birds are much less exclusively vegetarians than other members of the finch tribe, nearly half their food-supply consisting of animal substances. Moreover, the five species discussed in the pamphlet consume, on the average, nine times more wild seeds than grain and fruit, while the proportion of noxious to useful insects devoured by them is nineteen to one. Cardinal grosbeaks and their relatives are, therefore (after due allowance is made for certain injuries they inflict), of great economic value to the farmer, by whom they ought to be encouraged and protected.

WE offer our congratulations and best wishes for a successful life to the Transvaal Biological Society, the first meeting of which was held at the Transvaal Museum, Pretoria, on January 17, Dr. Theiler, C.M.G., being in the chair. We are unable to find space for descriptions of the papers read at the opening meeting, but the titles are given among our reports of societies and academies. The honorary secretary and treasurer of the society is Dr. L. H. Gough.

AN account of the sporangium in the Ophioglossaceæ, contributed by Mr. L. L. Burlingame to the *Botanical Gazette* (July, 1907), is based on an examination of the middle and later stages of development of the sporangium of *Ophioglossum reticulatum*. Irregular divisions of the sporogenous tissue, a remarkable difference in the stages of division of the mother cells, and an absence of definite arrangement in the positions of nuclear spindles in adjacent cells, were the chief points brought out in the investigation. A multipolar spindle changing to a tripolar, and subsequently to a bipolar, condition is figured. The development of the sporangia in the three genera Ophioglossum, Botrychium, and Helminthostachys is collated in tabular form.

DR. H. VON SCHRENK communicates to the report of the Missouri Garden for 1907 two interesting notes on growth connected with natural injuries to trees. In the one case sycamore buds were caught by the late frosts, with the result that the outer buds on the branches were killed, but the lower buds survived, and there was also a well-marked development of adventitious buds. The second note refers to hollow or button-like branch cankers formed on shrubs of *Rhododendron maximum* as a consequence of the slow growth of the healing callus tissue. Mr. H. Hus records his experiments on the germination of *Hydrastis canadensis*, a sylvestral plant yielding rhizomes that are officinal in certain pharmacopœias. The same author instances a case of virescence in the petals of *Oxalis stricta*, and mentions that the character was transmitted to the second generation.

THE annual report of the botanic station, agricultural school, and experiment plots in Dominica contains also an account of the inception and development of these establishments, and illustrations of local views. In Dominica much attention has been paid to the cultivation of limes; the establishment of a spineless variety of the fruit, and the introduction of the system of manufacturing citrate of lime for export, are expected to improve the industry. The characters of the spineless lime and the qualities of the juice are compared with those of the ordinary variety. Another feature has been the dissemination of the value of budding and grafting; in this connection, experiments in grafting cacao are noteworthy; training in these methods forms a part of the curriculum provided at the agricultural station. The manurial experiments on cacao plots indicate that various manures may be profitably applied, but the best results were obtained with mulchings of grass and lawn sweepings.

A REVISED list of the flora of Natal, compiled by Mr. J. M. Wood, has been published in the eighteenth volume (part ii.) of the Transactions of the South African Philosophical Society. The preponderance of the order Compositæ is very marked, and is partly due to the numerous species of Helichrysum, Senecio, Berkheya, and Vernonia. The next largest orders are the Gramineæ and Leguminosæ, then the Liliaceæ and Orchidaceæ. The genera Crassula, Indigofera, Royena, Selago, and Mahernia are well represented. The author recognises three botanical regions, and alludes to the palms *Hyphaene crinita* and *Phoenix reclinata*, *Strelitzia augusta*, and the handsome shade tree, *Trichilia Dregeana*, that grow in the coastal region. In the midlands the hills are grass-clad, and the forests are generally confined to the valleys, where two species of Podocarpus and *Ocotea bullata* occur. In the uplands, *Callitris cupressoides*—one of the three conifers indigenous to the country—forms isolated forests; two plants with conspicuous flowers are *Ranunculus Cooperi* and *Anemone Fanninii*, and the well-known *Galtonia candicans* is found.

IN the *Reliquary* for April, a noteworthy article is that by Mr. E. D. Goddard on certain fibulæ of the La Tène type found in Wiltshire, which may be dated about 200 B.C. This is a useful supplement to the discussions on the same subject by General Pitt-Rivers, Prof. Ridgeway, Mr. Reginald Smith, Dr. Arthur Evans, and others. The writer traces twenty-six examples found in England, of which Wiltshire and the adjoining counties claim no fewer than twenty—a fact which he thinks may imply a special connection of this part of England with Gaul in the period preceding the Roman invasion. In the same number Mr. J. L. Cowan contributes a well-illustrated article showing the evolution of house building in the Pueblo region of New Mexico, Arizona, Utah, and Colorado.

THE Observatory of Rio de Janeiro is doing very useful work in collecting and publishing in its *Boletim Mensal* series of meteorological observations made at various places in Brazil. In the number for January-March, 1907, which we have recently received, are to be found—in addition to the current tri-hourly observations at the observatory and ten-day means for other stations—monthly and annual summaries referring to several departments for 1906. Monthly and annual rainfall values are also given for Recife (Pernambuco) for fifty-four separate years between 1842 and 1906.

A COPY has just reached us of the observations made at the Royal Magnetical and Meteorological Observatory at Batavia in 1905; the principal change for this year is the omission of the hourly values of atmospheric humidity. In this valuable series of hourly readings the meteorological observations date from 1866, the magnetical from 1868; in both of these elements the influence of the moon has been taken into account. The seismometrical observations date from 1898. The present volume includes the results of meteorological observations for 1901–5, and for 1866–1905; we also note that a discussion of the rainfall at 700 stations in the archipelago is in the press. Three important appendices accompany the volume; one of these gives a list of magnetic disturbances during 1880–1899; some of the statistical results have been published by the Amsterdam Academy. We hope to refer to the others, dealing with meteorological subjects, later on.

THE Survey Department of the Ministry of Finance of Egypt has issued an account of the magnetic observations made in Egypt during the ten years 1895–1905, together with a summary of the observations made previously in northern Africa. According to the charts which embody the results, the declination at Alexandria has decreased from 13° to 3° west, and the dip from 47° to 42°, in the last 100 years. The lines of equal declination at present run nearly parallel to the Red Sea, where the declination is 2°. At the Victoria Nyanza it is 7°. The lines of equal dip run east and west, the dip being 43° north at Port Said and 23° south at the Victoria Nyanza. The horizontal force varies from 0·30 at Cairo to 0·35 at Aden, and the curves of equal force are not unlike ellipses with their major axes east and west and their centres in the Gulf of Aden.

A paper on "The Possibility of a Topography of the Air, based on Balloon Observations with Special Theodolites," by Captain C. H. Ley, appears in the last issue of the Quarterly Journal of the Royal Meteorological Society (vol. xxxiv., No. 145). The paper forms a further contribution to the investigation of the upper atmosphere, which now plays so important a part in meteorological work. In all experiments hitherto made to determine the motion of the upper air from the drift of pilot balloons, it has been necessary either to observe the motion of the balloon through two theodolites at either end of a measured base line, or, if only one theodolite was available, to assume a value for the upward velocity of the balloon. In the present experiments only one theodolite was used, and the remaining data necessary for determining successive positions of the balloon were obtained from measurements of its apparent diameter made with a special arrangement of cross-wires in the eye-piece. Allowance was made for the expansion of the balloon by assuming approximate values for the rate of decrease of temperature and pressure with height, and calculating the volume of the balloon from the usual laws for the expansion of gases. The experimental and other difficulties which arise are considerable, and it can hardly be claimed that the author has succeeded in overcoming them completely, but the advantages of a method which dispenses with a second theodolite are considerable, and it is to be hoped that the experiments will be continued. The results obtained go to show that the ascensional velocity of a pilot balloon is far from uniform, as is generally assumed in experiments with only one theodolite. The most striking variations were found to occur as the balloon passed over a ridge of hills. In the vast majority of cases, when this occurred a marked increase in the rate of ascent was observed as the balloon approached the ridge, even though it was at an altitude of several thousand feet above the summit. The increase in the rate of ascent of the balloon is regarded as direct evidence of an increase in the vertical component of the motion of the air in which it floats, so that the topography of the land appears to have a close connection with the vertical motion of the air even up to altitudes of 20,000 feet.

Some excellent photographs and drawings of the new Charing Cross Station of the South-Eastern and Chatham Railway are given by Mr. C. S. Lake in *L'Ingegneria Ferroviaria* of March 16. It is noted that the quantity of steel used in the construction of the new roof was 1000 tons.

The School of Mines at Golden, Colorado, with 329 students, possesses exceptional environment for mining and metallurgy, and the current issue of the school Bulletin (vol. iv., No. 2), published semi-annually by the Technical and Engineering Society, affords evidence that excellent work is being done by the students. Mr. F. H. Cronin gives an outline of the course in steam-power plant design. Mr. D. Hollis and others contribute an admirable paper on the electrometallurgical treatment of copper slimes, and Mr. C. D. Test gives an account of the occurrence, production, and commercial value of monazite.

An important contribution to the knowledge of the economic geology of Peru is afforded by a monograph, by Mr. Enrique I. Dueñas, on the mineral resources of the department of the Cuzco, forming *Boletin* No. 53 of the Corps of Peruvian Mining Engineers. Descriptions are given of the gold washings of the river Nusiniscato, of the nickel and cobalt ore deposits of Vilcabamba, of the Silurian gold veins in Paucartambo, of the oil fields of Pallpata and Pusi, of the Tertiary and Mesozoic coalfields of the department, of the iron-ore deposits of Chumbivilcas, and of veins of copper sulphide, argentiferous galena, gold quartz, and stibnite in various parts of the department. The occurrence of mica in pegmatite dykes, of asbestos, of tripoli, and of other non-metallic minerals of economic value is also recorded.

At the Institution of Mechanical Engineers on March 27, papers were read by Dr. F. J. Brislee on combustion processes in English locomotive fire-boxes, and by Mr. L. H. Fry on combustion and heat balances in locomotives. Dr. Brislee's object was to ascertain what percentage of carbonic oxide escaped unburned, and to this end he carried out interesting trials on the London and North-Western Railway. Mr. Fry gave selections from the data published in "Locomotive Tests and Exhibits, Pennsylvania Railroad," at the St. Louis Exhibition, a book which was issued in 1905. Both papers represent a great deal of labour, and the carefully tabulated experimental results will undoubtedly prove of permanent value, although it is doubtful whether either paper is likely to affect locomotive practice.

At the last meeting of the Institution of Engineers and Shipbuilders in Scotland, Mr. M. Kahn read a paper on the practical application of reinforced concrete. He expressed the opinion that reinforced concrete was the best form of construction when properly handled, and the worst when improperly handled. Such being the case, it behoves the owner and the architect to ensure that only the best class of contractor is employed on his work. Contractors can only afford to carry out work which will ensure them a fair amount of profit, and if, by the adoption of reinforced concrete, the owner is saved 10 per cent. of the cost of construction, it is advisable to grant the contractor any extra saving, so as to ensure his giving a construction which will prove satisfactory in every respect. When owners and engineers realise this point, and act accordingly, reinforced concrete will then reach that position in the category of structural materials where it justly belongs.

The preliminary official report on the mineral production of Canada in 1907 shows that the total value of the output was 86,183,477 dollars, the largest total ever reached. Compared with the production of the previous year, there are some decreases to record, such, for instance, as in gold and lead, in corundum, felspar, and graphite, but these are more than counterbalanced by large increases in the production of pig iron, silver, asbestos, coal, natural gas, petroleum, and cement.

A report on the work and results of the Khatanga Expedition, organised in 1905 by Dr. F. Schmidt, with the cooperation of the Russian Geographical Society, appears in the February number of *La Géographie*. The work of the expedition was divided into three sections—the exploration of the higher course of the Khatanga, and its relations with the tributaries of the Yenisei; the discovery of the main features of the lake region, and the course of the Moicro; and, finally, the exploration of the extreme north of the Khatanga and Anabar. A map of the Khatanga and its upper branches shows the important additions to geographical knowledge resulting from the expedition, which has proved that the supposed immense lakes of that district do not exist. In addition, geological information of great interest has been obtained, together with important zoological and ethnographic collections.

Prof. Aristide Fiorentino, writing in the *Rendiconti* of the Lombardy Academy, directs attention to a school-room experiment for showing the absorption of energy by an acoustic resonator. He places the resonator in the neighbourhood of a singing flame, and if the two are in unison the vibrations of the flame instantly cease. The author has further used the singing flame as a test for syntonised resonation. Thus he has demonstrated in the case of a gramophone horn that those tones are most readily absorbed which are most strongly reinforced. The failure to take account of this fact is no doubt partly the reason why gramophone reproductions usually represent little more than a caricature of the original music. The same records are habitually snorted out through horns of all sizes and shapes, whereas if the free vibrations of any particular horn were reduced by the absorbing action of similar horns in the manufacture of the records, the results would be much better.

Himmel und Erde for March contains the report of a popular lecture on electric transmission of power to great distances, delivered by Prof. H. Görges, of Dresden, before the Scientific Association of Berlin. The lecturer deals in a clear manner with the generation of electric current by the motion of a conductor through a magnetic field, and shows how the modern dynamo is merely an application of this principle. The generation of the power to drive the machines is also treated, special attention being given to the utilisation of the waste gases from blast furnaces and to water power. Prof. Görges believes that the greatest future lies open to the simple alternating as distinguished from the triphase current, and instances the recent installation of the Ohlsdorf-Hamburg-Blankenese electric railway as a step in this direction. The pressure in this case is 6000 volts, with 30,000 for transmission to distant portions of the line.

The London Geological Field Class excursions, conducted by Prof. H. G. Seeley, F.R.S., for the study of the Thames Basin, will commence on Saturday, May 9. Mr. J. W. Jarvis, St. Mark's College, Chelsea, S.W., is the honorary secretary.

A second edition of the "Guide to the Archives of the Government of the United States in Washington," by Messrs. C. H. V. Tyne and W. G. Leland, has been published by the Carnegie Institution of Washington. The new issue has been revised and enlarged by Mr. W. G. Leland; the usual work of correcting errors, verifying statements, supplementing the bibliographical data, altering classification when required by administrative changes, and bringing the accounts to date, has been performed, and in several cases the text has been much amplified.

OUR ASTRONOMICAL COLUMN.

The Recently Discovered Satellite of Jupiter.—The observations made at Greenwich of the object near Jupiter, recently discovered by Mr. Melotte, tend to confirm the assumption that this object is in reality a satellite, the eighth of the known Jovian satellites.

In the April number of the *Observatory* (No. 395, p. 177) there appears a note which states that the observed positions, from January 27 to March 23, may be satisfied by the assumption that the satellite has a retrograde motion; the pole of the orbit plane lies in R.A. $=334^\circ\ 48'$, N. dec. $=56^\circ\ 44'$; distance from Jupiter 0·24 astronomical unit; daily motion about Jupiter, $0^\circ{\cdot}266$. On February 18 it passed the minor axis of the apparent ellipse. The arc yet observed is so small that any solution can only be tentative, but it is hoped that sufficient observational material has been gathered to ensure the re-discovery of the satellite at the next favourable presentation.

Mutual Occultations and Eclipses of Jupiter's Satellites.—A partial occultation of Ganymede by Europa was observed by Mr. Whitmell on January 25, the phenomenon lasting for some fifteen minutes. Prof. Oudeman recently published some ephemerides for occultations to take place in June next, but in No. 395 of the *Observatory* (April, p. 178) there appears a list of times at which occultations will take place during the present month. In the following extract the first Roman figure indicates the eclipsed, the second the eclipsing, satellite:—April 17d. 10h. 41m., II., III.; 17d. 14h. 17m., II., I.; 21d. 12h. 19m., IV., II.; 22d. 9h. 41m., IV., III.; 22d. 11h. 27m., I., II.; 28d. 13h. 29m., IV., III.

The Transit of Mercury, November, 1907.—In No. 4238 of the *Astronomische Nachrichten* (March 9, p. 218) M. Gautier records the results of the observations made, at the Geneva Observatory, of the recent transit of Mercury. Neither the bright outer ring nor the central luminous spot was observed at any time during the transit. Times of the contacts and the positions of Mercury referred to the sun's limb at different times during the transit are given, and it is recorded that M. Pidoux, using the Plantamour equatorial of 271 mm. aperture, found the apparent diameter of the planet's disc to be $8''{\cdot}4$, an amount sensibly less than that given by the ephemerides.

Parallax Observations.—The results of various parallax observations made by Dr. Karl Bohlin at the Stockholm Observatory appear in No. 4240 of the *Astronomische Nachrichten* (March 23, p. 247). The first object considered is a nebula, G.C. 1532, and the second an adjacent star, Lalande 14512. Their respective parallaxes are $-0''{\cdot}036$ and $-0''{\cdot}058$, the Brünnow relative corrections for the aberration constant being $+0''{\cdot}186$ and $+0''{\cdot}149$ respectively, corrections to which Dr. Bohlin directs especial attention on account of their magnitude. The corresponding figures for Bossert 947 (= Lalande 18115) and 61 Cygni are $+0''{\cdot}085$ and $+0''{\cdot}363$ for the parallaxes, and $+0''{\cdot}102$ and $+0''{\cdot}048$ for the corrections.

Astronomical Photography with Portrait Lenses.—Some good examples of celestial pictures taken with portrait lenses are reproduced in No. 187, vol. xlvi., of the Proceedings of the American Philosophical Society (October-December, 1907, p. 417), in order to illustrate a paper by Prof. Barnard on the subject of astronomical photography. Prof. Barnard, in the first place, discusses the great advantages accruing from photography in the correct delineation of celestial objects, and then points out the special suitability of the earlier portrait lenses of large aperture for this purpose. This is followed by a discussion of each of the objects shown, including nebulæ, star clusters, meteor trails, comets, &c. Most of the pictures were taken with the 10-inch Brashear doublet of the Bruce telescope.

The Harvard College Observatory.—Prof. Pickering's report of the work done at the Harvard College Observatory during the year ended September 30, 1907, is the sixty-second of its series, and contains the usual brief summary of an immense amount of work. With the 11-inch Draper telescope, 356 photographs were secured, making 17,035 in all, and with the 8-inch Draper telescope the taking of 611 photographs brought the total to 34,886. The spectra of 456 stars, taken with the 11-inch instrument, were studied and classified by Miss Cannon, thus bringing near to completion a catalogue of the spectra of more than 1200 stars north of declination -30°. 2710 stellar photographs were taken at Arequipa, the total numbers now taken with the 13-inch Boyden and 8-inch Bache telescopes being 11,847 and 38,224 respectively. Other results, too numerous to mention here, are contained in the report, and it is announced that to private individuals a nominal charge will in future be made for the Harvard publications.

THE SATURN PERTURBATIONS OF VARIOUS COMETS.—An abstract (No. 3) from the *Archiv der deutschen Seewarte* (vol. xxx., 1907) contains an important mathematical discussion of the perturbations of several comets by Saturn. The first-order perturbations of comets 1889 V., 1896 VI., and 1903 V. (Brooks) are discussed, and the work has been carried out by Dr. Johannes Wendt.

THE GAMES OF NORTH AMERICAN INDIANS.[1]

IT has been known that Mr. Stewart Culin, formerly of the Free Museum of Science and Art in Philadelphia, and now of the Brooklyn Institute Museum, has for many years been engaged in a study of the games of the American Indians, and his monograph on the subject has recently been published in the "Twenty-fourth Annual Report of the Bureau of American Ethnology." The value of the memoir can partly be judged by the fact that, with the full index, it extends to 846 pages and contains 1112 figures in the text, in addition to twenty-one plates. The memoir itself is practically an illustrated catalogue of specimens in various museums, combined with extracts from numerous authors. Students of this interesting and suggestive branch of ethnology have now for the first time a mass of data at their disposal, and it is to be hoped that other regions of the world will be treated by equally qualified investigators in a similarly thorough manner. Some material for such studies occurs scattered in various publications and in unpublished museum specimens, but more fieldwork is necessary before anything so complete as Mr. Culin's monograph can be accomplished.

The collection has been confined to games in which implements are employed, but Indian children have many amusements played without accessories which belong to a different category from those described by Mr. Culin. It is to be hoped that these will eventually be studied, as they are of equal interest with the others.

The indigenous games of the American Indians, excluding purely children's games, may be divided into two groups:—(1) games of chance; (2) games of dexterity. Games of pure skill and calculation, such as chess, are entirely absent. In the first group are:—(1) games in which implements of the nature of dice are thrown at random to determine a number or numbers, and the sum of the count is kept by means of sticks, pebbles, &c., or upon a counting board; (2) games in which one or more of the players guess in which of two or more places an odd or specially marked lot is concealed, success or failure resulting in the gain or loss of counters. In the second group are:—(1) archery in various modifications; (2) a game of sliding javelins or darts upon the hard ground or ice; (3) a game of shooting at a moving target consisting of a netted wheel or a ring; (4) the game of ball in several highly specialised forms; (5) the racing games, more or less related to and complicated with the ball games. In addition, a few other games are described, and allusion is made to introduced games, such as cards and board games.

References to games are of common occurrence in the origin myths of various North American tribes. They usually consist of a description of a series of contests, in which the first man or culture hero overcomes some opponent or foe of the human race. The primal gamblers are the Divine Twins, the miraculous offspring of the Sun, who are the principal personages in many Indian mythologies. They, who are the morning and evening stars, live in the east and the west, ruling day and night, summer and winter. Their virgin mother, who also appears as their sister and wife, is constantly spoken of as their grandmother, and is the Moon or the Earth, the Spider Woman, the embodiment of the feminine principle in nature. Always contending, they are the original patrons of play, and their games are the games now played by men. Mr. Cushing thus described the Twins in his account of the Zuñi War Gods:—

"Lo! and of Chance and Fate were they the masters of foredeeming, for they carried the word-painted arrows of destiny, like the regions of men, four in number. And they carried the shuttlecocks of divination, like the regions of men, four in number. And they carried tubes of hidden things . . . and the revealing balls thereof. . . . Yea, and they bore with these other things, the feather bow and plume arrow of far-finding, tipped with the shell of heart-searching; and the race sticks of swift journeys and way-winning, two of them, the right and the left, the pursuer and the pursued of men in contention. All these things wherewith to divine men's chance, and play games of hazard, wagering the fate of whole nations on mere pastime, had they with them."

FIG. 1.—San Carlos Apache Indians playing hoop and pole, Arizona. From a photograph by Mr. S. C. Simms.

The gaming implements of most North American Indians "are almost exclusively derived from these symbolic weapons." Thus the stick dice are either arrow-shafts or miniature bows, and a similar origin may be asserted for the two or four bones employed in the hand-guessing game or in the four-stick game. Counting sticks in general and the numerous sticks of the widely spread stick game are arrows. The engraved and painted tubes used in the guessing game are arrow shaftments, and this variant probably arose in a country where strong, hollow reeds were used as arrows. In the games of dexterity we also find bows and arrows, often associated with the netted shield. The snow-snake, or game in which missiles are hurled along snow, ice, or frozen ground, appears to be confined to the northern range of tribes within the limit of ice and snow; the projectiles are apparently

[1] "The Games of the North American Indians." By Stewart Culin. Twenty-fourth Annual Report of the Bureau of American Ethnology, 1902–3. Pp. xl+846. (Washington: Government Printing Office, 1907.)

derived from clubs, bows or arrows, and may be referred to the weapons of the twin War Gods.

The opposing players are frequently the representatives of the two War Gods, and gaming implements are among the objects sacrificed upon the altar of the Twins Zuñi. In general, games appear to be played ceremonially, as pleasing to the gods, with the object of securing fertility, causing rain, giving and prolonging life, expelling demons, or curing sickness. There is no direct evidence of the employment of games in divination, apart from an observation by Cushing.

The game of hoop and pole, like the dice game, was played throughout the entire continent north of Mexico. It consists essentially in throwing a spear or shooting an arrow at a hoop or ring, the counts being determined by the way in which the darts fall with reference to the target. The game is remarkable for the wide diversity in the form of the implements employed, as well as in the method of play. A common and most widely distributed form of the hoop is twined with a network resembling a spider's web, the counts being determined by the particular holes which are penetrated by the darts. The author regards the plain hoop as a modification of the netted hoop, which represents the net shield of the twin War Gods. This object, which the Twins derived from the Spider Woman, is a feminine symbol, and may be used as an amulet. The dart or arrows are masculine. Dr. G. A. Dorsey, who has studied the symbolism of the ring employed in the Sun dance of the Arapaho, says it is symbolic of the creation of the world, for it represents the sun, earth, sky, water, and wind. Although Mr. Culin states "there is no record of women participating" in this game, it is played, as he himself notes, by Hopi maidens as a part of the prolonged Oraibi Oáqöl ceremonies (H. R. Voth, Field Columbian Museum, Anth. Series, vi. [1903], p. 42). Though this cult is largely concerned with producing rain, it seems to be essentially a germination ceremony, and probably has reference to the maturation of the maidens. Mr. Culin adduces other evidence in support of a fertility significance for this game, but he does not make any special allusion to it. Amongst some tribes the game is mythologically connected with the increase of buffalo; indeed, the Cheyenne and other Plains Indians call it the "buffalo game." The game had a religious character among the Apache, and probably this held good everywhere.

FIG. 2.—Altar of War God, Zuñi, New Mexico, with corn-cob darts used in the ring (or hoop) game. From a photograph of the reproduction in the United States National Museum.

Probably connected with the foregoing is the widely spread game played by one person which consists of catching a ring, perforated object, or a ball on a peg. Dr. G. A. Dorsey says the Klamath always play it in winter; it is called "splitting or punching out the moon," and in this way the winter months are shortened and the advent of spring is hastened.

Ball games are well developed in North America, and Mr. Culin deals with them as fully as possible. The game of cat's cradle receives some attention, and various figures are illustrated, but as no instructions are given as to how they are made, much of the information is of little value. Mrs. Jayne's remarkable book on the subject is not referred to, neither is the magical aspect of the game among certain Eskimo as recorded by Boas on the authority of Captain Comer. The holy spiders taught the game to the Navaho, but calamity would befal if it were played at any other time than winter. The Zuñi explain cat's cradle as the netted shield of the War Gods, the game having been taught to them when little boys by the Spider Woman for their amusement. Owing to the ubiquitous nature of this pastime, it is evident that the Zuñi explanation of its origin is purely secondary, and was invented to bring it into their mythological system. We may suspect that the same may have happened for the hoop and pole game, in spite of Mr. Culin's belief that the oldest forms of existing games occur in the south-western United States. Lack of space precludes due mention of the numerous minor amusements described by the author, though they are of considerable interest.

In introducing the memoir, Prof. W. H. Holmes, Chief of the Bureau, states that "the paper practically creates the science of games, and for the first time gives this branch its proper place in the science of man." This eulogy is somewhat exaggerated, as others on this side of the Atlantic have directed attention to the ethnological value of the study of games, and while Mr. Culin has produced a memorable monograph of lasting value, he can hardly be said to have introduced therein any general principles that had not previously been enunciated.

A. C. HADDON.

NERVE AS A MASTER OF MUSCLE.[1]

WE have on the table before us two muscles. The animal was dead when they were taken from it a short while ago. But the animal was, as we are ourselves, an assemblage of organs, and many of these organs go on living for a certain time after the animal, as an animal, is dead. Hence these muscles, carefully removed, are still alive. We notice a marked difference between their behaviour now. To understand the behaviour of organisms we have to think of them as processes rather than as structures. An animal is something happening. The function of muscles is to contract. Of the two muscles now before us, one still goes on contracting, although quite isolated from the body of which it formed a part; but the other does not contract, although that is its function in the body. The muscle which still goes on contracting is the heart; the other is a muscle like the biceps of our own arm. We might think that, as it rests there motionless, it is not alive. It is, however, fully alive. We can satisfy ourselves of that. If I apply to it a faint electric current, it answers by exhibiting its functional activity—it contracts. Yet it does not contract of itself, nor will it, however long we may preserve it; it will die without of itself even contracting once. What is the significance of this difference between the two?

The secret of this difference is largely an affair of the nervous system. The tie between muscular activity and nervous activity is always close; but it is very different in

[1] A discourse delivered at the Royal Institution by Prof. C. S. Sherrington, F.R.S.

different muscles. The nervous system has been called, with a picturesque truth, the master-system of the body. It controls the action of organs; it controls, quite especially, the activity of the muscles. This heart which we see beating here receives nerves. One of those nerves when stimulated will cause it to contract less, the other to contract more. The contraction of the heart is its "beat." The vagus nerve slows the beating, the other nerve quickens the beating.

The heart is a tubular muscle; it drives blood through itself. When it contracts it squeezes the blood from it into the arteries, and so the blood flows to feed all the myriads of minute lives—cells—composing the whole complex living animal. The lives of these myriad minute entities all depend on their supply of blood, and therefore the life of the whole creature depends on the contraction of the heart. At each beat the heart by squeezing the blood out of its arterial end maintains the flow of blood, and this flow resulting from its own contraction refills it, because the blood returns to it by the veins.

This beating is all which the heart has to do. Whatever happens it must continue to do this, or the creature perishes. Life-long, night and day, winter and summer, it must do this. Whatever act the creature may be accomplishing, sitting, walking, feeding, sleeping, catching its prey, or escaping its enemies, this beating must go on, in the frog about ten times a minute, in ourselves about seventy times a minute. The task is monotony itself. How admirably is the heart muscle adapted to fulfil it!

Self-adjustment to meet the environmental conditions differentiates animate from inanimate nature. As characteristic as this self-adjustment itself is its constant trend toward what has sometimes been termed "purpose." Animate objects are observed to adjust themselves to their own advantage, that is, so as to prolong their individual existence or that of their species. The more we know of them the more complete appears to us this trend in their reactions. The living organism advantageously adapts itself to its surroundings; and every part of a living organism exhibits this power. The heart-muscle reveals it clearly. It must not tire, and in normal circumstances the healthy heart, unlike other muscles, shows no fatigue. Its beat must always be strong enough to press its contents over into the artery against considerable resistance which opposes it. A heart-beat which did not expel the blood would be useless, worse than useless, wasteful, because it would be energy spent in vain. Its task can be roughly likened to that of a man with a bucket who has to keep lifting water from a tank at his feet to pour it over a wall of certain height before him. If he lift the bucket much above the wall he expends more energy than he need do; if he lift it less than the wall's height his work fails altogether. If he still, when the bucket is emptied, keep it above the wall's height, his work stops, although his effort does not.

The heart, whether its stimulus be weak or strong, beats always with sufficient power; it thus avoids the useless labour of a beat too weak to fulfil the office of a beat. If the heart were to give too prolonged contraction it would defeat its own purpose; after its beat, which empties it of blood, it must relax to refill for the next beat; to keep contracted would be for its purpose as harmful as to cease from beating; it would stop the blood instead of pumping it onward. In harmony with this, we find a prolonged stimulus to the heart does not keep the heart contracted; after the heart has replied to the stimulus by a beat it exhibits a refractory phase, during which it pays no attention to the further stimulation, and relaxes; and only after it has fully relaxed does it again pay attention to the stimulus and contract, that is to say, beat again. In short, it replies rhythmically to a continued stimulus which would keep the other muscle continuously contracted.

That the heart should go on beating after removal from the body does not seem greatly surprising, because it is still then alive. The wonder lies rather in its continuing to live so long when thus removed; that granted, it seems natural that it should do what it has done previously all its life.

But this other muscle, which likewise continues to live when removed from the body; it, though it *can* contract, does not. That seems—at least at first sight—the more remarkable. Why does this muscle stop? So long as it was part of the living creature it showed contraction over and over again. We must turn to the nervous system for our answer.

In the first place let us note that an animal, unlike that other great example of life, a plant, cannot nourish itself from naked earth and air alone. The plant strikes down roots and throws up leaves, and draws through these material and energy with which it can replenish its own substance and activities. Where it as a seed fell, there its foster-moster Earth gives it the food it wants. Not so the animal. It must have subtler and rarer stuffs, or die. The material it needs is not spread so broadcast. It, to replenish itself, must have more special material; it must have for food material that is living, or has lived. To obtain this it has to range about. It has to hunt for it; and it itself is hunted by other animals following the same quest. Therefore its very existence involves locomotion. It must find food and seize it, and must itself escape being found and seized. It is both hunter and hunted. Moreover, in a vast number of cases it has to seek its kind to propagate its species. The movement necessary in this great game of life is million-sided—subtle beyond words—and most animal lives are spent in nothing else. Existence for the individual and the race depends upon success in it. Man plays it also—let us hope that sometimes he plays something else as well. In all cases the chief instruments of the game are the skeletal muscles, those muscles of which the biceps of our arm may stand as type. An old philosophic adage has it that all which mankind can effect is to move things. The dictum illustrates how supremely chief an executant of man's activity his muscles are. All the things which man can move are moved in the first instance by that prime thing which he can move, his body; and for this his main agents are his skeletal muscles. These execute his movements, but in doing so are but the instruments of his nervous system. Therefore it is in reality the nervous system which is the player of the game; and it is because it is really the nervous system which is the player of the game that man is the most successful creature on earth's surface at the present epoch, for his is the nervous system which, on the whole, is the most developed, much best adapted to dominate the environment.

To understand a little how the nervous system compasses this end we may turn to examine its performance in some of its simpler governing of the muscles. Its main office is to react to changes in the environment. The animal body is provided with a number of organs specially attuned to react to changes in the environment. These changes, in so far as they excite these organs, are termed stimuli. Thus, it has organs stimulated by the radiant energy of light and heat, others by chemical particles drifting from odorous objects, others mechanically by objects touching the skin, and so on. These organs, specially adapted to environmental stimuli, are called *receptors*. Attached to them are nerves. Through these the excitement set up in the receptor by a stimulus spreads to the general nervous system. Arrived there, two kinds of effect ensue from it—one, a change in nerve-cells innervating muscles and glands, the other, a change in consciousness on the basis of sensation. These two effects are separable. The former, or "reflex" reaction, is not necessarily accompanied by any manifestation of the latter, though it may be so, and very often is so. We will confine ourselves to the former, or purely reflex effect, and to its operation on muscle.

The endowment with receptor organs is not equally rich in all parts of the body. It is the external surface of the animal which, as we might expect, has them in richest profusion; and the receptors of the external surface are likewise those most developed, specialised, and sensitive. This also we might expect; for it is the external surface that for countless ages has felt the influences of the illimitable outside world playing on it. Through refinement of the receptors of its outer surface the animal has been rendered sensitive in many cases to stimuli delivered even by the remotest stars.

It is a feature of receptors generally that they react most to their agent when the intensity of that agent changes, and the more so the more abrupt the change. It is, therefore, changes in the outside world that operate especially as stimuli, though, of course, only changes which have relation to the animal in question. If we regard the mutual relation between the animal and the world at any moment as an equilibrium, then we can say that any change in the world which changes that relation disturbs the equilibrium.

Take the instance of a child asleep. A thousand agencies of the external world are playing upon it. Upon its skin, for instance, there is the pressure of the child's own weight against the receptors, and there is the pressure of the clothes which cover it; yet it lies restful. Suppose we touch its foot. That is a change in the external world in relation to the child. The familiar fact is that the foot is drawn up out of harm's way, as it were. The change has acted upon the child as a stimulus to some receptors of the skin. It may be quite unconscious of the touch, for its sleep may be deep. Yet the reflex action has occurred, and has done the appropriate thing. A candle may be brought into the room and its light reach the face of the child. That is a change in the outside world in relation to the child. The familiar fact is that the child's head turns from the light. It *sees* no light, but reflex action averts its face. Or, turning to other forms of life, take a fish quiet in its aquarium. A worm is dropped into the water, and the disturbance of the water reaches the surface of the fish. The fish turns and seizes the morsel. Such a reaction on the part of such a creature is probably wholly reflex.

The point for us here is, that the changes in the outside world which act as stimuli bring about appropriate re-adjustments of the body to the external world, and that in doing so the instruments of readjustment are the skeletal muscles, worked by the nervous system. The child's heart goes on beating, whether the child's foot lies quiet or is moved, whether its face lies this way or lies that; the fish's heart whether the animal's skin was stimulated by fresh commotion in the water, or was not. But with the skeletal muscles it was different. Flexor muscles of the leg, that were relaxed, are by the touch to the foot thrown into action; muscles which lay relaxed were, when the light came, caused to contract, turning the head away. Muscles of the fish that were inactive were thrown into activity by the new commotion in the water. It is these skeletal muscles, therefore, that the daily thousand changes of the external world so repeatedly and constantly affect in this way or that, and in reflex action it is always the receptors and the nervous system which impel them to react; and the result is to re-adjust advantageously to the animal its relation to the altering external world. Hence these muscles are called the muscles of *external relation*. So prominent are these muscles in the everyday work of life that they are *the* muscles of ordinary parlance. The man in the street is hardly aware that he has in his body any other muscles. These muscles are, through the nervous system, driven by the external world. The world outside drives them by acting on the receptors. It is not surprising, therefore, that this little muscle, removed from the body, and therefore separated from the nervous system and all its receptors, remains, although still living and able to contract, as functionally inactive—for contraction is its function, and it does not contract—as if it were already dead.

Now this muscle, when in the body, was the servant of a thousand masters. It had to contribute to a thousand acts. In a certain sense, it, like the heart, had to do for them all but one thing, inasmuch as it had to pull the limb in one certain direction; and yet its task is a very varied one. It has to pull the limb sometimes far, sometimes very slightly, or through all intermediate grades. It has to pull it strongly against great resistance, or weakly, and with all intermediate grades of intensity. We may suppose that in the course of evolution it had become adapted to this scope of purpose.

And indeed we find it so. Unlike the heart muscle, this muscle when a strong stimulus is applied contracts strongly, when a weak stimulus, weakly; under a long stimulus it contracts long, under a brief, briefly. The nervous system, in making use of this muscle, wants of it just such varied action as this—now weak, now strong, now brief, now long, as may be suited to the act required. The little organ is admirably adapted to be the animal's instrument in the world in which it is placed. This muscle has its place in the economy of nature, and into it it fits as a key into the lock for which it has been made. Man's naïve view, until somewhat recently, was that the earth and the universe were made to fit him. Was the universe made to suit this little muscle or was this little muscle made to suit the universe? The problem concerning this muscle and that concerning man are, in so far, the same. Surely our answer is that the muscle and the rest of the universe fit each other because they have grown up together—because they are part of one great whole; they fit just as a lock and key fit because they compose one thing, and it is pointless to ask whether the lock was made to fit the key or the key the lock.

The office of the nervous system is to coordinate the activities of the various organs of the body, so that by harmonious arrangement the power and delicacy of the animal's mechanism may be obtained to the full. When reflex action withdraws the foot of a sleeping child, it is not merely one such muscle as this which moves the limb, but many. The limb has many muscles, and even in such a simple act many and many of them are employed.

That the act occurs during sleep shows that consciousness is not its necessary adjunct. A similar act can be similarly evoked in an animal when the brain—the seat of consciousness—has been removed. The brain can be removed under deep narcosis of chloroform without any pain or feeling whatsoever. After that removal the animal is no longer a sentient or conscious thing at all. Then we can study in it the power of reflex action sundered from conscient and sentient life altogether. Then it is that opportunity is given for further reverent analysis of those wonderful and subtle workings of the nervous system which in ourselves are so difficult to unravel for the very reason that their working goes on without appeal to, and often beyond access of, the conscious self.

When analysing the muscular action of even so simple a reflex act as that of drawing up the foot, a fact which early meets the observer is that the nervous system treats whole *groups* of muscles as single mechanisms. In lifting the limb it employs together muscles, not only of one joint of the limb, but of all the joints—knee, hip, ankle, &c. It deals with all these muscles as if they were but one single machine. If the movement is forcible, it throws them all into strong contraction; if weak, into weak. In the grading of the reflex action its influence is graded in all these muscles alike. So also the contraction in all of them is timed to begin together, to culminate together, and to desist together. Further, although the movement of this lifting of the limb is mainly flexion at its joints, the reflex accomplishes along with that some internal rotation of the hip and some abduction of the thigh. Why it should do so we shall see presently. Suffice us for the present that, besides the flexor muscles, the nervous system brings into play, at the same time and harmoniously with those, two other great groups of muscles, the internal rotators and the abductors. So perfect is its skill in using the muscles as its instruments that it can deal harmoniously and simultaneously with all these individually complex groups of motor organs as though they were but one.

Were we to attempt to produce this movement in the limb experimentally without employing its nervous system, we should have to apply I know not how many stimuli simultaneously to more than half the muscles of the limb. Not only that, but we should have to grade the stimulation of each of these most accurately to a particular strength. We should also have to arrange that, not only did each stimulus develop its full strength with the right speed, but that each should maintain it for the appropriate time and desist at the right speed and moment, and with proportioned intensity. Moreover, in the real reflex act the contraction of this or that muscle is now stressed, now subdued, with a delicacy and accuracy baffling all experimental imitation. The coordination in even the simple reflex we are considering may be likened to that exhibited by a vast assemblage of instruments in very perfect orchestration directed by a supremely capable conductor.

But it is more subtle and delicate than that, even in the simple reflex we are considering. The coordination goes much farther than we have yet assumed. The musculature of the limb is an instance of that kind of musculature which obtains where parts are adapted to move, not in one direction only or one way only, but in many. The limb has to do many different things. It has, according to circumstances, to bend or to straighten, to turn inwards at one time, at another to turn outwards, to move this finger or move that. Its musculature is therefore split up into many different muscles—some doing this, some doing that. Hence it comes that in the limb are muscles which when they contract do with the limb exactly opposite things. Thus we find a set of muscles which bend the knee, and another which straighten the knee; so, similarly, at hip and ankle, at elbow, shoulder, and wrist. These muscles of opposed action are called antagonists. Now in the flexion reflex—the reflex we are considering—when the reflex bends the knee by causing the flexor muscles to contract, what happens with regard to the muscles which straighten the knee? Do the opponents, the muscles which straighten the knee, contract, or does the reflex nervous influence leave these muscles untouched? It used to be taught that the muscles which straighten the knee, the extensor muscles, contract, and by their contraction exert a moderating influence on the muscles which execute the flexion. That was the anatomical speculation deduced from simple dissection of the musculature of the dead limb. Experiment with the living limb teaches that nature does not expend her muscular energy in using the power of one muscle simply to curb the power of another. When the knee is bent the reflex act does not hamper the working of the flexor muscles by causing a contraction of the extensors also. Nor does it simply leave the extensors out of account. No; it causes them to relax and lengthen at the same time as it causes the flexor muscles to contract and shorten. This it does by reflex *inhibition*; and it proportions the grade of this relaxation exactly to the grade of contraction of the opponent muscles.

The inhibition acts, not on the muscle directly, but on the motor nerve-cells innervating the muscle. These nerve-cells are long filaments; one end of each lies in the muscle, the other in the spinal cord. The reflex inhibition is exercised upon them at the end which lies in the spinal cord. In the reflex we are considering, the reflex action, besides *exciting* the motor nerve-cells of the three muscle groups—flexors, abductors, and internal rotators—before mentioned, *inhibits* the motor nerve-cells of three muscle groups antagonistic to those, namely, the extensors, the abductors, and external rotators. We see, therefore, that in even the simple reflex lifting of the foot, almost every one of the many muscles composing the whole musculature of the limb receives from the nervous system a controlling influence, either of excitation to contract or of inhibition which relaxes contraction; and all this in result of a simple touch of the skin of the foot. The reaction typifies in a simple manner the action of the nervous system to knit the heterogeneous powers of the body together into one harmonious whole.

Thus we see that in these actions when one group of muscles contracts the group antagonistic to it relaxes. This is a fundamental part of the coordination of the act, and its discovery throws a welcome light on the nature of certain maladies. Were the antagonistic group to contract at the same time as the protagonist, the desired movement would not result. The movement which then ensued would depend on which of the two muscle groups were the stronger, the protagonist or the antagonist. The alkaloid strychnine and the poison produced by the bacilli which cause the malady called "lock-jaw" possess the power of destroying reflex inhibition. What the intricate nature of the process of this inhibition is we do not yet know, but it seems to be the exact converse of the process of excitation, the nature of which is also unknown. Strychnine and tetanus-toxin change the process of inhibition into its converse, namely, excitation. If a minute dose of strychnine be administered, the reflex which, as we saw, causes the limb to bend, now causes the limb to straighten instead. This is because the extensors, when the flexors contract, instead of being relaxed by inhibition, are excited to contraction, and being more powerful than the flexors move the limb in exactly the opposite direction to that in which it should move in this reflex action. Similarly with the toxin of "lock-jaw." The muscles which close the jaws are much more powerful than those which open them. In the normal act of opening the mouth the relatively feeble opening muscles contract, and the powerful closing muscles are simultaneously relaxed by reflex inhibition. But in an animal or man poisoned with this toxin the normal inhibition of the closing muscles is changed to the exactly opposite process of excitation, so that their contraction results. Against the power of these strong closing muscles the contraction of the weak opening muscles can effect little. Each time, therefore, that the sufferer tries to open his jaws to take food or speak, he clenches his jaws instead of opening them—experiencing a torture which, although unaccompanied by physical pain, is inexpressibly distressing; and the disorder leads to death from inanition.

But to return to the reflex lifting of the leg, whence we set out. It was mentioned that in this reflex the limb was not merely lifted, but was slightly rotated inwards at the hip, and that the thigh was slightly abducted, that is to say, drawn sideways, separating it more from the fellow-limb of the opposite. These accessory movements have a significance coinciding with much other evidence into which we have not time to enter now. They, together with other evidence, show that this lifting of the leg, so easily produced reflexly, is nothing more nor less than the first movement of the taking of a step. In fact, in our rough and imperfect analysis of this little movement, we have been examining part of the great and extraordinarily complex and perfect act which is called walking—or more technically, so as to include the cognate acts of trotting and running—locomotion. A little reflection will suffice to assure you that included in the action of locomotion is also that of standing. We are apt to forget that the muscles have a static as well as a kinetic action—that they are the instruments of maintaining position, as well as of the execution of movements. Directly we begin to analyse locomotion we see that its basis, as it were, is the position of standing, upon which movements of stepping are, as it were, grafted. Not much is known as yet of how animals and ourselves stand, walk, and run. In these acts, probably, every skeletal muscle in the whole body is concerned. Rheumatism can make us aware of that. A little receptor organ in the ear is a great factor in the whole matter. But of this we may be sure, that foremost in its factors are reflex actions of the limbs. Great economic questions are involved in this unravelling of the act of locomotion—all beasts of draught and burden are chiefly useful to us because they can stand, and walk, and run. We can only employ their powers to full advantage and with due regard to them as they unfold these powers when we shall have learnt something of the way in which these movements are conducted and performed.

The crude and imperfect analysis which I have attempted to outline concerned but *one phase* of the step of a *single* limb. In the complete act the other limbs will at the same time be executing other phases of the whole cyclic reflex. The neck and trunk are also involved; so, likewise, the head itself. Our imperfect analysis threw sidelights on the nature of the mischief wrought by strychnine-poisoning and the malady "lock-jaw." Interesting and useful though these sidelights may be, more really interesting and valuable would be any light which such analysis, crude as it is, could throw on that great normal process of every-day health, animal (including human) locomotion. Analysis of the reflex movement in unconscious animals seems at the present time the only way by which such knowledge can be gained.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—Lord Rayleigh was on April 10 unanimously elected Chancellor of the University in succession to the late Duke of Devonshire. It is expected that the inauguration and the installation of the new Chancellor will take place during the May term.

Edinburgh.—At the spring graduation ceremony on April 10, the honorary degree of Doctor of Laws was conferred upon several guests in recognition of scientific work. Sir Ludovic Grant, dean of the faculty of law, in presenting these recipients of the degree, made the following references to their achievements in the field of science:—

Dr. J. O. Affleck.—Whether regard be had to Dr. Affleck's work as a teacher, or to his scientific contributions to medical literature, or to his eminence as a physician and his services in the practice of his profession, he is equally deserving of recognition at the hands of his old Alma Mater. Almost from the time that he graduated, Dr. Affleck has been an indefatigable writer. Indeed, the great bulk of the medical articles in the ninth edition of the "Encyclopædia Britannica" are from his pen. These, and his other papers, form together a veritable storehouse of scientific information.

Dr. Richard Caton, Lord Mayor of Liverpool.—Dr. Caton was one of the band of devoted labourers whose strenuous exertions were instrumental in calling into existence the University of Liverpool, and he himself discharged the duties of professor of physiology for many years with conspicuous success. With his scientific attainments Dr. Caton combines the accomplishments of the scholar and the zest of the archæologist. His lectures—embodying the fruits of visits to Greece and the Greek colonies—on the Greek and Egyptian gods of medicine throw a flood of light on the medical and sanitary aspects of the ancient world.

Sir Norman Lockyer, K.C.B., F.R.S.—The fairy-book of science contains no more fascinating and marvellous pages than those contributed by the illustrious astronomer whose name has been so long a household word amongst us. It is to his spectroscopic researches that the present generation is largely indebted for its knowledge of the material constituents of the sun and of the stars. He it is who, simultaneously with the French astronomer Janssen, devised a means of studying the luminous atmosphere surrounding the sun, and those gigantic flames which previously could only be observed in the brief moments of a solar eclipse. He it is who first detected helium in the sun before this element had been discovered on the earth, while his investigations into the sun's spots and corona are of the highest importance in solar physics. It is worthy of mention that he has acted as the leader of more eclipse expeditions than any contemporary astronomer. The stars, too, have yielded to him their secrets not less obediently than the sun. By means of the comparative study of stellar spectra, he has drawn up a classification of the celestial bodies according to their temperatures and the order of their evolution, which must be reckoned as not the least noteworthy of the achievements of modern science. The great subject of "orientation" has also engaged Sir Norman Lockyer's attention. He has examined the monuments at Stonehenge and elsewhere, in their relation to astronomical phenomena, a work which is of great value as serving to fix the dates of their erection. The cause of scientific education generally has had no more ardent and eloquent advocate than Sir Norman Lockyer, and, as editor of Nature and as founder of the British Science Guild, he has done as much as any man living for the diffusion throughout the country of the scientific spirit. The University is sensible that it is doing honour to itself in adding Sir Norman Lockyer's name to its roll of honorary graduates.

M. E. C. M. Senart, Chevalier de la Légion d'Honneur, Membre de l'Institut, Paris.—The literature of ancient India has been handled in modern Europe by no scholar of more exclusive erudition or more splendid attainments than by M. Senart. He first attracted the attention of the learned world by the publication, some thirty years ago, of his "Essay on the Legend of Buddha." Then followed the volumes on the "Inscriptions of Asoka," and a highly popular and instructive work on the Indian castes. Of his subsequent writings, none better exemplifies the remarkable range and accuracy of his scholarship than his edition of the famous Kharoshthi MS. of the Dhammapada, which was recovered from Central Asia by a French mission, while his monumental translation of the Mahavastu is sufficient by itself to place him in the highest rank of philologists. His long series of publications, viewed as a whole, possess an importance which cannot easily be exaggerated, alike from the point of view of history, of philology, and of archæology. M. Senart's achievements have received honorary recognition throughout the civilised world, and it is gratifying to relate that his influence has been instrumental in raising up in France a distinguished school of Orientalists, who, it may be hoped, will continue to carry on his work.

The degree was also conferred *in absentia* on Ramkrishna Gopal Bhandarkar, C.I.E., lately professor of Oriental languages, Deccan College, Poona. Prof. Bhandarkar is famed as a Sanskritist throughout the length and breadth of British India. His learned labours have extended over many years, and have been productive of a rich and valuable harvest of exegetical editions of Sanskrit works. These are chiefly remarkable in that they exhibit all that is best in the methods of interpretation traditional in India in combination with the critical scholarship of modern times. Prof. Bhandarkar has also devoted himself to the study of history and antiquities. He is the author of an admirable "History of the Deccan" and of numerous archæological essays.

Manchester.—The University kite station at Glossop Moor has now been equipped with a plant for the generation of hydrogen gas for use in work with captive and free balloons. Captain Ley has taken up residence on the moor in order to continue and extend his investigations for the study of the higher air currents by means of free balloons.

In the new Ministry formed by Mr. Asquith in consequence of the retirement of Sir Henry Campbell-Bannerman from the office of Prime Minister, Mr. W. Runciman has succeeded Mr. R. McKenna as President of the Board of Education, and Mr. McKinnon Wood has succeeded Mr. T. Lough as Parliamentary Secretary to the Board.

To the April number of *Science Progress* Prof. H. E. Armstrong contributes a vigorous article on the reform of the medical curriculum, in which he replies to Dr. Wade's remarks on a previous paper dealing with the same subject. The article covers a wide field, and is by no means confined to the question of medical education, as it deals with the broader issue of university education in general. In particular, the position of affairs within the University of London—the opposition existing between the external graduates and the internal schools, which has culminated in the formation of two representative bodies, the Graduates' Union and the Graduates' Association—calls for comment. A strong plea is urged for extending the internal system so as to allow each of the larger colleges to organise its own scheme of education for the final degrees according to the particular work it has to accomplish, without being hampered by external control through examination. Such a scheme is considered as by no means likely to lower the standard of the degree, but to tend in the opposite direction by making the education imparted more real and effective.

Sir William H. Preece, K.C.B., F.R.S., read a paper on technical education in America before the Royal Society of Arts on April 8. Referring to the munificent gifts made by American millionaires to assist educational development in the States, he directed attention to the fact that the distribution of wealth is much a matter of fashion. In 1906, in London alone more than ten millions sterling were bequeathed for various purposes, but of this only 123,778*l.* was allocated to education. The total amount bequeathed over the whole country must have exceeded fifty millions sterling, and of this probably only 1 per cent. was devoted to education. Speaking of American employers of industry, it was pointed out in the paper that they fully recognise the advantage of technical attainments in their employees, they encourage research, they equip their own laboratories, and they support college and university by financial help, and by the gift of machinery. In America, said Sir William Preece towards the close of his remarks, all are working on fixed methodical lines, and gradually a national coordinated system will be evolved which will make the United States the best secularly educated country in the world, and their education policy thoroughly organised.

An interesting comparison of examination statistics in 1906 with those in 1899 is made by Mr. G. F. Daniell in *The School World* for April. Dealing with the results of the matriculation examination of the London University, the article shows that, whereas in 1899, out of 1250 candidates, 842 selected a language and 402 a science "option," 3140 chose a linguistic and 2962 a scientific subject out of a total of 3253 in 1906. In the senior local examinations held by the Cambridge University, the stunted condition of the scientific side shown by the 1899 statistics gives place in 1906 to a more reasonable balance of science and the humanities, and, in the aggregate, the statistics of the junior examination show that science subjects are now receiving fair attention in secondary schools in general. Apparently, however, this cannot be said of the great public schools. Referring to the statistics published by the Oxford and Cambridge Schools' Examination Board, which examines pupils from public and high schools, Mr. Daniell remarks that out of 1027 candidates for the lower certificate of this Board, a total of thirty-four passes in the first class was obtained in the science subjects—of these thirty-four, no fewer than half were in botany, the successful candidates being mostly girls. Among some 2200 candidates for the higher certificate, eighty-three distinctions were obtained in science. It is justly pointed out that "this grudging admission of the claims of experimental science does not satisfy anyone who has realised the importance of educating the nation, especially the upper and middle classes, so that the future may find us not wanting in men of scientific intelligence."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 14, 1907.—"The Thermomagnetic Analysis of Meteoric and Artificial Nickel-iron Alloys." By S. W. J. **Smith**. Communicated by Sir A. W. Rücker, F.R.S.

As the result of purely magnetic researches, the author comes to the conclusion that a typical octahedral meteorite (containing about 7 per cent. Ni and about 93 per cent. Fe, and exhibiting very regular Widmanstätten figures) consists mainly of an alloy of the two constituents containing about $6\frac{1}{2}$ per cent. Ni. This alloy is kamacite. The thin intervening bands of more nickeliferous material (taenite) are shown in the same way to contain about 27 per cent. Ni, but, further, to be a mixture of nickel-richer and nickel-poorer constituents.

The view most commonly accepted hitherto, as the result of many careful chemical analyses, has been that taenite contains at least 36 per cent. Ni. A critical examination of these analyses shows, however, that they are in accord with the more certain conclusion derived from thermomagnetic data.

In the investigation of a problem of this kind chemical methods lead to ambiguous results, because it is impossible to isolate (from a material like meteoric iron) the secondary constituent (taenite) chemically without fear of partial solution. On the other hand, the taenite can be studied *in situ* by means of the change of its magnetic properties with temperature, because these properties vary in a markedly different way from those of the main constituent kamacite. Thus it can be shown that its properties correspond with those of the artificial 27 per cent. alloy, just as those of the kamacite correspond with those of the artificial $6\frac{1}{2}$ per cent. alloy.

The inference from the experiments that taenite is a eutectic mixture (of coarser structure originally than the artificial 27 per cent. alloy, which is proved also to be a mixture) is shown to be in accord with all that is known concerning nickel-iron alloys, and to afford an adequate conception of the way in which the characteristic structure of meteoric iron has arisen.

The behaviour of "irreversible" nickel-iron alloys during changes of temperature is shown also to be closely analogous to the behaviour of the metastable and labile fluid solutions studied by Prof. Miers.

An explanation is given of the important fact that an artificial nickel-iron alloy containing about 27 per cent. Ni is a "magnetic invar," of which the magnetic quality remains practically constant over a range of about 300° C. after the alloy has been cooled to the temperature of liquid air.

Further development of the thermomagnetic method is to be looked for in cases in which chemical and micrographic methods either fail to remove ambiguity or are inapplicable; meanwhile, if the interpretation of the thermomagnetic data considered is held to be established, a good many doubtful points in the relationship between iron and nickel in their alloys have been made clear.

January 23, 1908.—"Dietetics in Tuberculosis: Principles and Economics." By Dr. N. D. **Bardswell** and J. E. **Chapman**. Communicated by Sir T. Clifford Allbutt, K.C.B., F.R.S.

February 13.—"The Decomposition of Ozone by Heat." By Prof. E. P. **Perman** and R. H. **Greaves**. Communicated by Principal E. H. Griffiths, F.R.S.

The rate of decomposition of ozone has been measured under various conditions, with the following results:—

(1) In a glass vessel the reaction is approximately of the second order.

(2) The relation between the rate of decomposition and temperature may be expressed by the formula $\log k = a + bt$.

(3) The rate of decomposition is very largely influenced by the extent of the surface with which the ozone is in contact.

(4) The reaction is of the first order when the ozone is in contact with a porous substance (clay-pipe stems) or some oxides.

(5) Metallic surfaces have but little effect on the decomposition.

(6) Water vapour accelerates the decomposition, and the acceleration is proportional to the amount present.

(7) Nitric oxide greatly accelerates the decomposition.

(8) The rate of decomposition is a linear function of the oxygen pressure. A greater effect is produced by diluting with nitrogen than by simply reducing the pressure of the oxygen.

(9) At 100° the reaction appears to be very slightly reversible.

(10) Finally, the decomposition appears to take place mainly (if not entirely) at the surfaces with which the ozone is in contact, and pressure measurements give no indication of the number of molecules reacting.

Mineralogical Society, March 17.—Prof. H. A. Miers, F.R.S., president, in the chair.—The occurrence of metamorphic minerals in calcareous rocks in the Bodmin and Camelford areas: G. **Barrow** and H. H. **Thomas**. The pneumatolytic action is not contemporaneous with the thermo-metamorphism produced by granite intrusions; the gaseous intrusions are later, and often produce their greatest effect beyond the zone of "contact action." The species of mineral produced depends on the nature of the rock penetrated by the gases. In killas, tourmaline is commonly produced, but in calcareous rocks, axinite and a variety of other minerals result from the pneumatolysis. In the Bodmin area the minerals formed by pneumatolytic action in the calc-flintas are axinite, hedenbergite, epidote, yellow garnet, actinolite, and another amphibole occurring in minute dark-brown needles. In the Camelford area the minerals are mainly due to contact metamorphism. The most conspicuous are yellow garnet, epidote, and idocrase, a mineral which has not hitherto been recorded from Cornwall.—A protractor for use in constructing stereographic and gnomonic projections: A. **Hutchinson**. A short historical account was given of the stereographic projection, and a protractor designed to facilitate its construction was shown. By the aid of this protractor the radii of both great circles and small circles can be readily determined. It can also be applied to the construction of the gnomonic projection, and to measuring the angles between planes and zones.—Supplementary notes on the mineral kaolinite: A. B. **Dick.** Further observations on the optical characters of kaolinite from Anglesea lead to some alterations in the data given in a previous paper. The refractive index is about 1·563 for sodium light, and the optic axial angle, 2V, is about 68° instead of 90°. The double refraction is very low. Kaolinite from limestone at Hambleton Quarry, Bolton Abbey, Yorkshire, and from sandstone near Newcastle-on-Tyne were described.—An attachment to the goniometer for the measurement of complex lamellated crystals: H. L. **Bowman.** The apparatus, consisting of a small screen pierced by a pin-hole, can be attached to a goniometer, and is capable of adjustment so that minute portions of a crystal face can be successively illuminated.—A new form of quartz-wedge, a modification of the Wright-wedge: J. W. **Evans.** A quartz-wedge cut parallel to $\mathfrak{c}$ is placed over a gypsum-plate parallel to $\mathfrak{a}$ showing red of the first order, and extending beyond the thin end of the wedge, so that the projecting portions can be used as an ordinary gypsum-plate. The region where the wedge overlies the gypsum is graduated at the position of exact compensation, and at each thousand micromillimetres of relative retardation. If, when placed over a mineral in the diagonal position, the black band is moved towards the thin end of the wedge, the direction of insertion is that of the vibrations which traverse the mineral with the smaller velocity; if towards the thick end, the direction is that corresponding to the greater velocity.—Calculation of the chance that the double refraction of a crystal section cut at random shall exceed a particular fraction of the maximum: H. **Hilton.** The problem is soluble completely for a uniaxial, and partially for a biaxial, crystal.

Physical Society, March 27.—Dr. Charles Chree, F.R.S., president, in the chair.—Notes on the plug permeameter: Dr. C. V. **Drysdale.** In the instrument a drill is employed to cut a conical hole in a casting or forging, leaving a pin one-tenth inch diameter standing in the middle. A wrought-iron plug carrying a bobbin with magnetising and search coils completes the magnetic circuit, forming a miniature permeameter. Investigations have been made showing that the amount of the end effect can be compensated by correcting the value of H in the same ratio for all specimens. Curves were given showing the results obtained by the plug permeameter when the instrument had been empirically calibrated.—The use of shunts and transformers with alternate current measuring instruments: Dr. C. V. **Drysdale.** The paper deals mathematically and experimentally with errors in the magnitude and phase of the current. With shunts, the condition for accuracy at all frequencies is that the time constants of the instrument and shunt should be equal. For current transformers the best results are obtained by keeping the magnetising and core-loss currents as small as possible.—Dynamometer wattmeters: Dr. C. V. **Drysdale.** An investigation of the theory of the wattmeter, including the effects of shunt inductance and capacity, mutual inductance, eddy currents, wave-form and of iron. It is pointed out that the theory of the wattmeter is much obscured by the use of the correction factor. The correction of a wattmeter should be applied as a difference, and not as a ratio. A description of single and double forms of standard wattmeter and of deflectional wattmeters containing iron was given.

Institution of Mining and Metallurgy, April 9.—Mr. Bedford McNeill, vice-president, in the chair.—The electrical equipment of gold mines: H. J. S. **Heather.** A review of the present application and future possibilities of the application of electric power to mining operations, with practical notes of installations that have been made under the author's supervision. He points out the relative advantages or otherwise of the continuous and alternating current systems for the purposes of gold-mining work.—Addendum to paper on earth temperatures on Witwatersrand gold fields: Hugh F. **Marriott.** A matter dealt with in a previous paper by the same author centred round the mean earth temperatures at the surface in the vicinity of the Rand. This addendum records subsequent investigations tending to settle the point in dispute in connection with the attempt to establish a rule for the average increase of temperature with depth.—The carat weight: E. J. **Vallentine.** A concise account of the origin and present position of the carat weight as used by dealers in gold and precious stones, with records of the steps taken to establish a standard metric carat for universal adoption.—An electromagnet for testing the suitability of an ore for magnetic separation: L. H. L. **Huddart.** A description of a hand apparatus designed by the author for use abroad. It is suitable for the quantitative determination of the separation to be expected in treating a given ore by means of a powerful magnet.—The gold alluvials of the river Drau in Hungary: A. **von Gernet.** A brief account of the subject of the title, with comparisons of the relative efficacy for determining values obtained by panning small samples and counting "colours."

Royal Astronomical Society, April 10.—Mr. H. F. Newall, F.R.S., president, in the chair.—Description of a 24-inch long-focus cœlostat reflector: J. H. **Reynolds.** The instrument has been constructed for use in spectroheliographic work, but is also arranged for taking celestial photographs. The focal length is 38 feet, and the diameter of the plane mirror of the cœlostat 28 inches. Specimens of photographs taken with the instrument were shown on the screen.—Dr. A. W. Roberts's method of determining the absolute dimensions of an Algol variable star: Rev. J. **Stein.** Dr. Roberts had attempted to deduce from the light curve of such a variable the dimensions of the orbits of its components, but Mr. Stein showed that it is theoretically impossible to determine the absolute dimensions of the orbit in this manner.—Note on the newly discovered eighth satellite of Jupiter: **Astronomer Royal.** The moving object near Jupiter, found by Mr. Melotte upon photographs taken at the Royal Observatory, had been again photographed on March 27, 31, and April 3. It had also been photographed by Dr. Max Wolf at Heidelberg and at the Lick Observatory. It now appeared that the new object is a satellite of Jupiter, much more distant from the planet than the sixth or seventh satellites.—First approximation to the orbit of J. VIII.: A. C. D. **Crommelin.** The hypothesis of retrograde motion for the new satellite appeared at present most probable; from the preliminary elements obtained the sidereal period would probably be between three and four years, and the distance from the planet about three times that of Satellite VII.—Variable-star work at Rousdon Observatory: C. **Grover.**—A new "spanner" sextant: Captain **Gadsden.** The arrangement consisted of an attachment to a sextant to enable observations to be made when the horizon is obscured or hazy.—Note on the conditions for the passage of the earth through the plane of Saturn's ring: H. H. **Turner.** The late Mr. Proctor had given a general account of the manner in which the earth may pass through the plane of the ring, either once or three times at each favourable opportunity. The present paper gives the explanation in a more compact and complete form. Retrogradation of the sun's shadow: M. E. J. **Gheury.**—Series of photographs of the Milky Way taken with a small lens of $5\frac{1}{3}$ inches focal length: Dr. Max **Wolf.**—Experiment illustrating the gradually increasing red colour of the sun as it approaches the horizon at sunset: S. L. **Fletcher.**

PARIS.

Academy of Sciences, April 6.—M. H. Becquerel in the chair.—An isomer of diphenylcamphomethane and the conditions of its formation: A. **Haller** and E. **Bauer.** Details are given of the best method of reducing

$$C_8H_{14}\begin{cases} C{=}C(C_6H_5)_2 \\ CO \end{cases}$$

in alkaline solution. The substance obtained, diphenylcamphomethane, is isomeric with the substance obtained by carrying out the reduction in acid solution, and can be obtained from the latter by boiling with alcoholic potash, and in other ways. Various attempts have been made to elucidate the constitutions of these two isomers, but hitherto without success.—A new mineral species from the French Congo: A. **Lacroix.** The new mineral is a silicate of copper, differing from dioptase in being attacked with difficulty by acids, and in its composition,

$$Si_{12}O_{44}Cu_{15}H_{10} \text{ or } 12SiO_2.15CuO,5H_2O.$$

The name plancheite is proposed for the mineral.—The perception of relief and of depth in the simple image of ordinary photographs. Conditions and theory of this perception: A. **Chauveau.** By a suitable adjustment of the prisms of a stereoscope, the effect of relief can be obtained from a single photograph just as well as if the latter were replaced by the usual double stereoscopic photograph. The effect can be produced without any apparatus; the examination with one eye alone of a well-lighted photograph after some time causes the stereoscopic effect. To reduce this to the usual plane effect the other eye is required. The theory of these phenomena is considered in detail.—The acceleration and retardation of the coagulation of the blood in capillary tubes: Ch. **Bouchard.**—The Coal-measures of the southern Oran: H. **Douvillé** and M. **Zeiller.** A detailed description of the fossils met with is given, and the analogy with the Carboniferous deposits in England pointed out. This is the first time that a Westphalian flora has been discovered in such a low latitude.—The subgroups of the homogeneous linear group of four variables, and the systems of partial differential equations which correspond to them: M. **Le Vavasseur.**—The persistent conjugate networks comprising a family of minimum lines: L. **Raffy.**—The maximum useful weight that can be raised by an aëroplane: M. **Girardville.** It is shown that the maximum useful weight carried by an aëroplane depends upon five variables, and possibilities of improvement may be sought for in modifying each of these.—The conditions of utilisation of balloons capable of being steered, as existing at present: M. **Bouttieaux.** An account of modifications introduced with the view of economising ballast.—The spectroscopic study of flame of various kinds: G. A. **Hemsalech** and C. **de Watteville.** The method of feeding a flame with particles of metal obtained electrically, described in an earlier paper, has been applied to flames of hydrogen alone, coal gas and oxygen, hydrogen and air, and hydrogen and oxygen. Details of the results obtained with the pure hydrogen flame are given in the present communication.—The presence of spark lines in the arc spectrum: Ch. **Fabry** and H. **Buisson.** All the spark lines (the enhanced lines of Lockyer) are emitted in the arc spectrum of iron, but only by certain portions of the arc. Similar effects have been obtained with nickel and copper.—A new method of estimating the vapour of mercury in air: P. **Ménière.** The air is aspirated through boiling nitric acid in a special apparatus figured, and the minute proportions of nitrate of mercury treated with diphenylcarbazide. This gives distinctive colours in proportions of mercury varying from 1/100,000 to 1/5,000,000. The paper is accompanied by a plate showing twelve gradations of tint obtainable.—The combustion by incandescence of gases in presence of oxidisable and incombustible bodies: Jean **Meunier.**—The variations of composition of ammonium phosphomolybdate: application to the estimation of phosphorus in iron and steel: G. **Chesneau.** The author regards a double precipitation as absolutely necessary if the precipitate is to have a constant composition, and gives detailed instructions for carrying out the process.—The ammoniacal chlorides of dimercuriammonium: H. **Gaudechon.**—Arbutine and some of its derivatives considered from the point of view of their rotatory power and their hydrolysis by emulsin: Em. **Bourquelot** and H. **Hérissey.**—Comparative study of the dehydration of atrolactic and *p*-methoxyatrolactic acids. *p*-Methoxyatropic and di-*p*-methoxyatropic acids: J. **Bougault.**—The formation of mixtures of isomers of constant melting point in the Friedel and Crafts reaction: G. **Perrier** and H. **Caille.** The product obtained in the preparation of phenylnaphthylketone by the Friedel and Crafts reaction had a definite melting point, which was unchanged after several re-crystallisations. It was shown, however, to consist of a mixture of the α and β isomers. The constitution of the membrane in diatoms: L. **Mangin.**—The action of the hygrometric state in respiratory exchanges: J. **Cluzet.**—The action of the alcoholic extract of normal human urine on the arterial pressure: J. E. **Abelous** and E. **Bardier.**—The possible effects of carbon monoxide in poisoning by tobacco smoke: C. **Fleig.** The conclusion is drawn that the amounts of carbon monoxide given off during the smoking of tobacco can contribute nothing to the effects of tobacco poisoning. A NEW CALCULUS.

A First Course in the Differential and Integral Calculus. By Dr. W. F. Osgood. Pp. xv+423; with 125 figures. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1907.) Price 10s. 6d.

THE introduction of the Calculus at an early stage in a course of elementary mathematics has rendered necessary the substitution of simplified methods of treatment for those occurring in the earlier text-books; for example, an abandonment of the lavish and unnecessary use of infinite series, the convergency of which was generally ill-understood, in the differentiation of simple expressions.

A number of good books have recently appeared written more or less with this object in view, but we have seen none in which the survival of old and clumsy methods has been reduced to the vanishing point in the same way that has been done in this book.

The present reviewer has been in the habit of conducting a class in the calculus on simplified lines identical in nearly every respect with those adopted independently by Prof. Osgood; indeed, this book represents almost word for word what he would have wished to write had he undertaken to write a Calculus. The reviewer is thus greatly indebted to the author for having saved him this troublesome and thankless task, or the alternative of continuing the elaborate lecture notes which he has found necessary to dictate to his pupils on the bookwork of the subject. The following is a brief summary of some of the salient features of the book to which the reviewer attaches especial importance.

The methods of the calculus are discussed and exemplified in the first instance by the study of the differentiation of series of positive integral powers only. The reviewer would prefer to see the binomial theorem omitted from the proof for the derivative of x^n and a proof based on the product rule substituted, but this is a minor detail which any teacher can supply for himself and his class.

The very important method of "differentiating an equation as it stands" is explicitly used as such in finding the tangents to algebraic curves as well as in the differentiation of fractional powers, inverse functions, and the like. The introduction of this subject under the title of "differentiation of an implicit function" is quite unnecessary, and we are glad to see that the perfectly simple method really required for these cases is viewed in its right light.

In the chapter on transcendental functions the author clearly points out that the reason for measuring angles in radians is essentially explained by the calculus, and he also gives the differentiation formulæ for angles measured in degrees. The explanation is necessary in order to dispel any doubts the beginner may have previously formed as to the mental sanity of those mathematicians who deliberately chose an incommensurable unit for the measurement of commensurable angles.

The author's introduction of the incommensurable base e, though only one of a number of different possible methods, is even more satisfactory, no previous knowledge being assumed regarding this base, which is shown to make its existence felt as soon as we attempt to differentiate a power of any constant a with respect to its index, or to differentiate the logarithm of the variable to any assumed base a.

When integration is explained the author does not waste too much time in discussing the methods of integrating long and complicated expressions, but proceeds very soon to the consideration of definite integrals and of geometrical and mechanical illustrations.

"Volumes of revolution" only constitute a particular application of a general method of finding the volume of a solid the sections of which parallel to a fixed plane are circles, squares, triangles, or other simple figures. The examples on pp. 159–161 should make this point clear.

Curvature, evolutes, properties of the cycloid, moments of inertia, and attractions are discussed at an early stage. So also are harmonic motion, resisted motion, and damped oscillations.

When infinite series are introduced the student should be ready for the satisfactory and sufficiently rigorous treatment given, especially in connection with convergence.

In dealing with Taylor's theorem, the remainder is carefully attended to, and specially mentioned in connection with the binomial theorem. We should like to have seen the remainder given as a definite integral, but this can readily be supplied in lecture notes.

Partial differentiation is fully discussed, and we notice among the examples the familiar thermodynamic application

$$\frac{dp}{dv}\frac{dv}{dt}\frac{dt}{dp} = -1.$$

There is a useful chapter on solid geometry which introduces the notion of direction cosines, the orthogonal property of confocal conicoids, and the osculating plane of twisted curves.

Double and triple integrals are well discussed. The artifices so commonly used in the older treatment for calculating volumes and centres of gravity by means of single integrations in particular cases had the disadvantage, from which Prof. Osgood's treatment is exempt, of failing to familiarise the student with notions which he necessarily encounters in the study of electricity and other branches of physics.

Hyperbolic functions are not introduced until the end. In the opinion of the reviewer they have figured far too prominently in previous treatments of the calculus, with the result that the student has been encouraged to waste time in working out integrals in complicated forms involving "sneezes" and "coughs," and "sneeze and cough minus ones," which he cannot interpret. It is to be presumed that the above words represent the most natural equivalent in speaking of the new-fashioned hyperbolic notation, for to say "essaitch" and "secaitch" is too cumbersome. For computation integrals ought to be evaluated, as the author does, in the form of logarithms, as there are few students who, when they have obtained any result involving a "sneeze minus one," could calculate its numerical value.

We must not forget to mention the collections of examples, which are of the type approved by the most enlightened examining boards in Great Britain. They are for the most part based on practical applications, and are of such a character as to test the student's knowledge of the *calculus* itself, not his power of covering sheets of foolscap with uncomprehended formulæ.

To sum up, it had become necessary to introduce considerable changes in the elementary treatment of the calculus, not only in the interests of the students of physics and engineering whose claims have been most prominently put forward, but also for the sounder and more rational instruction of mathematical students. The present book admirably meets the requirements of the case. We do not say that further improvements are impossible, but we consider that a stage has now been reached when any attempt to make the treatment better in one particular is very liable to render it worse in another.

May not an analogy also be suggested between the coincidence of the author's and reviewer's views, and probably the views of other teachers, and the conditions in the calculus for maximum value, as showing that the methods adopted are the best possible, subject to present existing conditions.

PREHISTORIC EUROPE.

L'Europe préhistorique. Principes d'Archéologie préhistorique par Sophus Müller, traduit du danois avec la collaboration de l'auteur par Emmanuel Philipot. Pp. 212. (Paris: J. Lamarre, n.d.) Price 10 francs.

THE prehistoric period in Europe is so extended, the conditions during the period so varied according to place and time, our knowledge of the conditions so meagre and broken, that the task of putting the events of the period into the form of a connected narrative is not to be lightly estimated or easily fulfilled.

Dr. Müller decides at the outset to confine himself to the consideration of matters which have received general acceptance; from this resolution he, however, soon departs, or there would have been little to tell.

The work is not so complete as the title implies; the long and important palæolithic phase is summarily dismissed at the foot of the fifteenth page. The author, moreover, has drawn his facts from one source only—that of archæology; the evidence of craniology and philology is ignored. Nor has all the literature been consulted. In a book which deals so much with the prehistoric age of Greece it is strange to find no mention of Prof. Ridgeway and his work. Despite these defects, however, the book forms an interesting and suggestive study; it displays much thought and judgment.

The general argument, which is simple, can be expressed in a few words; it is that in prehistoric time, as in early historic time, Europe was indebted for her culture to Greece and Asia Minor; that the culture extended from the Ægean as a centre, undergoing more and more change as it neared the periphery. Dr. Müller likens south-east Europe, in its relation to the rest of Europe, to a town in its relation to the surrounding country. Just as the habits and culture of a town slowly spread to the rural districts, where they persist and not infrequently attain a greater development than was known in the town, so did the culture of Greece gradually extend over the whole of Europe. While on this analogy it may be well to refer to another feature—sometimes the country misses a step in the development of culture; for instance, in many districts the lamp has been directly superseded by electricity without the intermediate use of gas; so in the north of Europe the Bronze age followed on the heels of the Neolithic, whereas in the south of Europe a Copper age intervened. It will be seen that to establish his argument the author must prove that the different phases of culture appeared earlier in the south than in the north. The higher development of any phase in the north is not against the general trend of his argument. The evidence upon which he grounds his theory is obtained from art objects, polished stone weapons, articles of bronze and copper, pottery, particularly that exhibiting decorative designs, grain, domesticated animals, and the architecture of the graves.

As is well known, culture alone can prove a very misleading guide in correlating people, for where the same environment obtains, there will a similar culture tend to develop. The evidence which is at times admitted cannot be allowed to pass unchallenged. It is gravely argued, for instance, that a correlation existed between the people who lived in Spain and the Pyrenees during the Solutré period and the Iron-age inhabitants of Greece, since statuettes of similar form are forthcoming from both regions. No account is taken of the great difference in the age of the statuettes, a difference to be expressed in thousands of years.

To choose another illustration, the author finds that the polished stone celts are bigger and more numerous in the north than in the south, due to the Stone age enduring longer and attaining a higher development in the north. Moreover, in the north the stone celts are of flint, whereas in the south they are of nephrite, jadeite and chloromelanite, stones rare in Europe but more common in Asia. He thereupon argues that when Man began to polish his stone tools he would use such a soft stone as nephrite or jadeite, and would not begin to polish a stone so hard as flint until the art of polishing had made considerable advance. He therefore concludes that the nephrite celts are earlier than those of flint, and that the art of polishing extended from the south to the north. It may, however, well have been that it was the distribution of the various stones which governed the material of which the celts were made.

He takes again the spiral *motif*—in mid-Europe he finds it on pottery, in north Europe on bronze sword-handles. In each case the *motif* is decorative, and so is found on the most highly prized objects. In mid-Europe pottery, so he argues, was the most valued article, bronze not yet being known when the *motif* arrived. By the time the *motif* reached the north, the Bronze age had begun.

These arguments are more ingenious than weighty; they derive their importance from the fact that they all—or nearly all—support the contention that the culture of Europe came from the south.

Dr. Müller sees no evidence of any hiatus in man's occupation of Europe. He places the end of the Palæolithic period at a date 10,000 years ago. He accepts Piette's mesolithic phase and Pigorini's conclusion that in Italy the Moustier period passed without interruption into the Neolithic.

He discusses at considerable length the various late prehistoric periods, the Mycenæan, Dipylon, Villanova, Halstatt and la Tène. The book possesses 161 illustrations and three coloured plates; it is well printed and well planned. Its chief defect is that it is not in some respects quite up-to-date.

William Wright.

CHEMICAL RESEARCH.

Untersuchungen in der Puringruppe (1882–1906.) By Emil Fischer. Pp. viii+608. (Berlin: Julius Springer, 1907.) Price 15 marks.

Organic chemistry during the last twenty years has progressed with such marvellous rapidity that it is quite impossible for the modern chemist to keep in touch with every phase of the present-day movement. The old subdivision of the investigator into the classes inorganic and organic is no longer sufficient to indicate clearly the course followed by any individual worker. Every branch of chemistry is split up into innumerable microscopic divisions, each of which claims its own adherents. Further than this, the botanist, the biologist, and others are encroaching on the domain of pure chemistry, and demand a knowledge of the compounds related to their own particular science. Bearing these facts in mind, it follows as a natural consequence that such books as the present one find so welcome a position in the standard literature of chemistry.

The present volume contains the entire experiments of E. Fischer and his students for the last twenty-four years, and deals entirely with the purine group, including the brilliant syntheses of uric acid, xanthine, caffein, and allied compounds. The introduction, comprising the first eighty pages, appeared in the German literature in 1899 under the title of "Synthesen in der Puringruppe," and is well known to all students of chemistry. At this time the systematic study of the purine group had reached a definite issue, and since then no new principle has been evolved. The later work has been devoted to details, with perhaps the exception of one paper, which treats of the isomerism of methyl uric acids. The contents of this first chapter is almost complete, and gives a full survey of the subject as it is known to-day. Following this is the second part of the book, which contains the forty-seven publications of the author and his students. The first forty contain the work previous to 1899, while the remaining seven have been published subsequent to the compilation of the introduction. These papers contain the complete experimental data of the originals, and are given in the order of publication. It is quite impossible to read this book without marvelling at the wonderful fertility of the brain of this modern genius. No problem seems to be too great for his inventive faculty. Even the incomplete work of Baeyer receives new life in his hands. It is not with the purine derivatives only that one associates the name of E. Fischer, but many other groups have been added to the list.

It will be remembered that the author published his book on the amido-acids and proteins about a year ago. The success of this volume is the direct cause of the present one, which was written with the same object as the former. The literature on the subject is contained in various journals, and these are not always accessible to students of science. The demands of modern science, on the other hand are such that it is of vital importance to be able to acquire a detailed knowledge of many highly specialised subjects without any great inconvenience. The literature of the biologist, for example, is already voluminous enough to require his whole attention without having to keep in touch with chemical developments. For such students this book was originally intended, and these will undoubtedly feel grateful to the author. These, however, are not the only men of science who owe gratitude to E. Fischer. Every modern chemist should read this book, not only for the individual results, but to gain a better knowledge of the wonderful methods of manipulation employed. These are of general importance. Throughout, the well-worn track of modern methods is employed, but, as a rule, small alterations —vital to success—are made. It is here that the special genius of the author is seen at its best, for which the whole of the scientific world must express its thanks.

OUR BOOK SHELF.

Iron and Steel. By J. H. Stansbie. Pp. xiii+375. (London: Archibald Constable and Co., Ltd., 1907.) Price 6s. net.

During the last few years so many elementary books on iron and steel have been published that it would almost appear that an addition to the long list was unnecessary. Mr. Stansbie's book is, however, an excellent one. Written from the notes of his lectures to students of the Birmingham Municipal Technical School, it gives as comprehensive a view as its limits permit of the modern aspects of iron and steel manufacture, together with historical details sufficient to enable the student to follow the march of progress. It is printed in clear type, and the eighty-six illustrations, although they would have been improved by an indication of the scale, are well chosen and well adapted to indicate to students the construction of the furnaces described.

In arrangement of the subject-matter, the work differs but slightly from many of its predecessors. An introductory chapter on chemical principles is followed by chapters on iron ores and fuels, primitive methods of iron and steel production, pig iron and its manufacture, the refining of pig iron in small charges, crucible and weld steel, the Bessemer process, the open-hearth process, mechanical treatment of iron and steel, physical properties of iron and steel, iron and steel under the microscope, heat treatment of iron and steel, electric smelting, and special steels. The information given has been brought up to date by reference to the latest books and to papers read before the Iron and Steel Institute. The book is commendably free from misprints. The names of Brinell and Legénisel are, however, wrongly spelt; and there appears to be some inaccuracy in the statement that an American blast furnace producing 800 tons of Bessemer pig iron in twenty-four hours would yield 1200 tons of slag during that period. The author probably intended to have said that the furnace would yield 1200 lb. of slag per ton of pig iron made.

L'Énergétique et le Méchanisme au Point de Vue des Conditions de la Connaissance. By Abel Rey. Pp. 187. (Paris: Félix Alcan, 1908.) Price 2.50 francs.

In a former work, recently noticed in these columns, M. Rey analysed contemporary physical theories with the object of showing that, in spite of profound differences of procedure, they all bear witness to a common basis of assured experiential fact. In the present book he considers the two rival points of view under which modern theories are ranged—those of the Newtonian mechanics and of the newer energetics—with the more practical purpose of determining whether either of them possesses intrinsic superiority over the other.

There are two fundamental laws of progress in knowledge—it advances by repeated assimilation of the unknown to the known, and with constantly rhythmic alternation of generalisation and deduction. The progressive interpretation of the physical aspect of nature by the concepts of the traditional mechanics complies with each of these laws, while energetics, which seeks merely a single formula from which the established particulars of experience may be formally deduced, runs counter to both. Thus the former alone can be permanently an efficient instrument of investigation.

This, in brief, is M. Rey's thesis. It need be added only that it is worked out in a very interesting manner, and with a competence that should render his study of equal value to the man of science and the epistemologist. T. P. N.

Abel's Laboratory Handbook of Bacteriology. Translated from the tenth German edition by Dr. M. H. Gordon; with additions by Dr. A. C. Houston, Dr. T. G. Horder, and the Translator. (Oxford Medical Publications.) Pp. xi+224. (London: Henry Frowde, and Hodder and Stoughton, 1907.) Price 5*s.* net.

The fact that Abel's handbook of bacteriology has reached its tenth German edition is sufficient proof that it fulfils a useful purpose, and the appearance of this translation will render it available for British and American laboratories. It is just the book for the laboratory table, giving the practical details which are so often required immediately to hand, and the binding in glazed covers will render it less liable to be soiled. The work of British investigators is adequately noticed, and the section on the examination of water, milk, shell-fish, &c., is contributed by Dr. Houston, a sure guarantee of its trustworthiness. The translation is sometimes a little clumsy, *e.g.* "salad" potatoes (p. 26). The culture of the glanders bacillus on potato is inadequately and incorrectly described, and the proof reading has evidently been carelessly done. Thus NaCL for NaCl, and HCL for HCl occur several times, and the iodine solution used in Nicolle's modification of Gram's method is stated to have the following composition:—1K+2Ki+200 Aq. (for 1I+2KI+200 Aq.). Apart from such small blemishes, the book can be recommended as a most useful laboratory guide. R. T. Hewlett.

Die Bestimmung und Vererbung des Geschlechtes. By Dr. C. Correns. Pp. v+81. (Berlin: Gebrüder Borntraeger, 1907.) Price 1.50 marks.

In this volume, Dr. Correns makes another contribution to the subject that he has studied for many years, of hybrids and their hereditary characters. An attempt is made to throw some light on sex tendency in germ cells, to discover the stage at which the sex-character is determined, and to find out whether sex tendency appears to conform to Mendelian laws, or, in Mendelian phraseology, whether sex may not be a consequence of gametic segregation. The method has been to raise hybrids, using for one or both parents monœcious or diœcious plants. The earlier experiments were made with the monœcious *Bryonia alba* and the diœcious *Bryonia dioica*. When pollen of the former was applied to stigmas of the latter, the resulting plants were female, some few showing traces of monœcism. The converse produced half male hybrids, half female, but most of the latter showed a tendency to monœcism. Sterility of this first generation put a stop to further experiments. A result was also obtained by pollinating the flowers of *Melandrium album* with pollen from *Silene viscosa.* From his interpretation of the results, Dr. Correns concludes that sex determination is a simple inheritance phenomenon conforming to Mendelian laws of segregation; that the females are homozygotes, the males are heterozygotes. This last supposition is, however, opposed to the idea postulated by Castle that no sex characters are homozygous. Apart from the Mendelian argument, the reader will find some suggestive remarks with regard to the inheritance of sexual characters.

Lehrbuch der Physik. By Prof. H. A. Lorentz. Translation from the Dutch by G. Siebert. Second volume. Pp. iv+621. (Leipzig: J. A. Barth, 1907.) Price 10 marks.

This is a translation from the fourth Dutch edition of Prof. Lorentz's text-book. The mastery of the author over the facts of physics is, of course, a guarantee of the excellence of the exposition. The contents of this volume are connected with sound, light, electricity, and magnetism. The treatment is exceedingly simple; if we have any criticism to make it is that most students, even though not taking up physics as one of the principal subjects of their study, would like to learn more than the book offers. In other words, we think that in many places the treatment is unnecessarily meagre. We are sure that the chemist would like to be told more about theories of the voltaic cell. The large amount of work that has been done by physical chemists under the leadership of Ostwald and Nernst is left absolutely unnoticed.

We turn naturally to the chapter at the end on the electron theory. Here, as elsewhere, what there is is excellent; but we feel that we expected more on this subject from Prof. Lorentz. There are so many phenomena known now which are capable of being simply described and used in illustration and support of the modern fluid theory of electricity. This scantiness will probably tell against the book competing with others of a similar grade, in England at any rate.

A collection of 72 examples appears at the end; solutions are not given to these. There are also fifteen useful tables of data.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Condensation of Helium.

In addition to my short note printed in last week's NATURE (p. 559), let me begin by remarking that as recently as last year, in an address to the Dutch Congress of Natural Science and Medicine, I expressed the opinion that it would be scarcely possible to liquefy helium. Olszewski, from his expansion experiments, had deduced that the critical temperature of helium was lower than 2° K. Dewar had no more succeeded in liquefying it by expansion, and some experiences of my own on helium gas sinking in liquid hydrogen seemed to indicate that helium was nearly a perfect gas. At the same meeting I indicated the determination of the isothermals of helium, an investigation with which I was occupied, and which I had prepared by a series of researches, as the direct way to the calculation of the critical temperature.

The first results I obtained with the isothermals changed totally my views on the liquefaction of helium. From the isothermals down to −217°, it followed that the critical point of helium is at nearly 5° K., more in harmony with the estimate of the boiling point at 5° or 6° K. by Dewar, according to the helium absorbed in charcoal, and the determinations at −252° C. and −259° C. confirmed the result. It thence followed that it would be possible, by rapid expansion of helium compressed at 100 atmospheres at the melting point of hydrogen, to pass below the critical temperature, and to cause a mist to appear in the gas. Also liquefaction by the Joule-Kelvin effect seemed possible. It was to put the first conclusion to the test that I made my recent experiments.

The new features of my application of the expansion method to helium were:—(1) the great quantity of gas; (2) the application of a stop-cock on the tube to let off the gas from the tube into a gas-holder, a gas-bag, or a vacuum; (3) an extremely thin-walled beaker, placed in the thick-walled tube to protect the cooled gas against heat conduction. These devices had been used by Olszewski in his experiments on the expansion of hydrogen.

At the expansion a dense cloud appeared, from which solid masses separated out, floating in the gaseous helium, resembling partly cotton-wool, partly also denser masses, as if floating in a syrupy liquid, adhering to the walls and sliding downward, while at the same time vanishing rapidly (20 seconds). There was no trace of melting.

So far as I could judge, then, from my experiments, I considered it probable that this solid substance was helium. The helium had been burned with copper oxide and passed over charcoal at the temperature of boiling hydrogen, and I trusted to have a gas with only very small admixtures. If helium passed immediately to the solid state, then the position of the vapour-line to the adiabatics would be more favourable for condensation than if it passed into the liquid state, and the voluminous aspect of the solid mass was in harmony with this. By the above, and also by other observations, which afterwards gave rise to doubt or proved incorrect, I was for some time under the impression that I had seen solid helium rapidly giving off vapours of the pressure shown by the gas (once more than 15 atmospheres was shown). The continuation of my experiments has shown that they must be explained in quite a different way. By a not sufficiently explained cause, the gas proved to be not so pure as was supposed, considering the method of purification. In analysing what was absorbed by charcoal at the temperature of boiling hydrogen until the charcoal removed no more hydrogen, so that the gas could only contain traces of hydrogen, it could be proved that in one case the gas had contained only 0·45 and in another only 0·37 volume per cent. of hydrogen at most. (About a small possible quantity of neon I could not yet be certain.) But this small admixture must have had a very great influence: for at a first repetition of the experiment with the helium subjected to this new treatment no cloud at all was observed. In this experiment the velocity of expansion had been too small. At a second repetition with the same gas, but with greater velocity of expansion, a thin cloud appeared and vanished extremely rapidly (1 second). The mist now had a different aspect.

The explanation of the previous observation is to be found in solution phenomena of solid hydrogen in gaseous helium. The phenomena which made the impression of being the giving off of vapour had been the solution of deposited solid hydrogen in the gaseous helium, the latter rapidly returning from the lower temperature to that of melting hydrogen, and the pressure increasing in consequence. Helium at the temperatures that come into account here can, according to the theory of mixtures, take up at every temperature a percentage of hydrogen, determined by that temperature in such a way that it is not deposited at any pressure. With acceptable suppositions one can deduce that at temperatures above the melting point of hydrogen this percentage can be considerable, and that at this melting point itself it can be more than 1 per cent. From mixtures with smaller percentage, the hydrogen is only deposited at lower temperatures, *e.g.* by expansion. By the smallness of the quantity of hydrogen present it is also explained that, after prolonged blowing off of the helium, no solid hydrogen was left, for the quantity was so small that it could evaporate in the space which it found at its disposal. It is remarkable that so small a quantity of admixture as the gas contained has been able to give the total phenomenon of a substance condensing to a solid and re-evaporating, though the rapid evaporation is in harmony with the smallness of this quantity of substance, considering that even denser masses were seen to be blown away sometimes. There cannot have been much more than 1 milligram or 15 cubic millimetres of solid hydrogen in round numbers in the tube—probably there was less in it—and yet the tube of nearly 7 cubic centimetres was over its whole length for almost a quarter filled with dense, flaky substance.

So far as the experiments on the expansion of helium are now advanced, they show the curious forms that the solution phenomena of a solid in a gas take in the case of helium and hydrogen. They further point to the possibility of realising with mixtures of hydrogen and helium the rising or falling of the solid substance according to the pressure exerted on the gas, the barotropic phenomenon for a solid and a gas. But the question of condensing helium is to be considered yet as an open one.

Let me add a few words as to the mist observed in the repetition of the expansion experiment with the "coal-pure" gas. It is certain that this gas only contains very small quantities of hydrogen. The spectroscopic test also gives traces only. It is possible that the amount of the traces will prove sufficient to attribute the mist to the traces of hydrogen left in the gas. But it is also possible that the mist has been a liquid cloud, and the changed aspect seemed to point to this. If this might prove to be the case, then the critical point would be nearly what I calculated from the isotherms, and helium would obey tolerably well the laws of van der Waals. The tube broke, and so I could not attain more certainty about the nature of the cloud.

The preceding experiments show very strikingly how careful one has to be in arriving at conclusions from the appearance or non-appearance of a cloud by expansion. A decision about the critical point of helium is therefore only to be obtained by a prolonged systematic investigation, which will take much time.

April 14. H. KAMERLINGH ONNES.

Satellites of Yellow and Green Lines of Mercury.

Being engaged with the investigation of the Zeeman effect by using a 35-plate Echelon spectroscope constructed by Hilger, I made an experimental test of the resolving power of the instrument on the yellow and green lines of mercury. With a lamp of the Aron type (30 volts, 6 amperes), and by eye observation with a micrometer, I found the following satellites, some of which seem to be new. $\delta\lambda$ is given in Ångström units. The measurements by Janicki with an Echelon spectroscope, and by Baeyer with Lummer-Gehrcke plates, are cited for the sake of comparison :—

λ = 5790 (*Yellow line*).

Some of the lines not observed by Janicki and Baeyer, and marked with an asterisk, seem to be new, but the scanty literature on spectroscopy at my disposal does not permit me to conclude which of them were observed for the first time.

Of the numerous satellites of the green line, −0·232, observed by Janicki, is separated into two lines, −0·247 and −0·216, and −0·099 into two, −0·110 and −0·084. The lines −0·216 and +0·033 are evidently the same as −0·208 and +0·032 given by Gray and Stewart. The satellite +0·087 observed by Baeyer, +0·088 by Janicki, +0·093 by Gehrcke and Baeyer, +0·082 by Fabry and Perot, and +0·084 by Houston is resolved into two components of nearly equal intensity, +0·068 and +0·109. Gray and Stewart give only +0·067. The green line was separated into twenty-one components by Lummer and Gehrcke with a single interference plate; here it is separated into fifteen lines. Some of these lines will be separated into components by increasing the resolving power.

The spectrum produced by heating an ordinary vacuum tube of **H**-shape containing a few drops of mercury, and excited by an induction coil, gave results almost coinciding with those of Janicki, as observed by Mr. Amano and myself. The appearance of the satellites seems to be influenced greatly by the construction of the tube and the mode of excitement.

Mendelian Characters among Shorthorns.

I WAS much interested in Prof. James Wilson's letter in NATURE of April 2, and I sent the number to my friend, Mr. William Duthie, of Collynie, Tarves, Aberdeenshire, a well-known breeder of Shorthorns of the first class, in the hope that Mr. Duthie, from his own experience, might check some of the numbers given by Prof. Wilson. Mr. Duthie sent my note to Dr. Thomas F. Jamieson, of Ellon, who is also a famous breeder of Shorthorns, as well as an agricultural chemist of repute. Dr. Jamieson wrote to Mr. Duthie, and I have the authority of both to send the following extract from his letter, which will interest, not only Prof. Wilson, but also those who may be collecting statistics regarding the Mendelian aspects of the problem of heredity :—

"I have long been of opinion that the Shorthorns have arisen from a combination of a red breed and a white one. There is a remarkable tendency in them to produce animals which are *entirely* white (unless, perhaps, the ears), more so, I think, than those which are entirely red, and I find that of the white calves the majority are females. I would like you to test this latter point from your own knowledge, in order to see if you also find it so. There is no doubt that a red bull mated with a red cow will almost always produce a red calf, more especially if the bull's own parents were both red, and similarly with white upon white. My red bull "Topsman," 63,447, gave me 113 calves, and not one of them white. He was mated eleven times with a white cow, and the result was ten roans and one red. He was mated sixty times with a red or red-and-white cow, and *every one* of the calves was red. He was mated forty-two times with a roan cow, with the result that twenty-three of the calves were roan and nineteen red. "Topsman" had white socks on the hind shanks, and several of his calves had so too, probably about twenty-six of them, or 23 per cent."

JOHN G. MCKENDRICK.

Maxieburn, Stonehaven, April 11.

Ionisation of Air by Ultra-violet Light.

SINCE Lenard has shown that ionisation of the air is produced by light of short wave-length, it has seemed advisable to extend his researches into the region of the extreme ultra-violet, discovered by Schumann, and to investigate the effect on air of light of wave-length below λ 1850.

For this purpose, a discharge tube filled with hydrogen to a pressure of 1 mm. of mercury, and a screen-cell, were used, both similar to those described by Prof. Lyman in the *Astrophysical Journal*, March. Below the screen-cell was a chamber where ionisation took place. Dry, dust-free air was blown through this chamber into a cylindrical condenser system. The ionisation produced by the light from the vacuum tube was measured by the charge acquired by one of the cylinders, the other being kept at a constant potential. The air pressure in the screen-cell could be varied at will. Precautions were taken to guard against surface effects.

Under these conditions, it has been found that the ionisation increases in a most marked degree as the pressure in the screen-cell is decreased. It is, therefore, evident that ionisation is produced in air by light from that part of the spectrum discovered by Schumann, and that the effect increases considerably with decrease in wave-length, at all events, in the neighbourhood of λ 1800.

It is proposed to investigate the effect in some of the elementary gases.

THE INTERNATIONAL MATHEMATICAL CONGRESS AT ROME.

THE congress of 1908 has been considerably larger than its three predecessors. Up to April 4, the official membership list contained 648 names, but later additions have increased the number of those present to about 530 members, and 167 ladies accompanying them. The weather has been of the same unsettled character that we are accustomed to describe as "British Association weather," but the brilliancy of the gatherings has not been materially affected by the spells of rain.

The proceedings commenced with a reception at the University, given by the rector (Prof. Tonelli) on Sunday, April 5, but the congress was formally opened on the following morning in the Hall of the Horatii and Curiatii at the Capitol, in the presence of the King, when addresses were read by Mr. Nathan, Mayor of Rome, by Prof. Blaserna, representing the Reale Accademia dei Lincei, and by the Minister of Public Instruction.

A discourse was afterwards read by Prof. Vito Volterra on mathematical progress in Italy during the last half of the nineteenth century. Prof. Volterra discussed the work of Cremona, Betti, Brioschi, Beltrami, Fergola, Battaglini, and Dini, and directed attention to the recent publication of Galileo's complete works under the patronage of the King.

The subsequent meetings were held in the magnificent suite of rooms occupied by the Reale Accademia dei Lincei at the Palazzo Corsini, where ample accommodation was available for general and sectional meetings, as well as secretarial and post offices and a buffet. The pretty garden behind the palace was also thrown open, and in the groves the wild *Bellevallia romana* was in full flower. A service of automobiles running intermittently to and from the middle of the town was placed at the disposal of the members. At the first general meeting a report was presented by Profs. Segre, Noether and Poincaré, awarding the Guccia medal to Prof. Francesco Severi for his work on geometry of algebraic surfaces. Subsequently Prof. Mittag-Leffler gave a lecture on the arithmetic representation of analytic functions of a complex variable, and Prof. Forsyth lectured on the present condition of partial differential equations of the second order as regards formal integration.

The sectional meetings commenced on Tuesday morning, April 7, the sections being as follows:—i., analysis; ii., geometry; iii.*a*, dynamics and mathematical physics; iii.*b*, statistical and practical applications; iv., philosophy, history, and teaching of mathematics.

In the section of analysis, Prof. Marcolongo directed attention to the lamentable death on March 30 of Dr. Laura Pisati, who was at that time preparing her paper for the congress entitled "An Essay on a Synthetic Theory of Functions of a Complex Variable." From a long list of subsequent papers the following may be selected:—Jordan, solution of the sextic; Borel, theory of groups; Frizel, power of continuum; Young, applications of semi-continuous functions; Schlesinger, parametric problems in the theory of linear differential equations; Rémoundos, zeros of integrals of a class of differential equations; Volterra, method of images in the hyperbolic type; E. G. Moore, a form of general analysis; Fredholm, Fourier's integrals and theory of linear integral equations; Adhémar, equations of Fredholm and Volterra; Orlando, resolution of integral equations; Stéphanos, extension of invariant and covariant theory of binary forms.

In the geometry section, we note Andrade, theorem of Ampère-Stockes and Euclid's postulate; Bagnera, algebraic equations resolvable by meromorphic functions which are quadruply periodic in two parameters; Severi, certain results in algebraic geometry with special reference to the irregularities of a linear system; Bianchi, Darboux's transformation of surfaces of minimal area; Brouwer, a theory of groups independent of the axioms of Sophus Lie.

In section iii.*a*, Sir G. H. Darwin gave a communication on the rigidity of the earth, illustrated by diagrams showing the displacement of the vertical when the moon has a high north or south declination. It was estimated that the earth's surface rose and fell 17 cm. with the tides, and 20 cm. with variations of barometric pressure. Among other papers we notice Lauricella, certain extensions of the equation of elasticity; Lamb, a theoretical confirmation of the engineers' approximate treatment of bending of beams; E. E. Levi, discussion of certain elastic deformations which satisfy Weingastein's but not Volterra's condition; A. Korn, an attempt to build up a theory of pulsating spheres capable of accounting for electrical as well as gravitational phenomena; Levi Civita, retarded potentials; Garbasso, white light; Greenhill, geometry of gyroscopic motion, descriptive of a method of drawing families of curves hodographic to the Poinsot herpolhode; Sommerfeld, an attempt to account for turbulent motion of viscous liquids; Genese, reciprocal polars applied to statics; Kolosoff, elastic problems in two dimensions treated by complex variables.

Section iii.*b* met on three days only, the first two being devoted to statistical problems, with especial reference to life assurance. An address was given by the chairman, Signor Guido Toja, on the relations between mathematics and actuarial science, and the papers included Dawson, on necessary cautions in dealing with actuarial problems; Borel, application of probability to biology; Castelli, the teaching of actuarial science; Poussin and Elderton, papers of a graphical character; March, population statistics. The third sitting was devoted to the mathematics of engineering and building, a subject introduced by Prof. L. Luiggi. Papers were read by Prof. D'Ocagne, representing the French Office of Works, on the calculus in engineering, and the approximate rectification of circular arcs; by Swain, on teaching of mathematics for engineers; by Canevazzi, and finally by Claxton Fidler, on the theory of construction. The last-named communication derives considerable importance from the reference to the comparatively recent bridge disaster in America, which a mathematical investigation proved to have originated through one of the stays having had to play the part of a strut during the process of construction, thereby causing buckling, which would not have occurred in the completed structure.

The fourth section was devoted on the Tuesday morning mainly to philosophical aspects of mathematics, the subject being introduced by Prof. Federigo Enriques. A discussion between Profs. Itelson and Pastor was a noticeable feature of the proceedings. On the Wednesday and Saturday the discussions were mostly historical. Prof. Krazer directed attention to the publication of Euler's works, in accordance with a wish expressed at the previous congress, and proposed a vote of congratulation to the Swiss Society of Naturalists, which had undertaken the initiative in this task. It was further proposed to invite the Association of Academies, and the Academies of Berlin and St. Petersburg in particular, to assist in preparing the volumes. A proposal was made by Prof. Amodeo in favour of the publication of the collected works of Bonaventura Cavalieri. Thursday and Friday were devoted to the teaching of mathematics. A number of reports had been invited as to the position of mathematical teaching in the schools of various countries. Germany was represented by Gutzmer, France by Borel, Great Britain by Godfrey (whose paper was summarised by Vailati, and discussed by Gibson), the United States by D. T. Smith, Austria by Suppantschitsk, Hungary by Beke, Italy by Vailati and Conti, Switzerland by Fehr, Greece by Stéphanos. Prof. Archenhold proposed that a standing committee should be formed for the study of questions regarding the teaching of mathematics in secondary schools, this motion being carried in the section. Prof. Loria presented the first copy of the fourth volume of Moritz Cantor's "Vorlesungen über Geschichte der Matematik," and a volume containing the report of the educational committee of the German Association of Naturalists and Physicians was presented by Prof. Gutzmer.

The sectional meetings have, as a rule, lasted only about a couple of hours, leaving plenty of time for exchange of ideas between individual congressists outside the formal meetings.

The discourses, occupying a little under an hour each at the general meetings, have been another important feature of the congress. We have referred to the first three of these discourses; the remainder were as follows:—Darboux, methods and problems of infinitesimal geometry; von Dick, the Mathematical Encyclopædia; Newcomb, the theory of the lunar motion, its history and present state; Lorentz, partition of energy between matter and ether; Poincaré, an address read by Prof. Darboux on the future of mathematics; Picard, analysis in relation to mathematical physics; G. Veronese, non-archimedean geometry. A lantern lecture was given by Prof. Störmer on the trajectories of electrified corpuscles in the field of a magnetic molecule, with applications to the Aurora Borealis.

On the Wednesday evening a conversazione was given by the Municipality of Rome in the museum of the Capitol, which was brilliantly illuminated for the occasion; the reception commenced at 10 p.m., and lasted until the early hours of the next morning. On the Thursday the congress was entertained to a sumptuous tea, by invitation of the Minister of Public Instruction, at the Stadium discovered in 1893, on the Palatine Hill. The old mausoleum of Augustus has within the last two months been transformed into a concert hall, the stalls in which alone contained ample accommodation for the whole of the congressists. Here, on the Thursday evening, we listened to an orchestral concert conducted by Signor Luigi Mancinelli. The programme would be generally described as modern music; most of it was certainly very "modern."

A fitting termination to the work of the congress was afforded by a splendid open-air banquet at Tivoli, given in the grounds of the Hotel des Cascades on the Sunday, the morning being spent, so far as time allowed, in exploring Hadrian's Villa, where the *Anemone apennina* and other spring flowers were in full bloom, while a hurried visit to the cascades, temple of Serapis, and pretty gardens of the Villa d'Este, sometime known as the Villa Hohenlohe, occupied the too short interval after luncheon until the "steam rumbler" whirled us back to Rome, where we parted, hoping to meet in Cambridge in 1912.

In the official list of congressists we note about twenty-two English names, one with a German address and another from Egypt. That Great Britain should only be represented by four per cent. of the total number of congressists affords abundant evidence of the position of isolation into which our nation has drifted in its neglect of higher mathematics. There were many proofs that the Italian as well as the German mathematicians present constituted a powerful and influential body, and the presence of the King at the inaugural meeting—an honour rarely conferred on such occasions—together with the brilliancy of the receptions, afforded evidence of the esteem in which Italy holds the mathematical professors of her universities.

The French Government was represented officially by six delegates, besides special representatives of its Office of Works and statistical service. The Governments of Hungary and Roumania sent delegates, as did also many Continental actuarial societies and insurance companies. It is greatly to be hoped that the decision to hold the next congress in Cambridge may be the means of awakening our country to the great disabilities under which English mathematicians labour, in regard to higher study and research, in comparison with the mathematicians of other nations. If any good is to be done, the Cambridge congress must consist of something more than a mere display of hospitality towards foreign mathematicians. A determined effort must be made to work up a large English contingent to meet and exchange ideas with the congressists of other countries. A strong feeling has been expressed against the English practice at such occasions of officially providing private hospitality for some members and not for others, and it has been felt that the success of these foreign gatherings is largely due to the absence of any organised system of limited hospitality. Such a system necessarily divides the members into two parties, and raises up a barrier to free intercourse between them.

The invitation to Cambridge was proposed by Prof. Forsyth, who represented the Cambridge Philosophical Society. It was seconded by Prof. Blaserna, president of the present congress, and carried enthusiastically. For the congress of 1916, Stockholm has been proposed.

Before concluding, mention should be made of the special privileges offered by the Government and Municipality in throwing open all their museums and excavations to the congressists; the important concessions made by the Italian State Railways; and, last but not least, the unfailing courtesy of the local committee, under the secretaryship of Prof. G. Castelnuovo, through whose exertions everything passed off with the greatest success.

G. H. Bryan.

JUBILEE OF THE CALCUTTA UNIVERSITY.

Very few institutions have had such a remarkable influence on the history of any country as has been the case with the University of Calcutta, which celebrated its jubilee on March 14. To put the case on the lowest ground of mere numbers, while in the first year of its existence less than fifty students appeared at all its examinations from the matriculation upwards, during the last few years about 7000 students have appeared annually for its matriculation examination alone, while also in this its jubilee year no fewer than 855 students have taken their degrees in such subjects as arts, science, medicine, law and engineering.

Educational effort on Western lines has naturally been of comparatively recent development in India. For many years after the East India Company had taken over the administration of the territories which had been acquired in India, no attempt was made to establish any regular system of education, and, indeed, no pains seem to have been taken even to foster the indigenous systems which had been in existence throughout the country for many centuries. Later on spasmodic efforts were, however, made to try to prevent the higher forms of oriental learning from falling into decay by the establishment of the Calcutta Madrasah in 1782, intended for Mohammedans and for the study of Arabic and Persian, while a college for Hindus was started nine years later, the aim of which was to foster the study of Sanskrit and Sanskritic languages.

The general neglect of education by the administration continued up to about 1813, from which time public funds appear to have been set apart systematically for the furtherance of education. Up till about 1835 education was conducted largely by oriental methods and in oriental subjects, and the authorities were bent upon the improvement of education by the encouragement of those learned in Sanskrit and Arabic. At that time Lord Macaulay wrote a minute, which has since become historical, advocating the introduction of Western education into India, and the teaching of all the higher subjects through the medium of English. From 1835 to 1854 there was much controversy as to which of these two systems was best; but the teaching of English continued to make fairly rapid headway, and was popular with Indian gentlemen. A despatch from the Court of Directors of the East India Company, written by Sir Charles Wood in 1854, dealt with the whole question in a most masterly way, and practically set the question at rest in favour of the higher teaching being conducted on Western lines and through the medium of English. This despatch was quickly followed in 1856 by the creation of regular education departments in the great provinces of India, manned largely by graduates of English universities, and in 1857 by the establishment of the Calcutta University, and later on of the Universities of Madras and Bombay.

It says much for the faith and energy of those in power in India in 1857 that during the actual period of the Indian Mutiny steps were being taken to create Indian universities, and to foster in every way the educational advancement of the country.

The Calcutta University thus had a clear and favourable field for its operations, for the spread of education through the medium of English was at once warmly welcomed by Indian gentlemen, and year by year it continues to increase in favour. So rapid, indeed, has been the growth of high education in India that within the area originally allotted to the Calcutta University, two other universities (Punjab and Allahabad) have had to be created, and still the numbers from the restricted area are almost more than can be dealt with by that university.

At the time of the formation of the Calcutta University the London University was thought to be the best model to be followed, but judging by results it would probably have been better if the model of the older universities had been followed, if residential colleges had been formed, and if a teaching rather than an examining university had been started. In time probably the latter will be the ideal which will be aimed at in India.

The Calcutta University, for nearly the first fifty years of its existence, has confined itself mainly to the task of merely examining students sent up to it from recognised or affiliated institutions. Of course, by laying down subjects for examination the university has practically determined the subjects which had to be taught in the colleges and schools sending up the candidates, but the university has hitherto exercised no control as to the fitness of the affiliated institutions for the work they were supposed to carry on. At first little trouble arose from this fact, but great difficulties arose owing to the extraordinarily rapid growth in the number of colleges and schools, which rose at one time to about eighty colleges and about 600 schools, which had the privilege of sending up candidates. Many of such institutions were competing with each other with fierce rivalry, and some, if not many, attracted students largely by lowness of fees and laxity of discipline. Many institutions were thus working under unsatisfactory conditions, they were inadequately and imperfectly staffed, and they had few teaching appliances. They suffered indeed so acutely from extremely inadequate funds that really they could not do more than they were actually doing. With the sending up of very large numbers of imperfectly trained candidates for examination, and their consequent failure, the usual desire to lower standards was manifested, and the examinations almost necessarily became suited to the average level of the affiliated institutions and to the teaching there given.

It was with a view to raise the whole tone and standard of university education in India that a new University Act was passed some four years ago, and under this a complete set of new regulations has been framed. Under them standards are being raised, courses are being made more thorough, examinations are being made more practical, specially in the science subjects, original research is being fostered, and has been made compulsory for the higher degrees in science and literature, and post-graduate study is being encouraged by the creation of university readerships and professorships.

In other important matters attempts are being made to deal with the residence and discipline of college students, and to bring influence to bear on the formation of their characters. In the past the condition of affairs in these respects has been somewhat deplorable, and the general influence of the surroundings of students has left much to be desired. What is really wanted for India is a series of residential colleges of the type of the Mohammedan college at Aligarh, in the United Provinces, where most excellent work is being done, intellectually, physically, and morally. Under these new regulations, in order to retain affiliation or recognition, all institutions sending up candidates to the Calcutta University have to be inspected periodically by the university authorities, and are bound to conform to certain standards of work, of equipment, and of care for the well-being of their students, while numerous other reforms have been insisted on.

The new regulations are being gradually but firmly introduced, under the Vice-Chancellor, Mr. Justice Asutosh Mukerji, who is one of the most distinguished of the graduates of the Calcutta University, but it will naturally take many years before their full effect will be felt. In the future too much stress cannot be laid on the desirability of closer and closer union between the colleges and the university, and the assumption of the higher teaching by or under the immediate direction of the university itself. The development of the residential system is also much to be desired if discipline is to be improved and character formed. The eloquent speeches delivered at the Convocation on March 14 by H.E. the Chancellor (Lord Minto), and the Vice-Chancellor (Mr. Justice Mukerji), show that these objects are being steadily kept in view, and that the work of reform is progressing steadily, and perhaps even rapidly. It will hence be agreed that there is a bright future in store for the Calcutta University.

RECENT WORK ON PLAGUE.[1]

SINCE Yersin's discovery of the *Bacillus pestis* in 1894, bacteriological experiment has shown the possibility of spreading plague infection among rats and other mammals through the intermediation of fleas. The reports before us are concerned especially with the proof that this is the means by which epidemics are actually set up. Such proof may be summed up as follows:—

In the first place Major Lamb, with the members of the commission, who carried out the work under the ægis of the advisory committee, shows by numerous charts and by series of maps that the epidemic follows closely in time and place the distribution of the epizootic among *Mus rattus*. In Bombay this epizootic, in its turn, is similarly related to that among *Mus decumanus*. In earlier reports they have dealt with the results obtained by using

[1] (1) *Journal of Hygiene*, vol. vii., No. 6, December, 1907. Third extra number, containing Reports on Plague Investigations in India, issued by the Advisory Committee appointed by the Secretary of State for India, the Royal Society, and the Lister Institute (Cambridge: University Press.) Price 6*s*.
(2) "Report on Plague in Queensland (February 26, 1900–June 30, 1907)." By B. Burnett Ham. (Brisbane: Public Health Department, 1907.)
(3) "The Etiology and Epidemiology of Plague. A Summary of the Work of the Plague Commission." Pp. vi+93. (Calcutta, 1908.) Price 4 annas, or 5*d*.

Liston's ingenious method of experimentation with guinea-pigs. It has been shown that these animals are very rarely infected from soil or clothes grossly contaminated with cultures of the *Bacillus pestis*, or from other plague-infected guinea-pigs, so long as fleas are excluded. On the other hand, they readily contract plague when exposed to the attacks of fleas which have fed on plague-infected animals. Following up this method, the commission placed healthy guinea-pigs in buildings where it appeared that plague was contracted, and found that the test animals died of plague, and, further, that the fleas they picked up in these surroundings could be transferred to fresh animals in the laboratory and infect them also with plague. An exceedingly interesting experiment on these lines was carried out in Sion Village. One part of this village was evacuated by the inhabitants on the discovery of a dead rat. The commission at once took advantage of the "guinea-pig method," and substituted a population of healthy guinea-pigs for the decamped inhabitants. These guinea-pigs were confined to their several houses, and all chance of direct spread of infection among them was excluded. In these circumstances an epizootic appeared among the new population, which progressed through the village, following the distribution of a simultaneous epizootic among the rats (*M. rattus*). The guinea-pig plague was so severe that thirty-six out of fifty-one animals put in the houses died.

The evidence brought against the direct spread of plague from man to man rests on the immunity of hospital staffs, and of friends of patients in hospital, who very frequently lived at the bedside throughout the course of the disease. Again, the village of Worli offered an example of what often occurs. Three cases of plague were imported into the village, but in the absence of an epizootic the infection did not spread.

With regard to the beginning of an epizootic in a fresh locality, it seems that infection may be carried by a healthy man and spread from him to the rats of his dwelling. Such infection, the commission supposes, is flea-borne. The yearly recrudescence of plague may be due to such fresh importation, or to the persistence of acute plague throughout the year, affecting only a few rats. The commission found in two Punjab villages that cases of chronic plague abscess in rats occurred at intervals all the year round. Whether such cases might be able to rekindle an epizootic of acute plague is not clear, and seems to demand further experiment.

With regard to the spread of infection during an epidemic, the Queensland report gives us valuable data. Mr. Burnett Ham, dealing with small epidemics, and a population more amenable than that of Bombay to sanitary regulation, was able to trace definitely the source of infection in a large majority of cases to houses, stores, or ships where the presence of infected rats was proved. An exceptional occurrence was the outbreak of pneumonic plague in Maryborough in 1905. The infection in this instance spread directly from patient to patient; nine cases occurred.

The seasonal exacerbation of plague remains unaccounted for. In Queensland and in Bombay, in opposite hemispheres, the plague-seasons still broadly coincide, though the plague-maxima in Queensland varied considerably—from February to August—in different years. A study of the figures given for the variations in the flea-infestation of rats does not reveal a complete explanation of the phenomenon. For instance, the Punjab experiments show that fleas become frequent months before the plague season begins. Fleas were actually on the decrease when rat-plague was rising to its maximum in Kasel and Dhand. Nor can we suppose that the temperature in Bombay in the cold season is low enough to keep plague in abeyance until the spring. We learn from the reports that the mean temperature of Bombay for the cold season is about 75° F., and a glance at the chart, which gives meteorological data in connection with the Queensland epidemics, shows that plague may appear, spread, and maintain itself under a mean temperature varying between 50° and 70° F. The Queensland report, in addition to epidemiological data, gives a large amount of clinical information, and experiments on the prophylactic and curative value of anti-pest sera. Experiments with rat-viruses carefully maintained at high virulence gave results more encouraging in the laboratory than in the field.

Major G. Lamb is responsible for the third volume under notice, and he has used the opportunity to give us a very clear outline of the present state of knowledge on the subject of plague. He also indicates the lines along which sanitary measures may be taken with advantage. While stating that this summary represents his personal opinions, he shows how these opinions arise logically out of the experiments carried out by the commission.

The lacunæ in our knowledge are brought into a healthy prominence by a summary of this nature. We do not yet possess trustworthy information as to rat population (part ii. B.), while our only means of taking a census is that of recording the percentage number of rats caught per traps set. One thing is pretty clear—that the most efficient trapping will never of itself reduce the rats of any considerable area below the minimum necessary for the spread of an epizootic.

Part iii. disposes of transmission of infection by direct contact, by the air, by food, or through the soil, and gives the proofs for transmission by the rat-flea. Direct contagion certainly occurs in pneumonic plague, but this is so rare as to fall outside the main problem.

Though man plays a minor *rôle* in the spread of an epidemic (part iv.), yet he is directly concerned in the importation of the disease into healthy areas (part vii.). It has been shown that hungry rat-fleas will cling to man and yet refrain from feeding for a considerable time. The man in the meantime may have travelled some distance and have arrived at a house where rats are abundant. His guests will then leave him for their natural hosts, and thus the rats may become infected while the man remains healthy.

At the end of the plague season in any locality plague may die out completely, or the epizootic may continue at a low level through the off-season. In the latter case the locality becomes a focus from which infection will be spread, with the arrival of the next plague season, over the surrounding country. Thus rats with acute plague are caught in Bombay all the year round.

The sum of these investigations may perhaps be expressed as follows. Extinction of rats, extinction of fleas, or exclusion of rats from dwellings might any one of them put an end to human plague, but all are exceedingly difficult to realise. On the other hand, the conditions which determine the off-plague season are not fully known, and may still give an indication of some practicable method of fighting the disease. Further investigation is urgently demanded.

L. N.

NOTES.

According to the *Pioneer Mail*, the provision of a Pasteur Institute for Burma is now assured, but some little time must elapse before the work can be started. The local community has come forward liberally in subscribing nearly a lakh of rupees, and the Government of India is understood to be addressing the Burma Administration on the subject of ways and means for carrying the scheme into effect, the total cost of such an institution being, of course, much in excess of the sum that has been raised.

At the sixth annual meeting of the Association of Economic Biologists, held at University College, London, on April 15, Mr. A. E. Shipley, F.R.S., was elected president for 1908. A summary of the scientific proceedings appears among our reports of societies. The following resolution was passed at the meeting: "That this association, recognising the great need of an organised inquiry into the feeding habits of the birds of the British Isles with the view of obtaining a practical knowledge of their economic status, is of the opinion that a committee should be formed with the object of carrying on investigations on this subject."

On Tuesday next, April 28, Mr. Gerald Stoney will begin a course of two lectures at the Royal Institution on "The Development of the Modern Turbine and its Application"; on Thursday, April 30, Mr. W. Bateson will commence a course of three lectures on "Mendelian Heredity" (these are the Tyndall lectures); and on Saturday, May 2, Mr. G. F. Scott Elliot will deliver the first of two lectures on "Chile and the Chilians." The Friday evening discourse on May 1 will be delivered by Prof. Joseph Larmor, on "The Scientific Work of Lord Kelvin"; on May 8 by Mr. J. Y. Buchanan, on "Ice and its Natural History"; and on May 15 by Mr. Herbert Timbrell Bulstrode, on "The Past and Future of Tuberculosis."

At the London Institution on April 15, Mr. Valdemar Poulsen lectured on "Telephoning without Wires." The paper was translated and read to the audience, and showed that Mr. Poulsen has made a great advance in radio-telephony since his last lecture in London at the Queen's Hall two years ago. The progress made in wireless telephony is shown by the fact that conversation has been carried on across Denmark from Lyngby to another wireless telephone exchange at Esberg, 170 miles distant. The reproduction of the voice was clear and distinct, and easy to recognise. In addition to this, a further trial was made with a phonograph played in Berlin, the music of which was heard distinctly at Lyngby, near Copenhagen, 200 miles distant. At the close of the lecture some experiments with a phonograph were made, and the strains of two pieces of music were radiated to a telephone box in the roof of the building, whence the audience were enabled to hear the reproduction through telephone receivers. Mr. Poulsen showed an apparatus which was guaranteed to receive wireless messages in the Morse code, telephone cables, and wireless photographs. The wireless photographs are produced by the deflection of a recorder for the fraction of a second by wireless impulse. A ray of light shines on a photographic plate, and consequently a photographic negative of easily read signals is produced. Mr. Poulsen has also produced a practical transmitter of such a size that it can easily be carried in baggage, and thus enables an officer on sea or land to communicate with other units in his own voice.

Mr. J. R. Pennell, Mr. A. Kinnes, and Mr. H. C. Booth have been appointed to the vacant junior assistantships in the National Physical Laboratory.

Some months ago we had occasion to notice a paper by Mr. G. R. Marriner on the habits of the New Zealand kea parrot. A volume by the same observer, entitled "The Kea: a New Zealand Problem," is now announced by Messrs. Marriner and Spencer, of Christchurch, N.Z.

We have to acknowledge the receipt of two parts (vol. xi., part ii., and vol. xii., part i.) of the Transactions of the Leicester Literary and Philosophical Society. In the latter of these, special interest attaches to a paper by Mr. T. O. Bosworth on the origin and mode of deposit of the Upper Keuper beds of the county. In this paper, which was read at the Leicester meeting of the British Association, the author points out that the climate of the Carboniferous epoch, like that of the present day, had a highly disintegrating effect on the igneous rocks of Charnwood Forest. Where, however, the Charnwood rocks have been buried under Keuper deposits, they present a sharp, uneroded surface, indicating the existence of dry desert conditions at the date of deposition of the latter.

In the February issue of the *Bulletin international* of the Academy of Sciences of Cracow, Mr. K. Stolyhwo describes a human skull dating from the historic period which presents strong indications of close affinity with the Spy-Neanderthal type, the so-called *Homo primigenius*, of the Palæolithic epoch. The skull, it appears, formed part of a skeleton from a tomb in which was also buried a suit of chain-armour, together with iron spear-heads, &c. In the great development of the supra-orbital ridges and of the notch at the root of the nasals, the skull, which was found at Nowosiolka, closely approximates to the Neanderthal type. It may be added that, in view of Prof. Sollas's recent reference of the latter to the Australian stock, the occurrence in eastern Europe of a late survival of the same type is a matter of profound interest.

The Indian Forest Department has decided to issue two new serials, *Indian Forest Records* and *Indian Forest Memoirs*, for the publication of departmental literature. The first part of the *Records*, published in Calcutta in January, is devoted to an elaborate account, by Mr. E. P. Stebbing, entomologist to the department, of the lac-insect and its product. Although the exports of lac from India are of immense value, amounting in 1905–6 to more than three crores of rupees, a comparatively small revenue is yielded to the Forest Department from this source, and one of the objects of the inquiry was to ascertain whether matters could not be put on a more satisfactory footing in this respect. The inquiry also related to possible improvements in the methods of collecting the lac. The account is illustrated with two plates, one devoted to the life-history of the insect and the other to the mode of formation of the lac. It is unfortunate that, on its first page, the part bears the date of 1907 instead of 1908.

Insects injurious to the valuable sal-forests of Assam, together with the parasites and other insects by which they are infested or attacked, form the subject of an article by Mr. Stebbing, issued at Calcutta as *Forest Bulletin* No. 11. It has long been known that these forests are subject to severe damage from the attacks of leaf-eating caterpillars, but Mr. Stebbing considered it probable that the chief harm would be found due to a longicorn beetle akin to the one attacking sal-timber in central India. Unfortunately, this suggestion has proved only too true, great damage being caused to the Assam timber-supply by the species (*Hoplocerambyx spinicornis*) so harmful to the forests of Chutia Nagpur.

The report for the year 1906, prepared by Mr. J. H. Maiden, appertaining to the botanic gardens and Government domains in Sydney, has been received. A list of groups of plants specially interesting to students is provided, and the situations in which they may be found. The successful novelties introduced to the gardens include *Fagus sylvatica*, var. *heterophylla*, *Physostegia virginiana*, *Cassia occidentalis*, known as Negro Cuffee, the indigenous species *Angophora cordifolia* and *Cheiranthera linearis*, and some West Australian shrubs.

Dr. C. Hosseus communicates to *Engler's Botanische Jahrbücher* (vol. xl., part iv.) an account of the vegetation observed on Doi Sutap, a mountain situated in the Shan States attached to Siam. Ascending from the rice fields, a light wood of teak and Albizzia, carpeted with composites and leguminous plants, was first reached. The "Hill Eng" forest, composed of species of Dipterocarpus and allied genera, on which numerous epiphytes grow, began at an elevation of 1000 feet. After ascending 2000 feet higher a forest of *Pinus khasyana* was found, giving place to bamboo vegetation at 4000 feet. In this zone the new genus of the order Rafflesiaceæ, *Richthofenia siamensis*, was discovered; several new species were also found near and between the summits.

It is usual to associate Montserrat with the production of limes, so that it occasions some surprise to read in the annual report for 1906–7 of the botanical establishments on that island that cotton promises to become the most important industry. In the space of four years there has been a significant increase in the amount and value of the cotton exported. At the same time, the distribution list of the botanic station furnishes evidence of a considerable demand for limes, in addition to which cacao and Castilloa rubber trees have been in request. An introduced industry, in the shape of onions grown from Teneriffe seed, shows a remarkable development within the year, and it is stated that further expansion is only prevented by the limited shipping facilities.

An article by Mr. A. Maumerné on Japanese dwarf trees, their forms and cultivation, is published in the Journal of the Royal Horticultural Society (vol. xxxii., part i.). There are definite æsthetic canons regulating the forms and outlines that are produced. Many of the artistic effects are due to training of the branches, others to special development of the roots. Conifers are the favourite plants for working on, especially species of Thuya and Pinus. Grafting is frequently practised with species of Podocarpus and maples. In the same volume will be found a useful article on horticultural law, by Mr. H. M. Veitch, in which he discusses such points as rights with regard to overhanging trees, fixtures, and trespassers. An annotated list of Gesneraceæ is contributed by Colonel H. Beddome.

Messrs. Constable and Co. have just commenced the publication of a new monthly magazine—*The Country Home*—the scope of which is sufficiently conveyed in the title. Descriptions of artistic and famous country houses are provided in the accounts of Stoke D'Abernon Manor House and of several black-and-white timbered houses in Cheshire and adjacent counties. There is a sprinkling of natural history in various articles. Mr. F. Moore contributes an excellent article on the making of lawns, and one may expect useful hints on intensive cultivation in the legend of the gardener and the cook, told by Miss L. Yates. Mr. J. W. Odell writes the monthly notes on the garden and greenhouse. In extending a welcome to this new venture, which is attractively got up and well printed, it may be hinted that, possibly for the sake of variety, several of the articles are too short to arouse much interest.

"A Catalogue of the Library of Charles Darwin now in the Botany School, Cambridge," has been compiled by Mr. H. W. Rutherford, of the University library, and published by the Cambridge University Press. Mr. Francis Darwin has contributed an introduction, in which he gives interesting information, supplementary to the account contained in the "Life and Letters," concerning his father's methods of work and treatment of books. The collection of books now bequeathed to the University is not identical with that at Down; thus, the books Darwin wrote and some few others from Down remain in the possession of Mr. Francis Darwin. Darwin's pamphlets are not included in the catalogue, though part of them are on the shelves alongside his books. The introduction points out that Darwin hardly ever had a book bound, and the collection retains to a great degree its original ragged appearance. The general characteristic of the library is incompleteness, hardly any set of periodicals being perfect. The chief interest of the Darwin books lies in the pencil notes scribbled on their pages, or written on scraps of paper and pinned to the last page. Books are also to be found marked with a cypher, as described in "Life and Letters." Mr. Francis Darwin provides many facts of interest in connection with some of the more important books included in the library. In a preface, Prof. Seward expresses to Mr. Darwin the high appreciation of the botany school and University for rendering the library available to all students. The price of the catalogue is 1s. net.

In the *Engineering Magazine* for April, Mr. Jacques Boyer gives an illustrated description of the rescue appliances used in the French collieries, special attention being given to the Tissot respirator, which dates from 1907, and the Vanginot respirator, which has been in service for several years in the Paris Fire Department, and is coming into increasing use in the French collieries.

Bulletin No. 250 of the Michigan State Agricultural College contains a full description, with plans and illustrations from photographs, of the new college farm buildings recently erected at a cost of 15,000 dollars, of which 10,000 dollars was granted by the Michigan State Legislature. The buildings are designed solely for ordinary farm purposes, and not for special experiments, and the bulletin is issued with the idea of furnishing farmers with plans of buildings considered suitable for the local requirements.

At the Institution of Mechanical Engineers on April 10, Prof. Bertram Hopkinson read a paper on the effect of mixture strength and scavenging upon thermal efficiency. The method used for measuring the gas, described in the author's previous paper on the mechanical efficiency of a forty brake horse-power Crossley gas-engine, was especially advantageous, for it gave the actual volume of gas used in the series of forty or fifty explosions from which the indicator diagrams were taken, and the materials for a complete measurement could thus be obtained in a few minutes. Diagrams with three or four different gas-consumptions could be got within an hour, during which time the calorific value of the gas would remain constant, so that the effect of changing the strength of mixture or of scavenging by running without load could be very accurately determined. When allowance is made for the gas discharged unburnt, the efficiency is not much affected by scavenging provided the strength of mixture is kept the same, which implies an increase of about 15 per cent. in the gas-charge, with, of course, a corresponding increase of mean pressure. At the same meeting Mr. James Atkinson read a paper on the governing and regularity of gas-engines, in which the various methods of governing employed were critically discussed.

The report of the Observatory Committee of the Royal Cornwall Polytechnic Society for the year 1907 has been received. The Falmouth Observatory is one of the important meteorological establishments subsidised by the London Meteorological Committee for the tabulation of automatic records; it has a complete magnetic equipment, and during the year in question received material assistance from the Royal Society towards the maintenance of this branch of its useful work. The observations fairly represent the conditions in the west of England; the mean temperature of 1907 was $0^{\circ}{\cdot}4$ below, and the rainfall 2·78 inches above, the mean. During a brilliant display of aurora, on February 9, the magnetographs showed that a storm of great intensity was in progress.

The Stonyhurst College Observatory (Lancashire), which has likewise sent us a copy of the results for 1907, also receives some allowance from the Meteorological Office. Its records (together with those of the Liverpool Observatory) represent the meteorological conditions in the north-west district of England, and it possesses a valuable series of observations extending over sixty years. The rainfall of the year was 3 inches above, and the temperature $0^{\circ}{\cdot}6$ below, the average. Magnetic observations are carefully recorded, but the staff is too limited to undertake hourly tabulations from the curves. Some 198 drawings of sun-spots and faculæ were made, and Father Sidgreaves remarks on an unexpected revival of solar activity and magnetic diturbance.

The Royal Geographical Society has published a "Bibliography of Topographical and Geological Works on the Phlegræan Fields," by Mr. R. T. Günther, containing about 2200 titles of books, papers in scientific and other periodicals, maps, and drawings, relating to the city of Naples and the country to the west of it, together with the volcanic islands in the vicinity. The catalogue is specifically restricted to the geomorphology, topography, and physical features of the region, and is arranged as a subject catalogue, the entries being grouped in topographical sections or sections devoted to special subjects, and printed in each group consecutively in order of date of publication. When supplemented, as in this case, by an index of authors and subjects, no more convenient arrangement could be devised. The catalogue will be of great service to students of volcanic and kindred phenomena, and to others interested in the region dealt with, but the reference to geology in the title might well have been omitted, for the list is by no means complete in this department; we notice the inclusion of papers which have no real bearing on the subjects to which the bibliography is restricted, and the omission of others which should have been included.

The March number of the *Psychological Review* contains the second of two interesting articles, by Dr. Boris Sidis, setting forth a new explanation of hallucinations. It is based upon a novel theory of perception, the exposition of which was contained in the former article. The perception of an object involves, as is well known, a reference to other sense qualities of the object than those immediately presented. Thus we may "see," not only the transparency, smoothness, and whiteness of a lump of ice, but also its coldness and weight. Former doctrines of perception have regarded the latter factors of the perceptual complex as images; in opposition to this view Dr. Sidis maintains that, like the former, they are sensational. He distinguishes them from the sensational elements the material causes of which actually affect the sense organs, by calling the latter "primary" and the former "secondary sensory elements." In normal perception we have a group containing elements of both types organised round a nucleus of primary elements, but under abnormal conditions it may happen that the primary sensory elements become subconscious or fall entirely out of the patient's consciousness, leaving a group of secondary sensory elements standing as an independent synthetised compound. Such a dissociated group of secondary sensory elements constitutes an hallucination.

Dr M. Marage described before the Paris Academy of Sciences a method invented by him of photographing the vibrations of a thin india-rubber membrane when acted on by the tones of the human voice. A small mirror is attached to the membrane, and a beam of light is reflected from it upon a band of sensitised paper slowly moved by a small electromotor. After receiving the impression the photographic paper is drawn by the motor through two developing baths, and finally into a fixing bath. There is nothing strikingly novel in the method, and the examples of the tracings given in the paper published in the *Comptes rendus* of the academy do not seem to be clear or to give much information.

Mr. J. W. Giltay, of Delft, Holland, has sent us a descriptive catalogue of apparatus for demonstrating the action of light on selenium. The selenium cells listed are of the Shelford Bidwell type, their resistance in the dark ranging from 25,000 ohms to 500,000 ohms. Low resistance and high sensitiveness, it is noted, do not go together. These cells have been manufactured by Mr. Giltay ever since 1881, and among those to whom they have been supplied is Dr. Korn, who uses them in his well-known process of telegraphic photography. Their capabilities in this direction are demonstrated by a reproduction of an excellent portrait of Dr. Korn, which was transmitted electrically. Among other apparatus described is a miniature photophone. Words spoken into the mouth-piece of the transmitter act upon an acetylene manometric flame, which illuminates a selenium cell placed near it; the cell is connected in circuit with a battery and a telephone receiver in a distant room, and the speaker's voice is heard at the telephone. Several modifications of this apparatus are described. A compact battery of forty-nine cells, providing the high electromotive force requisite for experiments with selenium, is supplied at a moderate price.

Le Radium for March contains an account of the work done recently by M. A. Dufour on the effect of pressure on the wave-lengths of the absorption lines of nitrogen peroxide and bromine. The observations made hitherto on the effect of pressure on emission spectra have led to the conclusion that the lines of bands were unaffected. M. Dufour finds, on the contrary, that certain lines of the absorption spectra of the two vapours mentioned are influenced by pressures up to about 20 atmospheres. The whole of the lines of the absorption bands are broadened and rendered less sharp, but certain lines are unaltered in wave-length, while others increase by amounts of the order of a few hundredths of an Angström unit per atmosphere increase of pressure. There seems to be no connection between the influence of pressure on the wave-length and the Zeeman effect in the case of bromine, although there may possibly be such a connection in the case of nitrogen peroxide.

SOLUTIONS of the examples in "A Sequel to Elementary Geometry," by Mr. J. W. Russell, which was reviewed in the issue of NATURE for February 6 last (vol. lxxvii., p. 315), have been prepared by the author, and published at the Clarendon Press, Oxford. The price of this key is 3s. 6d. net.

OUR ASTRONOMICAL COLUMN.

STRUCTURE OF THE CORONA.—In No. 19, vol. ii., of the *Mitteilungen der Nikolai-Hauptsternwarte zu Pulkowo*, Prof. Hansky discusses the results derived from a study of the photographs of the corona taken by the Pulkowa expedition at Alcocèbre (Spain) during the total solar eclipse of August, 1905. The principal aim of the photographs was to determine the velocity of the propagation of coronal matter in space, and the eight exposures were therefore arranged symmetrically about mid-eclipse, and given approximately equal times.

Each streamer and prominence shown on the photographs is discussed very fully, and Prof. Hansky finally draws the following conclusions. The corona of 1905 was of the "maximum" type, and was divided into eight groups of streamers, arranged symmetrically about the sun's axis. It appears probable that the forms and directions of the coronal streamers depend upon the forms and directions of the prominences above which they are found. In this conclusion Prof. Hansky's result agrees with that recently published by Dr. W. J. S. Lockyer (see NATURE, No. 2005, p. 514). The centres of emission of the streamers, though often near spots, do not coincide with them. Those streamers which occur over great prominences are readily distinguishable by their forms. The jets of prominences resemble jets of matter, the observed velocity of which approximates to 200 km. per sec. Any movement of coronal clouds above prominences is shown to be very slow, its velocity not exceeding 30 km. per sec.; this is so small that any such movement during the three minutes of totality would not produce a change of position sufficiently great to exceed the limits of observational errors.

SPECTROSCOPIC BINARIES NOW UNDER OBSERVATION.—With the view of assisting in the prevention of unnecessary duplication in the observation of spectroscopic binaries, Prof. Frost, director of the Yerkes Observatory, recently addressed a circular letter to the principal observers in this work asking them to furnish him, for publication in the *Astrophysical Journal*, with a list of the objects now under observation at the several institutions. The various replies appear in No. 2, vol. xxvii., of the journal (p. 161), and show that duplicate observations are already in progress. Prof. Hartmann points out, whilst furnishing a list of stars, that duplication is not necessarily an evil, for, with the determination of radial velocities still in a state of evolution, such duplication serves as an independent check on the various results. Prof. Pickering suggests several pieces of work where cooperation would probably lead to useful results, and points out that, even with an objective-prism spectrograph, the star ζ Ursæ Majoris shows marked irregularities in its spectrum which have not yet been accounted for.

THE RELATION BETWEEN THE COLOURS AND PERIODS OF VARIABLE STARS.—In an interesting paper which appears in No. 4238 of the *Astronomische Nachrichten* (p. 209, March 9), Herr S. Beljawsky, Göttingen, discusses at some length the relation found to exist between the colours and the periods of variable stars. From the tables and curves given in the paper it is seen that in general the variable stars of long period are much redder than the short-period variables. Regarding the amplitudes of the typical light-curves, it is found that up to periods of 200 days the amplitude increases with the period, beyond 200 days it appears to remain constant.

A FIELD METHOD OF DETERMINING LONGITUDES.—Paper No. 5 of the Egyptian Survey Department is devoted to an explanation, by Mr. E. B. H. Wade, of an instrument designed by him for making field determinations of longitude by observations of the moon. By a system of mirrors placed at the object-glass end of a small $2\frac{1}{2}$-inch telescope, Mr. Wade successively brings the images of two stars in contact, tangentially, with the limb of the moon, thus finding the times of equal lunar distance. The apparatus is ingeniously designed, and is readily portable. Full explanations of the instrument and the method are given in the paper, which is illustrated by a number of diagrams and curves.

OBSERVATIONS OF EROS.—The results of ten measures of the position of Eros, made with the 15-inch refractor of the Uccle Observatory during the period September 25 to October 19, 1907, are published in No. 4240 of the *Astronomische Nachrichten* (p. 252, March 23) by Herr G. Van Biesbroeck. Comparing the positions thus determined with those given in the ephemeris published in the "Berliner Jahrbuch" for 1909, it is seen that the mean corrections to the latter are $-1 \cdot 10$s. in R.A. and $-8'' \cdot 0$ in declination.

VARIABLE RADIAL VELOCITY OF η VIRGINIS.—A note in No. 2, vol. xxvii., of the *Astrophysical Journal* (p. 160, March) gives the provisional elements of the orbit of the brighter component of η Virginis, as determined at the Ottawa Observatory by Mr. W. E. Harper. The period is found to be 71·9 days, the velocity of the system $+2 \cdot 2$ km. per sec., the eccentricity of the orbit 0·4, and the length of the semi-major axis 25,750,000 km. The velocity-curve shows a variation from -40 km. to $+20$ km.

AGRICULTURAL EXPERIMENTS AND REPORTS.

THE eighth report of the Woburn Experimental Fruit Farm contains a very valuable investigation of the washes commonly used for spraying fruit trees. They have hitherto been made up in rather a haphazard way, without much reference to the chemical changes involved, and Mr. Pickering is to be congratulated on having reduced them to a scientific basis. He shows that Bordeaux mixture (obtained by precipitating copper sulphate solution with lime) made in the ordinary way consists of

$$10CuO,SO_3,4CaO,SO_3,$$

but this is not so economical as another precipitate, $4CuO,SO_3$, for obtaining which full instructions are given. An investigation of the "Woburn wash" (paraffin emulsion and caustic soda) led to a very important examination of emulsions in general, which has enabled Mr. Pickering to state the conditions under which they may be expected to form. When oil is churned with water it is broken up into very minute particles; if still smaller particles of an insoluble substance are present they coat the oil drops and prevent them from coalescing; an emulsion is therefore formed. During the progress of this work Mr. Pickering discovered a new emulsion which promises to be of great service to the fruit-grower. Basic copper sulphate (obtained by adding lime to ordinary copper sulphate) was churned with oil and water, and gave a perfect emulsion to which caustic soda could be added without any adverse effect. The result is a wash containing the three things which have to be used in winter and spring; the grower can therefore get them all on in one operation instead of in three as hitherto. The insecticidal and fungicidal action of these and other washes was also investigated, and there is a discussion of the nature of the action of insecticides.

Of late years molasses has been increasingly used as cattle food, and various agricultural stations have investigated its digestibility and nutritive value. A Bulletin recently issued by the Massachusetts Experiment Station (No. 118) gives the results of experiments by Lindsey, Holland, and Smith. They found that any large quantity of molasses depresses the digestibility of the other constituents of the ration; this is known to be the general effect of too much carbohydrate. Molasses proved less economical than ordinary farm foods; it proved, however, a valuable condiment, and induced the animals to eat unpalatable and inferior fodder which otherwise they would have refused. It was also found to keep the animals in good condition. Two or three pounds a day is recommended as the proper allowance for cows and horses.

In a paper recently read before the Canterbury Farmers' Club, Mr. E. S. Salmon gives the history of the Gooseberry Mildew Order of July, 1907. This was the first order issued by the Board of Agriculture under the new Destructive Insect and Pest Act, an Act largely due to Mr. Salmon's tireless exertions on behalf of fruit-growers. By the terms of the order the gooseberry mildew is a notifiable disease under a penalty not exceeding ten pounds; the local authority, on receiving notice of its existence, is required to make the grower destroy immediately all diseased bushes, and then spray with an approved fungicide all surrounding bushes. The payment of compensation for the destroyed bushes is optional on the part of the local authority, but the necessary money must be provided out of the rates, as no Treasury grant is available. Mr. Salmon states that the order is not being carried out, and that there has been no systematic destruction of diseased bushes, because the councils have been unwilling to destroy bushes without compensation, and afraid to draw the necessary money from the rates. The result has been that the disease is spreading rapidly, and is now known in six counties. Instead of strengthening the order the Board has practically nullified it by issuing a second one permitting the grower to prune instead of burn his bushes. Mr. Salmon criticises the order strongly, and points out that pruning cannot keep the mildew in check. He goes on to say:—"The Board of Agriculture, without any scientific leadership, have again temporised at the most critical stage. There is now but one opportunity remaining of dealing with the American gooseberry mildew and preventing it sweeping through the country, and that is to deal with the disease this winter, but it must be by thorough and uncompromising measures." He recommends systematic destruction of every infected bush in the country, compensation to be awarded out of the Treasury. If this is not done, he thinks gooseberry growing will cease to be a commercial possibility in England.

A pamphlet has recently been issued by Mr. E. S. Salmon on the "black scab" or "warty disease" of potatoes (*Chrysophlyctis endobiotica*, Schilb.). This dangerous disease, which came over from the Continent about 1895, now occurs in nine counties in England and Scotland, and seems likely to spread throughout the country unless drastic preventive measures are taken. The fungus attacks the growing potatoes, causing the formation of wrinkled, warty excrescences which may become even larger than the actual potato itself; sometimes the stem and leaves are similarly attacked. Spores can remain in the ground for two years at least, and there is evidence that they can remain dormant for six years. Mr. Salmon urges the desirability of bringing this disease under the Destructive Insect and Pest Act. It would certainly seem desirable that the Board of Agriculture should have expert guidance in connection with this new Act, so that diseases could be brought within its scope directly they appear, instead of waiting until considerable damage has been done.

The *Agricultural Journal of the Cape of Good Hope* for January contains an account of the Kafir corn aphis (*Aphis sorghi*), an aphis which, as its name implies, badly attacks Kafir corn (*Sorghum vulgare*). It is stated that the pest is spreading, and is likely to be a serious matter in the near future owing to the great value of Kafir corn in Cape Colony; a thorough field study is desirable during January, February, and March, when the insect is on the corn. The same number also contains an article by W. Robertson on preventive inoculation of farm stock, dealing specially with lung sickness, anthrax, and black quarter.

The *Agricultural Journal of India* (October, 1907) contains several articles of interest to the large Indian agriculturist. The similarity between the conditions obtaining in Sind and in Upper Egypt is pointed out, a similarity which has enabled Egyptian cotton to be successfully grown where previously none could be obtained. Mr. Maxwell-Lefroy contributes a useful article on practical remedies for insect pests, and there is a good account, with illustrations, of the stock on the Government cattle farm at Hissar (Punjab).

Owing to the large number of new orchards coming into bearing in South Australia, the production of fruit is likely considerably to exceed the local demand; a detailed account of the process of fruit-drying is therefore given in the *Journal of Agriculture of South Australia* (December, 1907). The fruits dealt with are apricots and prunes; the instructions are very full, and should prove valuable to the fruit-grower. Another article deals with the banded pumpkin beetle (*Aulocophora hilaris*, Boisd.), which does considerable damage to melons.

The December (1907) number of the *Agricultural Journal of the Cape of Good Hope* contains an article by Mr. Lounsbury on the Plasmopara vine disease in Algeria, in which attention is directed to the similarity between Algeria and Cape conditions. No remedy for the disease is known, and the Cape authorities are naturally anxious that they may remain free from it. There is also a report on various methods tried for the destruction of the prickly pear. This tree spreads rapidly on ground which is not being actually cultivated, and is found seriously to injure the ground for cultivation. The best and simplest method found was to cut down the tree, spray the heaps with sodium arsenite solution, and then inject a 10 per cent. solution of the same salt into the stumps still left in the ground. This journal adopts the very useful plan of publishing the lectures given at the Rhodes University College during the vacation courses in agriculture, by which means they are made known to a much wider circle than would otherwise be possible. All the lectures deal with important agricultural problems. In the present number the breeding and grazing of Angora goats is gone into at length; there are also two articles on the management of ostriches.

We have received three leaflets from the Board of Agriculture, No. 195 dealing with the American gooseberry mildew, No. 199 with the pine disease, and No. 202 with the frit fly. The pine disease is caused by *Diplodia pinea*, Kickx., a wound parasite, the mycelium of which extends rapidly towards the tip of the shoot and takes up the food supply. After a short time all the leaves fall and the plant dies. The frit fly (*Oscinis frit*) is stated to be one of the chief cereal pests in Europe; the chief damage in Great Britain is to oats, and there are Continental records of attacks on barley, wheat, rye, maize, and various grasses. It appears that early sown crops are less liable to be attacked than late sown.

In the January number of the *Journal of the Department of Agriculture and Technical Instruction for Ireland* there is a full report of the first address by the new vice-president to the council, which affords eloquent testimony to the value of the work done by Sir Horace Plunkett. Itinerant instructors are now at work in every county; in addition, winter classes are held in thirteen counties at thirty-two centres, the number of pupils attending being estimated at five hundred. Twenty-six students are training at the Royal College of Science for teaching appointments, fifty-seven are studying at Glasnevin with the view of actual farming, and there are also three smaller institutions with fifty-nine students between them. The prosperity of the country is increasing; the export of eggs increases rapidly, and is now valued at 2,500,000*l.*; poultry are also being sent out in greater number and of better quality. Schemes are on foot to study the production of winter butter, to increase the forest land, to set up cattle dispensaries in certain counties, and to push the sale of Irish produce in the English markets. All this is excellent; we cannot, however, help feeling more than doubtful about another plan suggested for the future—of choosing Irishmen by preference for teaching posts. It would surely be much better to choose the best available man, quite regardless of his nationality

RECENT EARTHQUAKES.[1]

UNTIL recent years the attitude of the ordinary Englishman with regard to earthquakes has been one of apathy. He argued that, although every year 30,000 earthquakes might occur in the world, his country only contributed about half a dozen, and these, because they were so small, did more to excite curiosity than to create alarm. Although in 1883 Colchester, and in 1896 Hereford, lost a few chimney pots, and buildings were unroofed, also at intervals, reckoned by one or two hundred years, London has been shaken, still England could not be regarded as an earthquake-producing country. British-made earthquakes may be of rare occurrence, but should there be any relief of seismic strain similar to that of 1883 or 1896 in the synclinal on which our great metropolis stands, we might find as many chimney pots in the streets as there are inhabitants. A suggestion of this kind, however, does not disturb the mind of our ordinary Englishman. Hints respecting the possible instability of his country produce no effect, and he fails to see why he or his Government should be called upon to support seismological investigations. Recent earthquakes have, however, modified his opinion, and although England may be free from earthquakes, he finds he has to insure against and pay for the effects which these disturbances have caused in distant places. By observations on what has stood and what has been destroyed after violent shakings of the ground, and as the result of investigations together with elaborate and costly experiments carried out entirely in Japan, not only have new methods of construction been formulated, but these have had extensive applications. Experience has shown that the new types of buildings stand whilst the old ones are shattered. At the present moment, Valparaiso, San Francisco, Kingston, and very many other cities, towns, and villages, not only in America, but also in Europe and Asia, have by recent earthquakes been reduced to heaps of débris. When these are reconstructed, it is extremely likely that the well-tested rules and methods, the outcome of applied seismology, will not be neglected.

Seismological investigations have been made, not only for scientific reasons, but to minimise the loss of life and property. In connection with the destruction of San Francisco alone, we are told that British insurance companies are called upon to meet claims amounting to 12,000,000*l.*, while losses of like character may have to be met in other parts of the world. The Englishman living on his own little patch of *terra firma* is continually paying for earthquake effects all over the world. The thinking man now realises that insurance rates in many countries must vary with the seismicity of a district, together with the character of the structures to which they refer. Sub-oceanic seismic activity frequently results in the failure of cables. It is therefore of extreme importance that the sites of these submarine disturbances should be located (see map). In these and in many other ways it is easy to show that England has probably a greater practical interest in the results of seismological investigation than any other country. Finance and earthquake effects are close relations. Another incentive to the removal of apathy in regard to seismology lies in the fact that the mind of the public, like that of the individual, becomes fatigued by repetition. What is asked for is something new, and, if possible, it should be sensational. Newspapers and magazines do all they can to relieve this craving, with the result that the public is liberally supplied with stories about big catastrophes and deductions based thereon. A new *hors d'oeuvre* has been added to the daily scientific menu, and the halfpenny paper and the sixpenny magazines have given a stimulus to investigations bearing upon earth physics.

In countries where earthquakes have been severe, and where by their frequency they are continually forcing them-

Fig. 1.—Stations in cooperation with the British Association working with similar instruments (Milne pendulum). Number of world-shaking earthquakes since 1899 which have originated in districts marked **A**, **B**, **C**, &c., are indicated.

[1] Discourse delivered at the Royal Institution on Friday, March 20, by Prof. J. Milne, F.R.S.

selves upon public attention, a desire to investigate is furnished by the earth itself. Chili is now arranging to have a system of observing stations. Jamaica is speaking about the same, whilst the United States are extending what they now possess. Three recent earthquakes have awakened three different Governments to the fact that, although schoolmasters may not flog their children, nature is not always as indulgent to its people. Japan, in addition to establishing stations in Formosa, Saghalin, China, and Korea, has already more than 1000 observing stations, 120 of which have instruments for recording local shocks. For seismological investigations the Government of that country annually allocates 1000*l.* to 5000*l.*, and this is outside expenditure in connection with the chair of seismology, and concomitant with investigations of earthquakes in foreign countries. During the last ten or twelve years Japan has issued about seventy quarto volumes bearing upon seismological investigations. Russia has a series of well-equipped stations within its borders. For very many years Italy has given great attention to the movements of the ground. These are recorded at several hundreds of stations, 160 of which are provided with instruments. Austria, Germany, and many other States are also devoting great attention particularly to the collection of earthquake statistics. I fail, however, to see that these statistics, which are necessarily imperfect, will pass beyond the borderland of local interest. So far as I am aware, all foreign stations are subsidised by their respective Governments. Great Britain enjoys the cooperation of forty-five stations provided with similar instruments, which are distributed fairly evenly over the four quarters of the world. The names and positions of these stations are shown upon the accompanying map (Fig. 1). The home stations are supported by the British Association, the Royal Society, the *Daily Mail*, Mr. M. H. Gray, and other private individuals. So far as the recording of world-shaking earthquakes is concerned, I believe the British cooperation to be, at the present time, quite equal to a combination of the stations of all other countries. The last outcome in connection with observational seismology has been the establishment of an International Seismological Association. The central bureau is in Strassburg, its president is Prof. A. Schuster, and its general meetings take place once every four years. I am not aware that France has formally announced its adherence. The British Government, by subscribing 160*l.* a year to the central bureau, has accepted a shelter from a Continental ægis. For nearly fifty years the British Association has encouraged seismological research, but whatever prestige it may have gained, together with its attendant commercial and other advantages, these are passing under a new *régime* across the Channel.

A Government of a country does not wish to seek abroad for an explanation why telegraphic messages have ceased to flow. To confirm, extend, or disprove a cablegram, a Government, a business house, or the public of a given country would like to obtain information within its own boundaries. When a country or a colony finds itself cut off from the outside world in consequence of cable interruption, that country or colony, together with other countries, would like to have a ready means of saying whether the interruption had been due to submarine disturbances or to some other operation, as, for example, war. Those who lay cables would prefer to have information as to positions of suboceanic sites of seismic activity from records made in their own country rather than those which had been made abroad. When after great convulsions cities have to be rebuilt, and there are many at the present moment, it is natural that information bearing upon reconstruction to reduce earthquake effects would be sought for at the world's central office, and those who supply information would in all probability supply engineers and material. Insurance companies who wish to apportion rates to risks when insuring against earthquake effects might also think it best to seek their information at a central bureau. After an earthquake, when such

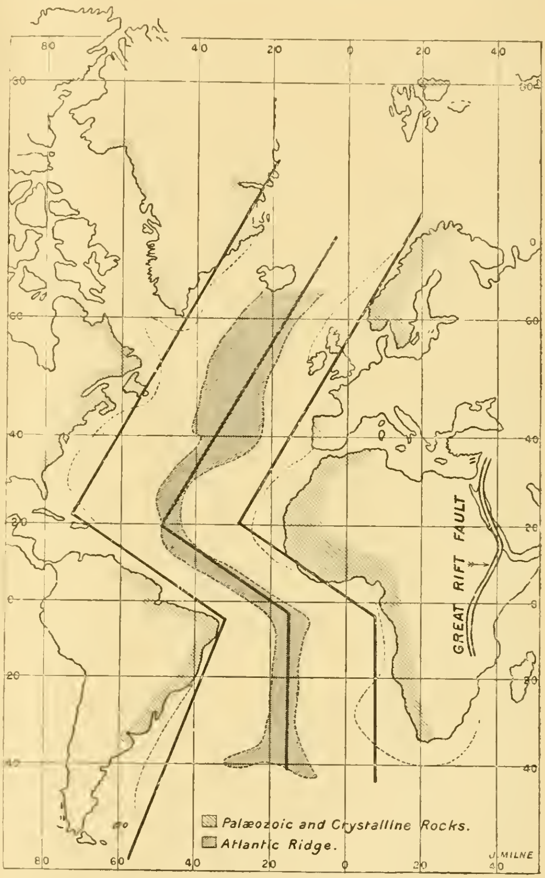

Fig. 2.—The folds and probable direction of fault lines in the Atlantic.

companies are called upon to pay the insured, many difficult questions arise which can only be answered by seismograms. Millions of pounds sterling are dependent upon these records, and it is therefore important that the same should be readily accessible. A seismogram, which travels quicker than a telegram, may affect the Stock Exchange. We no more require a central bureau to discuss applied seismology than we do to discuss the construction of torpedoes or flying machines.

A discovery which, during the last few years, has done much to popularise seismology is the fact that a very large earthquake originating in any one part of the world may be recorded in any other portion of the same. This means that the opportunity for carrying on seismological research is not a monopoly enjoyed only by those who reside in earthquake countries. Although only a few persons in Great Britain have been privileged to feel one of its home-made tremors, every one of its inhabitants is very many times per year moved by earthquakes. Back and forth motion of the ground is performed too slowly for us to feel, while, if there is a movement like the swell upon an ocean, the undulations are too long and flat for us to see.

Waves start out from their epicentral area, which is a district that has been fissured and shattered by the formation or extension of large faults in all directions. Observation, however, shows that these waves are propagated farthest in one particular direction. For example, the chief movement following the San Francisco earthquake, which originated from fault lines running parallel to the coast of California, was much more marked in countries lying to the east or west of California than in countries lying towards the south. England and Japan obtained large records of the disturbance, while in Argentina the records were extremely small. In the case of the Jamaica earthquake, where the lines of origin ran east and west, the phenomenon was reversed. Toronto received a large quantity of motion, and England a very little. Another peculiarity of this phase of earthquake motion is that it may be propagated in one direction round the world to a greater distance than in an opposite direction. The suggestion is that the initial impulse was delivered in the direction towards which motion was propagated farthest. If for illustration we assume that the slip on a fault line has been downwards towards the east, then the motion would travel towards the east farther than it would towards the west. That which happens corresponds to what we see if we dip the blade of a spade in water and suddenly push the blade in some particular direction. The water waves thus created travel farthest in the direction of the impulse.

Another curious phenomenon connected with the large waves of certain earthquakes is that they can pass their equatorial or quadrantal region unobserved. They may be very marked for 1000 miles round their origin, and recordable, but much reduced in size, about their antipodes, but not recordable in between. For example, an earthquake originating near New Zealand may be recorded in that country, but not in India, Egypt, West Asia, or east of Europe, though in Britain it may make itself evident by the thickening of a photographic trace. The phenomenon may be compared to a water wave running down an expanding estuary. At the mouth of such an estuary it may have become so flat that it is no longer recognisable. Should it, however, run up a second estuary, we can imagine concentration taking place, so that near the top of the second estuary it would eventually become instrumentally recordable. In these antipodean survivors we see the final efforts of a dying earthquake. It is only occasionally that the precursors and the followers of these large waves have sufficient energy to reach their antipodes. They die *en route*. The former, notwithstanding their comparative feebleness, because they throw considerable light upon the internal constitution of our earth, are the most interesting feature in a seismogram. They are of two kinds, a first phase and a second phase. These are usually regarded as compressional and distortional modes of wave propagation. The large waves are probably quasi-elastic gravitational waves, something like an ocean swell, which travel round the world with a constant velocity of about 3 km. per sec., causing continental surfaces to rise and fall like huge rafts upon a heaving ocean. The precursors behave quite differently. Phase i. may commence with a velocity of 3 km. or 4 km. per sec., but as the length of the wave-path increases this quickly rises to 10 km., and thence to a maximum of 12 km. per sec. These paths are assumed to be along chords, and so long as these chords do not lie at a depth greater than twenty or thirty miles, the speeds are such as we should expect to find in materials like those composing the outer surface of our earth. These waves, therefore, indicate a thickness for the earth's crust comparable to thicknesses which have been arrived at by other lines of argument. The rapid approximation to uniform speed suggests that below a depth of twenty or thirty miles we enter a nucleus which is very rigid and fairly homogeneous. The second phase waves, up to a distance of 120° from their origin, have a speed of about 6 km. per sec. For longer paths, Mr. R. D. Oldham points out that their velocity is apparently suddenly reduced. He seeks for an explanation of this by postulating the existence of a central core in the earth where waves are retarded and refracted, with the result that the wave-paths no longer follow chords. These waves may, therefore, emerge on the surface of the earth after having passed relatively to their starting point on the farther side of its centre. Whether we do or do not accept this central core, it is clear that the new seismology has added in a very marked manner to the knowledge we formerly possessed respecting the interior of the globe upon which we live. Our ideas respecting its homogeneity and its great rigidity have been changed by seismological investigations.

When large earth waves sweep round the world, it is found that at particular stations magnetic and electrometer needles have been disturbed. Magnetometers, when installed at Toronto, do not appear to have responded to the slow undulations of the earth's surface, while the same instruments, after being removed to Agincourt, only ten miles distant, are now affected. The inference from this and observations in other parts of the world is that the movements, rather than being caused mechanically, may be due to the disturbance of some adjacent magnetic magma. If this is the case, then at particular stations where the movements due to teleseisms correspond with unusual disturbance of magnetic needles, inasmuch as a magnetic magma is denser than common rock, at these stations the value for g should be higher than that which would be anticipated. For certain stations this appears to be the case.

Another series of investigations which may widen our knowledge respecting conditions and operations beneath our feet are based upon the light effects which have been so frequently observed at the time of large earthquakes. Accounts of luminosity in the heavens and on hills as accompaniments to large earthquakes are common. At the time of the Valparaiso earthquake, August 17, 1906, the attention of very many people was attracted to lights which appeared upon the hills. Captain Taylor, of the R.M.S. *Orissa*, compared these to chain lightning, which extended as far as the eye could reach. An acquaintance of mine, Mr. G. E. Naylor, of Valparaiso, told me that he saw the lights repeatedly, and they took place immediately before a shock, there being only a fraction of a second of time between the two. He described them as having a bluish tinge; to others, however, they appeared yellowish. An ordinary explanation for these appearances is that they are due to the rubbing together of rock surfaces or the discharge of frictionally produced electricity. These observations suggest that with a megaseismic collapse, not only do we get mechanical disturbances which pass through and over the surface of the world, but that part of the initial energy at the origin is converted into some other form of energy, which possibly may find a response at very distant places. This latter transmission would, however, take place with a velocity comparable with that of light. If anything of this sort has a real existence, seismologists may hope to record earthquakes at the moment they take place. This consideration, and the observation that from time to time a quarry in the Isle of Wight, known as Pan Chalk Pit, appeared to me to be luminous, suggested the possibility of hypogenic activities giving evidence of their existence in the form of light. Pan Pit faces north, and in winter it is not reached by the sun. Its glowings apparently rise and fall in intensity, and are most noticeable after a dull, damp day. The experiments I made were as follows:—at the end of a chamber twenty yards from the mouth of a tunnel driven into the chalk, a hole about 2 feet square was excavated. Into this a box with a light-proof door was cemented. The back of the box, which touched the chalk, was made of zinc. In the zinc three holes of different sizes were made along a vertical line. A cylindrical drum, covered with bromide paper and driven by clockwork, was brought up to within one-eighth of an inch from these holes. A rim on the bottom part of the drum had a clearance given to it by cutting a horizontal slit in the zinc plate beneath the holes. Neither the drum, the paper, nor the rim touched the zinc plate or the chalk. The rate of movement of the paper was 90 mm. per day. A small electric lamp moved about outside the box produced no effect upon the paper inside. A self-recording thermometer and a hygrometer showed that the temperature and the moisture in the chamber were practically constant. A similar piece of apparatus was installed at a depth of 160 feet in the King Edward Mine, Camborne, Cornwall. These experiments were commenced at Pan Chalk Pit in February, 1903, and were continued for four months. They were taken up again in the middle of August, 1906, and lasted eight months. A sheet of paper on development was frequently quite clear, but at times it was partly or entirely marked with dark bands, black lines, round black spots, or semi-circular spots along the lower edges. At Shide the dark bands have not been numerous, but they occurred on nearly all the sheets from Camborne. In certain cases we appear to have three bands, the positions of which apparently coincide with the three holes in the zinc plate. In some of these bands there are hard black lines broken along their length and made up of black spots.

The black spots vary in diameter from a fraction of a millimetre to 8 millimetres. In the centres of some of these there is a small white or brownish spot. As pointed out by Mr. W. H. Bullock, of Newport, these closely resemble spots which can be produced on bromide paper by a tiny electric spark. During a week we may have either no spots, one spot, or a hundred spots. The semi-circular spots, which I have called singeings, are found on the lower edge of the paper where the brass cylinder joins the aluminium rim. There may be two or three of these per week, whilst at other times they occur at intervals of about half an hour. As only ten black spots occurred at the time of large earthquakes, we can only regard these as coincidences. Neither dark bands, spots, nor singeings appear to be connected, beyond what I have mentioned, with any particular meteorological conditions. Neither is there any reason for supposing that these effects are due to radio-activity. If a piece of bromide paper is sealed up in a black envelope, and another piece is placed in a black envelope which has a thin glass window, and these are laid on a surface of chalk, the glass window touching the same, say, for a period of several days, it was found after development that one piece of paper showed the image of the window, whilst the other had only stains, which might be attributed to dampness. With the object of determining whether micro-organisms played any part in the phenomena observed, my friend Dr. R. C. Brown, of Parkhurst, has made cultures from scrapings from the surface of the chalk before which my cylinder was exposed. Cultures were also made from scrapings taken from the open chalk. Micro-organisms were found in both. These have been exposed to a moving photographic surface similar to that used in the pit, but they gave no evidence of luminosity. The conclusion for the present is that the luminosity occasionally seen at Pan Pit may result from a very feeble brush or glow-like electrical discharge. If this be the case, it would also account for the bands on the photographic paper, the other markings being due to minute sparks. Moreover, if this is so, and we assume that silent electrical adjustments have a real existence, it is difficult to escape the conclusion that these must have an effect on what we call "climate," and hence upon everything that lives upon the surface of the globe. We have many instances of places only separated by a few miles, as, for example, Newport and Sandown in the Isle of Wight, or Bournemouth and Swanage, the climates of which are said to be very different. The thermometer, barometer, and hygrometer do not explain these differences; the only apparent difference between such places appears to be one of soil and the moisture in the same. Inasmuch as we find great differences in the emanations from granite, clayslate, and chalk, it would seem extremely probable that we should find differences in the relative electrical conditions of different soils.

To determine whether earthquakes are increasing or decreasing, it is not only necessary to turn over the pages of many histories, but also to consult the geologist. Jules Verne might perhaps have dipped deeper into time than a geologist or physicist, and drawn pictures of the reactionary effect which might accompany the collision of one world with another, bombardments of great meteorites, a click that announced the birth of our moon, the sudden yieldings of a primitive crust covering an ocean of molten rock, and of many other things that float through the brains of those who entertain us with the results of their imaginations. The greater number of earthquakes, and certainly all that are large, originate from the formation or extension of faults. These operations have been most marked when secular movement amongst rock masses is in progress, as, for example, during the growth of mountains. Should this be in operation near large bodies of waters, volcanoes and earthquakes are found in the same region. If, therefore, we wish to know when earthquake frequency and intensity was at a maximum, we turn to those periods in geological history when mountain ranges were built, when volcanic activity was pronounced, and when great faults were made. The first of these periods would be coincident with the creation of the Urals, the Grampians, and other ancient mountain ranges. This took place in Palæozoic times. Another period of mountain formation was in early Tertiary times, when the Himalayas and the Alps were slowly, but intermittently, brought into existence. In both these periods volcanic activity was pronounced, and beds of coal were formed When the crust of the earth was crumbling, mountains grew spasmodically, faults gave rise to earthquakes, volcanic forces found their vents, and conditions existed which gave rise to the accumulation of materials to form coal.

In quite recent times, many large faults have been created at the time of earthquakes. In 1891 the Mino-Owori fault was created in central Japan, 10,000 people lost their lives, and 128,000 buildings were destroyed. On April 18, 1906, San Francisco and other towns were ruined by movements along a fault which can be traced for a distance of 200 miles. One estimate suggests that it may be 400 miles in length. The largest fault which has been created in extremely recent geological times seems to be the Great Rift Valley of Central Africa. We are told that it commences in the south near Lake Nyassa, passes northward through Tanganyika, the great lakes of Central Africa, branches north-eastward towards Lake Rudolph, up the Red Sea, through Akaba to the Jordan Valley, a distance of 4000 miles. In certain districts it shows itself as a strip of country let down between two parallel fractures. It has been compared to the cracks which can be seen in the moon. If we accept this as a reality, we have only to imagine this Great Rift fault to be extended as regards its length and breadth, and we have a trough in many respects similar to that which holds, not thirty lakes, but the waters of the Atlantic. If we look at the Atlantic, either as shown on a Mercator's chart or on a globe, we notice the complementary resemblances between the contours of the old world and the new. Then, if we draw a line down the submerged backbone of this ocean, we see that this is the reflection of the European and North African western coast line (Fig. 2). Next, if these old-world contours are pushed westwards towards this median line, while the contours of the two Americas are pushed eastwards, we find that one approximately fits in with the other. The fit becomes more marked if we bring together the submerged edges of continental shelves or lines representing the general direction of the opposing coast lines. Another point not to be overlooked is that the rock formations on the west side of the Atlantic are very similar to those in the same latitude on the eastern side. It is as if we had a street with the shops on one side of it exactly similar to those on the other side. In northern Spitsbergen, and again in Greenland, we find a large development of crystalline and Palæozoic rocks, and these continue southwards through Labrador, Newfoundland, Maine, and then through the Alleghanies. They again appear in Brazil as far south as Monte Video. On the eastern frontier of the Atlantic, from Scandinavia through Scotland and Ireland, Wales, western France, and western Africa as far as Cape Town, we see a replica of the two Americas. The Atlantic is a canal, the opposing banks which are symmetrical in form and geological material. An idea, but one which is not very probable, which this suggests is that at some very early period in the world's history two Rift Valleys, one parallel to the eastern submerged backbone of the Atlantic, and the other parallel to its western frontier, were formed. Separation subsequently took place along these faults, and these, under the influence of surface and underground activities, have continually increased. If, then, the Atlantic had an origin due to Rift Valley formation rather than to folding or contraction, then the greatest earthquake in the history of the world may have taken place when east became east and west became west, and our world was cracked from pole to pole.

Just as the frequency of earthquakes has fluctuated during geological time, similar fluctuations have taken place during historical time. In central Japan earthquake frequency had a maximum in the ninth century, and since that time, century after century, violent shakings have become less and less. In January, 1844, at Comrie, in Perthshire, twelve earthquakes were recorded. Now there may not be one per annum. At the present time, in consequence of the destruction of several large cities, the popular idea is that earthquakes are on the increase. As a matter of fact, the world as an earthquake-producing machine has a steady output. On the average, about sixty very large disturbances are recorded, and the greater number of these, fortunately for humanity, have their origins beneath ocean beds or in sparsely inhabited regions. In addition to these megaseismic efforts, it is estimated that about 30,000 small earthquakes take place per year, England's annual contribution to this number being about half a dozen. If we had records like these extending backwards through several ages, we might readily estimate the time when seismic activity would cease. When this ceases, rock folding will also cease, and the degrading processes resulting in surface denudation will be unopposed. Bit by bit land areas will be reduced to sea-level, and the habitable surfaces, as we now see them, will be no more.

An interesting observation bearing upon megaseismic frequency is found in the analyses of registers relating to the North Pacific. On the west side of that ocean seismic frequency is greatest in the summer, while on the east side it is greatest in the winter. An explanation for this is sought for in the seasonal alteration in the flow of ocean currents, the oscillations of sea-level, and changes in the direction of barometric gradients, which phenomena are interrelated. In summer, off the coast of Japan, the Black Stream runs perhaps 500 miles farther north than it does in winter, while Dr. Omori points out that, although barometric pressure may on the Japan side of the Pacific be low in summer, this decrease in load is more than compensated for by the increased height of ocean-level; the inference is that the pressure on the ocean bed is greater in summer than in winter, and this is the time of the greatest seismic frequency.

Another factor bearing upon earthquake frequency may perhaps be found in the change in position of the earth's pole. A chart showing the path of the earth's north pole indicates that its movements are by no means always uniform. Although at times these may be nearly circular, it also shows sharp changes in the direction of its motion. It has even been retrograde. If on a chart showing these pole displacements we mark the time positions of world-shaking earthquakes, it is seen that these are grouped round the sharper bends of the pole-path. World-shaking earthquakes have, in fact, been most numerous when the pole-path has deviated farthest from its mean position. The observations embrace a period of thirteen years, during which 750 large earthquakes were recorded. Although these earthquakes represent large mass displacements, it is not supposed that they would be sufficient to produce the observed pole movement. The pole movement, however, may have given relief to seismic strain, or both effects may arise from some common cause.

Mass displacements accompanying a megaseismic effort must, however, tend to produce some pole displacement, and thus set up strains. From time to time these should find relief in the weaker portions of the earth's crust. Large earthquakes should therefore occur in pairs, triplets, or in groups, after which we should expect a period of quiescence. This idea is due to the Rev. H. V. Gill, S.J. I find that the British Association registers lend considerable support to the hypothesis. The author of the idea, however, goes a step farther, and points out that if all matter within our globe or that which constitutes its crust was equally free to move, the secondary displacement should, with regard to the earth's axis of rotation, be symmetrically located in regard to the position of the primary disturbance. Out of 126 large earthquakes recorded between 1899 and 1905, I find that twenty of these appear as ten pairs, the members of each pair being in symmetrically located districts. This may or may not have been a matter of chance. The observation that a marked relief of seismic strain in one part of the world has frequently been followed by a smaller relief in some distant region also suggests the idea that earthquake begets earthquake. In my own mind the relationship of earthquake to earthquake has been fairly well demonstrated, but to place the matter beyond the borderland of doubt large earthquakes must be compared in regard to space and time with their kind, with small earthquakes, and with volcanic eruptions. All the volcanic eruptions of the West Indies have closely followed on the heels of great earthquakes which have originated, not in the West Indies, but on the neighbouring coasts of Central and South America. One general inference is that the faultings and freckles on the face of our world should have a distribution as symmetrically disposed as wrinkles are on the face of an elderly person.

Already when speaking about the length of faults which have been created at the time of large earthquakes, we have indicated at least one dimension of the earth block which has been disturbed. For instance, the earth block which was disturbed at the time of the San Francisco earthquake may have had a length of 400 miles; its breadth might be determined by the width of the country which had been broken up by branching and parallel faults. Harboe suggests that in a meizoseismic area hidden faults may be assumed to exist along lines drawn half-way between pairs of groups of places which have been struck at about the same time. R. D. Oldham attributes the Assam earthquake of 1897 to the sudden shifting of 10,000 square miles of territory over a thrust plain. The molar displacement determined by the method suggested by Harboe would be that 50,000 square miles had been disturbed. The fact that so many earthquakes shake the whole world, or will agitate an ocean like the Pacific for many hours, indicates that the initial impulse must have been delivered over a large area, or that sudden alterations have taken place in the contour of ocean beds. With regard to the magnitude of the latter changes, we have learnt much from cable engineers, who have given us many instances where cables lying in parallel lines, ten or fifteen miles apart, have been simultaneously interrupted, and ocean depths over considerable areas have been increased. The depth to which these large faults extend is a matter of inference. We may well imagine them as passing through the whole thickness of the earth's crust, and the displaced block falling to give up its energy to a nucleus which we know transmits undulatory movements all over our globe with uniform velocity. If we take this crust to be thirty miles in thickness, then with Harboe's area for the superficial disturbance, the block which was disturbed at the time of the Assam earthquake would be represented by $1\frac{1}{2}$ million cubic miles.

Following the initial impulse of a large earthquake, it frequently happens a few minutes later that a second severe movement is felt. In Japan this is popularly spoken of as the Yuri Kaishi, or the return shaking. This may be a second yielding within the disturbed district, but from its resemblance to the main shock it suggests an echo-like reflection. If we drop a bullet into a large tub of water, waves travel outwards to the sides of the tub, where they are reflected, and converge at the centre from which they set out. With the earthquake waves, the reflecting surface may be represented by the roots of mountain ranges. If these are at varying distances from the origin, the reflected waves would give rise to complications at the focus. The transmitting medium for these waves I take to be the more or less homogeneous material which lies beneath the heterogeneous crust of our world. This transmits large waves with a constant velocity. In the case of the Californian earthquake, which originated on fault lines on the western side of that country, I should imagine the reflecting surface to be the Sierras, 200 miles distant. The wave group would travel to these mountains and back in about four minutes, and this is approximately the time interval between the two first large wave groups in seismograms I have of that disturbance. After the first echo or echoes, an earthquake usually dies out as a series of surgings which frequently have a striking similarity to each other. One explanation of these rhythmical recurring groups is that they simply represent times when the movement of the ground has synchronised with the natural period of the recording instrument. Although the terminal vibrations seen on a seismogram may be attributed to this cause, it does not exclude the idea that rhythmical beats at an origin may result in rhythmical responses at a distance.

Side-issues of seismology are quite as instructive as the information we derive from the records of earthquakes. We have already referred to light effects which accompany large earthquakes. This, as we have seen, led up to investigations connected with micro-organisms. A long series of experiments, which commenced in Japan and were continued in the Isle of Wight, involved a series of investigations bearing upon the transpiration of plants. The fundamental object of these experiments was to determine whether valleys always retained the same form. Did they open and shut? To answer the question I set up on the two sides of a valley horizontal pendulums identical with those which are used to record teleseismic motion. These instruments, which are by photographic means self-recording, are exceedingly sensitive to small changes in level. What I found was that on fine days the booms of these instruments moved in opposite directions, each away from the bed of the valley. At night the motions were reversed, and the booms moved towards each other, that is, towards the bottom of the valley. Several instruments were employed, and the records were confirmed by the movements of the bubbles of sensitive levels. During the day the records indicated that the sides of the valley opened, and at night they closed. The two valleys I worked upon behaved like ordinary flowers, they opened when the sun was shining and closed at night. The best explanation I can offer is that the phenomenon is largely dependent upon the transpiration of plants. This is marked during the day, but not at night. On a bright day a sunflower or a cabbage may discharge 2 lb. of aqueous vapour. A square yard of grass will give off 10 lb. or 12 lb. The result of this is that during the day underground drainage has not received its full supply of water to load the bottom of the valley. At night time, when plants' transpiration is reduced, subsurface drainage is increased, and the load at the bottom of the valley is also increased. Therefore, at night the bottom of a valley, in consequence of its increased water load, is depressed, and this is accompanied by a closing of its sides. During the day the load runs off, and the valley opens. This may also explain why soak wells in valleys and streams carry less water during the day than they do at night, and at the same time it suggests that the side of a valley is a bad place for an observatory. Every day as the world turns before the sun, lamp-posts and tall structures salute the same, whilst many valleys open. At night time these movements are reversed.

One phenomenon which accompanies all large earthquakes, which, however, has never yet received the attention it deserves, is the influence which great disasters have exercised upon the emotions. Immediately after the Kingston earthquake, we read of the dazed and almost insane condition of the people. Many were affected with an outburst of religious ecstasy, thinking the last day had come. The negro population camped on the racecourse, and spent their time in singing hymns. Somewhat similar scenes took place in Chili; men and women ran hither and thither, mad with terror and devoid of reason. Amid shrieks and sobs, and the wailing of a multitude, an "Ora pro Nobis" or a "Pater Noster" might now and then be heard. In early civilisations underground thunderings have so far excited the imagination that subterranean monsters or personages have been conjured into existence, and these in many instances have played a part in primitive religions. At the time of an earthquake in Japan, the children are told that the shaking is due to the movement of a fish which is buried beneath their country, and in Japan we find references to this fish in the pictorial art, glyptic art, literature, and everyday conversation, all of which would be unintelligible if we did not know the story of the earthquake fish. In other countries the subterranean creature will be a pig, a tortoise, an elephant, or some other animal. The most interesting myths, however, relate to underground personages. The forty-five Grecian Titans, who were of gigantic stature and of proportionate strength, were confined in the bowels of the earth. According to the poets, the flames of Etna proceeded from the breath of Enceladus, and when he turned his weary side the whole island of Sicily was shaken to its foundations. Neptune was not only a god of the oceans, rivers, and fountains, but with a blow of his trident he could create earthquakes at pleasure. The worship of Neptune was established in almost every part of the Grecian world. The Livians, in particular, venerated him, and looked upon him as the first and greatest of the gods. The Palici were born in the bowels of the earth, and were worshipped with great ceremonies by the Sicilians. In a superstitious age the altars of the Palici were stained with the blood of human sacrifices. In Roman mythology, two very familiar deities are Pluto and Vulcan. These and a host of other deities, the outcome of imagination, excited by displays of seismic and volcanic activity, we meet with every day in picture galleries, in museums, in literature, and in our daily papers. The fact that we are enjoined not to make any graven image of that which is in the earth beneath suggests that in the time of Moses a certain form of worship called for some correction. Over and above adding a clause to the decalogue, large earthquakes have in very many ways affected religions. After the earthquake which shook England on April 6, 1580, the then Archbishop of Canterbury drew up a form of prayer which was approved by the Privy Council, and ordered by them to be read in all dioceses in the kingdom. In the world there are many instances of religious services being held on the anniversary of an earthquake, it being regarded as an exhibition of God's vengeance upon a wicked people. The belief that earthquakes are signs or warnings owes its origin in part to prophecies in the Bible, where, for example, we read that "there shall be famines and pestilences and earthquakes" as portending future calamities. Earthquakes have led to the abolition of oppressive taxation, the abolition of masquerades, the closing of theatres, and even to the alteration in fashions. A New England paper, of 1727, tells us that "a considerable town in this province has been so far awakened by the awful providence in the earthquake that the women have generally laid aside their hooped petticoats."

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

The success of the Children's Museum in Bedford Park, Brooklyn, as a factor in education forms the subject of an article by Miss A. B. Gallup in the April number of the *Popular Science Monthly*. At its commencement in 1899 the museum comprised only two rooms, containing little more than a few insects, shells, and stuffed birds. The eagerness with which these were visited by children soon led, however, to extension, and twelve exhibition rooms, furnished with specimens, models, and pictures illustrative of nearly every subject interesting to childhood, are now open to the public. These collections illustrate the chief branches of natural history, geography, art, and the history of the United States. Young people are encouraged to think and act for themselves, one result being the installation of a wireless telegraph apparatus by a party of boy visitors, some of the members of which subsequently obtained appointments as wireless telegraphists. The institution seems worthy of imitation in this country.

Dr. W. E. Hoyle, director of the Manchester Museum, speaking on children's museums at a museum conference held at Preston on April 11, remarked, in reference to the American institutions of this kind, that in the one at Brooklyn the following aims have been kept in view:—(1) to employ objects attractive and interesting to children, and at the same time helpful to teachers in every branch of nature-study; (2) to secure an arrangement at once pleasing to the eye, expressive of fundamental truth; (3) to avoid confusion from the use of too many specimens, and the consequent close crowding in cases; (4) to label with brief descriptions, expressed in simple language and printed in clear, legible type. The keeping of live animals is an important branch of the work, and a source of endless interest to the young visitors. A striking exhibit is a series of historic models illustrating the six chief types of people who formed permanent settlements in North America.

A SCHEME is under consideration for the establishment of a university in Hong Kong. Mr. Mody has placed at the disposal of Sir Frederick Lugard, the Governor of Hong Kong, a sum of 15,000*l.* for the purpose. At a recent meeting, according to Reuter's agent, Sir Frederick Lugard said he is willing to recommend the Government to provide a site, but cannot go further than that in view of the liabilities of the Government. He believes that if Hong Kong could establish a university with facilities equal or superior to those at Tokio, it would attract a large number of the wealthy Chinese students who now go to Japan, America, and Europe, and would increase the prestige and influence of Great Britain throughout the Chinese Empire. To provide an adequate endowment for even the modest beginning proposed, a sum of not much less than 100,000*l.* will be required.

THE treasurer of University College, Bristol, has received a donation of 550*l.* from the University College Colston Society for general purposes, and a grant of 50*l.* from the Board of Agriculture to enable the department of economic biology to carry on its investigations on the effect of electricity on plants. The County Council of Somerset has approved a scheme of research in connection with Cheddar cheese-making, and has authorised an expenditure of 200*l.* for the first year on this work. The Gloucestershire County Council has passed the following resolution in support of the movement for the establishment of a university in Bristol:—"That this council approves of the scheme for promoting the Bristol University, and will consider what, if any, financial assistance they can accord to it when the scheme is more fully developed."

IN an address at the graduation ceremony of the University of Edinburgh on April 10, Prof. Chrystal referred to reforms in secondary and university education in Scotland. In 1886 Prof. Chrystal placed before the Scotch Education Department a scheme for a general leaving certificate examination for schools. The department approved the suggestion, and Sir Henry Craik carried out the scheme in detail with very satisfactory results. Prof. Chrystal now proposes to make the Scotch Leaving Certificate examination the normal course of entrance to each university, and to abolish the university preliminary examination. Already the leaving certificate examination is accepted by Scotch universities in lieu of the preliminary examination for the subjects it covers, and it is desirable to make the examination a complete passport to the universities. Part of Prof. Chrystal's original proposal to the Scotch Education Department regarding the leaving certificate was the creation of a National Board of Surveillance, on which the department, the schools, the universities, and certain other public bodies were to be represented. His object was to avoid the necessity for the institution of a university preliminary examination. A generally accepted standard for entrance to the University is an inevitable element in university reform; but the administration of a general leaving examination for schools is not the proper business of the universities. No doubt one of the functions of a leaving certificate should be to qualify for an academic course, but it has many other functions besides, and all that the universities should claim is a share in the surveillance of the leaving certificate in so far as it concerns them. Prof. Chrystal went on to say that the advance of secondary education, in particular the opening of junior student centres all over Scotland, is rapidly preparing the way, if it has not already prepared it, for carrying out the ideal of the Universities' Commissioners. "I turn, therefore, with renewed hope and renewed insistence to the men of wisdom and of influence, who hold in their hands our educational destiny, and ask them to consider once more my old proposal for a National Board, which shall regulate the schools' leaving certificate, so that it shall become the normal portal of admission to the universities, and render the present preliminary examination and the present Joint Board and all its works unnecessary. This reform must, of course, be taken up as a national affair. It is no matter of the autonomy of the universities. It concerns the welfare and good government of all the secondary schools of the country; also, I may say, the relation of our standards of secondary education to similar standards all over the British Empire."

SOCIETIES AND ACADEMIES.

LONDON.

Linnean Society, April 2.—Lieut.-Colonel Prain, F.R.S., vice-president, in the chair.—The anatomy of some sapotaceous seedlings: Winifred **Smith.** The seedlings of the Sapotaceæ are remarkable on account of (1) their exceptional mode of transition from root to stem; (2) the lack of continuity in the different parts of the vascular system; (3) their tendency to a geophilous habit. To Dangeard's axiom:—"Le plan vertical médian des cotylédons correspond toujours à un faisceau vasculaire de la racine," the sole exceptions vouched for are trees, and occur in the Sapotaceæ and in two genera of the Fagaceæ.—Notes on some sponges recently collected in Scotland: Dr. N. **Annandale.**

Society of Chemical Industry (London Section), April 6.—Dr. Lewkowitsch in the chair.—Considerations affecting the "strength" of wheat flours: Julian L. **Baker** and H. F. E. **Hulton.** It is improbable that any one chemical or physical determination can be used for determining the "strength" of flours, as the generally accepted definition includes two distinct qualities, viz. size and shape of loaf. It is recommended that bakers should apportion marks independently for size and shape. A proteolytic enzyme capable of degrading the gluten, and so influencing the character of the loaf, appears to be absent, but there is a small quantity of an erepsin. Yeast enzymes can effect partial proteolysis of gluten. Aqueous flour extracts depart from Kjeldahl's law of proportionality. Maltose is the sole sugar formed during doughing. Flours on keeping display changes in enzymic activity. Doughs have a greater diastatic activity than either the aqueous extract of the flour or the flour itself, and this activity varies inversely with the amount of water present. Flours contain a starch-liquefying enzyme, and this enzyme is closely connected with gas production. The formation of gluten from gliadin and glutenin is independent of enzymic activity, and is probably only a hydration phenomenon. Gliadin separated from flour was re-combined with the residual gluten and starch, and the gluten, in a weakened condition, was recovered by washing out. The diastatic activity of gluten is confirmed, and shown to reside in the glutenin moiety.—The occurrence of cyanogenetic glucosides in feeding stuffs: T. A. **Henry** and S. J. M. **Auld.** In association with Prof. Dunstan, the authors have investigated a number of plants which yield prussic acid when in contact with water, and show that the prussic acid is formed by the interaction of a glucoside and an enzyme which decomposes it, liberating prussic acid. Several of these plants are employed as feeding stuffs, notably Java beans, and it is to this liberation of prussic acid that the numerous cases of poisoning of cattle by these beans are due. Linseed cake also contains a cyanogenetic glucoside, but the high temperature to which the cake is heated in the course of manufacture destroys the enzyme originally present in the seed. The seed of the Para rubber tree, sometimes used for feeding purposes in the tropics, also yields small quantities of prussic acid.—Note on murexide as a quondam dye-stuff and printing colour: Watson **Smith.** The author exhibited a specimen of commercial murexide manufactured about the year 1861, and also a specimen of calico printed with it, which still exhibited the characteristic bright rose tint.

Zoological Society, April 7.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—A monograph of the chiropteran genera Uroderma, Enchisthenes, and Artibeus: Dr. Knud **Andersen**. The work was based on an examination of the material in the British and United States National Museums, and contained a discussion of the homologies of the teeth and molar cusps in stenodermatous bats, a full description of the genera mentioned in the title, their species and subspecies, with a discussion of their probable inter-relations, and, finally, remarks on the bearing of the present geographical distribution of the species and subspecies on a former connection of the West Indian Islands with continental America.—Certain points in the structure of the cervical vertebræ of the okapi and giraffe: Sir E. Ray **Lankester**. The paper dealt chiefly with the posterior cervical and anterior dorsal vertebræ, the author concluding that where the okapi differed in these respects from the giraffe, it resembled other, and particularly bovine, Artiodactyles. It also included a discussion of the zygapophysial articulations of the cervical and dorsal vertebræ in the giraffe, okapi, and some other mammals.—Some Australian spiders: H. R. **Hogg**. The author gave further notes on the type species of the genus Missulena, hitherto known only by two specimens, a synopsis of the New Zealand genus Hexathele, with description of two new species, and a description of two new species of Dolomodes (Latreille) from Pitt Island of the Chatham Group, showing affinities with the only two species recorded from New Zealand.

Association of Economic Biologists, April 15.—Mr. A. E. Shipley, F.R.S., president, in the chair.—The pecking of fowls and their vision: E. **Steains**.—The inter-relation between entozoa and their hosts: A. E. **Shipley**. The author emphasised the important *rôle* internal parasites play in disease, the full weight of which had scarcely been realised as yet by the medical profession.—The predisposition of plants to parasitic diseases: H. T. **Güssow**.—The need of an organised inquiry into the feeding habits of British birds: C. Gordon **Hewitt**.—The possibility and danger of the introduction of the San José scale into Great Britain: Walter E. **Collinge**. The author had seen this scale alive on pears in this country, and twigs had been sent to him from Canada on which the insects had reproduced *by eggs*, and hatched out in his laboratory. In view of its spread northwards in Canada, he was of opinion that some stricter and more careful examination of imported nursery stock should without delay be organised and carried out in this country.—An important factor in the natural control of the large larch saw-fly, *Nematus erichsonii*: C. Gordon **Hewitt**. The factor referred to was the field vole (*Arvicola agrestis*), which extracts and eats the larvæ from the cocoons.

Royal Meteorological Society, April 15.—Dr. H. R. Mill, president, in the chair. Report on the phenological observations for 1907: E. **Mawley**. Wild plants came into blossom behind their usual dates throughout the whole of the flowering season. Such early immigrants as the swallow, cuckoo, and nightingale were also behind their average dates in reaching these islands. The only deficient farm crop, taking the country as a whole, was that of potatoes, most of the other crops being much over average. On the other hand, the yield of apples and pears, and particularly that of the former, was below average. There was also a deficient crop of strawberries, whereas plums, raspberries, currants, and gooseberries were over average.—Anticyclonic belt of the southern hemisphere: Colonel H. E. **Rawson**. From an examination of the daily synoptic charts of the northern hemisphere, the author was led to the conclusion that some of the permanent anticyclonic systems had a progressive seasonal movement which did not take place along the same latitude each year, but was in some years north and in others south of a mean latitude. This was noticeable in the years 1881–1891, and was capable of easy explanation if the belt itself in which they moved shifted its latitude from year to year in addition to migrating north and south with the sun. On analysing the isobaric charts of the southern hemisphere, the author found the seasonal migration of the anticyclonic belt to be accompanied by a real displacement of the action-centres within it to the northward and to the southward. It appears that there is a period of about 9·5 years between the greatest north and greatest south position of the anticyclonic belt over South Africa, the double oscillation thus taking nineteen years.

MANCHESTER.

Literary and Philosophical Society, February 11.—Prof. H. B. Dixon, F.R.S., president, in the chair.—A method of counting the number of α particles from radioactive matter: Prof. E. **Rutherford** and Dr. H. **Geiger**. The total number of α particles expelled per second from one gram of radium has been estimated (Rutherford, *Phil. Mag.*, August, 1905) by measuring experimentally the total positive charge carried by the α rays from a thin film of radium, on the assumption that each α particle has the same charge as an ion produced in gases. If the α particle is an atom of helium, it is necessary to assume that each α particle carries twice the ordinary ionic charge. The need of a method of directly counting the number of α particles shot out from radioactive matter has long been felt in order to determine with the minimum of assumption the charge carried by the α particle, and also the magnitude of other radio-active quantities. It can be calculated that an α particle expelled from radium produces about 80,000 ions in a gas before its ionising power is lost. With very sensitive apparatus, it should be just possible to detect the ionisation produced by a single α particle by electrical methods. The effect, however, would be small and difficult to measure with accuracy. In order to overcome this difficulty, the authors have employed a method which automatically increases the ionisation produced by an α particle several thousand times, and so makes the electrical effect easily observable with an ordinary electrometer. By counting at intervals the number of α particles expelled per minute, the authors have been able to obtain the curves of decay of activity of a plate coated with radium C or actinium B. The α particles from a constant source are shot out at irregular intervals. The time interval between the entrance of successive α particles has been observed over a long interval, and the results show that the distribution curve with time is similar in general shape to the probability curve of distribution of the velocity of molecules in a gas.

February 25.—Prof. H. B. Dixon, F.R.S., president, in the chair.—Notes on the greater horseshoe bat (*Rhinolophus ferrumequinum*) in captivity: T. A. **Coward**. The author, after giving a *résumé* of his previous notes on the habits of the greater horseshoe bat, showed that the conclusions he arrived at were confirmed by the behaviour of examples in captivity. The winter sleep of this species is not profound; the bats leave their retreats and feed in mild weather. Bats in captivity usually awoke every evening, but during the cold weather in January slept occasionally for one, two, or three nights. When awake they captured insects on the wing, and also, though unable to walk, dropped on the floor, seized beetles, and rose with them in their mouths without difficulty, proving how the bats are able to obtain flightless insects.—Cavity parenchyma and tyloses in ferns: Mary **McNicol**.

March 10.—Dr. W. E. Hoyle, vice-president, in the chair.—Report of the recent Foraminifera from the coast of the island of Delos (Grecian Archipelago), part v.: H. **Sidebottom**. The author restricted himself to a consideration of two forms (*Cymbalopora bulloides* and *Spirillina erecta*) as being of special interest, and described them in some detail.—The action of selenium and tellurium on arsine and stibine: F. **Jones**. In a previous paper it was shown that sulphur decomposes stibine in presence of light, and at a temperature of 100° C., but not in the dark. The action results in the formation of hydrogen sulphide and antimony trisulphide. It was also shown that the liberated hydrogen sulphide decomposes stibine with formation of antimony trisulphide and free hydrogen. A similar action was found to take place between sulphur and the two gases analogous to stibine, namely, arsine and phosphine. It appeared probable that selenium and tellurium would act on these gases in a similar manner to sulphur, and this has been found to be the case.

PARIS.

Academy of Sciences, April 13.—M. H. Becquerel in the chair.—The hovering of birds: Marcel **Deprez**. The author gives a simple mechanical explanation of the motionless hovering of birds, and has constructed an apparatus capable of imitating this flight.—The determination of longitude at sea by wireless telegraphy: E. **Guyou**. The views of the Bureau des Longitudes on this subject are stated, especial emphasis being laid on the necessity for international control.—The action of heat on the hydrates of lithia: M. **de Forcrand**. A description of the methods employed in obtaining LiOH, $LiOH,H_2O$, and Li_2O in a state of purity, together with some thermochemical data relating to these substances.—The adiabatic expansion of saturated fluids: E. **Mathias**.—An extremely sensitive electric hygroscope: J. **Pionchon**. A glass tube is silvered over the whole of its internal surface, and externally from one end to within about a centimetre of the other. The tube is placed in circuit with a mirror galvanometer and a battery of 100 volts. The resistance of the unsilvered portion of the tube varies with the amount of moisture present in the air, and forms a very sensitive hygroscope.—The magnetic changes in the spectrum of silicon fluoride observed parallel to the field: A. **Dufour**. It has been possible to separate the bands into three groups, in two of which the Zeeman effect is abnormal, or in a sense agrees with the existence of positive electrons.—The evaporation of water and solutions of sulphuric acid: P. **Vaillant**. A study of the effect of modifying some of the conditions in the gravimetric method described in a previous paper.—A new method of estimating phosphorus in organic materials: Isidore **Bay**. The substance is burnt in a bayonet tube with sodium carbonate and magnesia. Comparative results with this and the Carius method are given for trimethylphosphine and triethylphosphine.—The sulphur compounds of thorium: A. **Duboin**. By the action of sulphuretted hydrogen upon thorium chloride in presence of sodium chloride at a red heat, two new compounds were isolated. On analysis, these proved to be ThS_2 and ThOS.—Semicatalysis: the oxidation of hydrocarbons in air in presence of phosphorus: Albert **Colson**. Solutions of phosphorus in turpentine become oxidised in presence of air, and both the hydrocarbon and the phosphorus are oxidised simultaneously. The product $H_3PO_4(C_{10}H_{16}O_4)_2$ was isolated.—A simple reaction producing a disinfectant gas: G. **Carteret**. A mixture of bleaching powder and paraformaldehyde gives a vigorous evolution of gaseous formaldehyde when mixed with water.—The alloy of platinum with thallium: L. **Hackspill**. A description of the preparation and properties of the alloy TlPt.—Austenite: Ed. **Maurer**. Starting with a metal containing 2·2 per cent. of manganese, 1·94 per cent. of carbon, and 0·94 per cent. of silicon, heating for fifteen minutes at 1050° C., and tempering in ice-cold water, the author has been able to obtain pure austenite for the first time. Reproductions of photomicrographs are given showing pure austenite, the same after deformation and after tempering at 400° C. This steel is not magnetic, and is of relatively small hardness. It can be converted into martensite by mechanical treatment at the ordinary temperature, by re-heating to 400° C., or by immersion in liquid air.—Remarks on the communication of M. Maurer relating to austenite: H. **Le Chatelier**. The previous attempts to prepare austenite are detailed, and the theoretical and practical importance of M. Maurer's discovery pointed out.—The electrical transport of inorganic colloids: André **Mayer** and Edouard **Salles**.—Helicoidal structures: Paul **Gaubert**.—Observations on the development of the pistil in the Malvaceæ: Jean **Friedel**.—The cytological peculiarities of the development of the mother cells of the pollen of *Agave attenuata*: Er. de Lary **de Latour**.—The morphological and anatomical connections of the human cardia: R. **Robinson**.—The thoracic nephridia of the Hermellids: Armand **Dehorne**.—The structure of the epidermis of *Travisia Forbesii*: Louis **du Reau**.—Culture of the parasite of the Biskra boil (*bouton d'Orient*): Charles **Nicolle**.

DIARY OF SOCIETIES.

THURSDAY, APRIL 23.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—*Conclusion of Discussion*: Electric Supply Prospects and Charges as affected by Metallic Filament Lamps and Electric Heating: H. W. Handcock and A. H. Dykes.

MONDAY, APRIL 27.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*James Forrest Lecture*: On some Unsolved Problems in Metal Mining: Prof. H. Louis.

TUESDAY, APRIL 28.

ROYAL INSTITUTION, at 3.—The Development of the Modern Turbine and its Application: Gerald Stoney.

ZOOLOGICAL SOCIETY, at 8.30.—On the Amphipod Genus Trischizostoma: Mrs. E. W. Sexton.—On the Breeding-habits of a Cichlid Fish (*Tilapia nilotica*): C. L. Boulenger.—A Revision of the Sharks of the Family Orectolobidæ: C. Tate Regan.—A Revision of the Oriental Pelobatid Batrachians (Genus Megalophrys): G. A. Boulenger, F.R.S.

ROYAL SOCIETY OF ARTS, at 8.—Lace as a Modern Industry: Miss Isemonger.

WEDNESDAY, APRIL 29.

ROYAL SOCIETY OF ARTS, at 8.—Modern Roumania: Alfred Stead.

SOCIETY OF DYERS AND COLOURISTS (London Section), at 8. The Dyeing and Colouring of Paper Pulp: R. W. Sindall.—Further Notes on the Germicidal Value of Petroleum Benzine: F. J. Farrell and F. Howles.

BRITISH ASTRONOMICAL ASSOCIATION, at 5.—Time: Capt. F. L. Grant.

THURSDAY, APRIL 30.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On Scandium: Sir William Crookes, F.R.S.—Note on the Representation of the Earth's Surface by Means of Spherical Harmonics of the First Three Degrees: Prof. A. E. H. Love, F.R.S.—On the Hysteresis Loss and other Properties of Iron Alloys under very small Magnetic Forces: Prof. E. Wilson, V. H. Winson, and G. F. O'Dell.—The Relation between the Crystalline Form and the Chemical Constitution of the Picryl Derivatives: G. Jerusalem and Prof. W. J. Pope, F.R.S.—The Condensation of Certain Organic Vapours: T. H. Laby.—A Photographic Determination of the Elements of the Orbits of Jupiter's Satellites: Bryan Cookson.

ROYAL INSTITUTION, at 3.—Mendelian Heredity: William Bateson, F.R.S.

ROYAL SOCIETY OF ARTS, at 4.30.—Reminiscences of Indian Life: Lord Lamington, G.C.M.G., G.C.I.E.

MATHEMATICAL SOCIETY, at 5.30.—On a General Convergence Theorem, and the Theory of the Representation of a Function by Series of Normal Functions: Dr. E. W. Hobson.—On the Multiplication of Series: G. H. Hardy.—On q-Integration and Differential Equations: F. H. Jackson.

FRIDAY, MAY 1.

ROYAL INSTITUTION, at 9.—The Scientific Work of Lord Kelvin: Prof. Joseph Larmor, Sec. R.S.

SATURDAY, MAY 2.

ROYAL INSTITUTION, at 3.—Chile and the Chilians: G. F. Scott Elliot.

CONTENTS.

THURSDAY, APRIL 30, 1908.

ANCIENT BRITAIN.

Ancient Britain and the Invasions of Julius Caesar. By Dr. T. Rice Holmes. Pp. xi+764. (Oxford: Clarendon Press, 1907.) Price 21s. net.

THIS substantial volume divides itself, roughly speaking, into two halves, of which the first is the text of the author's story of ancient Britain extended so as to include Julius Cæsar's invasions and their more immediate results. The other is devoted to discussions and notes on special subjects, varying greatly in length and importance.

The summing-up at the end of the story is no cheerful reading. In some respects the author thinks we have sunk below the level of "those primitive ancestors" who form the subject of his work. He asks in what we have advanced, and answers that we have made giant strides in all that appertains to material civilisation. He proceeds in the following terms:—

"But such improvements hardly enable men to bear up under burdens which are ever increasing. The tourist in a Pullman car is not happier than those who travelled in stage-coach or waggon, and speed deprives him of as much as it bestows; machinery has but substituted fresh evils for those which it destroyed. New superstitions, less gross but not less false, have been engrafted upon the old: but 'pure religion and undefiled,'—how far has it strengthened its hold on the hearts of men?"

The reader will form some idea of the wide scope of his study of the primitive ancestors from the following headings of the chapters on ancient Britain: the Palæolithic age, the Neolithic age, the Bronze age and the voyage of Pytheas, the Early Iron age, Cæsar's first invasion of Britain, Cæsar's second invasion, the results of Cæsar's invasions.

It is to be hoped that Dr. Holmes may prove mistaken when he asserts in his introduction that we already know all, or nearly all, that sepulchres and skulls and coins can teach us of ancient Britain and its inhabitants. He goes on to express views which, if hardly more encouraging, are more likely to be in accord with those of his readers:—

"There is room also for many labourers in excavating stone circles, camps, and earthworks, and determining their age, in exploring habitations, wherever they can be found, and learning what they can teach about those who constructed them. What has been already done in this department has produced the most fruitful results. . . . But such work, which in other civilised countries is an object of national concern, languishes here for want of funds. No British Government can expect support from the intelligence and the public spirit of its constituents in spending money upon archæological research, or has the courage to give them a lead; and where are the wealthy Englishmen who will follow the example of their American cousins in endowing such work?"

At the risk of seeming to digress, we should like to point out that this state of things shows signs of coming to an end, and we may mention as one of our reasons for believing so the appointment not long since of a Royal Commission to report on the antiquities of Scotland. It is devoutly to be hoped that the Government will do more and extend the sphere of its activity so as to include other parts of the kingdom.

We shall now endeavour to give the reader an idea of ancient Britain and its populations as Dr. Holmes conceives of them. He regards the Bronze age as beginning in this country about 1800 years before the Christian era, but many centuries previously the island began to be invaded from various parts of northern Gaul by a Neolithic people, whom he describes as follows (pp. 64-5):—

"The skeletons that have been exhumed from the Neolithic tombs of England, Scotland, and Ireland . . . belong, for the most part, to the same general type. All, or almost all, had long narrow skulls: their faces were commonly oval, their features regular, and their noses aquiline: most of them were of middle height, and their limbs, as a rule, were rather delicate than robust. Men with the same physical characters lived contemporaneously in Gaul and the Spanish peninsula, and are still numerous in the basin of the Mediterranean; and the race to which they belonged is often called the Iberian, though there is no reason to believe that its British representatives belonged to the Iberian rather than to some other branch of the Mediterranean stock. But it is remarkable that while early in the Neolithic age Gaul and Spain, as well as Central Europe, were overrun by invaders of a totally different kind, who were extremely short and sturdy and had broad round heads, there is no evidence that men of this race reached Britain until the very end of the [Neolithic] period, and then only in comparatively small numbers. One would be inclined to infer that tribes of the Mediterranean stock began to migrate into Britain before many of the round-headed race had settled in Gaul. Vain attempts have been made to trace the [Neolithic] migration to its original starting-point by the distribution of the dolmens, or rude stone sepulchres, which are found in many European countries. . . . Everything points to the conclusion that the earliest dolmen-builders of Britain retreated from Gaul before the sturdy round-headed invaders; and it is useless to inquire whether the Mediterranean stock, to which the British, like the earlier French dolmen-builders, belonged, originated in Europe, in Asia, or in Africa. We only know that the oldest traces of the race were discovered in the Riviera."

At this point the author refers to certain philologists, who, like Prof. Morris-Jones, see in the syntax of the Neoceltic languages the influence of a language akin to the Hamitic dialects of Africa, with which it may be supposed to have come in contact after the advent of the Celts to Britain. He asks (p. 405) why it may not have been affected by some such contact before their arrival here. Doubtless that question occurred to Prof. Morris-Jones, but he was probably prevented from answering it in the way which Dr. Holmes would seem to suggest by the fact that there are some sentences of Continental Celtic extant, and that they show few traces, if any, of the non-Aryan syntax referred to. Whether Dr. Holmes noticed that difficulty does not appear, but if he is right in saying that the Neolithic short-heads chased the "Iberians"

D D

—a French historian would probably say "Ligurians" —across the sea to Britain, the difficulty is perhaps removed.

Perhaps the most valuable pages of the book are those in which he demonstrates that the short-headed race was not Celtic. He represents it as wholly different in physical type from the aborigines of Mediterranean stock whom it began to invade in the Neolithic age. Following the lead, if we mistake not, of the ceramic studies of Mr. Abercromby, he treats it as coming "from the Netherlands, from Denmark and its islands, perhaps also from Scandinavia and from Gaul." He gives the following description of it (p. 127):—

"Those immigrants have often been described as a tall, stalwart, round-headed race; but the evidence of sepulchral remains shows that they sprang from various stocks. Those of the type which is commonly regarded as specially characteristic of the Bronze age were taller and much more powerfully built than the aborigines: their skulls were comparatively short and round; they had massive jaws, strongly marked features, enormously prominent brow ridges and retreating foreheads; and their countenances must have been stern, forbidding, and sometimes almost brutal. Similar skulls, which have much in common with the primitive Neanderthal type, have been exhumed from neolithic tombs in Denmark and the Danish island of Falster. But the skeletons which have been found in some of the oldest Scottish cists belonged to men whose average height, although they were sturdy and thick set, was barely five feet three inches, and whose skulls, shorter and rounder than the others, as well as their milder features, proved that they were an offshoot of the so-called Alpine race of Central Europe, of which there were numerous representatives in Gaul. Again there were tall men with skulls of an intermediate type; while others, who combined harsh features and projecting brows with narrow heads, and whose stature was often great, would seem to have been the offspring of intermarriage between the older and the newer inhabitants. Not a single skeleton of the characteristic British round-barrow type is known to have been discovered on French soil: the round-headed inhabitants of Gaul were as conspicuously short as those of Britain were generally tall."

The short-headed invaders began to arrive in comparatively small numbers before the end of the Neolithic age, and bands of them "landed successively through long ages upon our eastern and southern shores" after the Bronze age set in (p. 127); but "there is no evidence that the brachycephalic people who built round barrows ever reached Ireland, at least in appreciable numbers" (p. 432). They seem to have intermarried with the Neolithic aborigines, and possibly in the course of ages they gave up their language in favour of the latter's. In any case, these conclusions would, to all intents and purposes, concern the eastern and southern coasts alone, which are not represented by any known Celtic language, living or dead. So it would be idle to suggest that, in case the language of the short-heads became firmly established here, its influence on subsequent Celtic on our southern and eastern coasts might be very different from that of the language of the Neolithic aborigines more to the west, let us say, on the syntax of Irish and Welsh; for the evidence is wanting in the shape of a Celtic speech embodying the results of the modifying influence in question. Dr. Holmes applies the term aborigines to the populations of Mediterranean stock that were here from the beginning of the Neolithic age, and extends that stock to Ireland (pp. 64, 109, 398). If, as we believe, he is right in his treatment and distribution of these people whom he claims to call the aborigines, it would be natural to suppose them to have left their name to the islands of our archipelago. We allude to the name underlying that of Πρεταννικαὶ Νῆσοι or Pictish Islands. Dr. Holmes will have none of this: he declines to admit that "the Picts represented that race in a special sense" (p. 409). For him "the Picts were a mixed people, comprising descendants of the Neolithic aborigines, of the Round Barrow race, and of the Celtic invaders" (p. 417). This conclusion leaves us not a little puzzled, not only as to how he distinguishes between his last-mentioned Celtic invaders and the main body of Celtic settlers, but as to how he proposes to settle the question of the distribution of his mixed people in the British Isles.

He has exposed with relentless industry all kinds of inconsistencies and mistakes in the theories to which he is opposed, and thereby has rendered great service to the history of ancient Britain. For all that, he is not at his best when teaching their business to the mistaken individuals who set out to study Celtic philology. His usual method is to pit the views of one against those of another, and in the case of views which he cannot accept himself he makes use of all the resources of his critical skill: not invariably so, however, with views which fall in with his own. Thus he virtually denies that ancient Irish had the sound of *p*, and states (p. 411) that M. d'Arbois de Jubainville "reminds his opponents, that *p* is absent from all Ogam inscriptions." This would not be true, as it occurs not less than a score of times in Ogam, and—a fact which excludes doubt as to the sound meant—two of the names which have it happen to be the Latin Pompeius and Turpillius. This statement surprised us not a little, as the learned Frenchman has not been known to devote much attention to Ogam inscriptions. On perusing the review in which he is represented as making his sweeping assertion, we discover that it is conspicuous by its absence. What he did say was that *p* is not found in the Ogam alphabet, which is by no means the same thing; the distance of time between the oldest Ogam alphabet (dating from the beginning of the twelfth century) and the oldest Ogam inscription containing a symbol for *p* may be put down as ranging from five to seven centuries. Dr. Holmes could if he liked have been more accurate, and at the same time leave M. d'Arbois de Jubainville's opponents with plenty of difficulties to engage their attention.

To take another instance, the author uses the following words (p. 421):—

"According to Bede, the place which marked the western termination of the wall of Severus was called in Pictish *Peanfahel*. *Pean* is commonly identified with the Welsh word *penn*, 'a head'; and accordingly it has been inferred that Pictish was 'a Kymric or semi-Kymric dialect.' Mr Nicholson, on the other hand, claims to have shown that *Pean* is 'a Goidelic borrowing from the Latin *penna* or *pinna*.'"

The astonishing allusion here to the *western* termination of the wall of Severus might seem at first sight to be a mere misprint for *eastern*; but, on looking at the original, it turns out to be something more, something calculated to create serious uneasiness as to other statements which one has not had time to verify in this volume. Bede's words, as given in Plummer's edition, I. xii. (p. 26), run thus:—

"Incipit autem duorum ferme milium spatio a monasterio Aebbercurnig ad occidentem in loco, qui sermone Pictorum Peanfahel, lingua autem Anglorum Penneltun appellatur; et tendens contra occidentem terminatur juxta urbem Alcluith."

Dr. Holmes rightly acquiesces in the view that *fahel* is an old form of the Irish genitive *fáil* matching a nominative *fál*, "a hedge, a wall"; but this does not, to say the least of it, help the theory that Pictish phonetics were like those of Welsh rather than of Gaelic. As to Bede's *pean* from Latin *pinna*, the author proceeds to show how absurd it is to think that this word "could beget a geographical name." In any circumstances whatsoever, that sort of statement must be hard to prove, so the argument comes dangerously near mere quibbling, and the appeal to Cæsar should have been an appeal to the German Diez, who derives from Latin *pinna* ("Zinne der mauer") the Italian *penna*, "the top, height, or peak of a hill or mountain," and the Spanish *peña*, "a rock, a cliff," instances of which Diez finds in the oldest Spanish records as Latin *penna*. This is not all; a passage in the second volume of Stokes and Strachan's "Thesaurus Palæohibernicus," from a famous Irish MS. written in the early years of the ninth century, has the words *a pinna montis Berbicis usque ad montem Mis*. The latter height was probably Slemish Mountain, in co. Antrim; the Top of the Mountain of the Wether (*vervex*) remains to be identified. But its name in the Book of Armagh shows that *pinna* was current in Irish Latinity, and was capable of forming part of a place-name. From Latin it passed into the Goidelic language, whence Bede's *Pean-fahel*, which is accordingly neither Kymric nor even semi-Kymric. One of the case forms of a feminine *pinna* in modern Irish would be *pinn*, and it was known to O'Reilly, who gives it in his dictionary as a feminine meaning "the summit of a hill or headland."

The foregoing instances will serve to show that the author has not been quite happy in his treatment of the philologists; whether he has been happier with the geologists and astronomers, the ethnologists and archæologists, they could best tell. We regret to be unable for want of space to pass under review the rest of the second part of the work: we have drawn on the excursus treating of the ethnology of ancient Britain. There are others, however, on such attractive subjects as the Cassiterides, the configuration of the coast of Kent in the time of Cæsar, Portus Itius, the place of Cæsar's landing in Britain, and many minor themes. The Clarendon Press has done its part with its wonted success, and the reader has the aid of useful maps, together with good illustrations. As to the work as a whole, one may say that, in spite of certain grave defects and a uniform lack of originality, it is a great monument to the author's industry.

LINEAR ALGEBRA.

Synopsis of Linear Associative Algebra. By J. B. Shaw. Pp. 146. (Washington: Carnegie Institution, 1907.)

THIS work serves three purposes: it gives a bibliography of the subject; a synopsis of the various algebras considered, in a fairly uniform notation, with a classification into families and types; and, in the introduction and § xiii. especially, some general remarks on algebra and its development. Part iii. (pp. 113–134) deals with applications.

Prof. Shaw points out that there are two views of complex algebra:—

"the one regards a number in such an algebra as in reality a duplex, triplex, or multiplex of arithmetical numbers or expressions; . . . the other regards the number in a linear algebra as a single entity, and multiplex only in that an equality between two such numbers implies n equalities between certain coordinates or functions of the numbers."

On this it may be remarked that both views are equally legitimate, and equally useful, but in different ways. The formulæ of a special algebra which are most characteristic and most powerful are those which most naturally associate themselves with the second point of view; an example is afforded by the quaternion formula $V(aV\beta\gamma)=\gamma Sa\beta-\beta Sa\gamma$. On the other hand, the place of quaternion algebra among its fellows is most clearly shown when we consider a quaternion as a complex (a, b, c, d) of four ordinary numbers, with rules for the addition and multiplication of two such tetrads.

The general impression produced by reading the synopsis is that, after Grassmann and Hamilton, the most remarkable work has been done by Benjamin Pierce. By developing his methods it has been possible to make a classification of linear associative algebras which, so far as it goes, is really exhaustive, and may be said, also, to be a natural classification. Of recent papers, those of Cartan, Frobenius, and Poincaré deserve particular mention; they tend to show that the characters of special algebras can be included in the all-embracing theory of groups.

A few lines (p. 18) are given to a definition of complex numbers by Mr. Bertrand Russell, in terms of logical constants. This is certainly interesting from a philosophical point of view, but it illustrates a tendency on the part of what may be called the Peano school to over-refine their definitions, and become verbose if not tautological. When the theory of real numbers has been logically established, it is sufficient to define a complex algebra in arithmetical terms, without bringing in logical notions *already* used in defining number and arithmetical operations. Why not make use of a symbolism which has been fully justified, and which immensely abbreviates the statement of new definitions? After all, Mr. Russell's definition, as here given, does not differ essentially from the "umbral" definition (the first of the two previously referred to).

The synopsis is so condensed that it appeals rather to specialists than to general readers. The latter, if interested in the subject, will find it easier to read the more important papers referred to on pp. 5–7, and then gain a comparative view by studying the synopsis.

Prof. Shaw himself has made various contributions to the subject, some of which are contained in the present volume. His summary will doubtless do much to further the study and comprehension of algebra in general.

G. B. M.

MEDICAL PHYSICS.

Lehrbuch der medizinischen Physik. By Prof. H. Boruttau. Pp. viii + 282. (Leipzig: Johann Ambrosius Barth, 1908.) Price 8 marks.

THIS book is intended for medical students who have completed a course of general physics, and is therefore limited to the study of the physical properties of tissues, the physical changes that take place in the tissues, and physical instruments of importance in physiology and pathology. In view of the slight equipment of most medical students in mathematics in Germany, as in this country, the treatment of the subject is not mathematical, diagrams and simple equations alone being used. Considering the variety of the subjects treated, the book is of very modest size. This result has been attained by keeping theoretical discussions within the narrowest limits, avoiding detail in descriptions of practical methods and apparatus, and by the use of small but excellent diagrams.

According to the author, no similar book to this has been published since that of Adolf Fick, the last edition of which appeared more than twenty years ago. As the scope of the book is therefore unusual, a brief account of its contents may be useful.

Chapter i. is introductory. Chapters ii. and iii. are devoted to the general properties of tissues, which are divided into fluids and solids, and include sections on velocity, energy and its transformations, density and elasticity of the different tissues, contraction of muscle, the levers of the body, locomotion, deformities, blood pressure, pulse, blood flow, surface tension, viscosity, osmotic pressure, and the secretion of urine. Chapter iv. deals with gases in relation to blood and respiration; chapter v. sound, including wave motion, the analysis of sounds, hearing, speech, percussion, and the sounds of respiration and the heart; chapter vi. heat production and temperature, and their relation to food, work and surface of the animal, conductivity of clothing materials, and the laws of thermodynamics; chapter vii. magnetism and electricity: therapeutic use of electricity, the electric properties of muscle and nerve, Röntgen rays, radioactivity, N-rays; chapter viii. optics: photometry, mirrors, lenses, the eye, optical measurements, correction of optical defects, the microscope, immersion lenses, polarimetry, spectroscopy, calorimetry. References to original papers are given.

A feature of the book is the inclusion of many tables of physical quantities, *e.g.* comparative velocities, densities and elasticities of tissues, specific rotations, conductivities of clothing materials.

That the book contains much useful information not usually found in medical students' text-books is undeniable, the section on blood pressure and pulse, and that on the respiratory murmurs, for example, but it is doubtful whether measurements of elasticity of tissues, to which considerable space is devoted, are of much value, owing to the fact that these tissues show great variations according to their nutrition, and that no tissue except bone is a true solid.

In conclusion, it may be doubted whether a book of this kind, dealing mainly with physiological subjects from a physical point of view with a physical classification, is entirely desirable. Physiologists, after a large number of careful researches on the physical phenomena of living tissues, have had to confess that they are no nearer to the discovery of a physical basis of life. The student should, therefore, arrive at a truer view of the present position of the science from books, which deal with the properties of the living organism as a whole, or as an association of different organs, than from a book with an essentially physical treatment such as this.

J. H. R.

OUR BOOK SHELF.

Musée ostéologique; Étude de la Faune Quaternaire, Ostéometrie des Mammifères. By E. Hue. Two vols. Pp. xix + 50 + 186 plates. (Paris: Schleicher Frères, 1907.) Price 24 francs.

To persons interested in cavern-research and cavern-animals, and having no means of access to a museum, these volumes—which are a monument to the industry and perseverance of their author—will no doubt be welcome, and afford adequate means of identifying their "finds" with comparative ease. In this country, however—apart from what may be the case on the Continent—the number of such persons must, we should surmise, be extremely small, and the sale of the work consequently limited. On the other hand, it may possibly be found of use to students of comparative osteology generally, without reference to cavern-research.

The plan adopted by the author is to take the skeletons of all the species of mammals the remains of which are commonly found in caverns, and to arrange their component elements in corresponding series, so that all the skulls, all the humeri, &c., are brought together in associated plates. Each bone (except, of course, those of the skull) and each tooth is figured separately to scale, the scale in the case of each plate being as large as circumstances permit. By means of these figures to scale and measurements, Mr. Hue is of opinion that it will be practicable for anyone to identify such cave-bones—even when imperfect—as may come under his observation.

For this purpose a series of measurements for each bone in the skeleton is recommended, the lines along which these measurements should be taken being indicated in a series of preliminary figures. By the aid of a rule and pair of compasses, such measurements can be compared with the corresponding dimensions of the specimens figured.

As the entire work is practically an atlas (the text, which is almost solely concerned with the methods of measurement, occupying only fifty pages), there is really no field for criticism. The figures, though perhaps a trifle crude, appear to be very accurate, and even in the case of the smaller teeth the details of structure are fairly well apparent. Practically the only criticism we have to make is that in plates 33 and 35 the last two upper molars of the jackal and Arctic fox are placed in positions different from those they occupy in the jaw, whereas in the case of the dog (plate 32) and fox (plate 34) they are correctly orientated. The work must have involved an enormous amount of labour, and the author is to be congratulated on the manner in which he has carried out what could scarcely have been anything else but a wearisome task.

R. L.

The Children's Book of Stars. By G. E. Mitton. Pp. xii+207; illustrated. (London: Adam and Charles Black, 1907.) Price 6*s.*

As a book for the instructors of small children, this volume should prove useful. As a book for the unaided juvenile, we fear that the "conventional phraseology" which the author deplores in ordinary text-books has not, even here, been sufficiently eliminated. It is, indeed, a very difficult matter to escape wholly from this evil when instructing juveniles, but, on the whole, the writer of the work under notice has succeeded admirably.

The arrangement of the matter is on familiar lines. The earth, the moon, the planets, the sun, comets, meteors, constellations, stars, and nebulæ are successively treated, concisely and clearly. The analogies by which the different points are illustrated are generally well chosen and apt, and are likely to be easily understood by the young people to whom they are expounded. The chapter (xii.) on "What the Stars are made of" appears to us, despite the relative difficulty of the subject of spectrum analysis, to be one of the simplest in the whole book. The volume contains but very few mistakes, though it is curious that the one in this chapter, on p. 169, should have been overlooked. In describing the preceding plate, which shows the coloured spectra of the sun and Sirius, the latter is called Arcturus, although on the plate and later in the same paragraph it is correctly named.

The illustrations are striking, the majority of them being printed in colours, but we fear that the juveniles to whom some of them would appeal would be hopelessly at sea if given the book to read by themselves. Whilst we are doubtful as to the value of the book if used in this way, there can be no doubt that to children of older growth who have young minds to train it will fill a gap, enabling them—with a few hours' start—to answer clearly all those questions which are bound to be asked if the previous instruction has been at all successful.

W. E. R.

Cradle Tales of Hinduism. By Sister Nivedita (Margaret E. Noble). Pp. xv+343. (London: Longmans, Green and Co., 1907.) Price 5*s.* net.

MISS NOBLE, urged by an enthusiasm for modern Hinduism as preached in Bengal which is shared by few of her countrywomen, has edited a pleasant selection of the classical religious tales of India. She divides them into several cycles—snake tales; the story of Siva; Indian wifehood, including the famous tale of Nala and Damayanti; selections from the Mahabharata and Ramayana epics; the adventures of Krishna; tales of the devotees and of great kings. The tales, of course, are derived from a literature familiar to all scholars, and Miss Noble would perhaps have done more useful service to folk-lore by collecting some of the great mass of folk-tales hitherto unrecorded. Her version is pleasant and interesting, but we are doubtful of the prospects of its success in English nurseries.

These stories exhibit too much of the dreamy mysticism of the East, and while largely occupied with phases of religious feeling, possess too little of that spirit of pure adventure which our children in their fairy-tale books are accustomed to expect. To those unfamiliar with classical Hindu religious literature they will form a useful introduction. The reader, however, will be well advised to accept these versions with some reservation, for a double reason. In the first place, there is too much of the Bengali spirit in them; secondly, all the eroticism and coarseness which are unhappily so prominent in this literature, and especially in that characteristic of Bengal, have necessarily been rigidly suppressed, and the student who reads these stories for the first time may be led to form an impression of their delicacy and purity of sentiment which will soon be dissipated on acquaintance with the originals.

The author, again, has hardly kept herself in touch with recent folk-tale study in India. In discussing the Krishna cycle, she appeals to native scholars for the dissection of the varied elements out of which it has obviously been composed. Here she is likely to be disappointed, because critical analysis of a sacred literature of this kind is hardly to be expected from faithful believers. If she had been aware of recent contributions to this subject, such as Mr. J. Kennedy's essay in a recent number of the Journal of the Asiatic Society, and other earlier studies of the same kind, she would probably have modified the rather crude suggestions contained in her preface. Hinduism possesses many merits of its own, but its claim to the attention of the West will not be advanced by carefully ignoring its most prominent characteristics.

Lehrbuch der mikroskopischen Technik. By Dr. Bernhard Rawitz. Pp. viii+438. (Leipzig: W. Engelmann, 1907.) Price 12 marks.

THIS book gives a very complete summary of modern methods employed in microscopical research as applied to animal tissues. The introductory chapter on the microscope is very brief; probably the author considered this part of the subject hardly came within the scope of his compilation. On the other hand, the preparation of material, hardening, embedding, and staining are dealt with at considerable length, and in the second part of the work the application of the methods to particular tissues and organs is detailed in a complete and thorough manner. When treating of apparatus, the author has avoided anything which simulates a list from instrument makers' catalogues, often a difficult matter in a work of this kind.

General staining methods occupy some sixty-five pages, and here we find an extremely useful summary of the uses and application of a large number of stains. Naturally German methods occupy the forefront, and the British reader misses references to such well-known modifications of the Romanowsky stain as the Leishman and the Wright.

In the second part every tissue and organ is separately considered, and the particular methods applicable in each case are detailed at greater or less length. Thus the nervous system has some seventy pages allotted to it. Little or nothing of importance seems to have been omitted from the book, which is adequately indexed, and should form a very useful compendium for the laboratory.

R. T. HEWLETT.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

The Presence of Water Vapour in the Atmosphere of Mars.

In February and March, 1908, Mr. V. M. Slipher succeeded in photographing the lines due to water vapour in the atmosphere of Mars. It was in the "a" band that its presence stood revealed. The detection was rendered possible by the use of plates specially prepared by him for the purpose—23 Seed, bathed in a mixture of pinacyanal, pinaverdol, dicyanin, water, and ammonia—which enabled the spectrum to be photographed somewhat beyond the "A" band. Comparison spectrograms were made of the moon at approximately the same altitude on the same plates, and with exposures to give a like density for both. Repeated plates of the sort were taken, and their consensus shows unmistakably the "a" band stronger in the spectra of the planet than in those of the moon. In the case of the moon, of course, we are looking through our own atmosphere only; in the case of the planet, through its atmosphere as well.

Previous observers—Huggins, Jansen, Vogel, Campbell—had reached discordant conclusions, Huggins and Vogel asserting the presence of water vapour in the atmosphere of the planet, Campbell with much improved spectroscopic means failing to get any indication of it. The reason of this was the instrumental inability at the time these researches were made to examine the spectrum sufficiently far into the red, for it is in the "a" band that the greatest absorption of water vapour occurs, and this was not only beyond the possibility of photography at the time, but beyond even that of visual detection. Thus Vogel went no further redwards than "C," while Campbell tells us in his account of his researches, in which he came to a negative conclusion:—"It is impracticable to observe the groups A, 7450 to 7160 and 7160 to 6870, which are at the extreme red end of the spectrum, and they will not be further considered." In this omission, rendered necessary by the instrumental appliances at the time, lay the failure to perceive the evidence of water vapour in the spectrum of the planet. For, as the following table shows, the intensity of the absorption is much greater in the "a" band than in the lines between it and the D lines, or even in those near the D lines themselves. This is borne out by examination of Mr. Slipher's plates, in which the difference in the "a" band is evident, the broadening of the D lines just perceptible, and nothing predicable of the fainter water-vapour lines.

Relative Strength of the Water-vapour Lines in the Spectrum, according to Rowland.

	Substance	Determination 1893. Strength: Lines probably identified	Determination 1893. Strength: Lines certainly identified	Determination 1895.	Wave-length
A 7604	Oxygen	120	120	—	7672 / 7594
a 7165	Water Vapour	124	50	128	7319 / 7176
	,,	9	—	6	7016
	,,	42	13	54	6999 / 6948
B 6867	Oxygen	170	—	—	6936 / 6867
C 6562 (Solar, H)	Water Vapour	5	5	20	6572 / 6480
α	Oxygen	14	—	—	6296 / 6278
	Water Vapour	2	2	10	5977
D_1 5896, D_2 5890 (Solar, Na)	,,	26	26	68	5920 / 5884

No water vapour lines of less wave-length than 5884.

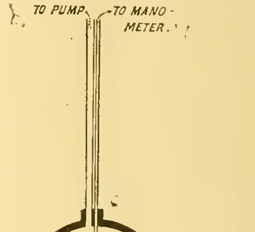
The great dryness of Arizona was no less a factor in the result. So dry was the air at times during the investigation that on more than one plate the "a" band is hardly to be made out in the lunar spectra, while in the Martian it is unmistakable. Great dryness in the climate is in other ways shown by the plates to be essential to the recording of a perceptible difference between the water-vapour lines due to Mars and the earth and those due to the earth alone. For examination of the oxygen bands, A, B, and α, in the two spectra reveals no perceptible difference between them, and yet the presence of water vapour in the spectrum of Mars is strong presumptive evidence that free oxygen exists in its atmosphere as well, since it is the heavier of the two.

Percival Lowell.

Lowell Observatory, Flagstaff.

The Condensation of Helium.

I have just read with great interest of Prof. Onnes's experiments with helium, and as one who has carried out investigations at very low temperatures, and to a certain extent in the same direction, I must congratulate him on having overcome difficulties of no ordinary nature. At the time of my departure for India I was engaged in an attempt to measure temperatures below the temperature of solid hydrogen, with the ultimate object of determining thermal constants for helium, but the work was broken off when I left Bristol, and it is not likely that I shall be able to resume it for some time. However, it is possible that brief information as to the method I intended to employ may be of use to others.



The measurement of low temperatures by any means other than by the gas thermometer appeared to me to be mere waste of time, and I decided to employ in these experiments a constant volume helium thermometer. Following the method of Olszewski, I proposed to compress helium to about 100 atmospheres in a vessel cooled in solid hydrogen, and containing the thermometer, and to measure the fall of temperature on expanding the gas. The only obvious difficulty lay in the construction of the apparatus.

The apparatus shown about natural size in the figure was made for me by Messrs. A. Hilger. The outer vessel was of thin steel, and had a capacity of about 40 c.c. Within were three concentric test-tubes, made as light as possible, and separated one from the other and from the steel vessel with fragments of cork. In the centre is a very light bulb of steel, to which was soldered a capillary steel tube such as is used for hypodermic needles. This bulb was intended to serve as a thermometer, the steel tube communicating with the manometric portion of one of the thermometers which I employed in the measurements of the temperatures of liquid and solid hydrogen (Phil. Trans., cc. A, 105, 1902). A steel tube connected the steel vessel with the pump, &c. A steel gasometer floating on mercury, and a steel pump working with mercury as a lubricant, had also been constructed for me by Messrs. Brin's Oxygen Co. Sir William Ramsay had placed a large quantity of helium at my disposal.

Preliminary experiments with oxygen led me to the conclusion that by this method it would be possible to attain to, and measure temperatures far below, the melting point of hydrogen. I may point out that for very low temperatures the reading of the manometer attached to the thermometer would give a direct measurement of the temperature, as the dead space correction would be very small.

Morris W. Travers.

Indian Institute of Science, Bangalore, March 20.

The Radio-activity of Ordinary Metals: the Penetrating Radiation from the Earth.

In a paper in the *Phil. Mag.*, December, 1907, I described some experiments made by me on the conductivity of air confined in metallic cylinders, 60 cm. long and 24 cm. in diameter, which were made of lead, of zinc, and of aluminium. With the zinc and aluminium carefully cleaned, a conductivity was obtained for the enclosed air, which on reduction gave the value 15 for q, the number of ions generated per c.c. per second in the air. With lead cylinders, which were investigated more extensively than those of other metals, the conductivity exhibited wide variations, and values were obtained which ranged from 160 to 23 ions per c.c. per second.

During the past eight months experiments on the conductivity of air confined in metallic vessels have been continued in the Physical Laboratory at Toronto by Mr. C. S. Wright, and he has now obtained under normal conditions with a particular lead cylinder of the dimensions given above, in a series of observations made in a room in the laboratory, a conductivity corresponding to the production of 15·3 ions per c.c. per second. With zinc and aluminium cylinders, the lowest conductivities obtained in this room by him correspond, respectively, to the values 13·4 and 12·5 ions per c.c. per second for q.

He has also, during this period, conducted a series of experiments on the conductivity of air enclosed in these cylinders in and about Toronto, and has found that the conductivity of the enclosed air varied considerably with the character of the soil and rocks in the neighbourhood of the points of observation.

In making measurements on the ice above the water of Lake Ontario, the conductivity was found to be very much lower over the surface of the water than at points on the land on either side of the lake at some distance from the shore. In these experiments on the ice the values 8·6, 6·0, and 6·55 ions per c.c. per second were found for q with cylinders of lead, zinc, and aluminium respectively, and in a more extended series of observations with the lead cylinder alone, the conductivity was found to be the same over water with depths varying from 2·5 to 10 metres. Measurements were also made on board the steamer *Corona* during one of her passages over the lake, and values were obtained for q uniformly lower by approximately 6 ions per c.c. per second than those found in the laboratory at Toronto, although the depth of the water at the wharf in Toronto, where the observations in this series were commenced, was not more than 6 or 7 metres, while it was approximately 150 metres in depth at the deepest point on the line of passage.

Observations made on a sand bar extending out into the lake near Toronto gave a value of 9 ions per c.c. per second for q, and others made on land, at some distance from the shore, at various points and over different soils, gave values ranging from 11·2 to 15 ions per c.c. per second.

From the investigation it would appear that the water of Lake Ontario, as well as the sand along the shore line, contains little, if any, radio-active materials, and consequently does not contribute any appreciable proportion of the penetrating radiation observed at points on the earth's surface.

It would appear, too, from the constancy of the observed drop in conductivity that the water of the lake completely screens off any radiation coming from the soil or rock beneath it. In order to confirm this view, some experiments were made on the absorbing power of the water for the γ rays from radium. Thirty milligrams of radium bromide were enclosed in a brass tube with walls about 1 cm. thick. This tube was laid on the ice, and the ionisation chamber placed 113 cm. above it. With this arrangement it was found that the conductivity added by the radium bromide corresponded to the generation in the air in the chamber of 4485 ions per c.c. per second. A hole was then made in the ice, and the tube was lowered to different depths in the water beneath, the conductivity being measured for each position of the radium. At a distance of half a metre below the surface the conductivity corresponded to the production of 447·2 ions per c.c. per second, at 1 metre to 16·11, at 2 metres to 0·69, and at 3 metres to 0·62 ions per c.c. per second. From these numbers it will be seen that a layer of water between 2 and 3 metres in thickness sufficed to absorb practically all the radiation issuing from the radium in the tube.

In view of these experiments and of those of Elster and Geitel, who observed a fall of 28 per cent. in the conductivity of air enclosed in an aluminium cylinder, on taking this cylinder from the surface of the earth to the bottom of a mine surrounded with a wall of rock salt, it would seem that the penetrating radiation observed by a number of investigators at the surface of the earth is more or less local in character, and that, while its existence may be traceable to active substances present in the soil and rocks, the effective intensity is largely determined by the amount of inactive substances it may have to pass through in order to reach the surface.

The extremely low values found for q with the cylinders of lead, zinc, and aluminium in the experiments on the ice are interesting on account of their uniformity. They are, as is evident, of the order of magnitude of effects which might easily be accounted for by active impurities in the metals, since differences as large as these values of q may easily be obtained with cylinders made from different samples of almost any metal selected at random. Considering also the difference in the atomic weights of the three substances aluminium, zinc, and lead, and having in mind that radio-activity is a property associated with atomic structure, it would seem that if these metals could be obtained entirely free from active impurities, and the conductivity of air contained in vessels made from them studied, it would be found, if the observations were carried out under conditions or in places where no ionisation was possible from penetrating radiations arising from external sources, to drop to a very low value, if it did not entirely vanish.

The experiments described in this note were made with one of Mr. C. T. R. Wilson's latest type of gold-leaf electrometers, which was found, on account of its portability, and of the facility and exactness with which readings could be made with it, to be most admirably suited to the purposes of the investigation.

Physical Laboratory, University of Toronto, March 30.

The Theory of Dispersion and Spectrum Series.

On p. 413 of Nature (March 5) Prof. Schott attempts to show that there is an irreconcilable inconsistency between Drude's dispersion formula and Balmer's formula for the lines in the hydrogen spectrum. I imagined that someone who could speak with greater authority than myself would make the obvious reply, but since no such reply has been forthcoming, and the arguments have been republished in another journal, I venture to ask for space to point out why they appear to me fallacious.

Prof. Schott's error consists in assuming that the λ_h in Drude's formula is the same as the λ in Balmer's formula. The λ_h in Drude's formula is the wave-length of the light for which the medium shows selective absorption; that in Balmer's formula is the wave-length of the light emitted by the gas when in a luminous state. An unintelligent application of Kirchhoff's law sometimes leads students to imagine that the two quantities are identical, but Kirchhoff's law applies only to purely thermal radiation (*cf.* Wood's "Physical Optics," chapter xix.). A gas, such as hydrogen, in its non-luminous condition does not absorb selectively the light emitted by luminous hydrogen. I do not think that any absorption bands in non-luminous hydrogen have been detected; they are probably far in the ultra-violet, and there is no reason for supposing that their wave-lengths will be connected by any formula similar to that of Balmer.

The reason for the difference in the frequencies of the absorption bands and the lines in the emission spectrum is sufficiently obvious. The emission of light by a gas is doubtless connected with the ionisation of its atoms. But, when an atom is ionised, the electrons in or surrounding that atom are subject to forces entirely different from those which act upon them when the atom is ionised; there must be a corresponding difference in the periods of free vibration. The absorption bands probably represent the vibrations of the electrons in the neutral atom, the emission spectrum those of the electrons in or around the ionised atom.

Nor is there any reason why the refractive index of a *luminous* gas should differ greatly from that of a non-luminous gas, except in the immediate neighbourhood of a line in the emission spectrum. (It is relevant to note that Drude's formula cannot be applied to such regions.) Only a very small proportion of the total number of atoms present is ionised even under the most favourable experimental conditions; most of the atoms are not ionised, and affect the light in the same way as those of a non-luminous gas. Of course, if the refractive index due to the luminous atoms were really infinite, the refractive index of the luminous gas would be infinite, however small the proportion of luminous atoms. But it is impossible that it should be infinite; if Balmer's formula were accurately true for all values of m, there would be an infinite number of lines in the emission spectrum, implying an infinite number of degrees of freedom in the vibrating system. According to the modern view, which seems to be accepted by Prof. Schott, this system is composed of discrete charged particles possessing a finite mass; the number of such particles must be finite, and they can only have a finite number of degrees of freedom. Experiment can never demand an infinite number of lines, for, if m is very great, the lines are so close as to be beyond the range of resolution.

The Oligochætous Fauna of Lake Birket el Qurun and Lake Nyassa.

In Nature of August 1, 1907 (vol. lxxvi., p. 316), Messrs. Cunnington and C. L. Boulenger wrote a preliminary account of the fauna of Lake Birket el Qurun. I am indebted to these gentlemen for the opportunity of supplementing their account by a note upon the Oligochæta of that lake. They were so good as to send to me two tubes with a large number of specimens of a small oligochætous worm collected in the lake. These specimens were found to belong, without exception, to the species *Paranais littoralis*. The occurrence of this Naid in northern Africa is a new fact in its distribution. It has hitherto been met with in many parts of Europe, both in fresh water and in brackish, even salt, water. As to its marine habitat, it has been collected on the shores of Denmark and near Odessa.

It is clear from the fact that this was the only aquatic Oligochæte met with by Messrs. Cunnington and Boulenger that it must at least be a prevalent form in the lake.

Mr. Cunnington has also kindly placed in my hands some examples of aquatic Oligochæta from Lake Nyassa. These belong to three species, and the contrast with the oligochætous fauna of the North African lake is very marked. The genera represented in Nyassa are Dero, Nais, and Pristina. Unfortunately, none of the examples submitted to me are sexually mature. The Pristina I identify with *Pristina longiseta*, a widely spread form. The genera Nais and Dero are also found in many parts of the world, and as all three genera have already been recorded from tropical East Africa (Michaelsen in *Zeitschr. f. wiss. Zool.*, Bd. lxxxii., 1905, p. 289), there is no cause for surprise at their occurrence in Nyassa. Still, the fact seemed to me to be worth putting on record.

Zoological Society's Gardens.

THE FORTHCOMING DUBLIN MEETING OF THE BRITISH ASSOCIATION.

The British Association will hold its fourth meeting in Dublin on September 2–8 of this year. The three previous meetings took place in 1835, in 1857, and in 1878. The 1878 meeting drew an attendance of 2578, which was well above the average, and it was marked by the presence of an unusually large number of men distinguished in scientific or other work at the time and since. In his presidential address before the Anthropology Section, Prof. Huxley spoke prophetically about those "who may be here thirty years hence—I certainly shall not be," little realising how both his prophecies were destined to come true.

Appropriately enough (though, I believe, not consciously in connection with Huxley's forecast), the invitation for 1908 originated with Prof. W. H. Thompson, of the physiological laboratory of Dublin University. It was originally intended for 1907, but 1908 was found to be more suitable, and the invitation was formally accepted at York in 1906, where a deputation attended consisting of the Provost of Trinity College, Prof. Thompson, Dr. Tarleton, Monsignor Molloy, Rev. Dr. Delaney, and the Lord Mayor of Dublin. The invitation was formally renewed at Leicester by Prof. Thompson, Rev. Dr. Delaney, and Sir Howard Grubb. At a first meeting at the Dublin Mansion House, general and executive committees were appointed, and these have been at work ever since, with the result that the arrangements are in an advanced state of preparation. Subcommittees were appointed to deal with finance, entertainments, hospitality, and the handbook respectively. The four local secretaries are Dr. Joseph McGrath, secretary of the Royal University, Prof. W. E. Thrift, Prof. W. H. Thompson, and Mr. John Mulligan, of the Hibernian Bank. About 3000*l.* has already been subscribed towards the expenses of the meeting. The reduced fare tickets will be available for a month, so as to include the excursions subsequent to the official meeting. Day excursions will be arranged during the week of the meeting to the Devil's Glen and Glendalough in county Wicklow, to Powerscourt Waterfall and the Dargle near Bray, to the Boyne Valley, and to the Shannon Lakes.

The presidential address will be delivered by Mr. Francis Darwin, F.R.S., on the evening of Wednesday, September 2, in the large hall of the Royal University. Here also will be delivered two of the evening discourses, one on "Halley's Comet," by Prof. H. H. Turner, F.R.S. (Friday, September 4), the other on "The Lessons of the Colorado Cañon," by Prof. W. M. Davis, of Harvard University (Monday, September 7). The third evening discourse will be delivered to operatives on Saturday, September 5. To this discourse ordinary members will not be admitted. The lecture hall has not yet been decided upon.

The serious work of the sections will, for the most part, be over each day by two o'clock, leaving the afternoon, and those evenings on which discourses are not held, free for entertainments of a social kind. Of the latter, not a few are already promised, including garden-parties by their Excellencies the Lord Lieutenant and the Countess of Aberdeen, by Lord and Lady Ardilaun, and by the provost and senior fellows of Trinity College; evening receptions are also to be held by the Viscount and Viscountess Iveagh, by the Royal Dublin Society, and by the Royal Irish Academy. The Lord Mayor and Lady Mayoress will be "At Home" at the Mansion House, to members of the association, on the afternoon of the opening day of the meeting.

The work of the Dublin meeting will be transacted in twelve sections, which, with their respective presidents, are as follows:—Mathematical and Physical Science (Dr. W. N. Shaw, F.R.S.); Chemistry (Prof. F. S. Kipping, F.R.S.); Geology (Prof. J. Joly, F.R.S.); Zoology (Dr. S. F. Harmer, F.R.S.); Geography (Major E. H. Hills, R.E.); Economic Science and Statistics (Mr. W. M. Acworth); Subsection Agriculture (Sir Horace Plunkett, K.C.V.O., F.R.S.); Engineering (Mr. Dugald Clerk, F.R.S.); Anthropology (Prof. W. Ridgeway); Physiology (Dr. J. S. Haldane, F.R.S.; Botany (Dr. F. F. Blackman, F.R.S.); Educational Science (Prof. L. C. Miall, F.R.S.). To increase the general interest in the doings of the association, these sections have been distributed over various institutions in the city, the governing bodies of which have kindly undertaken to provide suitable accommodation. Thus, Trinity College, the Royal University, the Royal College of Science, University College, the Royal Colleges of Physicians and Surgeons, the Royal Irish Academy, and the Royal Dublin Society all vie with each other in this respect.

The reception room and administrative offices during the meeting will be located in Trinity College. Until then, offices for the local reception committee have been kindly provided at the Royal University by permission of the Senate.

The official handbook is being prepared by Mr. R. Lloyd Praeger (author of "Irish Topographical Botany") and Prof. Grenville A. J. Cole, under the auspices of the Handbook Committee. It will comprise sections on local geology, botany, zoology, history and archæology, commerce and industries, and the usual official information. Among the articles will be one on glacial phenomena, by Mr. J. R. Kilroe, and another on mineralogy, by Mr. H. J. Seymour, both of the Geological Survey. Mr. Nathaniel Colgan, author of "Flora of Co. Dublin" and one of the editors of "Cybele Hibernica," will deal with botanical subjects. The zoology section will be prepared by Prof. G. H. Carpenter, and will comprise an essay on Irish mammals, by Dr. Scharff; birds, by Mr. R. M. Barrington (author of "Migration of Birds"); and numerous other special articles.

The history and archæology of the district round Dublin will be in charge of Mr. C. Litton Falkiner, secretary to the council of the Royal Irish Academy, and Mr. Elrington Ball (author of "History of the "Flora of Co. Dublin" and one of the editors of Murray's "Guide to Ireland") will deal with the prehistoric and other antiquities of the Boyne Valley, including the famous tumuli of Knowth, Dowth, and Newgrange, and with Dublin churches. There will also be articles by Mr. J. Westropp on the mediæval and ecclesiastical antiquities of Dublin and Wicklow; by Count Plunkett, the new director of the Dublin Museum, on old Dublin houses; and by Dr. Cosgrave, on old views of Dublin.

Dublin possesses attractions which very few capital cities can rival. Situated in the centre of Dublin Bay, its beautiful and prosperous suburbs extend northwards on to the promontory of Howth and southwards to Kingstown, Dalkey, and the far-famed Bay of Killiney, which, closed in by the Wicklow Mountains, presents an aspect of unsurpassed beauty.

A somewhat unusual element of local colour will be given to this year's Dublin meeting by the large number of bilingual street name-plates and signposts (an outcome of the Gaelic revival), on which the historic names are given in both Irish and English character and spelling. The well-known cordiality and hospitality of the Irish people may be trusted to render this year's visit of the devotees of science one of particularly agreeable memories.

E. E. F.

THE SCIENCE COURT OF THE FRANCO-BRITISH EXHIBITION.

THE fact that pure science will take a recognised part in the scheme of the forthcoming Franco-British Exhibition, and that it is being assigned a court specially for this subject, has already been recorded in these columns. It is believed that this is the first large exhibition at which such distinct recognition of the claims of pure science has been made, and it may be welcomed as being an example which should be followed at all future exhibitions.

The scheme of the court has been arranged so as to show apparatus and processes of historical value in the various sciences, and also, so far as possible, to illustrate various researches in science, both in the laboratory and in the factory, which have been and are being carried on. The exhibits will be arranged under the head of each of the great sciences, with subdivisions where necessary. Arrangements have also been made to illustrate the nature of the scientific work which is being carried on under the head of the exploration of the heavens, the air, the sea, and the land, which come naturally under the sciences of astronomy, meteorology, oceanography, geography, and geology. In this way it is hoped that a fairly complete review of all the important sciences will be obtained.

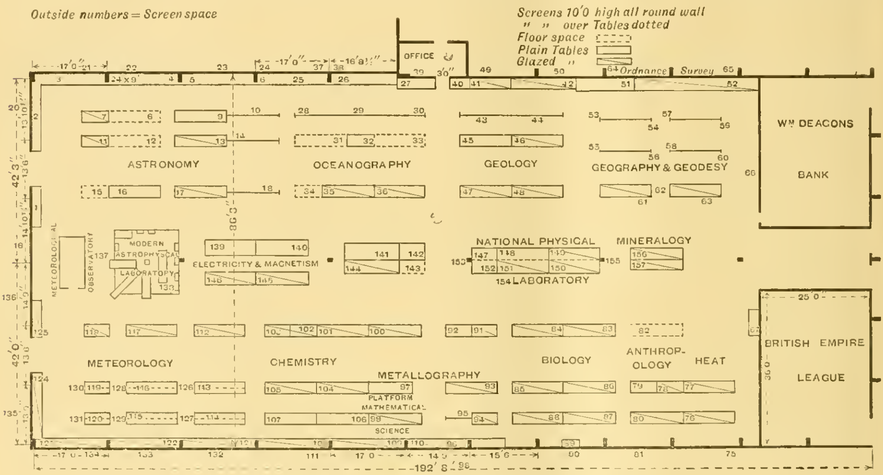
In the previous article in NATURE, the constitution and names of the full committee and of the various subcommittees were given. The preliminary arrangements and discussion of the principles to be followed, and the nature of exhibits to be asked for, occupied the committee several months, but the work of actually collecting the exhibits in each science which are to be shown was handed over by the committee to the various subcommittees and their respective Conveners, as they are the best and most appropriate judges of what exhibits are available. These subcommittees and their Conveners have really had a hard and difficult task in making representative and interesting collections, but they have, on the whole, been most successful.

The usual difficulties in securing historically valuable apparatus have been experienced, and many individuals and institutions have not found themselves able to allow such apparatus to pass out of their own custody. Further difficulties have also arisen, as is usual in such cases, in the matter of space and funds, for both have had to be provided by the exhibition itself, as no public funds have been forthcoming. The executive committee has generously given a court, comprising the space of about 14,000 square feet, free of cost, for the science exhibits, and has placed at the disposal of the science committee sufficient funds to allow the exhibits to be safely kept and properly displayed, though perhaps the exhibits will not be shown in such lavish surroundings as might have been desired.

The arrangement of the court is shown in the sketch-plan here reproduced. The north side of the court will be mainly devoted to "Exploration," and there will be a section devoted to astronomy which will have amongst its exhibits a very complete astrophysical observatory. The other sections in this part will be devoted to oceanography, geology, and geography.

In the centre of the court there will be most interesting exhibits from the National Physical Laboratory, also in electricity and magnetism, and in mineralogy and crystallography. The south side of the court will contain the meteorological exhibits, with a typical meteorological observatory, a large exhibit in chemistry, one of metallography, one of biology, one of anthropology, and one of heat, together with smaller exhibits of mathematical science and visible and invisible radiations.

It is also hoped that a meteorological observatory actually at work will be arranged in the grounds of the exhibition.



Franco-British Exhibition. Setting-out of Science Section. Building No. 11.

THE SCIENTIFIC STUDY OF STARVATION.[1]

TO the non-scientific mind the detailed study of inanition or starvation in men and animals may appear both useless and unnecessary. It is in reality one of the most important pieces of work the investigator of nutrition and allied problems can undertake. In the normal condition the processes of construction (anabolism) and decay (katabolism) are taking place simultaneously, and one can in that condition only obtain the net result of, or balance between, these two antagonistic phenomena. In order to understand the way in which the body builds itself up, it is obviously necessary that we should first know the amount and kind of the breakdown which accompanies vital activity, and so logically the study of katabolism must come first. This is only possible when anabolism is minimal; hence arises the importance of the knowledge of what occurs when the intake is limited to oxygen and water.

The work just published under the auspices of Dr. Benedict, the director of the Nutrition Laboratory at Boston, U.S.A., deals with this subject in a masterly way. It is a monument of prolonged and patient industry and self-sacrifice, as well as of admirably planned experiments on a large scale under careful and coordinated guidance. The book is not one which would be selected as a companion for a railway journey. It consists mainly of the protocols of the experiments, their ultimate valuation, and the general results to be drawn from them being left for the future.

A good deal of inanition work has been done in the past upon animals with useful results; a few observations have been made upon men, especially upon professional fasters. In order to obtain trustworthy averages, it is necessary that such experiments should be performed upon a large number of individuals, and this is the work which Dr. Benedict has, with the assistance of his colleagues, and the voluntary self-abnegation of a number of students and others, been successful in accomplishing. Experiments on man himself are more valuable than experiments on the lower animals in such a subject as this.

During Dr. Benedict's long association with the late Dr. Atwater, the celebrated respiration calorimeter was evolved, and the generosity of the Carnegie Institution of Washington has enabled now a special laboratory, situated in Boston, to be entirely devoted to work of this kind. English workers may well envy their more fortunate colleagues across the Atlantic in the ease with which funds are obtained both for higher education and research.

Each man who entered the calorimeter chamber was almost entirely shut off from the world for periods of two, three, and, in some cases, more days. His sole connection with his fellows was a telephone; he

[1] "The Influence of Inanition on Metabolism." By Francis Gano Benedict. Pp. v+542. (Washington: Carnegie Institution, 1907.)

could read, move about to some extent, and sleep for prescribed periods. But his every action was watched through a window and recorded. There were no meals to help him pass the time, and the principal occupation of the prisoner was counting his pulse, and respiration, and carefully collecting his excreta at frequent intervals. These were subsequently analysed, and their various constituents estimated. At the same time, the amount of oxygen used, of carbonic acid and water exhaled, of heat produced, and other factors too numerous even to catalogue, were all determined and recorded. One striking outcome of the work was that in the diaries reproduced comparatively little suffering apart from ennui was recorded. The same has been previously stated by professional fasters; we can therefore hardly doubt that in animals also the actual suffering has been small when they have been subjected to the withdrawal of solid food for a few days. The book is to be commended to all interested in physiological work, and especially to those engaged in a study of nutrition.

W. D. H.

RECENT PROGRESS OF THE METRIC SYSTEM.[1]

An important report by Dr. Guillaume, presented at the meeting of the General Conference of Weights and Measures at Paris in October last, has recently reached us. Dr. Guillaume commences his report with an interesting account of some recent investigations which have been made at the International Bureau of Weights and Measures with respect to the permanency and invariability of the iridio-platinum standards of the metre and the kilogram, which were distributed in 1889 to the several States participating in the Metric Convention of May, 1875. The result of these researches is very satisfactory, and says much for the high standard of accuracy maintained in the metrological determinations of the bureau. Among other investigations which have been undertaken at the bureau since the previous meeting of the general conference in 1901, attention is directed to the work of MM. Benoît, Fabry and Perot in connection with the interferential measurement of light waves. The results obtained confirm in a remarkable manner the value found by Michelson and Benoît in 1892–3 for the length of the metre in terms of the wave-length (λ) of the red radiation of incandescent cadmium, in dry air at 760 mm. pressure, and at the temperature of 15° on the normal hydrogen scale. The new value, viz. :—

$$\text{Metre} = 1,553,164 \cdot 13\ \lambda,$$

leads to the following equivalent for the length of the yard, viz. :—

$$\text{Yard} = 1,420,212 \cdot 04\ \lambda.$$

These values differ from the earlier determination of Michelson and Benoît by less than one part in 10,000,000, from which it may be inferred that the interferential method of linear measurement can lay claim to a degree of accuracy far surpassing that attainable with the best micrometer microscopes.

Another important research, which has occupied the bureau for many years past and has now reached its final stage, is the determination of the weight of a given volume of pure water at its maximum density. From this investigation, which has been conducted principally by MM. Chappuis and Guillaume, the weight *in vacuo* of a cubic decimetre of water at 4° C. has been ascertained to be 0·999972 kilogram.

[1] "Les récents Progrès du Système métrique." By Ch.-Ed. Guillaume. Pp. 94. (Paris: Gauthier-Villars, 1907.)

As the weight of a gallon of water at 62° F., weighed against brass weights in air at the same temperature and with the barometer at 30 inches, is defined as being 10lb. avoirdupois, the following value for the cubic contents of the gallon may be readily deduced from the above result, viz. :—

$$\text{Gallon} = 277 \cdot 420 \text{ cubic inches.}$$

It follows that, under the same conditions of temperature and pressure as in the gallon equivalent,

$$\begin{aligned} &1 \text{ cubic foot of water} = 62 \cdot 288 \text{ lb., and} \\ &1 \text{ cubic inch} \quad ,, \quad = 252 \cdot 325 \text{ grains.} \end{aligned}$$

Further investigations on the subject are in progress at the bureau, but it is unlikely that the final results will be found to differ appreciably from those given above. The values at present legalised in this country, which are based on determinations made by Kater in 1821, are far from accurate, but legislators are naturally chary of prescribing new relations between physical magnitudes before science has said her last word on the subject.

With respect to thermometry, researches undertaken at the bureau during the period covered by this report indicate that the normal scale of temperature adopted by the international committee in 1887 is practically in perfect agreement with the absolute thermometric scale. The corrections previously determined for reducing the readings of mercury thermometers to the latter scale are found to hold good even for instruments of the most recent construction. Formerly Tonnelot thermometers were employed at the bureau in metrological determinations, and thermometers of this type were supplied with the various national prototypes which were distributed in 1889. Of recent years preference has been given to instruments constructed by Baudin, which are subjected to a preliminary course of artificial heating in the vapour of sulphur. It has been found at the bureau that thermometers treated by this process acquire almost perfect stability.

Dr. Guillaume devotes one chapter of his report to recent legislation in different countries with respect to the metric system of weights and measures. During the last few years the metric prototypes of the bureau have been legally recognised in France and Roumania, and the laws of these countries have been brought into harmony with the present conditions of metrology. In Hungary a law was recently passed defining the units of force, pressure, and density in terms of the metric system. The legislature of Denmark has provided for the adoption of the system in that country by the year 1910. The system has also been made obligatory in the Portuguese colonies. On the other hand, Dr. Guillaume does not find much progress to record in Great Britain and its colonies or in the United States, so far as legislation is concerned. Canada has, however, with the acquiescence of the British Government, formally joined the Metric Convention on the footing of a separate State, and in New Zealand an ordinance has been passed prescribing the exclusive use of the system after an indefinite date.

A resolution of the general conference urging upon the various contracting States the formal adoption of a metric carat of 200 milligrams for use in the sale of diamonds and precious stones has been brought by the several Governments under the notice of the industry concerned. At present it is not possible to anticipate what response will be made by the trade. In this country the carat is not legally recognised, but as a customary weight its value is generally accepted as being 3·1683 grains, or 151½ carats to the ounce troy. This is equivalent to 205·3 milligrams. The carat is an extremely ancient weight, of uncertain origin so far as its present value is concerned, but it would appear to be in some way connected with the old standard of fineness for silver in England, viz., 10 oz. 2 dwt. of fine silver to the pound troy, this ratio of fineness being equivalent to the quotient of 64 grains by 24 carats.

In conclusion, it is pleasing to note the moderate tone and invariable accuracy of statement which characterise this report of Dr. Guillaume on a subject which is often discussed in print with considerable warmth.

NOTES.

A committee has been appointed for the purpose of erecting a monument to Marcelin Berthelot by means of an international subscription. The president of the committee is M. Loubet, who is to be assisted, we learn from the *Revue scientifique*, by MM. Gaston Boissier, Léon Bourgeois, Darboux, and Levasseur. Donations may be sent to M. Ch. Goudchaux, 16 rue Miromesnil. .

Prof. R. A. S. Redmayne, professor of mining in the University of Birmingham, has been appointed an Inspector of Mines, under the Coal Mines Regulation Acts, 1887 to 1905, the Metalliferous Mines Regulation Acts, 1872 and 1875, and the Quarries Act, 1894, under the title of "Chief Inspector of Mines."

The death is announced, in his seventy-first year, of Prof. Leopold Schrötter von Kristelli, professor of internal medicine in the University of Vienna, and distinguished for his work in the science of laryngology.

The management of the Municipal Exhibition, which will be opened at the Agricultural Hall on May 1, has arranged for an installation of Röntgen-ray apparatus in a special building in the hall, and for demonstrations, illustrating its use, to be carried out at certain hours each day.

We learn from the *British Medical Journal* that the Riberi prize, of the value of 800*l*., which is given every five years by the Royal Academy of Medicine of Turin, has been awarded to Prof. Bartolomeo Gosio, director of the Laboratories of Public Health of the Italian Ministry of the Interior, for his studies on the bio-reaction of arsenic, selenium, and tellurium.

A Bill has been passed by the Virginia Legislature establishing a Virginia State Geological Survey. According to *Science*, the bureau is to have its headquarters at the University of Virginia, and the board is to be composed of the Governor (*ex officio*), the president of the University, the president of the Virginia Polytechnic Institute, and two citizens. An annual appropriation of 2000*l*. is provided

An interesting exhibit of photographs, instruments, and other astronomical objects is now on view at Cardiff Museum. It was arranged by the Astronomical Society of Wales, and was opened by the Lord Mayor of Cardiff on April 23. Much interest is being taken in the exhibition, which will remain open for some weeks. The Cardiff City Council is now taking a commendable interest in the furtherance of popular astronomy, maintaining an observatory at Penylan Hill, which houses a 12-inch reflector. This observatory is also a meteorological station of the second class.

An appeal is being made for subscriptions to a fund for the widow and daughters of the late Mr. Gerald Massey, whose literary works on subjects relating to myth, religion, and Egyptology are known to many readers and widely admired. A donation of 200*l*. has been received from the Royal Bounty Fund, and friends of the family have felt that this sum might form the nucleus of a fund which would yield a small income. Subscriptions will be received by Mr. James Robertson, 5 Granby Terrace, Hillhead, Glasgow, Scotland, who will render an account to all senders.

A correspondent asks for information or references in regard to the deviation of rivers caused by the rotational velocity of the earth. Prof. G. A. J. Cole has kindly sent the following answer to the inquiry:—"The effect of the earth's rotation on the courses of rivers is regarded by many geographers as distinctly noticeable. The deflection is to the right in the northern hemisphere, the bank being, it is said, typically excavated on this side, while a shoal is left upon the other. In any series of meanders, therefore, those directed to the right side should tend to become more pronounced than those directed to the left. The reverse effects should occur in the southern hemisphere, the left bank being here eroded. Babinet and E. von Baer developed this theory in 1859 and 1860 respectively. The matter is discussed by G. K. Gilbert, *American Journal of Science*, vol. xxvii. (1884), pp. 427–32, and A. C. Baines, *ibid.*, vol. xxviii., pp. 434–6, and excellently and fully by A. Penck, 'Morphologie der Erdoberfläche' (1894), vol. i., pp. 351–60, with numerous references and examples; a sketch is also given by I. C. Russell, 'Rivers of North America,' Progressive Science Series (1898), pp. 39–43. F. Wahnschaffe, who has to deal with the great rivers moving in loose materials over the Prussian plain, throws doubt, like some other writers, upon the efficacy of the earth's rotation in producing a noticeable divergence by erosion ('Die Ursachen der Oberflächengestaltung des norddeutschen Flachlandes,' 1901, p. 188)."

The general type of weather was very wintry and unsettled during the past week, and at many places in the northern portion of the kingdom a lower minimum temperature has occurred than has been previously recorded in April for about forty years, the shade readings ranging from 18° to 22°. Much snow has also fallen in all parts of the country. The report of the weather issued by the Meteorological Office for the week ending April 25 shows exceptional conditions for the time of year. The mean temperature had a deficit of 10° in the east of Scotland and in the Midland counties, and of about 9° in many other parts of the kingdom. The absolute minima were generally registered on April 24 or 25. At Balmoral the sheltered thermometer fell to 10° on April 24, whilst on the grass the reading was as low as 4°. On April 25 the highest reading throughout the day was 35°, at Oxford, and 34°, at Cullompton and Buxton. Nearly all the precipitation took the form of sleet or snow, and the fall was exceptionally heavy in the east and south of England. At Oxford the gauge yielded 1·66 inches for the twenty-four hours ending 8 a.m. on Sunday, the depth of snow being 16 inches, whilst at Southampton the depth was 14 inches, and at Marlborough 11 inches. At Bournemouth the snow which fell for twelve hours during Friday night yielded 1·13 inches of water, equal to about 11 inches of snow. The snowstorm on our south coast on Saturday, April 25, has been characterised as a blizzard.

We welcome the formation of the Research Defence Society, the object of which is to make known the facts as to experiments on animals in this country. The society was formed in January last, and already numbers more than 800 members. It is not an association of men of science or of medical men alone; its membership has been drawn from all departments of public life. Lord Cromer is the president, and a long list of vice-presidents includes the names of men distinguished in most branches of intellectual activity. The annual subscription is 5*s*., to cover working expenses, but larger subscriptions or donations will be gladly received. The acting honorary treasurer, *pro tem.*, is Mr. J. Luard Pattisson, C.B., of the Lister Institute, and an account in the society's name has been opened with Messrs. Coutts and Co., 440 Strand. The honorary secretary is Mr. Stephen Paget, 70 Harley Street, London, W., to whom all communications should be addressed. Lord Cromer, in a letter which has been widely circulated in the Press, directs attention to the immense importance to the welfare of mankind of experiments on animals conducted with proper care, and instances, among many results which have already followed such investigations, the use of antiseptics, the modern treatment of wounds, the invention of diphtheria antitoxin, and the discovery of the causes of plague, cholera, typhoid fever, and sleeping sickness. He also explains that the society will endeavour to make it clear that scientific men who perform experiments on animals are not less humane than the rest of their countrymen who daily, though perhaps unconsciously, profit by them. It is proposed to give information to all inquirers, to publish *précis*, articles, and leaflets, to make arrangements for lectures, and to assist all who desire to examine the arguments on behalf of experiments on animals.

THE structure of the epidermis and epidermal glands of poisonous fishes forms the subject of an article by Mr. E. Pawlowsky in Nos. 7 and 8 of the *Comptes rendus de la Soc. Imp. Nat. de St. Pétersbourg* for 1907. In addition to the ordinary epidermal glands, poisonous fishes like the weavers (Trachinus) are furnished with large serous glands of a horny structure which secrete the harmful fluid. The sting-rays (Trygon) have, however, a numerous series of minute poison-glands in the tail.

RECENT papers received from America include an elaborate account of the early stages in the development of the Mississippi alligator, by Prof. A. M. Riese, issued in vol. li. of Smithsonian Miscellaneous Contributions, and illustrated with twenty-three plates. Also notes on Guatemala birds, by Mr. N. Dearborn, and on fishes from Mexico and Central America, by Mr. S. E. Meath, published by the Field Museum of Natural History. Schizopod crustaceans from Alaska form the subject of a paper by Mr. A. E. Ortmann, published as No. 1591 of the Proceedings of the U.S. National Museum; while in No. 1594 of the same, Mr. A. S. Pearse describes four new species of the amphipod group from the Gulf of Mexico, and in No. 1593 Miss Richardson records the occurrence of the parasitic isopod Leidya on an entirely new host.

THE first part of vol. vi. of the Annals of the South African Museum is devoted to a fourth instalment of the Rev. T. R. R. Stebbing's account of South African crustaceans, of which the earlier parts were published in "Marine Investigations in South Africa." In the present part the author describes as new seven species and one genus, but he takes occasion to point out that the most interesting results of his investigations are not so much novelty of characters in the new forms as the relationship between these South African types and others long known from remote parts of the globe. As an instance of this, it is mentioned that the description of the new Cape prawn, *Leontocaris paulsoni*, had only been published a few months when the discovery of a second species of the same specialised genus was announced in deep water off the Irish coast. The paper is illustrated by fourteen plates.

FROM the morphological standpoint, the rodent mammals form an exceedingly compact and uniform group. From the occurrence of the phenomenon known as inversion it has been suggested, however, that, developmentally, the murine section (Myomorpha) should be associated with the Subungulata, while the squirrel and hare groups (Sciuromorpha and Lagomorpha), in which inversion is absent, should constitute a section or order apart. On the other hand, it has been asserted that inversion, although most developed in the Myomorpha and Subungulata, does also occur in the other two groups, and the suggestion has been made that all rodents agree in their early developmental stages, although divergence takes place later. To test this, Mr. A. Ochs, of Düsseldorf, has undertaken an investigation of the intra-uterine development of the hamster, the results of which are published in vol. lxxxix., part ii., of the *Zeitschrift für wissenschaftliche Zoologie*. The conclusions with regard to the classification of rodents are, however, deferred.

ONE of the latest additions to the admirable series of "Guide-books" issued by the natural history branch of the British Museum is devoted to the elephant group, and explains in precise and yet popular language the wonderful story of proboscidean evolution revealed by recent discoveries in Egypt. The publication of such a guide-book was rendered practically imperative owing to the fact that the collection of proboscidean remains in the museum is more extensive than any other in the world. So large and so nearly complete is the collection that it is possible for the visitor to see with his own eyes practically every link in the chain between the primitive Egyptian Mœritherium, on the one hand, and the highly specialised Indian elephant and mammoth on the other. In the case of several of the early forms, complete models of the skull have been recently installed in the geological department. The interest of the series would be greatly increased if a life-sized model of the head of the long-chinned, four-tusked mastodon (*Tetrabelodon angustidens*) were prepared and placed alongside the heads of modern elephants. The guide, which is admirably illustrated, has been prepared by Dr. C. W. Andrews, the great authority on the group.

A PAMPHLET on the preparation and use of anti-plague vaccine has been issued by the Bombay Bacteriological Laboratory. It gives details of the preparation of the vaccine, and full directions as to the mode of inoculation. Another pamphlet on the same subject, "The Cause and Prevention of the Spread of Plague in India," a lecture delivered by Captain Glen Liston, summarises in a complete and interesting manner our knowledge of the parts played by the rat and flea in the dissemination of plague.

THE first part has reached us of a new publication, *Parasitology*, a supplement to the *Journal of Hygiene*, edited by Prof. Nuttall, F.R.S., and Mr. A. E. Shipley, F.R.S. *Parasitology* will include papers dealing with the anatomy of mosquitoes, fleas, protozoa, and other parasites, which have only an indirect relation to hygiene and preventive medicine. The present part is devoted to a paper by Dr. Karl Jordan and the Hon. N. C. Rothschild on a revision of the non-combed, eyed Siphonaptera, a group of fleas to which that carrying plague belongs.

THE March number of the Journal of the Royal Sanitary Institute (xxix., No. 2) contains an important paper by Dr. Rideal on the relative hygienic values of gas and electric lighting. The principal conclusions are that, owing to the better ventilation obtained by gas, the products of combustion are not present in the air in anything like the proportion that might be expected, the temperature and humidity in an occupied room being no greater than when the room is lighted with electric light; that carbonic acid has not the injurious effects formerly attributed to it; and that products—heat, carbonic acid, and moisture—are derived from the inmates more than from the illuminant.

The work of improving the sugar-cane is still going on at Barbadoes, and the results obtained during the season 1905–7 are recorded in a publication recently issued by the Imperial Department of Agriculture for the West Indies. One of the new canes yielded as much as 2000 pounds of saccharose per acre more than was obtained from the ordinary White Transparent; it is obvious that differences of this kind are of prime importance to the sugar planter. Manurial experiments are also recorded; these are intended to find profitable combinations of manures. One result is rather interesting; nitrate of soda gave a larger yield of sugar than sulphate of ammonia, although the latter is commonly preferred in the West Indies.

In the *Indian Forester* (February) prominence is given to an article by Prof. M. Henry on forests and rainfall. A theoretical discussion of the argument that the atmosphere contains more moisture in the neighbourhood of forests is clinched by the observation of an officer of engineers that a balloon will descend when passing over an extensive wooded area. It is also indicated how forests increase the rainfall of a locality and help to augment the supply of water from springs. A native apparatus for distilling camphor oil from the leaves of *Cinnamomum Tamala* is illustrated by Mr. B. Gopaliah.

The sixth number of the Quarterly Journal of the Liverpool Institute of Commercial Research in the Tropics (January) has been received. Dr. E. Drabble contributes several short articles on West African oil seeds, dealing with *Carapa procera*, *Poga oleosa*, *Irvingia gabonensis*, the source of Dika butter, and *Scyphocephalium Kombo*; also a comparison of the barks of the red (*Rhizophora mangle*) and the white mangroves (*Laguncularia racemosa*) from the same region. Mr. R. Newstead furnishes the identifications and descriptions of several coccids infesting plants in Madagascar, among them being the gum-lac insect, *Gascardia madagascariensis*, that is allied to Ceroplastes, but is very different from Tachardia, the Indian lac insect. In connection with analyses of latex from *Ficus Vogelii*, Dr. D. Spence directs attention to the high percentage of magnesium and chlorides contained, as compared with the latex of Hevea or Funtumia, in which phosphates are largely present, while chlorides are almost absent.

A second paper dealing with the fern genus Nephrodium is communicated by Mr. S. Yamanouchi to the March number of the *Botanical Gazette*. It is concerned with spermatogenesis, oogenesis, and fertilisation in the genus as exemplified in the species *Nephrodium molle*. The author obtained a very complete set of stages in the development of the spermatozoid. Blepharoplasts, arising in the cytoplasm, were observed in the sperm mother cell. The important modification of this body occurs in the sperm cell when it flattens out above the nucleus, becomes band-shaped, and finally wedge-shaped, with the narrow end joined to the nucleus. Thus the anterior part of the sperm is formed from the blepharoplast. The development of the ovum is normal; in fertilisation the sperm remains unchanged for a period after entering the egg nucleus, but eventually disintegrates with the formation of a reticular structure, and mixes with the egg nucleus.

Bulletin No. 14 of the Edinburgh and East of Scotland College of Agriculture contains a detailed statement of the yield of milk and the percentage of fat therein obtained from a herd of twenty-seven cows. The fact that cows vary considerably in their milk yield is clearly brought out, and farmers are urged to keep systematic records of each cow's yield in order to improve the general standard by eliminating the poor ones.

No. 6 of the Memoirs of the Department of Agriculture in India deals with the movements of water in the soil. Perhaps no subject is of more importance to the agriculturist, or so little investigated in Great Britain and the British dependencies. Dr. Leather furnishes an interesting set of measurements which will prove of great value if they succeed in attracting some competent physicist to direct his attention to the numerous physical problems awaiting investigation in agricultural science.

The February number of the *Agricultural Journal of the Cape of Good Hope* contains a report on the suitability of various South African fibre plants for paper-making. Four materials are discussed, matjesgoed fibre, palmiet fibre, papkuil fibre, and bamboo; samples of the first three sent over to the South African Products Exhibition in London yielded pulp valued at 6*l.* or 7*l.* per ton, whilst bamboo pulp is valued at 9*l.* to 10*l.* In view of the abundance of fibre material in Cape Colony for which no use at present exists, the possibility of preparing pulp on the spot, and either exporting it or making it into paper, seems worthy of very careful consideration.

A new national forest, named the Verde, and consisting of 721,780 acres, has just been created, says the *Scientific American*, in Maricopa and Yavapai counties, Arizona. The forest lies on the west side of the Verde River, and constitutes a great part of its watershed. Most of the reserve is covered with brush that has no commercial value, but a small part has merchantable timber on it. The protection of the brush-grown area is just as important as that of heavily forested land, the scrub being the only thing that conserves the water and saves the watershed of the Verde River from erosion.

In the *Mitteilungen* from German protectorates (vol. xxi., part i.), Dr. P. Heidke continues the discussion of meteorological observations made at Windhuk (South-West Africa) for the year ending June, 1906, commenced in the previous volume of this publication, dealing with the daily range of air-pressure and temperature and with their harmonic constituents. The effect of the continental climate is well shown in the small night minimum and evening maximum of pressure, as compared with the large morning maximum and afternoon minimum. The same number contains a valuable compilation, also by Dr. Heidke, of the monthly and yearly results, together with harmonic constituents, for twenty-five stations in the East African Protectorate, for the years 1903–4, deduced from tri-daily observations. References are also given to the periodicals in which the observations for previous years are published.

It is stated in *Engineering* of April 24 that H.M.S. *Tartar*, the turbine topedo-boat destroyer, has satisfactorily undergone a very severe series of trials, and has been taken into commission. The *Tartar* is the fastest warship afloat, its speed on the official trials being 35·672 knots as a mean of six runs. During six hours' run the mean speed proved to be 35·363 knots, while the fastest run was at the rate of more than 37 knots. The speed guaranteed by contract was 33 knots. The vessel is 270 feet long, the propelling machinery being Parsons turbines and six Thornycroft water-tube boilers.

There has been much controversy in recent years on the subject of that class of Palæolithic stone implements which have been called eoliths. The question has now been taken up in the April number of *Man* by Mr. Worthington Smith, who deals specially with discoveries in the North Herts and South Beds plateaux, and in particular with the contorted drift, which contains all the varieties of worked stones which were lying on its surface at the time of its deposition, including older and newer palæoliths and their ever-accompanying eoliths. The last class he thus attempts to define :—" At the present day all kinds of oddities in flint are passed off as 'eoliths'; one author says the examples must be bulbless; another describes well-formed bulbs. One says the secondary flaking is vertical; another that it is lateral. Sometimes a proof of authenticity is said to rest on the fact that the stones in question present no flaking at all, only rubbing. If museums are visited one sees ordinary palæoliths masquerading as 'eoliths,' and rubbing shoulders with minor well-known Palæolithic forms, iron-stained neoliths, surface flints, and late Victorian oddities of all sorts." In short, Mr. Smith concludes that there are no such things as "eoliths" at all, nine out of ten of the thousands sent to him for examination being only natural flint fragments. "The tenth has been a minor and well-known Palæolithic form, or, it may be, a bulbed, iron-stained, Victorian flake, knocked off by the hoof of a farm animal." None of those he has examined he believes to be as old as the Boulder Clay.

In a recently issued pamphlet (" Plato or Protagoras?" London: Simpkin, Marshall and Co., price 1s. net) Dr. F. C. S. Schiller propounds a novel and interesting view of the real significance of the speech attributed to Protagoras in Plato's dialogue, "Theaetetus." According to this view, the argument of the speech was not invented by Plato, but represents an attempt on his part to state fairly the actual case of an opponent whom he had not completely understood, and who had at the time of the composition of the dialogue passed beyond the reach of interrogation. Dr. Schiller seeks to justify his interpretation by maintaining that the criticisms which are directed by "Socrates" against the Sophist's arguments do not really refute them, and, in fact, prove merely that Plato had formed a very imperfect conception of their meaning and scope. Incidentally, Dr. Schiller takes occasion to claim that Protagoras was in all essential points an early exponent of his own doctrine of humanism, and that Plato's failure to refute him was prophetic of the superiority of the pragmatic philosophy over all forms of "intellectualism."

The *American Journal of Science* for April contains an article by Mr. H. M. Dadourian, of Yale, on the constituents of atmospheric radio-activity at New Haven. Mr. Dadourian suspended a negatively charged wire for three hours in a cavity in the ground, and another for four days in the air about 7 metres above the ground. On determining the rate of decay of the radio-activity of each wire, he found that 5 per cent. of the initial radio-activity of the first, and 20 per cent. to 30 per cent. of that of the second, was due to thorium and its products, the rest to radium and its products. From this he deduces that the amount of radium emanation present in the air of New Haven is about 40,000 times as great as the amount of thorium emanation.

The Adamson lecture, founded in 1903 in memory of the late Prof. Robert Adamson, of Manchester, was delivered last term by Prof. J. J. Thomson, and has recently been published by the Manchester University Press. It deals with the relation between ether and matter brought to light by recent electrical investigations. Prof. Thomson points out that in electrical phenomena we are brought into contact with cases of interaction between bodies charged with electricity, in which the action of the first on the second is not equal and opposite to the reaction of the second on the first. In such cases we suppose that both bodies are connected with the ether around them, and that Newton's third law holds when we consider the ether and the two bodies as constituting the system under examination. From this point of view, the potential energy of an electrical system may be regarded as due to its connection with an invisible subsidiary system possessing kinetic energy equal in amount to the potential energy of the original system. This conception may be further extended to non-electrified bodies, and the ether thus comes to play an important part in ordinary dynamics.

Prof. Andrew Gray delivered an oration on Lord Kelvin at the University of Glasgow on Commemoration Day, April 22. The address dealt largely with the early work of the great master at Glasgow, when he was making the electrodynamic and electromagnetic theories more explicit, and testing them experimentally under conditions the antithesis of those which exist in the well-equipped laboratories of the present day. Prof. Gray mentions two views held by Lord Kelvin to which we may at the present time well devote special attention. He believed that the study of natural philosophy ought not to be excluded from the arts curriculum, and he was strongly opposed to the tendency which has been manifesting itself to separate the experimental from the mathematical side of physical work. With him the mathematical symbol was merely the servant of the idea, and mathematical methods had their place among the tools and instruments of research. The printed copy of the oration contains portraits of Lord Kelvin in 1846, 1868, and 1905 respectively, and a view of the outside of the natural philosophy rooms of the old college buildings.

Prof. P. Zeeman, in his second note on the magnetic resolution of spectral lines and magnetic force (*Konink. Akad. Wetens. Amsterdam*, December 24, 1907), gives some striking measurements of asymmetric separation, with excellent photographic reproductions illustrating the various stages. By means of the method of the non-uniform magnetic field, described in the first article in the above Proceedings for April, 1907, he finds it possible to study at a glance any series of phenomena dependent on the field intensity for a series of different intensities. The class of asymmetric separations herein considered has been predicted from theory by Voigt, and has also been considered by Lorentz. One of the most interesting cases is the yellow mercury line at λ 5791, the structure of which cannot be satisfactorily made out by the interferometer. The first-order spectrum of a Rowland concave grating of 6·5 metres radius, with 10,000 lines to the inch, has been employed for the investigation. It is seen that while the 5791 line is resolved asymmetrically, the neighbouring line, 5770, is resolved into a perfectly symmetrical triplet. Of this pair of lines a nine-fold enlargement of the original negative is given, showing most distinctly the above effect. The intensity of the magnetic fields employed varied from 14,800 to 29,220 Gaussian units. There are several points requiring further investigation; the apparent inconstancy of the amount of asymmetry contrary to theory, also the apparent asymmetric intensities observed in the components of various lines. Careful measurements of the width of the lines show that the mean value is about 0·07 Ångström unit, and that the asymmetry amounts to about half this amount.

Sir William Ramsay contributes to the May number of *Cassell's Magazine* a popular article under the title "How Discoveries are made," in which he refers, among other matters, to the work of Priestley, Scheele, and Cavendish on air and combustion; Crookes, Lenard, and Röntgen on kathode rays; and Soddy and himself on radium emanation and its decomposition into helium, leading up to a short statement as to β rays and the corpuscular theory of electricity. The article provides general readers with a glimpse of scientific work, and is a welcome feature in a popular magazine.

The Institute of Chemistry has published a second edition of the "List of Official Chemical Appointments." It has been compiled by direction of the council of the institute, and under the supervision of the proceedings committee, by Mr. Richard B. Pilcher, registrar and secretary of the institute. The scheme adopted in the first edition has been adhered to, the information has been corrected carefully, and numerous additions, including an index of names, have been made. The list is arranged in two main divisions; the first contains appointments in the British Isles, and the second in India, Canada, Australia, British colonies and protectorates, Egypt, and the Sudan provinces. The appointments dealt with include those under State departments, local authorities, and public institutions, in addition to teaching posts at universities, colleges, and schools. An appendix gives concise information as to societies for the advancement of chemical science and of professional chemical interests. The publication, the price of which is 2*s.* net, should prove of great service to all who are interested in the applications of chemistry to State purposes and in the teaching of the science at its various stages.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences in May:—

May 1. 8h. 46m. to 12h. 28m. Transit of Jupiter's Sat. III. (Ganymede).
3. 21h. 59m. Venus in conjunction with the Moon. Venus 4° 15′ N.
4. 8h. 48m. to 9h. 46m. Moon occults μ Geminorum (mag. 3·2).
5. 0h. 51m. Neptune in conjunction with the Moon. Neptune 1° 20′ S.
6. 22h. 41m. Jupiter in conjunction with the Moon. Jupiter 1° 47′ S.
7. 10h. 56m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc = 0·388.
,, 8h. 42m. to 13h. 31m. Transit of Jupiter's Sat. IV. (Callisto).
16. 11h. 15m. to 12h. 22m. Moon occults ψ Ophiuchi (mag. 4·6).
19. 8h. 34m. Uranus in conjunction with the Moon. Uranus 0° 35′ N.
24. 23h. 47m. Saturn in conjunction with the Moon. Saturn 3° 15′ N.
29. Venus at maximum brilliancy.
30. 9h. 25m. Minimum of Algol (β Persei).
31. 13h. 52m. Mercury in conjunction with the Moon. Mercury 2 19′ N.

A New Star-finder.—The "Metron" star-finder submitted to our examination by the maker, Mr. C. Baker, 244 High Holborn, is an ingeniously designed instrument which will enable beginners in astronomy to become practically acquainted with the constellations and the brighter stars, and also with the more important problems usually placed under the heading "The Use of the Globes." It consists of a 4-inch celestial globe mounted on a tripod and stand so that it may be erected for any latitude. A date circle and a loose hour circle round the south pole enable the user to set the globe for any day and hour of the year. There is also a wire grip carrying a circle, with a pointer at its centre, and a pair of telescopic sights. Having set the globe for latitude, oriented it north and south by the fixed compass, and levelled the stand by means of the two bubbles set in it, the user sets the hour circle according to the directions, and places the pointer over the star, on the globe, which he wishes to locate and recognise; the real star may then be seen in the centre of the telescope field. In this way a number of constellations and important stars, of which the names are given on the globe, may be recognised. Conversely, knowing the date and the position of the star, the approximate time may be determined; special sights are supplied for work on the sun. To facilitate the reading of the globe and circles when working at night, a small electric lamp—and dry cell—is fitted to the stand.

The whole apparatus is nicely finished in nickel plate, and should prove useful in demonstrating problems in astronomy to beginners. For anything like accurate work, the apparatus in its present form and size is, we believe, on too small a scale; a very small error in the setting produces great confusion when magnified on the celestial vault, and the unaided beginner would probably find that his knowledge of the constellations was not considerably enlarged; when he began to be familiar with the instrument and the stars he would find in the combination a source of many hours of interesting work and problem-solving. Spare globes, covered with blank paper, may be obtained for the purpose of plotting the apparent paths of planets, &c.; on the present globe we notice one or two misspellings, *e.g.* Sygnus, Delphin, as the names of constellations. The price of the instrument, complete in box, is 2*l.* 12*s.* 6*d.*

Saturn's Rings.—In No. 4243 of the *Astronomische Nachrichten*, pp. 289 to 313 are devoted to records and discussions of observations of Saturn made by various observers during the end of 1907 and the beginning of the present year. Prof. Lowell and Mr. Lampland give the details of the Flagstaff observations, and the former discusses the appearance of the edge of the ring system and of the condensations remarked by Prof. Barnard, themselves, and other observers. When observing the shadow of the rings on the ball of the planet, all the Flagstaff observers noticed that it was traversed by a medial core the blackness of which was far more intense than that of the boundaries. This core was first observed on June 19, 1907, and was plainly visible on subsequent occasions; on November 5 the shadow generally was of a faint cherry-red tinge, and the black medial line was slightly undulatory, showing irregularities of outline. Drawing conclusions from the discussion of his results, Prof. Lowell finds that the rings approach more nearly to the body of the planet than hitherto measured, and that the middle and inner members of the ring systems are not flat rings, but tores; this would account for the condensations observed, and for the medial core of the shadow.

The Systematic Motions of the Stars.—From the analytical study of the motions of 1100 stars having proper motions of between 20″ to 80″ per century, and distributed over both hemispheres, Prof. Dyson has obtained results which confirm those previously obtained by Kapteyn and Eddington, viz. that the stars are moving in two streams.

The positions found for the apices of the two streams as found by the different observers are shown below:—

	Stream I.		Stream II.	
Kapteyn ...	R.A. 85°,	Dec. − 11° ..	R.A. 260°,	Dec. − 48°
Eddington ...	,, 90°,	,, − 19° ...	,, 292°,	,, − 58°
Dyson	,, 94°,	,, − 7° ..	,, 240°,	,, − 74°

The quick-moving stars considered in the latest discussion show the two distinct drifts very pronouncedly, particularly in the case of Stream II. For Stream I. the three determinations agree within 7° of the position R.A. = 90°, dec. = −12°, and for Stream II. within 14° of the position R.A. = 263°, dec. = −60° (Proc. Roy. Soc. Edinburgh, vol. xxviii., part iii., No. 13, p. 231, February).

DETERMINATION OF THE ERRORS OF THE PARIS OBSERVATORY RÉSEAUX.—In a paper communicated to the Paris Academy of Sciences, M. Jules Baillaud describes a novel method whereby he has determined the errors of the *réseaux* used in connection with the *Carte du Ciel* plates at the Paris Observatory. By this method the influences of variations of temperature and of deformation of the gelatin film during development are eliminated, and M. Baillaud finds that the errors attain the value 3 μ, the variations between measures on several plates not exceeding 0·5 μ. This is of the same order of size as the grain of the plate used, and it would probably be possible to reduce the apparent discordance by using plates of a finer grain (*Comptes rendus*, No. 12, March 23, p. 616).

THE HERSCHELS' NEBULÆ.—No. 4, vol. ii., of the *Rivista di Astronomia* (Turin, April, p. 82) contains an article of especial interest and value by Madame Dorothea Isaac-Roberts, who discusses the nebulæ discovered by the Herschels as photographed by the late Dr. Isaac Roberts. The author first gives a brief review of the history of nebulæ observations from the time that Galileo discovered the first true nebula in 1610; then follows an explanation of the classification of nebulæ made by Sir William Herschel, and of the code used by Sir John Herschel in his descriptions of nebulæ. A brief description of the plates shown in the latter's memoir of 1833 is followed by a discussion of the groups of nebulous bodies as classified by Dr. Roberts. The paper concludes with a brief sketch of the lines which the author's discussion of Dr. Roberts's plates will follow, and is to be continued in the following number of the review.

HORIZON AND PRIME-VERTICAL CURVES FOR LATITUDES +30° TO +60°.—In these columns for January 30 (NATURE, No. 1996, p. 302) we described briefly a useful sun and planet chart submitted for our inspection by Messrs. Carl Zeiss. The same firm has now sent us a transparent celluloid scale, devised by Herr H. H. Kritzinger, which, when used in conjunction with the charts, enables one to see at a glance the relative positions of the local horizon and prime vertical for any place between latitudes 30° and 60° north. This allows the approximate sidereal time of rising and setting of the stars, and of their transit through the prime vertical, to be found at once, and with no trouble beyond that involved in superposing two sets of lines. Messrs. Zeiss will be pleased to send copies of this new scale on receiving applications.

EDUCATIONAL LEAKAGE.

THE success of any system of technical instruction or higher education depends ultimately upon the preparatory education of the students in our technical schools and other institutions of higher education. The results hitherto obtained from the work of colleges and technical schools in this country have been discounted seriously by the inadequacy in the nature and supply of the education for boys of school age. Mr. V. A. Mundella, in an address delivered last year to the Association of Teachers in Technical Institutions, directed attention to the subject, and also by means of curves illustrating recent statistics demonstrated the serious leakage of children at twelve and thirteen years of age, who afterwards receive no education whatever.

The accompanying diagram shows the number of children at stated ages, and the grade of education, if any, they are receiving. Mr. Mundella states that there are in England and Wales, between the ages of eleven and twelve years, 718,000 children, of whom 620,000 are in elementary schools, and at the outside 40,000 in public and private secondary schools. The curve T shows the total number of children at each year of age up to twenty-one years, and the curve A the total number of these children in elementary schools. The form of A shows strikingly the rapid decrease in school attendance between the thirteenth and fifteenth years. The curve *t* exhibits the number of children surviving, at each year of age, who have attended an elementary school, and a comparison of this curve with those marked B, C, X, shows how little has been accomplished in the direction of continuing the education of the nation's children after the elementary school has been left. Curve B illustrates the total number of children in science and art classes, C in evening continuation schools, X in secondary schools, and U—a continuation of X—in universities and university colleges. The curve X is based upon statistics published in 1898, no later statistics being available. The curve D represents the number of surviving

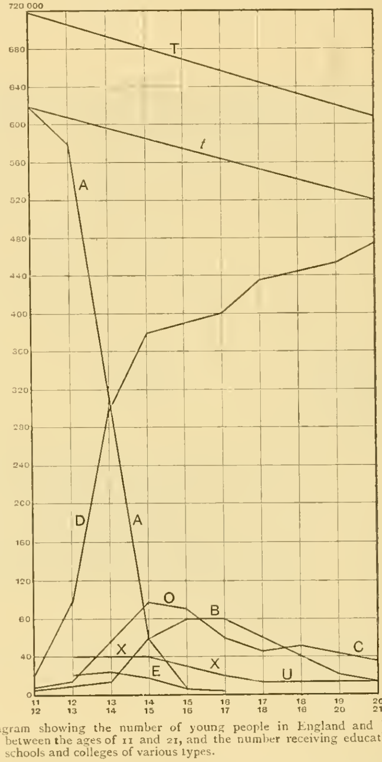


Diagram showing the number of young people in England and Wales between the ages of 11 and 21, and the number receiving education in schools and colleges of various types.

children who have attended elementary schools, but are receiving no further organised education, and E shows the total number of children at each age taking approved courses of instruction in State-aided secondary schools.

The facts embodied in this diagram demonstrate very clearly the need for strenuous national effort to insist upon children attending primary schools until they are fourteen years of age and abolish the present system of half-timers and other exemptions, to provide for continuation schools at which attendance shall be compulsory, and to establish secondary schools which are really schools of a high educational type. Schools in which 80 per cent. of the pupils leave at fifteen years of age or under are better described as higher elementary schools than as secondary schools, under which title they are at present classified.

THE SCIENTIFIC RESULTS OF THE VOYAGE OF THE S.Y. "SCOTIA."[1]

THE results of the meteorological, magnetical, and tidal observations made by the Scottish National Antarctic Expedition have now been published under the editorship of the leader, Dr. W. S. Bruce. This part of the work of the expedition was organised by Mr. R. C. Mossman.

The instrumental outfit was complete, well selected, and carefully standardised. Thus the barometers were compared with the Meteorological Office standard before and after the expedition, with the Argentine standard in January, 1904, with the Cape standard in May, 1904, and with the lighthouse barometer at the Falkland Islands.

Whilst at sea, and north of lat. 30° S., the meteorological observations were made four times a day. South of lat. 30° S. they were made hourly. From April to October, 1903, the *Scotia* was frozen up in Scotia Bay, Laurie Island, South Orkneys, and the observations were made on the ship. On November 1 the instruments were transferred to a stone hut which had been erected and called "Omond House." The observations were continued here while the ship went to Buenos Ayres to refit.

Besides the observations actually made by the staff of the expedition, the report also includes observations made at Cape Pembroke lighthouse. The *Scotia* took out to this lighthouse a number of instruments from the Meteorological Office, and the lighthouse keeper or his assistant made readings every four hours. The lighthouse was used by the *Scotia* as a base station.

In the discussion of the observations taken at sea, reference is made to the fact that it was necessary to have two sets of thermometers, one on each side of the ship, and to use the observations taken on that set which was to the windward, the heating effect of the ship fires being sufficient to cause those instruments on the leeward side to read one or two degrees too high.

During the summer cruise of 1902–3 the Weddell Sea was filled with pack ice as far north as lat. 60° S., whilst in the next summer the *Scotia* reached Coats Land, lat. 72° S., without meeting any obstacle.

Comparison of observations made in the Weddell Sea with those made at Snow Hill, Graham's Land, shows that in February and March the pressure and temperature are higher than at Snow Hill. The cloud amount is also high, for during 81 per cent. of the time during which observations were made the sky was overcast, and only 3 per cent. of the time cloudless.

The observations at the South Orkneys were under the direction of the Scottish expedition only eleven months (April, 1903, to February, 1904), and were continued under the auspices of the Argentine Republic. By permission of the Argentine meteorological director, Mr. Mossmann has been able to discuss observations taken during 1904, and records the mean temperature as 22°·7, the lowest reading being −26°, in June, 1903. The diurnal range of temperature varies from 1°·1 in autumn to 3°·2 in spring.

It was noted that, whereas on the eastern coast of Graham's Land the easterly winds are very conspicuous, the winds at Scotia Bay had only a very small easterly component.

As the expedition was not originally arranged with the intention of making magnetical observations, the only instruments taken were a portable magnetometer and a dip circle. There being no special non-magnetic area on the *Scotia*, no observations were made at sea.

A wooden hut erected not far from Omond House, and called the Copeland Observatory, was used to shelter these instruments. The observations were made under very adverse conditions. It was often found that the magneto-

View of Copeland Observatory, Central Cairn, and Omond House, Scotia Bay. Reduced from a Report of the Scottish National Antarctic Expedition.

[1] Scottish National Antarctic Expedition. Report on the Scientific Results of the Voyage of the S.Y. *Scotia* during the Years 1902, 1903, and 1904, under the leadership of W. S. Bruce. Vol. ii., Physics. Pp. xvi+324. (Edinburgh: Scottish Oceanographical Laboratory, 1907.) Price 1*l.* 1*s.*

meter had become crusted with ice spicules, and it had to be thawed out before it could be used. Many other difficulties had to be encountered, and it is surprising that any successful observations were made; but Mr. Mossman, assisted by Mr. W. Martin, secured, besides other observations, hourly observations on twenty days.

The magnetic observations are discussed by Dr. Chree, F.R.S., who remarks that the results show how very carefully the observations were made. The observations extended over the period May, 1903, to February, 1904.

The following values are given:—declination, 5° 31′·2 east; inclination, 54° 30′·6 south; horizontal force, 0·25704; mean daily range of declination obtained from the hourly readings, 8′·65.

While the *Scotia* was anchored and frozen in Scotia Bay observations of the tide were made by means of a very simple gauge. A long wire, fastened to the sea floor by a heavy weight, passed over a pulley, and was kept taut by a lighter weight at the other end. As the ship rose and fell with the tide this weight moved up and down a vertical scale, which was observed half-hourly.

The tides seem to be normal for a place in the Southern Ocean. The semi-diurnal tides are considerable, but the solar tide is unusually large compared with the lunar tide, the ratio being three-fifths, or 0·6, as compared with 0·465 of the equilibrium theory. The semi-diurnal tides are almost exactly "inverted," so that low water occurs very nearly when the moon is on the meridian.

THE METEORS OF HALLEY'S COMET.

IN view of the approaching return of Halley's comet, the Aquarid meteor shower of May ought to be awaited with special interest. We know comparatively little of this system, as it has been seldom observed. It is certain, however, that it is the richest of our May showers, and that its radiant point conforms very nearly both in date and place with the radiant and epoch of particles following the path of Halley's comet. This circumstance alone is significant, and the supposed connection of the comet and meteoric display will be sure to receive ample investigation during the next few years.

The Aquarids should be looked for after 1 a.m. in the mornings between the end of April and May 7, and they are directed from a region at about 337°−2°, just below the equator. Lieut.-Colonel Tupman determined the radiant as about 10° west of the point assigned, and further observations are required to ascertain the exact place, and also the precise date of the maximum of the shower.

If really associated with Halley's comet, the meteors ought, in immediate ensuing years, greatly to increase in numbers, though we possess no historical records of rich showers having been observed in 1759 or 1835, when the comet previously returned to perihelion. But many meteoric phenomena have eluded recognition, and it is very possible that some returns of these Spring Aquarids may have escaped notice, as they are only visible just before sunrise, and were never specially looked for until after their discovery nearly forty years ago by Lieut.-Colonel Tupman. This stream, like the Perseids and Leonids and many other showers, is evidently one visible nearly every year, and forming a complete ellipse. It now remains for observations in immediately ensuing years to determine whether, like the Leonids and Andromedids of November, it develops unusual intensity near the time of return of the parent comet.

W. F. DENNING.

SOME UNSOLVED PROBLEMS IN METAL-MINING.[1]

IN one sense every mine is an unsolved problem from the day the first pick is put into the ground until the mine is finally abandoned as exhausted, and even then it is not always certain that it really is worked out, and that sinking or driving another 10 feet might not give it a renewed lease of life. Unlike most engineering problems, which have generally to be solved before work is commenced, a mining problem is never fully solved until all work upon it is finally concluded.

At the very outset, even before we are in a position to attack the different subdivisions of the subject, we are brought face to face with what may almost be described as one of the fundamental problems underlying the whole of metal-mining, and one the solution of which can never attain finality. The work of the metal-miner being limited to the extraction from the earth's crust of the ores of the various metals, whilst it is the business of the metallurgist to smelt these, so as to reduce therefrom the metals that they contain, and to fit the latter for their use in the arts, the question what constitutes an ore is one that the miner cannot answer for himself, and for the reply to which he is dependent entirely upon the development of metallurgical science for the time being. Not all metalliferous minerals are ores from the smelter's point of view. Take, for example, an ordinary brick clay, which is a complex hydrous silicate containing, say, 15 per cent. of aluminium and 5 per cent. of iron; it is true that we can extract both these metals from it by a series of complicated laboratory processes, but no means for doing this economically on a practical working scale have yet been discovered. Hence no one would dream of calling clay an ore of aluminium, and far less of iron. Nevertheless, it is not beyond the bounds of possibility that our modern metallurgists, or their younger and more progressive brethren, the electro-metallurgists, may within a few years devise some practicable process for extracting aluminium from clay, when clay would straightway become an ore of aluminium, though it is not one now; and if perchance it happened that comparatively pure oxide of iron were obtained as a by-product in the same process, the clay might even be reckoned as an ore of iron also. Until some such process shall be devised, clay is looked upon by the metal-miner as a non-metallic mineral, as so much worthless gangue or waste. The history of metal-mining has shown again and again that the waste rock of one generation is the valuable ore of another, as, for example, the zinc blende of the Alston district, which is now being recovered from the waste which the old miners had left behind as worthless in their excavations, or had thrown aside on their waste heaps, the value of the mineral having been recognised when a Belgian metallurgist discovered how to extract zinc from it.

The point may be further illustrated by a consideration of the world's supply of iron ore; iron, the most useful of all metals, is at the same time, next to aluminium, the most abundant, geologists calculating that 4·7 per cent. of the earth's crust consists of iron; if this estimate be correct, the very small portion of the earth's crust underlying the London Metropolitan area (fifteen miles' radius) down to the depth of only one mile would contain no less than 360,000 millions of tons of iron, none of which is in the form of a true iron ore. At the present day no one would call a mineral containing less than 25 per cent. of iron an iron ore, and unless it contains double that percentage it will not find a very ready or a very appreciative market amongst iron smelters.

As the result of various improvements in the last few decades, the whole trend of modern mining is towards the utilisation of large deposits of low-grade material, the increased scale of operations enabling economies to be effected that were impossible whilst small quantities alone were dealt with. One of the cardinal problems that will confront our successors will be how to work with profit minerals of lower grade than any that we have yet attacked, so as to enable the miner to include within his sphere of operations deposits too poor for us to deal with to-day.

The possibility of determining by some means the whereabouts of the hidden treasures of the earth has long been an object of the miner's desire, the methods for accomplishing which range from the mediæval adept with his divining rod, belief in which is not wholly extinct to-day, down to a series of modern attempts to use electric currents for the same purpose. Up to the present these attempts have been unsuccessful, in spite of the ambitious claims of some of their advocates.

In view of the fact that minerals differ so widely in their electric and magnetic properties, it is quite possible

[1] From the "James Forrest" Lecture, delivered at the Institution of Civil Engineers on April 27 by Prof. Henry Louis.

to conceive that some method of detecting concealed mineral deposits by these means may be devised. Indeed, for one particular class of minerals such a method has long been in existence; in Scandinavia there are many deposits of magnetite, and many others of which magnetite forms a constituent, so that all such deposits distinctly affect a magnetic needle. The Swedish prospector has long used the so-called mining compass, which consists essentially of a small magnetic needle so suspended as to be able to move both horizontally and vertically. When this compass is brought over ground in which such deposits of magnetic mineral exist, the needle indicates their presence by its change of dip, so much so that it has been customary for years past in Sweden to buy and sell mineral properties by their "compass-drag," or their effect on the miners' compass.

When, by any means, some indication is obtained of the approximate position of a mineral deposit, it has to be more precisely located by boring. Boring is of but little value for tracing mineral veins, owing to their going down so nearly vertically and to their great irregularity, but it is often used to locate irregular masses of ore; for example, bore-holes have recently been employed successfully in Cumberland for proving deposits of red hæmatite in the Carboniferous limestone, even where this is overlain by Triassic rocks. Obviously bore-holes are most valuable when stratified deposits have to be tested, and everyone will remember the conspicuous success that attended their use in proving the permanence in depth of the auriferous banket beds of the Witwatersrand.

The deepest bore-hole put down up to the present is one at Paruschowitz, in Upper Silesia, which attained a depth of 6573 feet; it commenced at a diameter of 12·6 inches and finished at 2·7 inches, and it is easy to imagine the difficulties that attend the boring of so small a hole to the depth of $1\frac{1}{4}$ miles. The engineers in charge stated that they could not have reached this depth had not Mannesmann weldless steel tubes been available for the boring rods; I mention this fact as illustrating the dependence of mining upon the allied arts, for at first sight few would imagine that an improvement in special rolling-mill practice could increase our knowledge of the deeper portions of the earth's crust.

Bore-holes such as these are now always made by means of the well-known diamond drill, which brings up a core of the rocks passed through, and thus affords positive information respecting them. Unfortunately, the only kind of diamonds suitable for this purpose, the dark opaque stones, showing no distinct cleavage, known in the trade as "carbons," are very scarce and proportionately dear, so that diamond-drilling is now a very costly operation; I have, however, good grounds for saying that we are within measurable distance of seeing such "carbons," or at any rate "boot," produced artificially. For rocks of moderate hardness, these diamonds have of late years been replaced to some extent by shot made of specially hard chilled iron, but these are of little use in the harder rocks. One of our greatest needs at the present moment is a metal that shall be strong, tough, and very considerably harder than quartz; the production of such a material would conduce more to the technical advancement of several branches of mining than almost any other discovery that could be named.

Mineral deposits may be distinguished as superficial, shallow, or deep-seated in the earth's crust; the first of these require no opening up, properly speaking; the second can mostly be opened up by adit levels, whilst the third class can only be reached by means of shafts. The deepest shafts in the world are in the copper-mining district of Lake Superior, where there are at least two close upon 5000 feet in depth; with the exception of this district, of a few shafts in the Bendigo district of Victoria, a few at Johannesburg, and some in the Przibram mines in Bohemia, it may be said that there are practically no shafts in metal-mines more than 3000 feet deep, so that the ability to reach considerably greater depths than have hitherto been attained in most mineral fields may be taken for granted. Indeed, so far as the actual sinking is concerned, there would probably be no serious difficulty in sinking a shaft 10,000 feet deep, provided that it could be known with certainty that a deposit of ore would be met with of sufficient value to recoup the outlay incurred in such a sinking; in other words, the main problems connected with deep sinking are economic rather than technical.

For centuries the only property made use of to effect the separation of minerals was the difference in their densities; in 1858, however, an entirely new property was brought into play for the purpose, namely, the difference in their magnetic susceptibilities. This idea was due to a famous Italian engineer, Sella, whose name is well known in connection with the Mont Cenis tunnel. He was called upon to treat the iron ores of Traversella, in Piedmont, which consist of magnetite containing a certain proportion of copper pyrites (the mass carrying 2 per cent. to 4 per cent. of copper), which interfered with the use of the ore for iron smelting. Sella devised a machine carrying rotating electromagnets, by which the magnetic iron ore was separated from the non-magnetic copper ore, so that both could be utilised.

Other machines on similar principles were subsequently devised, and, naturally enough, they emanated from countries rich in deposits of magnetite, such as Scandinavia and some of the eastern States of America. Sweden especially took a prominent part in the development of the magnetic system of separation, and the Wenström machine, patented in 1884, which was one of the first practical machines brought out, is still largely used, as it is well adapted to the separation of lump ore. Other machines, more particularly designed for the treatment of finely crushed ore, were brought out in rapid succession, and to-day one of the main difficulties that beset the mining engineer lies in the selection of the most suitable machine for any given purpose out of the vast number with which the market is flooded. All these machines work either by means of a moving magnetic field, produced by travelling pole-pieces, passing through the mass of crushed ore, or by causing a stream of the ore to traverse a stationary field, these results being obtained either by travelling belts or revolving drums, or, as in the case of Edison's machine, by the deflection of a falling stream. It soon became apparent that, where very clean concentrates were required, the best results could only be obtained by applying magnetic separation to a pulp of mineral suspended in water, and wet magnetic separators were soon introduced, and are to-day preferred wherever possible; they avoid the necessity for artificial drying, which is, moreover, in the case of minerals that contain iron pyrites, apt to affect the magnetic susceptibility of this mineral sufficiently to interfere seriously with the success of the operation. Attempts have been made to devise magnetic separators without moving parts, by the use of polyphase rotating fields, but although the idea looks promising, no satisfactory machine on this principle has yet been constructed.

At first magnetic separation was only applied to the naturally magnetic ores, magnetite and magnetic pyrites; it was soon, however, extended to certain other minerals that can be rendered magnetic by heating, such as spathic iron ore, brown hæmatite, iron pyrites, &c. As early as 1875 a magnetic separator was used at Przibram for separating roasted spathic ore from zinc blende, this forming an excellent example of the value of magnetic separation. The presence of spathic iron ore causes great difficulties in smelting zinc ores, as it forms a readily fusible silicate of iron which destroys the zinc retorts; at the same time, the densities of the two minerals are so nearly the same that separation by ordinary dressing is impossible. The application of magnetic separation has solved the difficulty, and has rendered available for the smelter numerous ferriferous zinc ores that were previously useless. The process is receiving an extended application in America for treating argentiferous galena and zinc blende, finely divided, and intimately mixed with a large proportion of iron pyrites, in which the proportion of zinc is too high to admit of the ore being smelted direct, whilst the large amount of iron pyrites present interferes with ordinary wet dressing. This ore is crushed and then gently heated, which renders the pyrites magnetic, so that it can be removed by a magnetic separator; the dressing of the residual mixture of zinc and lead ores by the ordinary methods then offers no particular difficulties.

Whilst the ordinary methods of magnetic separation were thus extending the sphere of their applicability, another form of magnetic separation was coming to the front. For a long time the method was confined to minerals that were naturally or artificially magnetic in the everyday acceptance of that word, that is to say, were capable of being attracted by an ordinary horse-shoe magnet. Faraday had discovered so far back as 1845 that numerous bodies, not magnetic in this ordinary sense, were nevertheless affected by powerful magnetic fields, but it was not until 1896 that this principle was applied to the separation of minerals by J. P. Wetherill; he succeeded in separating a series of minerals, all very feebly magnetic, from the somewhat more feebly magnetic zinc oxide and other zinc ores of New Jersey by the use of very powerful magnetic fields, produced by means of electromagnets with wedge-shaped pole-pieces, and since his original invention this principle (the magnetic separation of non-magnetic material, as it is sometimes called) has found an extended application, one of the most recent being the magnetic concentration of specular hæmatite by the Edison deflection method, using pole-pieces of the Wetherill type. Such separations as that of wolfram from tinstone, of raw spathic ore from zinc blende, of garnets from silver ore, which are necessary before any rational metallurgical treatment of the ores is possible, but which offer insuperable difficulties to the ordinary methods of dressing, have been rendered possible by the adoption of the Wetherill principle, and I see no reason to doubt but that it will find still more extended application in the future. I may point out that no successful wet separator for feebly magnetic minerals has yet been devised; this is a problem presenting numerous difficulties, but probably quite capable of solution, and at the same time very well worth solving.

Magnetic separation, though so comparatively novel, has already been extensively applied, the largest installations being naturally those for the treatment of iron ores. At the present moment the output of high-grade magnetite concentrate, produced by this process, in Sweden cannot fall far short of half a million tons per annum, and in Norway active preparations are in progress for work on a much larger scale at Dunderland, Salangen, Ofoten, and Sydvaranger, from which a yearly output of fully two millions of tons of high-class iron concentrates is expected.

Attempts to utilise other properties of minerals for their separation may be said to belong wholly to the present century. Thus Messrs. Blake and Morscher in 1901, and Mr. Negreanu in 1902, have attempted to use electrostatic methods, depending upon the variations in the electrification of minerals due to their varying electric conductivities; the former of these two methods has been used with success for the dressing of blende in the United States.

Finally, the difference in surface tension has been employed in Elmore's oil separation process, in the various flotation processes, devised since the discovery of the principle by C. V. Potter in 1901, and applied to the very intractable zinc-lead ores of the Broken Hill district of New South Wales, and finally in the Elmore vacuum process. All these processes seem to depend upon the differential adhesive force, with which water, oil, or gas cling to the surface of different minerals. These methods are still in their infancy, and the underlying principles cannot yet be said to be properly understood, but already they promise to be of great value in recovering valuable material from slimes that are not amenable to any other mode of treatment, particularly for treating those intimate mixtures of zinc blende and galena that have for so long defied the ingenuity of both miners and metallurgists. There are grounds for hoping that many of the problems that have hitherto baffled the ore-dresser may be solved by some application of these modern methods.

SCIENCE AND INDUSTRY.

A SERIES of articles has appeared in the *Revue scientifique* (May 18 and July 13, 1907; February 22, 1908) comparing the teaching of technical chemistry in France with the instruction given in the same subject in other countries. The last article is of special interest as presenting a French view of the relation subsisting between science and industry in our own country. After describing in detail the excellent organisation of scientific education in Germany, Belgium, and Switzerland, and emphasising the closeness of the union existing in these countries between the manufacturer and the man of science, it is stated that the system of technical education adopted in England presents no feature worthy of commendation.

The English manufacturer fails to realise how much he may profit from the assistance of pure science:—"l'industriel anglais paraît ou veut ignorer le chimiste de carrière qui vient à lui avec un bagage scientifique; son but étant de produire 'beaucoup et à bon marché' il lui suffit quand il remarque un ouvrier plus intelligent et plus perfectible que ses camarades de l'envoyer aux écoles du soir, prendre un semblant d'instruction théorique et cela sur la seule partie de la chimie qui peut intéresser son métier." The many technical colleges under the control of municipal authorities in this country do not aim at producing highly trained "chemists" in the scientific sense of the word, but waste their resources in providing evening classes for workmen and artisans, and in imparting the rudiments of science to boys from the primary schools.

The university colleges, on the other hand, with the exception of the Central Technical College, provide only a training in pure chemistry. Until science and industry become more intimately united in this country it is predicted that the technical schools will go on producing merely good workmen and the universities men who are unable to investigate practical problems or apply discoveries made in the laboratory on an industrial scale.

It would appear that the chemist is as little appreciated in France as in our own country, and it is pertinently asked whether this is not due to his lack of "*general* culture" which prevents him from acquiring the broad ideas necessary for the initiation or development of important enterprises. The same question no doubt may be asked of the chemists in this country, but whatever be the answer there is no doubt that, for the proper development of our industry in the near future, a closer union between the industrialist and the chemist is vitally necessary.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The board of managers of the Arnold Gerstenberg studentship gives notice that a studentship will be offered for competition in the Michaelmas term of 1909. The competition will be open to men and women who have obtained honours in part i. or part ii. of the natural sciences tripos, and whose first term of residence was not earlier than the Michaelmas term of 1903. The studentship, which will be of the annual value of nearly 90*l*., will be tenable for two years.

The Linacre lecture will be delivered by Dr. W. Osler, F.R.S., on Wednesday, May 6, in the lecture-room of anatomy and physiology, New Museums. The subject of the lecture will be "Thomas Linacre, his Life and Works."

It is proposed to grant the use of the Senate House on May 15 for a meeting of the members of the University to be addressed by Mr. Haldane, Secretary of State for War, in the explanation of his scheme in connection with the training of officers for war.

Part i. of the natural sciences tripos will commence on Monday, May 25, and part ii. on Wednesday, May 27. The number of entries for the two parts is about two hundred and twenty.

Glasgow.—Among the recipients of the honorary degree of Doctor of Laws on Commemoration Day, April 22, were several distinguished by their scientific attainments. In the afternoon a portrait of Prof. M'Kendrick was presented to the University, with the sum of 450*l*. for the equipment of a laboratory of experimental psychology in the new physiological buildings, in honour of Prof. M'Kendrick's thirty years' service to the University as professor of physiology. In presenting the representatives of science for the degrees, Prof. Gloag, dean of the faculty of law, made the following references to their work:—

Mr. G. T. Beilby, F.R.S., chairman of the governors of the Glasgow and West of Scotland Technical College.—The present head of the Glasgow and West of Scotland Technical College, who is a Fellow of the Royal Society, has done much for the advancement of chemical science and of its applications to industry. He was president of the Society of Chemical Industry in 1899, and of the chemical section of the British Association at its meeting in South Africa in 1905. He was also vice-president of the Institute of Chemistry from 1903 to 1906. He is the inventor of novel processes which have created or transformed important departments of scientific production; he has devoted himself to the improvement of technological training in relation to our native industries, and he has contributed many researches of value to the memoirs of learned societies at home and abroad. The Senate, in presenting Mr. Beilby for the degree of Doctor of Laws, recognise the value alike of his scientific work and of his services to an educational institution so closely connected with the University and with the City of Glasgow.

Colonel David Bruce, C.B., F.R.S., Royal Army Medical Corps.—A graduate of Edinburgh University, Colonel Bruce has had a distinguished career in the Royal Army Medical Corps, and rendered eminent services to the nation in the Egyptian and South African campaigns. But his services have been not only to his country, but to humanity. To his discovery, at great personal risk, and by untiring labour, of the microbe which forms the inducing cause of Malta fever, and to the researches to which that discovery led, the naval and military population of Malta owe their present immunity from a disease which has been the bane of the island for centuries. Similar work in Africa has resulted in extending our knowledge of the causes which produce the dreaded tsetse-fly disease of South Africa, and the epidemic sleeping sickness of Uganda. Work of this kind, requiring all the courage of the soldier, all the patience and acumen of the man of science, renders him amply entitled to any honour which a university can bestow.

Dr. J. J. Dobbie, F.R.S., director of the Royal Scottish Museum.—In Dr. Dobbie the Senate proposes to honour a distinguished son of this University. Dr. Dobbie completed a successful career as a student by graduating with first-class honours in natural science, and obtaining the George A. Clark scholarship. After further studies in Germany and in the University of Edinburgh, he obtained the degree of Doctor of Science in that University. He acted as lecturer in mineralogy, and as assistant to the professor of chemistry in Glasgow, until his appointment as professor of chemistry in the University College of North Wales at Bangor. After holding that office for nineteen years, he was appointed to the important post he now holds—the directorship of the Royal Scottish Museum. During a life thus filled with important educational work, he has found time to make contributions of great value to scientific literature, in recognition of which the Royal Society of London has admitted him to the honour of its fellowship.

Mr. Robert Kidston, F.R.S.—Mr. Kidston has devoted much time and study to an important department of the science of geology, and is recognised as one of the leading authorities on palæophytology. A series of more than eighty papers, published under the auspices of the Royal Societies of London and Edinburgh, attest his knowledge of the Carboniferous flora. He has arranged and catalogued the collection of Palæozoic plants in the British Museum. His mastery of the subject, and his generous readiness to expend his labour for the advancement of science, have been taken advantage of by other countries than his own. He has been engaged in a catalogue of the fossil plants in the Royal Museum at Brussels, and has received an invitation to undertake similar work at Stockholm. The fossil remains, now being discovered in the recently opened coalfields of Holland, are being submitted for his determination. In presenting Mr. Kidston for this degree, the Senate of the University of his native city wish to express their appreciation of his manifold services to geological and botanical science.

Dr. J. C. M'Vail, medical officer of health for the counties of Stirling and Dumbarton.—A graduate of the University of St. Andrews, and a former examiner in medical jurisprudence and public health in this University, Dr. M'Vail holds the highest position in that important department of modern civil administration—the care of public health. For eighteen years county medical officer of health for Stirling and Dumbarton, he has been president of the Incorporated Society of Medical Officers of Health of Great Britain, of the Incorporated Sanitary Association of Great Britain, and of the Glasgow and West of Scotland Branch of the British Medical Association. In 1906 he delivered with acceptance the Lane lectures in Cooper Medical College, San Francisco, and the following year acted as medical investigator to the Royal Commission on the Poor Law. His published works, dealing with broad questions of State medicine and sanitary science, are recognised as authoritative in these important subjects.

There will be a reception at Bedford College for Women (University of London) on "Commemoration Day," Wednesday, May 6, after the presentation of graduates at the University of London.

An article by Mr. J. A. Venn in the issue for the Lent term of the *Oxford and Cambridge Review* deals with the number of matriculations at Oxford and Cambridge, respectively, from 1544 to 1906. The article is accompanied by a graph, in which the number of matriculations —calculated on an average of five years about any given year from 1540 to 1907—and the years are plotted. The essay shows how the history of England has been reflected with clearness on university life, as evidenced by the varying numbers of students who came to pursue their studies at Oxford and Cambridge. The graph reveals two striking features:—first, both universities were in the first quarter of the seventeenth century as large as they were destined to be until 1850; secondly, the way in which the curves for the two universities keep repeating each other's movements at exactly the same dates, in most instances, and very frequently to exactly the same extent, showing that similar influences were affecting both universities throughout different centuries. Readers must be referred to Mr. Venn's article for detailed comparisons, but an example of the kind of interesting information which may be gleaned from the article may be given:—in 1630 one out of every 3600 of the male population of England and Wales proceeded to either Oxford or Cambridge, but in 1700 the figures were one in 5600. These figures continued to get steadily worse until 1801, when they read one in 11,400, but at the present day they stand at one in 9000.

The Board of Education has issued (Cd. 4038) regulations for the preliminary education of elementary-school teachers in England, which will come into force from August 1 next. The new regulations contain various alterations, and among these, as being of special importance, may be mentioned that by which it will no longer be required that candidates for pupil teachership shall pass an examination test qualifying them for recognition by the Board as pupil teachers. A prefatory memorandum to the regulations points out that, since all pupil teachers must pass a leaving examination, which usually falls between the ages of seventeen and eighteen, it does not appear to the Board desirable, upon educational grounds, that they should also be called upon to pass an examination between the ages of fifteen and sixteen, except in so far as such examination may form part of the ordinary arrangements of the school at which they are being educated, or may be necessary in order to facilitate the proper selection of candidates. It is also satisfactory to find a recognition of the principle that the teacher should take a prominent part in any process of selection of suitable candidates. The Board hopes that, in view of the annually increasing proportion of candidates for pupil teachership who have received their preliminary education in secondary schools, it may be found possible, henceforward, for education authorities to base the selection and approval of candidates upon the advice of the teachers of the candidates rather than upon the results of an examination.

By the will of the late Dr. H. C. Sorby, F.R.S., several substantial gifts are made for scientific purposes. The Sheffield Art Gallery and Museum will receive Dr. Sorby's large series of animals and marine algæ, mounted as lantern-slides, and forming a continuous series illustrating the natural history of Kent, Essex, and Suffolk. Among other bequests to the University of Sheffield are :—(a) Such of his books not bequeathed to the Literary and Philosophical Society as the University shall select ; (b) optical and scientific instruments and apparatus ; (c) cabinets and cases of geological and mineralogical specimens and preparations not bequeathed to the citizens of Sheffield ; (d) manuscript books and notes upon geological and other scientific subjects ; (e) lantern-slides similar to those bequeathed to the citizens of Sheffield, and the whole of his large collection of lantern-slides illustrating many scientific and other subjects ; (f) microscopical objects of rocks, minerals and metals, and other things of a like nature. A legacy of 6500*l.* is bequeathed to the University, and the University is desired to appropriate out of other funds 3500*l.*, the amount of a gift which Dr. Sorby made to the University College of Sheffield in 1903, making together 10,000*l.*, as an endowment for a professorship of geology or such other subject as the University may think more suitable. This legacy is charged upon the funds to be appropriated to answer certain annuities given by the will and payable as and when the annuities fall in. To the Royal Society of London is bequeathed the sum of 15,000*l.*, the income therefrom to be devoted to the establishment of a fellowship or professorship for the carrying on of original scientific research. The object is to promote the discovery of new facts rather than the teaching of what is known. It is suggested that when possible the research shall be carried out in one of the laboratories of the University of Sheffield. This condition may, however, be dispensed with when the nature of the investigation requires that the work should be done elsewhere. So long as in the opinion of the council of the Royal Society the University of Sheffield is not efficiently equipped in laboratories and appliances, then the income shall be administered in such manner as the said council shall think best for the promotion of original research. Other legacies are :—the Literary and Philosophical Society of Sheffield, 500*l.*, and the Geological Society of London, 1000*l.*

SOCIETIES AND ACADEMIES.

London.

Royal Society, February 27.—" The Influence of Temperature on Phagocytosis." By J. C. G. **Ledingham.** Communicated by Dr. C. J. Martin, F.R.S.

(1) When serum, cocci, and leucocytes are mixed directly and incubated at different temperatures, the number of cocci taken up increases more or less regularly with the temperature. By this method it has been shown that the phagocytic intake at 18° C. is only about one-fourth to one-fifth of that at 37° C.

(2) This fall, at least within the temperature range 37° C. to 18° C., is due to the diminished rate of combination of the serum with the coccus as the temperature falls.

(3) When cocci which have previously been exposed to the action of serum, either at 37° C. or at 18° C., are put in contact with leucocytes, the intake is practically the same, whether the phagocytosis takes place at 37° C. or at 18° C. The number taken up, however, after combination at 18° C., and more especially at 7° C., falls very short of the number taken up after combination at 37° C.

(4) Experimental results, detailed above, lead one to assume that prolonged contact of a serum with cocci at a low temperature (18° C. or 7° C.) leads to a maximum absorption of opsonin by the cocci (corresponding to that temperature), so that the subsequent phagocytosis is identical whether it takes place at 37° C. or at 18° C.

(5) Provided that cocci loaded with opsonin up to a certain maximum are presented to the leucocyte, the phagocytic energy of the latter is independent of the temperature within a wide range.

(6) From the appearances on stained films, it would seem that sensitised micro-organisms exposed to the action of leucocytes at very low temperatures tend to congregate near the periphery of the leucocytes, although little or no phagocytosis may take place. Hence, within a suitable temperature range, it may be presumed that the inclusion of sensitised micro-organisms by the leucocyte is a surface-tension effect taking place between the coccus and the protoplasmic wall, amœboid energy playing only a subordinate part in the process.

Manchester.

Literary and Philosophical Society, March 24.—Prof. H. B. Dixon, F.R.S., president, in the chair.—An annotated list of the alien plants of the Warrington district : G. A. **Dunlop.** One hundred and seventy-five species, comprising with others several of Papaver, Senecio, and Sisymbrium, were enumerated in the paper. Thirty of these are now extinct.—Field notes on the birds of the Ravenglass gullery, 1906 : C. **Oldham.** The author describes in his paper the habits, during the breeding season, of the black-headed gull, common, lesser, and Sandwich terns, as observed by him at Ravenglass, on the Cumberland coast. The term " gullery " he applies to that portion of the sandhills which is occupied by colonies of these birds. He also mentions other species—such as the oyster-catcher and sheld-duck—which nest in or in the immediate vicinity of the " gullery."

Paris.

Academy of Sciences, April 21.—M. H. Becquerel in the chair.—An addition to the demonstration of the mechanism of monocular stereoscopy : A. **Chauveau.**—Concerning *Trypanosoma congolense* : A. **Laveran.** A goat, inoculated with *T. congolense* on November 15, 1906, was cured in July, 1907, from the infection produced by this trypanosome. Re-inoculated with the same organism on August 22, it was infected again, but the second infection was slight, and the animal was cured at the beginning of the following November. Two fresh inoculations, made December 20, 1907, and February 6, 1908, produced no re-infection ; the goat had acquired immunity for *T. congolense*. Further inoculation of the same animal with *T. dimorphon*, made on April 1, 1908, produced a well-characterised infection, tending to prove that *T. congolense* constitutes a distinct species from *T. dimorphon*.—A new French observatory : Robert **Jonckheere.** This is the Hem Observatory, situated 8200 metres north-east of the fortifications of Lille. Astronomical observations will be commenced before the end of the year.—The influence of the silent discharge on the isolation resistance of insulators : F. **Nègre.** The resistance of the insulators studied was found to be constant up to a certain critical tension. The latter depends on the dimensions, form, and condition of the surface of the insulator, the resistance falling rapidly as soon as the silent discharge appears over the surface.—The flame spectra of iron : G. A. **Hemsalech** and C. **de Watteville.** The metal is obtained in a fine state of division by passing one of the gases supplying the burner over two electrodes of the metal, either an arc or sparks passing between the latter. The spectra obtained depended on the nature of the flame ; thus with coal-gas and air in the region between λ 2250 and λ 5000 750 lines were obtained, with coal-gas and oxygen 250, and with hydrogen and oxygen 210.—The reducing power of the ferropyrophosphates : P. **Pascal.** Clear solutions of ferropyrophosphate of soda in water, together with a small amount of sodium pyrophosphate, reduce gold and silver, but not platinum salts. Salts of mercury and copper are also reduced, and there is a strong tendency to the production of highly coloured stable colloidal solutions of the metals.—Combustion without flame, and its application to lighting with incandescent mantles : Jean **Meunier.** The author holds that the temperature of the mantle is much higher than that of the flame surrounding it, and attributes this to the fact that each particle of oxide becomes the focus of an intense local combustion. The combustion by incandescence lowers considerably the inferior limit of inflammability of a gas mixture.—A demonstration of Gibb's phase rule : J. A. **Muller.**—Remarks on a wire-drawing machine of the seventeenth century : Ch. **Fremont.**—The progress of modern surgery judged by the statistics of operations on the knee (resections) : M. **Lucas-Championnière.** For this particular operation the mortality has been lowered from 36 per cent. or higher to less than 1 per cent. by the application of the antiseptic methods of Lister. These results were obtained without the use of an aseptic operating room.—The structure of the trachean network of the excretory canals of the kidneys of *Machilis maritima*: L. **Bruntz.** The Senonian and the Eocene of the north edge of the Moroccan Atlas: A. **Brives.** A fan-shaped apparatus of Cetorhinus found in the fossil state in the Antwerp Pliocene: Maurice **Leriche.**—The direct measurement of the vertical component of terrestrial magnetism. Application to the exploration of the chain of Puys: B. **Brunhes** and P. **David.**

DIARY OF SOCIETIES.

THURSDAY, April 30.

Royal Society, at 4.30.—On Scandium: Sir William Crookes, F.R.S.—Note on the Representation of the Earth's Surface by Means of Spherical Harmonics of the First Three Degrees: Prof. A. E. H. Love, F.R.S.—On the Hysteresis Loss and other Properties of Iron Alloys under very small Magnetic Forces: Prof. E. Wilson, V. H. Winson, and G. F. O'Dell.—The Relation between the Crystalline Form and the Chemical Constitution of the Picryl Derivatives: G. Jerusalem and Prof. W. J. Pope, F.R.S.—The Condensation of Certain Organic Vapours: T. H. Laby.—A Photographic Determination of the Elements of the Orbits of Jupiter's Satellites: B. Cookson.

Royal Institution, at 3.—Mendelian Heredity: William Bateson, F.R.S.

Royal Society of Arts, at 4.30.—Reminiscences of Indian Life: Lord Lamington, G.C.M.G., G.C.I.E.

Mathematical Society, at 5.30.—On a General Convergence Theorem, and the Theory of the Representation of a Function by Series of Normal Functions: Dr. E. W. Hobson.—On the Multiplication of Series: G. H. Hardy.—On q-Integration and Differential Equations: F. H. Jackson.—On the Upper and Lower Functions of a Sequence of Continuous Functions: Dr. W. H. Young.—(1) On Mersenne's Numbers; (2) On Quartans with numerous Quartan Factors: Lt.-Col. A. Cunningham.—The Relation between the Convergence of Series and Integrals: T. J. I'A. Bromwich.—Porisms: H. Bateman.—The Influence of Viscosity on Wave Motion: W. J. Harrison.—On the Ordering of the Terms of Polars and Transvectants: L. Isserlis.

FRIDAY, May 1.

Royal Institution, at 9.—The Scientific Work of Lord Kelvin: Prof. Joseph Larmor, Sec.R.S.

Geologists' Association, at 8.—Structural Analogies between Alloys and Igneous Rocks: W. G. Fearnsides.

SATURDAY, May 2.

Royal Institution, at 3.—Chile and the Chilians: G. F. Scott Elliot.

MONDAY, May 4.

Aristotelian Society, at 8.—The Methodological Postulates of Psychology: Dr. T. Percy Nunn.

Society of Chemical Industry, at 8.—The Manufacture of Sodium Nitrite: Dr. G. T. Morgan.—On some Simple and Mixed Esters of Cellulose. The Alkaline Decomposition of Nitro Derivatives of Cellulose and other Carbohydrates: Dr. W. Smith, junr.—The Mechanism of Filtration: E. Hatschek.—Metanil Yellow; its Use as a Selective Indicator: E. Linder.—The Conversion of Oleic Acid into Stearic Acid: Dr. J. Lewkowitsch.

Institute of Actuaries, at 5.—The Select and Ultimate Method of Valuation: M. M. Dawson.

TUESDAY, May 5.

Royal Institution, at 3.—The Development of the Modern Turbine and its Application: Gerald Stoney.

Royal Anthropological Institute, at 8.15.—Report on the Hythe Crania: F. G. Parsons.

WEDNESDAY, May 6.

Royal Society of Arts, at 8.—The Gramophone, and the Mechanical Recording and Reproduction of Musical Sounds: Lovell N. Reddie.

Geological Society, at 8.—Solution-Valleys in the Glyme Area (Oxfordshire): Rev. E. C. Spicer.—On the Stratigraphy and Structure of the Tarnthal Mass (Tyrol): Dr. A. P. Young; with a Note on Two Cephalopods, collected by Dr. A. P. Young on the Tarnthal Köpje (Tyrol): G. C. Crick.

Physical Society, at 8.—A Modified Theory of Gravitation: Dr. C. V. Burton.—An Examination of the Formulæ for the Grading of Cables: C. S. Whitehead.—Illustrations of Geometrical Optics: R. M. Archer.

SATURDAY, May 9.

Royal Institution, at 3.—Chile and the Chilians: G. F. Scott Elliot.

CONTENTS.

SUPPLEMENT TO "NATURE."

PHYSIOLOGICAL STIMULUS AND RESPONSE.

Comparative Electro-physiology. A Physico-physiological Study. By Prof. J. C. Bose. Pp. xliii+760. (London: Longmans, Green and Co., 1907.) Price 15*s.* net.

IN sequence to his books on response in the living and non-living (1902) and plant response (1906), Prof. Chunder Bose has published a third volume on comparative electro-physiology. Prof. Bose has great ingenuity in device of experimental apparatus, fertility in initiating new lines of observation, and a clear style of setting forth his experimental results and theoretical deductions; nevertheless, we feel far from satisfied with his performance. He strives constantly to group every result he obtains under "some property of matter common and persistent in the living and non-living substance," and to explain by this assumed common underlying property the diverse phenomena of response which occur in metal wires, plant and animal tissues, on mechanical, thermal, or electrical excitation.

Prof. Bose says he started his investigations seven years ago in order to demonstrate this underlying unity, and we cannot help feeling that he has prejudged his phenomena, and, biassed by his philosophical conceptions, may select his experimental results and set before his reader those which confirm the main line of his argument. Using the photographic method of recording, and the galvanometer as the indicator of electrical response, he has published a series of figures, each one of which illustrates some argument in the text. No tables are given showing the number of experiments done or the failures and contrary results which occur in all lines of fresh investigation, and thus, while we feel grateful to Prof. Bose for suggesting fresh and fruitful lines of research, we must wait for confirmation by others of his many new and somewhat startling conclusions.

To instance some of these, Prof. Bose maintains that nerve, which is universally regarded as non-contractile, "is not only indisputably motile, but also that the investigation of its response by the mechanical method is capable of greater delicacy, and freedom from error, than that by the electrical." He demonstrates the contractility of nerve by means of the deflection of a spot of light reflected from a mirror attached to a light lever, thus obtaining magnification up to 100,000 times, but at the same time states that it can be demonstrated even by a light aluminium lever magnifying 50 times. This is contrary to the result of an English physiologist, who has, to our knowledge, tried a similar experiment. Here we have a definite assertion supported by many photographic curves and details of experiment, and one which, when tested by others, can enable us to arrive at a definite valuation of Prof. Bose's work. Such an independent valuation is required, as Prof. Bose and the English authorities on electrical physiology have been greatly at variance.

Prof. Bose claims that the fibro-vascular bundles of plants, which can be isolated in long lengths from the frond of a fern or petiole of cauliflower, act as vegetable nerves, the response being in every respect similar to animal nerve, and being affected similarly by ether, alcohol, ammonia, carbon dioxide, tetanus, &c. He regards the fibro-vascular system which forms the venation of leaves as a "vast catchment basin" for the reception of light stimuli and their transmission to the parts of the plant which are in the dark. By this nervous system, he says, the tone of the whole plant is maintained. In regard to Pflüger's law of the polar effects of currents, Prof. Bose demonstrates photographs showing the like effects on plant and animal structures, but finds that "above and below a certain range of electromotive intensity the polar effects of currents are precisely opposite to those enunciated by Pflüger." He endeavours to prove that the response of nerve to excitation consists of a positive and a negative variation, and that the tones of sensation, pleasure and pain depend on the ascendancy of one or other variation. He seems to recognise no deficiencies in the galvanometric method, and is unaware or neglectful of the work done with the capillary electrometer and of the diphasic variations obtained with this instrument by Prof. Gotch. The galvanometer is far too inert an instrument to demonstrate the true electrical response of nerve. Prof. Bose says that

> "all the diverse phenomena of response may be summarised in the two following formulæ:—(1) Excitatory response takes place by contraction and galvanometric negativity. (2) Increase of internal energy induces the opposite effect of expansion and galvanometric positivity."
>
> "The first of these effects is simply demonstrated by direct excitation of an excitable tissue. In order to demonstrate the second, stimulus is applied at a distance from the responding point. In consequence of sudden local contraction at the receptive area, a wave of increased hydrostatic tension is transmitted with great rapidity. Energy is thus conveyed hydraulically, and at the distant point the transmitted effect induces expansion and galvanometric positivity. This is followed by the more slowly transmitted wave of true excitation, which on its arrival gives rise to the normal response of contraction and galvanometric negativity."

All we can say in criticism of this statement is that while it may be true for plant tissue, there is not a shadow of fact in favour of it holding good for muscle, and we must remain unconvinced by the evidence adduced by the author in favour of its holding good for nerve, until his experiments on the expansion and contraction of nerve have obtained confirmation.

Prof. Bose finds that a metallic wire, the stem of a plant, and a nerve when suddenly submitted to torsion give the same electrical response, and in consequence is led to make the following statement:—

> "By the conception of matter itself, on the other hand, as possessed of sensibility—that is to say of molecular responsiveness, we attain an immediate accession of insight into those physical interactions

which must furnish the terms of ultimate analysis . . . and are led to the discovery of the impressive continuity as existent between the responses of the most complex living and the simplest inorganic matter."

Sensibility is the power to feel, and is the function of the cerebral cortex of man, and also, we may assume justly from the similarity of the neuro-muscular reactions, the function of the brain of the higher animals. That it is a function of the fish or frog brain we cannot affirm with any certainty. To ascribe it to a plant or wire is altogether unwarrantable.

A similar condition of molecular strain may be present in a wire, a plant stem, and a nerve fibre, and give the same electrical response, but this is not sensibility, and we even cannot conclude justly from the similarity of electrical response that the same mechanism is present.

Suppose we see a cloud of steam rising over the wall of a field. It may be from a traction engine, from a dung heap, or from a team of horses heated with ploughing. Observations on the direction of the current of steam, and on the effect of modifying agents upon it, will tell us nothing as to the nature of the chemical process which results in the manifestation of heat and the evaporation of water. Prof. Bose's philosophy seems almost capable of asserting that the similarity in direction of the steam current proves the sensibility, not only of the horses, but of all three structures.

Apart from these criticisms, there are in Prof. Bose's book a great many very interesting observations and ingenious methods of experimentation which will repay the reader's attention. In particular, his experiments on root pressure and the rise of sap; those by which he seeks to demonstrate that not only sensitive plants but all plants respond to excitation by variations in turgescence and electrical state; his comparison of the glandular structures of sundew and pitcher plants with animal glands; his demonstration of Dr. Waller's "blaze current" in a brominated lead plate and assertion that it cannot be regarded as a sign of life; his demonstration on the motile leaflets of Biophytum of the anodic and kathodic effects of the constant current, and the velocity of transmission of excitatory waves; his comparison of retentiveness of molecular change in metals with memory. In fact, the whole book abounds in interesting matter skilfully woven together, and would be recommended as of great value if it did not continually arouse our incredulity.

L. H.

THE STEREOSCOPE AND STEREOSCOPIC INSTRUMENTS.

Die binokularen Instrumente. By Moritz von Rohr. Pp. viii+223. (Berlin: Julius Springer, 1907.) Price 6 marks.

THE scientific staff of the Zeiss firm have of late years devoted much attention to the theory of binocular instruments, and to the development of methods of measurement depending on stereoscopic vision. The impetus given by the successful realisation of the prism field-glass has carried them on to a more exact examination of the conditions under which binocular vision can be employed for the accurate determination of relative position, which has led to the design of a series of new instruments for surveying and other purposes, of which the stereo-comparator is the most widely known.

The thoroughness with which the problem has been considered is sufficiently illustrated by the present work of von Rohr, who has already in his previous writings dealt very completely with the theory of vision by means of binocular instruments. This previous work he has now supplemented with an examination into the historical evolution of stereoscopic instruments, systematically planned with the view of clearing the ground and avoiding loss of labour from the re-development of ideas already investigated by previous workers. The book is divided into three parts; the first gives in a few pages a concise statement of the theory; then follows the history, to which part i. is merely an introduction; and the volume concludes with a most useful systematic summary of the matter contained in part ii., assisted by what may be described as a logical guide arranged in the form of a genealogical table, showing the subdivisions of the subject and referring to the place of treatment. This third part, of course, includes a bibliography.

The history begins seriously with the work of Ch. Wheatstone, who is even better known as an electrician. Reference is indeed made to some previous writers and instruments, from the early binocular of Lipperhey, and the suggestive experiments of R. Smith. One notices some omissions here, but the book makes no pretence to be exhaustive; the object is only to trace out the development of correct principles of construction, and to indicate the most important workers and the advances due to them. From this aspect the book is almost too thorough and complete.

Much space is devoted to the famous controversy between Sir David Brewster and Wheatstone, again because of its value for the development of the theory. It is now generally recognised that Wheatstone had the much more correct grasp of the principles, and that the popularity of the Brewster type of prism stereoscope as against the Wheatstone mirror instrument was due to its superior handiness, which outweighed its optical deficiencies. It is interesting to note that Brewster records the sale of prism stereoscopes from the time of the Great Exhibition to 1856 as amounting to more than half a million; these for the most part on the improved mechanical design of Duboscq. One can still remember the wide interest aroused by this method of obtaining pictures in relief.

The interest, however, soon died down, only to be revived in comparatively recent years. The simple stereoscope was gradually improved, as well as the binocular microscope, and more especially the binocular field-glass. The advances of photography were accompanied by the invention of various methods of obtaining "stereograms." But public interest only revived with Abbe's introduction of the prism binocular. Since then Jena has been the centre for the spread of renewed enthusiasm for the subject, while in this country few developments have been made. More attention has been given probably in England to the binocular microscope than to any other form of stereoscopic instrument. Quite recently Theodore Brown has experimented with a method of monocular bio-stereoscopic projection, which will doubtless one day be perfected and become widely known. But only his earlier work is mentioned by von Rohr, who does not carry his account beyond 1900. For the same reason, perhaps, we find no mention of the Forbes stereoscopic range-finder, or of the Aitchison prism binocular.

To those interested in the history of optics, and more especially to workers in stereoscopy, von Rohr's compilation will be of great value. For the general reader it is to be feared the technical manner in which the subject is presented throughout will prove somewhat of a stumbling block. This is, we think, a matter for regret.

AMERICAN PHYSICAL GEOGRAPHY.

Physiography. By Prof. R. D. Salisbury. Pp. xx+770; xxvi plates, 707 figures. (London: J. Murray, 1907.) Price 21s. net.

THE large three-volume text-book of geology by Profs. Chamberlin and Salisbury has gained a firm place in this country owing to its full treatment of many questions, inadequately discussed in previous available English text-books. This companion volume on physical geography by Prof. Salisbury will accordingly be welcomed by British teachers of geology and geography. It is of great educational value owing to its wealth of lucid illustration and its clearness of exposition, while it will be indispensable as a reference work in geographical libraries owing to its detailed information regarding the physical geography of the United States.

The book is entitled "Physiography," but the term is used, as the author remarks in his introduction, as a synonym for physical geography, for it excludes many subjects which are included in physiography as that science was defined by Huxley and is accepted in the British Isles. The book consists in the main of a description of the structure of the earth's crust, of the working of the various agencies that attack it, and an account of the atmosphere and the oceans in so far as they affect the surface of the earth. Perhaps the most striking feature of the book is its illustrations, which are very numerous, well selected, and excellently reproduced. They are so clear that the author has been able to abridge his text, leaving his series of photographs to tell their own story. The excellence of the illustrations is probably in part secured by the use of heavy paper, so that the volume is of such weight as to hamper its use as a student's text-book.

As a book of reference its especial value is in its descriptions of the phenomena of physical geography taken from a country where the illustrations are unusually clear and suggestive; and it gives most useful summaries of such well-known geographical incidents as the San Francisco earthquake and of the fault which caused it; of the storm which destroyed Galveston in 1900, and the tornado which devastated Louisville in 1896.

In the chapter on the "weather-maps," the author summarises various reasons for the failure of weather predictions, and he remarks that occasional mistakes are inevitable, and that one mistake is remembered longer than many correct forecasts. He claims that in many cases the American forecasts have been of immense economic value; for example, fifteen million dollars' worth of property were saved in 1897 by warnings of impending floods; on one occasion half a million dollars' worth of fruit about Jacksonville, in Florida, and during 1901, 3,400,000 dollars' worth of produce were saved by warnings of approaching cold; the forecasts also render it possible to avoid unnecessary risks, as when, in September, 1903, vessels valued at 585,000 dollars were detained in ports on the coast of Florida, and thus avoided a heavy storm.

In a work of so wide a scope there are naturally many points on which there is room for difference of opinion, but the author is cautious and fair in his treatment of all controverted questions. We are glad to find that he is emphatic in his statement that the term "Gulf Stream" is of doubtful propriety for anything beyond Newfoundland, and that the climate of north-western Europe would be much more temperate than that of corresponding latitudes of North America even if there were no Gulf Stream (pp. 544–5).

He holds that the only explanation of glacial periods which has not been discredited is that based on variations in the composition of the atmosphere. In his discussion of the question there is no criticism of Schloesing's view as to the control of the amount of atmospheric carbonic acid by the sea. The author is a firm adherent of the view of the ice erosion of fiords.

Each chapter is followed by a table of useful exercises, and by a list of references to literature. They are mainly from American sources, which is natural in a book designed for American students, but an English edition might have included more references to work easily available to British students; for instance, among the excellent illustrations and account of the eruption of Mt. Pelée and St. Vincent, there is no reference to the reports of Anderson and Flett. It may also be remarked that the Aconcagua ascent no longer holds the record, and that while it did, Zurbriggen was not the only man who had made it.

J. W. G.

POLYPERIODIC FUNCTIONS.

An Introduction to the Theory of Multiply-Periodic Functions. By Dr. H. F. Baker. Pp. xvi+336. (Cambridge: University Press, 1907.) Price 12s. 6d. net.

THE saying that *Il n'y a que le premier pas qui coûte* certainly does not hold good of mathematics; and, oddly enough, it conspicuously fails in cases where it might be expected to justify itself. It is but a step from elliptic to hyperelliptic, from single to double Theta-functions; yet whereas Jacobi reduced all the essential theory of elliptic functions to a most elegant, and for some purposes a final, shape, it is only now becoming possible to construct a corresponding theory for the hyperelliptic functions.

Towards this Dr. Baker, in the first part of his treatise, has made a really valuable contribution. The first chapter contains an extremely clear account of the hyperelliptic integrals, and in particular gives the standard ones in their explicit algebraic form. The corresponding Theta-functions are defined, and their properties investigated; the solution of Jacobi's inversion problem is given in an unusually clear form, and art. 10 contains an instructive discussion of the vanishing of a double Theta-function—perhaps one of the most troublesome points in the whole theory.

Chapter ii. contains the differential equations for the Sigma-functions which are afterwards used to find their expansions. By means of Aronhold's symbolical notation they are expressed in a compact invariantive form; and the way in which they are obtained is an elementary one. At the same time, as the author would probably admit, the process is that of leading up to a known result, and not a heuristic one; this is not said by way of disparagement, because it often happens that tedious methods of discovery are properly replaced by others of a more artificial kind. Dr. Baker, in a note at the end, directs attention to the desirability of re-casting the demonstration so as to make it more strictly analogous to the method used for the elliptic Sigma-function.

Chapter iii. deals with the properties of Kummer's surface and Weddle's surface in connection with the properties of the hyperelliptic functions. Here the author's powers of dealing with algebraical analysis appear to great advantage. He has expressed the principal results in a form that is both explicit and elegant; and the English reader who has this book and Hudson's "Kummer's Surface" will be able to attack, if he likes, a very interesting and unusually definite field of research. Chapter v. is of a similar character, and contains, among other things, Mr. Bateman's proof of the differential equation of the asymptotic lines on Weddle's surface, and a geometrical interpretation of the addition theorem. Chapter iv. deals with the expansions of the Sigma-functions, and gives a great number of explicit terms; the invariantive character of the coefficients should be specially noticed.

The second part of the book, "on the reduction of the theory of multiply-periodic functions to the theory of algebraic functions," is of a much more recondite and difficult character. One of its main objects is to prove the theorem that the most general single-valued multiply-periodic meromorphic function is expressible by Theta-functions. The proof given partly depends upon Kronecker's theory of the definition of algebraic constructs (*Gebilde*) by means of systems of equations, partly upon the consideration of a set of "defective" integrals. Dr. Baker is admirably honest, and on p. 207 makes the remark:—"It seems certain that the values of k_{rs} can be taken so that the determinant $|c_{rs}|$ is not zero"; the temptation to make this a positive statement instead of a conjecture would have been considerable to many writers. Whether or not Dr. Baker's proof will stand minute examination in all its parts remains to be seen; it is at any rate an original and very interesting discussion of an extremely difficult and important problem. It is not easy at the present time to foresee what will be the ultimate shape assumed by the general theory of Abelian functions. So far as mathematical rigour is concerned, as well as in its definiteness and attention to detail, the work of Weierstrass is preeminent, and its influence may be continually noted, and is frequently acknowledged in the present treatise. On the other hand, the more intuitive methods of Riemann and his followers are extremely illuminating and fruitful in suggestions and results; while as regards algebraic functions, the method of Dedekind and Weber is very hard to improve upon. One main difficulty, of course, is the increase in the number of independent variables in the associated Theta-functions; to get a "geometrical" field for the variables we must either plunge into unknown spaces or take new elements (*e.g.* straight lines) in our own.

Much light on the general theory and its difficulties is afforded by some special examples which Dr. Baker gives here and there, for instance, on pp. 255–72. In fact, an accumulation of such examples would greatly help beginners to grasp the arguments of the general theory.

In conclusion, attention may be directed to the great economy of space which the author obtains by abbreviated notation for matrices. The only drawback is that matrices are continually denoted by letters of the same type as those indicating quantities. Moreover, double Theta-functions are expressed in the form $\theta(u)$, which stands for $\theta(u_1, u_2)$; consequently, the beginner must be careful to realise the full meaning of the symbols, and he must at once make himself familiar with the elementary theory of matrices. Perhaps, in another edition, matrices might be indicated by letters of a special type. G. B. M.

REINFORCED CONCRETE.

Principles of Reinforced Concrete Construction. By F. E. Turneaure and E. R. Maurer. Pp. viii+317. (New York: John Wiley and Sons, 1907.)

THIS is the latest text-book on a branch of engineering construction which during the past ten years has developed from its first small beginnings to such an important position that not only is it essential for civil engineers and architects to be familiar with its various applications, but they should also have a sound knowledge of the principles which underlie the design of reinforced concrete structures. The authors have therefore practically divided the book into two sections, the first part dealing with the theory of the subject, the results of tests, and such questions as working stresses and economical proportions, while the second part is devoted to the application of reinforced concrete to building construction, arches, retaining walls, &c.

After discussing fully the properties of the two materials, concrete and steel, both when used independently and when used in combination, the authors proceed to obtain working formulæ for the stresses in reinforced concrete beams and columns; in the case of beams of rectangular and T section, flexure formulæ are deduced, based on the assumption of linear variation of the compression of the concrete for working loads; and for rectanglar beams on the assumption of a parabolic variation of this compression for ultimate loads, in both cases neglecting the tension in the concrete; examples are fully worked out to illustrate the use of these formulæ. A considerable amount of lengthy arithmetical work is necessary in using these formulæ, and a series of diagrams has been prepared, published on pp. 213—223, by means of which problems may be solved with rapidity and with a degree of accuracy quite sufficient for all practical purposes. These diagrams are at the end of chapter vi., in which the authors have collected together into a convenient form for reference all formulæ deduced in the earlier chapters of the book. Any engineer or architect who did not wish to check the accuracy of these formulæ or to become familiar with the principles upon which they are based, but merely desired to apply the results directly to some problem of design, would find everything he wanted in a compact form in the forty pages of this chapter.

Since T beams are often continuous over their supports, and since at such points there is a negative bending moment throwing the flange into tension and the lower part of the web into compression, a system of double reinforcement must be adopted in such cases, and this problem is fully worked out, as is also the problem of computing the stresses when the resultant of the external forces acting on the one side of the section of a beam is not parallel to that section. The remainder of chapter iii. is devoted to a discussion on the shearing stresses in reinforced beams, and to the strength of reinforced columns; as the authors point out, in ordinary construction the ratio of length to least width seldom exceeds 15, hence they have dealt with the problem simply as one of short columns.

In chapter iv., the results of a large number of tests of reinforced beams and columns are given, including many tests carried out by the authors themselves; not only are the actual numerical results of these tests of importance, as they afford the only safe test of the accuracy of the formulæ used in their design, but also much valuable information in regard to the design of such reinforced members may be gained from a study of the way in which the final collapse takes place; several plates are given, reproductions of photographs of the fractured beams, which show clearly how the disposition of the reinforcing bars in the beam influences the manner in which it gives way when the destructive load is reached.

In the next chapter the working stresses which can be permitted with this material are fully treated, and such constructive details as the use of steel of high elastic limit, the durability of the material, and its power of resisting the effect of fire. In the last three chapters a number of practical details in reinforced concrete work is given, and the problem of the determination of stresses in arches is dealt with in a very neat and compact fashion. T. H. B.

THE EVOLUTION OF DRESS.

The Heritage of Dress, being Notes on the History and Evolution of Clothes. By W. M. Webb. Pp. xxvi + 393. (London: E. Grant Richards, 1907.) Price 15s. net.

THERE was certainly room for a scientific account of the evolution of dress. The present book, however, which professes to be "a popular contribution to the natural history of man," is hardly more than a collection of curious survivals in modern fashions, uniforms, the dress of the Court, the Church, the Bar, and other learned and official personages. The bibliography consists largely of articles in magazines and newspapers, and the author seems to have little acquaintance with the scientific literature of the subject, such as the frescoes of the Minoan Age unearthed by Mr. A. J. Evans; the contributions of Mr H. Balfour, Mr. Skeat, Dr. Westermarck, and Dr. Haddon on the evolution of ornament; Prof. Ridgeway on the penannular brooch; Dr. J. G. Frazer's classical paper on mourning as a disguise to baffle the ghost. He appears not to have read even such popular works as those of the late Mr. Elworthy on the "Evil Eye" and "Horns of Honour."

But if Mr. Webb has not written a scientific treatise on the "Heritage of Dress," he has given us, within its limits, an interesting and suggestive book, provided with excellent drawings which really illustrate the many topics with which he attempts to deal, and with an index which, if not quite accurate, is still sufficiently comprehensive. His aim is to furnish a record of survivals, and perhaps in no department of modern life are these more numerous than in that of dress. It is a fact of much scientific importance in connection with the history of social development that so many details in modern costume which we are inclined to believe capricious or accidental, due to the inventive genius of the tailor or the milliner, are really traceable to primitive forms, and that the perpetual changes of fashions are the result of a process of evolution, advancing on conservative lines, in which the influence of early ideas is apparent.

This can be readily illustrated from the wealth of material supplied by Mr. Webb. Thus perhaps the earliest form of dress is the shawl or wrapper, the fringes of which in the modern examples date back to the most early kind of loom. From this are derived the jacket of the woman as well as the trousers of the man. It is more hazardous to trace the shape of the hat to that of the primitive hut; but the band on our silk hats and "bowlers," now purely ornamental, is almost certainly a relic of the fastening of the original cloth headdress.

The origin of liveries, which represent the costume of the wearers' masters in earlier times, is equally curious. When we come to uniforms, almost all their distinguishing features have a history as survivals. The red coat took its colour from that of the best coat in the days of Charles II., and it has thus naturally descended to the fox-hunter and golfer; the baton of the field-marshal is the box in which he used to carry the orders of his sovereign; the epaulettes of the Imperial Yeoman take us back to chain-mail; the "prickers" of the hussar to the old flint-lock musket. Putties, which Mr. Webb traces back to Anglo-Saxon times, are proved by recent discoveries to be as old as the Mycenæan culture.

Much, of course, still remains mysterious. Why has a man's coat its buttons on the right, that of a woman on the left? Is the cockade descended from the chaperon headdress of the time of Richard II.? Whence come the buttons on the jacket of the page and on the trousers of the costermonger? Can it be, as Mr. Webb suggests, that grooms weave straw in the manes of horses because the horse was once thought to be a corn-spirit? Such matters require for their solution a wider range of induction and a more scientific study of the evidence than is provided by the present book, which raises, if it fails to solve, many other curious problems of the same kind.

MODERN VIEWS OF ELECTRICITY.

Modern Views of Electricity. By Sir Oliver Lodge, F.R.S. Third edition, revised. Pp. xvi+518. (London: Macmillan and Co., Ltd., 1907.) Price 6*s.*

WHEN Sir Oliver Lodge decided to issue a new edition of his well-known treatise, he set himself a very difficult task. The first edition was published in 1888, the second in 1892; he might well have thought that the development of the science during the past fifteen years had been so rapid that nothing short of complete re-writing could render the book deserving of its title. However, he has concluded that, since recent progress has amplified our views of electricity rather than altered them, the treatise has not lost its value; that it is still an expression of the truth, though it may be only a partial expression. Accordingly the general plan of the third edition is the same as that of the first; the changes that have been made consist of a few minor alterations and omissions, together with the addition of six appended lectures.

The earlier editions are so familiar that no detailed comment is necessary. Electrostatic, conductive, and magnetic processes are described and illustrated by a series of mechanical analogies, leading up to the representation of the electromagnetic ether as a medium made up of elastically connected gear wheels, separated in some regions by surfaces of slip. In the elaboration of these analogies the author is seen at his best; everything that he writes is extremely suggestive, though some students may be puzzled by the inconsistency between the different illustrations that are used in different parts of the book to represent the same action. We would direct special attention to the admirable treatment of the magnetic effect of materials with a permeability greater than unity.

However, we think that the author has underrated somewhat the change in even the simpler parts of the work, which has been necessitated by recent discoveries. It is true that these discoveries have affected our views of the electric properties of matter rather than the properties of electricity itself, but all electrical experiments involve the use of material bodies. Thus the discovery of the great difference between positive and negative electricity invalidates Sir Oliver Lodge's representation of the magnetic field. He can no longer account for the negative result of Maxwell's attempt to find a finite angular momentum in a closed current circuit by the existence of two oppositely directed streams of positive and negative electricity; there must be a gyrostatic effect, though it is too small to be detected by any arrangement devised at present.

Again, our view of the effect of a material dielectric on electrostatic phenomena has changed completely. It is not believed now that the presence of sulphur alters the properties of the lines of force issuing from a neighbouring charged body; the effect of the sulphur on electrostatic actions should be represented in the same way as the effect of iron on magnetic actions. The view that all electric actions take place in the medium surrounding a charged body and not in the body itself has been modified; attention has been concentrated once more on the importance of the conception of a charge. It is misleading to speak of the dispersion of light as obscure and to suggest that it has no causal connection with selected absorption. The old view that a dielectric resists the passage of a current but may be "broken down" by a force sufficiently great suggests that a perfect vacuum devoid of all resisting matter should be a perfect conductor, and is utterly discordant with modern views. If the author did not see his way to re-write the book completely, we think that at least he should have added copious notes on these and many similar points to warn the student that the older statements must be revised in the light of later knowledge. As it stands, the book is of immense interest to those to whom modern conceptions are familiar, for it enables them to grasp at once the bearing of those conceptions on fundamental problems, but it would be dangerous in the early stages of reading.

We have detected one misprint on p. 224, l. 24: for "infinite" read "finite." We must also protest strongly against the use on p. 255 of the expression "centre of gravity of the ether" in place of "centre of mass." There is no evidence whatever that ether has a centre of gravity. N. R. C.

ENGLAND AN EXAMPLE FOR GERMANY.

Der naturwissenschaftliche Unterricht auf praktisch-heuristischer Grundlage. By Dr. F. Dannemann. Pp. xii+366. (Hanover and Leipzig: Hahnsche Buchhandlung, 1907.) Price 6 marks.

WE are accustomed in matters relating to school teaching to have German methods and results eulogised by contrast with our own, so that it is especially gratifying for once to find the tables turned. The author is a leading exponent of science teaching in his country, a schoolmaster of high repute in secondary schoolwork, and he has written this elaborate work frankly on the model of teaching that he witnessed at Harrow and other English secondary schools; and he has produced an account which in some respects is more thorough and comprehensive than anything we have in England. The only work to compare with it is the American book by Smith and Hall which appeared two years ago, and that deals only with chemistry and physics, while Dr. Dannemann covers biology as well. One half of the work is taken up with detailed recommendations for class teaching in branches of natural science, viz. physics, chemistry, mineralogy, geology, astronomy, and biology, then chapters are added on the equipment of laboratories, the preparation and use of text-books, the training of science teachers, the treatment of scientific ideas in the order of their historical development; then some half-dozen appendices give documents taken partly from the regulations of the Kultus Ministerium in Prussia and in other German States, side by side with resolutions adopted by associations of science teachers, in which no doubt Dr. Dannemann is a leading personality.

The adoption of the term "praktisch-heuristisch" is sufficiently significant of the author's position. He does not give the history of the name "heuristic," and only incidentally refers to Prof. Armstrong, but in all his work he is definitely on the side of those who insist that the centre of a course of science teaching shall be at the bench in the laboratory, and that demonstration and discussion in the class-room must be associated with and take their cue from this centre of activity. He has nothing but scorn for the "Kreidephysik" which is still too commonly found in German schools, where the teacher with his chalk and blackboard demonstrates the truths of natural philosophy. It is very interesting to witness, from the pages of this work, how very reluctant German authorities are to adopt these reforms, and no doubt a strenuous advocate of English methods has not always a happy time among his countrymen. Indeed, the case is curiously paralleled by what is happening in England as regards modern language teaching. The "reformers" here look chiefly to Vietor and others in Germany for inspiration, and turn to many examples in German schools to show how a foreign language can be acquired. Dr. Dannemann tells his countrymen to look to the practical English teacher and to abandon their reliance on the parrot-like learning of scientific text-books.

Although much of the ground covered by these chapters will be familiar to the English teacher of science, there are portions which are novel, especially in the plans by which the author hopes to give a secondary schoolboy some grasp of the entire field of natural science before leaving school; and the sketch of science teaching from the genetic standpoint is also well worthy of careful perusal.

The chapter on the training of science teachers seems to us the weakest part of the book. It is difficult to see how university men can be kept for a year doing the very elementary work which Dr. Dannemann proposes for them; a man ought to have learned, during his university career in laboratories, to be able to secure himself and his scholars against accidents. But it is a little difficult to realise fully the conditions of German schools in these respects. We are sure from the quality of this and other writings by the author that any "Kandidat" who was sent to learn the business of a science teacher from him would gain a thorough understanding both of principles and practice.

WIRELESS TELEGRAPHY AND TELEPHONY.

Jahrbuch der drahtlosen Telegraphie und Telephonie. Band i., Heft i. Edited by Dr. G. Eichorn. (Leipzig: S. Hirzel, 1907.) Preis fur den Band, 20 marks.

Wireless Telephony in Theory and Practice. By E. Ruhmer. Translated by J. Erskine-Murray. Pp. xv+224. (London: Crosby Lockwood and Son, 1908.) Price 10*s.* 6*d.* net.

THE publication of the first number of a German year-book of wireless telegraphy and telephony affords an indication of the growing importance of this branch of electrotechnics. The volume before us is more of the character of an ordinary scientific magazine than of a year-book, since there is not really much attempt to summarise the progress during the past year, which, ve take it, is peculiarly the function of a year-book. This objection apart, the publication deserves praise on account of the merit of the articles which it contains. Of these the most important are one by Prof. F. Braun on directed wireless telegraphy, one by Dr. Simon on the production of undamped waves, and one by Prof. Fleming on some of the most recent developments.

Dr. Simon's article will be read with special interest at the present time on account of the experimental work which is being carried on in all countries for the development of wireless telephony. In addition to these and some minor papers, there is a valuable bibliography.

The development of wireless telegraphy during the twenty years which have passed since the discoveries of Hertz has presented some peculiar features. Grown out of a discovery which, theoretically regarded, was of a sensational nature, wireless telegraphy has always seemed to have a tendency to sensational rather than solid progress. Except in so far as its military and naval value is concerned, the world at large cannot be said to have derived as yet any very great advantage from its development, and we doubt whether financial success, the touchstone of utility, has as yet rewarded any of the companies which have been pioneering the various systems. On the other hand, sensational performances, in which the hearts of all wireless workers appear to rejoice, have been frequent. The Marconi Company's first attempts to establish Transatlantic communication, the signal failure of their first commercial system of Transatlantic wireless telegraphy, and the apparent failure, so far, of their more recent attempt, will be fresh in the minds of all. As we have before pointed out in these columns, it would appear that the enormous efforts and expenditure which have been lavished on the development of long-distance signalling might have been much more usefully spent on the development of less ambitious but more solidly useful schemes.

More recently the attention to the production of undamped oscillations on the principle of the Duddell musical arc (as in the Poulsen system) has stimulated research on the wireless transmission of speech, and considerable success has attended the experiments. In Germany successful transmission across ten miles of land (right across Berlin) has been attained, and in America, in addition to the equipment of the torpedo-boats of the Pacific fleet with wireless telephone apparatus on the De Forest system, one may note that stations have been working successfully on the Fessenden system over a distance of 200 miles (more than half over land).

A very full descriptive account of the experimental work which has been carried out on wireless telephony is to be found in Prof. Ruhmer's book. The volume is not confined to telephony by means of Hertzian waves, the particular branch which now occupies the most important and the most promising position. In fact, nearly one-third of the volume is devoted to wireless telephony by means of light, in which a speaking arc is utilised as transmitter and a sensitive selenium cell as receiver. This method, which owes much of its development to Prof. Ruhmer, has attained considerable success, fair distances having been bridged over both water and land. The volume is profusely illustrated by both photographs and drawings, and should prove a useful reference work for those directly or indirectly interested in the subject.

There can be no question that the successful solution of the problem of wireless telephony will mark a very considerable advance in the art of wireless communication. It is true that the difficulties of interference and lack of secrecy have to be met with telephony as with telegraphy, but there are, at any rate, the same compensating advantages which are to be found in ordinary telephony over telegraphy. It is to be remarked also that efforts to establish long-distance wireless telephony, across the Atlantic, for example, are not open to the same objection as applies to the attempts to establish Transatlantic wireless telegraphy, since in this case the field is not already occupied by cables performing the same service more efficiently.

M. S.

THE TABERNACLE AND THE TEMPLE.

The Tabernacle: its History and Structure. By the Rev. W. Shaw Caldecott. Pp. xxii+236. Second Edition. (London: Religious Tract Society, 1906.) Price 5s.

Solomon's Temple: its History and Structure. By the Rev. W. Shaw Caldecott. Pp. xiii+358. (London: Religious Tract Society, 1907.) Price 6s.

THE interest which Anglo-American Protestantism has always taken in the præ-Christian Biblical books, and in the land of Canaan, in which the events of ancient Israelitish history, traditionally described in them, took place, has again been exemplified in yet another addition to the long list of pious speculations as to the appearance of the Israelitish Tabernacle and of the Temple of Yahweh at Jerusalem. Mr. Caldecott is an enthusiast, like his forerunners, for none but an enthusiast would be bold enough to explain the meaning of doubtful cuneiform signs to cuneiform scholars, or to invite prefaces from a master of cuneiform science, Prof. Sayce, in which the ingenuous author of the book is publicly told that, however nice and interesting his discussion of the Tabernacle and the Temple may be, his cuneiform cannot be accepted. Mr. Caldecott's *naïveté* in thus rushing in where those who know the root of the matter fear to tread, necessarily vitiates the credibility of the remainder of his speculations in the mind of the scientific reader.

Nevertheless, Mr. Caldecott is more critical than most of his predecessors, which is an encouraging symptom. His sketch of the history of the Jewish Kingdom is very readable, and, though conservative, contains little at which a moderate "higher critic" might cavil, though no doubt a Jerahmeelite might consider it a sufficiently benighted performance. The views of the Jerahmeelites do not, however, any longer count among scientific archæologists in England, although the Germans, swayed by their quaint national delusion that no really valuable work in archæology or Biblical criticism can possibly be done by anybody but Germans (or non-Germans taught to perform the scientific *Parademarsch* by German drill-instructors), no doubt still believe in the wild "North-Arabian" theories of Winckler in which Cheyne found support for the Jerahmeel-cryptogram.

We are glad that Mr. Caldecott has not adopted the legend of the "second Musri," and that for him Esarhaddon's "Sib'e, the *Tartannu* of Pir'u King of Musri," is, as he is to every sane critic, "So (Seve) the general of Pharaoh King of Egypt," *i.e.* the King Shabak understood as an officer of the Ethiopian king, probably Kashta, who ruled in Upper Egypt. But we think that Mr. Caldecott, in his note on Sib'e ("Temple," p. 139), should have referred to Winckler's Musri-theory, and given his reasons for not accepting it. This would have been the scientific way of doing things. As it is, he lays himself open to the suspicion of not having known anything about an important theory, very germane to his subject, which archæologists and "higher critics" have been debating for years. And this possibility again makes one doubt the real value of this sort of work, despite the kind words of encouragement bestowed by Prof. Sayce upon the present author in respect of everything but his cuneiform. Whether, as he thinks, Mr. Caldecott's speculations will excite new interest in excavations in Palestine is doubtful; unluckily, these excavations have not always produced such "pat" results as seem generally to be expected from them. Those of the Austrians at Taanach seem to be the most interesting hitherto.

The identification of the modern Rāmet el-Khalīl with the ancient Ramah near Jerusalem, where the Tabernacle was set up, is, as Mr. Caldecott points out, due to the late Edward Robinson, who proposed it in 1838. The latter calls it quite correctly "er-Rameh"; Mr. Caldecott should be careful not to go on calling it, as he continually does, "Ramet" when he does not add the suffix "el-Khalīl"; the name of the place is Rāmeh or Rāma (usually with the definite article prefixed), which becomes "Rāmet" in the *construct state*, as "Rāmet el-Khalīl."

In conclusion, we would advise our author, before he publishes new editions of his books, to consult the articles "Tabernacle" and "Temple," by Dr. Benzinger, in the "Encyclopædia Biblica"; they may give him some novel information on certain points.
